TTCN Static Semantics

The following are those static semantics from the TTCN and ASN.1 standards which are checked by the Analyzer tool in the TTCN Suite.

Test Suite

SuiteId shall be the same as the SuiteId declared in Test Suite Structure table (Suite Structure).

Test Case Index

Test Cases shall be listed in the order that they exist in the dynamic part.

Test Step Index

TestStepId shall not include a formal parameter list.

Test Steps shall be listed in the order that they exist in the dynamic part.

Default Index

DefaultId shall not include a formal parameter list.

Defaults shall be listed in the order that they exist in the dynamic part.

Test Suite Type Definitions

Wherever types are referenced within Test Suite Type Definitions those references shall not be recursive (neither directly or indirectly)

Simple Type Definitions

The base type[1] shall be a Predefined Type or a Simple Type.

The set of values defined by a restriction must be a true subset of the values of the base type.

In specification of a particular length range, only non-negative INTEGER literals or the keyword INFINITY for the upper bound shall be used.

1. By Base Type we refer to the particular type in the Type production

If Minus is used in SimpleValueList then LiteralValue shall be a number.

The restriction type shall be a list of distinguished values of the base type.

Where a range is used in a type definition either as a value range or as a length range (for strings) it shall be stated with the lower of the two values on the left.

An integer range shall be used only with a base type of INTEGER or a type derived from INTEGER.

Where a value list is used, the values shall be of the base type and shall be a true subset of the values defined by the base type.

LengthRestriction shall be provided only when the base type is a string type (i.e., BITSTRING, HEXSTRING, OCTETSTRING or CharacterString) or derived from a string type

The LiteralValues shall be of the base type

In RangeTypeLength:
LowerTypeBound shall be a non-negative number
LowerTypeBound shall be less than UpperTypeBound

In IntegerRange:
LowerTypeBound shall be less than UpperTypeBound

Structured Type Definitions

Where elements may be of a type of arbitrarily complex structure; there shall be no recursive references.

The elements of Structured Type definitions are considered to be optional, i.e., in instances of these types whole elements may not be present.

A structure element Type shall be a PredefinedType, TS_TypeIdentifier, PDU_Identifier, or PDU.

If a Structured Type is used as a macro expansion, then the names of the elements within the Structured Type shall be unique within each ASP or PDU where it will be expanded.

The optional element length restriction can be used in order to give the minimum and maximum length of an element of a string type.

The set of values defined by LengthAttribute shall be a subset of the values of the base type.

ASN1 Type Definition

Types referred to from the type definition shall be defined in other ASN.1 type definition tables, be defined by reference in the ASN.1 type reference table or be defined locally in the same table, following the first type definition. Locally defined types shall not be used in other parts of the test suite.

ASN.1 type definitions used within TTCN shall not use external type references as defined in ISO/IEC 8824.

When ASN1 is used in a TTCN test suite, ASN1 identifiers from the following list shall be unique throughout the test suite:
a) identifiers occurring in an ASN1ENUMERATED type as distinguished values
b) identifiers occurring in a NamedNumberList of an ASN1 INTEGER type

Each terminal type reference used within the Type production shall be one of the following: ASN1_LocalType type reference, TS_TypeIdentifier or PDU_Identifier.

Test Suite Operation Definition

Only predefined types and data types as defined in the Test Suite Type definitions, ASP type definitions or PDU type definitions may be used as types for formal parameters. PCO types shall not be used as formal parameter types.

When a Test Suite Operation is invoked

1. the number of the actual parameters shall be the same as the number of the formal parameters; and

2. each actual parameter shall evaluate to an element of its corresponding formal type of parameter's.

Type in ResultType shall be a Predefined Type, TS_TypeIdentifier, PDU_Identifier or ASP_Identifier.

Test Suite Parameters Declarations

The type shall be a Predefined Type, TS_TypeIdentifier, PDU_Identifier or ASP_Identifier.

Test Case Selection Expression Definition

The expression shall use only literal values, Test Suite Parameters, Test Suite Constants and other selection expression identifiers in its terms.

The expression shall evaluate to a BOOLEAN value.

Expression shall not recursively refer (neither directly nor indirectly) to the SelExprIdentifier being defined by that Expression.

Test Suite Constant Declarations

The type shall be a predefined type, an ASN.1 type, a Test Suite Type or a PDU type.

The terms in the value expression shall not contain: Test Suite Variables or Test Case Variables.

The value shall evaluate to an element of the type indicated in the type column.

Test Suite Variable Declarations

Type shall be a Predefined Type, TS_TypeIdentifier, PDU_Identifier or ASP_Identifier.

The terms in the value expression shall not contain: Test Suite Variables or Test Case Variables.

Specifying an initial value is optional.

If an unbound Test Suite Variable is used in the right-hand side of an assignment, then it is a test case error.

The value shall evaluate to an element of the type indicated in the type column.

Test Case Variable Declarations

Type shall be a Predefined Type, TS_TypeIdentifier, PDU_Identifier or ASP_Identifier.

The terms in the value expression shall not contain: Test Suite Variables or Test Case Variables.

Specifying an initial value is optional.

The value shall evaluate to an element of the type indicated in the type column.

PCO Declarations

It is possible to define a PCO to correspond to a *set* of SAPs.

Timer Declarations

The terms in the value expression shall not contain: Test Suite Variables or Test Case Variables.

The timer duration shall evaluate to an unsigned positive INTEGER value.

ASP Type Definition

ASP type definitions may include ASN1 type definitions, if appropriate.

If only a single PCO is defined within a test suite then PCO_TypeIdentifier is optional. The PCO type shall be one of the PCO types used in the PCO Type Declaration proforma.

The macro symbol shall be used only with Structured Types defined in the Structured Types definitions.

Parameters may be of a type of arbitrarily complex structure, including being specified as a Test Suite Type (either predefined, Simple Type, Structured Type or ASN.1 type).

If a parameter is to be structured as a PDU, then its type may be stated either:

- as a PDU identifier to indicate that in the constraint for the ASP this parameter may be chained to a PDU constraint of a specific PDU type.
- as **PDU** to indicate that in the constraint for the ASP this parameter may be chained to a PDU constraint of any PDU type.

The boundaries shall be specified in terms of (non-negative) INTEGER literals, Test Suite Parameters, Test Suite Constants or the keyword INFINITY.

The parameters of ASP type definitions are considered to be optional, i.e., in instances of these types whole parameters may not be present.

The names of ASP parameters shall be unique within the ASP in which they are declared.

The optional attribute is Length.

In ASPs that are sent from the tester, values for ASP parameters that are defined in the Constraints Part shall correspond to the parameter or field definition. This means:
a) the value shall be of the type specified for that ASP parameter; and
b) In the case of substructured ASPs, either using Structured Types or ASN.1, the above rules apply to the fields of the substructure(s) recursively.

ASN1 ASP Type Definitions

The PCO type shall be one of the PCO types used in the PCO declaration proforma.

If only a single PCO is defined within a test suite, specifying the PCO type in an ASP type definition is optional.

Types referred to from the ASP definition shall be defined in other ASN.1 type definition tables, be defined by reference in the ASN.1 type reference table or be defined locally in the same table, following the first type definition.

Locally defined types shall not be used in other parts of the test suite.

ASN1 ASP Type Definition By Reference

The PCO type shall be one of the PCO types used in the PCO declaration proforma.

If only a single PCO is defined within a test suite, specifying the PCO type in an ASP type definition is optional.

PDU Type Definition

The PCO type shall be one of the PCO types used in the PCO declaration proforma.

The macro symbol shall be used only with Structured Types defined in the Structured Types definitions.

Fields may be of a type of arbitrarily complex structure, including being specified as a Test Suite Type (either predefined, Simple Type, Structured Type or ASN.1 type).

If a field is to be structured as a PDU, then its type may be stated either

- as a PDU identifier to indicate that in the constraint for the PDU this field may be chained to a PDU constraint of a specific PDU type; or
- as PDU to indicate that in the constraint for the PDU this field may be chained to a PDU constraint of any PDU type.

The boundaries shall be specified in terms of non-negative INTEGER literals, Test Suite Parameters, Test Suite Constants or the keyword INFINITY.

The fields of PDU type definitions are considered to be optional, i.e., in instances of these types whole fields may not be present.

The names of PDU fields shall be unique within the PDU in which they are declared

The optional attribute is Length;

In PDUs that are sent from the tester, values for PDU fields that are defined in the Constraints Part shall correspond to the field definition. This means

1. that the value shall be of the type specified for that PDU field; and
2. in the case of substructured ASPs and/or PDUs, either using Structured Types or ASN.1, the above rules apply to the fields of the substructure(s) recursively.

The set of values defined by LengthAttribute shall be a true subset of the values of the base type.

LengthAttribute shall be provided only when the base type is a string type (i.e. BITSTRING, HEXSTRING, OCTETSTRING or CharacterString) or derived from a string type.

ASN1 PDU Type Definition

The PCO type shall be one of the PCO types used in the PCO declaration proforma.

If only a single PCO is defined within a test suite, specifying the PCO type in an PDU type definition is optional.

Types referred to from the ASP definition shall be defined in other ASN.1 type definition tables, be defined by reference in the ASN.1 type reference table or be defined locally in the same table, following the first type definition.

Locally defined types shall not be used in other parts of the test suite.

ASN1 PDU Type Definition By Reference

The PCO type shall be one of the PCO types used in the PCO declaration proforma.

If only a single PCO is defined within a test suite, specifying the PCO type in an PDU type definition is optional.

String Length Specifications

TTCN permits the specification of length restrictions on string types (i.e., BITSTRING, HEXSTRING, OCTETSTRING and all CharacterString types) in the following instances:

1. when declaring Test Suite Types as a type restriction;
2. when declaring simple ASP parameters, PDU fields and elements of Structured Types as an attribute of the parameter, field or element type;
   and
3. when defining ASP/PDU or Structured Type constraints as an attribute of the constraint value. In the context of constraints, length restrictions can also be specified on values of type SEQUENCE OF or SET OF, thus limiting the number of their elements.

Alias Definitions

An Alias shall be used only to replace an ASP identifier or a PDU identifier within a single TTCN statement in a behaviour tree. It shall be used only in a behaviour description column.

Structured Type Constraint Declarations

If an ASP or PDU definition refers to a Structured Type as a substructure of a parameter or field (i.e., with a parameter name or a field name specified for it) then the corresponding constraint shall have the same parameter or field name in the corresponding position in the parameter name or field name column of the constraint and the value shall be a reference to a constraint for that parameter or field (i.e., for that substructure in accordance with the definition of the Structured Type).

ASP Constraint Declarations

If the ASP definition refers to a Structured Type by macro expansion (i.e., with <- in place of the ASP field name) then in a corresponding constraint either

- the individual elements from the Structured Type shall be included directly within the constraints.

- the macro symbol (<-) shall be placed in the corresponding position in the ASP field name column of the constraint and the value shall be a reference to a constraint for the Structured Type referenced from the ASP definition.

PDU Constraint Declarations

If the PDU definition refers to a Structured Type by macro expansion (i.e., with <- in place of the PDU field name) then in a corresponding constraint either:

- the individual elements from the Structured Type shall be included directly within the constraints;
  or
- the macro symbol (<-) shall be placed in the corresponding position in the PDU field name column of the constraint and the value shall be a reference to a constraint for the Structured Type referenced from the PDU definition.

Constraints Part

If an ASP and/or PDU is substructured, then the constraints for ASPs and/or PDUs of that type shall have the same tabular structure or a compatible ASN.1 structure (i.e., possibly with some groupings).

Structured Types expanded into an ASP or PDU definition by use of the macro symbol (<-) are not considered to be substructures. Constraints for such ASPs or PDUs shall either have a completely flat structure (i.e., the elements of an expanded structure are explicitly listed in the ASP or PDU constraint) or shall reference a corresponding structure constraint for macro expansion.

Whichever way the values are obtained, they shall correspond to the parameter or field entries in the ASP or PDU type definitions. This means

1. that the value shall be of the type specified for that parameter or field.
2. that the length shall satisfy any restriction associated with the type. (This will not be implemented.)

An expression in a constraint shall contain only literal values, Test Suite Parameters, Test Suite Constants, formal parameters and Test Suite Operations.

Neither Test Suite Variables nor Test Case Variables shall be used in constraints, unless passed as actual parameters.

Literal values, Test Suite Parameters, Test Suite Constants, Test Suite Variables, Test Case Variables and PDU or Test Suite Type constraints may be passed as actual parameters to a constraint in a constraints reference made from a behaviour description. The parameters shall not be of PCO type or ASP type.

In ASN.1 constraints, only ASP parameters and PDU fields declared as OPTIONAL may be omitted. These may be omitted either by using the Omit symbol or by simply leaving out the relevant ASP parameter or PDU field.

The constraint specification of an ASP and/or PDU shall have the same structure as that of the type definition of that ASP or PDU.

In tabular constraints, all ASP parameters and PDU fields are optional and therefore may be omitted using the Omit symbol, to indicate that the ASP parameter or PDU field is to be absent from the event sent.

An expression in a constraint shall contain only Values (including, for instance, ConstraintValue&Attributes), Test Suite Parameters, Test Suite Constraints, formal parameters, Component References and Test Suite Operations.

Matching Mechanisms

Complement: Each constraint value in the list shall be of the type declared for the ASP parameter or PDU field in which the complement mechanism is used.

ValueList: Each value in the ValueList shall be of the type declared for the ASP parameter or PDU field in which the ValueList mechanism is used.

Range: Ranges shall be used only on values of INTEGER type.

Range: A boundary value shall be either:

- INFINITY or -INFINITY
- a constraint expression that evaluates to a specific INTEGER value.

Range: The lower boundary shall be less than the upper boundary.

SuperSet: SuperSet is an operation for matching that shall be used on values of SET OF type. SuperSet shall be used only in ASN1 constraints.

SuperSet: The argument of SuperSet shall be of the type declared for the ASP parameter or PDU field in which the SuperSet mechanism is used.

SubSet: SubSet is an operation for matching that shall be used on values of SET OF type. SubSet shall be used only in ASN1 constraints.

SubSet: The argument of SubSet shall be of the type declared for the ASP parameter or PDU field in which the SubSet mechanism is used.

Permutation: Permutation an operation for matching that can be used only on values inside a value of SEQUENCE OF type. Permutation shall be used only in ASN1 constraints.

Permutation: Each element listed in Permutation shall be of the type declared inside the SEQUENCE OF type of the ASP parameter or PDU field.

Base Constraints and Modified Constraints

The name of the modified constraint shall be a unique identifier.

The name of the base constraint which is to be modified shall be indicated in the derivation path entry in the constraint header. This entry shall be left blank for a base constraint.

A modified constraint can itself be modified. In such a case the Derivation Path indicates the concatenation of the names of the base and previously modified constraints, separated by dots (.) A dot shall follow the last modified constraint name.

If a base constraint is defined to have a formal parameter list, the following rules apply to all modified constraints derived from that base

constraint, whether or not they are derived in one or several modification steps:

1. The modified constraint shall have the same parameter list as the base constraint. In particular, there shall be no parameters omitted from or added to this list
2. The formal parameter list shall follow the constraint name for every modified constraint
3. Parameterized ASP parameters or PDU in a base constraint fields shall not be modified or explicitly omitted in a modified constrain.

In tabular constraints Omit shall be denoted by dash (-). In ASN.1 constraints Omit is denoted by OMIT.

If the ASP or PDU definition refers to a parameter or field specified as being of metatype PDU then in a corresponding constraint the value for that parameter or field shall be specified as the name of a PDU constraint, or formal parameter.

The Behaviour Description

Statements in the first level of alternatives having no predecessor in the root or local tree belong to, shall have the indentation value of zero.

Statements having a predecessor shall have the indentation value of the predecessor plus one as their indentation value.

The parameters may provide PCOs, constraints, variables, or other such items for use within the tree.

Test Case root trees shall not be parameterized.

Formal parameters may be of PCO type, ASP type, PDU type, structure type or one of the other predefined or Test Suite Types.

TTCN Test Events

In the simplest form, an ASP identifier or PDU identifier follows the SEND symbol (!) for events to be initiated by the LT or UT, or a RECEIVE symbol (?) for events which it is possible for the LT or UT to accept.

If both a qualifier and an assignment are associated with the same event, then the qualifier shall appear first.

The tree header identifier used for local trees shall be unique within the dynamic behaviour description in which they appear, and shall not be the same as any identifier having a unique meaning throughout the test suite.

TTCN Expressions

The index notation is used to refer to elements (bits) of the ASN.1 BIT-STRING type. BITSTRING is assumed to be defined as SEQUENCE OF {BOOLEAN}. If certain bits of a BITSTRING are associated with an identifier (named bit) then either the dot notation or this identifier shall be used to refer to the bit.

Where a parameter, field or element is defined to be a true substructure of a type defined in a Structured Type table, a reference to the elements in the substructure shall consist of the reference to the parameter, field or element identifier followed by a dot and the identifier of the item within that substructure.

Where a structure is used as a macro expansion, the elements in the structure shall be referred to as if it was expanded into the structure referring to it.

If a parameter, field or element is defined to be of metatype PDU no reference shall be made to fields of that substructure.

The ATTACH Construct

Tree reference may be Test Step Identifiers or tree identifiers, where

1. A Test Step Identifier denotes the attachment of a Test Step that resides in the Test Step Library; the Test Step is referenced by its unique identifier
2. A tree identifier shall be the name of one of the trees in the current behaviour description; this is attachment of a local tree.

Constraints may be passed as parameters to Test Steps. If the constraint has a formal parameter list then the constraint shall be passed together with an actual parameter list.

When a parameterized tree is attached:

1. The number of the actual parameters shall be the same as the number of formal parameters
2. Each actual parameter shall evaluate to an element of its corresponding formal parameter type

Labels and the GOTO Construct

A GOTO to a label may be specified within a behaviour tree provided that the label is associated with the first of a set of alternatives, one of which is an ancestor node of the point from which the GOTO is to be made.

A GOTO shall be used only for jumps within one tree, i.e., within a Test Case root tree, a Test Step tree a Default tree or a local tree. As a consequence, each label used in a GOTO construct shall be found within the same tree in which the GOTO is used.

Labels used within a tree shall be unique within a tree.

The Constraints Reference

The actual parameter list shall fulfil the following:

1. the number of actual parameters shall be the same as the number of formal parameters;
   and
2. each actual parameter shall evaluate to an element of its corresponding formal type.

Verdicts

A predefined variable called R is available in each Test Case to store any Intermediate results. R can take the values *pass*, *fail*, *inconc* and *none*. These values are predefined identifiers and as such are case sensitive.

R shall not be used on the left-hand side of an assignment statement.

PASS or P, FAIL or F and INCONC or I are keywords that are used in the verdicts column only. The predefined identifiers pass, fail, inconc and none are values that represent the possible contents of the pre-

defined variable R. These predefined identifiers are to be used for testing the variable R in behaviour lines only.

A Verdict shall not occur in corresponding to entries in the behaviour tree which are any of the following: empty, an ATTACH construct, a GOTO construct, an IMPLICIT SEND or a RETURN.

Default References

Test Cases or Test Steps shall not be referred to as Defaults.

The actual parameter list shall fulfill the following:

1. The number of actual parameters shall be the same as the number of formal parameters.
2. Each actual parameter shall evaluate to an element of its corresponding formal type.
3. All variables appearing in the parameter list shall be bound when the constraint is invoked. (This won't be implemented.)

Formal Parameters

The formal parameter names which may optionally appear as part of the following shall be unique within that formal parameter list, and shall not be the same as any identifier having a unique meaning throughout the test suite.

A formal parameter name contained in the formal parameter list of a local tree shall header shall take precedence over a formal parameter name contained in the formal parameter list of the Test Step in which it is defined, within the scope of that local formal parameter list.

DataObjectReferences

A reference to a component of one of the following types: SEQUENCE, SET and CHOICE is constructed using a dot notation; i.e., appending a dot and the name (component identifier) of the desired component to the data object identifier; the component identifier shall be used if specified.

ASN.1 Static Semantics

IntegerType: Each identifier appearing in the NamedNumberList shall be different.

BitStringType: The DefinedValue shall be a reference to a value of type integer, or of a type derived from integer by tagging.

BitStringType: Each identifier appearing in the NamedNumberList shall be different.

BitStringValue: Each identifier in BitStringValue shall be the same as an identifier in the BitStringType sequence with which the value is associated.

SequenceType: The Type in the fourth alternative of the ElementType (COMPONENTS OF) shall be sequence type.

SequenceType: If OPTIONAL or DEFAULT are present, the corresponding value may be omitted from a value of the new type.

SequenceType: The identifiers in all NamedType sequence of the ElementTypeList shall be distinct.

SequenceType: The {} notation shall only be used if:
a) all ElementType sequences in the SequenceType are marked DEFAULT or OPTIONAL and all values are omitted
b) the type notation was SEQUENCE {}

SequenceType: There shall be one NamedValue for each NamedType in the SequenceType which is not marked OPTIONAL or DEFAULT, and the values shall be in the same order as the corresponding NamedType sequences.

SequenceOfType: Each Value sequence in the ValueList shall be the notation for a value of the Type specified in the SequenceOfType.

SequenceOfType: The {} notation is used when there are no component values in the sequence-of value.

SetType: The Type in the fourth alternative of the ElementType (COMPONENTS OF) shall be set type.

SetType: If OPTIONAL or DEFAULT are present, the corresponding value may be omitted from a value of the new type.

SetType: The identifiers in all NamedType sequence of the ElementTypeList shall be distinct.

SetType: The {} notation shall only be used if:
a) all ElementType sequences in the SetType are marked DEFAULT or OPTIONAL and all values are omitted
b) the type notation was SET {}

SetOfType: Each Value sequence in the ValueList shall be the notation for a value of the Type specified in the SetOfType.

SetOfType: The {} notation is used when there are no component values in the set-of value.

ChoiceType: The identifiers in all NamedType sequences of the AlternativeTypeList shall be distinct.

ChoiceType: If the NamedValue contains an identifier (in our case it contains always), it shall be a notation for a value of that type in the AlternativeTypeList that is named by the same identifier.

SelectionType: Type is a notation referencing the ChoiceType, and identifier is the identifier in the NamedType.

Subtype: When the SubtypeSpec notation follows the SelectionType notation, the parent type is the SelectionType, not the Type in the SelectionType notation.

Subtype: When the SubtypeSpec notation follows a set-of or sequence-of type notation, it applies to the Type in the set-of or sequence-of notation, not to the set-of or sequence-of type.

Chapter

39 *Using Diagram Editors*

This chapter describes the diagram editors you use for creating, drawing and printing OM (Object Models), SC (State Charts), DP (Deployment), MSC (Message Sequence Charts) and HMSC (High-level Message Sequence Charts) diagrams. Another name for HMSC is "road map".

The MSC Editor is also available in a flavor called *MSC Tracer* where the user is not allowed to add or remove symbols. This is only possible by an API which enables custom applications to interactively produce an MSC which reflects user defined events. Some features in the MSC Editor are not available in the MSC Tracer. For further information on this API, see the header file `<product install dir>/include/msctrace/msctrace.h`.

This chapter contains information about the functionality, menus, dialogs and windows of the diagram editors. For a guide to how to create and edit MSCs, see chapter 41, *Editing MSC Diagrams*.

Note: SDL Editor

The SDL editor is not covered in this chapter. For information regarding the SDL editor please see chapter 43, *Using the SDL Editor, in the User´s Manual*.

General

The editor described in this chapter is a combined OM, SC, DP, MSC and HMSC Editor. This editor is thus capable of showing five different types of diagrams, namely the Object Model (OM) diagrams, State Chart (SC) diagrams, Deployment (DP) diagrams, Message Sequence Chart (MSC) diagrams, and High-level MSC (HMSC) diagrams.

This combined editor is called **the editor** throughout this chapter. If only a specific editor is applied, that editor will be explicitly mentioned.

OM, SC, DP and HMSC diagrams are handled by one editor window, whereas MSC diagrams are handled by a separate editor window. This means that two editor windows are needed to handle all five diagram types.

The editor handling SDL diagrams is described in chapter 43, *Using the SDL Editor*.

How to edit MSC diagrams is described more closely in chapter 41, *Editing MSC Diagrams*.

Diagrams and Pages

The handling of diagrams and pages is common to the OM, SC, DP, MSC and HMSC diagrams. The editor can handle any number of diagrams.

The pages that the editor displays are always contained within a diagram. A diagram can contain any number of pages, but, must contain **at least one page**. The MSC and the DP Editor are exceptions as they always contain only **one** page. This page is enlarged when objects are added, etc.

The pages that are contained in a diagram are listed and handled according to a fixed order. While the order of pages is initially defined by the order in which the pages are added when created, pages can be renamed and rearranged with the *Edit* menu choice in the *Pages* menu.

This order is reflected in some of the menu choices that are related to pages. Also, the structure displayed by the Organizer will adopt the same order. See "The Organizer" on page 39 in chapter 2, *The Organizer*.

The Editor User Interface and Basic Operations

The Editor User Interface

The editor window can be used for viewing OM, SC, DP, MSC and HMSC diagrams.

The general user interface is described in chapter 1, *User Interface and Basic Operations*.

These functions are provided:

- The *Entity Dictionary Window*, which provides a name reuse facility as well as information for link endpoints.
- A symbol menu where you select the symbols that are to be inserted.
- A text window where you may edit text associated with symbols.

When you edit **OM** diagrams, three auxiliary windows are also provided:

- The *Browse & Edit Class Dialog* which you use to browse amongst and inspect and edit OM classes distributed across page and diagram boundaries.
- The *Line Details Window* which allows you to inspect and edit the various attributes of OM lines.
- The *Symbol Details Window* which allows you to inspect and edit OM symbol attributes.

When you edit **DP** diagrams, two of the auxiliary windows are also available:

- The *Line Details Window* which allows you to inspect and edit the various attributes of DP lines.
- The *Symbol Details Window* which allows you to inspect and edit DP symbol attributes.

When you edit **MSC** diagrams this function is also available:

- An instance ruler which allows you to view the kinds of instances, even if the instance head symbols are not currently in view.

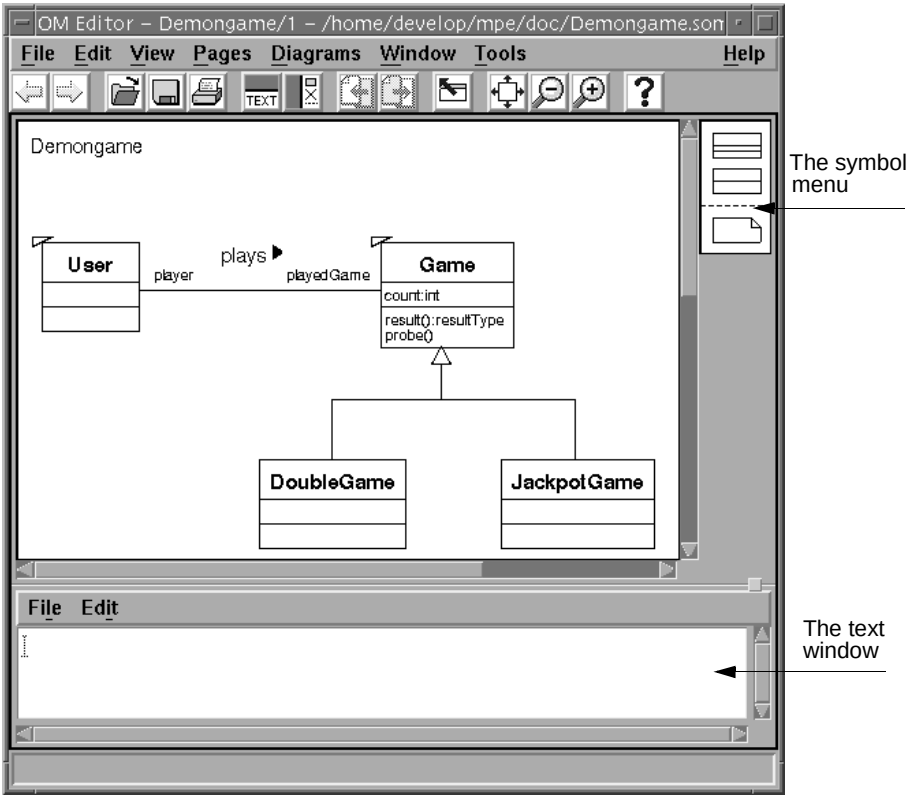

Figure 279: The editor window showing an OM diagram **(on UNIX)**

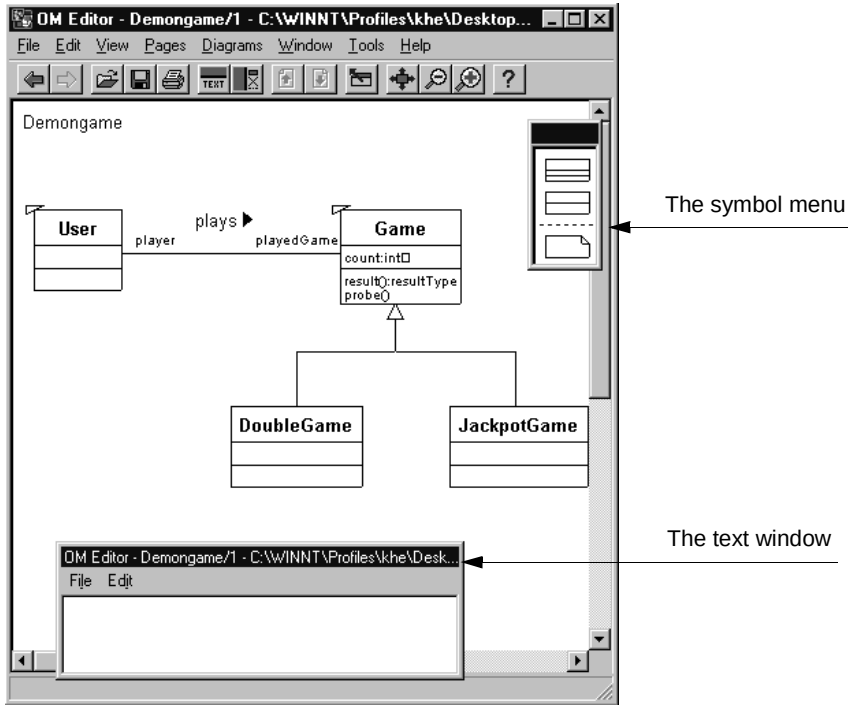

Figure 280: The editor window showing an OM diagram **(in Windows)**

The Editor Drawing Area

The drawing area is the part of the window which displays the symbols, lines and text that constitute a page (a diagram can contain multiple pages) or an MSC or DP diagram.

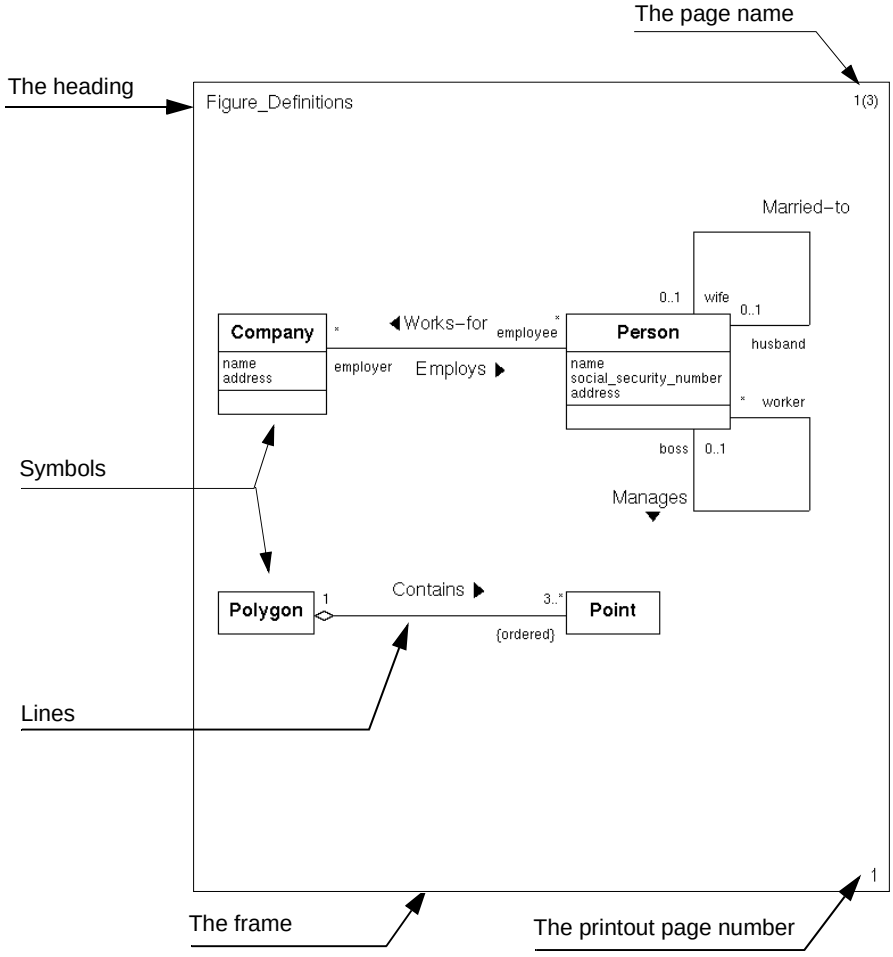

Figure 281: The drawing area with an OM page displayed

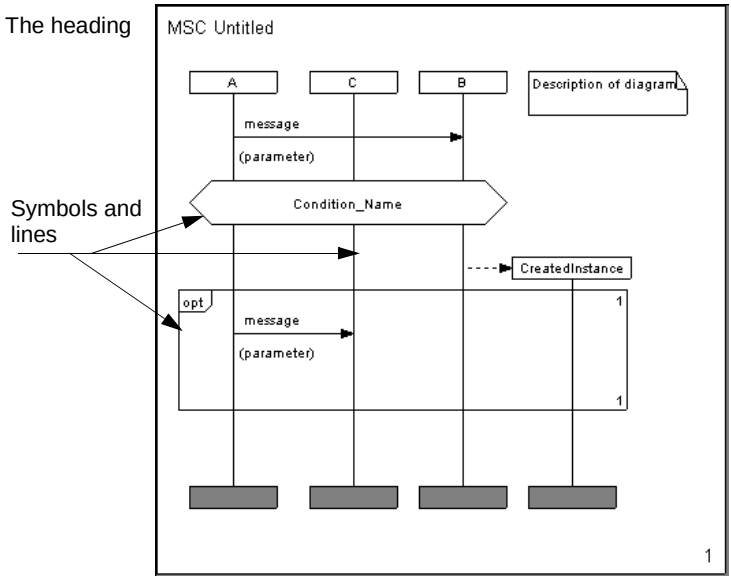

Figure 282: The drawing area with an MSC Diagram displayed

Drawing Area Boundaries

The drawing area is delimited by its boundaries, which correspond to the size of the page. No objects are allowed to be placed outside these boundaries. The drawing area uses a light background color, while the area outside the drawing area uses a grey pattern.

Within a diagram, each page has an individual size.

The Frame

The frame always coincides with the drawing area size. It is selectable but not editable. The frame is automatically selected with the *Select All* menu choice.

It is not possible to connect any diagram symbol to the frame. The frame only affects if the page is printed with or without a frame when printing selected objects, or when selected symbols are copied to a metafile **(Windows only)**.

The Heading

OM, SC and DP only: The heading contains the diagram name. The heading is editable but cannot be moved. The editor performs a textual syntax check on the name used in the heading, see "Diagram Name Syntax" on page 1732.

MSC and HMSC only: The heading identifies the chart type and name. The type cannot be edited.

The Page Name

All editors except MSC and DP.

In the upper right corner, the page name and the total number of pages in the diagram (within parentheses) are identified. The page name cannot be moved. To rename a page, use the *Edit* menu choice in the *Pages* menu.

The Printout Page Number

If a diagram page is larger than the paper format that is defined, the diagram page will be split into several printout pages. In this case, page numbers will be created. The page numbering follows a "down first, then right" fashion.

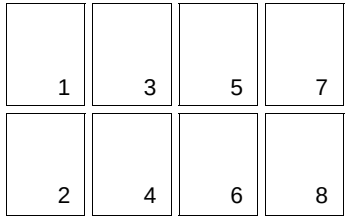

Figure 283: Page numbering in the editor

Grids

The editor uses two grids for an easy positioning of symbols, lines and textual elements:

- The symbol grid has a resolution of 5 * 5 mm, except for the **MSC** editor where it is 2.5 * 2.5 mm. All symbols adhere to the symbol grid.

- The line and text grid has a resolution of 2.5 * 2.5 mm. All lines and textual objects adhere to the line grid.

None of the grids can be changed.

Color on Symbols

All editors except MSC.

For each symbol type in the editor there is a preference for setting the color of the symbol. It is only the graphical part of the symbol and not the associated text(s) that will use the color setting. **On UNIX**, this setting is only valid on screen and all symbols will use the black color when printed on paper. **In Windows**, when using MSW Print the color settings will be sent to the printer as well. See "OM/SC/HMSC/MSC/DP Editor Preferences" on page 280 in chapter 3, *The Preference Manager*.

The text symbol is the same in OM, SC, DP and HMSC diagrams and has thus only one preference.

Keyboard Accelerators

In addition to the standard keyboard accelerators, the editor features the following:

Accelerator	Reference to corresponding command
`Ctrl+D`	"Next page" on page 1630
`Ctrl+U`	"Previous page" on page 1630
`Ctrl+T`	"Symbol Details" on page 1672
`<Delete>`	"Clear" on page 1670
`Ctrl+1`	"Show Organizer" on page 15 in chapter 1, *User Interface and Basic Operations*
`Ctrl+2`	"Connect to Text Editor" on page 1686

Quick-Buttons

In addition to the generic quick-buttons in all SDL Suite and TTCN Suite tools, the editor tool bar contains the following quick-buttons. See also "General Quick-Buttons" on page 24 in chapter 1, *User Interface and Basic Operations*.

Text window on / off
Toggle the text window between visible and hidden (see "Text Window" on page 1661).

Symbol menu on / off
Toggle the symbol menu between visible and hidden (see "Symbol Menu" on page 1632).

Previous page
(not valid for MSC and DP)
Open previous page in flow (similar to "<Page Name>" on page 1678). Dimmed if no previous page exists.

Next page
(not valid for MSC and DP)
Open next page in flow (similar to "<Page Name>" on page 1678). Dimmed if no next page exists.

Toggle Scale
Toggle the scale between a scale to show the complete diagram in the window (similar to *Overview* in "Set Scale" on page 1675) and a scale of 100%. For MSCs, the scale is adjusted to fit the diagram *width* in the window instead of the complete diagram.

Make space for new events
(MSC only)
Create space between two events (see "Make Space" on page 1673).

Remove space between two events
(MSC only)
Remove the unrequired space between two events.

Instance ruler on / off
(MSC only)
Toggle the instance ruler between visible and hidden (see "Instance Ruler" on page 1676).

Scrolling and Scaling

You can scroll the view vertically and horizontally by using the scroll-bars. The view may also be scrolled automatically when you move the cursor beyond the current view, for example when you move an object or add a symbol.

If you move the cursor close to the edge of the current view, the automatic scrolling is slow. If you move it further beyond, the scrolling is quicker.

You can scale the view by specifying a scale or by zooming in and out.

To specify a scale:

1. Select *Set Scale* from the *View* menu.
2. In the dialog that will be opened, you can either:
   - Use the slider for setting the scale and then click the *Scale* button.

   - Click the *Overview* button to adjust the drawing area to the size of the window. (This has the same effect as the *Scale Overview* quick-button.)

To zoom in or out:

- Click the quick-button for *zoom in* or *zoom out*.

Moving MSC Selection with Arrow Keys

You can move the selection using arrow keys in the MSC editor if there is one single symbol or line selected. The selection is moved along one instance in the vertical direction and between two instances in the horizontal direction.

In the MSC editor you are always in text editing mode, if there is a text to edit for the currently selected symbol. To move the symbol selection, press the arrow key one or several times in the direction you want to move. At first, only the text cursor position might be changed. But when the text cursor reaches the border of the text currently being edited (or

if there is no text being edited), then the symbol selection will be moved.

One shortcut is available for fast-forward moving to the next/previous condition or instance head symbol attached to the current instance: Shift+up or down arrow key.

Lock Files and Read-Only Mode

When you open a diagram or document file, e.g. `a.ssy`, a lock file `a.ssy.lck` is created. If another user tries to open the same diagram or document file before you close it, a dialog will appear informing the other user that the file is in use. There are two choices in the dialog:

- Open the file in read-only mode.
- Reset the lock and open the file in read-write mode. (This alternative should only be used if the existing lock file is obsolete.)

The read-write mode is the normal editing mode. In read-only mode, you are not allowed to make any changes to the diagram.

You will also enter read-only mode if you open a diagram file that you do not have write permission for. The read-only mode is indicated by the words *read-only* in the window title.

If you want to edit a diagram that is in read-only mode, there are two alternative actions:

- Change the file access rights in the file system to give you write permission for the diagram file. When that is done, you can change from read-only mode to read-write mode with the *Revert Diagram* operation.
- Select *File* > *Save As* to save the diagram in a new file with write permission.

Symbol Menu

The *symbol menu* contains the symbols that you can place into the drawing area.

On UNIX, the symbol menu is a fixed-sized, non-moveable auxiliary window, associated with the drawing area and placed to the right of it. Each editor window has its own symbol menu.

In Windows, the symbol menu is a fixed-sized, moveable window that can be placed anywhere on the screen, not necessary within the limits of the editor window. A single symbol menu is shared by all instances of the editor currently running.

The symbol menu can be made invisible and visible again with a menu choice, *Window Options*, or a quick-button. **In Windows:** When visible, the symbol menu will always be placed on top of the editor window, if the two windows overlap.

Basically, when you select a symbol in the symbol menu and click it into the drawing area, it is added to the diagram. This chapter does not describe how to work with symbols. Working with MSC symbols is described in chapter 41, *Editing MSC Diagrams*. See also "Working with Symbols" on page 1901 in chapter 43, *Using the SDL Editor*, as working with symbols in this editor is similar to working with symbols in the SDL Editor.

OM only: When a new class or object symbol is placed in the drawing area, it will automatically become an endpoint if the preferences AlwaysEndpointClass and AlwaysEndpointObject, respectively, are set.

The contents of the symbol menu depends upon the type of diagram that is displayed in the editor window, as can be seen in Figure 284. When you switch between diagrams of different types in the editor, the symbol menu changes accordingly.

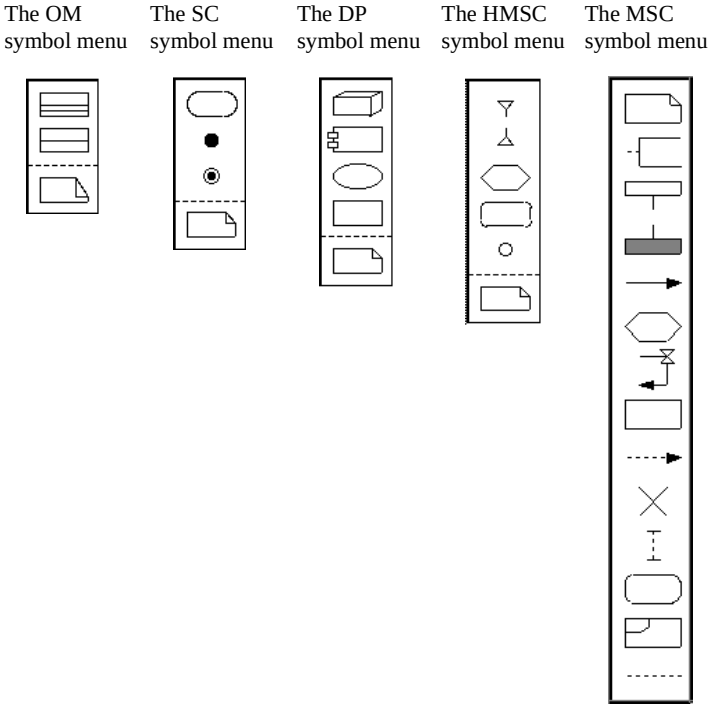

Figure 284: The editor symbol menus

About Symbols and Lines

The notation used for symbols and lines in the **OM Editor** complies with Static Structure (Class) diagrams defined in UML (Unified Modeling Language), version 1.3.

The notation used for symbols and lines in the **SC Editor** complies with State Chart diagrams defined in UML (Unified Modeling Language), version 1.3.

The notation used for symbols and lines in the **DP Editor** is based on the notation of Deployment and Component diagrams defined in UML (Unified Modeling Language), version 1.3.

The notation used for symbols and lines in the **HMSC Editor** complies with the ITU-T Z.120 recommendation from 1996. The comment symbol and the parallel frame symbol are not supported.

The notation used for symbols and lines in the **MSC Editor** complies with the ITU-T Z.120 recommendation from 1996. All MSC'96 symbols except the general ordering arrow are supported. Furthermore the MSC Editor does not support drawing of messages to the environment frame and message gates. Inline expressions are always global (i.e. they cover all instances).

For short explanations of when to use different symbols, see appendix 44, *Symbols and Lines – Quick Reference, on page 2053*.

Symbols

Diagrams contain different types of symbols that describe the structure of the diagram. All symbols must be placed inside the frame symbol. Figure 284 on page 1634 identifies these symbols in the symbol menu.

You can draw symbols in color, see “Color on Symbols” on page 1629.

All symbols that are available in the symbol menu are selectable and moveable; they can be assigned arbitrary locations by you, with the exception that symbols are normally not allowed to overlap[1]. **SC only:** symbols can however be placed inside a state symbol, see “State Symbols” on page 1641.

1. In certain situations symbols will overlap as a consequence of automatic resizing when new text is entered in the symbols. Such symbols can only be moved to areas where an overlap does not occur.

Common Symbol

A symbol common for all the editors is:

Symbol Appearance	Symbol Name	Summary
	Text	Informal specification, global comments

Text Symbols

Text symbols contain informal text. It is not possible to connect any lines to a text symbol.

Double-clicking on a text symbol minimizes the symbol if not already minimized and maximizes the symbol if not already maximized.

Text symbols are typically used to add comments to diagrams or to convey system information (**HMSC Editor**: on a global level) that cannot be captured using the constructs offered by the editor.

When all of the text within a text symbol is in view, the upper right corner looks like a piece of paper that has been folded. When any portion of the text within a text symbol cannot be seen (because the text symbol is too small), the upper right corner looks like it has been clipped.

OM Symbols and Lines

See also appendix 44, *Symbols and Lines – Quick Reference, on page 2053*.

Symbol Appearance	Symbol Name	Summary
	Class	Class definition
	Object	Class instance

Text in Class and Object Symbols

OM symbols have one or more text compartments, which should be filled with a textual expression. While the OM Editor does not require that symbol text compartments should contain text, it will perform a syntactic check on text compartments as soon as they are changed and deselected.

The syntax rules of OM diagrams are detailed in "Object Model Syntax" on page 1731.

> **Note:**
>
> The OM Editor does not enforce syntax correctness in OM class and object symbols. This means that it is possible to use any conventions you desire for the textual contents of symbols; however, some features offered by the OM Editor will not be available, notably the *Browse & Edit Class* dialog.

Syntax checking on text in general is described in greater detail under "Textual Syntax Checks" on page 1660.

Class Symbols

A class symbol is divided into three horizontal compartments. In order from the top, the compartments are:

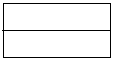
- The name compartment
- The attributes compartment
- The operations compartment

The text in these compartments is parsed by the OM Editor and should conform to the syntax specified in "Class Symbol Syntax" on page 1732.

In the name compartment two more extra text fields can appear. If adding text to the stereotype and properties fields in the Symbol Details window, these texts will also be visible inside the name compartment. These texts are not subject to syntactic checks.

Figure 285: Class symbol with stereotype and properties texts

If you double-click a class symbol, the *Browse & Edit Class* dialog will be opened (see "Browse & Edit Class Dialog" on page 1691).



Object Symbols

Used to describe an OM object, or an instance of a class.

An object symbol differs from a class symbol in that it does not contain an operations compartment. In addition, the remaining compartments require a somewhat different syntax, see "Object Symbol Syntax" on page 1734.

The object symbols handles stereotype and properties texts in the same way as the Class symbol.

If you double-click an object symbol whose name compartment includes a class name[1], the *Browse & Edit Class* dialog will be opened (see "Browse & Edit Class Dialog" on page 1691).

1. A class name is considered present only if the class name follows the object name after being separated by a colon ':' character.

Lines

Lines are the graphical objects that interconnect objects. Normally a line interconnects two symbols but it could also connect a symbol with another line. The following types of lines interconnecting symbols are defined in OM diagrams (see Figure 286):

- Association
- Aggregation
- Generalization

The only line interconnecting a symbol and a line in OM diagrams is:

- Link Class

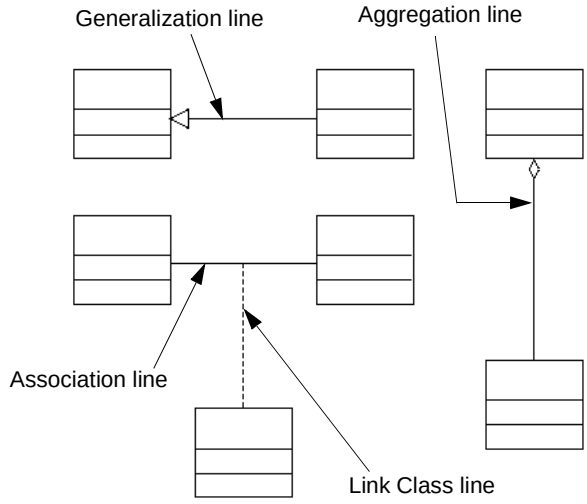


Figure 286: Lines in OM diagrams

To insert lines, select a class or object symbol, drag one of the *handles* that appear on the source symbol and connect it to the target symbol. There is one handle for each type of line.

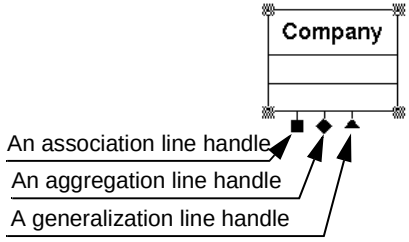

Figure 287: Handles for different line types

The Link Class line handle is placed on selected association and aggregation lines.

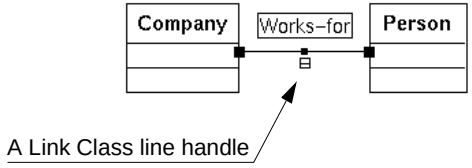

Figure 288: Handle for Link Class line

When a handle is clicked, the status bar shortly describes what the handle is used for and how to draw a line. This chapter does not describe how to work with lines. However, working with lines in the OM Editor is similar to working with lines in the SDL Editor; see "Working with Lines" on page 1932 in chapter 43, *Using the SDL Editor*.

Lines are always connected to objects; they are not allowed to exist on their own. A line is allowed to overlap any other object.

Lines are selectable; they can be moved and reshaped by you. Some layout work is performed automatically by the OM Editor.

Double-clicking on a line brings up the Line Details window (see "Line Details Window" on page 1696).

See also "Line Attribute Objects" on page 1653.

SC Symbols and Lines

See also appendix 44, *Symbols and Lines – Quick Reference, on page 2053*.

Symbol Appearance	Symbol Name	Summary
	State	State definition.
	Start	Starting point of the SC.
	Termination	Termination point of the SC.

Text in State Symbols

State symbols have three text compartments which should be filled with textual expressions, but are allowed to remain empty. A syntactic check on a text compartment is performed as soon as it is changed and deselected.

State Symbols

A state symbol contains a state section which is divided into horizontal compartments. In order from the top, the compartments are:

- The Name compartment
- The Internal Activity compartment

The text in these compartments should conform to the syntax specified in "State Symbol Syntax" on page 1736.

The state symbol may have an additional compartment with a graphic region holding a nested SC. This is called the *substate* compartment and states with this compartment are often called *hierarchical states* or *superstates*. The state will be extended with this compartment when a symbol is placed within it. The compartment disappears when the last symbol is removed from it.

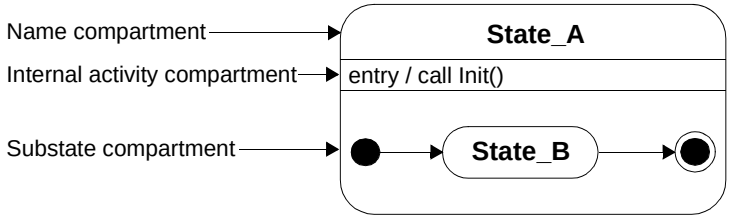

Figure 289: A state with its compartments

Text symbols are allowed to be placed inside the substate compartment but will not belong to the state. Thus, it will not automatically be part of the operations done on the state symbol, e.g. move, copy, etc.

Start Symbols

The start symbol is used to indicate where a SC starts.

Termination Symbols

The termination symbol is used to indicate where a SC terminates.

Lines

Lines are the graphical objects that interconnect objects. There is only one kind of line interconnecting symbols in SC diagrams, a transition line (see Figure 286):

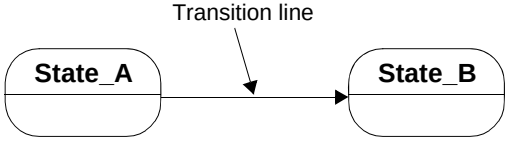

Figure 290: Transition line in SC diagrams

To insert lines, select a start or state symbol, drag the *handle* that appears on the source symbol and connect it to the target symbol.

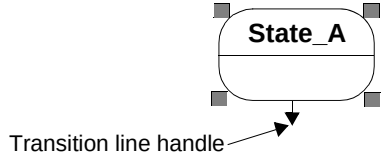

Figure 291: Handle for transition lines

When a handle is clicked, the status bar shortly describes what the handle is used for and how to draw a line. This chapter does not describe how to work with lines. However, working with lines in the SC Editor is similar to working with lines in the SDL Editor; see "Working with Lines" on page 1932 in chapter 43, *Using the SDL Editor*.

Lines are always connected to objects; they are not allowed to exist on their own. A line is allowed to overlap any other object.

Lines are selectable; they can be moved and reshaped by you. Some layout work is performed automatically by the SC Editor.

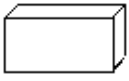
See also "Line Attribute Objects" on page 1653.

DP Symbols and Lines

See also appendix 44, *Symbols and Lines – Quick Reference, on page 2053*.

Symbol Appearance	Symbol Name	Summary
	Node	A run-time physical object that represents a computational resource (see [6] on page 1767).
	Component	A physical, replacable part of a system that packages implementation (see [6] on page 1767).
	Thread	An OS thread, i.e. a light-weight process. Not to be mistaken for an OS task, i.e. a heavy-weight process.
	Object	An SDL entity, i.e. a system, block or process.

Double-clicking on a DP symbol brings up the Symbol Details window (see "Symbol Details Window" on page 1714).



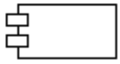
Node Symbols

For node symbols the following text attributes can be edited:

- The name text
- The stereotype text
- The properties text

The name text can be edited directly in the symbol and should conform with the syntax described in "Node Symbol Syntax" on page 1739. The other texts can be edited in the Symbol Details window and are not subject to syntactic checks.

Figure 292: Node symbol with stereotype and properties texts



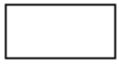
Component Symbols

The text attributes of component symbols are the same and follow the same rules as those of node symbols. You can select the integration model for a component symbol from the Symbol Details dialog box. The syntax rules that apply are described in "Component Symbol Syntax" on page 1739.

Figure 293: Component symbol with properties text

Thread Symbols

For thread symbols only the name text is visual. From the Symbol Details dialog box, you can edit thread priority, stack size, queue size and max signal size for a thread. The syntax rules described in "Thread Symbol Syntax" on page 1739 are applied.



Object Symbols

Object symbols have the following text attributes:

- The name text
- The stereotype text
- The properties text
- The qualifier text

In the Symbol Details window the stereotype, properties and qualifier texts can be added. If the stereotype text for an object symbol is **`process`** the appearance of the symbol is changed.

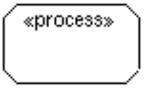


Figure 294: Object with stereotype "process"

The qualifier of an object symbol is displayed in the status bar when pointing the mouse at the symbol.

The syntax rules for the object symbol text attributes are described in "Object Symbol Syntax" on page 1739.

Lines

Lines are graphical objects that interconnect objects. Two types of lines are defined in DP diagrams (see Figure 295):

- Association
- Composite Aggregation

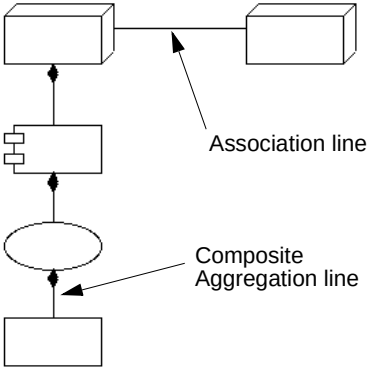

Figure 295: Lines in DP diagrams

To insert lines, select a symbol, drag one of the *handles* that appear on the source symbol and connect it to the target symbol. There is one handle for each type of line.

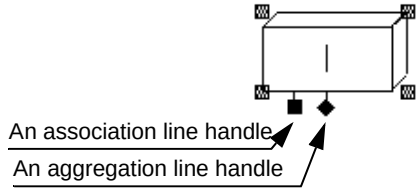

Figure 296: Handles for different line types

When a handle is clicked, the status bar shortly describes what the handle is used for and how to draw a line. This chapter does not describe how to work with lines. However, working with lines in the DP Editor is similar to working with lines in the SDL Editor; see "Working with Lines" on page 1932 in chapter 43, *Using the SDL Editor*.

Lines are always connected to objects; they are not allowed to exist on their own. A line is allowed to overlap any other object.

Lines are selectable; they can be moved and reshaped by you. Some layout work is performed automatically by the DP Editor.

Double-clicking on a line brings up the Line Details window (see "Line Details Window" on page 1711).

See also "Line Attribute Objects" on page 1653.

HMSC Symbols and Lines

See also appendix 44, *Symbols and Lines – Quick Reference, on page 2053*.

Symbol Appearance	Symbol Name	Summary
	MSC Reference	Reference to another MSC diagram or MSC reference expression
	Condition	Expresses alternative path in an HMSC
	Connection Point	Expresses that lines are connected at this point
	Start	Start of the HMSC road map.
	End	End of the HMSC road map.

Reference Symbols

The reference symbol is used to refer to other (H)MSC's of the MSC document. The MSC references are objects of the type given by the references MSC.

MSC references may not only refer to a single MSC, but also to MSC reference expressions. MSC reference expressions are textual MSC expressions constructed from the operators **alt**, **par**, **seq**, **loop**, **opt**, **exc** and **subst**, and MSC references.

The text is parsed by the HMSC Editor and should conform to the syntax specified in "Reference Symbol Syntax" on page 1742.

Double-clicking on a reference symbol opens the referenced MSC diagram. Note that if a reference symbol contains more than one name, you should place the cursor directly on one of the MSC names; otherwise an dialog is presented, see "Navigate" on page 1688.

Condition Symbols

The condition symbol in HMSC's can be used to indicate global system states and impose restrictions on the MSC's that are referenced in the HMSC.

The text is parsed by the HMSC Editor and should conform to the syntax specified in "Condition Symbol Syntax" on page 1741.

Connection Point Symbols

The connection point symbol in HMSC's is used to indicate that two (or more) crossing lines are actually connected.

Start Symbols

The start symbol in HMSC's is used to indicate where an HMSC road map starts.

End Symbols

The end symbol in HMSC's is used to indicate where and HMSC road map ends.

Lines

Lines are the graphical objects that interconnect objects. There is only one kind of line in the HMSC Editor.

To insert lines, select any[1] of the symbols, drag the *handle* that appear on the source symbol and connect it to the target symbol.

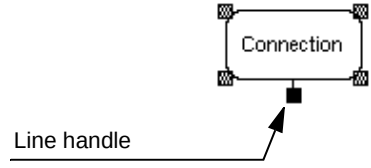

Figure 297: Symbol line handle

1. This does not apply to the stop symbols, since lines can not be drawn from it, only to it.

When a handle is clicked, the status bar shortly describes how to draw a line. This chapter does not describe how to work with lines. However, working with lines in the HMSC Editor is similar to working with lines in the SDL Editor; see "Working with Lines" on page 1932 in chapter 43, *Using the SDL Editor*.

Lines are always connected to objects; they are not allowed to exist on their own. A line is allowed to cross (but not overlap) another line. Since lines in HMSC's are directed, lines always starts at the bottom of a symbol and ends on the top of a symbol.

Lines are selectable; they can be moved and reshaped by you.

MSC Symbols and Lines

See also appendix 44, *Symbols and Lines – Quick Reference, on page 2053*.

Symbols are the graphical objects that build up the contents of an MSC. Lines are the graphical objects that interconnect symbols. Lines are available in the symbol menu and are thus handled as symbols.

Symbol Appearance	Symbol Name	References to Z.120
	Text	Z.120 2.3
	Comment	Z.120 2.3
	Instance head	Z.120 4.2
	Instance end	Z.120 4.2
	Message	Z.120 4.3
	Message-to-self	Z.120 4.3
	Found message	Z.120 4.3
	Lost message	Z.120 4.3
	Condition	Z.120 4.6
	Timer[a]	Z.120 4.7
	Separate timer set[b]	Z.120 4.7
	Separate timer reset	Z.120 4.7

Symbol Appearance	Symbol Name	References to Z.120
	Separate timer consumed / timeout	Z.120 4.7
	Action	Z.120 4.8
	Create	Z.120 4.9
	Stop	Z.120 4.10
	Coregion	Z.120 5.1
	MSC Reference	Z.120 5.4
	Inline expression	Z.120 5.3
	Inline separator	Z.120 5.3

a. The Z.120 symbols *timer set* and *time-out* are in this case merged into one symbol, the MSC Editor timer symbol.

b. A separate timer reset or timer consumed symbol is created by creating a separate timer set symbol, followed by changing its status to either reset or consumed.

Syntax Checking on Symbols and Lines

The MSC Editor checks that the **symbols** are positioned in the MSC in accordance to rules governed by Z.120. Lines are always connected to at least one symbol, they are not allowed to exist on their own. The MSC Editor checks that **lines** are connected to symbols in accordance to Z.120.

Graphical Properties of Symbols and Lines

All symbols that are available in the symbol menu are selectable and moveable. They can be placed automatically or you may, as long as the Z.120 syntax rules are respected, assign them arbitrary locations.

Lines are selectable; you can move them and reconnect them. Some layout work is performed automatically when a line is drawn.

Most of the symbols are not resizable; these are indicated by grayed selection squares. Other symbols may be resized; this is shown by a filled selection square.

Textual Attributes

Textual objects are the textual attributes that are related to a symbol or a line.

Some MSC symbols have one or multiple text attributes. A text attribute should be filled with an MSC/PR expression (textual expression) that is syntactically correct according to Z.120, alternatively filled with some informal text if the MSC concept is used informally.

Text attributes related to messages and timers may be moved freely by you. Textual objects are allowed to overlap any other objects.

Line Attribute Objects

This section applies to OM, SC and DP only.

Line attribute objects represent additional items of information associated with lines. It is not possible to create free line attribute objects that are not associated with any line; line attributes are always associated to, and destroyed with, their respective lines.

SC only: Each transition line has a line attribute object, the *transition label*, which is pre-created by the SC Editor when you create a line. You may ignore this attribute or fill in the textual contents, as appropriate. The text should conform to the syntax specified in "Transition Line Syntax" on page 1737.

OM only: Each type of line has a primary line attribute object, the *name* (for associations and aggregations) or *discriminator* (for generalizations) attribute, which is pre-created by the OM Editor when you create a line. You may ignore the primary attribute or fill in the textual contents, as appropriate.

DP only: Each type of line has a primary line attribute object, the *protocol* (for associations) or *multiplicity* (for aggregations) attribute, which is pre-created by the DP Editor when you create a line. You may ignore the primary attribute or fill in the textual contents, as appropriate.

OM and DP only: A number of secondary line attribute objects can be created for each line using the Line Details window (see "Line Details Window" on page 1696 and "Line Details Window" on page 1711 respectively). The exact number and types of line attribute objects depends on the type of line and is summarized in tables below.

Line attribute objects have a number of common characteristics:

- They are conceptually attached to the closest line segment of the associated line and will be moved and redrawn as appropriate whenever the line's layout is changed[1].
- A selected textual line attribute object is indicated by a small rectangle which shrink-wraps the actual text. If the textual attribute is editable, the text cursor will appear at the current insertion position inside the text, and the text window will contain the text of the selected attribute object.
- Textual line attribute objects always display their entire contents; it is not possible to collapse them to avoid displaying large amounts of text, as is the case with class and object symbols.
- **OM and DP only:** Syntax checks are not performed on textual line attribute objects.
- **OM and DP only:** All textual line attributes except the line's primary attribute will be destroyed if their textual contents is cleared and the attribute is selected. To recreate a destroyed attribute, use the Line Details window.

OM only: While most line attributes can be moved freely and are allowed to overlap other objects, some attributes, such as the association qualifier, are restrained by graphical layout restrictions and cannot be freely moved.

1. While the results are normally what you would prefer, it is always possible to manually adjust the position of moveable line attributes after repositioning the line.

OM Line Attribute Objects

Name and Graphical Appearance	Line Attribute Objects (• Primary and – Secondary)
Association	• Name of the association – Reverse Name – Role Name – Role Multiplicity – Qualifier – Sorted – Ordered – Derived Attribute – Constraint
Aggregation 	• Name of the aggregation – Reverse Name – Role Name – Role Multiplicity – Qualifier – Sorted – Ordered – Composite
Generalization 	• Discriminator of the generalization
Link Class	• *No line attributes*

OM Aggregation/Association Attributes[1]

Attribute Appearance	Attribute Name (Properties)	Summary
	Name (Pre-created, Editable, Optional arrow)	Names a conceptual connection between object instances. While always bidirectional, the name usually denotes traversal of the association in the "forward" direction, as defined by the optional arrow.
	Reverse Name (Editable, Optional arrow)	Allows a separate name to be used when the link is traversed in the opposite direction.
	Qualifier (Editable, Not moveable)	Describes an association between two objects that is defined by the identity of a third object.
	Ordered (Not editable)	The *ordered* attribute puts additional constraints on a one-to-many association.
	Sorted (Not editable)	The *sorted* attribute puts additional constraints on a one-to-many association.
	Role Name (Editable)	Each end of an association is called a role. While redundant, well-named roles can sometimes facilitate analysis.
	Role Multiplicity (Editable)	Multiplicity is used to constrain the number of related objects. Multiplicity can be fixed, a closed range, an open range, or any combination of these.

1. While these attributes are available both for associations and aggregations, they are much more often used for associations. The use of these attributes for aggregations depends on how sharply the analysis or design separates between association and aggregation.

Attribute Appearance	Attribute Name (Properties)	Summary
	Derived Attribute (Not editable, Not moveable)	Indicates that the association represents redundant information, that can be calculated by following other associations.
	Constraint (Editable)	Allows the specification of arbitrary constraints. The specified text is automatically placed between '{' and '}'.

OM Aggregation Attributes

Attribute Appearance	Attribute Name (Properties)	Summary
	Composite (Editable)	Indicates aggregation with strong ownership.

OM Generalization Attributes

Attribute Appearance	Attribute Name (Properties)	Summary
	Discriminator (Pre-created, Editable)	The discriminator describes which property of an object is being abstracted by a particular generalization relationship.

SC Line Attribute Objects

Name and Graphical Appearance	Line Attribute Objects
Transition 	• Transition label of the transition

SC Transition Attributes

Attribute Appearance	Attribute Name (Properties)	Summary
event (arguments) [guard-condition] /actions 	Transition label (Pre-created, Editable)	Describes the transition. For a description of the syntax, see "Transition Line Syntax" on page 1737.

DP Line Attribute Objects

Name and Graphical Appearance	Line Attribute Objects (• Primary and – Secondary)
Aggregation 	• Name of the association – Protocol – Encoding – Direction
Composite Aggregation 	• Multiplicity of the composite aggregation

DP Association Attributes

Attribute Appearance	Attribute Name (Properties)	Summary
	Protocol (Pre-created, Editable)	The protocol of the communication path.
name 	Name (Editable)	The name of the communication path.
{BER} 	Encoding (Editable)	The encoding of the communication path.
	Direction (Editable)	The direction of the communication path.

DP Aggregation Attributes

Attribute Appearance	Attribute Name (Properties)	Summary
3,*	Multiplicity (Pre-created, Editable)	Multiplicity is used to constrain the number of related objects. Multiplicity can be fixed or an infinite number.

Editing Text

General

The drawing area is a container for different types of objects that each may contain zero or more *text compartments*. In addition, the lines that connect objects also have zero or more *textual attribute objects*.

The editor allows these textual objects to be edited directly in the drawing area, allowing you to see directly how the textual object resizes to shrink-wrap the text.

To directly edit a textual object in the drawing area, simply position the text insertion cursor at the desired position in the text. To indicate that a textual object is being edited, a thin vertical bar designating the text insertion cursor appears at the selected text insertion point. As soon as you type some text, the keyboard input mode will change to *text editing mode*. This is indicated by a flashing and thicker insertion bar.

In text editing mode, all accelerator keys are interpreted as input to the text. As an example, the `<Delete>` key will in text editing mode delete a character, but in non-text editing mode it will remove (*Clear*) an entire symbol. This means that you can only use text editing keyboard accelerators like `<Home>`, `<End>`, `<Ctrl+A>` and `<Ctrl+E>` in text editing mode only.

While useful for quickly editing small texts, direct editing in the drawing area suffers from some restrictions:

- While it is possible to position the insertion cursor in the text using the mouse or the arrow keys, it is not possible to make any selections in the text, for deletion or replacement.

- If the text becomes large enough to cross the drawing area boundary, parts of the text will no longer be visible.

To alleviate these and other limitations, the editor offers a *text window* that provides a more complete set of text editing features. See "Text Window" on page 1661 for more information. In addition, it is possible to use an external text editor for larger amounts of texts; see "Connect to Text Editor" on page 1686.

Regardless of whether editing takes place directly in the drawing area or in the text window, the editor makes sure that the contents of both displayed texts are consistent, which makes it convenient to use both text editing mechanisms in the same diagram.

Textual Syntax Checks

Some texts in the editor are subject to syntactic checks as soon as they are changed. Errors detected during syntax checks will be displayed in the textual object by underlining the first characters at the position where the first syntax error was detected.

Minimum Size of Textual Symbols

While symbols are resized automatically to fit the containing text, the editor defines a minimum size for each symbol, ensuring that even empty symbols will be recognizable:

- The predefined minimum width of any symbol with text is 20 mm.
- The minimum height for symbols with text is calculated based on the height of the symbol font.
- The minimum height for text symbols is 10 mm.

Delayed Updating of the Drawing Area

When you edit the text in the text window, the updating of the drawing area is at least delayed for the value of the preference FontText*MinimumTextUpdateDelay.

If the text is large, the update delay is extended proportionally. The text window is however always updated immediately.

In addition, any attempt to enter an illegal character will always result in an audible warning.

Text Window

The text window works in the same way for OM, SC, DP, MSC and HMSC diagrams. There is one text window common for OM, SC, DP and HMSC diagrams, and a separate text window for MSC diagrams.

On UNIX, the text window is a pane of the editor window and can be resized vertically.

In Windows, the text window is a resizable and moveable window that can be placed anywhere on the screen, not necessary within the limits of the editor window. A single text window is shared by all instances of the editor currently running.

If you select one object in the editor window, the text window is updated to contain the text associated with that object, but not if you select more than one text object.

Each line (except for the last line) in the text window is terminated by a carriage return, and may consist of any number of legal characters.

The text window provides a menu bar with two menus which are described in:

- "File Menu of the Text Window" on page 1690
- "Edit Menu" on page 1669

Hiding and Showing the Text Window

You can hide and show the text window with the *Window Options* command from the *View* menu, or by using a quick-button.

In Windows: When visible, the text window will always be placed on top of the editor window.

Searching and Replacing Text in an MSC

The text window provides standardized functions for searching and replacing text in an MSC.

If all the textual objects you want to search in are not visible (i.e. *instance name*, *instance kind*, *instance composition*, *message name* and *message parameters*) adjust the *Diagram Options*.

Copying, Cutting and Pasting Text

The text window provides standardized clipboard functions for copying, cutting and pasting text between different **symbols, lines and text attributes**. These functions do not interfere with the clipboard functions for cutting, copying and pasting **objects**.

Programmable Function Keys (UNIX only)

On UNIX, it is allowed to tie a function key to a defined text string. When typing that defined function key, the programmed text string will be inserted at the current cursor location. You can customize your own programming of function keys.

Global X Resources

The function keys are set up as X resources. It is possible to set up both system default and user-defined X resources, allowing you to customize your environment. The X resources are defined in a file that is common for all users, namely

```
/usr/lib/X11/app-defaults/SDT
```

To program the function keys, insert the following lines anywhere into the `SDT` file:

```
/* Any suitable comment */
SDT*XmText.translations: #override \n\
<Key>F1: insert-string("F1Text") \n\
<Key>F2: insert-string("F2Text") \n\
<Key>F3: insert-string("F3Text") \n\
<Key>F4: insert-string("F4Text") \n\
<Key>F5: insert-string("F5Text") \n\
<Key>F6: insert-string("F6Text") \n\
<Key>F7: insert-string("F7Text") \n\
<Key>F8: insert-string("F8Text") \n\
<Key>F9: insert-string("F9Text")
/* Note the absence of \n\ on line 9 */
```

Note:

Omitting to define some of the function keys is permissible.

User-Defined X Resources

You can define your own function keys. This is done by defining the X-resources described above in a personal copy of the definition file and to store that file into your home directory:

```
~username/SDT
```

Alternatively, any directory designated by environment variable `XAPPLRESDIR` can be used.

Restrictions

1. Only one line for each function key can be defined. Attempting to define more than one line into one function key may cause an unpredictable result when pressing that key.

   For instance, it is not certain that the following line will produce the expected result:

   ```
   <Key>F1: insert-string("F1Line1\nLine2") \n\
   ```

2. Only the keys F1–F9 can be defined.

Changing Fonts on Text Objects

You may change the font faces and font sizes used in the textual objects displayed by the editor. All textual objects use the same font faces and font sizes, meaning that they cannot be changed individually and cannot be changed during an editor session.

The font faces which are available depend on the target system on which you are running the SDL Suite.

Defining What Font to Use

To modify the desired font size and font face, you must use the Preference Manager. See chapter 4, *Managing Preferences*.

Textual Objects Preferences

When the setting is in effect, the SDL Suite diagram editors will use the font face names given by the preference settings

OME*ScreenFontFamily
OME*PrintFontFamily

to select font face names. Note that in this way you can select different font names for screen and for print.

On UNIX, if you leave the Editor*FontText*ScreenFontFamily preference setting empty, you will edit your documents using the *SDT Draft* font, but print them using the font you specified with the Editor*FontText*PrintFontFamily setting.

Supported Font Faces

On UNIX, the availability of font faces is determined by the version of the X Windows server which is running. With revision 5 or higher (X11 R5), scalable fonts are supported. In that case, the available list of predefined font faces would be:

- Times
- Helvetica
- Courier
- SDT Draft (mapped to the Schumacher font)
- Other (mapped to a user-defined font)

In Windows, the availability of font faces is determined by the True-Type fonts that are currently installed on the computer (use for instance the Windows Control Panel to determine what is available).

Default Font Face

The default font face is Helvetica (see the preferences ScreenFontFamily and PrintFontFamily described in "OM/SC/HMSC/MSC/DP Editor Preferences" on page 280 in chapter 3, *The Preference Manager*).

On UNIX, if scalable fonts are not supported, the font face will be replaced by a *Schumacher* font which may be used in all circumstances **(MSC only)**.

Default Font Size

Font sizes are described in "NameTextHeight" on page 281 and "TextHeight" on page 282 in chapter 3, *The Preference Manager*.

They are used as follows:

Common Font Sizes

Text Object	Font Size	Other
Heading symbol	NameTextHeight	
Text symbol	TextHeight	

OM Font Sizes

Text Object	Font Size	Other
Class symbol name	NameTextHeight	Bold
Object symbol name	NameTextHeight	Bold
Stereotype text	TextHeight	
Properties text	TextHeight	Italic

SC Font Sizes

Text Object	Font Size	Other
State symbol name	NameTextHeight	Bold

DP Font Sizes

Text Object	Font Size	Other
Symbol name	NameTextHeight	Bold
Stereotype text	TextHeight	
Properties text	TextHeight	Italic

HMSC Font Sizes

Text Object	Font Size
Reference Symbol	TextHeight
Condition symbol	TextHeight

MSC Font Sizes

Text Object	Font Size
All MSC special symbols	TextHeight

Determining Which Scalable Fonts Your Server Can Access (UNIX only)

On UNIX, use the `xlsfonts` command to list installed fonts. Font names containing 0 for width and height are scalable.

Example 313: How to determine which fonts are available

From the OS prompt, typing:

```
hostname% xlsfonts | grep "\-0\-0\-" | more
```

will return a list of accessible scalable fonts.

Scalable Fonts Under R5 Servers

To use scalable fonts under X11R5 you must normally first connect to a font server.

Example 314: How to Start the Font Server

1. Start the font server on any local host:

   ```
   hostname% fs
   ```

2. Connect the server to `fs` indicating which host the font server is running on (which can be the same host that the X server is running on):

   ```
   hostname2% xset +fp tcp/<hostname>:7000
   ```

For further information see the X11R5 documentation or use `man fs` to read the manual page describing the font server you are running.

Disabling Font Scaling (UNIX only)

On UNIX, if the fonts look poor on the screen, a possible work-around is to disable the scaling option.

> **Note:**
> Disabling font scaling effectively disables WYSIWYG!

To do this, you should edit the `SDT` resource file.

1. Open the file `SDT` in a text editor.
2. Locate the line with the text: `SDT*sdtUseScalableFonts`
3. Change the line to `SDT*sdtUseScalableFonts: false`
4. Save the file and restart the SDL Suite environment.

Menu Bars

The editor menu bar provides the following menus:

- *File Menu*
- *Edit Menu*
- *View Menu*
- *Pages Menu*
- *Diagrams Menu*
- *Window Menu*
- *Tools Menu*
- *Help Menu*

The Help menu is described in "Help Menu" on page 15 in chapter 1, *User Interface and Basic Operations*.

File Menu

The *File* menu supports the following commands on diagrams:

- *New*
- *Open*
- *Save*
- *Save As*
- *Save a Copy As*
- *Save All*
- *Close Diagram*
- *Revert Diagram*
- *Print*
- *Exit*

The *File* menu choices are described in "File Menu" on page 8 in chapter 1, *User Interface and Basic Operations*, except *Print* which is described in *"The Print Dialogs in the SDL Suite and in the Organizer" on page 316 in chapter 5, Printing Documents and Diagrams*.

Edit Menu

The *Edit* menu provides editing functions that you can perform on objects in a diagram, or on text in the text window. The *Edit* menu contains the following menu choices:

- *Undo*
- *Cut, Copy and Paste*
- *Paste As*
- *Clear*
- *Clear Objects*
- *Keep Objects*
- *Expand/Collapse*
- *Line Details*
- *Symbol Details*
- *Class*
- *Drawing Size*
- *Select All*
- *Redirect*
- *Connect*
- *Status*
- *Make Space*
- *Decompose*

Undo

This command restores the content of the drawing area to its state prior to the most recently performed operation. Text editing operations cannot be undone.

Editor	Operations you can undo
OM, SC, DP, HMSC	• *Cut, Copy and Paste* and *Clear* • Resizing a page • Adding/moving symbols • Drawing/reshaping/redirecting lines
OM	• Editing a symbol (Symbol Details Window) • Editing a line (Line Details Window)
DP	• Editing a symbol (Symbol Details Window) • Editing a line (Line Details Window)

Editor	Operations you can undo
OM	• Editing a class (Browse & Edit Class Dialog) **Note:** Undoing an Edit Class operation will undo the changes in all affected diagrams.
SC	• Expanding/collapsing symbols
HMSC	• Editing a symbol • Editing a line
MSC	• *Cut, Copy and Paste* and *Clear* • *Undo* • *Redirect* • *Connect* • *Moving Objects* • *Adding and Removing Objects*

Cut, *Copy* and *Paste*

These commands provide standardized clipboard functions for copying, cutting and pasting objects in the drawing area or text in the text window.

You can interrupt a *Paste* operation by pressing `<Esc>`.

The **MSC** specific rules regarding the *Paste* command are described in "Pasting in MSC Diagrams" on page 1717.

Paste As

Pastes the currently copied object (from the OM or Text Editor) as an OM symbol or MSC object in the drawing area. The object is transformed and a link is optionally created between the copied and pasted objects.

The Paste As dialog is opened. See "The Paste As Command" on page 448 in chapter 9, *Implinks and Endpoints*.

Clear

This command removes the selected objects from the drawing area, or the selected text from the text window.

Also see "Deleting an Object" on page 461 in chapter 9, *Implinks and Endpoints*.

Clearing an *instance head* symbol or its *instance axis* line in an MSC diagram will also remove all objects that were connected with the instance axis regardless of if they were selected or not.

- A created instance left without "parent" is kept in the chart as static instance.
- Clearing an instance end reconnects the instance axis to the bottom of the chart.

Clear Objects

This **MSC** command removes all objects similar to the selected objects. For instance, select one message A object and one message B object and invoke this command to remove all occurrences of message A and B. To remove the empty spaces after removed objects, use *Rearrange*.

Keep Objects

This **MSC** command removes all objects of the same type as the selected objects that are not similar to the selected objects. For instance, select one message C object and one message D object and invoke this command to remove all messages except C and D. To remove the empty spaces after removed objects, use *Rearrange*.

Expand/Collapse

If a text symbol or a comment symbol is selected, this command allows you to expand or collapse the symbol from or to its minimum size.

If an MSC diagram is selected, the *Collapse* command collapses the selected instance axes to give you an overview of the diagram. A complex MSC can in this way be viewed in several decomposed MSCs. Two diagrams are created; one where the instances you have selected are collapsed into a decomposed instance and one where the behavior of the instances you have selected are shown. You can *Navigate* from a decomposed instance to the referenced diagram.

If an OM class, OM instance or SC state symbol is selected, this command selects whether all compartments should be displayed or not. A collapsed symbol will only display the name compartment (including

the stereotype and properties texts for an OM symbol), which is particularly useful when referring to a symbol that is defined elsewhere.

Line Details

This **OM and DP** command brings up the modeless Line Details window, that is used to inspect and edit the properties of the currently selected line. If there is none or more than one selected object, the items in the Line Details window will be dimmed.

The Line Details window and its appearance for different type of OM lines is described in "Line Details Window" on page 1696. For DP lines it is described in "Line Details Window" on page 1711.

Symbol Details

This **OM and DP** command brings up the modeless Symbol Details window, that is used to inspect and edit the stereotype and properties texts of the currently selected OM class or object symbol. If a DP node or component symbol is selected the stereotype and properties texts can be edited. For a component symbol, integration model can also be selected. For a DP thread symbol, the thread priority, stack size, queue size and max signal size texts are editable. For a DP object symbol the stereotype, properties and qualifier texts can be edited.

The Symbol Details window and its appearance are described in "Symbol Details Window" on page 1701 (for OM symbols) and in "Symbol Details Window" on page 1714 (for DP symbols).

Class

This **OM** command brings up the modal *Browse & Edit Class* dialog on the currently selected OM class or object. This dialog is used to inspect and edit OM classes and objects over page and diagram boundaries.

The Browse & Edit Class dialog is described in detail "Browse & Edit Class Dialog" on page 1691.

Drawing Size

Issues a dialog where the width and height can be adjusted. The values will be saved.

Enlarging the drawing, the current page may not fit any longer into the paper that is defined with the Print preferences; the result may be a page that requires multiple sheets of paper when printed.

Select All

This operation selects all objects contained within the drawing area, or all text in the text window.

Status

This **MSC** command displays and possibly modifies the *status* of timers.

For more information see "Displaying and Modifying Status" on page 1721.

Make Space

This **MSC** command presents the *Make Space* dialog, where space for events may be inserted.

- The radio buttons *Before selected object* and *After selected object* define whether space for insertion of events should be created **before** or **after** the currently selected object.
- The *Space of* text field allows to specify how many events should be possible to insert.
- Clicking *OK* inserts space according to the number of events. All objects which are found after the currently selected object are pushed downwards.

Redirect

This **OM** command changes the orientation of the selected aggregation or generalization line.

This **SC** command changes the orientation of the selected SC transition line(s).

This **DP** command changes the orientation of the selected DP association line, if the line currently has a direction. The direction of a DP association line can be changed in the Line Details window.

This **MSC** command changes the orientation of a selected *message*. The new direction is indicated by a change in the orientation and position of the *message end* and of the *message parameters*.

Connect

This **MSC** command opens a dialog that is used to connect a selected *condition* or *MSC reference* symbol to one or multiple instances.

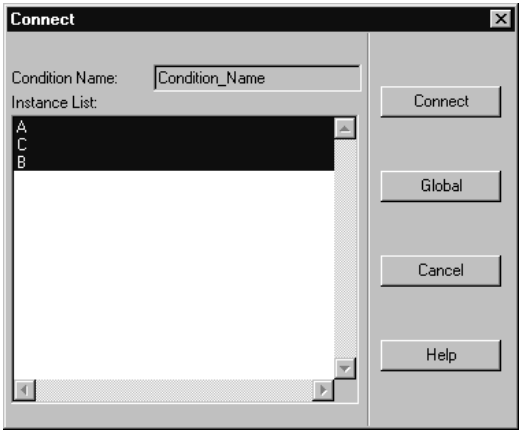

Figure 298: The Connect dialog (for a condition)

The *Name* field allows you to enter or change the name of the condition or MSC reference.

The *Instance List* lists all possible instances that are concurrent with the condition or MSC reference.

- Instances in the list that are selected or already connected are highlighted. Clicking an entry in the list toggles its state between highlighted and not highlighted.
- Select *Connect* connects the condition or MSC reference symbol to the instances in the instance list that are currently selected.
- Selecting *Global* connects the condition or MSC reference symbol globally to all instances in the list.

Decompose

This **MSC** command creates a new diagram of an instance axis in the original diagram. The instance axis you decompose is marked decomposed. In the new diagram you can specify the interior of the decomposed instance.

The messages to and from the decomposed instance are displayed as found and lost messages (see "MSC Symbols and Lines" on page 1651), showing the communication with other instance axes. The decomposed diagram is editable and it is displayed in the Organizer.

View Menu

The *View* menu provides rescaling functions and access to various options that affect the behavior of the editor. The *View* menu contains the following menu choices:

- *Set Scale*
- *Temporary Colors > Remove*
- *Window Options*
- *Diagram Options*
- *Editor Options*
- *Insert Options*

Set Scale

This menu choice issues a dialog where you can adjust the scale.

Temporary Colors > Remove

Temporary colors are colors that are not saved in the diagram. These colors are used by certain operations, such as *Compare Diagrams* in the MSC or HMSC editor, to highlight symbols of interest. Before doing a new operation that relies on color, it might be useful to remove already existing temporary colors. This can either be done by using this menu choice or by closing down the editor.

Window Options

This menu choice issues a dialog where you can set the options that affect the window properties.

In the dialog, you can set if you want the following items to be displayed:

- *Tool Bar*
- *Status Bar*
- *Symbol Menu*

  On UNIX, the space allocated to the symbol menu will be reused by the drawing area when you hide the symbol menu.

- *Instance Ruler*

  The space allocated to the **MSC** instance ruler will be reused by the drawing area when you hide the instance ruler.

- *Text Window*

  On UNIX, the space allocated to the text window will be reused by the drawing area when you hide the text window.

- *Page Breaks*

  This option determines whether physical page breaks, with the appearance of dashed horizontal and vertical lines, should be displayed or not in the drawing area. These page breaks are defined by the print preferences. Also, a number is shown in the bottom of each printout page, indicating the physical page number when printed.

- *Show Grid*

Click *OK* to apply the options in the dialog to the current window only.

Click *All Windows* to apply the options in the dialog to all windows opened by the editor.

Diagram Options

This **MSC** command issues a dialog where you can set the options that determines what should be displayed in the drawing area:

- *Show Instance Name*
- *Show Instance Kind*
- *Show Instance Composition*
- *Show Message Name*
- *Show Message Parameters*

Click *OK* to apply the options to the current MSC. The diagram options will be saved when you save the file.

Editor Options

Opens a dialog where you can customize the behavior of the editor.

The options are controlled by toggle buttons. They are:

- *Always new Window*

  This option indicates whether or not a new window should be opened when a new diagram is opened or created. The default behavior is not to open a new window.

- *Sound*

  This option indicates whether or not improper actions in the editor, such as attempting to append a symbol to an illegal position, should be brought to your attention by producing an alert sound. The default value for this option is on.

- *Show Link Endpoints*

  This option indicates whether endpoint markers should be displayed for symbols having link endpoints. The default value is on.

Insert Options

This **MSC** command issues a dialog where spacing between symbols may be specified. (The dimmed parts of the dialog are for future use.)

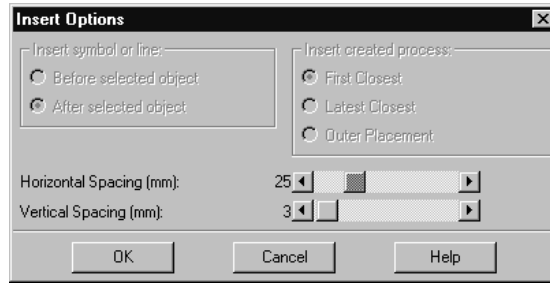

Figure 299: The Insert Options dialog

Spacing

This option allows to modify the space which is automatically inserted between the symbols and lines when appended to the chart.

There are two scales for setting the minimum horizontal distance between *instance axes* and the minimum vertical distance between *messages*.

Pages Menu

This section applies to all editors except MSC and DP.

The *Pages* menu holds commands that assist you in navigating among the pages in a diagram that are currently being edited in the editor. It also contains commands for adding, renaming and clearing pages as well as clipboard functions for copying, cutting and pasting entire pages.

The *Pages* menu contains the following menu choices:

- *First*
- *<Page Name>*
- *Last*
- *Add*
- *Edit*

First

This menu choice opens the first page contained in the diagram. The first page is defined according to the order of appearance in the *Edit Page* dialog.

<Page Name>

Activating the *Pages* menu presents up to four menu choices that consist of the names of the two pages that are sequentially immediately before and after the page being edited. If the first page of the diagram is being edited, the next four sequential pages are shown. If the last page of the diagram is edited, the previous four pages are shown.

Selecting one of these page names opens or restores that page in the editor. To open other pages, the *Edit* menu choice is used.

Last

This menu choice opens the last page of a diagram.

Add

This menu choice is a shortcut for adding one page to the current diagram. The *Add Page* dialog is issued and after pressing the *OK* button the new page is shown.

Edit

This menu choice allows to *Add*, *Rename*, *Move up*, *Move down*, *Clear*, *Cut*, *Copy* and *Paste* a page. Following this menu choice, a dialog is issued.

The meaning of the various components is as follows:

Edit Pages List

Presents a list with all pages that are included in the diagram. Clicking on a page in this list selects it and makes it the subject of the operation to follow.

Edit Button

Clicking this button opens the selected page and displays it in an editor window. The *Edit Page* dialog is closed.

Cut

Clicking this button removes the selected page from the diagram and saves it in the clipboard buffer.

Copy

Clicking this button copies the selected page into the clipboard buffer.

Paste

Clicking this button pastes the page contained in the clipboard buffer into the current diagram. A new dialog is issued.

The dialog allows to specify:

- The new name of the page. By default the page is autonumbered (the preference is described in "AutoNumberPages" on page 280 in chapter 3, *The Preference Manager*).
- If the new page should be pasted before or after the current page.

- Clicking the *Paste* button pastes the page according to the options as set up in the dialog and returns control to the *Edit Page* dialog.

Clear

This operation clears (removes) the selected page from the diagram.

To confirm the operation, click on *Clear*. The editor will automatically rename autonumbered pages.

> **Caution!**
>
> As stated in the dialog, *Clear* on a page cannot be undone.

Move up

If a diagram page is selected and you click the *Move up* button, the page will be moved up.

> **Note:**
>
> The undo function in the Organizer and in the SDL Suite will have no effect on page moves. It is, however, easy to undo a page move operation by just moving the page back again.

Move down

If a diagram page is selected and you click the *Move down* button, the page will be moved down.

> **Note:**
>
> The undo function in the Organizer and in the SDL Suite will have no effect on page moves. It is, however, easy to undo a page move operation by just moving the page back again.

Add

This command creates a new page which is added to the current diagram.

A new dialog is issued, in which you must insert the page name. You can insert the new page either before or after the current page.

The dialog allows to specify:

- The page name. By default the page is autonumbered (this preference is described in "AutoNumberPages" on page 280 in chapter 3, *The Preference Manager*).
- *Before / After current page*
  The new page is inserted according to the status of these radio buttons.
- Clicking *OK* adds the page and returns control to the *Edit Page* dialog.

Rename

Click this button to open a dialog where you can rename the selected page.

> **Note:**
> Autonumbered pages cannot be renamed. The *autonumbered* option must first be turned off.

- Type in the new name of the page.
- Click *OK* to rename the page. Control is returned to the *Edit Page* dialog.

Autonumbered

When turning the *Autonumbered* option off, the editor first prompts to confirm the removal of autonumbering on that page.

- Click *Yes* to remove autonumbering on the page and then open a dialog where you can rename the page (see "Rename" on page 1681).
- Click *No* to cancel the operation. The page remains autonumbered.

Turning the *Autonumbered* option on applies a numeric name to the selected page (1, 2, etc...). A dialog is issued where:

- *Yes* auto-numbers the selected page.
- *All Pages* auto-numbers all pages contained in the diagram.
- *No* closes the dialog without autonumbering the pages.

Open this page first

This toggle button designates what page to be opened first when opening a diagram in the editor, if no particular page is specified.

Diagrams Menu

The *Diagrams* menu records all diagrams that are opened by the editor. The menu choices are:

- *Back*
- *Forward*
- *<Diagram Name>*
- *List All*

Back

Select this menu choice to browse back to the diagram that was previously displayed in the window.

Forward

Select this menu choice to browse forward to the diagram that was displayed in the window before you selected *Back*.

<Diagram Name>

The last edited diagram always goes to the top of the list, and subsequently moves the other diagrams down a position. A maximum of 9 open diagrams can be shown. A tenth one will be put at the top of the list, but any subsequent opening of a diagram will only show the last 9 that have been opened.

Each item in the menu provides information about the diagram type, its name, a slash (‘/’) followed by a page name, a hyphen and, possibly, the file it is stored on (the file information is missing if the diagram has never been saved).

A diagram that is preceded by an asterisk (‘*’) denotes that it has been modified during the editor session.

> **Note:**
>
> OM, SC, DP and HMSC diagrams are listed in the same *Diagrams* menu, whereas MSC diagrams are listed only in the *Diagrams* menu of the MSC Editor window.

List All

This menu choice becomes available when a maximum of 9 open diagrams has been surpassed. When *List All* is selected, it provides a dialog containing all diagrams that are currently open in the editor. Select a diagram and click *Edit* to display it.

Window Menu

The *Window* menu contains the following menu choices:

- *New Window*
- *Close Window*
- *Entity Dictionary*
- *Info Window*
- *<Window Name>*
- *List All*

New Window

This command opens a new editor window containing a new view on the page, MSC or DP diagram contained in the source window from which this menu choice was operated. The page, MSC or DP diagram can be edited in any window.

Close Window

This option closes the open window, **but**, not necessarily the diagram.

If more than one editor window is opened, only the current window is closed and not the diagram. If the last open editor window is closed, the editor will act as if *Exit* has been chosen, possibly in conjunction with a save of information.

For more information, see "Close Diagram" on page 14 in chapter 1, *User Interface and Basic Operations*).

Entity Dictionary

Opens the Entity Dictionary window. See "The Entity Dictionary" on page 434 in chapter 9, *Implinks and Endpoints*.

Info Window

This **MSC** command issues a dialog as shown in Figure 300, displaying additional information about the currently selected MSC object.

Figure 300: The Info dialog

The dialog presents:

- A scrollable information window providing information about the currently selected object. What information is available depends on the selected object. See "Displaying Information About the Selected MSC Object" on page 1722.
- *Show SDL Symbol*

  A button that allows, **if the MSC has been automatically generated, using the SDL Simulator or SDL Explorer**, to obtain a trace-back to the SDL source diagrams. Manually inserted symbols and lines do not, of course, contain any trace-back information. Clicking this button displays the SDL source symbol in an SDL Editor window. To behave properly, this feature requires that the SDL source diagram is consistent with the generated MSC, e.g. the SDL diagram may not have been modified so that the source symbol has been removed.

<Window Name>

If more than one editor window is open the other windows are listed here. The behavior of this list will be similar with the diagrams list in the "Diagrams Menu" on page 1682. The only difference is that the menu items will not provide the diagram file information.

List All

This menu choice will be available only if more than 9 editor windows are open, and have the same functionality as the *List All* menu choice in the *Diagrams* menu.

Tools Menu

The *Tools* menu contains the following menu choices:

- *Show Organizer*
- *Link > Create*
- *Link > Create Endpoint*
- *Link > Traverse*
- *Link > Link Manager*
- *Link > Clear*
- *Link > Clear Endpoint*
- *Search*
- *Spelling > Comments*
- *Spelling > All Text*
- *Connect to Text Editor*
- *Show GR Reference*
- *Create Bookmark*
- *Convert SC to SDL*
- *Filter*
- *Tidy Up*
- *Navigate*
- *Rearrange*
- *Generate MSC PR*
- *Generate Input Script*

All Link commands are described in "Link Commands in the Tools Menus" on page 442 in chapter 9, *Implinks and Endpoints*.

Search

This menu choice allows you to search for a text in the current diagram or document in an editor. The search can be restricted to a selected symbol type by using the *Search In* option menu.

You can search several diagrams and documents at the same time by using search from the Organizer, see "Search" on page 142 in chapter 2, *The Organizer*.

Spelling > Comments

Check the spelling of comments in the current diagram. For more information about the spelling operation, see "Spelling > Comments" on page 147 in chapter 2, *The Organizer*.

Spelling > All Text

Check the spelling of all text in the current diagram. For more information about the spelling operation, see "Spelling > Comments" on page 147 in chapter 2, *The Organizer*.

Connect to Text Editor

This command issues an external text editor and creates a temporary file from the currently selected text. The text can from now on only be edited in the external editor. The editor is updated every time the external text editor saves the temporary file. When the temporary file is no longer edited, the editing control returns to the editor.

Which external text editor to use is defined by the preference SDT*TextEditor.

Show GR Reference

This command issues a message where the graphical reference for the currently selected object is displayed.

The syntax of the graphical references used in the editor is described in chapter 18, *SDT References*.

Create Bookmark

This command creates a bookmark in the Organizer for the object you have currently selected.

Convert SC to SDL

This **SC** command transforms a State Chart to an SDL process diagram.

When the conversion is done, the SDL Editor displays the newly created process diagram. A new diagram is created for every conversion. The diagram resides in an unsaved SDL Editor buffer.

The transformation rules that are applied to the SC diagram are described in "Converting State Charts to SDL" on page 1702.

Filter

This SC command allows you to hide uninteresting states, transitions or signals in a statechart. All three filters are combined, making it possible to hide stateX, transition (stateA)-signalB->(stateC) and signalZ at the same time.

Information about hidden entities is saved in a collapsed text symbol, to be able to recreate the entities when the filter is removed. The text in the text symbol starts with “HiddenTransitions:”.

The dialog has the following options:

Apply filter

The current filter will be used when the dialog is closed with the OK button.

Create new editor buffer

A new statechart is created as a new editor buffer. If this option is off, the current statechart and editor buffer will be reused instead.

Always tidy up afterwards

The Tools>Tidy Up operation will be invoked after the filter has been applied. If this option is off, then the Tidy Up operation will only be invoked when needed, i.e. when states or transitions that was not visible before the operation become visible.

Create filter script text symbol

When the dialog is closed with the OK button, another dialog will appear, asking for a name for the filter. A text symbol, containing information about the current filter, will be created, starting with the text “Filter:<newline><filter name>”. To reuse a filter saved in this way, select the text symbol before invoking the filter operation.

Tidy Up

This **SC** command rearranges the graphical layout of states and transitions in the State Chart. State hierarchies are flattened out, i.e. states in states are replaced with other constructs. Positions and sizes are determined by a default layout algorithm.

Navigate

The *Navigate* menu choice displays a (H)MSC diagram referenced by the reference symbol or a decomposed MSC.

Since a reference symbol may contain more than one reference name the HMSC Editor presents a dialog where you can choose reference name.

Goto

Pressing this button will show the diagram selected in the Navigation names list. If an (H)MSC diagram with that name is not present in the Organizer, a dialog will be shown. If more than one (H)MSC with the same name is present in the Organizer, an error message will be issued.

There are a number of situations when the dialog is not presented and the referenced diagram is shown immediately:

1. There is only one reference name in the symbol.
2. The caret is positioned in a reference name. This name will be automatically selected for navigation.

For reference navigation to work correctly it is required that the expression in the symbol is syntactically correct so that the names in the symbol can be extracted. Check out "Syntax rules in Symbols" on page 1740. If you try to navigate from a symbol with incorrect syntax you will be notified with a dialog that points out the location of the error in the reference symbol text.

If you select a symbol that is not present in the Organizer you will be presented with a dialog where you can create either an MSC or an HMSC diagram.

Rearrange

This **MSC** command rearranges the symbols and lines in the MSC diagram to get a compact version of the same diagram. This command might for instance be useful after having removed several signals from the diagram.

Generate MSC PR

With this **MSC and HMSC** command you can save an MSC using the Z.120 MSC/PR format. (MSC/PR can also be read by the MSC Editor,

see "Managing MSCs" on page 1797 in chapter 41, *Editing MSC Diagrams*). The MSC Editor normally stores the MSCs using a binary storage format.

To generate MSC/PR:

1. Display the MSC you want to generate MSC/PR from.
2. Select *Generate MSC PR* from the *Tools* menu. A dialog is issued.
3. Specify a file where to store the generated MSC/PR. The default file that the MSC Editor suggests consists of the name of the MSC, with the `.mpr` file extension, i.e. `<diagramname>.mpr`
4. Make sure the *Generate GR references*[1] radio button is turned on.
5. Click *Generate*.

Comment Symbols and MSC/PR

Since free comment symbols, i.e. comment symbols that are not connected to any other symbol, are not permitted in MSC/PR but can be defined using the MSC Editor, free comment symbols are converted to text symbols in the generated MSC/PR.

Generate Input Script

This **MSC** command makes it possible to convert an MSC expressed in a certain, restricted way to an input script that can be used as a script in the SDL Simulator UI. In the Simulator UI, use the Execute>Input Script menu choice or the execute-input-script command to execute an input script.

How MSCs should be expressed to be able to use them as test scripts for the SDL Simulator is described in "Simulator Test > New Simulator" on page 156 in chapter 2, *The Organizer*.

Note that normally, you do not manually convert MSCs to input scripts using this menu choice. Instead, the Organizer Tools menu choice Simulator Test > New Simulator auto-converts MSCs to input scripts when they are needed as test cases. Manual conversion is only needed if you

1. Event oriented MSC/PR describes the MSC using the order in which the events occur, i.e. starting with the top of the diagram and downwards, providing the feeling of a global event order.

want to stop working on the MSC level and start working on the textual Simulator UI command level instead.

Compare Diagrams

With this menu choice you can compare the contents of two MSC or HMSC diagrams. See "Comparing and Merging Diagrams" on page 1745.

Merge Diagrams

With this menu choice you can compare the contents of two MSC or HMSC diagrams and create a new diagram by merging the two diagrams. See "Comparing and Merging Diagrams" on page 1745.

File Menu of the Text Window

The *File* menu provides functions that transfer text from a file to the text window and vice-versa. The basic intention is to provide you a means to edit larger portions of text with a more suitable text editor. Another possibility to edit text externally is to use the *Connect to Text Editor* command in the *Tools* menu. The available menu choices are:

- *Import*
- *Export*

Import

Import imports the contents of a file into the text window and inserts the contents of the file at the current I-beam cursor position, possibly replacing selected text in the text window. A file selection dialog is issued, where the file to import text from is to be specified. The file name filter is set to `*.txt` by default.

Export

Export exports the text window contents to a file. A file selection dialog is issued, where the file to export the text to is to be specified. The file name filter is set to `*.txt` by default.

OM Editor Specific Information

Browse & Edit Class Dialog

The Browse & Edit Class dialog is opened when you select *Class* from the *Edit* menu. The dialog allows inspection of OM diagram classes and objects across page and diagram borders.

An object model class is defined as the union of the attributes and operations in the class and object symbols, see "Class Definition Summary" on page 1731, and the purpose of the Browse & Edit Class dialog is to display and ensure consistency when editing this combined information.

The Browse & Edit Class dialog is a modal dialog which is divided in two parts. The browsing functionality is placed at the top part of the dialog, where all classes in the scope, and all occurrences of each class are listed in two option menus. Below, in the editing part, the name of the class, all attributes and all operations are available.

The Browse & Edit Class dialog is available when a single class or object symbol has been selected:

- If a class symbol is selected, the Browse & Edit Class dialog will operate on the class defined by that symbol. If the class name is empty or contains incorrect syntax, the Browse & Edit Class dialog will not be available.
- If an object symbol is selected, the Browse & Edit Class dialog will operate on the class that the object symbol instantiates. If the object symbol does not include the name of the class it instantiates, the Browse & Edit Class dialog will not be available.

Browse

By using the topmost part of the Browse & Edit Class dialog it is possible to browse amongst all class and object symbols within the scope. The scope is either the entire Organizer module where the diagram is contained, or the diagram itself if it is not contained in an Organizer module. The module concept is described in "Module" on page 43 and in "Module" on page 52 in chapter 2, *The Organizer*.

Edit

By using the lower part of the Browse & Edit Class dialog it is possible to edit the name, attributes and operations of a class. The change will propagate into all class symbols of this class in OM diagrams within the module where the diagram is contained. The attributes and operations will be presented in a list. This list is parsed information from the texts in the class symbols. If a particular text contains syntax errors, it may lead to that attributes and operations contained in the same text do not appear in this list.

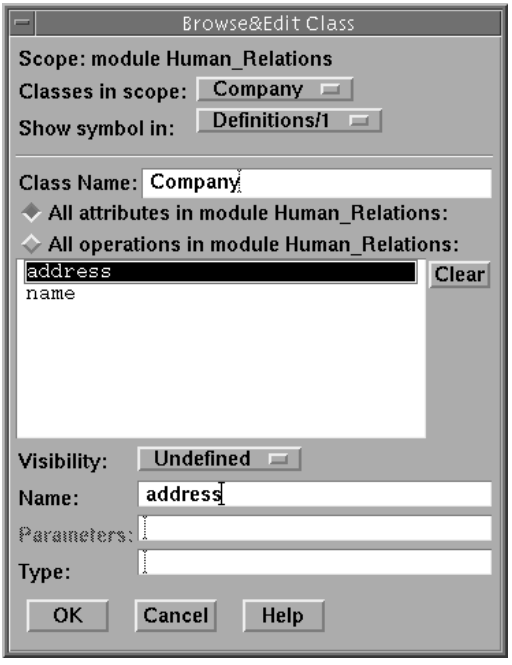

Figure 301: The Browse & Edit Class dialog

The *Scope* Label

The scope label is a non-editable text field that describes the scope that the Browse & Edit Class dialog is operating in. The scope can be either a single OM diagram or all OM diagrams within an Organizer module.

- If the diagram containing the object from which the Browse & Edit Class dialog was invoked is not part of a module in the Organizer, the scope label contains the text “Scope: diagram <*diagram name*>”.
- If the diagram containing the object from which the Browse & Edit Class dialog was invoked is part of a module in the Organizer, the scope label contains the text “Scope: module <*module name*>”.

The *Classes in Scope* Option Menu

The *Classes in Scope* option menu contains a list of all classes within the scope. By selecting one of the classes in this menu the corresponding symbol will be shown and selected in the drawing area.

The *Show Symbol in* Option Menu

One class can be represented by several class symbols. The *Show Symbol in* option menu lists all occurrences of the class currently selected in the Classes in Scope option menu. The notation in the menu is <diagram-name>/<page-name>. By selecting an occurrence in this menu the corresponding symbol will be shown and selected in the drawing area.

The *Class Name* Field

The name field is an editable text field that initially contains the name of the class that is being edited.

By editing the class name field, it is possible to update all occurrences of that class name in class and object symbols in the current scope when the *OK* button is clicked.

The *Attributes/Operations* Buttons

The Attributes and Operations buttons select whether the attributes/operations list will contain a list of all attributes or all operations defined for the selected class. Only one of the attributes and operations buttons will be selected at any time.

The *Attribute/Operations* List

The attributes/operations list contains an alphabetically sorted list of the attributes or operations defined for the currently selected class.

The *Clear* Button

The clear button removes the currently selected operation or attribute from the *Attribute/Operations* list.

By clearing an attribute or operation using the clear button, that attribute or operation will be removed from all relevant class and object symbols using the current class name in the current scope when the *OK* button is clicked.

The *Visibility* Option Menu

The visibility option menu contains the visibility of the currently selected attribute or operation in the *Attribute/Operations* list, if any.

By selecting one of the predefined values in this menu and later clicking the *OK* button, the visibility of the selected attribute or operation will be updated in all relevant class symbols using the current class name in the current scope.

The *Name* Field

The name field contains the name of the currently selected attribute or operation in the *Attribute/Operations* list, if any.

Editing this field will change the definition of that attribute or operation in all relevant class and object symbols using the current class name in the current scope when the *OK* button is clicked.

The *Parameters* Field

The parameters field is an editable text field that contains the parameters of a class operation. It is only editable when an operation is selected in the *Attribute/Operations* list.

Editing this field will change the definition of the selected operation in all relevant class and object symbols using the current class name in the current scope when the *OK* button is clicked.

The *Type* Field

The type field is an editable text field that is only editable when an attribute or an operation is selected in the *Attribute/Operations* list.

Depending on the current selection, the type field contains:

- If an attribute is selected, the type of that attribute, if any.
- If an operation is selected, the return type of that operation.

By editing this field, the type of the selected attribute or the return type of the selected operation and later clicking the *OK* button, the type of the selected attribute or operation will be updated in all relevant class and object symbols using the current class name in the current scope.

Note that default values for attributes cannot be inspected or changed in the Browse & Edit Class dialog.

The *OK* Button

The *OK* button will close the Browse & Edit Class dialog and update all appropriate class and object symbols in the diagrams in the current scope as described for the scope label.

Note that no changes are made in the diagrams until the *OK* button is clicked. This makes it possible to specify several changes in the dialog and later disregard them by clicking the *Cancel* button.

The values are syntactically checked, so it is not possible to add syntax errors to your classes by using the Browse & Edit Class dialog. Also, it may be impossible to delete syntactically incorrect text from symbols using the Browse & Edit Class dialog, since the Browse & Edit Class dialog relies on information obtained by parsing the relevant symbol text compartments.

It is possible to undo the changes made by the Browse & Edit Class operation. Note that this undo operation may affect more than one diagram.

The *Cancel* Button

The *Cancel* button will close the Browse & Edit Class dialog and discard any changes specified in the dialog. However, if the selection has changed in the drawing area after using any of the browsing functionality, this selection will not be canceled.

All changes made in the Browse & Edit Class dialog will be lost.

Line Details Window

The Line Details window is opened when you select *Line Details* from the *Edit* menu. It is used to inspect, and edit the properties of the currently selected line. In particular, most of the line attribute objects that are available for the different line types can only be created from the Line Details window[1].

Some line attribute objects contain editable text, and clearing that text, whether by editing in the Line Details window or directly in the diagram, will remove the attribute.

Changes made in the Line Details window will take immediate effect and will be shown in the drawing area. These changes can be undone with the *Undo* menu command.

Unlike the Browse & Edit Class dialog, the Line Details window is modeless and can remain open while you continue to work with the diagrams. The contents of the window will be updated to reflect the current selection. If there is none or more than one selected line, the fields in the Line Details window will be dimmed.

The OM Editor supports four different types of lines and the contents of the Line Details window depends on the type of the currently selected line:

- If an *Association* line is selected, all items except the Composite button in the Line Details window will be active. See Figure 302.
- If an *Aggregation* line is selected, all items in the Line Details window will be active. See Figure 303.
- If a *Generalization* line is selected, only a single editable text field, containing the generalization's discriminator, will be available. See Figure 304.
- If a *Link Class* line is selected, all items in the Line Details window will be dimmed.
- If none or more than one line is selected, all items in the Line Details window will be dimmed.

1. Once created, however, all editable textual line attribute objects can be selected and edited directly in the diagram, without the use of the Line Details window.

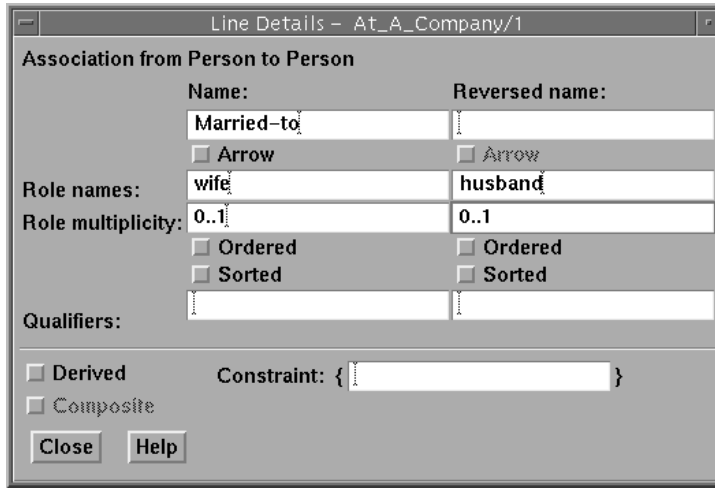

Figure 302: The Line Details window when an association line is selected

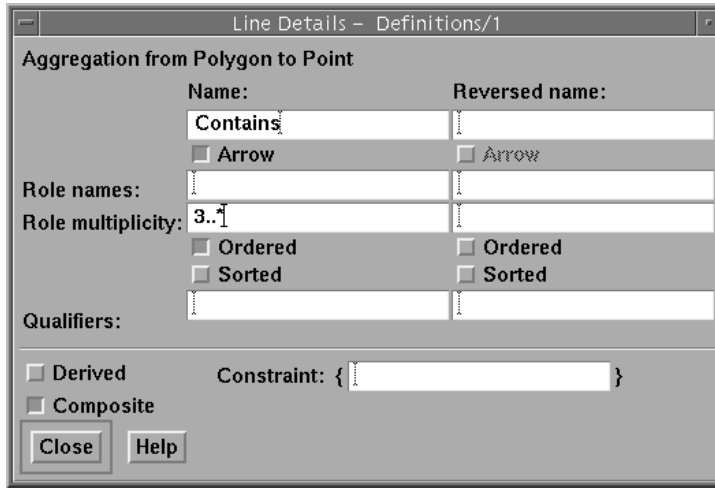

Figure 303: The Line Details window when an aggregation line is selected

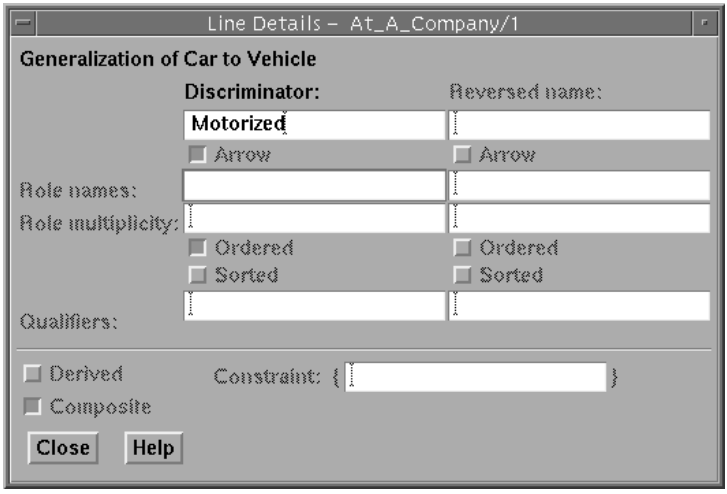

Figure 304: The Line Details window when a generalization line is selected

The *Name* Field

The *Name* field is an editable text field that contains the name of the selected aggregation or association.

Unlike the other text fields in the Line Details window, the line attribute object defined by the name field is permanent and is not destroyed even if the name field is cleared.

This field is only available when an aggregation or association line is selected.

The *Discriminator* Field

The *Discriminator* field is an editable text field that changes the discriminator text attribute of the generalization.

This field is only available when a generalization line is selected.

The *Reversed Name* Field

The *Reversed Name* field is an editable text field that allows the specification of a reversed name for an aggregation or association.

This field is only available when an aggregation or association line is selected.

The *Arrow* Buttons

Each of these two buttons toggle an option that shows or hides the optional arrow defining the direction of the name attribute or the reversed name attribute, respectively.

The direction and position of the arrow will be automatically calculated from the position and size of the associated name attribute as well as the direction of the line.

Typically it is desirable to use arrows to enhance clarity when defining both name and reversed name fields.

These buttons are only available when an aggregation or association line is selected.

The *Role Name* Fields

The *Role Name* fields are editable text fields that allow you to create and edit the role attributes belonging to each end of the association or aggregation.

These fields are only available when an aggregation or association line is selected.

The *Role Multiplicity* Fields

The *Role Multiplicity* fields are editable text fields that allow you to create and edit the multiplicity attributes of each end of an association or aggregation.

The name field is only available when an aggregation or association line is selected.

The *Ordered* Buttons

Selecting the *Ordered* toggle creates an uneditable text attribute containing the text "{ordered}". Deselecting the *Ordered* toggle removes this text attribute.

The ordered text attribute can be specified both in the primary and the reverse direction.

These buttons are only available when an aggregation or association line is selected.

The *Sorted* Buttons

Selecting the *Sorted* toggle creates an uneditable text attribute containing the text "{sorted}". Deselecting the *Sorted* toggle removes this text attribute.

The sorted text attribute can be specified both in the primary and the reverse direction.

These buttons are only available when an aggregation or association line is selected.

The *Qualifiers* Fields

The *Qualifiers* fields are editable text fields that allow you to create and edit the qualifier fields in the forward and reverse direction respectively.

These fields are only available when an aggregation or association line is selected.

The *Derived* Button

The *Derived* button is a toggle option that indicates whether the selected association or aggregation should be marked as derived, i.e. crossed by a small slanting line.

This button is only available when an association line is selected.

The *Composite* Button

The *Composite* button is a toggle option that indicates whether the selected aggregation should be marked as composite, i.e. the diamond shape of the aggregation line should be filled.

This button is only available when an aggregation line is selected.

The *Constraint* Field

The *Constraint* field is an editable text field that allows you to create and edit the constraint line attribute object.

This field is only available when an association or aggregation line is selected.

The *Close* Button

The *Close* button closes the Line Details window.

Symbol Details Window

The Symbol Details window is opened when you select *Symbol Details* from the *Edit* menu. It is used to inspect, and edit the stereotype and properties fields of the currently selected class or object symbol. These two symbol attribute types can only be created from the Symbol Details window. However, when created they can be edited directly in the diagram.

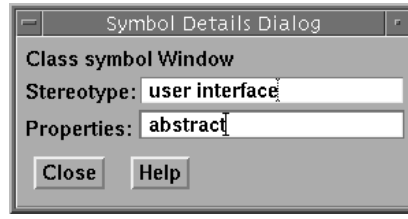

Figure 305: The Symbol Details dialog

Changes made in the Symbol Details window will take immediate effect and will be shown in the drawing area. These changes can be undone with the *Undo* menu command.

Unlike the Browse & Edit Class dialog, the Symbol Details window is modeless and can remain open while you continue to work with the diagrams. The contents of the window will be updated to reflect the current selection. If multiple class or object symbols or any other symbol or line is selected the Symbol Details window will be dimmed.

The placement of the stereotype and properties texts in the class and object symbol is described in "Class Symbols" on page 1638.

SC Editor Specific Information

Converting State Charts to SDL

To convert state charts to SDL, you select *Convert SC to SDL* from the *Tools* Menu.

Following are the transformation rules that are applied to the SC diagram:

Transformation Rules for Diagrams and Symbols

SC	SDL
SC diagram	Process diagram
“Heading”	Process “Heading”
Text symbol	Text symbol
Start symbol  Note: This rule does not apply if the start symbol belongs to a hierarchical state.	Start symbol 
If an event is defined on the transition from this state or if more than one transition from this state:	Start symbol connected to ‘initial’ state symbol named SDLInit. 
SC	SDL
Termination symbol  Note: 1. This rule does not apply if the termination symbol belongs to a hierarchical state. 2. If more than one transition to the termination symbol, the stop symbol is duplicated.	Stop symbol 
State symbol 	State symbol 
Hierarchical state symbol	Nothing
Substate symbol 	State symbol with a comment symbol 
Transformation Rules for State Internal Activities

SC	SDL
For all transitions from A to B 	Add action symbol  * See “Transformation Rules for Actions” on page 1710

SC	SDL
For all transitions from A to B 	Add action symbol  * See "Transformation Rules for Actions" on page 1710
	Comment symbol 	 * See "Transformation Rules for Transitions" on page 1704

Transformation Rules for Transitions

If actions are specified in the transition labels, insert actions last in the generated transition.

SC	SDL
	Spontaneous transition 		Continuous signal  Note: Priority is required if more than one continuous signal exist from the same state. This must be manually added.
	Enabling condition 
SC	SDL
	Timer with the name "<A>_T<counter>", where <counter> is an integer.  For all transitions to <A> add:  For this transition from <A>:  For all other transitions from <A> add: 	As above, but add an enabling condition: 
SC	SDL
	Continuous signal  Note: Priority is required if more than one continuous signal exist from the same state. This must be manually added.
	Continuous signal  Note: Priority is required if more than one continuous signal exist from the same state. This must be manually added.

Transformation Rules for State Internal Activities on Hierarchical States

- An **Entry** action of a hierarchical state is always performed when one of its substates is entered from the outside. This is applied for any number of state boundaries crossed.
- An **Exit** action of a hierarchical state is always performed when one of its substates takes a transition to a state outside the substate region. This is applied for any number of state boundaries crossed.

- An **Event** action of a hierarchical state is applied to all of its sub-states, at any nesting depth, unless a transition with the same event exists on the substate.
- A **Do** action of a hierarchical state is applied to all of its substates, at any nesting depth.

Transformation Rules for Transitions on Hierarchical States

SC	SDL
 Note: Exactly one start state, with an unlabeled transition, should exist in the hierarchical state.	 * See "Transformation Rules for Transitions" on page 1704
 Note: An unlabeled transition should exist out from the hierarchical state.	 * See "Transformation Rules for Transitions" on page 1704

SC	SDL
 Note: 1. This rule applies for every substate at any nesting depth. 2. Exception: This rule does not apply if a transition with the same trigger (event[guard]) exists on the substate.	 * See “Transformation Rules for Transitions” on page 1704

Transformation Rules for Actions

Depending of text contents:

SC	SDL
If text starts with ‘call’: *call proc(params)*	Procedure call If text starts with ‘output’: *output sig*	Output If quoted text: *“action”*	Informal task Otherwise: *a := 1*	Task 
DP Editor Specific Information

Line Details Window

The Line Details window is opened when you select *Line Details* from the *Edit* menu. It is used to inspect, and edit the properties of the currently selected line. In particular, most of the line attribute objects that are available for the different line types can only be created from the Line Details window[1].

Some line attribute objects contain editable text, and clearing that text, whether by editing in the Line Details window or directly in the diagram, will remove the attribute.

Changes made in the Line Details window will take immediate effect and will be shown in the drawing area. These changes can be undone with the *Undo* menu command.

The Line Details window is modeless and can remain open while you continue to work with the diagrams. The contents of the window will be updated to reflect the current selection.

The DP Editor supports two different types of lines and the contents of the Line Details window depends on the type of the currently selected line:

- If an *Association* line is selected, the text fields for the name, protocol and encoding as well as the direction option menu in the Line Details window will be active. See Figure 306.
- If an *Composite Aggregation* line is selected, only the multiplicity text field in the Line Details window will be active. See Figure 307.
- If none or more than one line is selected, all items in the Line Details window will be dimmed.

1. Once created, however, all editable textual line attribute objects can be selected and edited directly in the diagram, without the use of the Line Details window.

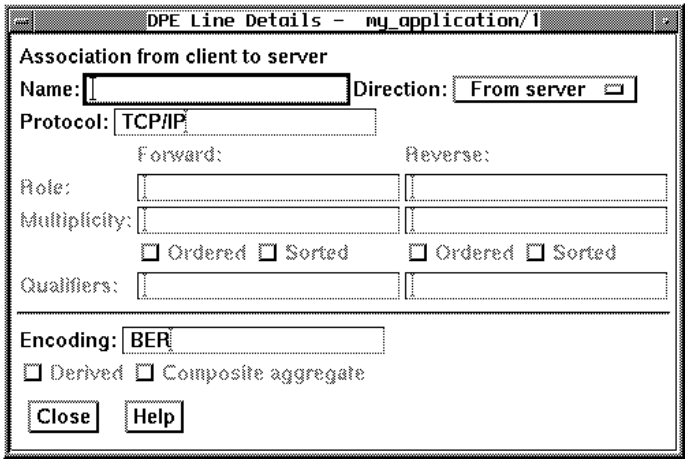

Figure 306: The Line Details window when an association line is selected

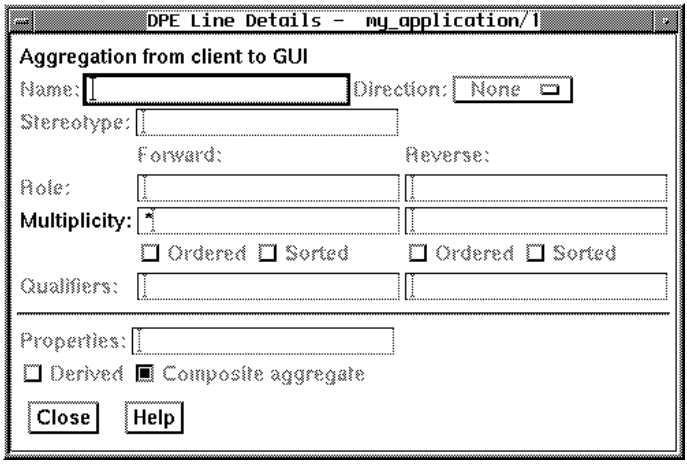

Figure 307: The Line Details window when an aggregation line is selected

The *Name* Field

The *Name* field is an editable text field that contains the name of the selected association.

This field is only available when an association line is selected.

The *Direction* Option Menu

By selecting one of the predefined values in the direction option menu the direction attribute of the currently selected association can be set. If any other value than None is selected an arrow will appear at one of the ends of the association line.

This option menu is only available when an association line is selected.

The *Protocol* Field

The *Protocol* field is an editable text field that allows you to create and edit the protocol attribute of an association.

The protocol field is only available when an association line is selected.

For an association line the line attribute object defined by the protocol field is permanent and is not destroyed even if the protocol field is cleared. In this respect it differs from most of the other text fields in the Line Details window.

The *Encoding* Field

The *Encoding* field is an editable text field that allows you to create and edit the encoding attribute of an association.

The encoding field is only available when an association line is selected.

The *Multiplicity* Field

The *Multiplicity* field is an editable text field that allows you to create and edit the multiplicity attribute of an aggregation.

The multiplicity field is only available when an aggregation line is selected.

For an aggregation line the line attribute object defined by the multiplicity field is permanent and is not destroyed even if the multiplicity field is cleared. In this respect it differs from most of the other text fields in the Line Details window.

The *Composite aggregate* Button

The *Composite aggregate* button is a toggle option that indicates that the selected aggregation is a composite aggregation, i.e. the diamond shape of the aggregation line is filled.

This button is set automatically depending on the current selection and is therefore never available.

The *Close* Button

The *Close* button closes the Line Details window.

Symbol Details Window

The Symbol Details window is opened when you select *Symbol Details* from the *Edit* menu. It is used to inspect, and edit the stereotype and properties fields of the currently selected node, component, thread or object symbol. For the component symbol the integration model can be selected. For the thread symbol you can edit thread priority, stack size, queue size and max signal size. For the object symbol you can enter a qualifier. These symbol attribute types can only be created from the Symbol Details window. However, when created the stereotype and properties texts can be edited directly in the diagram. All other settings can only be inspected and edited in the Symbol Details window.

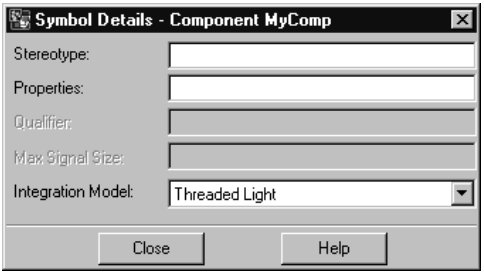

Figure 308: The Symbol Details dialog

Changes made in the Symbol Details window will take immediate effect and will be shown in the drawing area. These changes can be undone with the *Undo* menu command.

The Symbol Details window is modeless and can remain open while you continue to work with the diagrams. The contents of the window will be updated to reflect the current selection. If multiple symbols or a line is selected the Symbol Details window will be dimmed.

Generating a Partitioning Diagram Model

The Partitioning Diagram Model is used by the Targeting Expert as an hierarchical overview of the entities that are to be built. Partitioning Diagram Models can be generated from Deployment Diagrams. More information about this can be found in chapter 40, *The Deployment Editor, in the User´s Manual*. That chapter contains guidelines for modeling Deployment Diagrams that can be used for targeting, as well as information on the available integration models.

You generate Partitioning Diagram Models from the Organizer by selecting a Deployment diagram and then selecting “Targeting Expert” in the pop-up menu. You can also select “Targeting Expert” from the Generate menu. If the generation is successful the Targeting Expert is launched with the Partitioning Diagram Model as input.

Mapping Rules

Associations are ignored in Partitioning Diagram Model generation.

The stereotype “external” on a component or node symbol means that the symbol and its sub-tree are not included when the Partitioning Diagram Model is generated. This makes it possible to model the environment that surrounds an SDL system in a deployment diagram.

Graphical Syntax Rules

In order to generate a valid Partitioning Diagram Model that can be used by the Targeting Expert the rules listed below have to be followed:

- A valid diagram contains at least one node, one component and one object, which are connected.
- at least one component must belong to each node
- at least one thread or one object must belong to each component
- at least one object must belong to each thread
- every symbol must have a name
- names of nodes must be unique within the diagram
- names of components must be unique within their node

- names of threads must be unique within their component
- each thread must be connected to exactly one component
- each object must be connect to one component or one thread

Object symbols

For object symbols several text attributes have to be correct in order to result in valid Partitioning Diagram Models.

The name of each object symbol in the diagram should be the name of the corresponding SDL entity. Whether it is a system, block or process should be specified by the stereotype and the qualifier text should describe how the SDL entity fits into the tree structure of the SDL system.

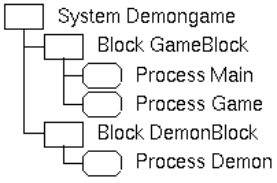

Figure 309: The tree structure of the system Demongame

Figure 309 shows the system Demongame. An object representing the process Main in a deployment diagram should have the following text attributes:

- qualifier: **`Demongame/GameBlock/Main`**
- stereotype: **`process`**
- name: **`Main`**

In the same way an object representing the system Demongame should have **`Demongame`** as qualifier text, the stereotype **`system`** and the name **`Demongame`**.

MSC Editor Specific Information

Pasting in MSC Diagrams

To paste, you select *Paste* from the *Edit Menu*. The rules for *Paste* will be described below.

When pasting the selection, the MSC Editor will process each individual object contained in the selection, adjust it to the grids if required and connect it, if feasible, to the “closest” object(s) in the drawing area.

If the MSC Editor fails in pasting some of the objects contained in the selection, the rest of the objects will nevertheless be pasted but without an error message being displayed.

Pasting of Multiple Objects

When pasting a selection that consists of multiple objects, the MSC Editor attempts, as long as feasible, to preserve the original appearance of the selection.

Pasting of Individual Objects

When pasting individual objects, the MSC Editor processes the objects as follows:

- *Text*

  A text symbol may be pasted anywhere.

- *Comment*

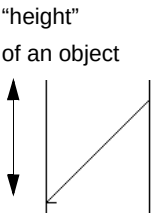
  A comment symbol may be pasted anywhere. The line connecting the comment symbol to another symbol is however lost when pasting.

- *Instance head* / *Instance axis*

  The instance head and its axis may be pasted anywhere.

- *Instance end* and *Stop*

  An instance end or stop may only be pasted at a location where it overlaps an instance axis.



- *Message*

  A message is connected to the instance axes which are closest to the message's base and end point, preserving the direction and "height" of the message.

- *Message-to-self*

  A message-to-self is connected to the closest instance axis. The "height" of the message is preserved.

- *Condition* and *MSC Reference*

  A condition or an MSC reference is connected to the instance it was previously connected to (before copying it to the clipboard).

- *Timer*

  A timer is connected to the closest instance axis. The "height" of the timer is preserved (see *Message* above).

- *Action*

  An action is pasted on the closest instance axis.

- *Create*

  The create symbol may be pasted anywhere, but only together with the instance it is creating.

- *Coregion*

  A coregion is connected to the closest instance axis, to the left or right. The "height" of the coregion is preserved (see *Message* above).

Adding Symbols

Adding an Instance Head Symbol

When you add an instance head symbol, an instance axis line is drawn that connects the symbol to the bottom of the drawing area. The instance axis line cannot be drawn manually. It will be truncated or elongated when you add or move an instance end or stop symbol upwards or downwards. See "Adding an Instance End Symbol" on page 1807 in chapter 41, *Editing MSC Diagrams* and "Adding a Stop Symbol" on page 1808 in chapter 41, *Editing MSC Diagrams*.

The instance head symbol has three text fields:

- The instance name field
- The instance kind field
- The decomposition field. See Figure 310.

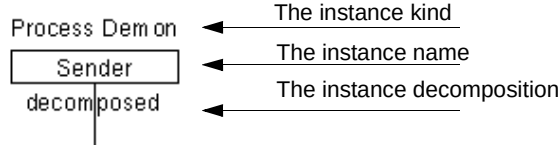


Figure 310: The meaning of the instance head text fields

The ITU recommendation Z.120 discusses several ways of using the instance name and instance kind text fields. In the MSC Editor, the text fields are used as follows:

- Basically, the *instance kind* reflects what kind of instance is represented. That is, an identifier which reflects the name of the corresponding SDL block/service/process/procedure; and an optional identifier which identifies if it is a block, a service or a process (the *kind denominator*).
- The *instance name* reflects the current function of the instance.
- The *instance decomposition* shows if the instance is in turn decomposed as a sub MSC. This text field is by default empty, but can contain the text *decomposed* or *decomposed as <diagram name>* to indicate that the instance is in turn decomposed. To decompose an instance, you select *Decompose* from the *Edit* menu.

Adding a Condition, MSC Reference or Inline Expression Symbol

A *condition* or *MSC reference* describes either a global system state referring to all instances contained in the MSC or a state referring to a subset of instances (a non-global condition or MSC reference). The minimum subset is a single instance.

For two MSCs, the second is a continuation of the first if its initial global condition is identical to the final global condition of the first. Identifying an intermediate global condition can be used when breaking down an MSC into two parts.

By means of non-global conditions, combinations of MSCs with different sets of instances can also be defined. The continuation then refers only to the common subset of instances.

The following general rule applies to the continuation of two MSCs (MSC1 and MSC2, with a non-empty common set of instances).

MSC2 is a continuation of MSC1 if, for each instance which both MSCs have in common:

- MSC1 ends with a (non)global condition
- MSC2 begins with a corresponding[1] (non)global condition
- Each (non)global condition of MSC2 has a corresponding (non)global condition in MSC1.

An *inline expression* symbol is always global and connected to all instances. The inline expression symbol is created from two inline expression symbol parts:

- The inline expression symbol starts a new inline expression symbol. The inline expression text in this symbol determines the inline expression type:
  - The keyword **loop** identifies a loop. Example: “LOOP <1, 5>” means that the contents of the inline expression symbol will be executed between one and five times.
  - The keyword **opt** identifies an optional part. The contents of the inline expression symbol will either not be executed or executed once.
  - The keyword **exc** identifies an exceptional part. The contents of the inline expression symbol will either not be executed or executed once. If it is executed, then the rest of the MSC is skipped.
  - The keyword **par** identifies parts that are executed in parallel.
  - The keyword **alt** identifies alternative parts. Only one part will be executed.
- The inline expression separator symbol starts a new part in a parallel or alternative inline expression.

1. *Corresponding* in this context means that both conditions refer to the same subset of instances and both conditions agree with respect to name.

Displaying and Modifying Status

To display and modify status, you select *Status* from the *Edit* menu.

Timer Status

Z.120 specifies two appearances for the timer symbol, depending on whether the timer has expired (i.e. time-out) or whether the timer is reset. The appearance of the timer is illustrated in Figure 311.

- **Timeout** – A timer expires.
- **Reset** – The timer is stopped.
- **Implicit reset** – Assigned a new value while active.

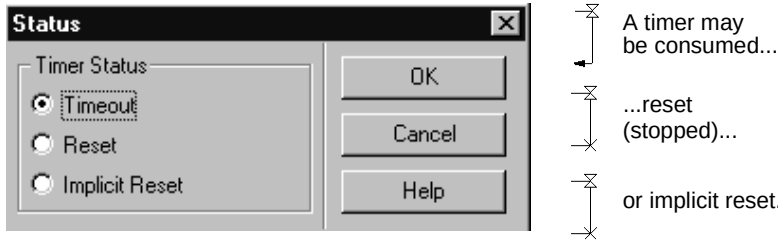

Figure 311: Timer status

Separate Timer Status

Separate timer symbols has no need for an implicit reset. The timer can be set two times in a row without an implicit reset in-between.

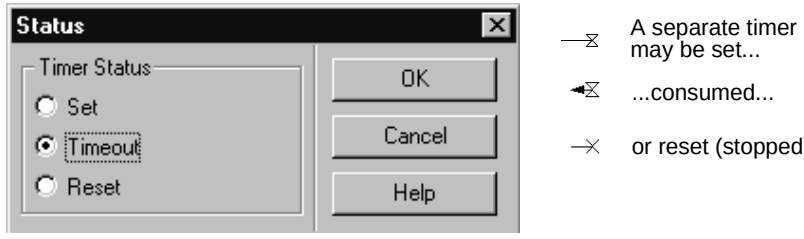

Figure 312: Separate Timer status

Displaying Information About the Selected MSC Object

To display information about a selected MSC object, you select *Info Window* from the *Window* menu.

This opens a dialog displaying additional information about the currently selected MSC object. The information that is available depends on what object is selected, and this is described in the table below.

Selected Object	Information Available
Instance head	• Instance name • Instance kind • Composition • Creating instance
Instance end	• Instance kind
Stop	• Instance kind
Process create	• Creating instance • Created instance • When the instance was created[a] • SDL Reference[a]
Message output (the message output is selected by clicking close to the message base)	• Message name • Sending instance • Receiving instance • Message status = – Sent[b] – Consumed[c] • When the message was sent (now)[a] • Message parameters • SDL Reference[a]

Selected Object	Information Available
Message input (the message input is selected by clicking close to the message end)	• Message name • Sending instance • Receiving instance • Message status= – Sent[b] – Consumed[c] • When the message was consumed • Message parameters • SDL Reference[a]
Timer	• Timer name • Instance kind • Timer status= – Reset (stopped) – Implicit reset – Timeout • When the message was sent (now)[a] • Timer value (Set) • Timer parameters • SDL Reference[a]
Separate timer	• Timer name • Instance kind • Timer status= – Set – Reset (stopped) – Timeout • When the message was consumed (now)[a] • Timer parameters • SDL Reference[a]
Action symbol	• Instance kind • Action text • SDL Reference[a]
Condition	• Condition or MSC reference name • Instances connected to the condition • SDL Reference[a]

Selected Object	Information Available
MSC Reference symbol	• Condition or MSC reference name • Instances connected to the condition
Text symbol	• Symbol text
Comment symbol	• Symbol text
Inline symbol	• Instances connected • Operator (inline expression)

a. Only for diagrams created through a simulation.

b. A message is *sent* when it has been sent and received, but has not yet been *consumed* by the receiving instance. Typically, it is waiting in the receiving process input queue.

c. A message is *consumed* when it has been processed by the receiving instance.

Instance Ruler

When managing working on a long (vertically extended) MSC, the *kind* of instance in the *instance head* may not be visible in the drawing area.

The *instance ruler* (illustrated in Figure 313) shows the kind of the instance heads that are not currently visible in the drawing area. It reduces the amount of scrolling up or down when working on an MSC. The instance ruler may be shown or hidden with an option (see "Instance Ruler" on page 1676).

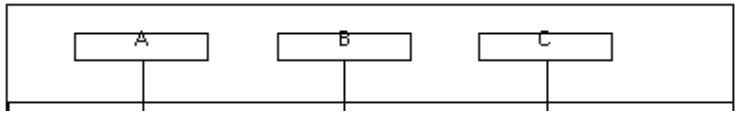

Figure 313: The instance ruler

Tracing a Simulation in a Message Sequence Chart

This section describes the functionality behind tracing a simulation in an MSC.

General

The MSC Editor may be used as a graphical trace tool, which features the automatic generation of an MSC from a simulation.

- The results of the simulation may be presented on line in an MSC Editor window, in which each event of interest will be appended to the chart in order to build up an MSC which reflects the history of the simulation.
- It is also possible to run the simulation, save the results on a simulator MSC log file and open the file from the MSC Editor.
- The commands that start up the logging of MSC events, set up the scope of trace, stop the logging of events, and so on, are given to the simulator monitor. See chapter 50, *Simulating a System*.

Defining the Scope of Trace

First, the scope of trace should, if necessary, be set to the unit which is currently of interest. This is done with the command Set-MSC-Trace.

The graphical trace is then started with a dedicated command from the simulator monitor. See *"Start-Interactive-MSC-Log" on page 2178 in chapter 49, The SDL Simulator*. In response to this command, the following happens:

1. In the Organizer, a reference to an MSC is added. The diagram is assigned an unique name.
2. An instance of the MSC Editor window is activated on the newly created MSC.
3. The current status for the simulation is presented by displaying all SDL process instances that exist at the time when ordering the command Start-Interactive-MSC-Log.

Mapping Between SDL and MSC

The mapping rules which govern how SDL events are transformed into MSC symbols, lines and textual elements are summarized in the following table:

SDL concept	MSC Concept
Signal • Output • Input	Message • Sending • Consumption
Signal to self • Output • Input	Message to self • Sending • Consumption
Timer • Set • Reset • Implicit Reset • Input	Timer • Set • Reset • Implicit reset[a] • Time-out
Create a process	Process Create
Stop a process	Stop
Environment	Environment[b]
System <system name>	Instance <instance kind>
Substructure <system name>	Instance <instance kind>
Block <block name>	Instance <instance kind>
Process <process name> <instance number>	Instance <instance kind> <instance name>
State	Condition[c]
Task	Action[d]
Comment	Comment

a. See "Implicit reset" on page 1729.

b. The system's environment is denoted by env_1

c. The mapping is only completely valid for a condition connected to only one instance. A condition connected to several instances expresses a logical AND-combination of the states of the processes corresponding to those instances.

d. The *action* symbol corresponds to a task symbol containing informal text. This translation is, however, not supported when generating an MSC from a simulation.

Generating the MSC

When running the simulation, each SDL event of interest (in the scope of MSC Trace) that takes place will cause the corresponding MSC symbol to be drawn in the drawing area of the MSC Editor.

Drawing Conventions

Layout

Default layout algorithms are used. Each event causes the insertion point to be translated downwards with one vertical spacing unit, keeping the intuitive feeling of **absolute order** between events. An event could be, for instance, the output or the input of an SDL signal. However, if an output event is immediately followed by an input event, no translation will take place.

Auto-Resizing of MSC

The MSC Editor will automatically enlarge the MSC size when the MSC has grown so that it reaches the bottom or right of the drawing area. The MSC is enlarged according to a preference parameter.

Messages

A distinction is made between the *reception* and the *consumption* of messages:

- **Reception** of a message: Once an SDL signal is output in the simulator, it is immediately placed into the input port of the receiving process instance. There may, however, be other pending SDL signals in this queue, which means that the signal might not be input immediately. Therefore, when a signal is output, it is illustrated as a

lost message, marked at its end with the name of the receiving instance, from the *sending instance* to the *receiving instance*.

- **Consumption** of a message: When an SDL signal is input, the vertical position for the next event may have moved down in comparison to the position of the signal output. An input of a signal is illustrated by redrawing the line representing the message with its end point connected to the new vertical position. (If an output event is immediately followed by an input, there is no change in vertical position.)
- In the case messages remain lost for a “long” time, this may be interpreted as some kind of erroneous behavior which requires special attention. Messages that are never consumed indicate that some design error might have been introduced in the SDL system. It is up to you to decide whether the time which has elapsed since a message was sent should be considered as exceeding a reasonable value.

Create of Process

Each time an SDL process is dynamically created, a process create will be drawn from the source instance axis, and the created instance will be positioned according to the insert and grouping modes that is set. This guarantees that no overlapping instance axes will take place.

The MSC Editor will automatically enlarge the MSC size when the MSC has grown so that it reaches the bottom or right of the drawing area. The drawing area is enlarged according to the value of a preference parameter.

Process Stop

If an instance is stopped (by a stop symbol), the space which becomes available beneath the instance end symbol will not be reused for new instance axes.

Timers

- The MSC Editor can handle four different timer statuses resulting from a simulation:

  – *Set*
  – *Reset (stopped)*
  – *Implicit reset*
  – *Timeout*

  On the MSC they are shown according the figure below:

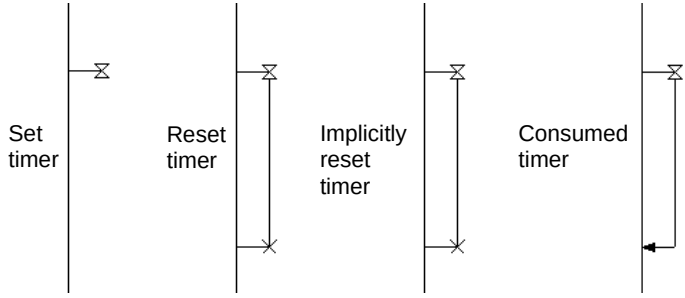

Figure 314: Timer status as shown on the MSC

  – *Implicit reset*

    The *implicit reset* timer status is a non-Z.120 addition to the MSC Editor. An implicitly reset timer is immediately set again to its original parameters after reset. It is illustrated in the same way as a *reset* timer, but the status information is reflected in the *Info* dialog (see "Requesting Detailed Information on an Object" on page 1802).

Instances

- **The Environment Instance**

  All interchange of information between the SDL system and its environment is displayed by sending / receiving messages to or from an instance with the name `env_1`. This instance is normally placed at the left of the drawing area.

- **The Void Instance**

  Graphically, in the Message Chart Editor, the concept *conditional trace* (see *"Scope of Trace for Generation of Message Sequence Charts" on page 2187 in chapter 49, The SDL Simulator*) is illustrated as sending or receiving messages to / from an *instance* with the name *Void*. The purpose of the *Void* instance is to document that a message exchange actually took place without focusing on the sending / receiving instance.

- **The Instance Name and Instance Kind Text Fields**

  The ITU recommendation Z.120 allows several ways of using the two text fields *Instance Name* and *Instance Kind*. This was discussed earlier in "Adding an Instance Head Symbol" on page 1806 in chapter 41, *Editing MSC Diagrams*.

  When generating an MSC, the SDL *Process Name* and the internal *instance number* managed by the simulator monitor are concatenated to build up one (MSC) *Instance Name*. The SDL *diagram type* and *diagram name* are concatenated to build one *Instance Kind*.

  Example 315 Instance Name and Instance Kind in Simulation Trace

  Assume the simulation program contains an instance of the SDL diagram type = *process* with the *diagram name* = Demon and monitor *instance number* = 2 This would be displayed as the following instance:

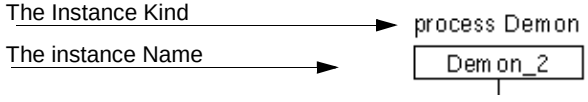

Figure 315: The use of the instance text fields in a simulation

Terminating the Trace

Having terminated the trace (either by stopping the simulation or turning the MSC trace off), **you are responsible for saving** the MSC(s) that are the results of the simulation.

Syntax Summary

Object Model Syntax

While the intent of Object Model diagrams is to give as large flexibility as possible to analysis and specification activities, the different editing support facilities provided by the OM Editor requires textual data to follow certain syntactic conventions.

This section details the syntax rules that are imposed by the OM Editor on textual data only. Graphical syntax rules are enforced automatically by the OM Editor and are not described here.

Summary of Lexical Rules

In general, a somewhat restricted version of the lexical rules of SDL apply for names. These rules have the following noteworthy properties:

- It is possible to break a name over more than one line by using the underscore at the end of the line to escape the newline.
- It is possible to have identifiers consisting entirely of numeric characters; e.g. “223” is a valid identifier.
- Identifiers are not case sensitive.
- Comments can be used anywhere in the texts. A comment is defined as an SDL comment, i.e. `/* this is a comment */`

For more information on the SDL lexical rules, see the Z.100 recommendation.

The primary restriction is that identifiers containing spaces are not considered legal.

```
<name> ::= identifier as described above.
<c-string> ::= string as bounded by " characters.
<sdl-string> ::= string delimited by '
(apostrophes).
```

Class Definition Summary

When interpreting OM diagrams, all class and object symbols within all pages within all diagrams in a single module must be considered. A class definition is considered to be the conceptual union of the informa-

tion contained in all class symbols with the same name, as well as all object symbols declared as instances of that class.

This means that the definition of a class can be distributed over several symbols, pages and even diagrams. The definitions in class symbols with the same name are then merged to obtain the complete definition of the class; support for this is provided by the *Browse & Edit Class* dialog.

Thus, when defining classes, it is acceptable to have identical attributes or operations defined several times, either in the same or different class or object symbols. The identical definitions are simply redundant, and do not affect the correctness of the complete class definition.

Note, however, that each unnamed class objects is considered distinct, so that each unnamed class symbol defines its own class.

Diagram Name Syntax

Diagram names must follow certain restrictions since they are used to identify the diagram with respect to other tools.

```
Diagramname ::= <name>
```

Page Name Syntax

```
Pagename ::= <name>
```

Each page name must be unique within its containing diagram.

Class Symbol Syntax

The textual information in class symbols is divided into five compartments of which three have their own syntax. The stereotype and properties compartments are not checked for syntax.

In the attributes and operation compartments the *stereotype concept* as described in "Object Model Literature References" on page 1767 can be used. The syntax chosen supports the single characters left/right guillemet («») but it can also be written as two angle brackets. To type the left/right guillemet in the text window, press `<Ctrl>` when you type the left/right angle bracket.

Class Name Compartment Syntax

```
Classname ::= <name> |
   <name> ':' ':' <name> |
   <empty>
```

Class Attributes Compartment Syntax

```
ClassAttributesCompartment ::=
   { <stereotype> <classattribute> <note> }*
<stereotype> ::= '<' '<' <name> '>' '>' |
   '«' <name> '»' |
   <empty>
<classattribute> ::=
   <visibility> <attribute>
<visibility> ::=
   '+' |
   '-' |
   '#' |
   <empty>
<attribute> ::=
   <name> <value> |
   <name> ':' <type> <value>
<type> ::= <name>
<value> ::= '=' <valueitem> | <empty>

<valueitem> ::=
   <name> |
   '-' <name> |
   '+' <name> |
   <c-string> |
   <sdl-string> |
   '(' <valueitemlist> ')' |
   '{' <valueitemlist> '}'
<valueitemlist> ::=
   <valueitem> |
   <valueitemlist> ',' <valueitem>
<note> ::=
   '{' <name> '}' |
   '{' <name> '=' <name> '}' |
   <empty>
```

Two attributes are considered identical if they have the same name and type. Note that attributes defining different values are still considered identical.

Class Operations Compartment Syntax

```
ClassOperationsCompartment ::=
   { <stereotype> <classoperation> <note> }*
<classoperation> ::=
   <visibility> <operation>
<operation> ::=
   <name> <return> |
   <name> '(' ')' <return> |
   <name> '(' <parameterlist> ')' <return>
```

```
<parameterlist> ::=
   parameter |
   parameterlist ',' parameter
<parameter> ::=
   <type> |
   <name> ':' <type>
<return> ::=
   ':' <name> |
<empty>
```

Two operations are considered identical only if the name, parameter list and the return fields are all the same. Thus “op”, “op(a)” and “op:t” are all unequal, while “op(a)”, “OP(A)” define the same operation.

Note however that “op” and “op()” are not considered equal, since the OM Editor does not interpret an omitted parameter list as an empty parameter list.

Object Symbol Syntax

The textual information in object symbols is divided into four compartments of which two have their own syntax. The stereotype and properties compartments are not checked for syntax.

Object Name Compartment Syntax

```
Objectname ::=
   <name> ':' <classname> |
   <name> |
   <empty>
```

Object Attributes Compartment Syntax

```
ObjectAttributesCompartment ::=
   { <stereotype> <attribute> <note> }*
```

Text Symbol Syntax

Text symbols are not subject to any syntax rules.

Line Syntax

The current version of the OM Editor does not implement any syntax checks on the contents of the textual attribute objects of lines.

State Chart Syntax

While the intent of State Chart diagrams is to give as large flexibility as possible to analysis and specification activities, the different editing support facilities provided by the SC Editor requires textual data to follow certain syntactic conventions.

This section details the syntax rules that are imposed by the SC Editor on textual data only. Graphical syntax rules are enforced automatically by the SC Editor and are not described here.

Summary of Lexical Rules

In general, a somewhat restricted version of the lexical rules of SDL apply for names. These rules have the following noteworthy properties:

- It is possible to break a name over more than one line by using the underscore at the end of the line to escape the new line.
- It is possible to have identifiers consisting entirely of numeric characters; e.g. “223” is a valid identifier.
- Identifiers are not case sensitive.
- Comments can be used anywhere in the texts. A comment is defined as an SDL comment, i.e. `/* this is a comment */`

For more information on the SDL lexical rules, see the Z.100 recommendation.

The primary restriction is that identifiers containing spaces are not considered legal.

```
<name> ::= identifier as described above.
```

State Definition Summary

UML allows some expressions in text segments to be defined by the tool vendors. For State Charts such expressions should follow SDL/PR syntax, but this is not checked by the SC Editor.

When interpreting SC diagrams, all state symbols within all pages within all diagrams in a single module must be considered. A state definition is considered to be the conceptual union of the information contained in all state symbols with the same name.

This means that the definition of a state can be distributed over several symbols, pages and even diagrams. The definitions in state symbols with the same name are then merged to obtain the complete definition of the state.

Thus, when defining states, it is acceptable to have identical activities defined several times, either in the same or different state symbols. The identical definitions are simply redundant, and do not affect the correctness of the complete state definition.

Note, however, that each unnamed state object is considered distinct, so that each unnamed state symbol defines its own state.

Diagram Name Syntax

The diagram name identifies the diagram.

```
<DiagramName> ::= <name>
```

Page Name Syntax

The page name identifies the page within a diagram.

```
<PageName> ::= <name>
```

Each page name must be unique within its containing diagram.

State Symbol Syntax

The textual information in state symbols' state sections is divided into three compartments with different syntax.

Name Compartment Syntax

The name identifies the state.

```
<NameCompartment> ::=
     [<name>]
```

Internal Activity Compartment Syntax

Internal activities' syntax is defined by the following grammar:

```
<InternalActivityCompartment> ::=
     {<internal-activity>}*

<internal-activity> ::=
     <event-signature>
     [<guard-condition>]
```

```
      ['/' <action-expr>]
      |
      <reserved-action-label> '/' <action-expr>

<reserved-action-label> ::=
      'entry' | 'exit' | 'do'

<event-signature> ::=
     <name> [<argument-list>] |
     <predefined-event> '(' <argument> ')'

<predefined-event> ::=
      'when' | 'after'

<argument-list> ::=
     '(' [<argument> {',' <argument>}*] ')'

<argument> ::=
      <expression>

<guard-condition> ::=
      '[' <expression> ']'

<action-expr> ::=
      <expression>

<expression> ::=
      SDL/PR expression
```

Two events are considered identical only if the name and the argument list are all the same. Thus “op” and “op(a)” are unequal, while “op(a)”, “OP(A)” define the same event.

Note however that “op” and “op()” are not considered equal, since the SC Editor does not interpret an omitted parameter list as an empty parameter list.

Text Symbol Syntax

Text symbols are not subject to any syntax rules.

Transition Line Syntax

The textual information in the *transition label* attribute of transition lines is defined by the following grammar:

```
<TransitionLabel> ::=
      [<event-signature>]
      [<guard-condition>]
      [<action-list>]
```

```
<action-list> ::=
     '/' <action-expr> {';' <action-expr>}*
```

DP Syntax

While the intent of Deployment diagrams is to give as large flexibility as possible to analysis and specification activities, the different editing support facilities provided by the DP Editor require textual data to follow certain syntactic conventions.

This section details the syntax rules that are imposed by the DP Editor on textual data only. Graphical syntax rules are enforced automatically by the DP Editor and are not described here.

Summary of Lexical Rules

In general, a somewhat restricted version of the lexical rules of SDL apply for names. These rules have the following noteworthy properties:

- It is possible to break a name over more than one line by using the underscore at the end of the line to escape the newline.
- It is possible to have identifiers consisting entirely of numeric characters; e.g. “223” is a valid identifier.
- Identifiers are not case sensitive.
- Comments can be used anywhere in the texts. A comment is defined as an SDL comment, i.e. `/* this is a comment */`

For more information on the SDL lexical rules, see the Z.100 recommendation.

The primary restriction is that identifiers containing spaces are not considered legal.

```
<name> ::= identifier as described above.
```

Diagram Name Syntax

The diagram name identifies the diagram.

```
<DiagramName> ::= <name>
```

Node Symbol Syntax

The name identifies the node.

```
<NodeName> ::= <name> |
                    <empty>
```

There are no syntax checks on the stereotype and properties texts.

Component Symbol Syntax

The name identifies the component.

```
<ComponentName> ::= <name> |
                    <empty>
```

There are no syntax checks on the stereotype and properties texts.

Thread Symbol Syntax

The name identifies the thread.

```
<ThreadName> ::= <name> |
                    <empty>
```

Object Symbol Syntax

The name identifies the object.

```
<ObjectName> ::= <name> |
                    <empty>
```

There are no syntax checks on the stereotype, properties and qualifier texts.

Text Symbol Syntax

Text symbols are not subject to any syntax rules.

Line Syntax

The DP Editor does not implement any syntax checks on the contents of the textual attribute objects of lines.

HMSC Syntax

While the intent of High level MSC diagrams is to give as large flexibility as possible to analysis and specification activities, the different editing support facilities provided by the HMSC Editor requires textual data to follow certain syntactic conventions as specified in MSC'96.

This section details the syntax rules that are imposed by the HMSC Editor on textual data only. Graphical syntax rules[1] are enforced automatically by the HMSC Editor and are not described here.

Summary of Lexical Rules

The lexical elements follow MSC'96. These rules have the following noteworthy properties:

- An underscore followed by on or more spaces is ignored completely, e.g. A_ B denotes the same <name> as AB. This use of underline makes it possible to split keywords over multiple lines since control characters (e.g. newline) is treated as a space.
- It is possible to have identifiers consisting entirely of numeric characters; e.g. "223" is a valid identifier.
- Identifiers are not case sensitive.
- Comments (`<note>` in Z.120) can be used anywhere between lexical units. A `<note>` is started by the characters `/*` outside a `<note>` and terminated by the characters `*/` inside a `<note>`.

For more information on the MSC lexical rules, see the Z.120 recommendation.

Syntax rules in Symbols

The descriptions below describes what text is allowed in the different symbols, it is not a description of the grammar in PR-form.

The grammar below informally describes the lexical units used as terminal symbols. Refer to Z.120 for a complete description.

```
<name> ::= identifier as described above.
<text> ::= approximately the ASCII character set.
```

1. No checks are made on completeness, however.

In the sections below each symbol will be described in the following manner:

1. A *short* description of the symbol and/or its contents and purpose.
2. The symbols textual grammar
3. Possibly any semantic restriction and/or notes. Refer to Z.120 for a complete description of the semantics that apply.

Diagram Name Syntax

The diagram name identifies the MSC to the outside world.

```
Diagramname ::= <name>
```

Diagram names must follow certain restrictions since they are used to identify the diagram with respect to other tools.

Page Name Syntax

The page name identifies the page within a document.

```
<page name> ::= <name>
```

Each page name must be unique within its containing diagram.

Text Symbol Syntax

The text in a text symbol is an informal explanatory text.

```
<text text> ::= <text>
```

The text has no (formal) semantic and no restrictions.

Condition Symbol Syntax

Global conditions can be used to restrict how MSC's can be composed in High level MSC's.

```
<condition name list> ::=
   <condition name> { ',' <condition name> }*

<condition name> ::= name
```

Global conditions indicate possible continuations of Message sequence charts containing the same the same set of instances by means of condition name identification.

Reference Symbol Syntax

MSC References are used to refer to other MSC's of the MSC document.

```
<msc ref expr> ::=
   <msc ref par expr> { 'alt' <msc ref par expr> }*

<msc ref par expr> ::=
   <msc ref seq expr> { 'par' <msc ref seq expr> }*

<msc ref seq expr> ::=
   <msc ref exc expr> { 'seq' <msc ref exc expr> }*

<msc ref exc expr> ::=
   [ 'exc' ] <msc ref opt expr>

<msc ref opt expr> ::=
   [ 'opt' ] <msc ref loop expr>

<msc ref loop expr> ::=
   [ 'loop' [ <loop boundary> ] ]
   {
     'empty' |
     <msc name> [ <parameter substitution> ] |
     ( <msc ref expr> )
   }

<parameter substitution> ::=
   'subst' <substitution list> 'end'

<substitution list> ::=
   <substitution> [ ';' <substitution list> ]

<substitution> ::=
   <replace message> |
   <replace instance> |
   <replace msc>

<replace message> ::=
   [ 'msg' ] <message name> 'by' <message name>

<replace instance> ::=
   [ 'inst' ] <instance name> 'by' <instance name>

<replace msc> ::=
   [ 'msc' ]
   { 'empty' | <msc name> } 'by'
   { 'empty' | <msc name> }

<msc name> ::= <name>

<message name> ::= <name>

<instance name> ::= <name>
```

MSC Syntax

While MSC diagrams allows the user to specify the analysis and specification activities in great detail with graphical symbols, there are also fields that get their meaning from textual information only. The different editing support facilities provided by the MSC Editor checks textual data to follow certain syntactic conventions as specified in MSC'96.

This section details the syntax rules that are imposed by the MSC Editor on textual data only. Graphical syntax rules[1] are enforced automatically by the MSC Editor and are not described here.

Summary of Lexical Rules

The lexical elements follow MSC'96. They are identical to the lexical rules for HMSC, see "Summary of Lexical Rules" on page 1740 for further information.

Syntax Rules in Symbols

The descriptions below describes what text is allowed in the different symbols, i.e. it is not a description of the grammar in PR-form.

The grammar below informally describes the lexical units used as terminal symbols. Refer to Z.120 for a complete description.

```
<name> ::= identifier as described above.
<text> ::= approximately the ASCII character set.
```

In the sections below each symbol will be described in the following manner:

1. A *short* description of the symbol and/or its contents and purpose.
2. The symbols textual grammar
3. Possibly any semantic restriction and/or notes. Refer to Z.120 for a complete description of the semantics that apply.

Syntax Common with HMSC

All symbols that can take textual input in the HMSC are also present (and the same) as those found in the MSC. See "Syntax rules in Symbols" on page 1740 for further information.

1. No checks are made on completeness, however.

Syntax Specific for MSC

In addition to the symbols that are common HMSC symbols, the MSC Editor supports the following symbols that contains text.

Comment Symbol Syntax

The text in a comment symbol is an informal explanatory text.

```
<comment text> ::= <text>
```

The text has no (formal) semantic and no restrictions.

Instance, Message and Timer Name syntax

The text identifies the entity

```
<instance name> ::= name
<message name>  ::= name
<timer name>    ::= name
```

Parameter Syntax

Both on messages and instance creations have parameters. In addition the MSC also supports parameters on timers (currently nonstandard). The Z.120 grammar for parameters is defined as follows:

```
<parameter list> ::=
       <parameter name> [ ‘,’ <parameter list> ]
```

This grammar is neither able to allow empty parameter lists, nor to take parameters that are generated from SDL. Furthermore, the grammar does not allow string literals. The MSC Editor (and associated tools) supports the following, more relaxed, grammar:

```
<parameter list> ::=
        [ <relaxed name> { ‘,’ <relaxed name> } * ]
<relaxed name> ::=
        <parameter name> [ ‘(‘  <relaxed name> ‘)’ }
<parameter name> ::=
        <name> |
        <character string> |
        <character string 2>
```

The grammar of `<character string 2>` is the same as the grammar for the Z.120 `<character string>` except that the apostrophe is regarded as the Z.120 `<other character>` and the double quote ‘”’ is regarded as an `<apostrophe>`.

Instance Kind Syntax

The instance kind describes the type of the instance

```
<instance kind>::=
        [ <kind denominator> ] <identifier>
<kind denominator> ::=
        'system' | 'block' | 'process' | 'service'
        | <name>
<identifier> ::= [ <qualifier> ] <name>
<qualifier> ::= '<<' <text> '>>'
```

Decomposition Syntax

This text is present if the instance is decomposed and describes the name of the diagram that explains the decomposed instance in greater detail.

```
<decomposition> ::=
         'decomposed' [ <substructure reference> ]
<substructure referrence> ::=
         'as' <message sequence chart name>
```

Inline Heading Syntax

This is the syntax for the text area in the inline expressions symbols.

```
<inline heading> ::=
        'alt'
        'par'
        'exc'
        'opt'
        'loop' [<loop boundary>]
<loop boundary> ::=
        '<' <inf natural> [ ',' <inf natural> ] '>'
<inf natural>   ::= 'inf' | <natural name>
<natural name>  ::= {0|1|2|3|4|5|6|7|8|9}+
```

Comparing and Merging Diagrams

Overview

Compare and Merge for MSC diagrams

This section describes more details about how the comparison is done in the Compare and Merge functionality for MSC diagrams. The intention is that this should be of interest for a user who wants to understand how the comparison is done and to anticipate what a resulting Compare/Merge will look like.

Compare operation

Two MSC or HMSC diagrams are input to the Compare operation. In general when differences are found related objects are grouped together to form difference groups. In the graphical report it is possible to navigate between these difference groups using the Next and Previous buttons.

For MSC diagrams the algorithms to find difference groups are as follows:

- First the heading is checked
- Then instances are checked
- Then for each instance the events connected to this instance are checked
- Then text symbols are checked
- At last unconnected comment symbols are checked

Comparing Headings

The heading texts will be compared in the two diagrams. If they differ the heading will form a difference group of its own.

Comparing Instances

When instances are compared the algorithm will for each instance try to find a matching instance in the other diagram. To find the match, first of all it uses the name to find the match. If there is no name match, the objectID for the instances will be used to find the match. The objectID is a unique (within each diagram) number that every object has, this is normally not visible for the user but it can be shown using the Info Window. By using objectIDs we will hopefully match instances where the difference is that the name has been changed. When instances have been matched, differences will be reported if any of the three text fields, name, kind and decomposition will differ.

Instances that have not been matched in the two diagrams will then be classified as being added or removed. Each instance will form a difference group of its own.

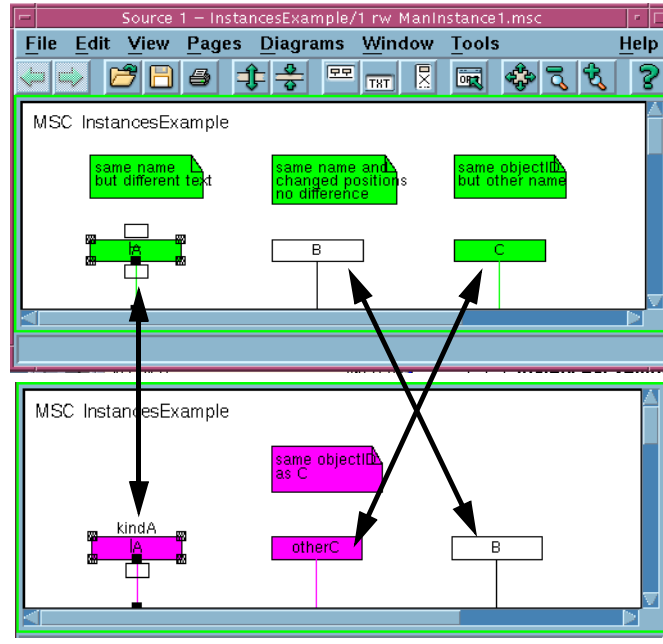

Figure 316 Comparing instances

In Figure 316 on page 1747 two diagrams are shown. When using the Compare command, the instances with the name A will be matched and they will also differ as the instance kind texts are different. Instances with the name B will match and no difference will be detected even though the positions of the instances are not the same. The instance with the name C will be matched and differ against the instance with the name otherC because both have the same objectID. The figure also indicates by the color that all the text symbols differ as either the text has changed or they only appear in one of the diagrams.

Comparing Events

The events will be checked for one instance at a time. All events connected to one instance are ordered from top to bottom. For the corresponding matched instance in the other diagram the event sequences are compared using an algorithm similar to the UNIX diff function for text comparison. The events are group in sequences that have been un-

changed, changed, added or removed. Each such sequence will then form a difference group.

If there is an instance without a match in the other diagrams all the events connected to this instance will be considered as being added and they will all form a difference group.

Special treatment is made for events that are connected to more than one event. For messages the event will be treated together with events connected to the instance where the message starts, except for found messages that are treated on the incoming instance.

Multi instance events like conditions, references and inline expressions are treated in the event sequence for the instance that first encounters the multi event.

After all the event sequences have been checked, difference groups that differ will be sorted from top to bottom according to the Y-position of the objects in the group. Thus, when they are presented in the graphical report they are shown in this order.

Comparing Comments

A comment that is connected to an object will be handled together with that object. This means that if the comment texts differ the whole object will be considered as being different.

An unconnected comment will be matched using the geometrical position of the object or if this check fails the objectID will be used.

Each unconnected comment having differences will form a difference group of its own.

Comparing Text Symbols

The text symbols uses the same algorithms to find differences as the unconnected comments described in the previous section.

Merge operation

The merge operation has two source diagrams as input. The Source2 diagram is merged with Source1 and the resulting diagram is placed in the Result diagram. An optional input is the Ancestor diagram which is used to drive the automerge functionality.

The algorithm for the merge operation is to use the difference groups found when comparing Source1 and Source2. All objects not belonging to any difference group, these are objects being the same in both Source1 and Source2, will be copied from Source1 to Result. For each difference group, the objects in the group are compared with the Ancestor diagram, if no Ancestor is specified the behavior is the same as if the Ancestor diagram was present and it had no objects. If the difference group is a group that has changed and Source1 is the same as the Ancestor, then Source2 is copied to the Result, and if Source2 is the same then Source1 is copied. If none of Source1 or Source2 is the same as Ancestor then the group is classified as being unresolved and the user must decide what the Result should look like.

If a difference group indicates that there are objects in Source1 that have no matching objects in Source2, these objects will be added to Result if they also do not have any matching objects in the Ancestor diagram. However, if there are unchanged matching objects for the whole difference group in the Ancestor they will not be added to Result as in this case they have been removed in Source2. If only parts of them match the group will be classified as unresolved. Similar if a group indicates that objects have been added to Source2 the objects will be added to the Result diagram if the objects also are missing in the Ancestor diagram. If they all have matching objects in Ancestor they will not be added, otherwise the group is set as unresolved.

Figure 317 on page 1750 shows an example of the merge operation.

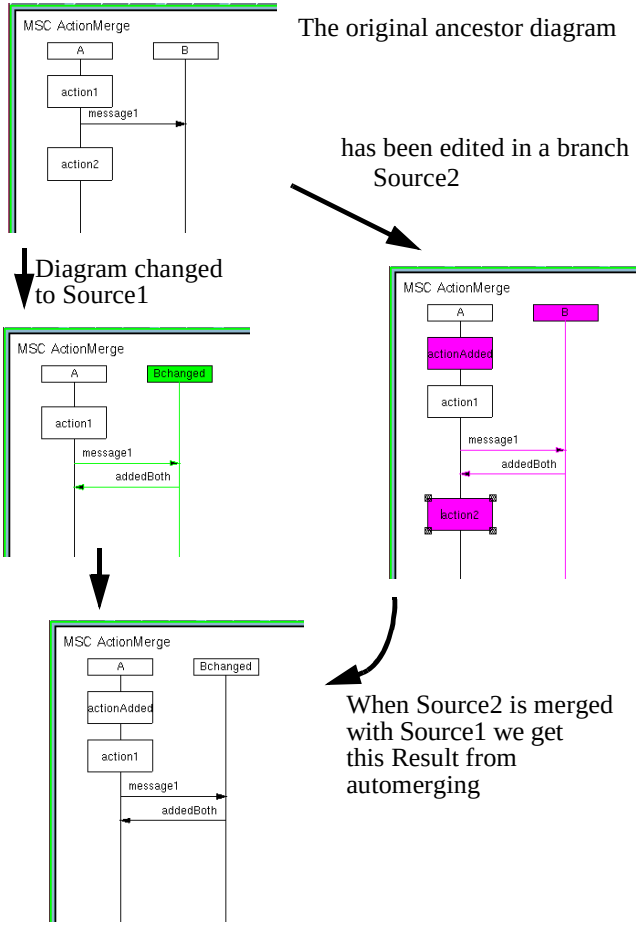

Figure 317 Example using automerge

The automerge gives the following result when the Source2 diagram is merged into the Source1 diagram and the Ancestor diagram has been specified:

- The instance B and Bchanged has been matched and the Result will use the version from Source1 as Source2 and Ancestor are identical.

- The action actionAdded has been added to the Result because there is no match against this in Source2 and it is also missing in Ancestor.
- The action action2 has been removed in Result as it has been removed in Source1 and it was the same in Ancestor and Source2.
- The message addedBoth has been added to Result as it appears both in Source1 and Source2.

Merged diagram with layout changes

During a merge the normal behavior is that, if necessary, a Make Space operation will be performed when a merged object is added to the Result diagram. This will make sure that objects are placed in the correct order and that the diagram will not have overlapping objects.

However, in some circumstances the resulting diagram from a merge operation can have objects placed at positions, which can not be obtained when editing the same diagram by hand. This can happen when the source diagrams do not have much free space in them or when matched objects from the sources are placed at different geometrical positions.

Specifically, please note the following observations:

- As the comparison of the objects is based on the semantic information in the diagram, the geometrical positions of objects can be changed in the merged resulting diagram compared to the positions in the source diagrams. For objects that are the same in both sources and thus being added to the Result diagram, the position from Source1 is used. When objects are inserted from Source2 they will in general not have the same geometry appearance in the Result diagram.
- When objects are merged as the first object on an instance axis they can be placed on the same position and therefore overlap each other. If e.g. both objects are action symbols the visible object can completely hide the object below.
- When messages are merged, the order of events on the given instance will be preserved. This applies to both the in event and the out event. Sometimes this will result in a merged Message object where the message goes “upwards”.

- The geometrical layout of an added difference group might not be same if the Accept/Reject button is pressed several times. However, the semantic information should always be the same.

Merged diagram with unresolved instances

When instances are merged and an unresolved difference is detected for a given instance, all events connected to this instance will be grouped together in one or more difference groups and will be classified as unresolved. If, from the merge dialog, one of the versions of this instance is accepted, the events can also be accepted in later difference groups. If the difference groups will wrap, i.e. by pressing Next many times the difference groups will start from the beginning again, the events connected to this merged instance might not be presented again. They will appear only if there is a real difference for the events. This happens because after a wrap all difference groups are dynamically recalculated and difference groups are first of all found from the differences between Source1 and Source2, and secondly they are formed if any of the instances does not appear in the merged diagram. After the instance has been manually merged the unchanged events connected will then not be part a any difference group.

Performance

The time it takes to perform a Compare/Merge operation depends on how many instances the diagram contains and also on the height of the diagram. There is also a dependence on the type of objects that are used in the diagram, use of multi axis objects like inline expressions, conditions and reference symbols will increase the time used. A 5 pages long diagram with 10 instances and 10 multi-axis objects can take about a minute to perform the Compare/Merge operation.

Unsymmetrical differences can give unexpected difference groups

The use of the diff algorithm when comparing the event sequence on two instance axis can in certain situations give rise to some unexpected results. The diff algorithm looks for the longest sequences of identical events when finding differences. Sometimes this results in two different results for the same sources. Assume Source1 has the sequence ABCD and Source2 has the sequence ACBD. A diff on Source1 and Source2 gives as a result that in Source2 C is unchanged but B has been removed and then B has been added. If instead Source2 is compared with

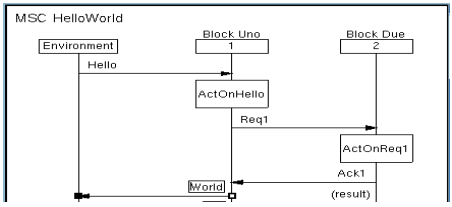
Source1 we will get that B is unchanged and that C has been removed and added. Thus the comparison is not symmetrical.

To compensate for this unsymmetry the resulting difference groups after the diff algorithm are checked for patterns like the one described above. For each unchanged difference group (Ug) the following check is done. If there is a changed or added difference group (CAg) preceding the unchanged one, Ug, and all objects belonging to CAg also can be found in a changed or removed difference group following Ug, the Ug group will also be set as being a changed difference group. Similar if there is a changed or removed difference group (CRg) preceding Ug and all objects belonging to CRg also can be found in a changed or added group following Ug, the Ug group is set as being changed.

Using the example above, we will then get that both B and C will appear in some difference group and thus be considered to have been altered. For the user this can be unexpected, as for example if we only change the diagram by moving object B by dragging it below C we would expect that only B will appear in a difference. However as the compare algorithm rely on semantical information rather than geometrical the tool cannot decide whether it is B or C that has been changed. With the extra check done, we set both as changed and we then will get more difference groups than expected.

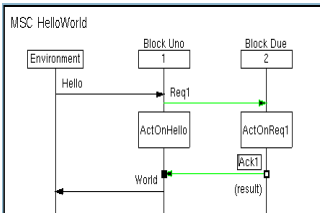
With the extra check made there can still exist some unsymmetry left when comparing. There will be difference groups for the same objects but the difference groups can be of different kinds. This can result, in an automerge situation, that the merged result will not be the same if Source2 is merged into Source1 or if Source1 is merged into Source2. Also the kind of conflicts appearing might be different.

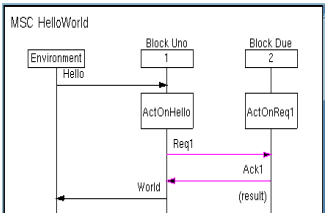
In Figure 318 on page 1754 an example illustrates how this can affect the resulting diagram from an automerge.



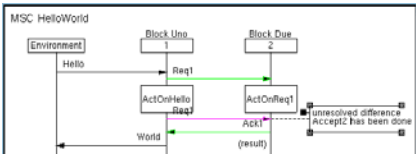
The original ancestor diagram

Source1 and Source2

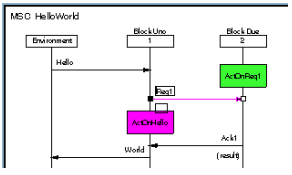




This is what we get when merging Source2 into Source1



This is what we get when merging Source1 into Source2



Here there will be a conflict for the Req1 message. The diagram shows the result after Accept2 but the diagram will have the same appearance if Accept1 has been used instead.

Figure 318 Result from automerge

From the changes in Source1 and Source2 it is uncertain what the result of a merge will look like. Is the changed that the message Req1 will be either after or before the action symbols? or is the change that the action symbols are moved relative to the message? Both expectations could be justified and in the automerge, both when merging Source2 into Source1 or Source1 into Source2, we will get a merge conflict (however

not the same conflict), which signals the user that he must check this more carefully.

The conclusion is that you should be careful when using automatic merge, sometimes your expectations will not come true.

Compare and Merge

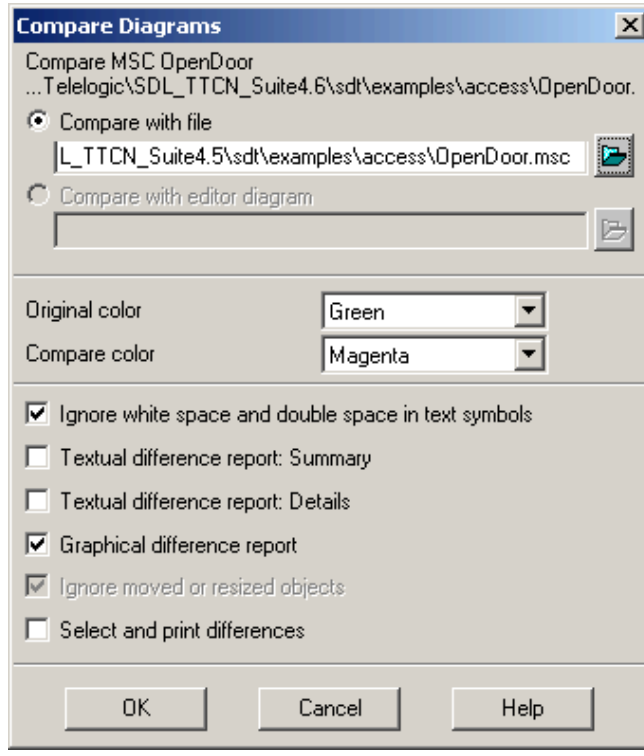


Figure 319: The Compare Diagrams dialog in the MSC Editor

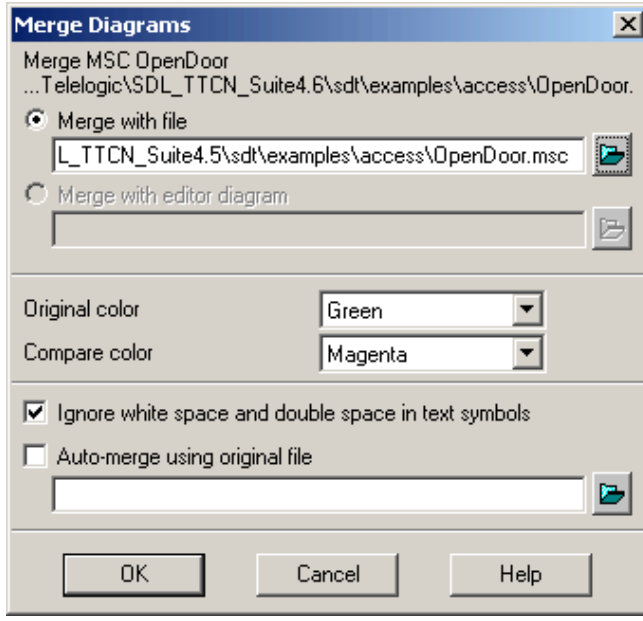

Figure 320 The Merge Diagrams dialog in the MSC Editor

When you select *Compare Diagrams* or *Merge Diagrams* from the *Tools* menu in the MSC Editor or in the HMSC Editor, a dialog will be opened where you can select the diagram to compare with. (It is also possible to compare more than one diagram pair in one operation, but to do this you should use the corresponding menu choices in the Organizer. See "Compare > MSC Diagrams" on page 151 in chapter 2, *The Organizer*, "Compare > HMSC Diagrams" on page 151 in chapter 2, *The Organizer*, "Merge > MSC Diagrams" on page 151 in chapter 2, *The Organizer* and "Merge > HMSC Diagrams" on page 152 in chapter 2, *The Organizer*.

Specifying the Diagram to Compare With

There are two ways for specifying the diagram that should be compared with the currently displayed diagram:

- You may specify the file in the *Compare with file* field.

- You may specify another diagram already opened in the editor in the *Compare with editor diagram* field. When you click the folder button, a dialog will be opened with a list of all diagrams opened in the editor (except for the currently displayed).

  The option *Compare with editor diagram* has the two restrictions:

  – It can only be used if more than one diagram is currently opened in the editor.

  – The folder button can only be used if more than two diagrams are loaded into the editor.

Selecting the Report Type

In the Compare Diagrams dialog, there are six alternatives for reporting differences between diagrams: *Ignore white space and double space in text symbols*, *Textual Difference Report: Summary*, *Textual Difference Report: Details*, *Graphical Difference Report (with Merge Facility)* and *Select and Print Differences*.

The Merge Diagrams dialog does not allow you to get a textual difference report. Instead, you always get a graphical difference report and the only option available is *Auto-merge using original file*.

Ignore white space and double space in text symbols

When this option is on, differences caused by different usage of white space are ignored when comparing texts. One space character is considered equal to two space characters.

Textual Difference Report: Summary

This option is only available when comparing using the *Compare Diagrams* menu choice.

A summary of how many differences that has been found is presented in the Organizer log. The summary may look like this:

```
Comparing /home/lat/x.spr
     with /home/lat/y.spr
27 differences (16 symbols, 11 lines) :
  7 changed objects (7 symbols, 0 lines)
  13 removed objects (6 symbols, 7 lines)
  7 added objects (3 symbols, 4 lines)
```

When you read this report, notice the following:

- 27 is the total number of found differences in this diagram pair. This is the total of all changed, removed and added objects.
- An object is considered to be changed if you have moved or resized it, or if you have changed a text associated with the object.

If at least one of the two compared diagrams has more than one page, then a summary is also presented for each page pair. It may look like this:

```
Comparing /home/lat/version1/registeredcard.spt
     with /home/lat/version2/registeredcard.spt
5 differences (1 symbol, 4 lines) :
  1 changed object (1 symbol, 0 lines)
  2 removed objects (0 symbols, 2 lines)
  2 added objects (0 symbols, 2 lines)

Page details:

Page ValidateCard
5 differences (1 symbol, 4 lines) :
  1 changed object (1 symbol, 0 lines)
  2 removed objects (0 symbols, 2 lines)
  2 added objects (0 symbols, 2 lines)

Page RegisterMode
0 differences
```

Textual Difference Report: Details

This option is only available when comparing using the *Compare Diagrams* menu choice.

This option will print information about each found difference in the Organizer log. This makes it possible to navigate from the Organizer log to every found difference by using the *Show Error* operation in the Organizer log. See "Organizer Log Window" on page 183 in chapter 2, *The Organizer*.

The detailed textual difference report may look like this:

```
Comparing /home/lat/d1/db.sbk
     with /home/lat/d2/db.sbk

Comparing page 1

#SDTREF(SDL,/home/lat/d1/db.sbk(1),119(50,35))
ERROR This symbol has been changed...
#SDTREF(SDL,/home/lat/d2/db.sbk(1),119(50,40))
ERROR ...and now looks like this.
```

```
#SDTREF(SDL,/home/lat/d1/db.sbk(1),176(95,60))
ERROR This symbol has been removed.

#SDTREF(SDL,/home/lat/d2/db.sbk(1),182(60,60))
ERROR This line has been added.
```

Graphical Difference Report (with Merge Facility)

The merge facility is only available when merging with the *Merge Diagrams* menu choice, but you can get a graphical difference report both when comparing with the *Compare Diagrams* menu choice and when merging with the *Merge Diagrams* menu choice.

Two windows, named *Source 1* and *Source 2*, displaying the two diagram versions and their differences, and one dialog will be opened. For merge, there will be a third window, named *Result*, showing the merge result.

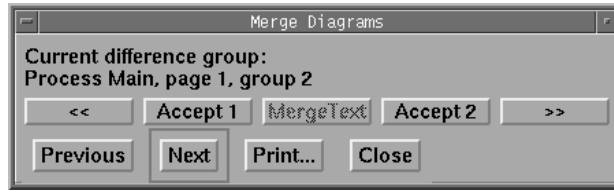

Figure 321: The Merge Diagrams dialog

The Compare Diagrams dialog is similar to the Merge Diagrams dialog. The difference is that the Compare Diagrams dialog is missing the first row of buttons. (“<<“, Accept1, Accept2 and “>>”.)

In the dialog that will be opened, you can:

– Navigate between difference groups with the *Next* and *Previous* buttons.

– (*Merge Diagrams* only.) Navigate between unresolved (not-yet merged) difference groups with the “<<“ and “>>” buttons.

– (*Merge Diagrams* only.) Do a merge, i.e. update the merge result diagram with information from the current difference group

and one of the compared diagram versions, with the *Accept1/Reject1* and *Accept2/Reject2* buttons.

– Compare or merge a text in a text symbol in the current difference group.

– Print the current difference found in the current page pair.

When the second compare dialog is closed, the editor windows are restored to how they appeared before the compare operation.

Comparing text in text symbols

When two text symbols differ the *CompareText* button will be available in the Compare Diagrams dialog and it will be possible to enter the Compare Text Symbols dialog.

The Compare Text Symbols dialog consists of two lists of text that are placed side by side with a "gutter" that will contain extra information about the differences. This gutter-information consist of:

– A "-" indicates that there is no corresponding line in the text compared to the other text.

– A "|" character indicates that this line differs in the two texts.

The current difference is indicated with a highlight. Buttons make it possible to navigate to *Previous* and *Next* difference item.

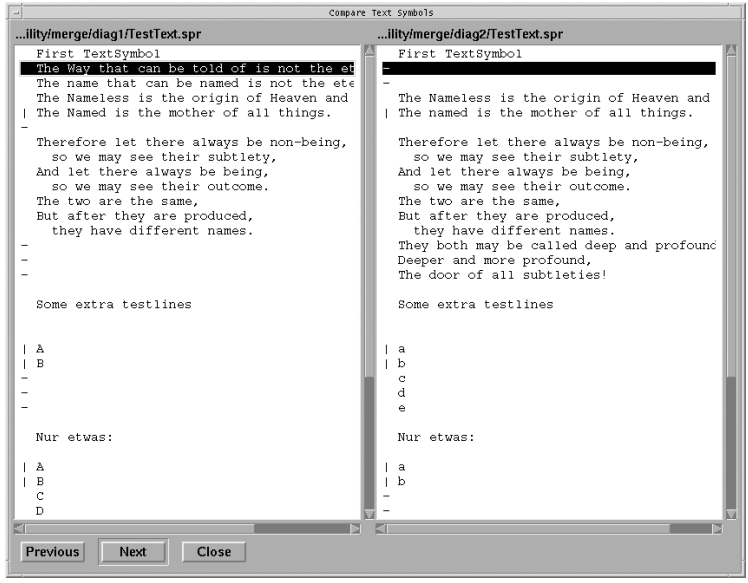

Figure 322: The Compare Text Symbols dialog

Merging text in text symbols

When manual merges are conducted the option to merge text symbols will always be available in the Merge Diagrams dialog. When merging a *MergeText* button is available as in the compare function. When a text symbol is selected there will be an option to select either symbol or merge the text in the symbols into a new symbol.

If the text merge is selected a Merge Text Symbols dialog is presented with three text lists, the two source texts and the result text. It is possible to navigate between the unresolved differences or between all differences.

Figure 323: The Merge Text Symbols dialog

This works in the same way as in the normal merge. The buttons "<<" and ">>" will jump between the unresolved differences and the *Previous* and *Next* buttons will jump between all differences.

The use of *Accept 1*/*Reject 1*, *Accept 2*/*Reject 2* buttons will select neither, either or both the texts for merge. The selections from the source files are presented in the result-list the gutter will show what version is selected. Additional symbols in the result list are:

- A "|" character indicates that this line differs in the two texts.
- A "=" character indicates that the selected text are equal in both versions.
- A ">" character indicates that the right text has been selected for merge.
- A "<" character indicates that the left text has been selected for merge.

It is also possible to edit the result line-by-line by selecting a line and edit it below the list. Clicking the *Change* button will replace the changed line in the result list.

Ignore moved or resized objects

If this option is on, the compare operation tries to ignore differences only caused by moved or resized symbols. You should only use this option if the two compared diagrams originates from the same diagram. (For instance, you have used Save as on the original diagram to get the second copy.) This option will not work well if you create two diagrams from scratch and compare them, because the operation uses object IDs to match moved or resized objects.

Select and Print Differences

If this option is on and there are differences, then a print dialog will pop up when the first dialog is closed. Only diagram pages containing differences will be printed, and the differences will be highlighted with selection markers. If the same page containing differences can be found in both compared diagrams, then the two pages will be printed after each other, beginning with the page from the diagram that was visible in the editor when the compare operation was invoked.

Auto-merge using original file

This option is only available in the Merge Diagrams dialog. It allows you to specify the original diagram file that both the diagram versions that are compared originates from. If you specify the original diagram file, then the merge operation can auto-merge all non-conflicting changes for you. Note that if you give the wrong original diagram, then the auto-merge operation may merge the two versions in the wrong way. If you do not specify an original diagram, then the merge operation leaves all merging of differences to you.

Differences That Will Be Reported

When you use *Compare Diagrams* or *Merge Diagrams*, all visual object differences will be found:

- An object that has been moved, resized, removed, added or painted in a different color.
- A text, associated with an object, that has been changed

An object is considered to be moved if it has been moved relative to the upper left corner of the diagram frame. This means that if you move the frame, it will have no effect.

Diagrams are compared one page pair at a time. A page pair is one page from the original diagram and one page from the other diagram where both pages have the same name. If there is no page with the same name in the other diagram, then the complete page is considered to be a difference.

Difference Groups

Differing objects from the same page pair are grouped into *difference groups*. Two differing objects are placed in the same group if:

- The objects are from the same diagram and they are connected to each other. For instance, a flow line connected to a task symbol.
- The objects are from different diagrams and they would overlap if they were in the same diagram, that is, it would be impossible to place the two objects in the same diagram without changing the position within the diagram for one of them.
- The objects are from different diagrams and the difference operation can conclude that it is the same object that has been moved.

Color and the Current Difference Group

In the graphical difference report, all differing objects are given temporary background colors as specified in the initial dialog. As default, the color is green in the original diagram and magenta in the other diagram. Temporary colors are not saved in diagram files. How temporary colors are removed is described in "Temporary Colors > Remove" on page 1675.

The dialog that will be opened during the graphical difference report, allows you to navigate between difference groups using previous and next buttons. All objects in the current difference group are selected.

Normally, version 1 of the compared diagrams (the diagram that was in the editor when the compare operation was invoked) is shown in a window in the top left corner of the screen. Version 2 (the diagram that was specified in the first compare dialog) is shown in the top right corner off the screen. For complete page differences (a difference where a page can not be found in the other diagram), the window that misses the page is hidden.

Note that it is possible to manually edit the compared diagrams while the compare operation is ongoing. This can be seen as a light-weight alternative to the full merge operation (described next).

Merging

During a merge operation, three windows are used in addition to the second merge dialog:

- The top left corner of the screen is used to show version 1 of the compared diagrams, in the editor window named *Source 1*. This is the diagram that was visible in the editor window when the merge operation was invoked.
- The bottom left corner of the screen is used to show version 2 of the compared diagrams, in the editor window named *Source 2*. This is the diagram that was specified in the first merge dialog as the diagram to compare with.
- The right part of the screen is used to show the merge result diagram, in the editor window named *Result*. This is a new diagram that has been created from the two compared diagram versions.

The second Merge dialog does not only have previous and next buttons to navigate between differences. It does also have *Accept/Reject* buttons and “<<” (fast backward) / “>>” (fast forward) buttons.

- Pressing *Accept 1* (*2*) will add symbols to the merge result diagram. It is the symbols from version 1 (2) of the current difference group that will be added.
- Pressing *Reject 1* (*2*) will remove symbols from the merge result diagram. It is the symbols that can be found in version 1 (2) of the current difference group that will be removed.
- Pressing “<<” (fast backward) will navigate to the previous unresolved difference group. An unresolved difference group is a difference group where both version 1 and version 2 are not accepted.
- Pressing “>>” (fast forward) will navigate to the next unresolved difference group.

Note that it is possible to manually edit diagrams while a merge operation is ongoing. This can be useful if you want the merge result diagram to look different from both version 1 and version 2 of the compared diagrams.

When the second merge dialog is closed, the editor will ask you to save the merge result by displaying a save dialog above the window with the

merge result diagram buffer. When the save dialog is closed, the editor windows are restored to how they appeared before the merge operation was invoked.

Literature References

Object Model Literature References

There is a growing number of publications devoted to object modeling techniques. The following two sources have been selected as defining the Object Model supported by the OM Editor:

Chapter

40 *The Deployment Editor*

The Deployment Editor is a tool for graphical partitioning of SDL systems, which allows you to model how SDL systems execute in their target environment. See also chapter 64, *Integration with Operating Systems*.

Diagrams in the editor, deployment diagrams, use notation from UML. Information from a deployment diagram can be used when targeting one or several SDL systems. See chapter 59, *The Targeting Expert*.

This chapter contains a description of the deployment diagram as well as guidelines for modeling different deployment scenarios. The connection with the Targeting Expert is also described.

Introduction

The Deployment Editor allows you to graphically deploy one or several SDL systems. SDL systems can be partitioned into components, i.e. executable files, which in turn are partitioned into threads of execution. Finally, SDL entities, i.e. objects, are mapped to the threads, showing the execution architecture at compile-time.

The information in a deployment diagram can be used by the Targeting Expert through the Partitioning Diagram Model. In the Targeting Expert, you can set build parameters on each component and build an application from this model.

Applications

You can use the Deployment Editor in two ways:

- As an editor for graphical partitioning of SDL systems.
- As a pure modeling tool.

The Deployment Editor gives you freedom in modeling partitioning and communication. There are few restrictions in drawing rules and no syntax checking is performed. There are, however, restrictions how to use deployment diagrams for generating partitioning data for the Targeting Expert. This chapter describes the requirements for using the Deployment Editor for partitioning. The diagram symbols are described as they are interpreted when used for partitioning.

Starting the Deployment Editor

You start the Deployment Editor the same way as the other editors in the SDL Suite. There are four alternatives:

- Select *Tools -> Editors -> Deployment Editor* in the Organizer to start with an empty diagram.
- Select *Edit -> Add New...* in the Organizer and *UML -> Deployment* in the *Add New* dialog to add a new diagram.
- Select *Edit -> Add Existing...* in the Organizer to add an existing diagram.
- Right-click on an existing deployment diagram symbol in the Organizer and select *Edit -> Edit* in the pop-up menu.

The Graphical User Interface

The graphical user interface in the Deployment Editor is similar to that used in the other SDL Suite editors. For a description of the user interface in general, see chapter 1, *User Interface and Basic Operations, in the User´s Manual*.

Connection to the Targeting Expert

The Deployment Editor generates data that can be used by the Targeting Expert. Deployment diagrams are translated to the data format Partitioning Diagram Model (PDM), which contains build-related information. See "Generating Partitioning Diagram Data for the Targeting Expert" on page 1787.

To start the Targeting Expert with PDM data for a deployment diagram:

1. Click on the deployment diagram (.sdp file) in the Organizer
2. Select *Targeting Expert* from the *Generate* menu.

See chapter 59, *The Targeting Expert, in the User´s Manual* for information on how to build using the Targeting Expert.

Using Information from SDL System(s)

The Deployment Editor has no automatic access to information about SDL systems in the Organizer. You must enter information about SDL objects manually in a deployment diagram.

For SDL objects, the following information is mandatory to enter:

- *Name*

  It is recommended that the name of the object in the Organizer is used.
- *Qualifier*

  This is the *path* to the SDL object in the Organizer. The qualifier should include the name of the object in the Organizer.
- *Stereotype*

  This shows the type of SDL object and should have one of the following values: `system`, `block` or `process`.

See "Object" on page 1777 for more information about SDL objects.

Note:

It is possible to deploy objects from many SDL systems in one deployment diagram. The only requirement is that the SDL systems must be contained within the same `.sdt` file. This `.sdt` file must be loaded in the Organizer when working with the deployment diagram.

The Deployment Diagram

In this section, the deployment diagram is described. The view and the symbols as well as drawing rules for the different integration models are explained.

Note:

Following the naming convention in the SDL Suite, diagrams edited in the Deployment Editor are named deployment diagrams. This notion must **not** be mistaken for the UML deployment diagram. In this chapter, “deployment diagram” implicitly means the SDL Suite diagram.

Note:

In the Deployment Editor, it is only possible to use one page per diagram. This differs from the OM Editor, where an arbitrary number of pages can be used. See “OM Editor Specific Information” on page 1691 in chapter 39, *Using Diagram Editors, in the User´s Manual*.

The View

The deployment diagram uses a view that is similar to the UML component view. The most important similarities are:

- Both views are type-based, i.e. no instance-specific information can be modeled. This implicates that the thread and object symbols in the Deployment Editor diagram can be regarded as stereotyped UML class symbols.
- Both views are static, i.e. partitioning at compile-time is modeled.

There are some important differences between the Deployment Editor view and the component view:

- The Deployment Editor view uses the node symbol, which is not used in the UML component view. In UML, the node symbol is only used in the deployment view.
- The Deployment Editor view does not support the interface notion, which is used for modeling communication between components in the UML component view.

The Deployment Editor diagram shows a static view of the partitioning, i.e. you can deploy SDL systems by how they look at compile-time.

The Symbols

The deployment diagram contains four symbols that can be used for modeling partitioning: Node, Component, Thread and Object. Each symbol is described in the following subsections. See "About Symbols and Lines" on page 1635 in chapter 39, *Using Diagram Editors, in the User´s Manual*.

> **Note:**
>
> The deployment diagram terminology must not be mixed up with the syntax used in buildscripts, i.e. scripts containing SDL Analyzer commands. Some terms, such as *thread*, are similar, while other, such as *component*, represent completely different things.

All symbols, except the thread symbol, contain information that can be edited in the *Symbol Details* dialog box. Properties and stereotype information are graphically visible on the symbols.

Node

A node symbolizes a computational resource, i.e. something with processing power and possibly some memory and other peripherals. A node should be seen as a platform on which software execute. Only components can be attached to nodes.

A typical stereotype for a node is a description of the processor and a common property is the operating system that is being used. Figure 324 shows a node called **My_Computer** with the stereotype **PC** and the property **Windows NT 4.0**.

Figure 324 A node with name, stereotype and properties

For a node, you can set the stereotype to *external*, indicating that the node does not execute any code from your SDL system(s). This makes it possible to model external non-SDL parts that communicate with your SDL system(s). Setting the stereotype to `external` implicates that the node is ignored when building a Partitioning Diagram Model from the deployment diagram.

Note:

Stereotype and property information for a node is ignored when generating partitioning diagram data. The only exception is when stereotype is set to `external`.

Component

A component symbolizes an executable file, i.e. a sort of container for software entities. Components contain objects, i.e. SDL systems, blocks or processes, that are organized in threads of execution. You can attach either objects or threads to a component.

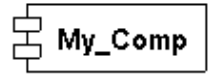

Figure 325 A component symbol named "My_Comp"

As for nodes, you can set `external` as stereotype on a component, which means that the component does not contain any SDL object from the system(s) that are deployed.

Note:

Stereotype and property information for a component is ignored when generating partitioning diagram data. The only exception is when stereotype is set to `external`.

For a component, you can select an integration model in the *Symbol Details* dialog box. The integration model reflects how the code that is generated is integrated with your target operating system. Three integration models are available:

- *Light Integration.* This is the default selection.
- *Tight Integration.*

- *Threaded Integration.*

See "Integration Models" on page 1780 for more information.

Thread

The thread symbol symbolizes a static thread of execution at compile-time. Threads can only be attached to components. Only objects, i.e. SDL entities, can be attached to a thread.

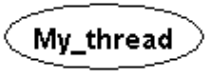

Figure 326 A thread symbol named "My_thread"

The thread symbol can only be used for modeling threaded integrations, i.e. for a Deployment Diagram with threads. Partitioning Diagram Data can only be generated if the component has "Threaded" as integration model.

You can make four settings for a thread through the "Symbol Details" dialog box. These are:

- *Thread Priority*
- *Stack Size*
- *Queue Size*
- *Max Signal Size*

The settings are available to the Targeting Expert through the Partitioning Diagram Model. The settings are common among real-time operating systems.

The values that are entered are platform-specific and are used when compiling the system for your target environment. You are free to enter any value, e.g. a number or a macro, that makes sense in your target environment.

You can choose to either explicitly set a value, or leave it empty. Any setting that is not filled in is considered undefined. In that case, a default value is used.

Note:

Your target operating system may have thread settings that do not exactly match the available thread settings in the Deployment Editor. If you know that a setting is not available in your Operating System, leave the text box empty.

Object

The object symbol is a general notion of an SDL system, block or process. The stereotype field is used to state the type of SDL symbol. This information is mandatory and has three possible values:

- `system`
- `block`
- `process`

The stereotype value is shown within the object symbol. Figure 327 shows an object with `process` as stereotype.

Figure 327 An object symbol with name and stereotype

Note:

It is recommended that the object name in the deployment diagram correspond to the name of the SDL object which is deployed. However, it is not required that the names are identical. For instance, if you add two SDL objects with identical SDL names to the same namespace, you might want to separate them by changing the object name of one the SDL objects. You can freely change the object name, as the object is uniquely identified by its qualifier.

For an object, it is mandatory to enter information in the Qualifier field in the Symbol Details dialog box. The qualifier consists of the *path* for an SDL object in the Organizer tree structure. '/' is used as a separator. The path must include the object name itself.

Some examples of object qualifiers for the AccessControl system are shown in the table below. You can verify the qualifiers by opening the AccessControl system in the Organizer (`< SDL Suite installation directory>/examples/AccessControl/Accesscontrol.sdt`) and comparing them with the entries in the table.

Object Name	Qualifier
CodeReader	`AccessControl/Local/CodeReader`
Controller	`AccessControl/Local/Controller`
Central	`AccessControl/Central`
Display	`AccessControl/Local/Display`
Doors	`AccessControl/Local/Doors`

An example of an object with all mandatory information entered is given in Example 316.

Example 316: Object Name, Qualifier and Stereotype

In the AccessControl system, the process *Central* in block *CentralUnit* has `AccessControl/CentralUnit/Central` as qualifier. For readability, the object is given the name `Central`. The stereotype is set to `process`.

Associations and Aggregations

The Deployment Editor diagram uses associations for modeling relations between nodes. Composite aggregation is used for the following relations:

- Node - Component
- Component - Thread
- Component - Object
- Thread - Object

There is a *Line Details* dialog box, which is common for all sorts of relations. For an association, you can model protocol, encoding and direction data. For a composite aggregation, only multiplicity data can be edited. For a more detailed description of the dialog box, see "DP Editor Specific Information" on page 1711 in chapter 39, *Using Diagram Editors, in the User´s Manual*.

> **Note:**
>
> Associations between nodes are ignored when partitioning diagram data is generated.

Integration Models

The Deployment Editor supports three different integration models. The choice of integration model is set at component level.

Light Integration

In the light integration model, one or many SDL objects execute within one single task. The integration model is called *Light* in the *Symbol Details* dialog box.

The thread symbol is not used when modeling a light integration. All objects that should execute in a component with a light integration should be attached directly to the component. See Example 317 for an example of a light integration.

Example 317: A Light Integration ----------

This example (see Figure 328) shows a light integration containing two objects from the *AccessControl* system. All process instances run in one single task in one executable file. The objects are connected directly to the component, which has *Light* as integration model. The `Control` block has `AccessControl/LocalStation/Control` as qualifier and the `DoorControl` block has `AccessControl/LocalStation/DoorControl` as qualifier. Both objects have `block` as stereotype.

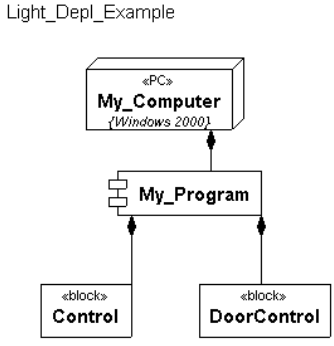

Figure 328 A light integration

Tight Integration

In a tight integration, each SDL process instance is put in a task of its own. The number of tasks varies at run-time, as process instances are created and terminated dynamically.

As described in "The View" on page 1773, the deployment diagram shows a static view of SDL systems at compile-time. The thread symbol symbolizes one static thread of execution, which makes it inappropriate for modeling tight integrations. Therefore, the thread symbol is not used for modeling tight integrations. Always attach objects directly to a component when you model a tight integration.

> **Note:**
>
> The Deployment Editor does not prevent you from attaching threads to a component with *Light* or *Tight* as integration model. The check is performed when partitioning diagram data is generated for the Targeting Expert. If you have an invalid diagram, you will get error messages in the Organizer Log.

An example of a typical tight integration is shown in Example 318.

Example 318: A Tight Integration ––––––––––––––––––––––––––––

This example (see Figure 329) shows a tight integration where two processes from the AccessControl system are executing in one component. The component is deployed on a node.

Each process instance of the two SDL processes will execute in an OS task of its own on the target operating system.

The component has *Tight* as integration model (not visible in the figure). DoorController has `AccessControl/LocalStation/DoorControl/DoorController` as qualifier and `process` as stereotype. Controller has `AccessControl/LocalStation/Control/Controller` as qualifier and `block` as stereotype.

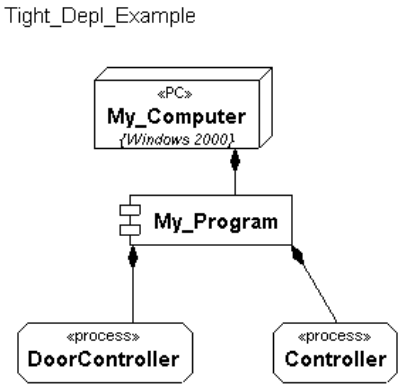

Figure 329 A tight integration

Threaded Integration

Using the threaded integration model, you can map an arbitrary number of SDL objects to an arbitrary number of threads. Each thread symbolizes a light-weight process in the executable file that is generated.

All objects that are connected directly to a component, having a threaded integration, are considered executing together in one implicit thread. Only default values for thread priority, stack size, etc. are available for an implicit thread.

The most common deployment case is that the smallest, indivisible entity is the process instance set. This is the smallest entity that can be graphically represented in a Deployment Diagram. However, it is possible to make each single instance of an object execute in a separate thread in the threaded integration model. This is modeled using multiplicity on the aggregation between a component and the thread that contains the SDL object. Set the multiplicity of the aggregation between the component and the thread to '*' to model this scenario. For a thread with '*' as multiplicity, the values of thread priority, stack size and queue size, etc. will apply to all threads that are created in the target environment.

A complete example of a threaded integration that illustrates the concepts is shown in Example 319.

Example 319: A Threaded Integration ––––––––––––––––––––––––

Figure 330 shows a component with many threads attached. The thread `T` has two objects (`CentralUnit` and `PanelControl`) attached to it. All process instances in these two blocks will execute within one thread. The component should execute on Windows 2000. Thus, Windows-specific thread settings are given. The following values are set: Thread Priority: `THREAD_PRIORITY_ABOVE_NORMAL`, Stack Size: `2048`. The other fields are left empty, as default values should be used.

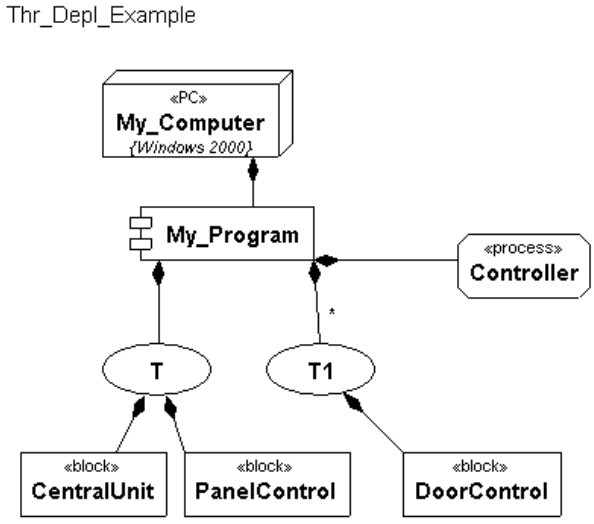

Figure 330 A threaded integration

The `Controller` object is attached directly to the component and will thus execute in an implicit thread. If there were more objects attached directly to the component, they would execute in the same thread as `Controller`. As the thread is implicit, default values are used in the thread settings.

The thread `T1` has '*' as multiplicity in the aggregation between itself and the component. This indicates that all process instances in objects attached to `T1` will execute in a thread of its own. The thread settings for

`T1` are: Priority: `THREAD_PRIORITY_BELOW_NORMAL`, Stack Size: `1024`. These settings will apply to all threads that are created.

All objects have stereotype and qualifier values set as shown in the previous examples.

Deployment Workflow

Drawing a Deployment Diagram

One or many SDL systems can be deployed in the same deployment diagram. However, it is necessary that all the deployed SDL systems reside in the same `.sdt` file.

Perform the following steps to draw a complete diagram:

1. Start the Deployment Editor with a new diagram. See "Starting the Deployment Editor" on page 1770 for instructions.
2. Name the diagram. As the diagram name is used for naming the target directory root, it is important to select a descriptive name.
3. Identify the nodes on which your system(s) will execute. Draw the nodes in the deployment diagram.
4. Name each node and edit stereotype and properties values in the *Symbol Details* dialog box, if desired.
5. For each node, identify the executables. Each executable is symbolized by a component.
6. Draw the components in the deployment diagram and draw aggregations from the node symbols to the components that should execute on them.
7. Set name and edit the integration model for each component.
8. Draw the threads that you wish to use and enter thread settings for each thread.
9. Draw the objects that you wish to deploy. Collect name, qualifier and stereotype information from the Organizer view of your SDL systems and enter this information in each object.
10. Connect each object to a component or thread, depending on the integration model chosen.

> **Tip:**
>
> Let the Organizer window be visible when you edit the diagrams for easy access to SDL object information.

Example 320 shows a deployment scenario where components with different integration models are combined.

Example 320: AccessControl Deployment ----------

This example shows a Deployment Diagram for the AccessControl system. The complete system is deployed on two nodes, as shown in Figure 331. On each node there is a component. The component `Prog1` has Threaded as integration model and uses threads. See Example 319 for a more detailed description of threaded concepts.

The node named `Ethernet_Hub` is contained in the diagram to show how the nodes are physically connected to its external environment in a network. As this node has `external` as stereotype, it is ignored when partitioning diagram data is generated. The associations between the nodes are also ignored.

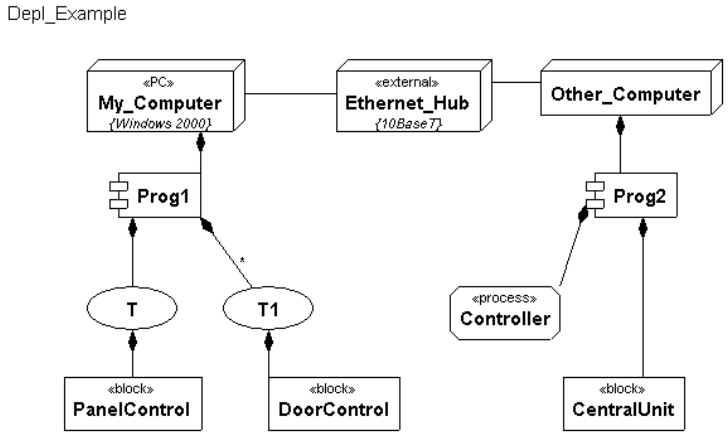

Figure 331 Deployment of the AccessControl system

The component `Prog2` has *Tight* as integration model. The SDL objects are attached directly to the component. Note that the integration model is not visible in the diagram. It is set in the “Symbol Details” dialog box.

Tip:

Draw several Deployment Diagrams to experiment with different deployment situations for your SDL systems. This can be useful when you experiment with different thread configurations.

Generating Partitioning Diagram Data for the Targeting Expert

The Targeting Expert uses the Partitioning Diagram Model (PDM) to structure an application that should be built. It uses the node and component concepts from the Deployment Diagram.

PDM files can be generated from Deployment Diagrams using the Organizer. In order to start the Targeting Expert with partitioning diagram data from a deployment diagram, perform the following tasks:

1. Right-click the deployment diagram symbol (`.sdp` file) in the Organizer.
2. Select *Targeting Expert* from the pop-up menu.

A partitioning diagram model is now generated. If there are errors or information messages, the Organizer Log is opened. If the generation passes, the Targeting Expert is started in interactive mode with the partitioning diagram.

The PDM file is saved in the same directory as the `.sdp` file and has the name as the `.sdp` file except for the extension, which is `.pdm`. As the PDM data is saved on file, it can be used by the Targeting Expert both in interactive mode and batch mode.

Note:

When the Targeting Expert is started in interactive mode with a deployment diagram, the `.sdt` file that contains the referenced SDL objects must be loaded into the Organizer. The Targeting Expert cannot be started from a deployment diagram without an `.sdt` file which has been saved.

PDM in Targeting Expert Interactive Mode

To start the Targeting Expert in interactive mode with data from a deployment diagram, you must right-click the .sdp file symbol in the Or-

ganizer and select Targeting Expert. The Partitioning Diagram Model is not visible from the Organizer.

The Partitioning Diagram Model for the deployment diagram is shown in the upper-left corner in the Targeting Expert window. The application is seen on node and component level. For each component, you make build settings. Depending on the integration model selected in the deployment diagram, specific predefined integration settings are available.

For more information on the Targeting Expert batch mode, see "Interactive Mode" on page 2910 in chapter 59, *The Targeting Expert*.

PDM in Targeting Expert Batch Mode

The Targeting Expert can use PDM files in batch mode by either setting the flag `-pdm` or by giving the command `Open-PDM` as a batch mode command. A PDM file from a Deployment Diagram must be generated using the Organizer. After that, the PDM file can be used in either interactive or batch mode.

For more information on the Targeting Expert batch mode, see "Batch Mode" on page 2958 in chapter 59, *The Targeting Expert*.

Chapter

41 *Editing MSC Diagrams*

This chapter describes how to create and edit MSCs (Message Sequence Charts).

If you only have a MSC Trace license this chapter is still applicable since you are allowed to move symbols in a generated trace. Adding and removing symbols is however blocked.

For a reference to the MSC Editor, see chapter 39, *Using Diagram Editors*.

General

Editing Functions

The MSC Editor is the graphical tool that you use to create, edit, print and store Message Sequence Charts. The MSC Editor provides, among other things, the facility of including MSCs into SDL systems.

The basic editing functionality that the MSC Editor provides can be summarized as:

- Creating and managing MSCs
- Appending, moving, resizing symbols
- Interconnecting symbols with lines
- Editing text
- Printing MSCs

Tracing a Simulation

You can also use the MSC Editor as a graphical trace tool, which enables the automatic generation of an MSC from a simulation. The results of the simulation will be presented in an MSC Editor window, in which each event of interest will be appended to the chart in order to build up a chart which reflects the history of the simulation. The results of a simulation can be saved in MSC/PR form and re-read by the MSC Editor.

The commands that start up the logging of MSC events, set up the scope of trace, stop the logging of events, and so on, are given to the Simulator. See chapter 50, *Simulating a System*.

Validating a System

An MSC can be used as a means to express the requirements on an SDL system. With the MSC Editor and the SDL Explorer, a powerful validation environment is provided. The basic idea is to draw an MSC using the MSC Editor and then use the Explorer to check if there is a possible execution path for the SDL system that satisfies the MSC.

The commands that validate a system are given to the Explorer. See chapter 53, *Validating a System*.

Tracing user-defined events

The MSC editor also contains an API that enables any user or tool vendor to make interactive traces of events of their own choice (custom trace). Please see the header file `<product install dir>/include/msctrace/msctrace.h` for further details on this API.

Supported MSC Formats

The MSC Editor supports reading MSCs stored in either:

- The MSC/GR format used by the MSC Editor (in which case the default file extension is `.msc`)
- The MSC/PR format (stored on MSC/PR files, where the default file extension is `.mpr`)

By default, the MSC Editor stores diagrams in the MSC/GR format, but it can also generate MSC/PR for a diagram.

MSC/PR files can be expressed in two forms, *event-oriented*[1] or *instance-oriented*[2]. See the Z.120 recommendation for more information on these two alternative formats.

Compliance with ITU Z.120

MSC Diagrams

The MSC Editor supports virtually all of the ITU Z.120 language definition for MSCs, including most of the MSC'96 additions.

For information on the MSC support compared to Z.120, see "Compatibility with ITU MSC" on page 5 in chapter 1, *Compatibility Notes, in the Release Guide*.

1. Event oriented MSC/PR describes the MSC using the order in which the events occur, i.e. starting with the top of the diagram and downwards, providing the feeling of a global event order.
2. Instance oriented MSC/PR describes the MSC on an instance by instance basis. The feeling of a global event order within the MSC is lost.

Pagination

MSCs cannot be split into multiple pages in the same way as SDL diagrams. However, if your MSC requires more than one sheet of paper when printing, the MSC Editor takes care of splitting the chart into multiple parts to print on separate sheets of the paper size you have specified. You set up the printer pages with the Preference Manager. You can use the *Window Options* menu choice from the *View* menu to show the page boundaries on the screen.

Each part of a multiple-part chart can be printed with adjacent page markers to assist you in making up the complete chart. This feature is by default disabled and must be set as a preference or specified in the *Print* dialog.

Syntax Rules at Editing Time

Some of the MSC syntax rules are enforced during edit when you append symbols and lines to your MSC. These rules determine:

- Which symbols and lines are allowed to be interconnected
- Where symbols can be placed

This syntax checking cannot be disabled. All text is checked during editing.

Basic Operations

Starting the MSC Editor

In the Organizer, MSCs are handled as references, which you can add and remove from any of the Organizer chapters. There are several ways you can start the MSC Editor:

- *Starting the MSC Editor Stand-alone*
- *Starting on an Existing MSC Icon*
- *Starting on an Existing MSC, not Managed by the Organizer*
- *Starting on an Unconnected MSC Icon*
- *Starting on a New MSC Icon*

Starting the MSC Editor Stand-alone

You have the possibility to start the MSC Editor stand-alone. This is however only recommended if you are using the MSC Editor for viewing a generated trace since you will not be connected to the Organizer and you will loose e.g. MSC reference navigation capabilities. If you have bought the MSC as a trace tool only (i.e. only at trace license) this will be your only option.

> **Note:**
>
> If you are making a custom interactive trace, you should not start the MSC Editor/Tracer yourself, since in that case the editor will not be able to connect with the tracing application. You need only start the MSC Editor manually when viewing saved MSC diagrams or generated MSC/PR files.

On Windows you start the MSC Editor by writing **`sdtmsce.exe [ <filename> ]`** at the command prompt. It is also possible to set up a shortcut. Please refer to your operating system documentation for further information.

On UNIX you start the MSC Editor by writing **`sdtmsc [ <filename> ]`** at the command prompt.

The optional <filename> may either refer to a GR file (usual suffix .msc) or an MSC/PR file (usual suffix .mpr). If you enter an incorrect filename the MSC Editor will terminate without giving any notice.

Starting on an Existing MSC

To start the MSC Editor on an existing MSC, you either use an MSC icon connected to an MSC diagram file, or add a new MSC icon for an MSC diagram.

Starting on an Existing MSC Icon

To start the MSC Editor on an existing MSC managed by the Organizer:

1. In the Organizer select the icon that represents an MSC. (The MSC icon must be connected to a file.)
   - Alternatively, if the MSC is associated with an SDL diagram, you can select the associated MSC link icon (looking like an MSC icon displayed in dashed form).

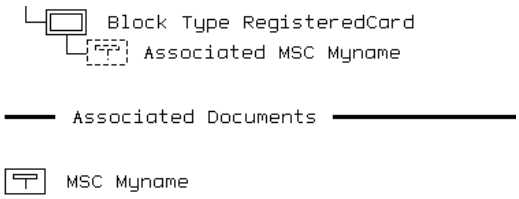

Figure 332: An MSC icon and an associated MSC icon

2. Start the MSC Editor by the *Edit* menu choice on the Organizer's *Edit* menu or by double-clicking the MSC icon.

   The MSC Editor window is displayed, the current MSC data is read from file and the upper left portion of the chart is displayed.

Starting on an Existing MSC, not Managed by the Organizer

To start the MSC Editor on an existing diagram that is not managed by the Organizer (i.e. not contained in the Organizer structure) you must first include it into the Organizer, before the MSC Editor can be started.

To include an existing MSC into the Organizer:

1. Select the place in the Organizer where you want to add the MSC. The MSC will be added as a new root diagram after a selected document or chapter, or at the top level of a selected module.
2. Select *Add Existing* from the Organizer's *Edit* menu.
3. In the dialog that is opened, find and select an MSC diagram file. Set the filename filter to `*.msc` to only list MSCs. The MSC is added to the Organizer structure, and is opened in the MSC Editor.

   If an SDL diagram was selected in the Organizer, an association link to the MSC is also added to the SDL diagram.

Starting on a New (Nonexisting) MSC

To start the MSC Editor on a new MSC, you either use an unconnected MSC icon, or add a new MSC icon.

Starting on an Unconnected MSC Icon

To start the MSC Editor on an existing but unconnected MSC icon:

1. Select an unconnected MSC icon in the Organizer.
2. Open the unconnected MSC by the *Edit* menu choice on the Organizer's *Edit* menu or by double-clicking the MSC icon. A dialog is opened:

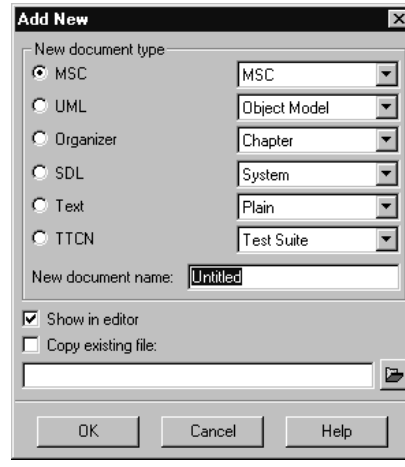

Figure 333: The Edit dialog

3. Make sure the *Show in editor* option is set. Then click *OK* to open the MSC Editor on the new, empty diagram.
   - You can also change the name of the MSC diagram before it is opened.
   - To copy the contents of an existing MSC diagram file before opening the new diagram in the MSC Editor, select the option *Copy existing file* and enter a filename.

Starting on a New MSC Icon

To add a new MSC icon to the Organizer and start the MSC Editor on that icon:

1. Select the place in the Organizer where you want to add the MSC. The MSC will be added as a new root diagram after a selected document or chapter, or at the top level of a selected module.
2. Select *Editors > MSC Editor* from the Organizer *Tools* menu. A new MSC diagram icon is added to the Organizer structure, and the new diagram is opened in the MSC Editor. If an SDL diagram was selected in the Organizer, an association link to the MSC is also added to the SDL diagram.
   - Alternatively, select *Add New* from the Organizer *Edit* menu. A dialog is opened. Select an MSC diagram type, enter a name in the *New document name* field and click *OK*.

Exiting the MSC Editor

1. Select *Exit* from the *File* menu. If the MSC Editor holds any MSC that you have modified but not saved, a dialog is issued, prompting you to save the changes before the application terminates.
2. The dialog informs you about the name of the diagram in turn to be saved. Depending on if you want to save the changes or not:
   - Click *Save* to save changes made to the current diagram. The MSC Editor prompts you to save the next modified diagram, alternatively exits if there are no more diagrams to save.
   - Click *No Save* to close the current diagram without saving it. The MSC Editor then prompts you to save the next modified diagram, alternatively exits if there are no more diagrams to save.
   - Click *Save All* to save all changes made to all diagrams. Once all diagrams are saved, the MSC Editor will exit.
   - Click *Quit All* to exit the MSC Editor without saving any MSCs.
   - Click *Cancel* if you want to continue the MSC Editor session.

Managing MSCs

You create MSCs in the MSC Editor. Once an MSC has been created, you may include it into the structure that is managed by the Organizer, in order to take full advantage of the functionality that is provided. MSCs can however be handled as separate entities.

The following operations are described in this section:

- *Creating an MSC*
- *Renaming an MSC*
- *Opening an MSC*
- *Saving an MSC*
- *Saving a Copy of an MSC*
- *Displaying an Opened MSC*.

Creating an MSC

You can create MSCs in two ways.

Creating an MSC from the MSC Editor

1. Select *New* from the *File* menu. A dialog is displayed.
2. Enter the diagram name and type and click *New*.

   The MSC is saved as a separate entity that is not automatically appended to the Organizer structure. You may want to add the MSC to the Organizer in order to provide an instant access to it from the Organizer. See "Starting on a New MSC Icon" on page 1796.

Creating an MSC from the Organizer

The procedure is identical to starting the MSC Editor with no existing MSC icon. See "Starting on an Existing MSC" on page 1793.

Renaming an MSC

You can change the name of an MSC. The name of an MSC is reflected in the MSC heading.

To change the name, simply edit the heading.

Opening an MSC

You can open an MSC from the MSC Editor or from the Organizer.

Opening an MSC File from the MSC Editor

1. Select *Open* from the *File* menu. A File Selection Dialog is issued.
2. Select a file and click *OK*.

You can open binary GR files (`*.msc`) or textual PR files (`*.mpr`).

Opening an MSC from the Organizer

1. Select an MSC in the Organizer.
   - Alternatively, if the MSC is associated with an SDL diagram, you can select the associated MSC link icon (looking like an MSC icon displayed in dashed form, see Figure 332 on page 1794).
2. Double-click the MSC icon.

Saving an MSC

There are several ways to save an MSC. Either you can save changes made to one specific MSC or all MSCs modified during the current session.

Saving an MSC in the MSC Editor

- Select *Save* from the *File* menu or click the quick-button for *Save.*

  If the diagram is newly created, a file selection dialog is issued where you can specify the file to save the diagram on.

Saving All MSCs

You can make a global save of all the MSCs that are open in the current session, and that are modified:

- Select *Save All* from the *File* menu. (You will be prompted to specify a file for new diagrams that have never been saved on file.)

Saving an MSC in MSC/PR Format

You can save an MSC in the MSC/PR format. See *"Generate MSC PR" on page 1688 in chapter 39, Using Diagram Editors*.

Saving a Copy of an MSC

You can save the MSC you are working on into another file. You may either continue working with the original file or with the newly created copy.

Continuing Working with the New Copy

1. Select *Save As* from the *File* menu. A file selection dialog is issued.

   The default file name which is suggested is the same file as the original was stored on, appended with an integer suffix (1, 2,..., N) in order to build up a unique file name.

2. Click *OK*. The MSC is copied to the specified file, the file containing the original is closed, and the window from where the save was made remains open for editing the newly created file.

Continuing Working with the Original

1. Select *Save a Copy as* from the *File* menu. A file selection dialog is issued.

   The default file name which is suggested is the same file as the original was stored on, appended with an integer suffix (1, 2,...,N) that guarantees a unique file name.

2. Click *OK*. The MSC is saved on the specified file, and the window with the file from where the save was made remains open for editing.

Displaying an Opened MSC

You can display an MSC that is currently opened by the MSC Editor. (The MSC that you would like to see may reside in a window which is not on top of the screen.)

The *Diagrams* menu shows all MSCs (up to a maximum of the last nine to have been opened). If more than nine MSCs are open, a tenth menu choice, *List All*, provides access to a list dialog where all MSCs currently opened are listed.

Rearranging an MSC

The following topics are discussed:

Resizing an MSC

Resizing Automatically

When you append objects by double-clicking, the MSC Editor will automatically enlarge the MSC size when the MSC has grown so that it reaches the bottom or right of the drawing area. The drawing area is enlarged according to the value of a preference parameter.

Resizing Manually

1. Display the MSC you want to resize.
2. From the *Edit* menu, select *Drawing Size*. A dialog appears.
3. Type in the new width and height for the MSC within the allowed range.
4. Click *OK*. The MSC is resized accordingly.

Changing the Spacing

When the MSC Editor layouts an MSC, it makes use of a horizontal and vertical spacing parameter that affect the total height and width of the MSC. All instances and events on instances are positioned with an integer multiple of the spacing parameters.

1. From the *View* menu, select *Insert Options* (see *"Insert Options" on page 1677 in chapter 39, Using Diagram Editors*). A dialog appears.
2. Drag the sliders for a coarse adjustment. Click left or right on the slider bar for a fine adjustment.
   - Smaller values will give the chart a compact appearance that may possibly make it more difficult to read. Text associated to

symbols may overlap other symbols and text. Symbols may overlap each other.

– Larger values will give the chart a less cramped appearance and makes it easier to read to the price of a larger size.

3. Click *OK*.

Managing Windows

Each MSC Editor window shows one MSC, but you may open new windows on a diagram and close windows that are no longer needed.

A newly opened window is a mirror image of the window from which the selection to open a window was made. Multiple windows may be opened and are all identical to the first. Any subsequent modifications made will reflect the same in either the original window, or any of the newly opened window(s). This option affords the possibility of viewing in more than one window, and can ideally be used in conjunction with the scaling factor when looking at a detailed MSC.

Opening and Closing Windows

You open and close windows with the *New Window* and *Close Window* menu choices in the *Windows* menu. If you close the last opened window, the editor will exit.

Hiding and Showing Parts of the Window

The component parts of the MSC Editor window can be shown or hidden as required. **On UNIX**, if they are hidden, it increases the drawing area available to be used in the creation or modification of a diagram.

To change the options for hiding and showing parts of the window, select *Window Options* from the *View* menu. These options can also be set as preferences, and some of them are available from quick-buttons:

- The quick buttons for *text window on / off* or *symbol menu on / off*.

- The quick button for *instance ruler on / off*.

Selecting Objects

To select an object, you click it. The object will be marked with selection squares that indicates that it is selected. A filled selection square (not a grey) means that you can resize or move the object by dragging the square.

Related topics are:

- *Selecting an Object That Has Associated Objects*
- *Extending, Reducing or Cancelling a Selection*
- *Requesting Detailed Information on an Object*.

Selecting an Object That Has Associated Objects

An object may have other objects associated to it. When you select an object, all of the object's attributes are also selected:

- A **symbol** may have associated **lines** and **text** attributes.
- A **line** may have associated **text** attributes.
- A **text** object has **no** associated attributes.

Associated text, for example symbol text, symbol names and timer names, will be displayed in the text window.

When you open a condition or MSC reference symbol, the *Connect* dialog is also opened.

Extending, Reducing or Cancelling a Selection

The editor provides standard functions for extending, reducing and cancelling selection of objects.

Requesting Detailed Information on an Object

The *info window* is an auxiliary window that provides additional information about the object you have selected.

To open an info window:

1. Display the diagram on which you want additional information.
2. Select *Info Window* from the *Window* menu. The info window is displayed.

Adding and Removing Objects

The topics discussed in this section are:

Adding and Placing Symbols

1. You can add a symbol from the *symbol menu* to a chart in two ways:

   – **Automatically**, by double-clicking the symbol in the symbol menu. The symbol will be placed at a location defined according to the type of symbol and in relation to the current selection. This will be further described for each symbol type.

   – **Manually**, by first selecting it in the symbol menu and then clicking at the desired location in the drawing area. To cancel the operation before the symbol is added, press `<Esc>`.

2. Enter the symbol's text attributes.

Adjusting Objects to the Grid

The MSC Editor positions symbols and lines automatically. When you draw and move symbols and lines, each object is positioned on the closest intersection in the grid.

Inserting Space for Events

When you work on an MSC, the space available between two events on an instance axis may not be sufficient for inserting new objects on the instance axis. The MSC Editor can reorganize the MSC in order to provide the required space.

1. Select the object before or after where to insert space.

2. From the *Edit* menu, select *Make Space*. Alternatively click the quick-button for *Make space for new events*. The *Make Space* dialog is issued.
3. Turn the appropriate radio button on, depending on if you have selected the object before or after where to insert space.
4. Type in the required number of events to insert (the default is 1 event). A negative number implies removal of space.
5. Click *OK*. The MSC is rearranged and space is created on the instance axis/axes.

Inserting Space for Events Automatically

Space is made on the instance axis when you select and add new symbols from the symbol menu or when you move symbols in the diagram.

1. Select a symbol in the symbol menu and move the cursor to the place on the instance axis where you want to insert the symbol.
2. Click the mouse. The MSC is rearranged and space is created on the instance axis/axes.

Removing Space between Events

1. Select the object before where to remove space.

2. Click the quick-button for *Remove space between events*.

Removing Objects

You can remove any selected object(s) this way:

1. Select the objects to remove.
2. Choose *Clear* from the *Edit* menu. The objects are removed.

> **Note:**
> Selecting an object to clear may implicitly select other objects. The *Clear* command will delete them all. See Figure 334.

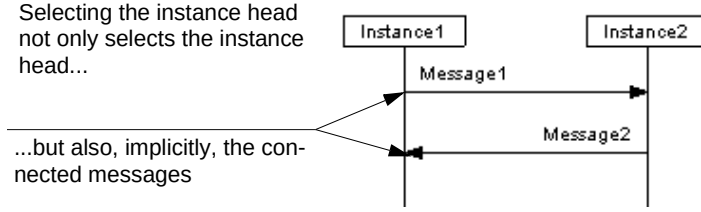

Figure 334: Selecting an object that has associated objects

Clearing the instance Instance_1 will also remove the messages Message 1 and Message 2.

Adding a Text Symbol

To add a text symbol automatically, double-click the text symbol in the symbol menu. The text symbol will be placed at the first available position at the top of the drawing area, starting from the left of the diagram.

Adding a Comment Symbol

The following conditions apply to comment symbols in the MSC Editor:

- A comment symbol can only be connected to **one** symbol or event.
- Only one comment symbol may be connected to an object.
- A comment symbol cannot be connected to another comment symbol or a text symbol.

To add a comment symbol automatically:

1. Select the object to which you wish to connect the comment.
2. Double-click the comment symbol in the symbol menu. The comment symbol will be placed to the right of the selected object and be connected to it. (If no object was selected, the comment symbol will be placed at an empty position, and you will have to connect the symbol to an object manually, as described next.)

To add a comment symbol manually:

1. Select the comment symbol in the symbol menu and place it in the drawing area.
2. Click the handle on the comment symbol, and then click on the object you wish to comment. A dashed line is drawn between the objects.

Adding an Instance Head Symbol

You can add a new instance either directly by using the instance head symbol, or you can visualize an instance that is started dynamically by using the *process create* line. The latter approach is described in "Drawing a Process Create" on page 1816.

To add an instance head symbol automatically:

1. Select, if you wish, an object to use as reference point when positioning the instance head.
2. Double-click the instance head symbol in the symbol menu.
   - If an object was selected in the drawing area, the instance head symbol will be placed to the right of the selected object.
   - If no object was selected, the instance head symbol will be placed on top of the MSC, at the first available location starting from the left.
3. Fill in the instance head text fields. See Figure 335.

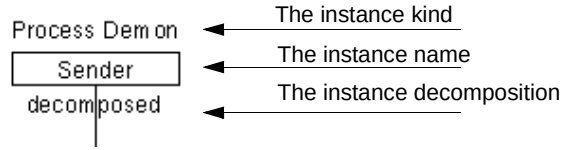

Figure 335: The instance head text fields

Adding an Instance End Symbol

The instance end symbol determines the end of the description of an instance within an MSC. It does not describe the actual termination of the instance. That is done with the *stop* symbol, see "Adding a Stop Symbol" on page 1808.

If you position the instance end symbol above (before) a symbol or line on the instance axis, all symbols and lines below (after) that object will be deleted. This is also true when you add a stop symbol:

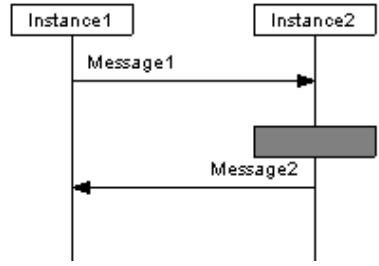

Figure 336: Placing an Instance End

The placement of the instance end symbol deletes message Message2 but not Message1.

To add an instance end symbol automatically:

1. Select an object on the instance axis immediately above (before) the desired endpoint.
2. Double-click the instance end symbol in the symbol menu.

All symbols and lines on the instance axis below it are deleted. The instance axis line is truncated and connected to the instance end symbol.

Adding a Stop Symbol

The *stop* symbol at the end of an instance body indicates the termination of that instance, as opposed to the *instance end* symbol, which only determines the end of the description of the instance within the MSC.

If you position the stop symbol above ("before") a symbol or line on the instance axis, all symbols and lines below ("after") that object will be deleted. See Figure 336 on page 1807.

To add a stop symbol automatically:

1. Select an object on the instance axis immediately above (before) the desired endpoint.
2. Double-click the stop symbol in the symbol menu.
3. The instance axis line is truncated and is connected to the stop symbol.

Drawing a Message

To draw a message you need to know from which instance it should be issued (the *source instance)* and to which instance it should be sent (the *target instance*).

Drawing a Message Automatically

1. Select the object on the source instance axis immediately above (before) the place where you wish to draw the line.
2. Double-click the message symbol in the symbol menu. The MSC Editor inserts the base end of the message on the instance axis, with the target end of the message (the arrow) marked as unconnected (lost) and facing right. (Figure 337)

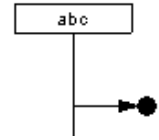

Figure 337: A lost message

3. Drag the target end to (or close to) the target instance axis and release the mouse button to connect the line. If you do not connect the end of the message, it will remain unconnected (lost), indicated by the filled circle.

4. Enter the message name and its parameters.

Drawing a Message Manually

1. Click the message symbol in the symbol menu.

2. To create a **message** or **lost message**:

   Point at the source instance axis and click once (the circle indicating a found message disappears when you are close enough to an instance axis). From now on, the base of the message is fixed to the source instance. The message is displayed as lost, following the mouse motion. (See Figure 337.)

   Or

   To create a **found message**:

   Point between two instance axes and click once. The base of the message is fixed at this position.

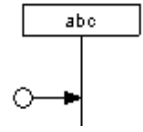

Figure 338: A found message with a connected end

3. Point at or close to the target instance axis, and click to connect the message end to the target instance. The line is connected pushing down subsequent symbols on the instance axis when necessary.

If you do not connect the end of the message to an instance axis, it will remain unconnected (lost), indicated by the filled circle.

4. Enter the message name and message parameters.

Inserting the Message Name and Message Parameters

1. The message name can be entered immediately.
2. Click the parameter selection rectangle (the lower one) so that it is the only selected object. Type the parameter list. The parenthesis around the parameter list are not displayed on the screen until you have entered a parameter.

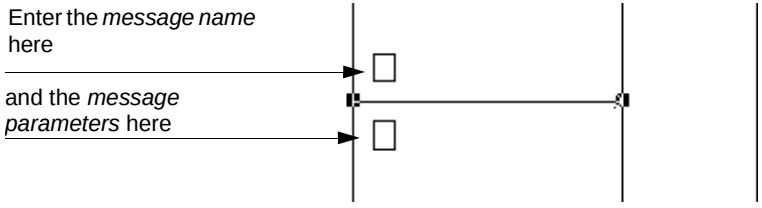

Figure 339: The message text fields

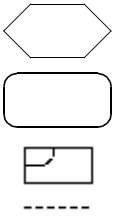
Drawing a Message-to-self

Drawing a message-to-self is done similarly to drawing a message. (See "Drawing a Message" on page 1808.) The source instance is however always the same as the target instance.



Adding a Condition, MSC Reference or Inline Expression Symbol

Adding a Condition, MSC Reference or Inline Expression Symbol Automatically

1. Select the object immediately above (before) the place on the instance axis where you wish to insert the symbol.
2. Double-click the condition, MSC reference or inline expression symbol in the symbol menu.
3. Type the condition or MSC reference name, or fill in the inline expression text.

4. Connect the condition to the instances. See "Connecting the Condition or MSC Reference Symbol" on page 1811.

Adding a Condition, MSC Reference or Inline Expression Symbol Manually

1. Select the condition, MSC reference or inline expression symbol in the symbol menu.
2. Position the symbol at the desired point of the instance axis. The symbol is placed on the instance axis, pushing down subsequent symbols on the instance axis when necessary.
3. Type the condition or MSC reference name.
4. Connect the symbol to the instances. See "Connecting the Condition or MSC Reference Symbol" on page 1811.

Connecting the Condition or MSC Reference Symbol

In the MSC Editor you can connect the condition or MSC reference symbol to individual instances or perform a global connection.

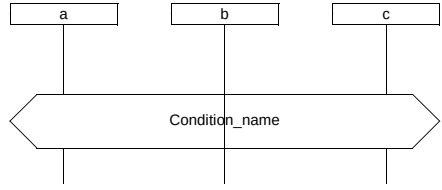


Figure 340: A condition symbol

When a symbol straddles an instance axis to which it is not connected, the axis line is drawn through the symbol. In Figure 340 the condition symbol with name Condition_name is connected to the instances a and c, but not to the instance b.

To connect a condition or MSC reference to a number of instance axes:

1. Select the symbol to connect.
2. Select *Connect* from the *Edit* menu. The *Connect* dialog is opened:

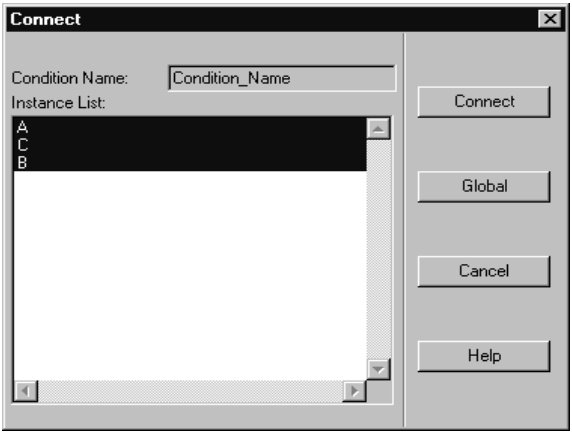

Figure 341: Connecting an instance

3. Select the instances to be connected in the instance list. The instances that will be connected are highlighted.
   - Click *Connect* to connect the condition or MSC reference symbol to the instances you have selected.
   - Click *Global* to connect the condition or MSC reference symbol globally to all instances in the list.

Drawing a Timer

Drawing a *timer* is done similarly to drawing a message line. The *source* instance is always the same as the *target* instance.

Drawing a Timer Automatically

1. Select the object on the instance axis immediately above (before) the place where you wish to draw the timer.
2. Double-click the timer symbol in the symbol menu. The MSC Editor inserts the timer.
3. Drag the target end and release the mouse when you have reached the point where the timer should expire.

4. If required, change the status of the timer by selecting *Status* from the *Edit* menu (see "Changing the Status of a Timer" on page 1814).
5. Enter the timer name and its parameters.

Drawing a Timer Manually

1. Click the timer symbol in the symbol menu.
2. Point at or close to the instance axis. Click once. The base of the timer is fixed and the timer is displayed as a vertical line, following the mouse motion.
3. Point at or close to the point on the axis where the timer should expire and click to connect the *timer end*. The timer end is connected and the timer is assigned the status **timeout**.
4. Enter the timer name and parameters.

Drawing a Separate Timer Manually

1. Draw a timer.
2. Select one of the outermost selection squares (i.e. the selection squares **not** on the instance axis) and drag it so that the vertical extension of the timer disappears.
3. Enter the timer name and parameters.

Changing Between Timer and Separate Timer

- Change a timer to a separate timer by selecting one of the outermost selection squares (i.e. the selection squares **not** on the instance axis) and dragging it so that the vertical extension of the timer disappears.
- Change a separate timer to a timer by selecting a selection square and dragging it vertically.

Inserting the Timer Name and Timer Parameters

1. The timer name can be entered immediately.
2. Click the parameter selection rectangle (the lower one) so that it is the only selected object. Type the timer parameters. The parenthesis around the timer parameters are not displayed on the screen until you have entered a parameter.

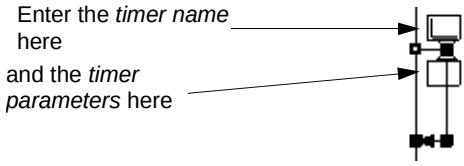

Figure 342: The timer text fields

Changing the Status of a Timer

Z.120 specifies two appearances for the timer symbol, depending on whether the timer has expired (i.e. timeout) or whether the timer is reset.

- **Timeout** – A timer expires.
- **Reset** – A timer is stopped.
- **Implicit reset** – A timer is assigned a new value while active.To change the status of a timer:

1. Select the timer.
2. From the *Edit* menu, select *Status*. The *Timer status* dialog is issued.

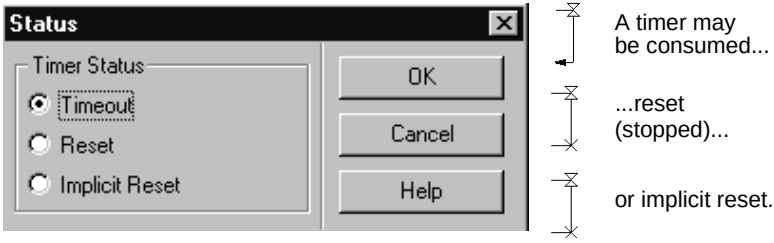

Figure 343: Setting the timer status

3. Click a radio button and then click *OK*. The status of the timer is changed accordingly.

Changing the Status of a Separate Timer

The status of a separate timer:

- **Set** – A timer is activated but has not yet expired.
- **Timeout** – A timer expires.

- **Reset** – A timer is stopped.

To change the status of a timer:

1. Select the timer.
2. From the *Edit* menu, select *Status*. The *Timer status* dialog is issued.

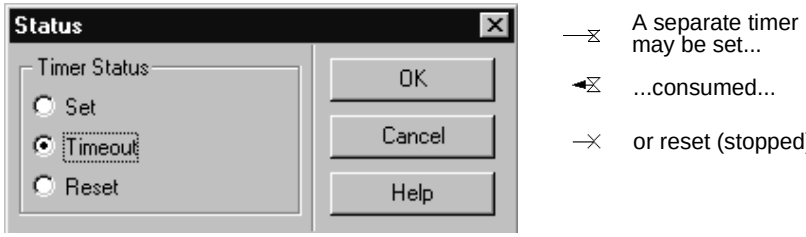

Figure 344: Separate Timer status

3. Click a radio button and then click *OK*. The status of the timer is changed accordingly.

Adding an Action Symbol

An *action* symbol corresponds to the SDL *task* symbol. You may choose to fill it with formal or informal expressions.

To add an action symbol automatically:

1. Select the object on the desired instance axis immediately above (before) the place where you wish to insert the symbol.
2. Double-click the action symbol in the symbol menu. The symbol is placed on the instance axis, pushing down subsequent symbols when necessary.
3. Fill in the action text.

Drawing a Process Create

Drawing a Process Create Automatically

1. Select the object on the **source** instance axis immediately above (before) the place where you wish to draw the process create.
2. Double-click the *create process* line in the symbol menu. The editor draws the create process line and places the instance head to the right of the source instance axis.
3. Enter the create parameters and the created instance head text fields (see Figure 335 on page 1807).

Drawing a Process Create Line Manually

1. Click the process create symbol in the symbol menu.
2. Click once on the **source** instance axis. The base of the process create line is fixed to the source instance. The line is displayed as a dashed line.
3. Click at the location where you wish to place the head of the created instance. The instance head and instance axis are automatically drawn.
4. Enter the create parameters and the created instance head text fields.

Adding a Coregion Symbol

The coregion allows you to specify unordered events on an instance. A coregion covers for instance the practically important case of two or more incoming messages where the ordering of consumption may be interchanged.

1. Select the coregion symbol in the symbol menu.
2. Click once to designate the start point of the symbol at the instance axis.
3. Click a second time on the same instance axis to designate the end point.

Collapsing and Decomposing Diagrams

You can create new high level and low level diagrams of your original diagrams. The topics discussed are:

Collapsing a Diagram

You can collapse the selected instance axes in a diagram to get an overview of the diagram.

1. Select two or more instance axes.
2. Select *Collapse* from the *Edit* menu.

   Two diagrams are created from the original diagram. One displaying the collapsed instances and one displaying the collapsed diagram.

See "Expand/Collapse" on page 1671 in chapter 39, *Using Diagram Editors* for more information.

Decomposing a Diagram

You can create a new diagram of a segment of the original diagram.

1. Select an instance axis.
2. Select *Decompose* from the *Edit* menu. A dialog is opened.
3. Enter or change the name of the decomposed instance and click *OK*.

   The instance in the original diagram will be marked as decomposed. A decomposed diagram is created and it is displayed in the Organizer.

See "Decompose" on page 1675 in chapter 39, *Using Diagram Editors* for more information.

Moving Objects

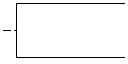
You can move one or several objects on the chart. Move several objects by first selecting them by framing or by using the shift buttons. The various procedures are described below:

- *Moving a Text Symbol*
- *Moving a Comment Symbol*
- *Moving an Instance Head Symbol*
- *Moving an Instance End Symbol and a Stop Symbol*
- *Moving an Instance Axis*
- *Moving a Message*
- *Moving a Message-to-self*
- *Moving a Timer*
- *Moving a Process Create*
- *Moving a Condition or MSC Reference*
- *Moving an Inline Expression Symbol*
- *Moving an Action Symbol*
- *Moving a Coregion Symbol*.

Moving a Text Symbol

You can move the *text* symbol freely across the drawing area.

- Drag the symbol to the new location.



Moving a Comment Symbol

You can move the *comment* symbol freely across the drawing area.

- Drag the symbol to the new location. The symbol and the line are redrawn accordingly.

  The orientation of the symbol may change and the connecting line is redrawn as required:

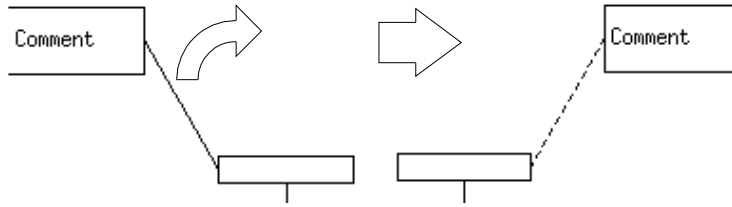


Figure 345: Moving the comment symbol.

Moving the comment symbol as shown in Figure 345 mirror flips the symbol in order to provide the shortest possible connection line.

If you move the object that the comment symbol is connected to, the comment symbol moves with it.

Moving an Instance Head Symbol

The *instance head* symbol can be moved horizontally or vertically.

- Drag the instance head to the new location.
  - If you induce a horizontal movement, the entire instance axis and the connected objects are redrawn accordingly.
  - If you induce a vertical movement, only the instance head is moved. The objects on the instance axis are not affected.

Restrictions

The following restrictions apply when moving an instance head vertically:

- You can move the instance head symbol upwards until it reaches the limit of the drawing area. See (1) in Figure 346 on page 1820. No other symbols or lines are affected by this operation.
  - An instance head symbol that belongs to a process create line cannot, however, be moved above the head of its parent instance axis.
- You can move the instance head symbol downwards until it reaches the *instance end symbol* or until it reaches the first *event (condition, action, message, timer, stop* or *process create*) that is connected to

its *instance axis*. No other symbols or lines are affected by this operation. See (2) in Figure 346 on page 1820

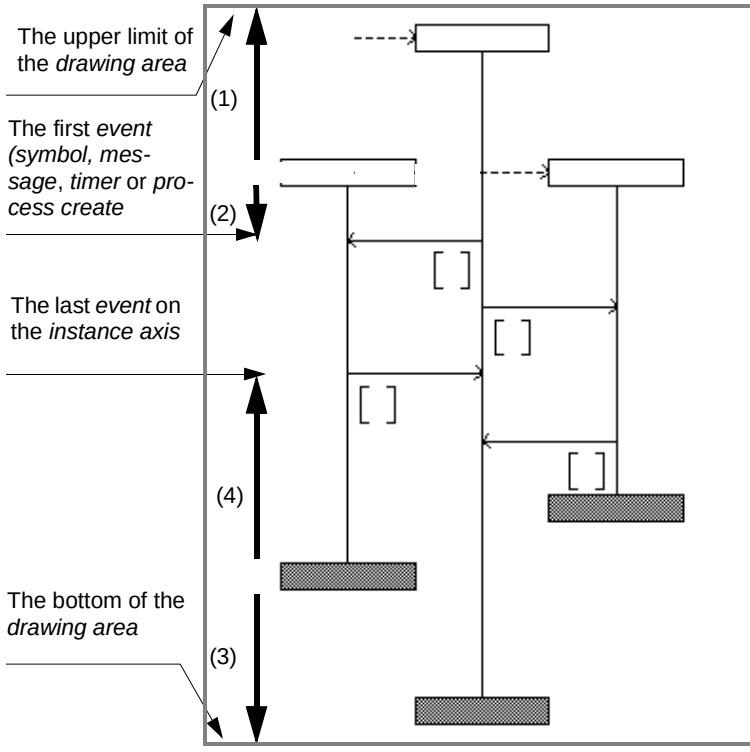

Figure 346: Moving the instance head and the instance end symbols

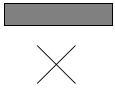
The bold arrows show the limitations applied on the leftmost instance head and instance end.



Moving an Instance End Symbol and a Stop Symbol

You can move the instance end symbol and stop symbol vertically but not horizontally. The instance end is moved horizontally when you move the instance head or the instance axis horizontally.

You can move the symbol vertically:

- Down until it reaches the bottom of the drawing area. See (3) in Figure 346.
- Up until it reaches the last event (action, condition, message, timer or process create) that is connected to the instance axis (or reaches the instance head symbol). See (4) in Figure 346 on page 1820.

Moving an Instance Axis

You can move the instance axis line left or right by dragging it with the mouse. All connected messages and process create lines remain connected as they were initially. The instance head and instance end or stop symbols will be moved accordingly. See (1) and (2) in Figure 347.

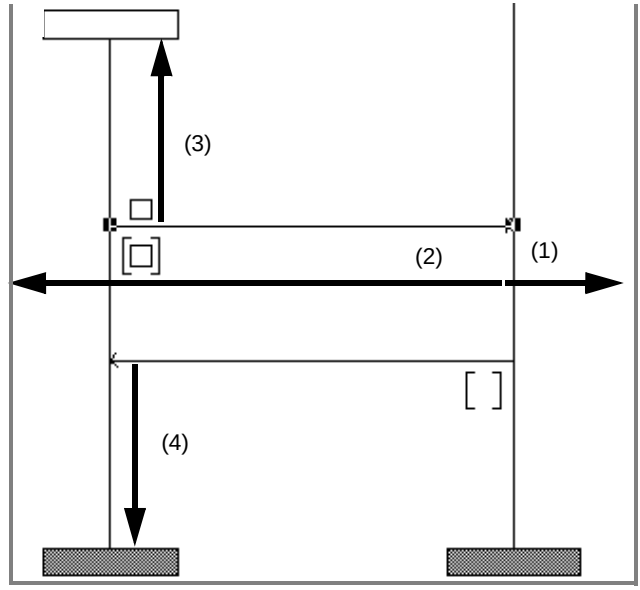


Figure 347: Moving lines

To move an instance axis:

- Drag the instance to the new location. The entire instance axis and the connected objects are redrawn accordingly.

Moving a Message

You can move a message vertically to any position within the limits set by the instance head symbol and the instance end or stop symbol of the source and target instances.

Moving the Entire Message

The base and the end of the message remain connected to the original source and target instances. The related message name and message parameters will be moved accordingly. See (3) and (4) in Figure 347.

You can also move the entire message to another pair of instance axes.

To move a message:

- Drag the message to the desired position. The message and its text attributes are redrawn accordingly.

Moving the Base or End of a Message

You can move the base or end of a message up or down along the axis that it is connected to by pointing to and dragging the appropriate (base or end) selection square to the new position. The opposite selection square will remain fixed.

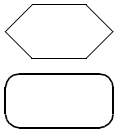
The end (message input) cannot be moved above the base (message output).

Moving a Message-to-self

You can move a message-to-self up or down along its instance axis or between instance axes by dragging it as you would move a message. See "Moving a Message" on page 1822.

Moving the Base or End of a Message-to-Self

Use the same procedure as for a message to move the end (message input) or base point (message output) of a message-to-self (see "Moving the Base or End of a Message" on page 1822).



Moving a Condition or MSC Reference

You can move the *condition* and *MSC reference* symbol vertically along an *instance axis* to which it is connected; between the instance head and instance end, stop, or the bottom of the drawing area. To connect or disconnect instances to the symbol, use the *Connect* dialog on the *Edit* menu.

To move the condition and MSC reference symbol:

- Drag the symbol to the new location on the instance axis. The symbol is redrawn at its new location.

Moving an Inline Expression Symbol

You can move the *inline expression symbol* vertically along the instance axis.

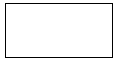
- Click the left or right side of the inline expression and move it.

If the inline expression contains an involved axis, the inline expression cannot be moved below the instance end or stop symbol of that axis.

Moving a Timer

You can move a timer up or down along its instance axis or between instance axes by dragging it as you would move a message. The related timer name and parameters will be moved accordingly. See "Moving a Message" on page 1822.

Use the same procedure as for a message to move the end (the time-out or reset (stopped) arrow) or base point (the set symbol) of a timer (see "Moving the Base or End of a Message" on page 1822).



Moving an Action Symbol

You can move the *action* symbol vertically along the instance axis between the instance head and instance end, stop or the bottom of the drawing area or to another instance axis.

Moving a Process Create

To move a process create line along its source instance axis, either move the process create line or its associated instance head symbol upwards or downwards. See "Moving an Instance Head Symbol" on page 1819.

Moving a Coregion Symbol

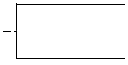
You can move a *coregion* up or down along its instance axis by dragging it as you would move a message. See "Moving a Message" on page 1822.

If you point close to the start or end point of the coregion and start dragging the mouse, the coregion will be resized accordingly.

Reconnecting Objects

Some of the objects that are managed by the MSC Editor can be reconnected:

- *Reconnecting a Comment Symbol*
- *Reconnecting a Condition or MSC Reference Symbol*
- *Reconnecting a Message*
- *Reconnecting a Message-to-self*
- *Redirecting a Message*.
- *Reconnecting a Process Create*



Reconnecting a Comment Symbol

A *comment* symbol can be reconnected to a different object or disconnected completely from all objects.

1. Drag the comment symbol connection handle towards the new connection point. The existing connection line is erased and a new line that follows the position of the mouse pointer is drawn.
2. Click the connection point on the new object. The connection line is fixed to the new object.

Disconnecting the Comment Symbol

- Select the dashed line to the comment symbol and delete it.

Reconnecting a Message

You can reconnect the base or the end of a message to another instance axis:

1. Drag the base or end of the message towards the desired instance axis. As soon as you move the mouse the message is unconnected.
2. When the mouse pointer is close to the new instance axis, release the mouse button. The message is now reconnected.

Reconnecting a Message-to-self

You can reconnect the base or end of a message-to-self to another instance axis. This changes the message-to-self to an ordinary message.

- Drag the end (or the base) of the message-to-self away from the instance axis. As soon as you move the mouse, the line is displayed as an ordinary message line. Continue dragging the end of the line up or down to the new connection point and release the mouse button.

Redirecting a Message

When you draw a message, the message goes from the source instance to the target instance. It is possible to redirect a message (i.e. change its direction):

1. Select the message to redirect.
2. Select the *Redirect* command on the *Edit* menu. The message is redrawn in the opposite direction, and the text attributes are positioned accordingly.

Messages-to-self and *overtaken messages* cannot be redirected.

In Figure 348 two messages are shown. The message sent first is consumed after the message sent last, i.e. it is overtaken.

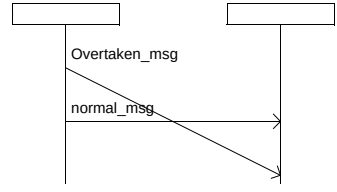


Figure 348: An overtaken message

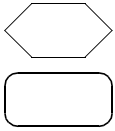

Reconnecting a Condition or MSC Reference Symbol

To connect or disconnect instances to the symbol:

- Use the *Connect* dialog on the *Edit* menu, see *"Connect" on page 1674 in chapter 39, Using Diagram Editors*. (Remember, at least one instance must be left connected.)

Reconnecting a Process Create

You can reconnect the *base* of a *process create* from one instance axis to another in a similar way as when reconnecting a message (see "Reconnecting a Message" on page 1825).

Resizing Objects

All objects that are managed by the MSC Editor are automatically resized according to the size of the text. However, you can manually resize a text or comment symbol.

- *Resizing a Text or Comment Symbol*

Resizing a Text or Comment Symbol

There are two methods of resizing the text and the comment symbol:

- Select the *Expand/Collapse* command on the *Edit* menu to toggle between maximum and minimum size.
- Double-click the symbol, which causes the symbol to toggle between its minimal and maximal size.

Printing Objects

It is possible to print only selected parts of an MSC.

1. Select the objects to be printed.
2. Select *Print* from the *File* menu.
3. Click the *Setup* button.
4. Select the option *Print only selected symbols*.

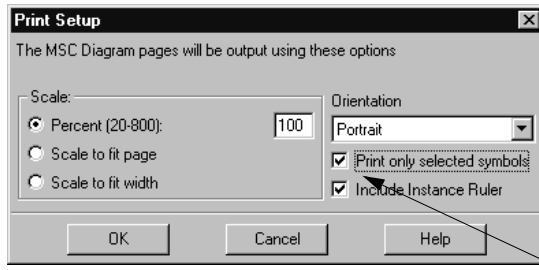

Figure 349: Printing only selected objects

5. Adjust, if necessary other *Print options* and click the *OK* and *Print* buttons.

See also "Printing from the MSC Editor" on page 312 in chapter 5, *Printing Documents and Diagrams*.

Chapter 41 Editing MSC Diagrams

Chapter

42 *The UML2SDL Utility*

The UML2SDL utility converts a model described in UML to an SDL system. This includes conversion of UML Static Structure diagrams to corresponding SDL concepts, as well as translation of UML (Harel) State Chart diagrams to SDL process diagrams.

This chapter includes setup instructions and a description of the functionality of the tool. In the end of the chapter, the mapping rules are described.

This guide assumes that you are familiar with the concepts of UML – static structure diagrams – as well as SDL.

Setting Up the UML2SDL Utility

To efficiently run the UML2SDL utility, you will need to set up a specialized Organizer menu bar containing the menu *UML To SDL*. This modified Organizer menu is defined in the file `org-menus.ini` that is located in `/orca/uml2sdl/examples/` in the installation directory. How to add the UML2SDL menu to the Organizer is described in "Defining Menus in the SDL Suite" on page 18 in chapter 1, *User Interface and Basic Operations*.

Converting UML Diagrams

When UML diagrams are to be converted into SDL diagrams, the UML diagrams need to be placed within a module in the Organizer. The diagrams may be either static structure diagrams or state charts. If multiple diagrams exist within the module, all diagrams will be converted at the same time.

To convert UML diagrams in a module:

1. Select a diagram within the module.
2. Select the desired conversion alternative from the *UML To SDL* menu (see below).

The UML2SDL converter will create a new module with the same name as the converted module, but with the prefix "SDL_" added. The new module will contain all the resulting SDL diagrams.

The *UML To SDL* Menu

The *UML To SDL* menu in the Organizer contains four alternatives:

- *Generate SDL System* – generates a system using the default transformation options.
- *Generate SDL Package* – generates a package using the default transformation options.
- *Generate SDL System* – allows you to configure the generation of an SDL system using transformation options.
- *Generate SDL Package* – allows you to configure the generation of an SDL package using transformation options.

Transformation Options

The UML2SDL utility is run as a command-line tool, but is started from the Organizer. If you select an alternative in the *UML To SDL* menu that allows you to change the transformation options, a dialog is opened in which you may specify the transformation options to UML2SDL:

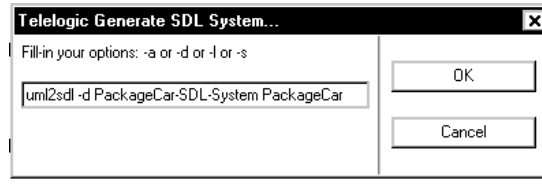

Figure 350: Setting transformation options for a package generation

If you select an alternative in the *UML To SDL* menu that uses the default transformation options, the dialog is not opened and none of the options described below are used.

The UML2SDL utility accepts a set of flags which allow you to configure the transformation:

```
uml2sdl [ -a | -d | -l | -o | -p | -s ] <module>
```

- `-a`
  Avoid types: All *«process»* and *«block»* classes that can have a type property, will automatically have this type set to “false”.
- `-d <directory>`
  The name of the sub directory that will contain the generated SDL files. A suggestion is given in the dialog, which you can alter. If the directory name does not match an existing sub directory, a new one will be created inside the current working directory.
- `-l`
  Local types: Push all type definitions as low as possible in SDL block hierarchies.
- `-o`
  Output SDL/PR to stdout, that is, the generated SDL/PR will be output in the Organizer log. No SDL diagram is created in the Organizer.

- `-p`
  If used, the UML package will be translated to an SDL package; otherwise it will be translated to an SDL system. This option is preset on the command line if you selected *Generate SDL Package* from the *UML To SDL* menu.
- `-s`
  Signal default: All operations with no return values are considered to be signals and not remote procedures. If not used, only operations following the *«signal»* stereotype or operations with a property "{async}" will be mapped to signals.
- *<module>*
  The name of the package or system that will be created. A suggestion is given in the dialog, which you can alter.

Transformation Rules

The transformation rules for UML static structure diagrams are described below. For information about the transformation rules applied when converting state charts, please refer to *"Converting State Charts to SDL" on page 1702 in chapter 39, Using Diagram Editors*.

General

To ensure traceability between the UML model and the SDL model, all mapped entities keep their name throughout the models.

An Organizer module is considered to represent a UML package. A module may contain several UML static structure diagrams. The module, including all UML static structure diagrams, is transformed into an SDL package or system.

Each SDL system or package will also contain a block type representing the architecture of the UML model.

Classes

The UML2SDL utility makes some basic assumptions about how a class should be interpreted in the SDL context. The basic approach is however to instruct the tool by using stereotypes. A stereotype is a meta classification of a class. The tool relies on the following stereotypes:

- A class with the stereotype «newtype» becomes an SDL newtype.
- A class with the stereotype «process» becomes an SDL process.
- A class with the stereotype «block» becomes an SDL block.

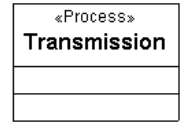

Figure 351: A class with the stereotype « process »

A class may have attributes and operations. Depending on how the class is interpreted, attributes become variables in a process, or fields in a struct. An attribute have a name and a type; the type may be omitted. The notation for the attribute is:

```
< name > [ ':' < type >]
```

An operation has a name. It may also contain parameters and return values. An operation with a return value is translated to a remote procedure; otherwise it is translated to a signal. The notation of an operation is:

```
< name > ['(' { < parameter > [':' < type > ] }*
')' ] [':' < return value >]
```

A UML static structure diagram may contain references to classes defined in other packages. Such classes are given the name according to the following notation:

```
< Name of external package > '::' < class name >
```

Each externally defined class will generate a use clause, referring to the external package, in the generated SDL system or package.

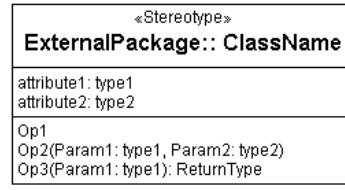

Figure 352: The notation for a process

Relations

Inheritance

Two classes connected with an inheritance relationship will generate an inheritance clause in the subtype. If two «process» classes are related by the inheritance relationship, there will be an inheritance clause in the process type representing the subclass.

Inheritance relationships between two «newtype» classes are not allowed due to limitations in SDL.

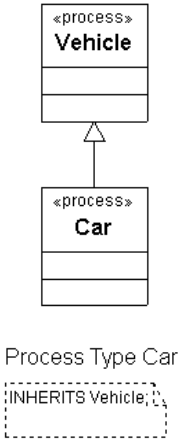

Figure 353: An inheritance relationship in the UML model will result in an inheritance relationship in the SDL model

Aggregation

Two classes may be related by an aggregation. Depending on the context the following translations will be made:

An aggregation between a «block» class and a «process» class will place the process inside the generated block type:

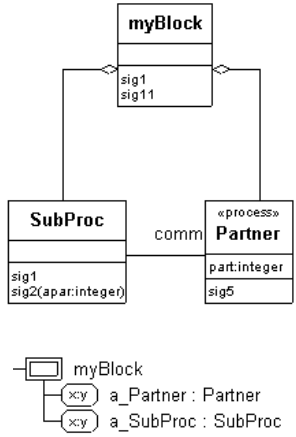

Figure 354: Aggregation expressed in UML and the generated SDL diagrams in the Organizer view

An aggregation between a «process» class and a «newtype» class will place a variable of the newtype in the process. The newtype definition will be placed in the block containing the process.

Association

Two classes connected with an association will be transformed as two classes and connected with a signal-route and/or a channel depending on the context.

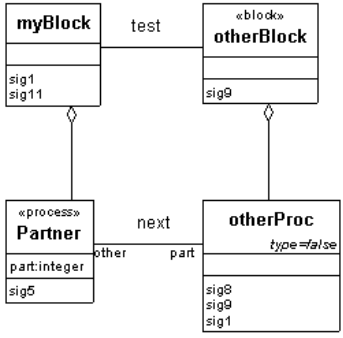

Figure 355: Communicating classes

In Figure 355 above, two classes “Partner” and “otherProc” are connected by an association. In the generated SDL the two processes “otherProc” and “Partner” will exist in two separate blocks and they will be able to communicate through a channel and two signal routes.

State Charts

State Charts placed inside the module will be converted together with the other diagrams inside that module. The converter assumes that if a state chart has the same name as a process then the converter will try to merge the resulting SDL process behavior into the diagram of that process.

A Small Example

This example is intended to show how the UML2SDL utility can be used. The example contains a small analysis model of a game – the Demon game – which is intended to be implemented in SDL through a design model. The Demon game is used as an example in other parts of the documentation. For example, see "The Demon Game" on page 41 in chapter 3, *Tutorial: The Editors and the Analyzer, in the SDL Suite 6.2 Getting Started*.

Model Relationships

The purpose of an analysis model is to identify the problem: **what** is to be done? The following model is the design model which identifies the solution. The design model answers the question **how** it is to be done. Good practice is to have clear dependencies between the two models, that is, traceability. Traceability is one of the key factors in a successful project.

Very often, the analysis model can be reused when the design model is created. The information provided by the problem statement is needed in the design model. The purpose of the UML2SDL utility is to automate this reuse as much as possible.

The Analysis Model

The Class Diagram

The analysis model is presented in Figure 356. It contains a set of classes which describes an overview of the Demon game. A pure analysis model might not be as detailed as the one given in the example, but the level of detail in the example is chosen to highlight the functionality of the UML2SDL utility.

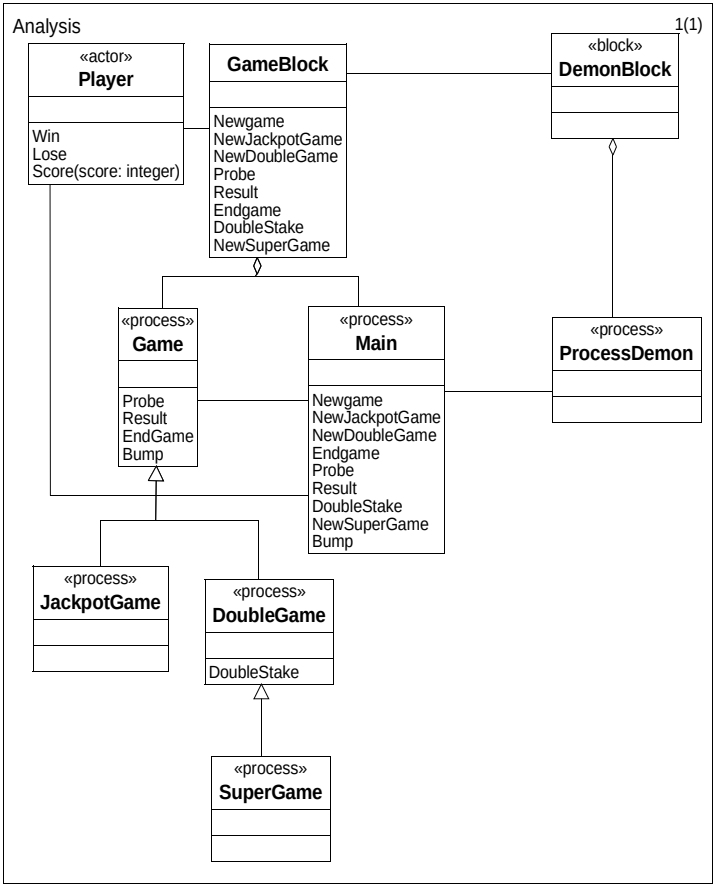

Figure 356: The Analysis Object Model

All operations of the classes in the Analysis Object Model will be mapped to signals since no operation contains a return value. Aggregate classes containing «process» classes, or marked with the stereotype «block», like GameBlock and DemonBlock, will become SDL blocks. The aggregations also tell the UML2SDL utility where to place the «process» classes. For example, the process Demon will be placed inside the block DemonBlock and the other processes will be placed inside the GameBlock.

Associations between classes are mapped to channels and signal routes. The association between the two classes GameBlock and DemonBlock will become a channel between the corresponding blocks. The association between the classes Main and the ProcessDemon will result in a path of communication between the resulting processes.

The inheritance relationship between the Game class and its sub-classes will become inheritance relationships between the corresponding processes as well. Since associations are inherited in UML but signal routes or channels are not inherited in SDL, the UML2SDL utility creates signal routes/channels for inherited associations. This results in signal routes between the process Main and Game, as well as between Main and the sub-processes of Game.

Classes with the stereotype «actor» is mapped as communication with the environment. In our example the class Player will become a channel to the environment. The operations of the class Player will be signals to the environment.

The State Charts

There exist two state charts named Main and Game in the module that will be converted, see Figure 357. The intention of using state charts in the analysis is to get an overview of the behavior of important classes, see Figure 358. The state charts will be transformed together with the class diagram. Since two «process» classes Main and Game exist the result of the UML to SDL conversion will be two complete process descriptions.

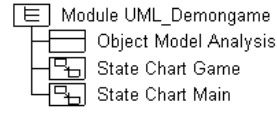

Figure 357: The module that will be converted.

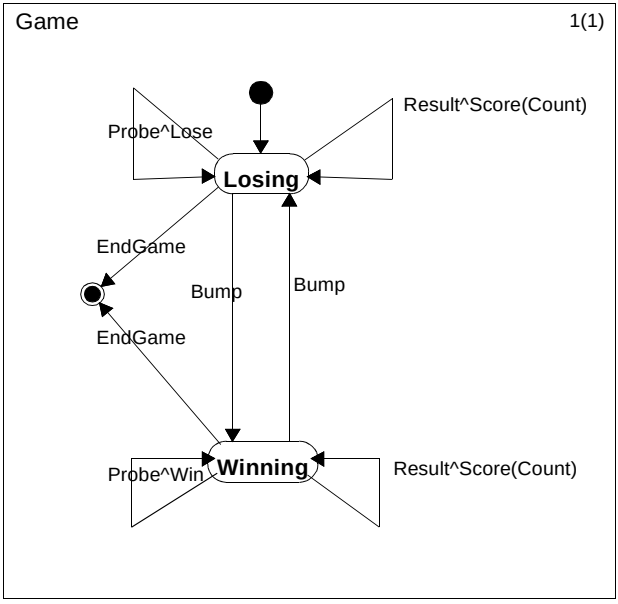

Figure 358: The behavior of Game.

The Design Model

The nature of software engineering always requires design information to be added to the analysis at some stage, because we can never solve a problem without providing a solution. This is also true when the UML2SDL utility is used.

Typically, information that needs to be added is behavior that is not described at the UML level. For instance, there is no good way of describing behavior that is redefined in a sub-class at the UML level. For example, such behavior is added to the sub-processes of process Game. Also, there was no need of modeling the simple behavior of ProcessDemon at the stage of analysis, but we have to do that in the design.

Besides adding the basic behavior, we also need to provide a full design. This includes actions like introducing variables, timers, etc. For example, in the process Main we need to describe how the process is responsible for the creation of Game processes, see Figure 359.

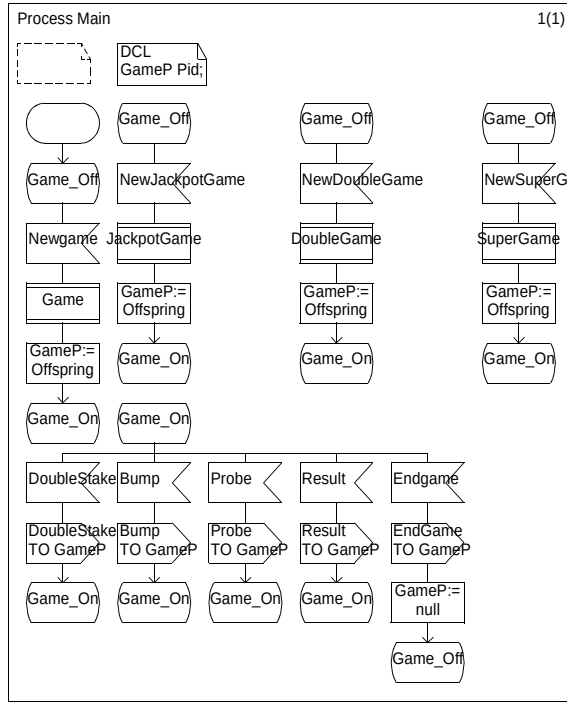

Figure 359: The complete process Main

When these steps are taken, the Demon game should be complete and possible to simulate like other SDL systems.

Summary

The intention with the UML2SDL utility is to automate the transfer from the analysis model to the design model as much as possible. The transfer will most likely include manual steps, but in theory it is possible to generate an SDL model which is detailed enough to simulate.

Chapter 42 The UML2SDL Utility

Chapter

43 *Using the SDL Editor*

This chapter describes the functionality, menus, dialogs and windows of the SDL Editor. You can also find information about how to use the editor for creating and drawing SDL (Specification and Description Language) diagrams.

General

Editor Information

The editor described in this chapter handles SDL diagrams.

Another editor is capable of handling four different types of diagrams, namely the Object Model (OM) diagrams, State Chart (SC) diagrams, Message Sequence Chart (MSC) diagrams, and High-level MSC (HMSC). That editor is described in chapter 39, *Using Diagram Editors*.

SDL Diagrams

The SDL Editor can handle any number of SDL diagrams of any type. Virtually all of the Z.100 recommendation is supported.

The SDL Editor supports three kinds of SDL diagrams:

- Interaction Diagrams
- Flow Diagrams
- Overview Diagrams

The editing functionality that is available depends on what type of diagram the SDL Editor is handling.

This chapter describes the functionality the SDL Editor provides when you edit interaction and flow diagrams.

In Figure 360–Figure 362, you can find an example of interaction diagrams (in the example there is one system diagram and two block diagrams) and the resulting overview diagram.

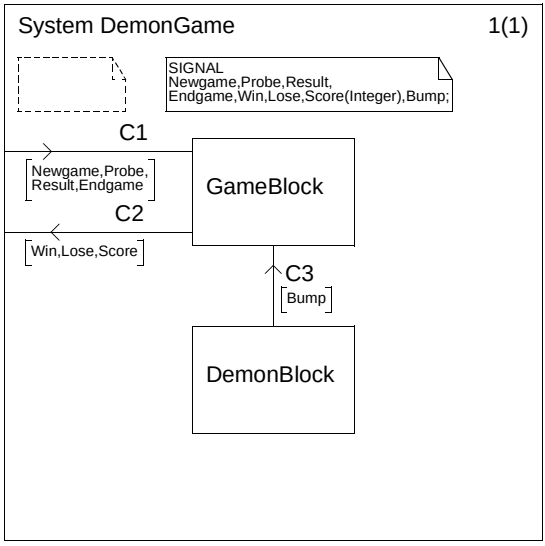

Figure 360: System diagram

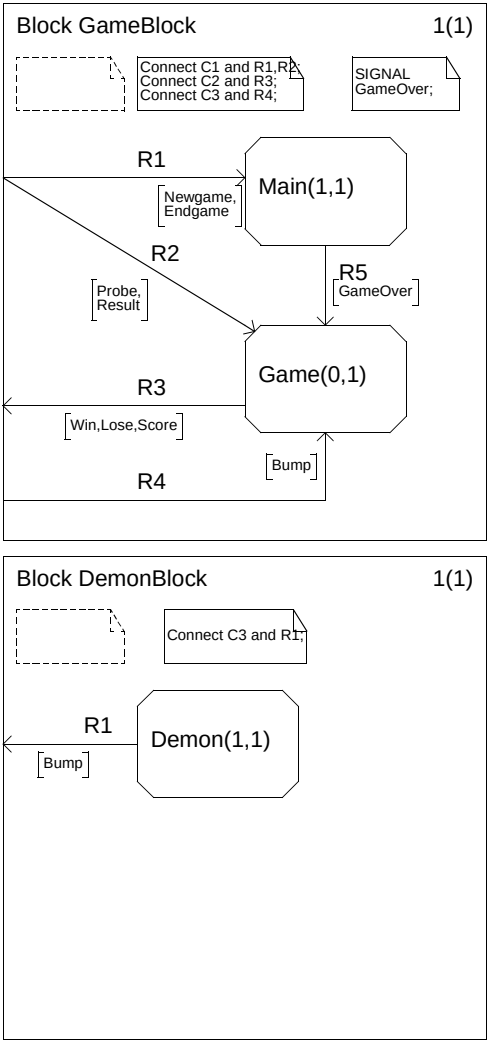

Figure 361: Block diagrams

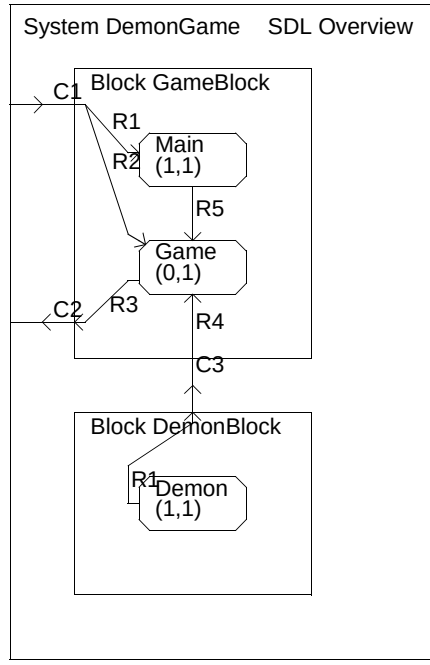

Figure 362: Resulting overview diagram

Interaction and Flow Diagrams

The SDL Editor works with SDL diagrams in graphical form, SDL/GR, and allows graphical editing of *symbols*, *lines* and *text*.

You may open multiple windows in an SDL Editor to be shown at the same time; each window will hold an SDL page. This can be useful if you want to edit different diagrams and pages and refer between them, or if you want to see the interface between two processes on different hierarchical levels. This is the normal mode in which diagrams are edited.

Interaction diagrams are: *system, system type, block, block type, substructure, package* diagrams.

Flow diagrams are: *process, process type, service, service type, procedure, operator, macro* diagrams.

Overview Diagrams

You can also use the SDL Editor to view *SDL overview diagrams*. An SDL overview diagram consists of a number of diagrams that are built up into a diagram subtree in which the symbols are drawn in a nested fashion, giving a more comprehensive overview of a required set of diagrams. You may have multiple SDL overview pages associated to one SDL system, at different SDL levels, and thus presenting different views of the system. You generate overview diagrams in the Organizer (using the *SDL Overview* command), and you can open the overview diagrams for display in the SDL Editor. Various parameters allow you to generate overview diagrams to meet your requirements.

Once an SDL overview diagram is generated, you cannot modify it in the same way that you would normally edit interaction and flow diagrams (unless you regenerate it). However, you can do limited editing on the text of overview diagrams in the SDL Editor.

Essentially, the editor works in read-only mode with regard to graphical operations. General restrictions in editing Overview diagrams are:

- There is no *symbol menu.*
- Only *textual elements* can be modified, not symbols and lines.

SDL Pages

The pages that the SDL Editor displays are always contained within an SDL diagram. An SDL diagram can contain any number of pages, but, must contain at **least one page**, and can be any of the following types.

- *Block interaction, process interaction, service interaction, package* (the *interaction pages*)
- *Graph, service, procedure, macro, operator* (the *flow pages*)
- *Overview*

Relationship between Diagrams and Pages

Pages and diagrams must be associated with each other according to the rules of SDL. There follows a list of what type of pages can be added to different diagrams and what type of pages can be pasted into those diagrams.

Diagram type	Page types that can be added to the diagram	Page types that can be pasted to the diagram
system	block interaction	block interaction package
block	block interaction process interaction	block interaction process interaction package
substructure	block interaction	block interaction package
service	service	service graph procedure macro operator
process	graph service interaction	graph service interaction service procedure macro operator
procedure	procedure	procedure service graph macro operator
system type	block interaction	block interaction package
block type	block interaction process interaction	block interaction process interaction package
service type	service	graph procedure macro operator

Diagram type	Page types that can be added to the diagram	Page types that can be pasted to the diagram
process type	graph service interaction	graph service interaction service procedure macro operator
macro	macro	macro service graph procedure operator
operator	operator	operator service graph procedure macro
package	package	package block interaction
overview	overview (one page only)	-

SDL Page Order

The SDL pages that are contained in an SDL diagram are listed and handled according to the order they were added when they were created.

This order is reflected in some of the menu choices that are related to SDL pages. Also, the structure displayed by the Organizer will adopt the same order. See "Chapters" on page 47 in chapter 2, *The Organizer*.

SDL pages can be renamed and rearranged by the *Edit* menu choice in the *Pages* menu.

Tracing Simulations (Graphical Trace)

Graphical trace, GR trace, is a method to follow the execution of transitions in SDL/GR source diagrams. It is mainly intended to be utilized together with the simulator's *Step-Symbol* command and should normally only be used for a small number of processes to limit the amount of information displayed. The GR trace facility will always show the next SDL symbol within the transition to be executed. After a nextstate or stop operation (e.g. between two transitions), the nextstate or stop symbol is still selected.

The GR tracing is activated from the SDL Simulator. The SDL Editor selects the symbol currently being executed. The Simulator automatically highlights the symbol and displays it. You can use either SDL to see what is being traced, or MSC to see the interaction between processes.

If you use an MSC to trace the simulation, the instances concept of MSC is mapped to the instances concept of SDL processes. The mapping rules which govern how SDL events are transformed into MSC symbols, lines and textual elements are described in "Mapping Between SDL and MSC" on page 1726 in chapter 39, *Using Diagram Editors*.

GR trace will take place in an SDL Editor window containing the appropriate diagram. If the SDL Editor does not hold the current page, but if the diagram can be found in the Organizer, then the page will be opened by the SDL Editor.

If the Organizer cannot find the diagram, or the SDL Editor cannot find an appropriate symbol to select, due to, for example, modifying the diagrams after the generation of the simulator, error messages will be issued by the Organizer or SDL Editor, but the simulation program will continue to execute without tracing graphically.

Setting Breakpoints in Simulations

During simulations, the SDL Editor can show all breakpoints that have been set in the Simulator. It is also possible to set and remove breakpoints directly in the SDL Editor by using the special *Breakpoints* menu that will be shown while this function is operating. The functionality is activated by the *Connect-To-Editor* command in the Simulator.

Compliance with ITU Z.100

The SDL Editor complies with the SDL rules as defined in the ITU Z.100 recommendation. Virtually all parts of the recommendation are supported by the SDL Editor. More information on the SDL support compared to Z.100, see "Compatibility with ITU SDL" on page 2 in chapter 1, *Compatibility Notes, in the Release Guide*.

Syntax Rules when Editing

Some of the SDL syntax rules are enforced during editing when you create diagrams, add pages to these diagrams, add symbols and lines to your pages and edit the text inside the symbols and lines.

Next follow the syntax checks that are performed by the SDL Editor:

- The SDL Editor checks that names on diagrams and pages adhere to the SDL definition.
- The type of a page that you add to a diagram must comply with the diagram type.
- The set of the symbols you are allowed to add to a page is in accordance to the page type. Also, the SDL Editor ensures that symbols are interconnected in a way that is syntactically correct.
- The text that is entered into a symbol or a line is instantly checked for syntax errors. When an error is located a red bar will underline the text where the error occurs.

Turning Syntax Checking On and Off

The syntax checking for entered texts, for what symbols you are allowed to use, and how you can interconnect symbols can be disabled and enabled again.

To disable or enable syntax checking:

1. The operation applies on one diagram at the time. Therefore, make sure you are editing the correct diagram.
2. Select the *Diagram Options* menu choice from the *View* menu. In the dialog which is issued, toggle the *Layout Syntax Check* and/or *Textual Syntax Check* button on or off and click *OK*.

Note: No Retroactive Syntax Checking

Turning the switch from off to on will not perform a retroactive syntax check for not allowed interconnection of symbols. Only the objects that you insert while syntax checking is enabled are checked. However, the syntax check on texts will be performed on all the texts when syntax check is set to on.

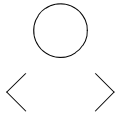
Syntax checking in Kernel Heading and Reference symbol

The syntax check for texts in the kernel heading or any reference symbol is always on independent of the diagram options setting.

Pasting and Syntax Checking

Only symbols that are valid according to what is displayed within the symbol menu may be pasted into a page. Non-valid symbols will be omitted whether or not syntax checking is enabled.

Identical Symbols – Different Syntax



SDL contains some symbols which appear identical, but are distinguished by their syntax. The symbols are:

- The **in connector** and the **out connector**
- The **continuous signal** and the **enabling condition**.

When layout syntax checking is on, the SDL Editor automatically determines from the context what kind of symbol it is. If syntax checking is off, the symbols are always treated as in connector and enabling condition, respectively.

Note: No Layout Check means Syntax errors

When disabling the layout syntax check and using connectors in the diagram mean that it will not be possible to analyze the diagram without errors as all connectors are treated as in connectors. Thus never turn off this switch if you want to analyze the diagram.

SDL Grammar Help

The SDL Editor provides a versatile context-sensitive support function – the *Grammar Help* window. The grammar help windo*w* is available to assist you when entering and editing the syntax of SDL text elements

that are correct according to Z.100 definition. It simplifies writing statements with the correct SDL syntax.

The SDL Grammar Help facility is described in "Using Grammar Help" on page 1972.

Signal Dictionary Support

The SDL Editor also provides a means of access to a *signal dictionary* where the signals that are already defined can be accessed. The Signal Dictionary window provides functions for listing SDL signals that are available when looking up or down in the SDL hierarchy or by looking at the current diagram. Also, you can ask the tool to list signals that are used in the current diagram or defined and visible according to the SDL scope rules.

Furthermore, the signal dictionary has the ability to import messages from a Message Sequence Chart (each MSC message will be mapped to an SDL signal) and to import an external signal dictionary.

For more information on this topic, see "Using the Signal Dictionary" on page 1983.

The SDL Editor User Interface and Basic Operations

The SDL Editor User Interface

The SDL Editor consists of a main window and three auxiliary windows:

- The *Grammar Help window* where SDL textual grammar support helps you entering correct textual expressions.
- The *Signal Dictionary window* which gives you access to signals already defined in the SDL hierarchy.
- The *Entity Dictionary Window* which provides you a name reuse facility as well as information for link endpoints.

The SDL Editor also contains the *symbol menu*, where you select the symbols (objects) that are to be inserted into the page, and the *text window*, where you may edit textual objects.

The general user interface is described in chapter 1, *User Interface and Basic Operations*.

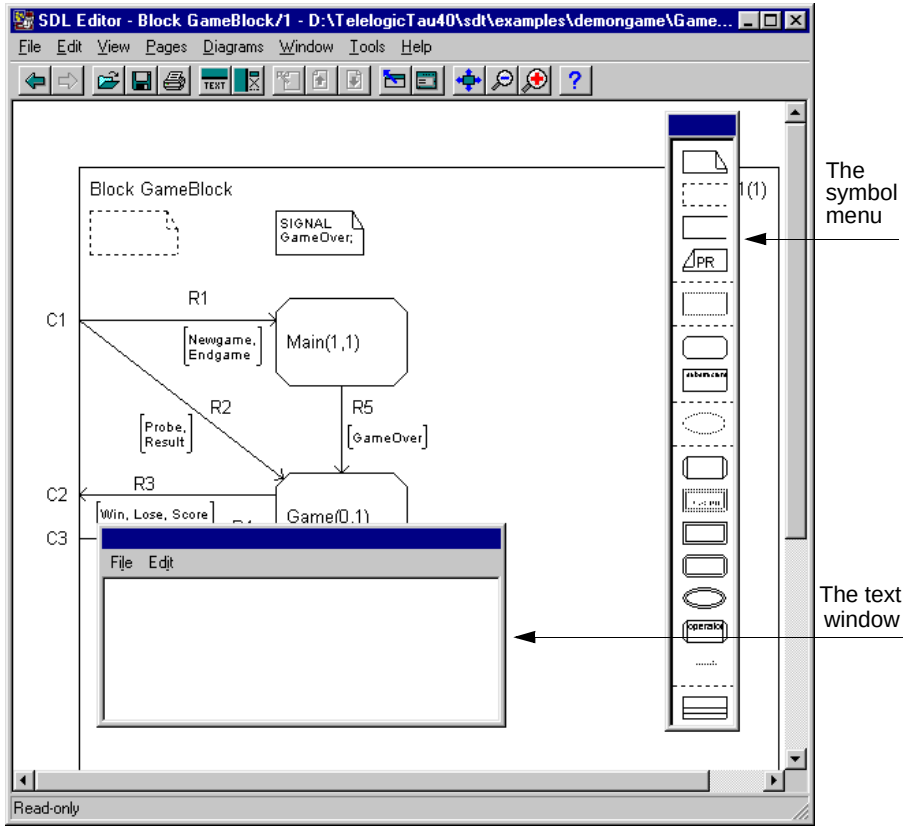


Figure 363: The SDL Editor window **(in Windows)**

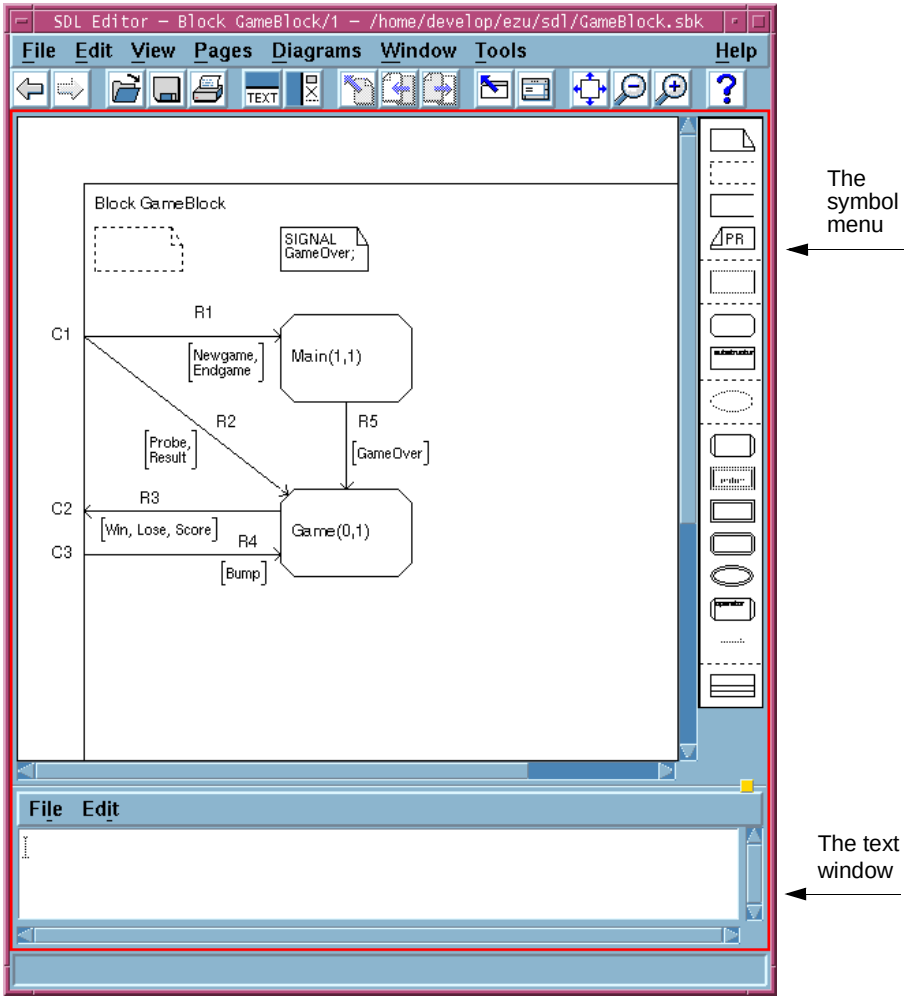

Figure 364: The SDL Editor window **(on UNIX)**

Drawing Area

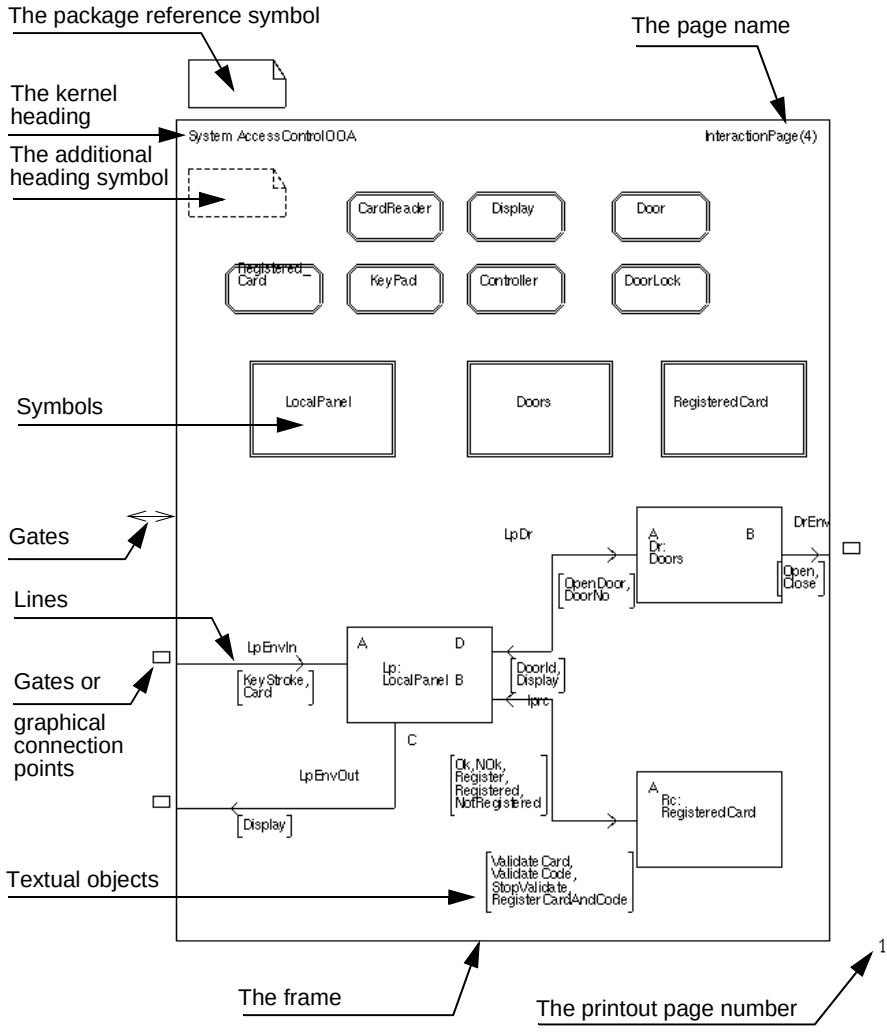

Figure 365: The Drawing Area

The *drawing area* (see Figure 365) is the part of the window that displays the symbols, lines and text that constitute an SDL page (an SDL diagram can contain multiple pages). Most of the graphical notation that is used in the SDL Editor is inherited from the Z.100 definition. In addition, some tool specific notations have been added to facilitate the work with the SDL Suite tool set in general, and the SDL Editor in particular.

The Drawing Area Boundaries

The drawing area is delimited by its boundaries, which correspond to the size of the SDL page. Within a diagram, each page has an individual size. No objects are allowed to be placed outside these boundaries. The drawing area uses a light background color, while the area outside the drawing area uses a grey pattern.

The Frame

You can select and resize the frame. All objects, except the package reference symbol, gates and printout page number must reside entirely within the frame.

The Kernel Heading

The kernel heading identifies the diagram type and its name. Alternatively, an SDL qualifier expression can be used. You can edit but not move the kernel heading. The SDL Editor performs a textual syntax check based on the grammar used in this heading.

The SDL Suite supports the following syntaxes for the kernel heading:

Case	Syntax
1.	`SYSTEM <name> [: <type expression>]`
2.	`BLOCK <identifier>`
3.	`PROCESS <identifier> [<number of instances>]`
4.	`SERVICE <identifier>`
5.	`<procedure preamble> PROCEDURE <identifier>`
6.	`SUBSTRUCTURE <identifier>`
7.	`MACRODEFINITION <name>`

Case	Syntax
8.	SYSTEM TYPE <identifier>
9.	[<virtuality>] BLOCK TYPE
10.	[<virtuality>] PROCESS TYPE
11.	[<virtuality>] SERVICE TYPE
12.	OPERATOR <operator identifier>
13.	PACKAGE <name>

For an explanation and reference to the notation used in the table above, see the Z.100 recommendation.

The kernel heading is repeated trough all pages contained in an SDL diagram.

The Page Name

The page name identifies the name of the SDL page and, within parentheses, the total number of SDL pages contained in the current SDL diagram.

The contents of the page name are assigned by the tool. You can not select, move, or edit the page name.

Printout Page Number

This object is created by the SDL Editor to inform you about the physical page numbering that will be the result of an SDL page which is larger than the paper format that is defined. You can neither select nor edit it. Page numbering follows a “down first, then right” fashion.

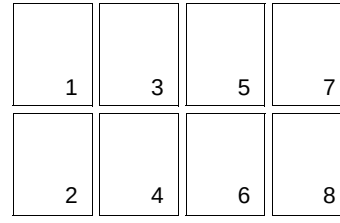

Figure 366: The page numbering in the SDL Editor

Grids

The SDL Editor uses two grids for an easy positioning of symbols, lines and textual elements.

- The symbol grid, that can be set by an SDL Editor preference, has a minimum resolution of 5 * 5 mm. All symbols adhere to the symbol grid.
- The line and text grid has a resolution of 2.5 * 2.5 mm, i.e. half the symbol grid. All lines and textual objects adhere to the line grid.

Default Size of Symbols

The symbols are assigned default sizes when added to the drawing area:

- For interaction pages, the predefined size of a symbol is by default 30 * 20 mm.
- For flow pages, the predefined size of a symbol is by default 20 * 10 mm. The width / size relationship is always 2:1.

You can change the default symbol size in the SDL Editor preferences.

> **Note:**
>
> The size of a class symbol is automatically calculated by the SDL Editor, and may thus differ from the default size.

Color on Symbols

For each symbol type there is a preference for setting the color of the symbol. It is only the graphical part of the symbol and not the associated text(s) that will use the color setting. **On UNIX**, the setting is only valid on screen and all symbols will use the black color when printed on paper. **In Windows**, when using MSW Print the colors will be sent to the printer as well. For more information, see *"The SDL Suite Specific Preferences" on page 267 in chapter 3, The Preference Manager*.

Keyboard Accelerators

In addition to the standard keyboard accelerators, described in "Keyboard Accelerators" on page 35 in chapter 1, *User Interface and Basic Operations*, the SDL Editor features the following:

Accelerator	Reference to corresponding command
`Ctrl+D`	Opens the next page in the diagram, similar to "<Page Name>" on page 2020
`Ctrl+G`	"Split Text" on page 2009
`Ctrl+I`	"Insert Paste" on page 2007
`Ctrl+L`	"Show High-Level View/Show Detailed View" on page 2015
`Ctrl+M`	"Mark as Important/Mark as Detail" on page 2011
`Ctrl+U`	Opens the previous page in the diagram, similar to "<Page Name>" on page 2020
`<Delete>`	"Clear" on page 2008 (i.e. remove, delete)
`Ctrl+1`	"Show Organizer" on page 15 in chapter 1, *User Interface and Basic Operations*
`Ctrl+2`	"Connect to Text Editor" on page 2025

Quick-Buttons

In addition to the generic quick-buttons described in "General Quick-Buttons" on page 24 in chapter 1, *User Interface and Basic Operations*, the SDL Editor tool bar contains the following quick-buttons:

Text window on / off
Toggle the text window between visible and hidden, as described in "Window Options" on page 2016.

Symbol menu on / off
Toggle the symbol menu between visible and hidden, as described in "Window Options" on page 2016.

Reference page
Open the page where this diagram is referenced, similar to "Edit Reference Page" on page 2020.

Log Window
Pop up the Organizer Log window.

Previous page
Open the previous page in the diagram, similar to "<Page Name>" on page 2020.

Next page
Open the next page in the diagram, similar to "<Page Name>" on page 2020.

Toggle scale
Toggle the scale between a scale to show the complete page in the window and a scale of 100%.

Scrolling and Scaling

You can scroll the view vertically and horizontally by using the scrollbars. The view may also be scrolled automatically when you move the cursor beyond the current view, for example when you move an object or add a symbol.

If you move the cursor close to the edge of the current view, the automatic scrolling is slow. If you move it further beyond, the scrolling is quicker.

You can scale the view by specifying a scale or by zooming in and out.

To specify a scale:

1. Select *Set Scale* from the *View* menu.
2. In the dialog that will be opened, you can either:
   - Use the slider for setting the scale and then click the *Scale* button.

   - Click the *Overview* button to adjust the drawing area to the size of the window. (This has the same effect as the *Scale Overview* quick-button.) The smallest scale is 20%.

To zoom in or out:

- Click the quick-button for *zoom in* or *zoom out*.

Moving Selection with Arrow Keys

You can move the selection using arrow keys in the SDL editor if there is one single symbol or line selected. (In this context, we regard a flow symbol together with its attached flow lines to be one symbol.)

Note that you can only move the selection when in symbol editing mode. In text editing mode, the arrow keys will move the cursor position within the text. To get into symbol editing mode, click on the symbol outside of a text area. If you are in text editing mode, you can go to symbol editing mode by pressing the escape key. If you are in symbol editing mode, you can go to text editing mode by pressing the tab key. Pressing the tab key immediately after that will either select another text for the same symbol to edit or go back to symbol editing mode.

You can move to the next page by moving forward from the last symbol on the current page. You can move to the previous page by moving backward from the first symbol on the current page.

Two shortcuts are available for fast-forward moving to colored symbols (symbols not using black as a border color and white as a background color) on pages in the current diagram:

- Shift+arrow key to move to the next/previous colored symbol.
- Shift+alt+arrow key to move to the next/previous colored symbol on another page than the current page.

Symbol Menu

The *symbol menu* contains the SDL symbols that you can place into the drawing area.

On UNIX, the *symbol menu* is a fixed-sized, non-moveable auxiliary window, associated with the drawing area and placed to the right of it. Each editor window has its own symbol menu.

In Windows, the symbol menu is a fixed-sized, moveable window that can be placed anywhere on the screen, not necessary within the limits

of the editor window. A single symbol menu is shared by all instances of the editor currently running.

The symbol menu can be made invisible and visible again with a menu choice, *Window Options*, or a quick-button **In Windows:** When visible, the symbol menu will always be placed on top of the editor window.

Basically, when you select a symbol in the symbol menu and click it into the drawing area it is added to the diagram. How to work with symbols is described in "Working with Symbols" on page 1901.

The contents of the symbol menu depends upon the type of diagram that is displayed in the SDL Editor window and the settings of the SDL Editor preferences depends upon whether the symbols should be used or not.

- For *process*, *process type*, *procedure*, *macro definition* and *operator diagrams* (the *flow* diagrams), the default symbol menu looks like the left picture in Figure 367.
- For interaction diagrams (*system*, *block*, *substructure*, *service*, *package*, *system type*, *block type* and *service type*), the default symbol menu looks like the right picture in Figure 367.

For a reference to these symbols, see "Symbols on Interaction Pages" on page 1885 and "Symbols on Flow Pages" on page 1887.

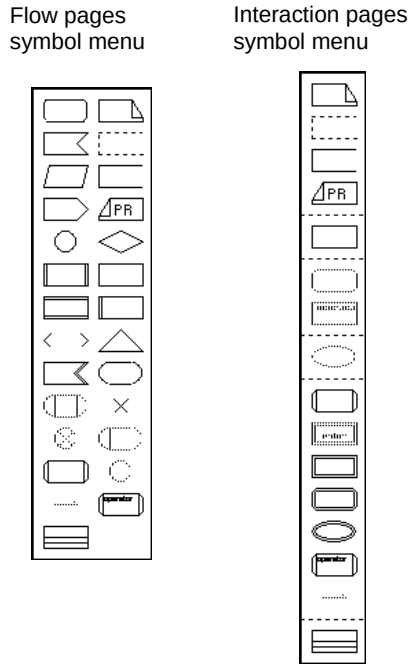

Figure 367: The Symbol menu

Syntax Checking on SDL Symbols

If layout syntax checking is enabled, some of the symbols displayed in the *symbol menu* may be dimmed. This indicates that those symbols are not valid within the current context, and that you cannot select them.

- When layout syntax checking is disabled, you can select all symbols.

- When layout syntax checking is enabled, the following rules apply:

Type of page	Unusable symbols (dimmed)
System / System type	process reference service reference block substructure reference system type reference gate
Block diagram / Block interaction page	process reference service reference block substructure reference system type reference gate
Block diagram / Process interaction page	block reference service reference system type reference gate
Service	procedure start procedure return macro inlet macro outlet gate
Process diagram / Graph page	procedure start procedure return macro inlet macro outlet gate
Process diagram / Service interaction page	block reference process reference block substructure reference system type reference block type reference process type reference gate

Type of page	Unusable symbols (dimmed)
Procedure	start stop macro inlet macro outlet gate
Block type diagram / Block interaction page	process reference service reference block substructure reference system type reference
Block type diagram / Process interaction page	block reference service reference system type reference
Macro	gate
Service type	procedure start procedure return macro inlet macro outlet
Process type diagram / Graph page	procedure start procedure return macro inlet macro outlet
Process type diagram / Service interaction page	block reference process reference block substructure reference system type reference block type reference process type reference

Type of page	Unusable symbols (dimmed)
Operator	state input save output procedure call enabling condition / continuous signal create request priority input procedure reference start stop macro inlet macro outlet gate
Package	block reference process reference block substructure reference service reference gate

Working with Diagrams

This section describes the methods you use when performing the following tasks on SDL diagrams:

Creating a Diagram

You can create diagrams from within other diagrams. When created, they form part of the current active system in the SDL Editor, and their presence is instantly reflected in the Organizer. This is achieved by inserting SDL diagram *reference symbols*.

You can also create diagrams as separate unrelated new entities. They will however not be incorporated in the Organizer.

Creating a Related Diagram from Another Diagram

1. Open the SDL diagram from where to start.
2. Insert the SDL reference symbol.
3. Assign the symbol a name.
4. Deselect the reference symbol. The Organizer's diagram structure is updated accordingly.
5. Double-click the newly added reference symbol. You should specify what action to perform, either:
   - Create a new diagram in the SDL Editor from scratch.
   - Copy an existing file.

   Select an option and click *OK*.

The SDL Editor will now create a new diagram, possibly a new window, and display the newly created diagram.

6. Save both the parent and the child diagram later on in your editing session, to make changes permanent.

Example in an Organizer Structure

As an example, in the Organizer structure in Figure 368, a system is shown with only one block diagram.

Figure 368: A basic system shown in the Organizer

Suppose the system diagram is being edited. We now add a new block reference symbol, name it Block_B and deselect it. The Organizer diagram structure becomes:

Figure 369: Having added a reference symbol

The SDL Suite shows, with the `[unconnected]` identifier, that the newly added reference symbol is not yet connected to any physical file.

Now, double-click the Block_B symbol. Specify whether you want to create a new file or to connect the newly created block to an existing file.

Make sure the *Show in Editor* radio button is on and click *OK*. In some cases a new dialog appears, where you are to specify the name and type of the first SDL page to add to the diagram (an SDL diagram must contain at least one SDL page).

Assign a page name (see "Adding a Page" on page 1954) and click *OK*.

A new block diagram with the name Block_B is created. The SDL Editor responds by issuing a window showing this diagram. Also, the Organizer's diagram structure is updated, showing the new diagram icon, inserted at the corresponding place in the SDL hierarchy.

Figure 370 on page 1871 shows the result:

- A newly created diagram, empty except for the diagram heading
- The resulting diagram structure
  - The parent diagram needs to be saved (marked with a gray pattern)
  - The child diagram needs to be saved.

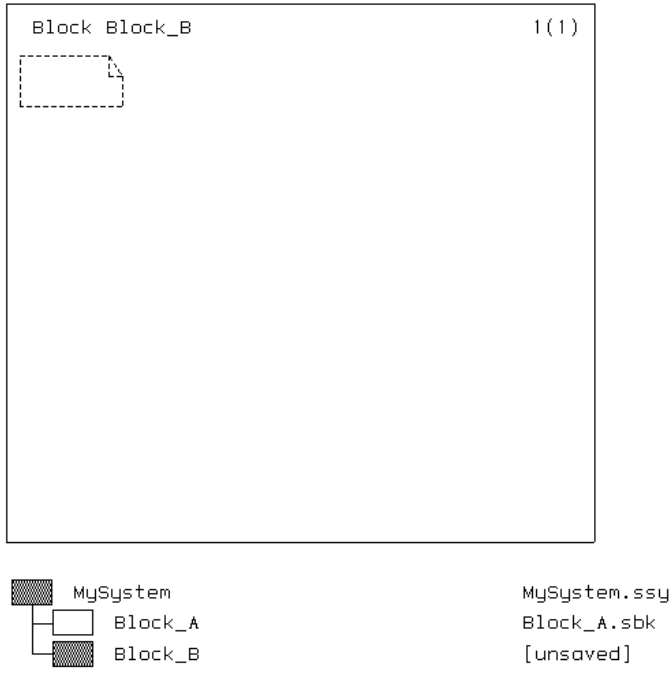

Figure 370: The newly created diagram and the resulting diagram structure

Creating an Unrelated New Diagram

1. Select *New* from the *File* menu of the SDL Editor. A dialog will be opened.
2. Enter the name of the new diagram in the *Diagram Name* field. The name should be in keeping with SDL naming conventions.

3. Choose the type of diagram from the *diagram type* menu.
4. Click *New*. In some cases a new dialog box is shown where you can add a page, as each diagram must have at least one page. See the section "Adding a Page" on page 1954 for this.

   A window on the newly created diagram is opened.

Including a Diagram

Including a Diagram into the SDL Hierarchy

When you have created a diagram, it needs to be brought into the SDL hierarchy to be available for future selection in the Organizer. Otherwise, you will only be able to open it from the SDL Editor.

1. Create the diagram using the *New* command from the SDL Editor. *Save* the diagram on file.
2. Open the diagram that will have a reference to the newly created diagram.
3. In the diagram you just opened, add a diagram reference symbol with a type and name that matches the newly created diagram. A new icon appears in the Organizer structure.
4. With the Organizer *Connect* command, connect the new icon with the file on which the diagram is stored. See "Connect" on page 92 in chapter 2, *The Organizer*.

Once a reference symbol is placed in the newly created page of the new diagram in the SDL Editor, the Organizer is updated to reflect this. This indicates that the SDL hierarchy is updated.

Including a Diagram into the Organizer

If a diagram is not managed by the Organizer (i.e. not contained in the Organizer structure) you must first include it into the Organizer, before you can start the SDL Editor.

1. Select the place in the Organizer where you want to add the SDL diagram. It will be added as a new root diagram after a selected document or chapter, or at the top level of a selected module.
2. Select the Organizer's *Add Existing* command from the *Edit* menu. A file selection dialog will be opened.
3. Select a SDL diagram file.

   The SDL diagram is added to the Organizer structure, and opened in the SDL Editor.

Opening a Diagram

There are several ways you can open a diagram for editing, depending on where you are and what you need to access.

Lock Files and Read-Only Mode

When you open a diagram or document file, i.e. *a.ssy*, a lock file *a.ssy.lck* is created. If another user tries to open the same diagram or document file before you close it, a dialog will appear informing the other user that the file is in use.

There are two choices in the dialog:

- Open the file in read-only mode.
- Reset the lock and open the file in read-write mode. (This alternative should only be used if the existing lock file is obsolete.)

The read-write mode is the normal editing mode. In read-only mode, you are not allowed to make any changes to the diagram.

You will also enter read-only mode if you open a diagram file that you do not have write permission for. The read-only mode is indicated by the words *read-only* in the window title.

If you want to edit a diagram that is in read-only mode, here are two alternative actions:

- Change the file access rights in the file system to give you write permission for the diagram file. Then change from read-only mode to read-write mode with the *Revert Diagram* operation.
- Use *File >Save As* to save the diagram in a new file with write permission.

Opening a Diagram File from the SDL Editor

1. Select *Open* from the *File* menu or click the quick-button for *Open*. A file selection dialog is opened.
2. Select a file in the files list and click *OK*. If the file is already opened by the SDL Editor, a message is issued.

> **Note:**
> The *status bar* at the bottom the SDL Editor provides information about the diagram type and name stored on the file which is selected in the file list.

Opening a Diagram from the Organizer

You can open a diagram in different ways:

- Select an SDL diagram icon or the text line next to it in the Organizer. Select *Edit* from the Organizer's *Edit* menu.
- Double-click on an SDL diagram icon in the Organizer.

Opening a Diagram – via Organizer – to Show Analyzer Reports

When analysis has been performed, you can show the source of Analyzer error reports in an SDL Editor.

- Select *Show Error* from the *View* menu in the *Organizer Log Window*. An SDL Editor window is opened with the source of error (i.e. an SDL symbol) selected.

Opening a Diagram via a Reference Symbol

You can open a diagram from the SDL Editor by double-clicking on a reference symbol, or by using the *Navigate* command.

1. Locate the SDL reference symbol referring to the diagram you want to open.
2. Double-click the symbol or select it and choose the *Navigate* command from the *Tools* menu. The diagram is opened.

Opening a Diagram from the Simulator

If you have performed a GR trace in the SDL Simulator, invoking the Show-Next-Symbol or Show-Previous-Symbol simulator commands will display either the next symbol to be executed or the previously executed symbol in a diagram in an SDL Editor window.

Opening a New (Nonexisting) SDL Diagram

To open a new SDL diagram, you either use an unconnected SDL diagram icon or add a new SDL diagram icon.

Opening an Unconnected SDL Diagram Icon

To open an existing but unconnected SDL diagram icon:

1. Select an unconnected SDL diagram icon in the Organizer.
2. Double-click the SDL diagram icon. A dialog is opened.
3. Make sure the *Show in editor* option is set. Click *OK*. A new, empty diagram is opened.
   - To copy the contents of an existing SDL diagram file before opening the new diagram, select the option *Copy existing file* and enter a filename.

Opening a New SDL Diagram Icon

To add a new SDL diagram icon to the Organizer and opening that icon:

1. Select the place in the Organizer where you want to add the SDL diagram. The diagram will be added as a new root diagram after a selected document or chapter, or at the top level of a selected module.
2. From the Organizer's *Tools* menu, select the *Editors > SDL Editor* command. A new SDL diagram icon is added to the Organizer structure, and the new diagram is opened in the SDL Editor.
   - Alternatively, select the Organizer's *Add New* command from the *Edit* menu. A dialog is opened. Select a SDL diagram type, enter a name in the *New document name* field and click *OK*. The *Add Page* dialog is displayed, see "Adding a Page" on page 1954.

Opening an Existing SDL Page

To open a specific page, the SDL pages must be visible in the Organizer diagram structure.

1. To display page icons in the Organizer, select the Organizer's *View Options* command from the *View* menu. In the dialog, make sure *Page symbols* is highlighted and click *Apply*.
2. Select the icon representing the SDL page in the Organizer.
3. Double-click the SDL page icon. The SDL diagram page is displayed.

Saving a Diagram

There are several ways to save a diagram. The effect is saving any changes made to either one specific diagram, or all diagrams modified during the current session.

Saving a Diagram in the SDL Editor

- Select *Save* from the *File* menu or click the quick-button for *Save.*

  If the diagram is newly created, a file selection dialog is issued where you can specify the file to save the diagram on.

Saving All Diagrams in the SDL Editor

You can make a global save of all the diagrams that are open in the current session and have been modified.

- Select *Save All* from the *File* menu. All diagrams which are modified are saved.

Saving a Copy of an SDL Diagram

You can save the diagram being edited into another file. You may either continue working with the original file or with the newly created copy.

Continue Working with the New Copy

1. Select *Save As* from the *File* menu. A file selection dialog is issued.
   - The file name which is suggested is the same file as the original was stored on, appended with an integer suffix (1,..., N) in order to build up a unique file name.
2. Click *OK*. The SDL diagram is copied to the specified file, the file containing the original is closed, and the window where you made the save remains open for editing the newly created file.

Continue Working with the Original

1. Select *Save a Copy As* from the *File* menu. A file selection dialog is issued.
   - The file name which is suggested is the same file as the original was stored on, appended with an integer suffix (1,...,N) that guarantees a unique file name.
2. Click *OK*. The SDL diagram is saved on the specified file, and the window where you made the save remains open for editing.

Closing a Diagram

Closing a diagram also means closing all instances of all windows displaying any page contained in that diagram.

- Select *Close Diagram* from the *File* menu.

  If you have modified the diagram, a *Close* dialog is shown where you can save the modifications before closing the diagram.

Printing a Diagram

You can print an entire SDL diagram or a selection of pages or objects contained in the diagram. You print multiple SDL diagrams from the Organizer.

See *"The Print Dialogs in the SDL Suite and in the Organizer" on page 316 in chapter 5, Printing Documents and Diagrams*.

Displaying an Opened Diagram

You can open the diagram that is currently read by the SDL Editor. (The diagram that you would like to see may reside in a window which is not on top of the screen.)

The *Diagrams* menu shows all SDL diagrams and pages (up to a maximum of the last nine to have been used). If more than nine pages are open, a tenth menu choice, *List All*, provides access to a list dialog where all diagrams and pages are listed.

Reorganizing a Diagram

The SDL Editor can reorganize the layout of an SDL diagram, for instance if you run out of space on any of the pages that build up the diagram.

To reorganize an SDL diagram:

1. Display the diagram you want to reorganize.
2. Select *Tidy Up* from the *Tools* menu. A dialog is opened.
3. Click *Tidy Up*. The SDL Editor reorganizes the diagram (this may take some time, depending on how complex your diagram is).
4. Check the diagram before continuing working with it (you can undo the operation from the *Edit* menu).

Transforming the Type of a Diagram

A useful operation when e.g. transforming to a more object-oriented version of the SDL system is to change the SDL88 diagrams into type diagrams and make instantiations of these types. The following shows some examples how to perform such an operation and similar ones

where you want to change the type of a diagram or want to work with an SDL structure that is almost a copy of an already existing hierarchy.

Example 1

Assume that the system S consists of block B, which contains process P. The exercise to solve is to transform the block into a block type BT and put this into a package P and instantiate the block B from BT.

There is no direct command to accomplish this task in the SDL Suite; instead there are many solutions, more or less complicated and time consuming. The proposed one is easy to use and will take advantage of the possibility to cut and paste complete sub-hierarchies, thereby eliminating loosing file connections and the need for making manual connections to existing files.

Solution: Open the system S, add a new block type symbol and name it BT. Open the block B and change the kernel heading from “block B” to “block type BT”. Note that the sub-hierarchy in the Organizer, previously below B, has now been moved to BT. In system S, change the text in the block symbol to “B:BT” to make it an instance of BT and cut the block type symbol to the clipboard. Create a package diagram named P and paste the block type into this diagram.

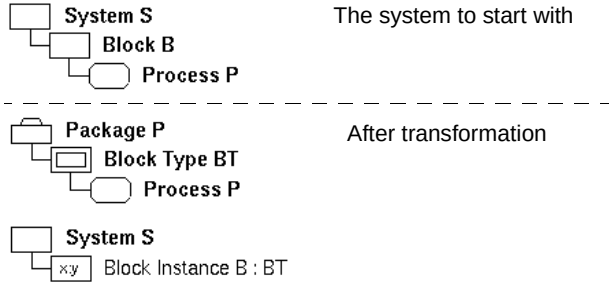

Figure 371: The Organizer view

To make the new system complete you need to add the text “use P;” in the package reference symbol in system S, define the gates inside the block type BT and use these gates to connect the existing channels for the block B. If needed, you can change the filename of the block type with the *Save As* command in the SDL Editor to use a filename that re-

sembles the block type name and also use the file name extension that conforms to the SDL Suite conventions.

Example 2

This is a variant of example 1. Assume we want to keep the original diagram but want to have a new block type BT in package P that is a copy of the existing B.

Solution: In package P place a new block type symbol and name it BT. Double click on it and in the appearing Edit dialog tick the *Copy existing file* option and use the file connected to the existing block diagram B. Click *Continue* in the warning about recommended file name extension. In the opened diagram, change the kernel heading to "block type BT".

For all diagram references in BT (in the example there is only one), use the *Connect* command in the Organizer to connect them to the existing files. In the Connect dialog be sure to use the *Expand Substructure* option to get automatic connections for possible sub-hierarchies.

As an alternative to connecting the diagram references you can copy the reference symbols from block B and paste them into block type BT, then you will get automatically all the connections for sub-hierarchies below the pasted references.

Note that in either case you will use the same file connection for process P in our example for both the original process and also for the process P referenced in the block type, meaning that if you change the contents of this file you will change both the behavior of the block B and the block type BT, which might lead to unexpected results. If you want unique file connections you should take a copy of the existing file, for example copy `P.spr` to `P1.spr`, and reconnect one of the processes to this new file instead.

Example 3

The SDL system consists of system S, block B, process P and procedure subPr inside P. You want to transform most of the process including its procedure subPr into a new procedure Pr defined in the system S.

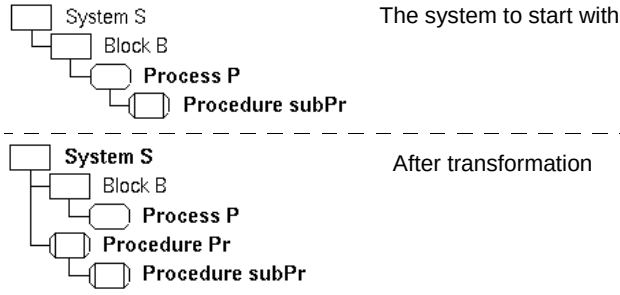

Figure 372: The Organizer view

Solution: This solution is similar to the solution to example 2. Open the system diagram S and place a procedure reference symbol named Pr. Double click it and open a copy of the existing file connected to process P. Edit the kernel heading to contain the text “procedure Pr”. Save the procedure as a new file. Connect all referenced procedures inside Pr or copy the procedure references from the process P to get all the sub-hierarchy file connections. Finally edit process P and procedure Pr to make them useful in their new context.

The symbol is dashed and the change is immediately reflected in the Diagram Structure (this is only true if the *Dashed Diagram* option is on in the Organizer’s *View Options*).

- You may at any time *undash* a dashed symbol. Select the symbol and select *Undash* from the *Edit* menu.
- If the symbol (prior to the dash operation) was connected in the Organizer the following dialog will appear:

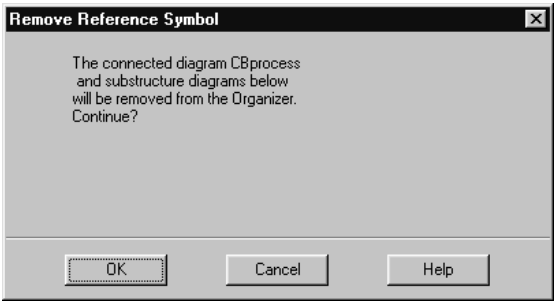

Figure 373: Removing substructure by dashing

- If you click *OK*, the substructure will be removed. However, you may undo this.

About Symbols and Lines

Following is a description of the components in the drawing area. See also appendix 44, *Symbols and Lines – Quick Reference, on page 2053*.

The Additional Heading Symbol

Symbol Appearance	Symbol Name	References to Z.100
	Additional heading	Z100: 2.2.5 Additional heading Z100: 6.1.1.3 Process type heading Z100: 2.4.4 Formal parameters, Signalset Z100: 6.3 Specialization Z100: 6.3.1 Inherits Z100: 6.3.2 Virtual, Redefined, Finalized Z100: 6.3.2 Virtuality constraint (atleast) Z100: 6.2 Actual context parameters Z100: 6.2 Formal context parameters Z100: 6.2.1 - 6.2.9 Formal context para

The additional heading symbol is not defined further according to Z.100. In the SDL Editor, it looks like a dashed text symbol or it is shown without any border; this is controlled by the Editor preference ScreenZ100Symbols. The symbol is editable and resizeable, but cannot be moved. Its intended use is to define:

- Inheritance and specialization, using the following keywords:
  - `INHERITS`
  - `ADDING`
  - `ATLEAST`
- Formal parameters for a process / procedure, using the keyword `FPAR`

- Directives to the SDL to C Compiler. A directive uses the SDL comment notation and a hash character, such as:
  `/*#INCLUDE file.pr */`
- `SIGNALSET` and instance information.

The additional heading symbol is either repeated through all pages contained in an SDL diagram or it is only shown on the first page. This is controlled by the editor preference AdditionalHeadingOnlyOnFirstPage and can also be specified with the SDL Editor command *Diagram Options*.

Note that the combined text in the Kernel Heading and the Additional Heading symbol must use the syntax as specified for a heading in SDL/PR to be accepted in the SDL Analyzer.

The Package Reference Symbol

Symbol Appearance	Symbol Name	References to Z.100
	Package reference	`Z100: 2.4.1.2 Reference in Package` `Z100: 2.4.2 Reference in System`

The package reference symbol is available on system and package diagrams only. It is located outside the frame, on top and to its left. It contains references to package(s) containing definitions that are to be included in the SDL system.

You can select and resize, but not move the package reference symbol.

Other SDL Symbols

These are the symbols that describe the structure or behavior of the SDL diagram. They must be placed inside the frame.

You can draw symbols in color, see "Color on Symbols" on page 1860.

Syntax Checking on Symbols

The SDL Editor checks that the symbols you add to a diagram are in accordance with the syntactic rules imposed by SDL. Symbols that are not allowed in a diagram / page of a specific type are dimmed in the symbol

menu. Also the text entered is checked for syntax errors. See "Layout syntax check" on page 2017.

Symbols on both Interaction Pages and Flow Pages

Symbol Appearance	Symbol Name	References to Z.100
	Class	Not included (Z100 11/99)

Symbols on Interaction Pages

Symbol Appearance	Symbol Name	References to Z.100
	Text	Z100: 2.5.4 Signal Z100: 2.5.5 Signal list Z100: 5.2.1 Newtype Z100: 5.3.1.9 Syntype Z100: 5.3.1.13 Synonym Z100: 5.3.1.12.1 Generator Z100: 4.13 Remote variable Z100: 4.14 Remote procedure
	Comment	Z100: 2.2.6
	Text extension	Z100: 2.2.7 (depends on the symbol connected to)
	Text Reference	None
	Block reference	Z100: 2.4.2 Block definition Z100: 6.1.3.2 Block def based on block type Z100: 6.1.2 Type expression Z100: 6.2 Actual context parameters

Symbol Appearance	Symbol Name	References to Z.100
	Process reference	Z100: 2.4.3 Process definition Z100: 2.4.4 Number of instances Z100: 6.1.3.3 Process def based on block type Z100: 6.1.2 Type expression Z100: 6.2 Actual context parameters
	Block substructure reference	Z100: 3.2.2
	Service reference	Z100: 2.4.4
	System type	Z100: 6.1.1.1
	Block type	Z100: 6.1.1.2
	Process type	Z100: 6.1.1.3
	Service type	Z100: 6.1.1.4
	Operator reference (an SDL/GR extension defined in the SDL Suite)	Z100: 5.3.2 Referenced operator in SDL/PR

Symbol Appearance	Symbol Name	References to Z.100
	Gate	Z100: 6.1.4 Gate Z100: 2.5.5 Signal list

Symbols on Flow Pages

Symbol Appearance	Symbol Name	References to Z.100
	State or nextstate	Z100: 2.6.3 State Z100: 4.4 Asterisk state Z100: 4.5 Multiple appearence of state Z100: 2.6.8.2.1 Nextstate Z100: 4.9 Dash nextstate
	Text	Z100: 2.5.4 Signal Z100: 2.5.5 Signal list Z100: 5.2.1 Newtype Z100: 5.3.1.9 Syntype Z100: 5.3.1.13 Synonym Z100: 5.3.1.12.1 Generator Z100: 2.6.1.1 Variable Z100: 2.6.1.2 View Z100: 2.8 Timer Z100: 4.13 Remote variable Z100: 4.13 Imported variable Z100: 4.14 Remote procedure Z100: 4.14 Imported procedure
	Input	Z100: 2.6.4 Input Z100: 4.6 Asterisk input Z100: 4.14 Remote procedure input Z100: 6.3.3 Virtual transition z100: 5.4.3 Variable z100: 5.4.3.1 Indexed variable z100: 5.4.3.2 Field Variable
	Comment	Z100: 2.2.6

Symbol Appearance	Symbol Name	References to Z.100
	Save	Z100: 2.6.5 Save Z100: 4.7 Asterisk save Z100: 6.3.3 Virtual save
	Text extension	Z100: 2.2.7 (depends on the symbol connected to)
	Output	Z100: 2.7.4
	Decision	Z100: 2.7.5 Decision Z100: 5.3.1.9.1 Range condition Z100: 2.2.3 Informal text
	In-connector or out-connector	Z100: 2.6.7 In-connector Z100: 2.6.8.2.2 Out-connector
	Task, set, reset or export	Z100: 2.7.1 Task Z100: 5.4.3 Assignment Z100: 2.8 Set, Reset Z100: 4.13 Export
	Procedure call	Z100: 2.7.3 Call Z100: 2.7.2 Actual parameters
	Macro call	Z100: 4.2.3
	Create request	Z100: 2.7.2
	Transition option	Z100: 4.3.4 Transition option Z100: 5.3.1.9.1 Range condition

Symbol Appearance	Symbol Name	References to Z.100
	Continuous signal or enabling condition	Z100: 4.11 Continuous signal Z100: 4.12 Enabling condition
	Start	Z100: 2.6.2 Start Z100: 6.3.3 Virtual transition
	Priority input	Z100: 4.10 Priority input Z100: 2.6.4 Stimulus Z100: 6.3.3 Virtual transition z100: 5.4.3 Variable z100: 5.4.3.1 Indexed variable z100: 5.4.3.2 Field variable
	Stop	Z100: 2.5.8.2.3
	Procedure start	Z100: 2.4.6
	Inlet	Z100: 4.2.2
	Return	Z100: 2.6.8.2.8
	Outlet	Z100: 4.2.2
	Procedure reference	Z100: 2.4.6 Procedure definition

Symbol Appearance	Symbol Name	References to Z.100
	Operator reference (an SDL/GR extension defined in the SDL Suite)	Z100: 5.3.2 Referenced operator in SDL/PR
	Gate	Z100: 6.1.4 Gate Z100: 2.5.5 Signal list

Note:

The operator reference symbol is not part of the current Z.100 recommendation. It has been added to the SDL Editor as a convenience for the user. It makes operators visible in the SDL structure which is handled by the Organizer and facilitates thus navigating.

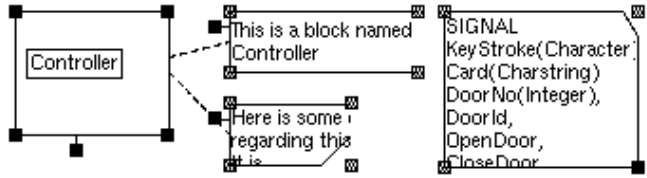
The operator reference symbol does not, however, refer to the operator diagram implicitly. References to operator diagrams must be explicitly entered in SDL/PR, as stated in Z.100.

Graphical Properties of Symbols

You can select and move all symbols that are available in the symbol menu, and you can assign the symbols arbitrary locations.

You can resize certain symbols; these are indicated by filled selection squares. Other symbols can only be partially resized or cannot be resized at all[1]; this is shown by grayed selection squares.

1. The size of non-resizeable symbols is computed by the SDL Editor to fit the text contained in the symbol.



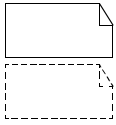
This symbol can be resized...

...while that one can be either full sized or clipped...

...and the third one can be resized by dragging the lower right corner.

Figure 374: Resizeable and non-resizeable symbol

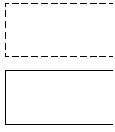
No symbol is allowed to overlap any other symbol except the text symbol and the additional heading symbol.



Text / Additional Heading / Package Reference Symbols

The text, additional heading and package reference symbols look like a piece of paper. When all of the text within a text symbol is in view, the upper right corner is “folded” down. When any portion of the text within a text symbol cannot be seen (because the text symbol is too small), the upper right corner is clipped or diagonally cut off. See Figure 374.

Clipped text symbols are printed in their whole on a separate sheet of paper.



Comment / Text Extension Symbols

The comment and text extension symbols can be shown either in full size enclosing the complete text or clipped (collapsed) where the symbol is in the minimum size and only the first part of the text is visible. The clipped symbol is visualized as if the lower right corner has been cut off. See Figure 374.

Block Substructure Symbol

The appearance of this symbol differ from the drawing rules in Z.100. The non editable text “substructure” is drawn inside the symbol. Without this extra text it is impossible to distinguish the block symbol and the block substructure symbol by their visual appearance.

The appearance can be set to be according to Z.100 by the Editor preferences ScreenZ100Symbols and PrintZ100Symbols. Setting these to on means that the extra text will not be drawn or printed.

Symbol Text Attributes

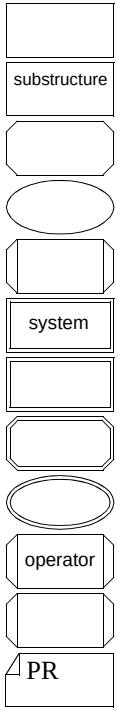
Most SDL symbols have one or multiple text attributes. A text attribute should be filled with an SDL/PR expression (textual expression) that is syntactically correct according to Z.100. Depending on the correctness of the text, the SDL Suite tool set has the ability to perform the following operations:

- Syntactic Analysis
- Semantic Analysis
- Pretty-printing
- Generation of reports
- Generation of code.

Syntax Checking on Text Attributes

You are not forced by the SDL Editor to fill text attributes with text. However, a context sensitive syntax check is performed for each text attribute. The first located syntax error is indicated by a red bar underlining the text where the error occurs.

A global syntax check for the complete diagram is performed by the SDL Analyzer.



Reference Symbols

Diagram reference symbols allow to build an entire SDL system by referring to diagrams that are structurally related. Reference symbols are the following:

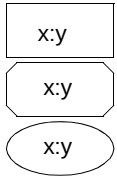
- Block reference
- Process reference
- Block substructure reference
- Service reference
- System type
- Block type
- Process type
- Service type
- Operator reference
- Procedure reference
- Text Reference

These symbols are handled by the SDL Editor in order to ensure consistency between the SDL diagrams and the SDL structure that is handled by the Organizer. Because of that, the SDL Editor imposes the restriction that a reference symbol must be unique within an SDL diagram (this restriction is not in conflict with Z.100).

You are permitted to have diagram reference symbols that are not assigned any name.

The SDL Editor performs a number of checks when you edit an SDL reference symbol. Furthermore, when you double-click a reference symbol, the SDL diagram that the symbol refers to will be opened.

See also "Working with Diagram Reference Symbols" on page 1901.



Instantiation Symbols

You may use any of the following reference symbols for the instantiation of a type:

- Block reference
- Process reference
- Service reference.

An instantiation symbol differs from a “normal” reference symbol in the sense that the syntax of the symbol’s text differs. The syntax is:

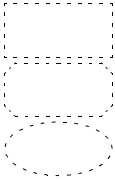
```
a:a_type
```

where *a_type* is the name of the SDL type diagram (block type, process type or service type diagram) that is instantiated into the diagram with the name *a*.

Instantiation symbols are visualized in the Organizer structure. The Organizer structure is updated to reflect the nature of the changes applied to the SDL diagram, in a similar fashion as for diagram reference symbols (see “Reference Symbols” on page 1893).

The names of instantiation symbols must be unique within an SDL diagram.

See also “Working with Diagram Instantiation Symbols” on page 1901.



Dashed Reference Symbols

Any of the following reference symbols may be dashed:

- Block reference
- Process reference
- Service reference.

Dashed symbols are visualized in the Organizer structure. The Organizer structure is updated to reflect the nature of the changes applied to the SDL diagram, in a similar fashion as for diagram reference symbols (see “Reference Symbols” on page 1893).

The names of dashed reference symbols must be unique within an SDL diagram.

See also “Working with Dashed Symbols” on page 1902.

Lines

Lines are the graphical objects that interconnect symbols. One line only is available in the symbol box, namely the gate, which is handled as a symbol. You can insert it by selecting it and placing it into the drawing area.

You insert the other lines by selecting a symbol and dragging the *handle* that appears on the source symbol and connecting it to the target symbol. (Some symbols have multiple handles).

Lines are always connected to symbols, they are not allowed to exist on their own.

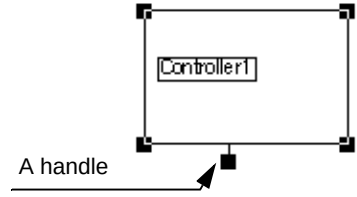


Figure 375: A handle

You can select, move and reshape lines. Some layout work is performed automatically by the SDL Editor.

A line is allowed to overlap any other object.

Lines in Interaction Diagrams

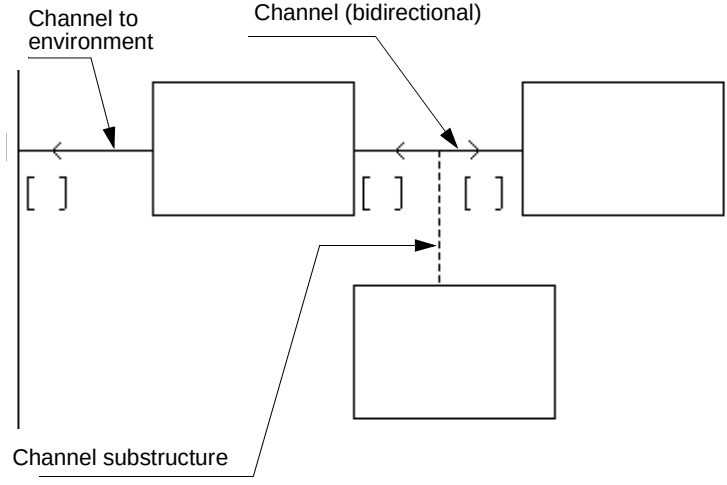

Figure 376: Lines (1)

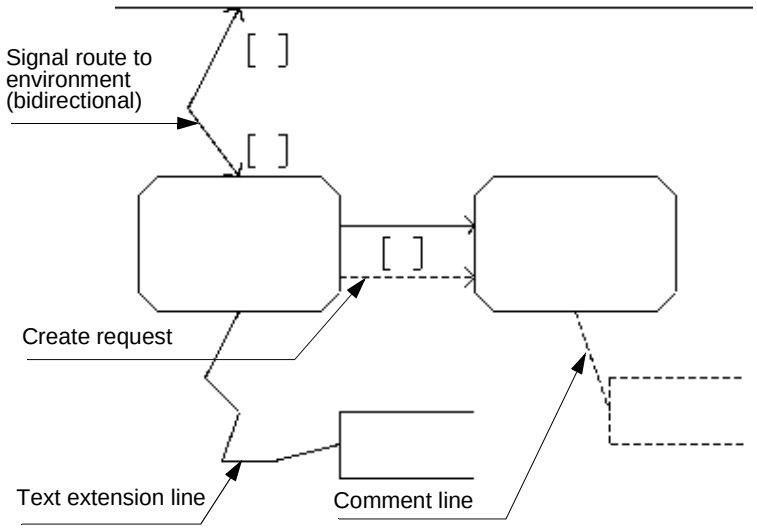

Figure 377: Lines (2)

The following lines are defined in interaction diagrams (see Figure 376 and Figure 377):

- channels
- channel substructures
- signal routes
- create requests
- text extension lines
- comment lines

You can reshape each of these lines and you can also move the connection points.

Lines in Flow Diagrams

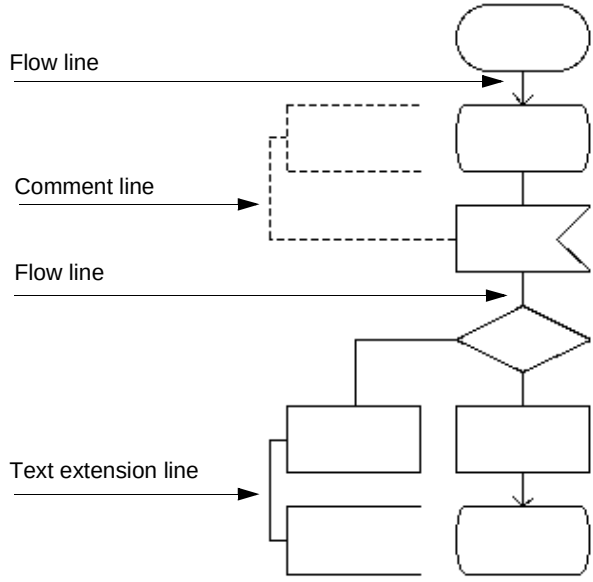

Figure 378: Lines (3)

On flow diagrams, the following lines are defined (see Figure 378):

- flow lines
- comment lines
- text extension lines

Line segments on flow pages always use a 90-degree angle. You can add segments on a line, but connection points are fixed.

Syntax Checking on Lines

The SDL Editor checks that the target symbol is in accordance with the syntactic rules imposed by SDL. If not, the SDL Editor will refuse to connect the symbol. When you edit the text attributes are instantly checked for syntactical errors.

Textual Objects

Textual objects are the textual attributes that are related to a symbol or a line. Each of these attributes is prepared by the SDL Editor – you need of course to fill in their textual contents.

Textual attributes are indicated by a small rectangle which appears upon selection of the symbol or line the attribute belongs to.

You can select and edit textual objects. You can move them freely, as long as their location does not violate the rules defined by Z.100.

Textual objects are allowed to overlap any other objects.

Textual Objects in Interaction Diagrams

The following textual objects are defined in interaction diagrams:

Graphical Appearance	Textual objects
	• Name of a diagram reference symbol – Includes the *number of instances* for a process reference symbol
	• Name of a diagram type reference symbol
	• Name of a diagram instantiation symbol (e.g. `inst:blk_type`) – Names of graphical connection points in diagram instantiation symbol (e.g. `CON1`)

Graphical Appearance	Textual objects
	• Name of a channel or signal route (e.g. `CH`) – Signal list on a channel / signal route (there are 2 signal lists if the line is bidirectional, e.g. `Sig1` and `(Siglist)`) – Connection point for channel / signal route to / from environment, e.g. `CON`
	• Name of a gate, e.g. `GA` – Signal lists on a gate (there are 2 signal lists when the gate is bidirectional, e.g. `Sig1` and `Sig2`)

Textual Objects in Flow Diagrams

In flow pages, the following textual attributes are defined:

Graphical Appearance	Textual objects
	• Decision expressions connected to a decision symbol or transition option, e.g. `Expr1` and `Expr2`.
	• Name of a gate, e.g. `GA` – Signal lists on a gate (there are 2 signal lists when the gate is bidirectional, e.g. `Sig1` and `Sig2`

Graphical Connection Points

Connection points are text objects which are created automatically by the SDL Editor when you draw a channel or signal route to the frame or to an instantiation symbol.

They are handled in a similar way as other text attributes. You are free to fill connection points on the frame or not. The alternative is to define textual connection statements between channels and signal routes in a text symbol.

Change Bars

A change bar is a vertical line to the left of a text in an SDL diagram. It visually identifies changes in the SDL system.

A solid change bar indicates that the text has been changed. A dotted change bar indicates that a text or its associated symbol has been moved.

The change bars associated with the diagram name and the page name act as change bars for the complete page. As soon as a change has been made to a page, change bars for the diagram name and the page name are added.

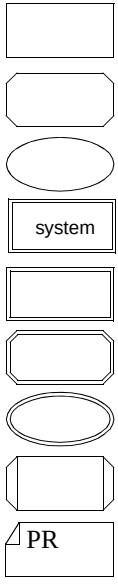
You can turn change bars on and off and also clear them from the Organizer. See "Change Bars" on page 147 in chapter 2, *The Organizer*.

Working with Symbols

The main operations provided by the SDL Editor on symbols is described in this section.

- *Working with Diagram Reference Symbols*
- *Working with Diagram Instantiation Symbols*
- *Working with Dashed Symbols*
- *Selecting Symbols*
- *Adding Symbols*
- *Inserting a Symbol into a Flow Branch*
- *Navigating in Flow Diagrams*
- *Navigating from Symbols*
- *Cutting, Copying and Pasting Symbols*
- *Moving Symbols*
- *Resizing Symbols*
- *Mirror Flipping Symbols*
- *Adjusting Symbols to the Grid*
- *Editing the Diagram Kernel Heading*.

In addition, text editing functions are provided for the text associated with the symbols.



Working with Diagram Reference Symbols

When you perform certain modifications to the diagram reference symbols listed in the left margin (*system type*, *block*, *block type*, *substructure*, *service*, *service type*, *process*, *process type*, *procedure and text reference symbols*), the SDL Editor checks with the Organizer to verify that the modifications are valid. This occurs in the following situations:

- *Adding a Diagram Reference Symbol*
- *Adding an Operator Diagram Reference Symbol*
- *Renaming a Diagram Reference Symbol*
- *Removing Symbols*

Working with Diagram Instantiation Symbols

Instantiating a Diagram Type

The implication of an instantiation symbol is that the description of the type diagram is actually instantiated, i.e. a physical copy is created. This

copy may then be given additional properties using SDL's inheritance and specialization mechanisms.

When a diagram type is to be *instantiated*, do as follows:

1. Make sure the type diagram is visible according to the SDL scope rules.
2. Insert a diagram reference symbol. When specifying the name of the symbol, use the syntax `<instance_name>:<type_name>`.
3. When the symbol is deselected, the diagram structure is immediately updated to show the instantiation (this is only true if the *Instance Diagram* option is on in the Organizer's *View Options*).

Working with Dashed Symbols

Dashing and Undashing a Reference Symbol

Dashed reference symbols are used to refer to an object that is defined elsewhere in one of the supertypes of the current subtype.

To *dash* a reference symbol:

1. Select the reference symbol.
2. Select *Dash* from the *Edit* menu.

Note that a symbol cannot be dashed if there are syntax errors in the name attached to the symbol. Also if a syntax error is introduced in a dashed symbol the symbol will automatically be undashed.

Selecting Symbols

With the SDL Editor, you often perform actions that apply on a selection. This section discusses topics related to selection of symbols.

Selecting a Flow of Symbols

You often want to select a flow of subsequent symbols in a flow page, including all branches - the *tail* of the flow. To select a flow of symbols:

1. Click on the symbol where the flow starts.
2. From the *Edit* menu point to *Select Tail*. The tail of the flow is selected. See Figure 379, where the left picture shows only one select-

ed object and its associated connections, whereas the right picture shows the selected symbol and its connections plus the selected rest of the flow diagram – the *Selected Tail*.

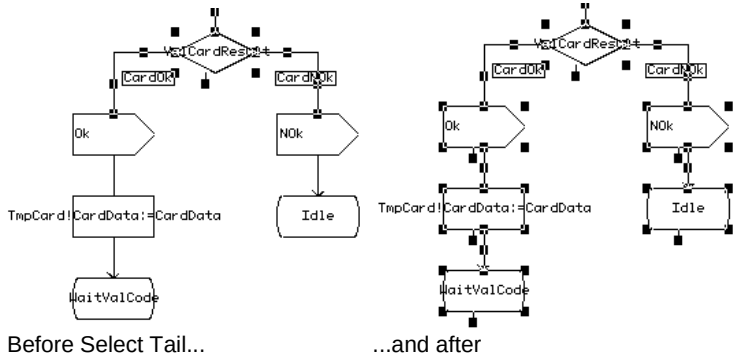


Figure 379: Selecting the tail of a subtree

Selecting a Symbol That Has Associated Objects

Consider the following when you select a symbol which has lines or text associated with it:

- When you select a symbol, you implicitly select the associated objects as well. A text cursor is inserted directly in the text associated with a symbol, and the *text window* will be updated to contain the text.
- If you point to a line associated with a symbol, you will select the line, **not** the symbol. The process of selecting lines is described in "Selecting Lines" on page 1932.
- If you point to the text associated with a symbol, the resulting selection depends upon the type of the symbol.

Displaying Selected Symbol Attributes

Selected symbol attributes are displayed as follows:

- When you select a symbol from which you can draw lines, it is displayed with a *handle* which you use when drawing lines from that symbol. Handles are shown in Figure 380.

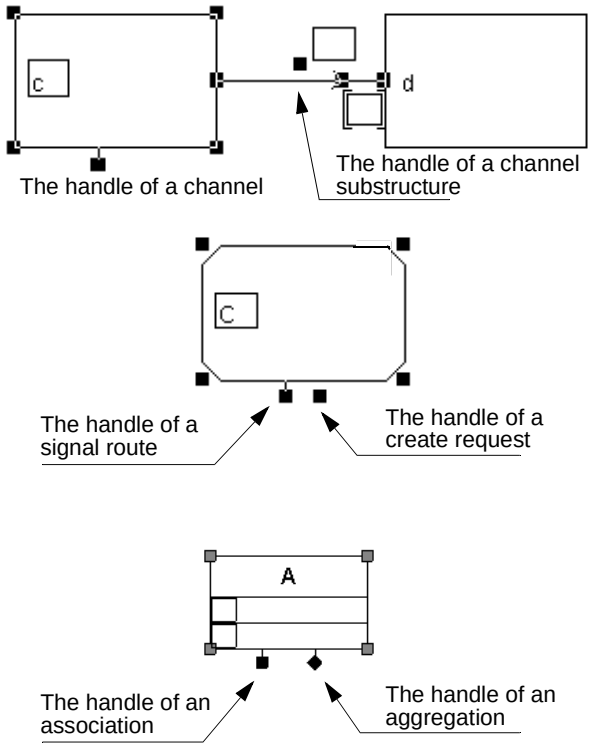

Figure 380: A selected symbol's handles

- *Text attributes* associated with a selected symbol are marked by a rectangle around the text, as shown in Figure 381. For class symbols, this only applies when text attributes contain no text.

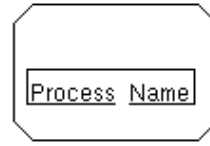

Figure 381: A selected symbol's text attributes

- In an interaction page, a line is marked by drawing filled *selection squares* at the line's starting point, ending point, and each breakpoint. In the middle of each line segment is a tiny selection square that provides an easy way to create new breakpoints. See Figure 382.

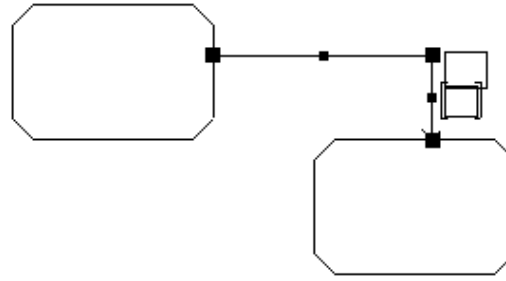

Figure 382: The selection squares of a line in interaction pages

- In a flow page, a selected flow line is marked by drawing filled *selection squares* in the middle of each line segment. This indicates that you can move the individual line segments (but not the flow line as a whole). See Figure 383.

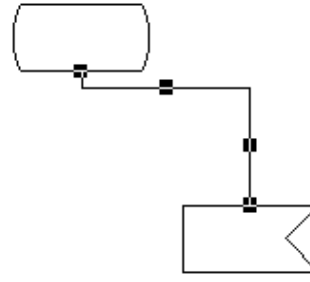

Figure 383: The selection squares of a line in flow pages

Adding Symbols

You may place symbols into the drawing area in either manual mode or in automatic mode.

Adding Symbols in Manual Mode

This section describes how to do this in manual mode. The automatic mode is described in "Adding Symbols in Automatic Mode" on page 1908.

Selecting and Placing a Symbol

1. Click the symbol in the symbol menu.
2. Click at the desired location in the drawing area. Overlap of symbols is not allowed.

   The symbol is drawn and adjusted to the symbol grid.

Entering Symbol Text Attributes

Once a symbol has been added, you can enter the text into the symbol's text attributes. The symbol remains selected. Enter the text required directly using the keyboard or edit the text inside the *text window*.

Connecting the Symbol to Another Symbol

Once the symbol is at the desired location it can be connected to another symbol as required.

To connect two symbols:

> **Note:**
>
> The line will be drawn only when the SDL syntax rules allow the symbols to be interconnected.

1. Add the *source symbol*, i.e. the symbol from where you want to draw the line.
2. Point the mouse onto the handle of the source symbol, and start dragging the handle. As soon as mouse motion has begun, you can release the mouse button. Point to the *target symbol* and click the mouse button. The line is drawn to the symbol and required text attributes are added to the connecting line. The box without brackets

is reserved for the name of the channel, while the box with brackets [ ] is for the signal list.

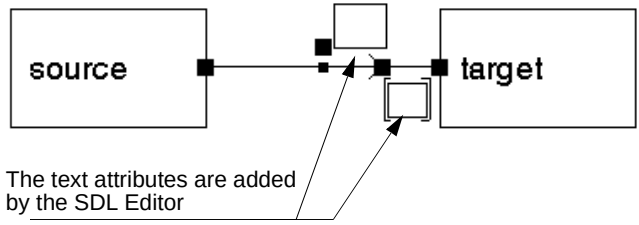

Figure 384: Having connected two symbols

3. Fill in the text attributes.

Conversely, once you have placed a symbol in the drawing area, you can follow the same procedure from a symbol resident in the drawing area to the new symbol.

Connecting the Symbol to the Environment

1. Hold the mouse pointer on the handle of the symbol, drag it to the frame (environment) and release the mouse button.
2. Enter text in the channel or signal route and connection point boxes.

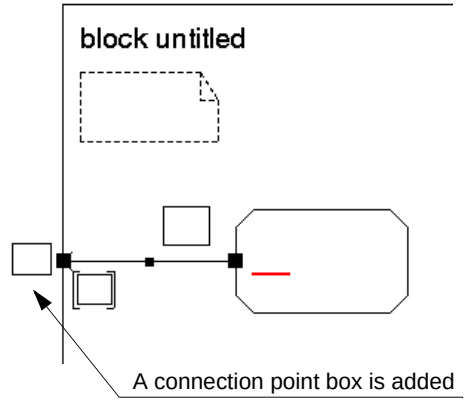

Figure 385: Having connected the symbol to the environment

Adding Symbols in Automatic Mode

The automatic mode is particularly useful when you want to add symbols sequentially or in parallel in a symbol flow. Both situations are described below.

Adding in Sequence

To add symbols sequentially within a flow page, proceed as follows:

1. Select the source symbol in the drawing area.
2. Double-click the *target symbol* in the *symbol menu.*

   The target symbol is added to the source symbol, and a flow line is drawn between the two symbols if the syntax rules allow it.
3. Fill in the text in the target symbol.

The target symbol is positioned directly beneath the source symbol if possible. Otherwise, the added symbol is placed in the first available location to the right.

After this operation, the target symbol is automatically selected and the source symbol is de-selected.

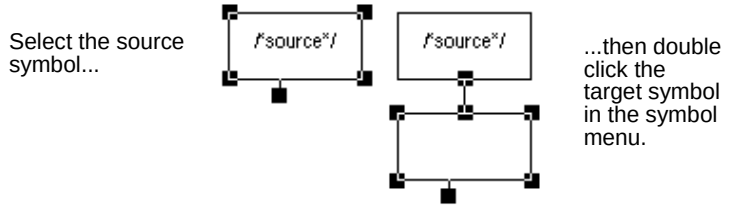

Figure 386: Adding in sequence

Adding in Parallel

To add symbols in parallel in a flow page:

1. Select the *source symbol* in the drawing area.
2. Press `<Shift>` and double-click the *target symbol* in the *symbol menu*.

   The target symbol is added to the selected symbol. The source symbol remains selected.

You can repeat this procedure in order to add additional symbols to the selected symbol. The target is positioned immediately below the source symbol, if possible. Otherwise, the target symbol is placed in the first available location to the right.

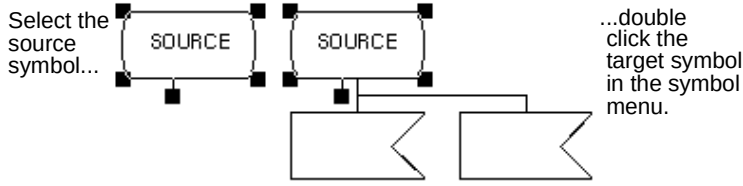

Figure 387: Adding in parallel

Using Default Placement

You can also take advantage of the auto-placement by double-clicking a symbol without having to connect it to other symbols.

Insufficient Space Left

When you insert a symbol using the double-click facility, there may not be any space left to perform the operation, The SDL Editor informs you of this with a message.

You have the following options:

- Click *OK* to increase the page. The *Drawing Size* dialog will be opened, where you can specify the new size of the SDL Page.

  If you select this method, the SDL page may not fit any longer into the paper that you have set up with the Print preferences. The result may be an SDL page that requires multiple sheets of paper when printing it (unless you rescale it).

- To *Cancel* the operation. Try to find a more suitable location for the new symbol and use manual placement (see "Adding Symbols in Manual Mode" on page 1906).

Adding a Gate Symbol

The gate symbol differs slightly from other symbols when you add it.

Adding a Gate in Manual Mode

1. Select the gate symbol.
2. Move the pointer into the drawing area. The gate is immediately displayed and connected in a 90-degree angle to the frame and the environment.
3. Move the mouse to a suitable location. The gate symbol follows the mouse motion and is automatically reconnected.
4. Click the mouse.
5. Enter the name of the gate and the signals it conveys.

> **Note: Coalesced Gates and Connection Points**
>
> See "Connecting a Gate Symbol with a Channel or Signal Route" on page 1919 if you get a message with the text "A Gate has coalesced with a connection point...".

Adding a Gate in Automatic Mode

You may add and connect a gate to a channel or signal route with a double-click. The channel or signal route must not be already connected to a gate or connection point.

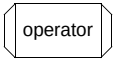
1. Select the channel or the signal route.
2. Double-click the gate symbol in the symbol menu.
3. If required, redirect or bidirect the gate so that it matches the direction of the channel or signal route.
4. Enter the name of the gate and the signals it conveys.

Adding a Diagram Reference Symbol

When you add a diagram reference symbol, the SDL Editor checks that the name and type are unique within the SDL diagram. The SDL Editor will refuse any duplicates. The newly added reference symbol is then inserted into the Organizer's diagram structure.

1. Select the symbol to be added from the symbol menu and add it to the diagram.
2. Type in the name of the symbol.
3. Deselect the symbol. The SDL Editor checks that the name and type are unique within the SDL diagram being edited.

   If the new reference symbol is accepted, it is inserted into the diagram structure, located beneath the referring diagram.

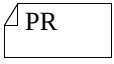


Adding an Operator Diagram Reference Symbol

In a data type construct it can be stated that an operator diagram is referenced elsewhere. This means that the operator will not be described in the current place, but in an operator diagram.

The SDL Editor does not know that the operator is referenced in a data type. The operator reference symbol is available for this situation. It is a convenience that has been added to the SDL Suite tool set to facilitate navigating within an SDL system. Its presence in an SDL diagram does not modify the meaning of the diagram.

You add an operator reference symbol in a similar manner as when adding any other reference symbol. See "Adding a Diagram Reference Symbol" on page 1911.



Adding a Text Reference Symbol

The Text reference symbol is used to include SDL PR into the SDL system.

You add an operator reference symbol in a similar manner as when adding any other reference symbol. See "Adding a Diagram Reference Symbol" on page 1911.

Inserting a Symbol into a Flow Branch

The SDL Editor allows you to insert symbols into a flow branch. When inserting symbols, the SDL Editor will rearrange the page in order to prepare the required space for inserting the symbol. This can be done in different ways:

- By pushing the tail of the branch downwards. This is the preferred method.
- By increasing the size of the SDL page.

Inserting a Symbol into a Flow Branch

1. Select the symbol in the symbol menu.
2. Point to the line interconnecting the symbols where the new symbol is to be inserted.
3. Click the mouse.

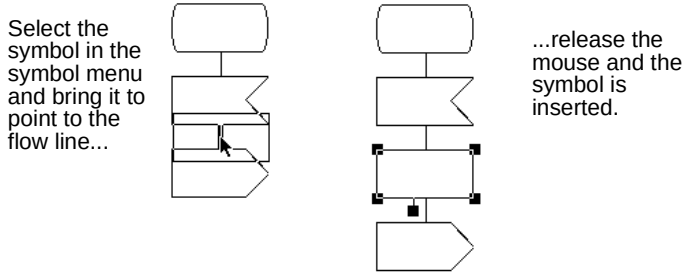


Figure 388: Inserting a symbol into a flow branch

Inserting a Symbol by Double-Click

To insert a symbol into a flow branch by double-clicking it:

1. Select the line that interconnects the two symbols. Alternatively you can select the symbol preceding the line, see "Insert Paste" on page 2007.
2. In the symbol menu, double-click the symbol to be inserted.

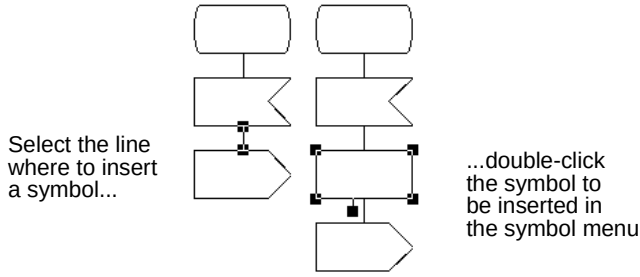

Figure 389: Inserting a symbol with double-click

Navigating in Flow Diagrams

For certain symbols you can use the *Navigate* command in the *Tools* menu or double click on the symbol to navigate around in the diagrams. These symbols are:

- Create request, procedure call and macro call
- State and nextstate
- Inconnector and outconnector
- Reference symbols; see further "Navigating from a Diagram Reference Symbol" on page 1914

> **Note: Navigating from a Class Symbol**
>
> Navigating from a class symbol is possible only by using *Tools>Navigate*. See further "Navigating from Class Symbols" on page 1915

Navigating from Create Request and Procedure/Macro Call

For a create request, procedure call or macro call the *Navigate* command will show the corresponding process, procedure or macro diagram. The diagram is found by searching in the Organizer structure for all relevant diagram types matching the name used in the symbol. If one and only one match is found this diagram will be shown in the editor. If there exists more than one diagram a dialog is issued.

Navigate to the desired diagram by selecting it in the dialog.

Navigating from State/Nextstate

For a state or nextstate the *Navigate* command will show other occurrences of the same name(s) in other state or nextstate symbols within the same diagram. If only one symbol matches the name search this symbol will be shown. If more than one symbol have the same name, a dialog is shown.

Navigating from Connectors

For an outconnector, the *Navigate* command will show the corresponding inconnector in the same diagram having the same name as the outconnector.

Similarly for an inconnector; you can navigate to all occurrences of outconnectors within the same diagram having the same name as the inconnector.

Navigating from Symbols

Navigating from a Diagram Reference Symbol

When you double-click or choose the Navigate command on a diagram reference symbol, the SDL diagram that the reference symbol refers to is opened, provided that the diagram is included in the Organizer structure.

This feature allows easy navigation down an SDL hierarchy.

See also "Navigating from an Instantiation Symbol" on page 1914 and "Navigating from a Dashed Symbol" on page 1915.

Navigating from an Instantiation Symbol

You may use instantiation symbols to navigate in the diagram structure.

When you choose *Navigate* in the *Tools* menu or double-click on an instantiation symbol, the SDL Editor matches the name of the type referred to in the instantiation symbol against the existing type diagrams in the Organizer structure. The following happens depending on how many type diagrams that match the given diagram name.

- **One and only one diagram is found**: This diagram will be shown.

- **No diagram matches the name**: A dialog will appear which offers the possibility to open the Type Viewer window which can be used to navigate among the inheritance and redefinition trees extracted from the SDL system:
- **More than one diagram is found**: A dialog will appear showing the file names of all the found diagrams. Additionally the possibility to show the Type Viewer window is available.

Navigating from a Dashed Symbol

When you select *Navigate* in the *Tools* menu or double-click a dashed symbol, a scenario similar to the action of navigating from an instantiation symbol takes place. See "Navigating from an Instantiation Symbol" on page 1914

Navigating from Class Symbols

For a class symbol, the *Navigate* command will show other occurrences of the same name(s) in other class symbols within the same diagram. If only one symbol matches the name search, this symbol will be shown. If several symbols have the same name, a select dialog is shown.

Cutting, Copying and Pasting Symbols

The clipboard of the SDL Editor allows you to cut or copy a selection of symbols. The selection may then be pasted to:

- The same page
- Pages of the same diagram, provided the page types match
- Other diagrams, provided the diagram types match

See also "Cutting, Copying and Pasting Reference Symbols" on page 1917.

Cutting and Pasting Symbol(s)

A dialog may appear when cutting or pasting an object with link endpoints. See "Deleting an Object" on page 461 in chapter 9, *Implinks and Endpoints* or "Pasting an Object" on page 461 in chapter 9, *Implinks and Endpoints*.

Limitations when Pasting

> **Note: Effect of Syntax Check when Pasting**
>
> Some symbols may not be pasted if the syntax check is on. The clipboard buffer content must comply with the SDL syntax rules. Any **symbols which do not comply will be omitted**. (The clipboard buffer content may have been copied from a page edited with syntax checking turned off.)

Pasting is not always possible. Note the following cases, and refer to "Relationship between Diagrams and Pages" on page 1848.

- The selection cannot be pasted if the page is too small. In this case, you need to enlarge the page. See "Resizing a Page" on page 1958.
- You are not allowed to paste symbols so that they overlap existing symbols in the drawing area. If you attempt to do this, the *Paste* operation is cancelled. Try another suitable location.
- You are not allowed to paste flow symbols into an interaction page and vice versa. In this situation, the *Paste* menu choice is dimmed.

Pasting on Flow Pages

On a flow page, symbols are pasted along with the flow lines that interconnect them.

Pasting on Interaction Pages

On an interaction page, symbols are pasted along with the lines that interconnect them. Any lines that connect the pasted symbols to the environment will also be drawn.

Pasting Symbols into a Flow Branch

On a flow page, symbols can be pasted into a flow branch in a similar manner as "Inserting a Symbol into a Flow Branch" on page 1912.

1. Copy or Cut one or more symbols in a flow page. The symbols must be connected and placed below each other.
2. Go to the page where you want to insert the symbols and select a symbol or a flowline.
3. Select *Insert Paste* from the *Edit* menu.

4. The pasted symbols will be placed below the selected symbol and inserted into the flow branch. Any previously following symbols will be automatically shifted downwards to make place for the inserted symbols.

Cutting, Copying and Pasting Reference Symbols

When you cut or copy a reference symbol, the possible sub-hierarchy shown in the Organizer below this reference symbol is also placed in the clipboard. When pasted in the same diagram or in another diagram this sub-hierarchy will be restored at the new position.

> **Note:**
>
> When a reference symbol is cut, the sub-hierarchy that is shown in the Organizer will be removed. However, the hierarchy will be restored if you select *Paste* or *Undo*.

When you copy or paste a diagram reference, it is assigned a new name that consists of the original name, preceded with the prefix *CopyOf*. The prefix is repeated as many times as necessary in order to build a name / type combination that is unique within the SDL diagram being edited. If the cut/copied symbol had an underlying structure this structure is restored after the paste.

Cutting, Copying and Pasting Class Symbols

When cutting, copying or pasting a class symbol, one or more operators with a defined body code may be completely removed, i.e. there is no longer any class symbol that refers to a specific operator. If so, the following dialog is shown:

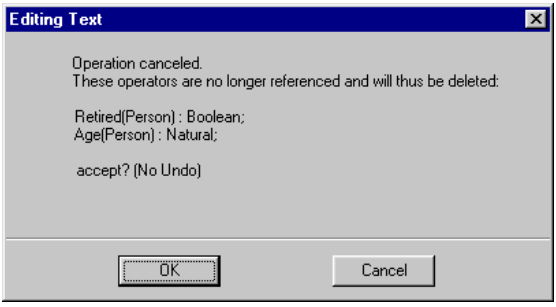

Figure 390: Checking with user if OK to remove operators

You have the following options:

- Accept the deletion of the listed operators and their defined body code by pressing *OK*.
- Cancel the issued operation by pressing *Cancel* and try to correct the error.

Caution!

By confirming the deletion of the operators, you accept that the listed operators, and possibly defined body codes, will be permanently removed. No *Undo* option is available.

Moving Symbols

You may move one or more symbols in a single operation. The lines and text objects that are related to the symbol will be moved accordingly in order to preserve as much as possible of the original appearance. When you move a symbol, its position is automatically adjusted to fit exactly into the symbol grid.

Symbols are not allowed to be moved to positions where they would overlap other symbols.

Moving Symbols and Text Attributes

You can move symbols and text attributes by pointing and dragging to the desired position. To grab the text attribute the pointer must be at the border of the text extent.

You cannot move text within flow symbols and class symbols.

Connecting a Gate Symbol with a Channel or Signal Route

When you move a gate symbol in order to reconnect it to a line or vice versa (channel or signal route that is connected to a connection point), the following takes place:

- If the connection point is not assigned any name, the SDL Editor connects the gate symbol and the line.
- If the connection point is assigned a name, a conflict occurs, since the line cannot be connected to the connection point and the gate simultaneously. The following dialog is issued:

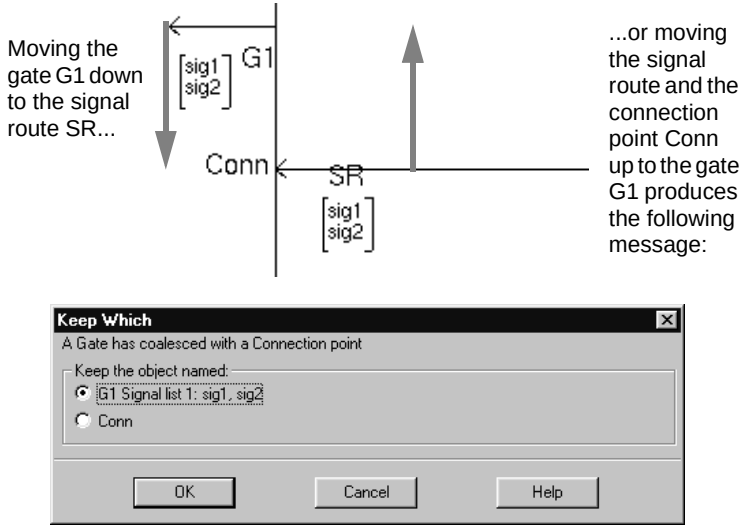

Figure 391: Prompting to solve connection conflict

You have the following options:

– To keep the gate G1 and to connect the line to it. The connection point Conn is removed.

– To keep the connection point Conn and to connect the line to it. The gate G1 is removed.

- Click *OK* to reconnect the line and symbol accordingly.

Note:

The situation above also occurs if you add a new gate symbol and place it on a connection point.

Resizing Symbols

The procedure for resizing a symbol differs slightly depending on whether the symbol is a flow page symbol or an interaction page symbol. When you resize a symbol, its size is automatically adjusted to fit exactly into the symbol grid. Any lines connected to the symbol are similarly adjusted to preserve as much as possible of the original appearance.

The text, the additional heading, the package reference, comment, class, and text extension symbols are handled differently. Their size is determined by the SDL Editor to fit the text they contain.

Specifying Default Size of Symbols

You define the default sizes for symbols in the Preference Manager:

- For interaction pages, the predefined size of a symbol is 30 * 20 mm.
- For flow pages, the predefined size of a symbol is 20 * 10 mm. The width / size relationship is always 2:1.

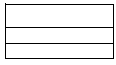
Resizing Interaction Page Symbols

1. Point to a corner of the rectangle that delimits the symbol. From this point on, the corner that you are pointing to is movable, while the opposite corner is fixed.
2. Drag the corner until the symbol has the desired size. An interaction symbol cannot be adjusted to a size less than 15*10 mm.

3. Release the mouse button. The symbol is redrawn with its size adjusted to fit exactly into the symbol grid. The lines connected to a resized interaction symbol are automatically adjusted to preserve a nice appearance.

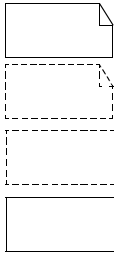
Resizing Flow Page Symbols.

1. Point to a corner of the rectangle that delimits the symbol. From this point on, if you pointed to any of the lower corners, the top of the symbol is fixed (and in a similar way, if you were pointing to any of the upper corners, the bottom of the symbol is fixed).
2. Drag the corner until the symbol has the desired size. The symbol shrinks or swells both horizontally and vertically, the proportions remaining 2:1. A flow page symbol cannot be adjusted to a size less than 20*10 mm.
3. Release the mouse button. The symbol is redrawn.



Resizing the Class Symbol

The class symbol contains three text boxes. Whenever the text in any of the boxes grows bigger than the symbol, the class symbol is automatically re-sized.



Resizing Text / Additional Heading / Package Reference / Comment / Text extension Symbols

The text, additional heading and package reference symbol look like a piece of paper. When all of the text within a text symbol is in view, the upper right corner is “folded” down. When any portion of the text within a text symbol cannot be seen (because the text symbol is too small), the upper right corner is clipped or diagonally cut off. See Figure 392 on page 1922.

Clipped text symbols are printed in their whole on a separate sheet of paper.

These symbols react in the same way for resizing. There are several ways you can resize these symbols:

Adjusting to a Specific Size (only for Text / Additional Heading / Package Reference)

1. Place the mouse pointer on the filled selection square at the bottom right corner of the symbol.
2. Holding the left mouse button down, make the symbol smaller by pushing to the left or larger by pulling the corner to the right.

Toggling Between Minimum and Maximum Size

You may rapidly toggle between a text symbol's maximum and minimum size. This can be accomplished in two ways:

- Select the symbol and choose the *Collapse/Expand* command in the *Edit* menu.
- Double-click on any part of the symbol.

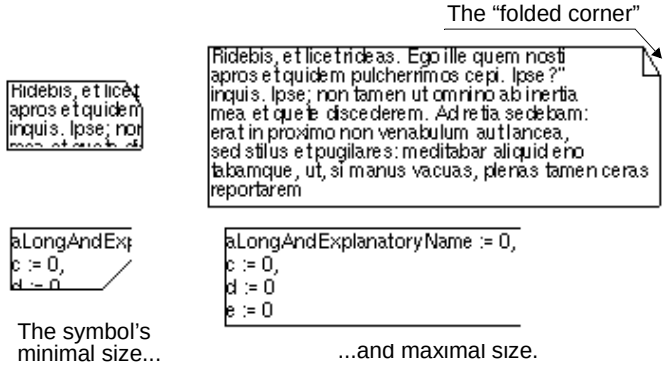


Figure 392: Minimizing and maximizing a symbol

Mirror Flipping Symbols

The input, priority input, output, comment and text extension symbols are drawn by default as displayed in the symbol menu. In some cases, the layout of the connecting lines would be nicer if the symbols were drawn flipped L/R.

1. Select the symbol.
2. Choose *Flip* from the *Edit* menu. The symbol is flipped L/R.

Flipping the text extension symbol mirrors it and redraws the connecting line

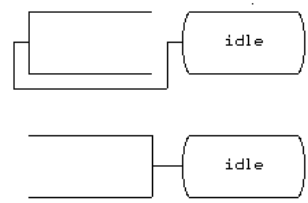

Figure 393: Flipping a symbol

Note:

By using the Preference Manager you can specify whether the output symbol in the symbol menu should point to the left or to the right, or you can have both. The same applies for the input and priority input symbols.

Adjusting Symbols to the Grid

The drawing area of the SDL Editor provides two grids for easier positioning of objects. These are the *symbol grid* and the *line grid*, which are invisible.

After you move or resize symbols, the position of the upper left corner of each symbol is positioned on the closest intersection in the symbol grid. In addition, resizing a symbol will adjust the size so that it matches the resolution of the grid, horizontally as well as vertically. The resolution of the symbol grid is variable and can be set with the Preference Manager. The default is 5 * 5 mm for interaction pages, and 25 mm * 15 mm for flow pages.

You can temporarily disable the grid by toggling the *Use Grid* to off in the *Diagrams Options* dialog.

Handling Symbols of Different Sizes

Since symbols adhere to the symbol grid, mixing symbols of different sizes may imply that symbols cannot be aligned symmetrically, and that enlarging symbols becomes impossible due to overlap of symbols already laid out.

You can align symbols of different sizes by disabling the symbol grid.

Editing the Diagram Kernel Heading

You can rename, retype and re-qualify a diagram with the SDL Editor, by modifying the diagram's kernel heading.

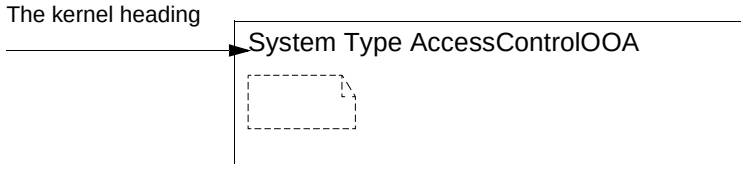

Figure 394: The kernel heading

See also "Transforming the Type of a Diagram" on page 1878 for more complicated transformation of diagram types.

The SDL Suite accepts a number of syntaxes for kernel headings, 13 in all. See "The Kernel Heading" on page 1858.

Note:

Changing the kernel heading of a diagram may have a large impact on the diagram's meaning. Also, the SDL diagram structure where the diagram is included may be affected to a large extent. You may, however, want to change the kernel heading in order to create a new diagram that you will use in a different context than the SDL structure it originally is tied to, or in order to perform a simple rename of diagrams.

Changing the Name of a Diagram

This is the bottom-up method you would use when renaming diagrams in an SDL structure.

1. Select the kernel heading.
2. In the text window, edit the kernel heading text.

3. Deselect the kernel heading. The SDL Editor checks that the name is still valid according to SDL rules. Any syntax error will cause a dialog with the following alternatives to be issued:

   – Clicking *OK*, you are returned to the text window where you should correct the error.

   – Clicking *Revert*, the kernel heading is reverted to its original contents.

   – Clicking *Ignore*, the erroneous kernel heading is accepted. The error will probably lead to other kind of error reports, typically when verifying the diagram with the Analyzer tool.

   The Organizer detects that the name of the diagram no longer matches the name that is expected in the diagram structure, and marks the diagram icon as mismatch. (A warning is also added to the Organizer Log window.)

4. To correct the mismatch, you have to update the name of the reference symbol accordingly. Use the command *Edit Reference Page* to bring the page with the reference symbol into view. Locate the reference symbol and rename it accordingly.

For renaming diagrams in a top-down fashion., see "Renaming a Diagram Reference Symbol" on page 1929.

Changing the Type of a Diagram

It is possible to re-type a diagram, provided the old and the new types are "compatible" from the SDL Editor's point of view. The basic compatibility criteria is that the old and new type of diagram must both be interaction diagrams or both be flow diagrams. Also checks are made on the pages that are contained in a diagram (some diagram types are allowed to have different types of pages in the same diagram, see "Relationship between Diagrams and Pages" on page 1848. The table below summarizes the type changes that are allowed.

case	A diagram of type...	...can be changed to any of:
1.	SYSTEM	SYSTEM TYPE BLOCK SUBSTRUCTURE BLOCK TYPE PACKAGE

case	A diagram of type...	...can be changed to any of:
2.	BLOCK	BLOCK TYPE SYSTEM SUBSTRUCTURE SYSTEM TYPE PACKAGE
3.	PROCESS	PROCESS TYPE SERVICE PROCEDURE SERVICE TYPE MACRODEFINITION OPERATOR
4.	SERVICE	SERVICE TYPE PROCESS PROCEDURE PROCESS TYPE MACRODEFINITION OPERATOR
5.	PROCEDURE	PROCESS SERVICE PROCESS TYPE SERVICE TYPE MACRODEFINITION OPERATOR
6.	SUBSTRUCTURE	SYSTEM BLOCK SYSTEM TYPE BLOCK TYPE PACKAGE
7.	MACRODEFINITION	PROCESS SERVICE PROCEDURE PROCESS TYPE SERVICE TYPE OPERATOR
8.	SYSTEM TYPE	SYSTEM BLOCK SUBSTRUCTURE BLOCK TYPE PACKAGE
9.	BLOCK TYPE	SYSTEM BLOCK SUBSTRUCTURE SYSTEM TYPE PACKAGE

case	A diagram of type...	...can be changed to any of:
10.	PROCESS TYPE	PROCESS SERVICE PROCEDURE SERVICE TYPE MACRODEFINITION OPERATOR
11.	SERVICE TYPE	SERVICE PROCESS PROCEDURE SERVICE TYPE MACRODEFINITION
12.	OPERATOR	PROCESS SERVICE PROCEDURE PROCESS TYPE SERVICE TYPE MACRODEFINITION
13.	PACKAGE	SYSTEM BLOCK SUBSTRUCTURE SYSTEM TYPE BLOCK TYPE

To change the type of a diagram:

1. Select the kernel heading.
2. In the text window, edit the kernel heading text to apply a new type. See the table above for allowed transformations.
3. Deselect the kernel heading. The SDL Editor checks that the type is still valid according to the table above. Any violation of these rules will cause a dialog with the following alternatives to be issued:
   - Clicking *OK*, you are returned to the text window where you should correct the error.
   - Clicking *Revert*, the kernel heading is reverted to its original contents.
   - Clicking *Ignore*, the erroneous kernel heading is accepted. The error will probably lead to other kind of error reports, typically when verifying the diagram with the SDL Analyzer.

Changing the Qualifier of a Diagram

By changing the qualifier that appears in the kernel heading, you can change the context of the diagram.

The SDL Suite accepts the two Z.100 notations for a qualifier, namely with and without the surrounding "<< >>".

Example 321: An SDL Qualifier ––––––––––––––––––––––––––––––

```
PROCESS TYPE <<SYSTEM MYSYS/BLOCK MYBLOCK>> Myproc
```

Alternatively:

```
PROCESS TYPE SYSTEM MYSYS/BLOCK MYBLOCK Myproc
```

––

To change the qualifier:

1. Select the kernel heading.
2. In the text window, edit the kernel heading text to apply the new qualifier.

3. Deselect the kernel heading. The SDL Editor checks that the new qualifier is syntactically correct. Any syntax error will cause a dialog with the following alternatives to be issued.

   – Clicking *OK*, you are returned to the text window where you should correct the error.

   – Clicking *Revert*, the kernel heading is reverted to its original contents.

   – Clicking *Ignore*, the erroneous kernel heading is accepted. The error will probably lead to other kind of error reports, typically when verifying the diagram with the SDL Analyzer.

Renaming a Diagram Reference Symbol

When you change the name of a diagram reference symbol, the SDL Editor checks that the new name is not in conflict with existing symbols. If the reference symbol passes this check, the Organizer structure is updated accordingly.

When renaming diagrams in a top-down fashion, you start by changing the name of a reference symbol. After the reference symbol is renamed, you should also update the referenced diagram's kernel heading accordingly to maintain consistency in the diagram structure.

To rename a diagram reference symbol and the referred diagrams:

1. Select the symbol to be renamed.
2. Change the name of the reference symbol.
3. Deselect the symbol. The SDL Editor checks that the name and type are still unique within the diagram.

   If the new name of the reference symbol is accepted, the diagram structure is updated to reflect the nature of the change.

4. To ensure that the change also applies to the referred diagram, you should use the Organizer command *Update Headings* (see "Update Headings" on page 100 in chapter 2, *The Organizer*). This command verifies and possibly changes the name in the diagram kernel heading against the expected name (which is the one that now is shown in the reference symbol). The mismatch between the name of the diagram is reported in a dialog:

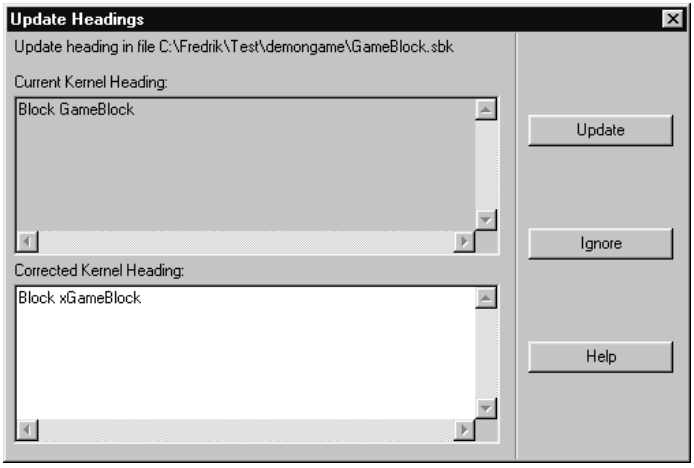

Figure 395: The mismatch in headings is reported

– Correct the mismatch by clicking *Update*.

Note that if you select not to update the kernel heading, you simply postpone the problem.

For renaming in a bottom-up way, see "Changing the Name of a Diagram" on page 1924.

Removing Symbols

When you remove a diagram reference symbol, the underlying structure is also removed from the Organizer structure. However, the hierarchy will be restored if the remove operation is restored by doing Undo.

1. Select the symbol(s) to be removed.
2. Select *Clear* from the *Edit* menu. The symbol(s) are removed, as well as the lines that were connected to these symbols.

Printing Symbols

A selection of symbols can be printed. This allows for instance to print only the portion of a diagram which is of interest.

1. Select the symbols to be printed.
2. Select *Print* from the *File* menu.
3. In the *Print Dialog*, click the *Setup* button. The Print Setup dialog will be issued. In the dialog, select the *Print only selected symbols* option.
4. Adjust, if necessary, other *Print options* and click the *OK* and *Print* buttons. See "Printing a Diagram" on page 1878 for more information.

Working with Lines

The main operations provided by the SDL Editor on lines, and their associated text attributes are:

- *Selecting Lines*
- *Drawing Lines*
- *Re-Routing and Reshaping Lines*
- *Redirecting and Bidirecting Lines*
- *Adjusting Lines to the Grid*

In addition, text editing functions are provided for the text associated with the lines.

Operations on lines are performed slightly different depending if you are editing

- *flow pages*
- *interaction pages*

The main difference between the two is that flow pages may only allow vertical and horizontal lines.

Some restrictions also apply when connecting symbols in flow pages, depending upon whether or not the syntax checking is enabled

Selecting Lines

You select lines and extend and reduce selections of lines with standardized selection commands.

Selecting a Line That Has Associated Objects

When you select a line, you implicitly select the associated attributes as well. To be able to edit a text attribute you must click on the text attribute and a text cursor will be inserted directly in the text, at the same time the text window will be updated to contain the text.

Displaying Selected Line Attributes

Selected line attributes are displayed as follows:

- Each text attribute is displayed inside a text selection rectangle.

- The following attributes are displayed with a filled selection square:
  - Each arrow (on interaction pages only)
  - Each line breakpoint (on interaction pages only)
  - The middle of each line segment (on interaction pages only a tiny selection square marks the handle to create a new breakpoint)
  - The middle of each line segment (on flow pages only)

Selecting Overlapping Objects

On a page, objects may overlap each other. A *layer order* is defined so that it is possible to determine how overlapping objects are stacked.

Drawing Lines

This section describes how to interconnect symbols with lines. Two modes are supported in the SDL Editor.

Drawing a Line with Layout Syntax Checking Enabled

The way that you draw a line differs somewhat depending upon whether you are working on an interaction page or a flow page. The differences will be pointed out later in this section.

When syntax checking is enabled, you are only allowed to draw lines that are correct according to the SDL rules. When syntax checking is disabled, the rules are less strict.

Designating the Start Point

1. Select the symbol from which the line will originate.
2. Point to the handle and drag it to begin forming the line. The line that is formed ends where the mouse pointer is located. Note that the mouse button can be released as soon as you have moved the mouse pointer.

Designating the End Point

1. Designate the start point. See previous section.
2. You can route the line and specify where it will end either automatically or manually.

- To route the line automatically:
  - Click any valid target symbol to specify where the line should end.

    A symbol is valid if the syntax rules enforced by the SDL Editor at edit-time allows the drawing of a line from the first symbol to the second symbol.
- To route the line manually, indicating where *line breakpoints* are to be inserted, follow the steps below.

  1. To enter manual mode, click any location in the drawing area other than a valid destination symbol.
  2. Click each location where you want to insert a line breakpoint.
  3. Click on a valid destination symbol.

     As long as you do not point to a valid destination symbol, the line will be routed from the selected symbol to the current mouse position. The automatic line drawing facility will determine the layout of the line until you have inserted the first breakpoint.

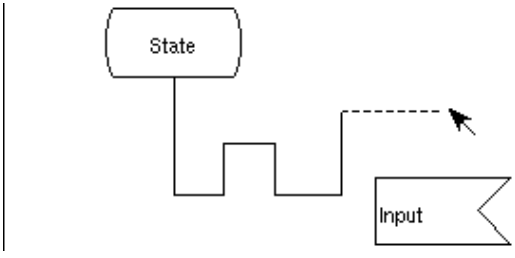

Figure 396: Drawing a line in manual mode

Drawing Multiple Lines

When you draw lines between symbols and keep the <Control> key pressed, the start point for the next line to draw is automatically transferred to the target symbol.

This feature provides the easiest way to draw multiple lines in rapid succession.

Differences between Flow and Interaction in Line Drawing

The way that you draw a line differs somewhat depending upon whether you are working on an interaction page or a flow page:

- On an interaction page, you can draw lines in all possible directions.
- On a flow page, you can only draw lines horizontally or vertically. The last line breakpoint, even if determined manually, will be adjusted so that the destination symbol is connected correctly, normally in the middle of the upper edge of the symbol. Exceptions are made for comment and text extension symbols, which are connected to the center of the right or left edge of the symbol.

Cancelling the Line Drawing Operation

You can cancel a line drawing operation in either of the following ways:

- Press <ESC>.
- Double-click any part of the drawing area that is not a valid destination symbol.

Drawing a Line with Layout Syntax Checking Disabled

The process of drawing a line is the same regardless of whether or not syntax checking is enabled. To enable and disable syntax checking, see "Turning Syntax Checking On and Off" on page 1852.

When drawing lines with syntax checking disabled, you may interconnect symbols in any way you want.

Re-Routing and Reshaping Lines

Reshaping a line refers to changing the path that the line follows. This operation does not affect the endpoints of the line. The flow lines only move in either a horizontal or vertical way.

Re-routing a line denotes changing the ending point of the line from one symbol to another symbol.

Reshaping a Flow Line

1. Point to one of the segments of the line.
2. Press the mouse and, holding down the mouse button, drag the segment to the required position.
3. Release the mouse button.

Re-Routing a Flow Line

You can move the ending point of a flow line, and reconnect it to any valid destination symbol. You can redraw the line either manually or automatically.

To move a line's ending point:

1. Point at the ending point that you want to reconnect.
2. Press the mouse. Start dragging the ending point. As soon as you move the mouse, the line's last segment follows the mouse motion and you can release the mouse button.
3. You can click additional *line breakpoints* where you like.
4. Click the destination symbol to complete the operation. If it is a valid symbol, the line will be re-routed automatically.

Re-Routing an Interaction Line

You can move any starting or endpoint to and from a symbol and the environment.

1. Point to the starting or ending point of the line.
2. Press the mouse and, holding the mouse down, drag it to the desired symbol.
3. If required, click to add line breakpoints at desired positions.
4. Terminate by clicking on the new symbol. The line is redrawn accordingly.

Moving an Interaction Line Breakpoint

To move a line breakpoint in an interaction page:

1. Point to the breakpoint that you want to move.
2. Press the mouse and drag the breakpoint to the desired location.
3. Release the mouse button to redraw the line.

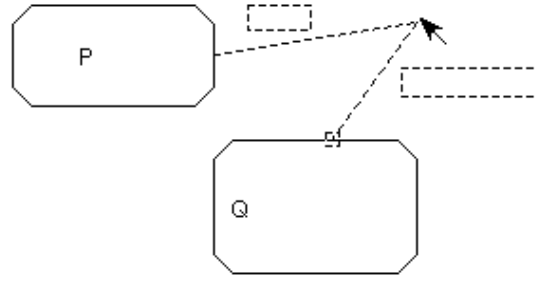

Figure 397: Moving an interaction line breakpoint

Inserting Breakpoints in an Interaction Line

1. Point at the middle of a line segment. When the line is selected a tiny selection square will be displayed at this point.
2. Press the mouse and drag it to shape the breakpoint.

An alternative way to insert breakpoints on an interaction line:

1. Press `<Ctrl>`
2. Point in a line segment where you want to insert a new breakpoint.
3. Press the mouse and drag it to shape the breakpoint.
4. Release the `<Ctrl>` key.

Moving an Interaction Line Segment

You can move a line segment in an interaction page as long as it is not a starting segment or ending segment.

1. Point to the line segment to be moved.
2. Press the mouse and drag the line segment to the desired location.

3. Release the mouse button. The line segment and the adjacent line segments are redrawn accordingly.

Moving Arrows

Arrows on channels, gates and signal routes denote the orientation of flow on that line. They are assigned default locations when creating the line.

You can manually move arrows **on channels** along the line.

1. Point to the arrow.
2. Press the mouse. Still holding the mouse down, drag it until the arrow reaches the new place.
3. Release the mouse. The arrow and the signal list are redrawn accordingly.

To create a non-delay channel you simply drag the arrow to the starting or ending breakpoint.

Moving a Line and Its Connection Point

A channel or a signal route may be connected to a connection point (usually located close to the line, immediately outside the frame).

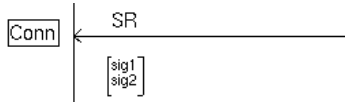

Figure 398: A signal route connected to a connection point.

Moving the line's ending point with the connection point unselected will move the line only and create a new connection point. The old connection point is removed.

To move the line **and** the connection point:

1. Click on the ending point of the line. Make sure the connection point is selected (i.e. the selection rectangle appears).
2. Drag the line's ending point to the new location. The connection point follows the mouse motion as well.
   – If the line's new ending point coincides with a gate symbol and the connection point has a name, a dialog is issued. The meaning of this message is described in "Connecting a Gate Symbol with a Channel or Signal Route" on page 1919.

Moving a Line Text Attribute

A line text attribute is a textual element that is related to a line. The following lines have associated text attributes:

- Gates
- Channels
- Signal routes
- Flow lines after decision, transition option and macro call symbols.

When drawing a line, the SDL Editor positions the text attribute close to the source symbol and originating line, so that it is easy to identify what line the text attribute is related to. You are however free to move the text attribute to any location in the drawing area within the frame.

To move a line text attribute:

1. Point to the border of the text attribute.
2. Press the mouse, and, still holding the mouse down, drag the text attribute to its new location.
3. Release the mouse button.

Redirecting and Bidirecting Lines

When you add a channel or signal route to an interaction diagram, the line is initially drawn in a uni-directional manner, originating from the source symbol and pointing to the target symbol.

The only way to draw a line from the environment to a symbol is to first draw it from the symbol and then redirect it.

Redirecting a Line

1. Select the line
2. Choose *Redirect* from the *Edit* menu. The line is redirected.

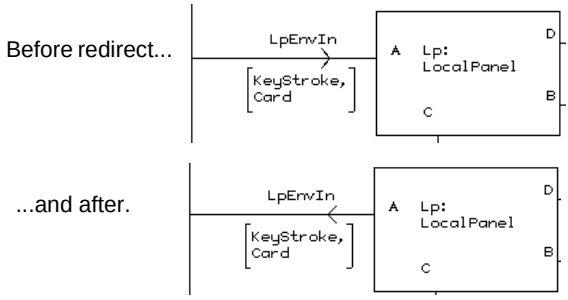

Figure 399: Redirecting a line

Bidirecting a Line

1. Select the line.
2. Choose *Bidirect* from the *Edit* menu. The line is bidirected.
3. Fill in the second signal list.

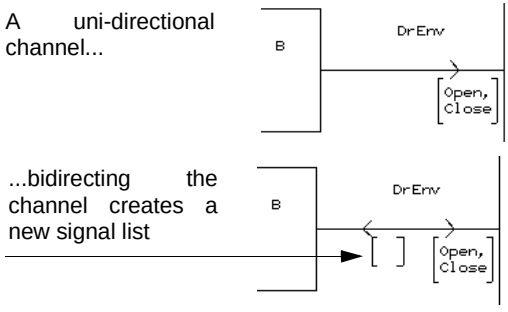

Figure 400: Bidirecting a line

Uni-Directing a Bidirected Line

1. Select the bidirected line.
2. Choose *Unidirect* from the *Edit* menu. A dialog will appear asking what arrow to keep.

Adjusting Lines to the Grid

When you move or reshape interaction lines, the line breakpoints are adjusted to the line grid, which cannot be disabled and has a fixed resolution of 2.5 mm.

Flow line segments and line text attributes are always placed so that they match the resolution of the line grid.

Working with Classes

This section describes how Classes are handled graphically.

The class symbol is a graphical syntax for defining SDL data structures, instead of writing textual newtype definitions. It is allowed in every diagram where textual data definitions are allowed.

When analyzing the SDL specification, class symbols are translated to standard textual newtype definitions, that are used as input to the analyzer.

It is important to notice that, in a diagram, all class symbols with the same class name are treated as if they were a single, merged class. Thus two classes, both named “a_class” but defining two separate operators, would be the same as a single class named “a_class”, defining both operators.

While attributes and operators may be defined and edited in the SDL Editor directly, they may also be edited in the *Browse&Edit Class* dialog, see “Browse & Edit Class Dialog” on page 1943.

The complete definition of all classes may be viewed in the *Browse&Edit Class* dialog, but also, in SDL/PR form, in the *Class information* dialog. The *Class Information* dialog may also be used for traversing among the classes that define the SDL/PR code, see “Class Information” on page 1942.

> **Note:**
>
> Both the *Browse&Edit Class* dialog and the *Class Information* dialog present the aggregate of all graphical class symbols with the same class name.

Class Information

The complete class may be presented in textual (SDL/PR) form. This is done in the read-only *Class information* dialog.

The dialog can be started from the *Windows* menu, and will also be started automatically in response to a *Show symbol* request concerning a class, e.g *Show Error* from the *Organizer Log*. Since the sum of all class symbols with the same name is a single class, some information may be duplicated. The PR-representation of an error is shown in the

class information dialog, and it will be possible to navigate to the symbol(s) that generated the PR-code.

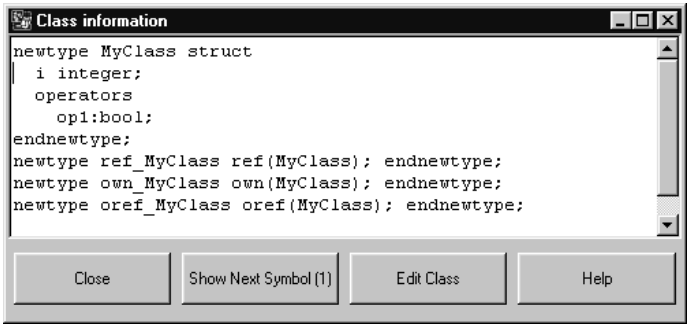

Figure 401 Class Information window

Buttons:

- *Show Next Symbol* shows the next symbol described by the PR code line on which the cursor is placed. The number within brackets shows the total number symbols in the current SDL diagram that that are described by this line. If a line does not refer to any particular symbol, *Show Next Symbol* shows the next symbol belonging to the current class. Each time *Show Next Symbol* is clicked, the next symbol that is described by the current line is shown.
- *Edit Class* will show the *Browse & Edit Class* dialog for the current class.

If the cursor is moved to another line in the text area, the *Show Next Symbol* button is updated.

Browse & Edit Class Dialog

The *Browse & Edit Class* dialog is opened when you select *Class...* from the *Edit* menu. The dialog allows inspection of classes in the SDL diagram.

A class is defined as the union of attributes and operators in the class symbols, and the purpose of the *Browse & Edit Class* dialog is to display this union and ensure consistency when editing this combined information.

The *Browse & Edit Class* dialog is a modal dialog, which is divided into two parts. The browsing functionality is placed at the top part of the dialog, where all classes in the diagram, and all occurrences of each class, are listed in two drop-down menus. Below, in the editing part, the name of the class, its attributes and all its operators are listed.

The *Browse & Edit Class* dialog is available when a single class symbol is selected, unless the class name contains incorrect syntax.

Browse

In the topmost part of the *Browse & Edit Class* dialog, you can browse all class symbols within the current diagram.

Edit

In the lower part of the *Browse & Edit Class* dialog, you can edit the name, attributes and operators of a class. Any changes will propagate into all class symbols of this class within the SDL diagram. The attributes and operators will be presented in a list. This list contains parsed information, derived from the texts in the class symbols. If a particular text contains syntax errors, attributes and operators contained in the same text might be missing from this list.

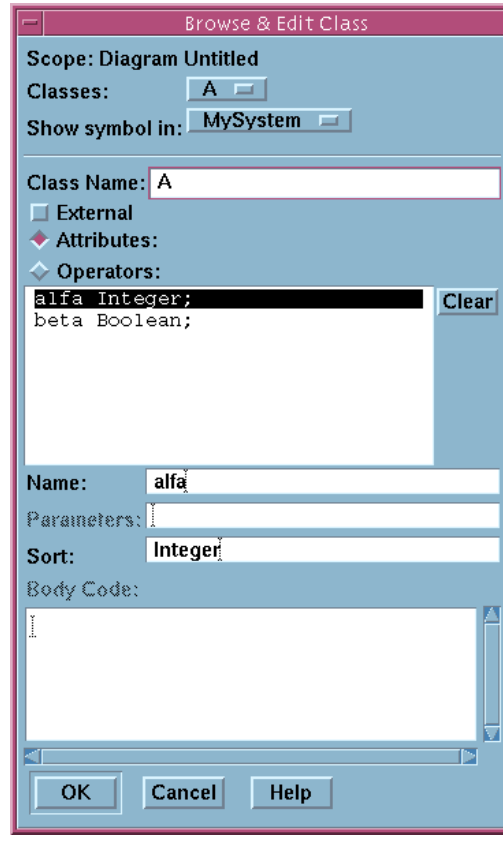

Figure 402: The Browse & Edit Class dialog

The *Scope* Label

The *Scope* label is a non-editable text field, indicating which SDL diagram the *Browse & Edit Class* dialog operates on.

The *Classes* Drop-Down Menu

The *Classes* drop-down menu lists all classes within the current SDL diagram. When a class is selected from this menu, its attributes and operators are displayed in the editing part of the dialog.

The *Show Symbol in* Option Menu

A class can be represented by several class symbols. The *Show Symbol in* drop-down menu lists the name of all pages with occurrences of the current class (the current class is displayed in the *Classes* drop-down menu). By selecting a page name in this menu, the corresponding page will be shown in the work area.

The *Class Name* Field

The *Class Name* field is an editable text field, containing the name of the class being edited.

When the *OK* button is clicked, changes to the *Class Name* field update all occurrences of the class name in all class symbols, within the current SDL diagram.

The *External* Check Box

The *External* check box is checked when a class is externally defined. This means that no PR code will be generated for this class.

When the *OK* button is clicked, changes to the *External* check box update all occurrences of the external flag, in all relevant class symbols using the current class name, within the current SDL diagram.

The *Attributes* and *Operators* Buttons

The *Attributes* and *Operators* buttons are used to select the contents of the attributes/operators list. Clicking Attributes will list all attributes defined for the selected class, while clicking *Operators* will list all operators.

The *Attributes/Operators* List

The *Attributes/Operators* list lists all attributes or all operators defined for the selected class.

The *Clear* Button

The *Clear* button is used to remove the attribute or operator currently selected in the *Attributes/Operators* list.

When the ‘OK’ button is clicked, the selected attribute or operator is removed from all relevant class symbols with the current class name, within the current SDL diagram.

The *Name* Field

The *Name* text field contains the name of the attribute or operator currently selected in the *Attributes/Operators* list, if any.

When the *OK* button is clicked, changes to the definition of the attribute or operator are applied to all relevant class symbols with the current class name, within the current SDL diagram

The *Parameters* Field

The *Parameters* field is an editable text field, containing the parameters of a class operator. It is only editable when an operator is selected in the *Attributes/Operators* list.

When the *OK* button is clicked, changes to the parameter list are applied to the definition of that operator in all relevant class symbols with the current class name, within the current SDL diagram.

The *Sort/Returnsort* Field

The *Sort/Returnsort* field is an editable text field that is editable only when an attribute or an operator is selected in the *Attributes/Operators* list.

Depending on the selection, the field contains:

- the sort of the selected attribute,
- or the return sort of the selected operator.

When the *OK* button is clicked, the sort of the selected attribute, or the return sort of the selected operator, is updated in all relevant class symbols with the current class name, within the current SDL diagram.

The *Body Code* Text

The *Body Code* field is a text field, containing the body code of a class operator. It is only editable when an operator is selected in the *Attributes/Operators* list.

The declaration part of the body code is automatically generated, and all code should be added between the two comments indicating start and

end of the user defined part, respectively. The comments themselves should never be edited. For example, the operator `myOp:Boolean;` will have the following default declaration:

```
operator myOp returns Boolean {
/* Start of user defined body code */
/* End of user defined body code */
}
```

When the *OK* button is clicked, changes to the body code definition are applied to the operator in the class with the current class name, within the current SDL diagram.

The *OK* Button

The *OK* button closes the *Browse & Edit Class* dialog, and updates all appropriate class symbols in the current SDL diagram.

No changes are made in the diagram until the *OK* button is clicked. This makes it possible to specify several changes in the dialog and disregard them later, by clicking the *Cancel* button.

All values are syntactically checked, so it is not possible to add syntax errors to your classes by using the *Browse & Edit Class* dialog. This might make it impossible to delete syntactically incorrect text from class symbols using the *Browse & Edit Class* dialog, since the dialog relies on information obtained by parsing the relevant symbol text compartments. A syntactically incorrect text must then be corrected by editing individual symbols.

Once the *OK* button is clicked, changes cannot be undone.

The *Cancel* Button

The *Cancel* button will close the *Browse & Edit Class* dialog and discard any changes specified in the dialog.

Syntax and Definition of Class Symbols

Name

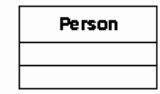

Figure 403 Class symbol

The syntax for the name field is `<SDL_name>`, where `<SDL_name>` is a name in accordance with the SDL lexical rules.

The above class symbol will generate the following newtype definition.

```
newtype Person
endnewtype;
newtype Ref_Person Ref(Person); endnewtype;
newtype Own_Person Own(Person); endnewtype;
newtype Oref_Person Oref(Person); endnewtype;
```

The three pointertypes, Ref_Person, Own_Person and Oref_Person, are generated for use when creating associations and aggregations.

Attributes

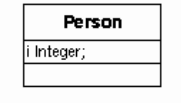

Figure 404 Class symbol with attribute

The syntax for the attribute field is `<name><sort><end>`, where `<name>` and `<sort>` are names in accordance with the SDL lexical rules.

The above class symbol will generate the following newtype definition.

```
newtype Person struct
  i Integer;
endnewtype;
newtype Ref_Person Ref(Person); endnewtype;
newtype Own_Person Own(Person); endnewtype;
newtype Oref_Person Oref(Person); endnewtype;
```

Operators

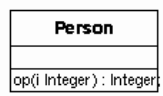

Figure 405 Class symbol with operator

The syntax for the operator field is

```
<name>['('<par>{','<par>*')'][<returns><sort>]<end>
```

where `<par>` is defined as

```
[<kind>]<name>[<colon>]<sort>
```

and `<kind>` is defined as

```
'in'|'in/out'
```

The above class symbol will generate the following newtype definition.

```
newtype Person
  operators
    op: Integer -> Integer;
endnewtype;
newtype Ref_Person Ref(Person); endnewtype;
newtype Own_Person Own(Person); endnewtype;
newtype Oref_Person Oref(Person); endnewtype;
```

Syntax and Definition of Association Lines

Figure 406 Association line

The syntax for the role name of an association is `[<name>][<constraint>]`, where `<constraint>` is in the format `'{'name'}'`.

Associations can be of a number of types, depending on the constraint:

- if there is no constraint, the type is `Ref_<opposite_class_name>`
- if the constraint is “own”, the type is `Own_<opposite_class_name>`

- if the constraint is “oref”, the type is `Oref_<opposite_class_name>`
- if there is a constraint, but not “own” or “oref”, the type is `<constraint_name>`.

The above association will generate the following newtype definition.

```
newtype Company struct
  e Ref_Employee;
endnewtype;
newtype Ref_Company Ref(Company); endnewtype;
newtype Own_Company Own(Company); endnewtype;
newtype Oref_Company Oref(Company); endnewtype;
newtype Employee
endnewtype;
newtype Ref_Employee Ref(Employee); endnewtype;
newtype Own_Employee Own(Employee); endnewtype;
newtype Oref_Employee Oref(Employee); endnewtype;
```

Syntax and Definition of Aggregation Lines

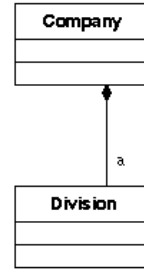

Figure 407 Aggregation line

The above aggregation will generate the following PR code.

```
newtype Company
  a Ref_Division;
endnewtype;
newtype Ref_Company Ref(Company); endnewtype;
newtype Own_Company Own(Company); endnewtype;
newtype Oref_Company Oref(Company); endnewtype;
newtype Division
endnewtype;
newtype Ref_Division Ref(Division); endnewtype;
newtype Own_Division Own(Division); endnewtype;
newtype Oref_Division Oref(Division); endnewtype;
```

Working with Pages

This section describes the more important aspects of page handling.

Each diagram page must have a unique name for identification purposes. This name must be correct in accordance with the naming convention for pages in SDL. Each diagram must contain at least one page, and there is no maximum amount of pages that a diagram may contain.

The *autonumbering* facility available for pages relates to automatically updating the sequential numbering when pages are added or deleted.

When diagrams are opened, the default way of presentation is that the first page of the requested diagram is shown (first in accordance to the order in which pages have been added). This default can be overruled, and you can go directly to a specific page that has been predetermined.

Most of the page managing functions are available through the menu choices on the *Pages* menu.

A number of functions are available through the *Edit* menu choice in this menu:

- *Ordering Pages*
- *Naming Pages*
- *Adding a Page*
- *Renaming a Page*
- *Clearing (Deleting) a Page*
- *Pasting a Page*
- *Transferring to a Page*
- *Printing a Page*
- *Resizing a Page*

Other page functions are also available in the SDL Editor:

- *Applying Autonumbering on Page Names*
- *Removing Autonumbering on Page Names*
- *Designating the Page to Open*
- *Transferring to a Specific Page*
- *Transferring to the Referring Page*
- *Transferring to the Next or the Previous Page*
- *Transferring to the First Page*
- *Transferring to the Last Page*

Ordering Pages

Within an SDL diagram, page locations are set according to the order in which they are added (see "Adding a Page" on page 1954). This order is reflected in:

- The Organizer structure
- The listing order for pages in the *Edit Pages* dialog

To re-order pages, you use the *Cut* and *Paste* button.

Naming Pages

Whenever you name a page, the names that you use must strictly adhere to SDL naming conventions. If you use unacceptable notation (e.g. blank spaces or a semi-colon), you receive a message.

Applying Autonumbering on Page Names

If autonumbering is required, a feature can assign numeric names to the pages in the diagram. The page names will be assigned 1, 2, 3 and so forth.

1. Select *Edit*.
2. Select the page to autonumber in the page list.
3. Toggle the *Autonumbered* toggle button to on in the *Edit Pages* dialog. You are then prompted if you want to autonumber the selected page only or all pages in the dialog which is issued.

   – If you click *Yes*, the SDL Editor assigns the page name the highest assigned numeric value + 1. You are then returned to the *Edit Pages* dialog.

   – If you click *All Pages*, all pages will be assigned numeric names, starting with 1. The numbering will follow the listing order in the page list. You are then returned to the *Edit Pages* dialog.

Removing Autonumbering on Page Names

The autonumbering feature can be turned off. This must for instance be done if you want to assign a specific name to a page.

1. Select *Edit*.
2. In the page list, select the page to remove autonumbering on.
3. Toggle the *Autonumbered* toggle button to off in the *Edit Pages* dialog. You are then prompted to confirm the operation in the dialog which is issued.
   - Clicking *Yes* transfers you to a *Rename Page* dialog where you assign the page a new name. Autonumbering is removed.

Adding a Page

To add a page to an existing diagram:

1. Select *Edit*.
2. In the list of existing pages, select the page to precede or succeed the new page to be added.
3. Click the *Add* button. The *Add Page* dialog is issued.

A faster way to add a page before or after the current page is to select the *Add* menu choice directly. In this case, the *Add Page* dialog is issued directly.

In the *Add Page* dialog:

1. Enter the required page name in keeping with SDL conventions. If the same name is given for two pages they are automatically renamed to name_1 and name_2. The enumartion character, where '_' is the default, used for naming pages with the same name can be set by the preference Editor*Page*EnumerationCharacter. Select *Autonumbered* if you want the pages to be automatically renumbered to incorporate the new page.
2. Select the position of the new page – before or after the current page.
3. Select the type of page required. The dialog box automatically shows the page options that are available to you under SDL rules.

4. Click *OK*. Control is returned to the *Edit Pages* dialog.
5. Click *Done*.

Designating the Page to Open

When a diagram is opened without specifying a particular page, the default is that it is opened at the first page that has been added to the diagram, showing the upper left part of the page.

You can however open a diagram at a specific page in the SDL Editor.

To specify the page to be opened first:

1. Bring up the *Edit Pages* dialog.

   The *Open this page first* field, below the toggle button, reflects the page to be opened first (page 1 in Figure 408).

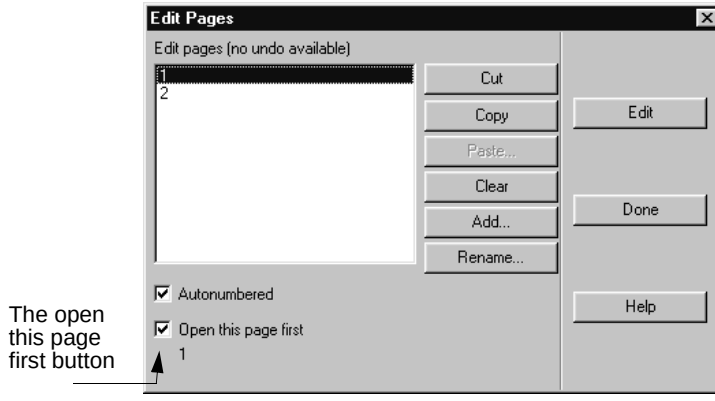

Figure 408: Specifying what page to open first

2. To specify another page, select the page to be opened first in the *Edit pages* dialog.
3. Turn the *Open this page first* button on. The identification of the page to be opened is then placed under the *Open this page first* button.
4. Click *Done*.

Renaming a Page

1. Select *Edit.*
2. Select the page to rename.
   - To rename an auto-numbered page, first click the *Autonumbered* button off. Autonumbering is removed on the selected page and the *Rename Page* dialog is issued. Go to step 4.
3. Click the *Rename* button. The *Rename Page* dialog is issued.
4. Fill in the required new name in keeping with SDL naming conventions. For block and process diagrams, an option is available to also change the page type.
5. Click *OK*. Control is returned to the *Edit Pages* dialog.
6. Click *Done*.

Clearing (Deleting) a Page

If there is only page in a diagram, you cannot remove it. A message is then shown.

Caution!

Clear pages with caution as there is no *Undo* option available.

1. Select *Edit*.
2. Select the page to be deleted in the page list.
3. Click on the *Clear* option and then on *Clear* to delete the page.
4. Click *Done*.

Pasting a Page

1. Open the SDL diagram where to paste the page.
2. Select the *Edit* menu choice.
3. In the list of existing pages, select the page to precede or succeed the new page to be pasted. Click the *Paste* button. The *Paste Page* dialog is issued.

4. Enter the required page name in keeping with SDL conventions (the name must be unique within the diagram). Otherwise, select *Autonumbered* if you want the pages to be automatically renumbered to incorporate the page to be pasted.
5. Select where to paste the page - before or after the current page.
6. Click *Paste*. Control is returned to the *Edit Pages* dialog.

   If there are reference symbols on the pasted page all the underlying substructure is also pasted. See "Cutting, Copying and Pasting Reference Symbols" on page 1917.
7. Click *Done*.

Transferring to a Page

There are several ways to transfer to another page of the current diagram. When you transfer to a page, it will be placed on the top of the stack in the window if you are using one window only. Otherwise, that page will be displayed in a window of its own.

Transferring to a Specific Page

- Transfer to a page, located not further than two pages from the current page, by selecting that page in the *Pages* menu.
- In the *Edit Pages* dialog, transfer to a page by clicking on the required page and then click on the *Edit* button.
  - Alternatively, double-click the page icon in the Organizer.

Transferring to the Referring Page

To transfer to the page where the current page is referenced from (i.e. where the SDL reference symbol referring to the current diagram is located):

- Select *Edit Reference Page* from the *Pages* menu or the *Reference Page* quick-button.

Transferring to the Next or the Previous Page

You may transfer to the next or previous page in the diagram. The order is specified according to the listing order in the *Edit Pages* dialog.

To transfer to the next or previous page:

- Use the quick-buttons for *Previous Page* or *Next Page*.

Transferring to the First Page

Select *First* from the *Pages* menu. You are transferred to the first page of the diagram.

Transferring to the Last Page

Select *Last* from the *Pages* menu. You are transferred to the last page of the diagram.

Printing a Page

The SDL Suite allows to print individual pages from the SDL Editor. You can also restrict the scope of printing to a part of the page. A number of options which affect the resulting printout are possible to specify.

Resizing a Page

1. Transfer to the page to resize.
2. Select *Drawing Size* from the *Edit* menu. A dialog is issued, showing the current width and height.
3. Type in the new values. Click *OK*.

> **Note:**
>
> If you enlarge a page so that the page size becomes wider or larger than the physical page size defined in the *Print Options*, your printouts will require more pages than before, if you use a fixed printout scale.

Working with Windows

Each SDL Editor window shows one SDL page. The SDL Editor is a multi-window tool, allowing you to open new windows on a page and close windows that are no longer needed.

A newly opened window is a mirror image of the window from which the selection to open a window was made. Multiple windows may be opened (one at a time) and they are all identical with the first one. Any subsequent modifications made will reflect the same in either the original window, or any of the newly opened window(s). This option affords the possibility of viewing in more than one window, and can ideally be used in conjunction with the scaling factor when looking at a detailed page.

For information on how you open:

- The Grammar Help Window, see "Opening the Grammar Help Window" on page 1972.
- The Signal Dictionary Window, see "Opening the Signal Dictionary Window" on page 1984.

Opening and Closing Windows

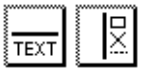
Standardized functions for opening and closing windows are provided in the *Window* menu: *New Window* and *Close Window*. If you close the last window opened by the SDL Editor, the editor will exit.

Hiding and Showing Parts of the SDL Editor Window

You can show and hide the various component parts of the SDL Editor window. **On UNIX**, if they are hidden, it increases the drawing area available to be used in the creation or modification of pages of a diagram.

You find all the available options for hiding and showing parts of the window in the dialog box accessed via the *Window Options* command on the *View* menu. You can set all of these options as preferences.

All of these options are turned on and off with a toggle button. Some of these options are available with quick-buttons:



- The quick-button for *text window* on / off or *symbol menu* on / off.

  – If you click *All Windows* it applies the values to all instances of the SDL Editor windows.

Editing Text

General

There are several ways of editing text in the SDL Editor, i.e.

- In the drawing area
- In the text window
- In an external text editor

Two support functions are provided, namely:

- Grammar Help, see "Using Grammar Help" on page 1972.
- Signal Dictionary, see "Using the Signal Dictionary" on page 1983.

Editing in the Drawing Area and Text Window

The SDL Editor allows you to edit textual objects directly in the drawing area.

If you select a text attribute to an object in the SDL Editor window, a text cursor is inserted directly in the text associated with the object, and the *text window* will be updated to contain the text. This is explained in "Selecting a Symbol That Has Associated Objects" on page 1903 and "Selecting a Line That Has Associated Objects" on page 1932.

When you type text in the drawing area, all accelerator keys are interpreted as input to the text. As an example, the `<Delete>` key will in text editing mode delete a character, but in non-text editing mode it will remove (*Clear*) an entire symbol. This means that you can only use text editing keyboard accelerators like `<Home>`, `<End>`, `<Ctrl+A>` and `<Ctrl+E>` in text editing mode.

When editing text directly in the drawing area it is possible to select text by dragging the mouse over the text or select words by double-clicking.

You can extend or reduced the selection by clicking while pressing the <shift> key.

To edit large texts it might be more convenient to use the *Text Window* to edit the text. If you select more than one text object, the text window is not updated. Each line (except for the last line) in the text window is terminated by a carriage return, and may consist of any number of legal characters.

Regardless of whether you edit directly in the drawing area or in the text window, the SDL Editor makes sure that the contents of both displayed texts are consistent.

A context sensitive syntax check is performed on all texts being edited. If a syntax error is found a red bar underlining the text will appear where the first error occurs in the text. See also "Syntax Rules when Editing" on page 1852.

You can also edit text in an external text editor by using the *Connect to Text Editor* command in the *Tools* menu. This allows you to use the Text Editor, the Emacs text editor **(on UNIX)** or MS Word **(in Windows)** to edit large pieces of text.

The SDL Editor also supports editing text outside its context, by transferring text to / from a file.

Text Window

On UNIX, the text window is a pane of the SDL Editor window.

In Windows, the text window is a floating, resizeable and moveable window that can be placed anywhere on the screen. A single text window is shared by all instances of the SDL Editor currently running.

The text window contains two menus described in:

- "The File Menu of the Text Window" on page 2029
- "Edit Menu" on page 2004

Hiding and Showing the Text Window

You can hide or show the text window with the *Window Options* command from the *View* menu, or by using a quick-button.

In Windows: When visible, the text window will always be placed on top of the SDL Editor window.

Basic Text Editing Functions

Delayed Updating of the Drawing Area

When you edit text in the text window, both the text window and corresponding text in the drawing area will be updated. The the drawing area will be updated after a slight time delay and this can be set by an editor preference.

If you try to type an illegal character, you will be warned by a beep.

Standardized Text Editing Functions

When you edit text, you can:

- Position the cursor by clicking or by using the arrow keys.
- Insert characters after the current position of the text pointer.
- Delete one character backward by pressing `<backspace>`.
- Delete one character forward by pressing `<delete>`.
- Replace selected text by typing.
- Delete selected text by pressing `<backspace>` or `<delete>`.
- Select text by dragging or by clicking and `<Shift>`-clicking.
- Select a word by double-clicking it.
- Select a line by triple-clicking it.

Searching and Replacing Text

In the SDL editor, you can search for and replace text in a page or in a diagram. In the Organizer, you can search for and replace text in a diagram or in a diagram structure that is managed by the Organizer. In both the SDL editor and the Organizer, there are two search variants:

- Dialog search
- Fast search

Searching for Text in a Diagram using Dialog Search

To search for text in the current page from the SDL editor:

1. Select *Search* from the SDL editor's *Tools* menu or click the SDL editor quick-button for *Search*. The *Search dialog* is issued.

2. Specify the text to be found in the *Search for* text field.
   - Click the *Consider case* button on to search case sensitive.
   - Click the *Wildcard search* button on to use wildcard matching, where an asterisk ('*') matches a sequence of zero or more characters of any kind.
   - Turn the *Search all pages* button on to specify that the scope of search should comprise all pages in the diagram. If you turn the button off, the scope of search will only comprise the current page.
   - Click the *Whole word search* button on to search only whole words.
3. Click the *Search* button. The object where the next occurrence of text is found will be selected and the text window updated accordingly.
   - The diagram that the tool is currently processing is displayed to the right of the *Search In* field.
4. Click *Close*.

Searching and Replacing Text using Dialog Search

1. Open the Search dialog as described in "Searching for Text in a Diagram using Dialog Search" on page 1962.
2. Specify the text to be found in the *Search for* text field.
3. Specify the text to be replaced with in the *Replace with* text field.
4. Click the *Search* button to find the first occurrence.

5. If the text is found, the object where the next occurrence of text is found will be selected and the text window updated accordingly. You may use any of the following options:
   - Search further by clicking *Search* repeatedly
   - Replace the text by clicking *Replace*
   - Replace and continue search with the *Replace & Search* button.
   - Replace all occurrences with the *Replace All* button.
6. Close the Search dialog by clicking *Close*.

Fast Search

Fast search is like dialog search but without the dialog. The setting from the last dialog search is used for *Wildcard search*. Fast search do never consider case, and does always search all objects and all pages. To invoke Fast search, type ctrl+F when the SDL editor is not in text editing mode. If you are in text editing mode, you can click in the diagram background first to get out of text editing mode.

When Fast search is invoked, the message area displays the text that will be searched for. Initially, the text is *Search for:*. When you type on the keyboard with the mouse pointer over the drawing area, the characters will turn up in the message area. When you have typed the text pattern to search for, press enter or return to start the search operation.

The same search operation as for Dialog search is used. If the search operation finds a match, you can search for another match by pressing enter or return once more.

To finish the Fast search operation, click in the drawing area or select another operation.

The next time Fast search is invoked with ctrl+F, the search text that was used the last time is proposed as a search text once more. To use it, press enter or return. To use another search text, press ctrl+F once more or the delete key several times, to erase the search text.

Editing Text by Using an External Text Editor

Whenever a text object is selected and the text is visible in the text window, the command *Connect to Text Editor* in the *Tools* menu is avail-

able. This command opens an external text editor containing the text of the selected object. Which external text editor to start is defined by the preference SDT*TextEditor, which can be set either to the Text Editor or to the Emacs text editor **(on UNIX)**.

From this point on, you can only edit the text by using the external text editor.

The text in the SDL Editor is updated every time the external text editor saves the text. When the text is no longer edited in the external text editor, the editing control returns to the SDL Editor.

Importing / Exporting Text

The SDL Suite allows you to import and export text from / to a file. You can, for instance, import text from files that contain SDL/PR into text symbols and export the contents of text symbols to files.

Importing Text from a File

Caution!

Importing text from a file replaces existing text as well. Use the *Undo* facility to revert to the original text, as long as the symbol is selected – deselecting the symbol will disable *Undo*.

You can import the contents of a text file into an object managed by the SDL Editor in the following way:

1. Select the object where you want to import the contents of a file.
2. Select *Import* from the text window's *File* menu.
3. Specify the file to import.
4. Click *OK*. This **replaces** the contents of the text window with the contents of the file you have specified in the file selection dialog.

Exporting Text from a File

To export the contents of the text window into a file:

1. Select the object which text you want to export to a file.
2. Select *Export* from the text window's *File* menu.

3. Specify the file to export the text to.
4. Clicking *OK* possibly creates a new file and replaces the contents of the file with the contents of the text window.

Copying, Cutting and Pasting Text

In the text window, you can cut, copy and paste text between different symbols, lines and text attributes. You can also transfer text between different applications.

Programmable Function Keys (UNIX only)

On UNIX, the SDL Suite allows to tie a function key to a defined text string. When you type that defined function key, the programmed text string will be inserted at the current cursor location. You can customize your own programming of function keys.

Global SDL Suite Resources

The function keys are set up as X resources. It is possible to set up both system default and user-defined X resources, allowing you to customize your environment. The X resources are defined in a file that is common for all SDL Suite users, namely

```
/usr/lib/X11/app-defaults/SDT
```

To program the function keys, insert following lines anywhere into the `SDT` file:

```
/* Any suitable comment */
SDT*XmText.translations: #override \n\
<Key>F1: insert-string("F1Text") \n\
<Key>F2: insert-string("F2Text") \n\
<Key>F3: insert-string("F3Text") \n\
<Key>F4: insert-string("F4Text") \n\
<Key>F5: insert-string("F5Text") \n\
<Key>F6: insert-string("F6Text") \n\
<Key>F7: insert-string("F7Text") \n\
<Key>F8: insert-string("F8Text") \n\
<Key>F9: insert-string("F9Text")
/* Note the absence of \n\ on line 9 */
```

Note:

Omitting to define some of the function keys is permissible.

User-Defined Resources

You can define your own function keys. You do this by defining the X resources described above in a personal copy of the definition file and to store that file it into your home directory:

```
~username/SDT
```

Alternatively, any directory designated by the environment variable `XAPPLRESDIR` can be used.

Restrictions

- You can only define one line for each function key. If you attempt to define more than one line into one function key may cause an unpredictable result when you press that key.

  For instance, it is not certain that the following line will produce the expected result:

  ```
  <Key>F1: insert-string("F1Line1\nLine2") \n\
  ```

- You can define the keys F1–F9.

Changing Fonts on Text Objects

You may change the font faces and font sizes used in the textual objects displayed by the SDL Editor. All textual objects use the same font faces and font sizes, meaning that you can neither change them individually nor change them during an SDL Editor session.

There is one exception though – it is possible to use a separate font for text symbols. This is useful in process diagrams where you may want a proportional font in most symbols to save space, while you may want a non-proportional font in text symbols to be able to align words on different lines.

The font faces available depend on the target system on which you are running the SDL Suite.

Defining What Font to Use

To modify the desired font size and font face, you must use the Preference Manager. See chapter 4, *Managing Preferences*.

Textual Objects Preferences

When the setting is in effect, the SDL Suite will use the font face names given by the preference settings

Editor*FontText*ScreenFontFamily
Editor*FontText*PrintFontFamily

to select font face names. Note that in this way you can select different font names for screen and for print.

On UNIX, if you leave the Editor*FontText*ScreenFontFamily preference setting empty, you will edit your documents using the *SDT Draft* font, but print them using the font you specified with the Editor*FontText*PrintFontFamily setting.

Text Symbol Preference

For text symbols, the preference Editor*FontText*TextSymbolFontFamily is used both for on-screen viewing and printing.

Supported Font Faces

On UNIX, the availability of font faces is determined by the version of the X Windows server which is running. With a revision 5 or higher (X11 R5), scalable fonts are supported. In that case, the available list of predefined font faces would be:

- Times
- Helvetica
- Courier
- SDT Draft (mapped to the Schumacher font)
- Other (mapped to a user-defined font)

In Windows, the availability of font faces is determined by the TrueType fonts that are currently installed on the computer (use for instance the Windows Control Panel to determine what is available).

Default Font Face

The default font face is Helvetica. **On UNIX**, if scalable fonts are not supported, the font face will be replaced by a *Schumacher* font (which can be used in all circumstances).

Default Font Sizes

The default font sizes are as follows:

Page Font Sizes (except overview pages)	
Text Object:	**Font Size**
Kernel heading, texts in reference symbols, channel names, signal route names, gate names	12 points
Other text objects	9 points

Overview Page Font Sizes	
Text Object:	**Font Size:**
All texts except signal lists	10 points
Signal list symbol	8 points

Setting Alignment

Normally the alignment of the text inside symbols are automatically set. However, you can use the preference setting Editor*Font-Text*TaskSymbolLeftAligned to set the alignment for the task symbol, procedure call symbol, macro call symbol, create request symbol and the save symbol. The default value is “off”, meaning that the text will be centered, but if you set it to “on” the text in these symbols will be left aligned.

Determining Which Scalable Fonts Your Server Can Access (UNIX only)

On UNIX, use the `xlsfonts` command to list installed fonts. Font names containing 0 for width and height are scalable.

How to Determine what Fonts are Available

From the OS prompt, typing:

```
hostname% xlsfonts | grep "\-0\-0\-" | more
```

will return a list of accessible scalable fonts.

Scalable Fonts Under R5 Servers

To use scalable fonts under X11R5 you must normally first connect to a font server.

How to Start the Font Server

1. Start the font server on any local host:

   ```
   hostname% fs
   ```

2. Connect the server to `fs` indicating which host the font server is running on (which can be the same host that the X server is running on):

   ```
   hostname2% xset +fp tcp/<hostname>:7000
   ```

For further information see the X11R5 documentation or use `man fs` to read the manual page describing the font server you are running.

Disabling Font Scaling (UNIX only)

On UNIX, if the fonts look poor on the screen, a possible work-around is to disable the scaling option.

> **Note:**
> Disabling font scaling effectively disables WYSIWYG!

To do this, you should edit the `SDT` resource file.

1. Open the file `SDT` in a text editor.
2. Locate the line with the text: `SDT*sdtUseScalableFonts`
3. Change the line to `SDT*sdtUseScalableFonts: false`
4. Save the file and restart the SDL Suite environment.

Grammar Help and Signal Dictionary

General

Besides the context sensitive syntax check performed on the texts, there is a *grammar help* support function. It assists you in entering the correct text, according to the SDL grammar, in the selected text attribute to an object.

Designing using SDL implies to large extent defining, sending and receiving signals. A *signal dictionary* assists you in reducing the time it takes to find out names and parameters for a signal that you already have used somewhere in a diagram. The signal dictionary also incorporates timers.

Keyboard Accelerators (UNIX only)

In addition to the standard keyboard accelerators, described in "Keyboard Accelerators" on page 35 in chapter 1, *User Interface and Basic Operations*, the Grammar Help and Signal Dictionary window features the following:

Accelerator	Command / functionality
`g`	Select the *Grammar* section if the option is enabled and bring the separator into view
`u`	Similar to `g` but applies on *Up*.
`t`	Similar to `g` but applies on *This*.
`d`	Similar to `g` but applies on *Down*.
`a`	Similar to `g` but applies on *All*.
`m`	Similar to `g` but applies on *MSC*.
`e`	Similar to `g` but applies on *External*.
`Ctrl+g`	Toggles the *Grammar* option on / off (see "Grammar" on page 2031). When the option is enabled, brings the Grammar separator into view and selects it.
`Ctrl+u`	Same as `Ctrl+g`, but applies on the *Up* option.

Accelerator	Command / functionality
Ctrl+t	Same as Ctrl+g, but applies on the *This* option).
Ctrl+d	Same as Ctrl+g, but applies on the *Down* option.
Ctrl+a	Same as Ctrl+g, but applies on the *All* option.
Ctrl+m	Same as Ctrl+g, but applies on the *MSC* option.
Ctrl+e	Same as Ctrl+g, but applies on the *External* option.
Ctrl+f	Finds the **last** occurrence of the first word in the currently selected object in the SDL Editor drawing area and selects it in the *This* section. The first word is defined as the text string from the start of the object's text and until one of the following characters: ' ' (space) ',' (comma) '(' (left parenthesis) <TAB> '\n' (newline)

Using Grammar Help

The Grammar Help window is a multi-functionality window; it can also provide signal dictionary capabilities. These functions are further described in "Using the Signal Dictionary" on page 1983. What functionality is provided depends on the options defined in the *Select* menu.

Each SDL Editor window has its associated Grammar Help window.

Opening the Grammar Help Window

- Select the *Grammar Help* menu choice from the *Windows* menu.

  The *grammar help window* is issued (see Figure 409 on page 1974).

Requesting Grammar Help

If you select the object you need assistance on, you will see the keywords and options available for use in given situations, and the corresponding reference to sections of the ITU Z.100 SDL Definition, followed by the grammar syntax of the meta language.

To request grammar help:

- Select the object of interest. The grammar help window contents are automatically updated to list the following:
  - The nature of the selected object
  - The grammar for that object
  - The various “use cases”.

Inserting Text

This operation inserts the contents of the grammar help window into the SDL Editor text window.

To insert the text related to a given “use case”:

1. Locate the “use case” of interest. The left part of the window provides a list of situations, named using some abbreviation that associates to the situation.
   - The first item(s) in the list reads *GRAMMAR*, possibly with a suffix that informs you about the grammar context. You can take advantage of the GRAMMAR items either as using the references to Z.100 if you need more detailed information about the selected sort of object, or if you need to read more about the concrete grammar.

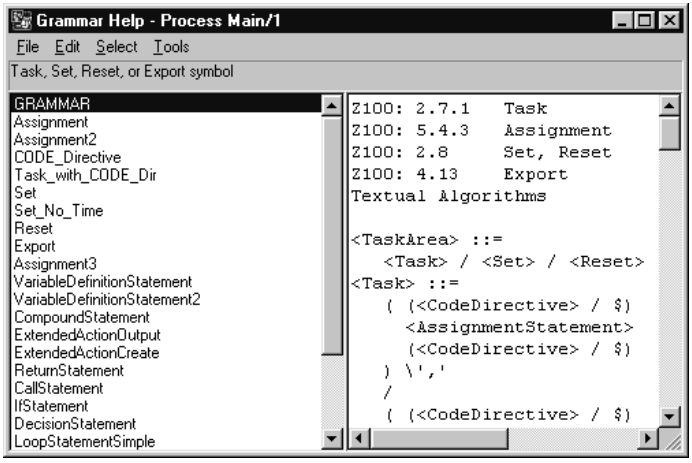


Figure 409: The grammar for a task symbol

– The next items contains a number of “use cases”. As an example, if you select a task symbol, the first “use case” reads *Assignment*, while the second reads *Assignment2*. This is to be interpreted as:
An assignment statement,
Multiple assignment statements in a task symbol.

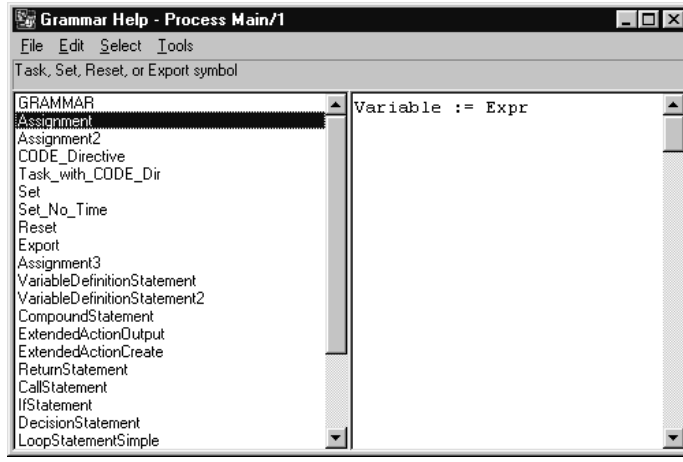

Figure 410: The Assignment "use case"

2. Click on the item of interest to select it.
3. Select *Insert* from the *Edit* menu or double-click the item in the list. The contents of the right part of the window are inserted into the SDL Editor text window, at the current I-beam cursor position.
4. Finally, replace the formal notation with the appropriate values, variables, signals, etc. used in your diagram.

Replacing Text

This operation signifies replacing the contents of the SDL Editor text window with the contents of the grammar help window.

- Proceed as described in "Inserting Text" on page 1973, but select *Replace* from the *Edit* menu.

Customizing the Grammar Help

With the SDL Suite, a standard grammar help template file is provided. In addition to this, the SDL Editor allows you to use your own templates and to merge these with the standard templates.

To create grammar help definitions:

1. Copy an existing grammar help file.
2. Edit the file using any text editor (the grammar help file is an ASCII file). See "The Grammar Help File" on page 1978 for a description of the contents and syntax of the file.

To use another grammar template definitions:

- Select *Load* from the *File* menu. In a File Selection Dialog you then specify what template definitions to load.

To merge the current grammar template definitions with another one:

- Select *Load* from the *File* menu. In a File Selection Dialog, you then specify what template definitions to merge with the current.

The *Symbol* Label

The *symbol label* field is a non-editable text field that displays the type of symbol that is currently selected in the SDL Editor.

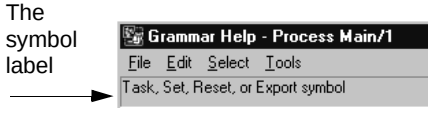

Figure 411: The symbol label

The symbol label reads "No single symbol selected" in the following circumstances:

- No symbol or line is currently selected in the SDL Editor
- More than one symbol is selected
- The symbol type is not defined in the *Grammar Help* file.

The *Name* Field

The *name field* consists of a scrollable list that contains a list of names of templates associated with the currently selected symbol.

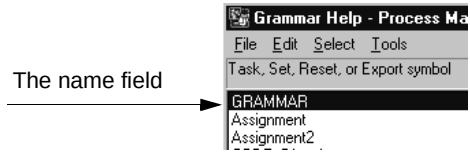

Figure 412: The name field

The list is updated automatically each time an object in the SDL Editor's drawing area is selected, to reflect the templates that are currently available for that object. By default, the first item in the list is selected.

The name field is empty in the following circumstances:

- The symbol label reads "No single symbol selected"
- The symbol type information is missing in the *Grammar Help* file.

When selecting an item in the list, the corresponding template definition appears in the grammar field, allowing to check its contents before inserting it into the text window (see "Insert" on page 2030 and "Replace" on page 2030).

The *Grammar* Field

The *grammar field* is a scrollable field from which text can be copied. Its contents are updated to reflect the definition for the currently selected item in the name field.

The grammar field is empty if no item is selected in the name field (or if the name field is empty).

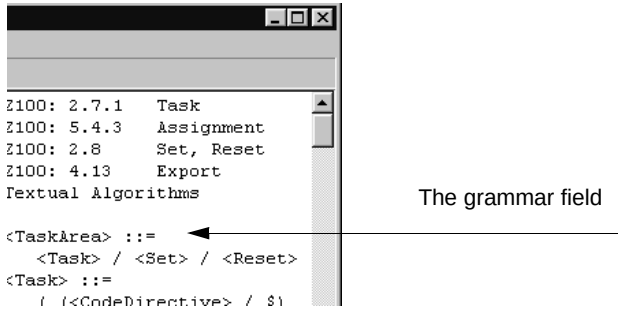

Figure 413: The grammar field

To copy and paste text from the template definition field to the text window, you can:

- Use the *Insert* command, described in "Insert" on page 2030.
- Use the *Replace* command, described in "Replace" on page 2030.
- Copy and paste by using the graphical environment clipboard functions.

The *Grammar Help File*

This section is a reference for the format of the files that contain SDL Grammar Help definitions.

The template definition file format is line-oriented, and uses two separator characters chosen so as to not interfere with the possible contents of templates appearing in the file.

> **Note:**
>
> The characters `'@'` and `'$'` are separator characters. They are **reserved for that purpose.**

The template definition file is divided into **sections** defining templates for a particular symbol type. A section begins with a *Grammar Help Declaration* part and ends with a *Grammar Help Definition* part.

The **grammar help declaration** of a new section has the following syntax:

```
@<editortype>@<symboltype>[@[<symbolcomment>]]
```

<editortype>, <symboltype> and <symbolcomment> are to be replaced with the adequate text strings.

Comments in Grammar Help files are also permissible.

Example 322: The Declaration of a Channel Template ––––––––––––

```
@SDL@CHANNEL@Channel symbol
```

The declaration is to be interpreted as:

- `SDL`
  Valid for the SDL Editor only
- `CHANNEL`
  A channel line
- `Channel Symbol`
  An informative text that will be displayed to you (see "The Symbol Label" on page 1976).

––

editortype

editortype may currently be of one of the keywords:

- - The section contains templates relevant for the SDL Editor.
- - The section contains templates for the Message Sequence Chart Editor.

> **Note:**
> Grammar Help is currently not supported by the MSC Editor. The MSC keyword is reserved for future functionality extensions.

symboltype

symboltype is defined per editor and the allowed names are the following:

```
ADDITIONAL_HEADING_BLOCK
ADDITIONAL_HEADING_BLOCK_TYPE
ADDITIONAL_HEADING_PROCEDURE
ADDITIONAL_HEADING_PROCESS
ADDITIONAL_HEADING_PROCESS_TYPE
ADDITIONAL_HEADING_P_AS_SERVICE
ADDITIONAL_HEADING_SERVICE
ADDITIONAL_HEADING_SERVICE_TYPE
ADDITIONAL_HEADING_SYSTEM
ADDITIONAL_HEADING_SYSTEM_TYPE
BLOCKSUBSTRUCTURE
BLOCK_REF
BLOCK_TYPE_REF
CALL
CHANNEL
CHANNELSUBSTRUCTURE
CONNECTION_POINT
CONNECTOR
CONTINUOUS_SIGNAL
CREATE
DECISION
ENABLING_CONDITION
GATE
INPUT
KERNEL_HEADING
KERNEL_HEADING_BLOCK
KERNEL_HEADING_BLOCK_TYPE
KERNEL_HEADING_PROCEDURE
KERNEL_HEADING_PROCESS
KERNEL_HEADING_PROCESS_TYPE
KERNEL_HEADING_SERVICE
KERNEL_HEADING_SERVICE_TYPE
KERNEL_HEADING_SYSTEM
KERNEL_HEADING_SYSTEM_TYPE
MACROCALL
OPERATOR_REF
OUTPUT
CLASS
PACKAGE_REF
PAGENUMBER
PRIORITY_INPUT
PRIORITY_OUTPUT
PROCEDURE_REF
PROCEDURE_START
PROCESS_REF
PROCESS_TYPE_REF
RETURN
SAVE
SERVICE_REF
SERVICE_TYPE_REF
```

```
SIGNALROUTE
START
STATE
STOP
TASK
TEXTSYMBOL_BLOCK_SUBSTR
TEXTSYMBOL_MACRO
TEXTSYMBOL_PROCEDURE
TEXTSYMBOL_PROCESS
TEXTSYMBOL_P_AS_SERVICE
TEXTSYMBOL_SERVICE
TEXTSYMBOL_SYSTEM
TRANSITION_OPTION
```

Note:

If the same section appears more than once, all template definitions under those sections will be available.

symbolcomment

symbolcomment is an optional feature, which allows specification of a text to be associated with each *symboltype*. The text for a specific *symboltype* appears in the symbol type field of the Grammar Help window whenever a symbol of that type is selected in the editor.

Comments

Also, comments may appear in the file using the following syntax:

```
@COMMENT@<commenttext>
```

Note:

Such a comment signals the end of the previous section and should only be used before another section.

Grammar Help Definition

A SDL grammar template has significance only if it is located after a valid declaration. The template will be added to the list of templates for that section.

A template definition is started with a line beginning with a '$' sign and continues until either:

- A line beginning with a '$' sign is read.
- A line beginning with a '@' sign is read.
- End of file is encountered.

The **syntax** of a template definition is simply:

```
$<templatename>'Newline'
<multiple lines constituting the template
definition>
```

Example 323: The definition of a channel example ––––––––––––––––

```
$GRAMMAR
Z100: 2.5.1 (p.45)
Z100: 2.5.5 (p.50) Signal list

<ChannelName> ::= <Name>
<SignalList> ::=
  ( <SignalName> / '(' <SignalListName> ')' )",'
$SignalList
SignalName, SignalName
$SignalList2
SignalName, SignalName, (SignalListName)
```

––

Note:

Neither leading nor trailing newlines will be added to the template definition. These can be added to the template simply by adding a leading empty line and/or a trailing empty line in the template definition.

File Handling

When a Grammar Help window is opened, the SDL Editor will try to locate a SDL grammar help file and to load it, if found. The search order is as follows:

1. The SDL Editor starts by fetching the preference value `Editor*TemplateFile`.
2. If no value is specified for the preference parameter, it will use the **default file name** `sdt.tpl`.
3. The directories where the SDL Editor will search for the file are:
   - The current directory
   - Your home directory (`$HOME` **on UNIX** and `%HOME%` **in Windows**)
   - The installation directory (`$sdtrelease` **on UNIX**)
4. If no file can be located, either with a specified name or the default name, you get the option of searching manually (i.e. from a File Selection Dialog) for files with the standard file name extension `.tpl`.

5. If you decline by clicking *Cancel*, the Grammar Help window will appear without contents. You can now locate a grammar help file by choosing *Load* (or *Merge*, which will have the same effect in this case).

Using the Signal Dictionary

Messages from a Message Sequence Chart and signals from an external signal dictionary may be included into the SDL Editor's signal dictionary.

All functionality is provided in the *signal dictionary window*. Each SDL Editor window has its associated Signal Dictionary window.

> **Note:**
>
> The signal dictionary function requires a file with grammar help templates (`sdt.tpl`) in order to function properly. See "The Grammar Help File" on page 1978.

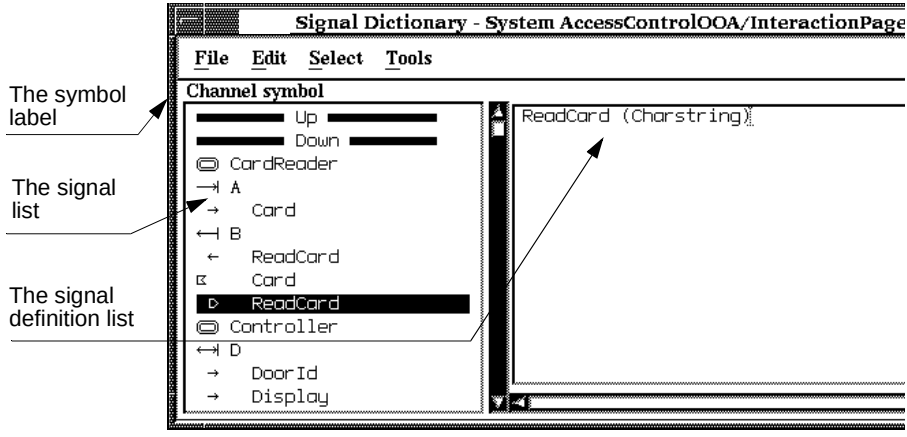

Figure 414: The Signal Dictionary window **(on UNIX)**

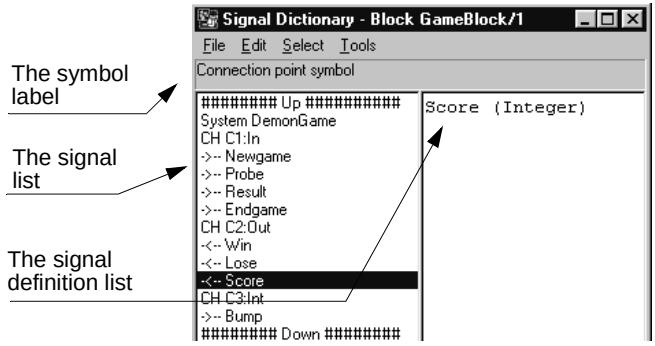

Figure 415: The Signal Dictionary window **(in Windows)**

Signal Dictionary Update

The signal dictionary function stores information about signals in an *information server*. The information server updates its contents **each time an SDL diagram is saved**. When the diagram is saved by the SDL Editor, the SDL Analyzer is invoked and produces a mirrored image which is an SDL/PR description of the SDL/GR diagram. That information is then loaded into the information server which serves the SDL Editor with information upon request. All of this is done automatically.

> **Note:**
>
> In order to extract signal information from a diagram, the SDL Suite requires the diagram to be syntactically correct in the sense that SDL/PR code can be generated from the SDL/GR diagram without encountering errors.

Opening the Signal Dictionary Window

- Select *Signal Dictionary* from the SDL Editor *Windows* menu. The signal dictionary window is issued (see Figure 414 on page 1983 and Figure 415 on page 1984).

Setting the Mode to Graphical or Textual (UNIX only)

On UNIX, the signal dictionary window can take advantage of your computer's font capabilities to present the information in a graphical way, using SDL-like notation. This is the default mode.

If the information is presented using strange characters, your terminal does not support the font family used by the signal dictionary window. You should use the textual mode.

To turn the mode to textual:

1. Set the environment variable `SDLENOGRAPHICS`
   - If you are to run several Signal Dictionary sessions in this mode, you may want to set the environment variable in a file that you will automatically source (e.g. `.cshrc`)
2. Exit all SDL Suite tools.
3. Restart the SDL Suite to have the environment variable affect the behavior.

Requesting Signal Dictionary Services

When you select an object where a reference or definition of a signal makes sense, the signal dictionary window is automatically updated to reflect the signals and *signal conveyors*[1] that are available according to what options you have selected.

The signal dictionary function responds when selecting the following objects (see "Object" on page 1995 for more details):

- channel
- signal route
- connection point
- gate
- signal input
- signal output
- priority input
- save of signal
- text symbol

Updating the Signal Dictionary

The signal dictionary is automatically updated each time you save an SDL diagram or an MSC that is referred to in the Organizer's SDL System Structure chapter.

1. The term *signal conveyor* denotes a communication path that conveys signals; a channel, signal route, a gate or connection point.

When modifying an SDL diagram, you may have unintentionally introduced SDL constructs that are incomplete and thus cause the signal dictionary to fail in providing signal information for that diagram.

Where the signal dictionary fails on a diagram, a bug symbol **(on UNIX)**, or an error message **(in Windows)** will appear after the diagram name in the signal list. Correct the source of error and save the diagram again. For a reference on signal dictionary errors, see "Error Notification" on page 2001.

Specifying the Signal Dictionary Options

You can customize the signal dictionary to fit your needs, by restricting or extending the amount of information that is presented through a set of options that you can activate or deactivate.

Depending on the method you are following when designing with SDL, you should activate the required options.

Next follows a guide for when to use the available options.

To enable an option:

1. Activate the *Select* menu.
2. Toggle the appropriate option on by selecting it (an option which is enabled is indicated with an asterisk preceding the option name). Selecting the option once again disables it.
   - Alternatively, select the *Options* menu choice and toggle the buttons on or off. When satisfied, click *OK*.

> **Note:**
>
> The more options are enabled, the more information is computed by the SDL Editor and the more time it takes.

Bellow follows a few general guidelines for enabling the various options, depending on the approach you are following when designing with SDL.

Working Top-Down

This expression means starting by designing the root diagram (e.g. the system diagram) and continuing with the block diagrams, next the process diagrams and so forth.

If you follow this approach, selecting the *Up* option will enable access to signals used one level up in the SDL hierarchy. This option is enabled by default.

– You may also type `<Ctrl+u>` to toggle the option. Typing **`u`** brings the *Up* option into view (if enabled).

Working Bottom-Up

Following this method means starting with the diagrams at a deeper level (e.g. procedures) and working upwardly in the SDL hierarchy.

If you work bottom-up, select the *Down* option to enable access to signals used one level down in the SDL hierarchy. This option is enabled by default.

– You may also type `<Ctrl+d>` to toggle the option. Typing `d` brings the *Down* option into view (if enabled).

Working with Local Signals

If you look for entities that are used locally in a diagram, select the *This* option. Remember, a diagram needs to be saved in order to update the signal dictionary.

– You may also type `<Ctrl+t>` to toggle the option. Typing `t` brings the *This* option into view (if enabled).

– To find the definition of the signal in the *This* section, you may select an object in the drawing area that uses the signal and type `<Ctrl+f>`.

Listing all Signals

You can list all signals that are visible according to the SDL scope rules by turning the *All* option on. For instance, a signal that you declare on the system level will be available in all diagrams in the SDL hierarchy.

– You may also type `<Ctrl+a>` to toggle the option. Typing `a` brings the *All* option into view (if enabled).

Using Packages

If you want to gain access to signals that you have declared in a package, you should enable the *All* option.

Using Diagram Types

If you use the diagram type concept, you should enable the *All* option to gain access to the signals that are defined in the diagram types.

Listing MSC Messages

If you describe the dynamic behavior of an SDL diagram using the MSC Editor, you may take advantage of this by turning the *MSC* option on.

> **Note:**
>
> Messages used in an MSC will be available in the signal dictionary only if it is associated with an SDL diagram, i.e. linked into the SDL diagram structure.

Importing an External Signal Dictionary

You may import an external signal dictionary into the SDL Suite through the Postmaster interface. This is described in *"Load External Signal Definitions into the Information Server" on page 684 in chapter 12, Using the Public Interface*.

Locating the Source Diagram

Note: Signal Dictionary and OO

If you are looking for a source diagram that is an SDL-92 type (system type, block type, process type or service type) and that you access through an instance of the type, the following conditions must be respected in order to have the signal dictionary window list the diagram and list all of the signals and signal conveyors that are used in the diagram:

- The type diagram **must be referred in the same diagram as where it is instantiated**. In the signal dictionary window, only the type will be listed, not the instance. Figure 416 shows an example of this.
  - As a consequence of this, you will not be able to look into the instance of a type that is defined in a package diagram and used in the current SDL system.
- In the case the type is inherited from a supertype, the entities that you are looking for **must be defined in the child type**.

The main cause of this limitation is that channels and signal routes are connected to the instance, not to the type.

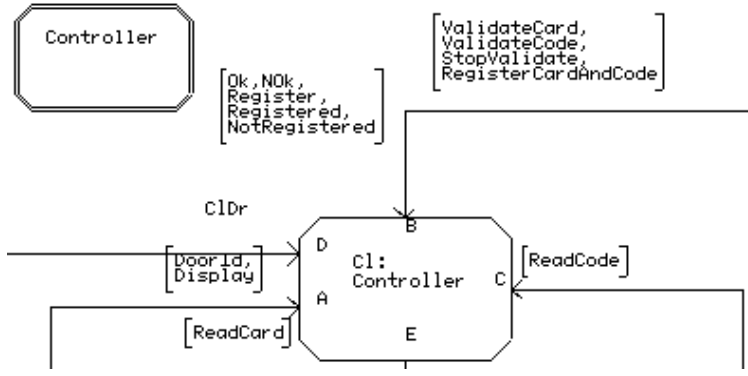

Figure 416: The type is referred where instantiated

The process type Controller is instantiated as Cl. The process instance Cl will be visualized as the process type Controller, and you can list signals conveyed on the gates A, B, C, D and E.

To locate the source diagram (i.e. the diagram where the signal is used or where the signal conveyor is available):

1. Locate the section (*Up*, *This*, *Down*, *All*, *MSC* and *External*) by scrolling up or down. The sections are listed in that order and the start of each section is identified with a separator with the corresponding name.

   – You may also use the keyboard accelerators `<Ctrl+u>`, `<Ctrl+t>`, `<Ctrl+d>`, `<Ctrl+a>`, `<Ctrl+m>` and `<Ctrl+e>` to toggle the respective option on and off.

   – Use the keyboard accelerators `u`, `t`, `d`, `a`, `m` and `e` to bring the respective section into view.

2. Identify the source diagram by its type and name. Diagrams are listed alphabetically by their name. The diagram type is identified either by a graphical SDL-like symbol (see Figure 424 on page 1997) in the left margin **(UNIX only)**, or by a text string that consists of the diagram type.

Updating the Text in the Target Diagram

Once you have located the source diagram your next task is to insert the text belonging to the object you have selected in the target diagram (the diagram where the change is to be done).

Updating a Signal / Timer Output, Input, Priority Input or Save

This operation makes sense only on pages where the implementation is described, i.e. the flow pages.

1. Locate the matching signal or timer in the signal list.

   – Signals are identified graphically with the SDL signal input and/or signal output symbol **(UNIX only)**, or with the characters ‘I’, ‘O’ or ‘?’ (see “Signal and Signal List” on page 1999.

   – Timers are identified with the MSC timer symbol **(UNIX only)**, or the character ‘T’ (see “Timer” on page 2001).

2. Make sure the signal output, input, priority input or save symbol to be updated is selected in the target diagram.

3. Select the signal or timer item in the signal list. Use *Insert* or *Replace* from the *Edit* menu to update the symbol contents. The target symbol is updated with the signal name and its formal parameters.

   – Alternatively, double-click the signal or timer.

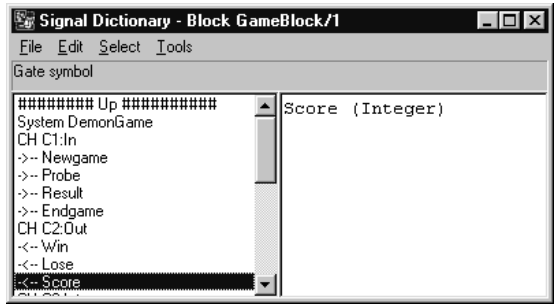

Figure 417: Selecting the signal Display

4. Update the signal's formal parameter type with a current parameter.

Updating a Signal Conveyor (Channel, Signal Route, Connection Point or Gate)

1. Locate the signal conveyor that constitutes the corresponding item that interfaces to the channel, signal route or gate that you are to update in the current diagram.

   – In graphical notation **on UNIX**, these entities are identified graphically by a symbol which has the appearance of the corresponding SDL concept (see Figure 425 on page 1998, Figure 426 on page 1998 and Figure 427 on page 1999).

   – Channels, signal routes and gates are identified textually with the abbreviations CH, SR and GA, respectively.

2. Make sure the **signal list** is selected in the target diagram.

3. Select the signal conveyor. Use the *Insert* or *Replace* from the *Edit* menu to update the signal list contents.

   – Alternatively, double-click the signal or timer.

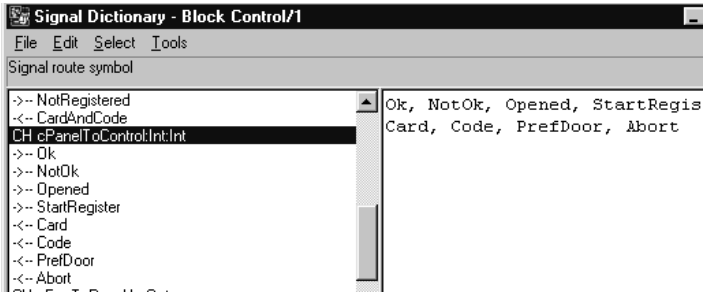

Figure 418: Selecting the Channel cPanelToControl:int:int

4. In the case of a bidirectional conveyor, you will see lines of text in the right window, each one corresponding to a signal list (as in Figure 418, above). You should copy each line of text to the corresponding signal list. Select the signal list in the SDL Editor and a line, then use *Insert* or *Replace* to update the signal list.

Updating a Text Symbol

When updating a text symbol, you are likely to declare signals and timers that you have referred to in the current diagram or referred to in the SDL hierarchy descending from the current diagram.

1. You should make sure the *Down* and *This* options are selected.
2. Remember to add a SIGNAL or TIMER keyword in the text symbol, before the enumeration of signals.
3. Locate all diagrams of interest. Look for signals / timers that you want to declare. Double-click each signal, and insert the necessary commas to create a syntactically correct declaration. Terminate the operation by inserting a semicolon.

Finding a Definition

When you select an object in the SDL Editor's drawing area and then type `<Ctrl+f>` the first occurrence of the first word in the object is looked for and selected in the This section.

Closing the Signal Dictionary Window

You close the signal dictionary window by selecting *Close* from the signal dictionary *File* menu.

The Symbol Label

The *symbol label* field is a non-editable text field that displays the type of object that is currently selected in the SDL Editor.

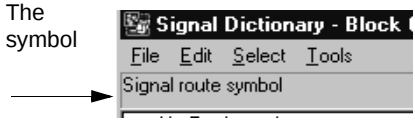

Figure 419: The symbol label

The symbol label reads “No single symbol selected” in the following circumstances:

- No object is currently selected in the SDL Editor
- More than one object is selected.
- The symbol type is not defined in the Grammar Help file.

The Signal List

The *signal list* is a selectable list where all occurrences of signals that are found according to the current selection criteria are listed.

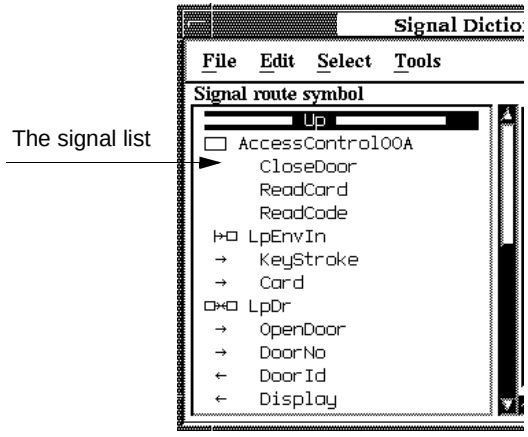

Figure 420: The signal list **(on UNIX)**

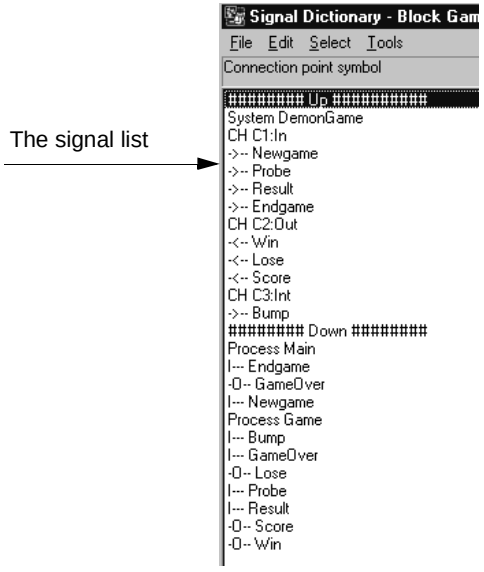

Figure 421: The signal list **(in Windows)**

The signal list is empty when:

- The symbol label reads “No single symbol selected”
- The signal dictionary function does not make any sense on the selected object. i.e. the selected object does not refer/define a signal.

The following objects are recognized as carrying signal information:

Object	Usage
channel line channel name signal list in channel	Reference to signal
connection point	Reference to signal
gate gate name signal list in gate	Reference to signal
input	Reference to signal
output	Reference to signal
priority input	Reference to signal
save	Reference to signal
signal route line signal route name signal list in signal route	Reference to signal
text	Declaration of signal

Signal List Notation and Syntax

Each line in the signal list follows a notation that informs about the various diagrams and symbols where signals are used and also about the context.

In Windows, this notation is purely textual.

On UNIX, the notation that is adopted is an SDL-like graphical notation. It is also possible to select a textual notation if the font face used in the graphical notation is not supported by the computer. You select the textual notation by setting the environment variable `SDLENOGRAPHICS` before you start the SDL Suite .

Each item in the signal list is one of the following:

- *Separator*
- *Diagram Identifier*
- *Gate*
- *Channel*
- *Signal Route*
- *Signal and Signal List*
- *Timer*

Separator

The signal list is divided into several sections. The top of each section is clearly marked with a separator, having the appearance of a thick line (graphical notation **on UNIX**) or a number of hashes ("###...###") preceding and following a text that identifies the section.

Figure 422: A signal list separator (graphical notation **on UNIX***)*

```
######## Up ##########
```

Figure 423: A signal list separator (textual notation)

Each of these sections corresponds to an option that is enabled in the *Select* menu (see "Select Menu" on page 2031). Their meaning and order of appearance in the signal list is as follows:

- *Grammar*

  SDL Grammar Help section. See "Using Grammar Help" on page 1972 for more information about this topic.

- *Up*

  A list of all SDL signals that are available[1] by looking one level up in the SDL hierarchy. The *Up* section is empty when working on the top diagram (e.g. a system diagram).

- *This*

  All SDL signals that are available by looking at the current diagram, i.e. *this* diagram.

1. The term "available" means defined and / or referenced.

- *Down*

  All SDL signals that are available by looking at all diagrams one level down in the SDL hierarchy. The Down section is empty if the current diagram has no diagrams below it in the hierarchy.

- *All*

  All defined SDL signals that are visible for the current diagram according to the *SDL scope rules*.

- *MSC*

  Signals that have been exported from a Message Sequence Chart into the SDL Editor signal dictionary facility. An MSC must be *Associated* with an SDL diagram in the Organizer's diagram structure in order to include its signals into the Signal Dictionary (see "Associate" on page 98 in chapter 2, *The Organizer*).

- *External*

  Signals that have been imported from an external signal dictionary. An external signal dictionary is imported through the public PostMaster interface of the SDL Suite. See *"Load Definition File" on page 627 in chapter 11, The Public Interface*.

Diagram Identifier

In the graphical notation **on UNIX**, diagrams are identified with an SDL Reference symbol in the left margin which identifies the diagram type, followed by the diagram name:

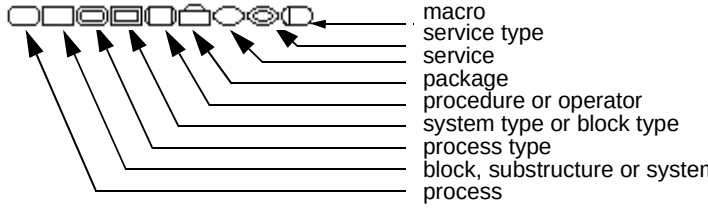

Figure 424: Diagram type symbols (graphical notation **on UNIX***)*

The textual notation reads `<diagramtype diagramname>`

All information that is listed after a diagram identifier is related to that diagram, until the next diagram identifier or separator.

Gate

In the graphical notation **on UNIX**, gates are identified by an arrow pointing into or out from the frame, followed by the name of the gate:

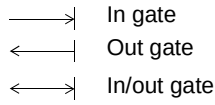

Figure 425: Gate symbols (graphical notation **on UNIX***)*

The textual notation reads:

```
GA <Gatename>:<In>|<Out>|<In:Out>
```

Signals on a gate are the lines that appear after the gate and before the next gate, channel, signal route or diagram identifier. The lines consist of all signals or signal lists that are conveyed on the gate, the signals sent to the diagram appearing first and the signals sent from the diagram appearing last.

Signals are listed according to the order of appearance in the respective signal lists.

If you select a gate in the list, one or two lines is displayed in the signal definition list. In the case of a bidirectional gate, the first line holds the signals sent to the diagram while the second line holds the signals sent from the diagram.

Channel

In the graphical notation **on UNIX**, channels are identified by an arrow between the frame and a block symbol (in the case of a channel to/from the environment), alternatively with an arrow between two block symbols (an internal channel):

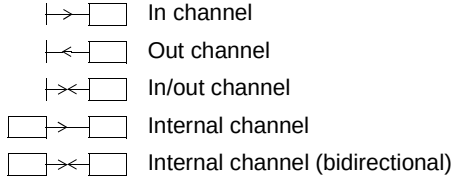

Figure 426: Channel symbols (graphical notation **on UNIX***)*

The textual notation of a channel is:

```
CH <Channelname>:<In>|<Out>|<In:Out>|<Int>|<Int:Int>
```

Channels are present on package, system, block, block substructure and system type diagrams only.

The lines of information that follow a channel consist of the signals that are conveyed on it. The appearance is similar to listing signals on a gate. See "Gate" on page 1998 for information about listing order.

Signal Route

In the graphical notation **on UNIX**, signal routes are identified by an arrow between the frame and a process symbol (a channel to/from the environment), alternatively with an arrow between two process symbols (an internal signal route).

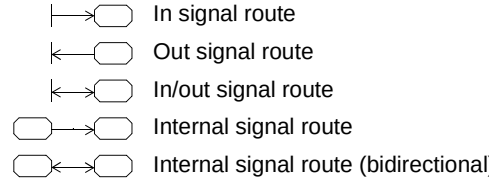

Figure 427: Signal route symbols (graphical notation **on UNIX***)*

The textual notation of a signal route looks like this:

```
SR <Signalroutename>:\
<In>|<Out]>|<In:Out>|<Int>|<Int:Int>
```

Signal routes are present on block and block type diagrams only.

The lines of information that follow a signal route consist of the signals that are conveyed on it. The appearance is similar to listing signals on a gate. See "Gate" on page 1998 for information about listing order.

Signal and Signal List

Signals and signal lists can appear in the following contexts:

- Signal Definitions (i.e. declarations in text symbols)
- Signal References on Lines (i.e. references in gates, channels and signal routes)

- Signal References in Flow Diagrams (i.e. references in flow diagrams; processes, process types and procedures).

The notation that is adopted differs slightly depending on the context.

A **signal definition** appears directly after the diagram identifier where the signal is declared. The signal is identified by its name and its location to distinguish it from other items.

The indentation is filled with blank space (see Figure 428).

```
System AccessControlOOA
     CloseDoor
     ReadCard
     ReadCode
```

Figure 428: Signal definitions

Note:

Each signal appears only once within a diagram. If a signal is referenced at least once within the diagram, it is not listed in the signal definitions section for that diagram, only references are listed.

A **signal reference** on a line uses a similar notation as for signal definitions. The indentation consist of an arrow that identifies the direction of the signals (see Figure 429).

```
lprc:Int:Int
-->- ValidateCard
-->- ValidateCode
-<-- StopValidate
```

Figure 429: Signal references on a line

Signal references in flow diagrams are listed along with the context the signal is used. This is indicated by the following attributes (multiple attributes can be set):

- Input[1]
- Output
- Reference to an undefined signal.

1. Save of signal is also considered as input by the Signal Dictionary function.

In the graphical notation **on UNIX**, these attributes are shown using SDL input and SDL output symbols, and a question mark for showing that the signal is not declared:

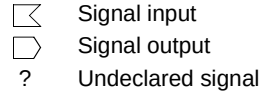

Figure 430: Signal symbols (graphical notation **on UNIX***).*

The textual notation uses the characters:

```
[I][O][?]
```

These characters appear at fixed positions. Where an attribute is not set, this is indicated with a hyphen (‘-’). See Figure 431.

```
IO?- Undefined
```

Figure 431: An undeclared signal which is input and output

Timer

A timer is handled identically as described in “Signal and Signal List” on page 1999. To indicate that the item is a timer, the graphical notation **on UNIX** uses the MSC symbol for timer.

Figure 432: Timer symbol (graphical notation **on UNIX***).*

In the textual notation, a ‘T’ appears as the rightmost attribute.

Timers can appear in the following contexts:

- Definitions of timers
- Set statements
- Reset statements
- Active statements.

Error Notification

If the SDL Suite fails in extracting signal information from some SDL diagrams, the information contained in that diagram is not available to the signal dictionary function.

In the graphical notation **on UNIX**, this is indicated in the signal list by a “bug” symbol located to the right of the diagram names.

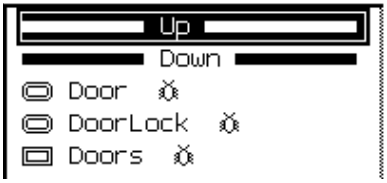

Figure 433: Errors were detected when extracting signals (graphical notation **on UNIX***)*

The SDL Suite failed in extracting signal information from the process type diagrams Door, DoorLock and the block type diagram Doors (one level down in the SDL hierarchy)

In the textual notation, this is indicated by an error message following the diagram name:

```
<diagramtype diagramname> :GrPrError
```

```
######## This ########
Process Type Door :GrPrErr
```

Figure 434: Errors were detected when extracting signals

The current diagram (This diagram) is process type Door. The SDL Suite could not convert this diagram to SDL/PR.

These error situations are either caused by:

- Syntactically incorrect SDL which causes the SDL Suite to fail when converting the SDL/GR diagram to SDL/PR.
- Syntactically incorrect SDL which causes the information server to fail when parsing the contents of the SDL/PR file. When possible, the signal definition field will contain a graphical reference to the source of error. Double-clicking that graphical reference will display the source of error in an SDL Editor window.

The error reports are listed in the Organizer low window. See also “Signal Dictionary Update” on page 1984.

The Signal Definition

The signal definition contains the following information:

- If a signal or timer is selected in the signal list, the signal or timer is listed with its parameters (see Figure 435).

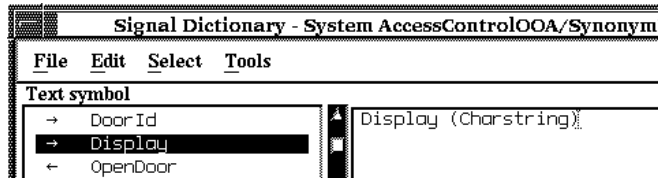

Figure 435: Selection of a signal

The signal Display is selected. The signal definition shows the signal along with its parameters - one parameter of type Charstring in the example.

- If a channel, signal route or gate is selected, the signal definition holds one or two lines of information. Each line contains a list of all signals that are conveyed (see Figure 436).
  - The first line contains the signal list to the parent diagram
  - The second line contains the signal list from the parent diagram.

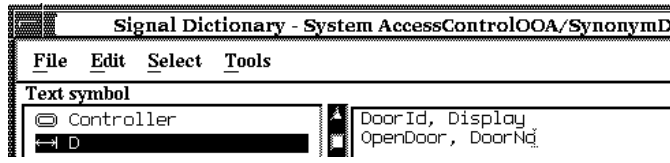

Figure 436: Selection of a gate

The gate D, which is an in/out gate is selected. The signal definition shows one line with all in-signals (Door, Display) and one line with all out-signals (OpenDoor, DoorNo) in relation to the parent diagram (Controller)

- If a signal list[1] is selected, the signal definition holds one line of information containing a list of all signals contained in the signal list. The syntax is

```
SignalListName = Signal1, Signal2,...,SignalN
```

1. A signal list is identified with its name within parentheses, such as `(SignalListName)`

Menu Bars

The SDL Editor's menu bar provides commands available in menus and menu choices for editing diagrams and pages of diagrams. Most of the functionality that the SDL Editor offers is contained within the commands from the menu bar. The menu bar provides the following menus:

- *File Menu*
- *Edit Menu*
- *View Menu*
- *Pages Menu*
- *Diagrams Menu*
- *Window Menu*
- *Tools Menu*
- *Help Menu*

The *File* menu is described in "File Menu" on page 8 in chapter 1, *User Interface and Basic Operations* and the *Help* menu in "Help Menu" on page 15 in chapter 1, *User Interface and Basic Operations*.

In addition, other menus may appear; one is the *Simulator* menu which appears when you set breakpoints in the SDL Editor (see *"Connect-To-Editor" on page 2150 in chapter 49, The SDL Simulator*).

Edit Menu

The *Edit* menu provides editing functions that you can perform on the objects in the drawing area. The *Edit* menu functions that are available differ depending on the type of diagram you edit, either:

- *Interaction Diagrams*
- *Flow Diagrams*
- *Overview Diagrams*

The *Edit* functions are as follows:

- *Undo*
- *Cut*
- *Copy*
- *Paste*
- *Insert Paste* (available on flow diagrams only)
- *Paste As*
- *Clear*
- *Collapse/Expand*

- *Redirect*
- *Bidirect/Unidirect*
- *Class...*
- *Flip*
- *Split Text*
- *Dash/Undash*
- *Mark as Important/Mark as Detail*
- *Mark Types...*
- *Drawing Size*
- *Select All*
- *Insert signal*
- *Complete Word*
- *Select Tail* (available on flow diagrams only)
- *Symbol Border Color > Set Color...*
- *Symbol Border Color > Set Default*
- *Symbol Border Color > <Color>*
- *Symbol Border Color > List All Colors...*
- *Symbol Fill Color > Set Color...*
- *Symbol Fill Color > Set Default*
- *Symbol Fill Color > <Color>*
- *Symbol Fill Color > List All Colors...*
- *Symbol Visibility > Hide*
- *Symbol Visibility > Show*
- *Include Expression*

Undo

With this command you restore the content of the drawing area to its state prior to the operation you performed most recently. It is only available for operations on symbols, lines and text attributes. You can undo the following operations:

- *Cut*, *Paste* and *Clear*
- *Flip*, *Redirect*, *Bidirect/Unidirect*
- *Adding Symbols*
- *Moving Symbols*
- *Resizing Symbols*
- *Drawing Lines*
- *Re-Routing and Reshaping Lines*
- *Resizing a Page*
- *Tidy Up*.

Note: Undo for text editing

You can undo text editing operations in the text window, such as *Import*, *Cut*, *Paste*, and *Clear*. There is also an *Undo* function available for text entered via the Grammar Help or Signal Dictionary functions. See "Undo" on page 2030.

Note: Undo for Class Symbols

If a class symbol is cut and thus also cleared, *Undo* will be enabled. If the Undo command is used, operators will be restored, including their body code.

Cut

This command removes the current selection from the drawing area or text window, and saves it in the clipboard buffer. Also see "Deleting an Object" on page 461.

In text editing mode the command will work on the current text selection.

Copy

This command makes a copy of the current selection, and saves it in the clipboard buffer.

In text editing mode the command will work on the current text selection.

Paste

This command inserts the contents of the clipboard buffer into the drawing area or text window.

No lines will be drawn between the pasted symbols and the symbols already present in the drawing area.

You can interrupt the *Paste* operation by pressing `<Esc>`.

Also see "Pasting an Object" on page 461.

In text editing mode the text contents from the clipboard buffer will be inserted at the current text insertion point.

Note: Cut, Copy and Paste for Class Symbols

When a class symbol is cut or copied, defined body codes are saved on the clipboard, along with their operators. When a class symbol is pasted, previously copied body codes are inserted as well, unless an operator already has defined another body code.

If any operator will be deleted as a result of the operation, a warning is shown, the command is canceled and a dialog similar to the one in "Cutting, Copying and Pasting Class Symbols" on page 1917 is shown.

Insert Paste

This function has the similar functionality as the *Paste* function, but is only available for **flow pages**. It inserts necessary space after the selected symbol before pasting the clipboard buffer and connecting the two flows.

The function requires that the clipboard is not empty and that you have selected exactly one symbol or line. Otherwise, the menu choice is dimmed. The menu choice is also dimmed if connecting the two symbol flows would violate the Z.100 syntax rules.

The functionality differs depending on if you have selected a symbol or a line. If you have selected a symbol the pasted symbols are inserted following the selected symbol. If for example you have selected a decision, the Insert Paste command will create a new branch. Also if a line following the selected symbol joins another line and the selected symbol only can have one follower, the inserted symbols will be placed following both the lines.

If you have selected only a line the pasted symbols will be inserted onto that line. For example if a line following a decision is selected, the inserted symbols will be inserted into the selected decision branch.

Before inserting the selection, the SDL Editor allocates the necessary space by pushing the required objects downwards. If this is not possible, a dialog is displayed.

- Clicking *Increase Page* in the dialog transfers control to the *Drawing Size* dialog, where you can specify the new width and height of the SDL page. The SDL Editor then carries on the operation and inserts the selection.

Paste As

Pastes the currently copied object (from the OM or Text Editor) as an SDL object in the drawing area. The object is transformed and a link is optionally created between the copied and pasted objects.

The *Paste As* dialog is opened. See "The Paste As Command" on page 448 in chapter 9, *Implinks and Endpoints* for more information.

Clear

This command removes the current selection from the drawing area or text window. The content of the clipboard buffer is not affected by this menu choice.

Also see "Deleting an Object" on page 461 in chapter 9, *Implinks and Endpoints*.

In text editing mode the current text selection will be removed.

> **Note: Deleting Class Symbols**
>
> When deleting a class symbol, a warning dialog is shown if an operator will be deleted as a result of this operation. See "Cut, Copy and Paste for Class Symbols" on page 2007.

Collapse/Expand

This command is available for symbols that can be clipped. These are the package reference symbol, additional heading symbol, text symbol, comment symbol and text extension symbol. A collapsed symbol has the minimum size and an expanded symbol will automatically adjust its size to the text.

Redirect

This command changes the direction of a selected channel, signal route or gate. The new direction is denoted by changing the orientation and position of the arrow, leaving the arrowhead pointing in the opposite direction. Subsequent redirections result in the signal list toggling between two directions.

Note:

The **only** way to draw a channel **from the environment to a symbol** is to:

1. Draw a channel from that symbol to the environment
2. *Redirect* the channel.

Bidirect/Unidirect

This command changes the selected channel, signal route or gate to be bidirectional/unidirectional. The Bidirect command will generate a new arrowhead and an empty signal list. The Unidirect command will show a dialog asking what signal list that should be kept.

Class...

This command opens up the *Browse & Edit Class Dialog*. The command is available only when a single class symbol has been selected. The command is not available if the class name contains incorrect syntax.

Flip

This command creates a vertically symmetrical copy of the symbol(s) you have selected. It is valid on the following symbols only:

- Input symbol
- Output symbol
- Priority input symbol
- Text extension symbol
- Comment symbol

The flow lines connected to a mirrored text extension symbol or comment symbol are redrawn in order to reconnect them to the opposite side.

Split Text

This command splits the text from a symbol and its associated text extension symbol (if any) into two parts, where the first part is placed in the symbol itself, and the second part in an associated text extension symbol. The split is done where the text insertion marker is, in the selected symbol.

To place all text in an associated text extension symbol, place the text insertion marker first in the text for a normal symbol and invoke this operation.

To remove an existing text extension symbol associated with a normal symbol, place the text insertion marker last in the text extension symbol and invoke this operation.

Dash/Undash

A dashed reference symbol is used in an SDL subtype when referring to an object that is defined elsewhere in one of the supertypes of the current subtype.

In a similar fashion, a dashed gate indicates that the gate is already defined in one of the supertypes in the inheritance chain.

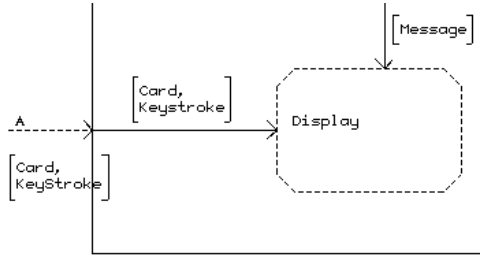

Figure 437: A dashed process reference symbol and a dashed gate

The *Dash/Undash* command is available on the following diagrams:

- *System Types*
- *Block Types*
- *Process Types*
- *Service Types*

The Undash is a toggle command.

Note that a symbol cannot be dashed if there are syntax errors in the name attached to the symbol. Also if a syntax error is introduced in a dashed symbol the symbol will automatically be undashed.

Mark as Important/Mark as Detail

In the high-level view, only symbols which are marked as “important” will be shown. For more information, see “Show High-Level View/Show Detailed View” on page 2015.

Symbols that are marked as “important” will be shown with border and fill colors different from ordinary symbols. These colors can be changed through the Preference Manager.

The Mark as Detail command sets the view status of a symbol to “normal”, meaning that it will only be shown in the detailed view.

Mark Types...

This command brings up a dialog with a list of symbol types. The selected symbol types will be visible in the high-level view, while unselected symbol types will only be visible in the detailed view.

Drawing Size

This menu choice sets the size of the *drawing area* for the current SDL page. A dialog is issued where you can type in the width and height. The values are saved on file when you save the diagram.

> **Note:**
>
> Enlarging the drawing, the current SDL page may not fit any longer into the paper that is defined with the Print preferences; the result may be an SDL page that requires multiple sheets of paper when printed.

Select All

This command selects all of the text contained in the text window or all objects within the drawing area.

Insert signal

When an input or output symbol is selected this menu-choice will show a sub-menu with a list of signals available to the system. If an input symbol is selected it will list input signals and if an output symbol is selected output signals will be listed. Selecting a signal will place it in the symbol.

Complete Word

> **Note:**
>
> You can also complete a word by having the mouse pointer in the drawing area and pressing the tab key, provided that the preference Editor**TabEqualsCompletion* is true.

Word completion helps you complete long words that have already been used in the same context. Type the beginning of the already used word and invoke word completion to get the rest of the word. If there are several ways to complete the word, the word completion operation will initially give you the common part of the possible completions. If you invoke word completion again, you will get one of the alternatives. To get another alternative, invoke word completion once more.

Word completion takes the word closest to the current cursor position and tries to complete that word by adding characters at the end of the word.

The word completion operation uses the following sources to look for already used words:

- The current diagram page.
- Pages in the beginning of the diagram. The number of pages that the word completion operation examines is determined by the preference Editor**CompletionMaxPages*.
- The names of entities listed in any running index viewer. This makes it possible to reuse names from other diagrams than the current diagram.
- All words listed in the file .../sdt/include/keywords/sdl.txt in the installation. As default, this file contains SDL keywords.

Select Tail

This command selects the currently selected symbol and all objects beneath it within the tree (following the flow lines).

Symbol Border Color > Set Color...

This command calls the color dialog where it is possible to set a custom color for the selected objects.

Symbol Border Color > Set Default

This command restores the default color for the selected objects. Default color for Symbol borders are set by the Preferences.

Symbol Border Color > <Color>

This command sets <Color> for the selected objects. Default available choices are Black, Blue, Green, Cyan, Red, Magenta, Yellow, and White. Custom colors are added to the menu when they are first used. The most recently used color is moved to the top of the list.

Symbol Border Color > List All Colors...

This menu choice becomes available when a maximum of 20 used colors has been surpassed. When you select *List All Colors* a dialog is issued containing all colors that has been used in the current SDL Editor session and you have the possibility to set them for the selected objects.

Symbol Fill Color > Set Color...

This command calls the color dialog where it is possible to set a custom color for the selected symbols.

Symbol Fill Color > Set Default

This command restores the default color for the selected symbols. Default fill color is set by the Preferences.

Symbol Fill Color > <Color>

This command sets <Color> for the selected symbols. Default available choices are Black, Blue, Green, Cyan, Red, Magenta, Yellow, and White. Custom colors are added to the menu when they are first used. The most recently used color is moved to the top of the list.

Symbol Fill Color > List All Colors...

This menu choice becomes available when a maximum of 20 used colors has been surpassed. When you select *List All Colors* a dialog is issued containing all colors that has been used in the current SDL Editor session and you have the possibility to set them for the selected symbols.

Symbol Visibility > Hide

This command hides the selected symbols. The hidden symbols will be replaced with a thick vertical line. The flow line structure will not be altered. The [Screen, Print]Z100Symbol preferences makes the replacement line as this as the flow line. See also *Show hidden symbols* and *Include Expression*.

Symbol Visibility > Show

This command restores the selected symbols.

Include Expression

This command displays a dialog, where it is possible to specify the include expression that is presented above the top left corner of a symbol, for the selected symbols.

The include expression is a name of a boolean variable (or external synonym). The value of the include expression is checked before analyzing an SDL system, when SDL/GR is converted to SDL/PR. Only those symbols that...

- have no include expression
- have an include expression that evaluates to true

...are included in SDL/PR and are visible for the analyzer and the code generator.

As default, all boolean variables have a value of false. To change a boolean value to true, an external synonym file (a plain text file with extension *.syn) must be created and placed close to the SDL system in the Organizer. The external synonym file closest to the SDL system will be used. An external synonym file contains lines of name value pairs. For instance:

```
DEBUG true
VERSION1 false
VERSION2 true
```

Note that all lines going to a symbol that is removed, will also be removed. An exception to this rule is that flow lines going to a symbol that will be removed, are reconnected to the first following symbol that will not be removed, if there is one and only one such symbol.

It is also possible to decide if SDL/GR symbols should be included or excluded in SDL/PR by hiding symbols. See "Analyze" on page 112 in

chapter 2, *The Organizer*, Symbol Visibility > Hide and Symbol Visibility > Show.

View Menu

The *View* menu provides rescaling functions and access to various options that affect the behavior of the SDL Editor.

The following menu choices are available in the *View* menu:

- *Set Scale*
- *Show High-Level View/Show Detailed View*
- *Temporary Colors > Remove*
- *Temporary Colors > Make Permanent*
- *Window Options*
- *Diagram Options*
- *Editor Options*

Set Scale

Issues a dialog where you can adjust the scale.

Show High-Level View/Show Detailed View

The high-level view shows only symbols which are marked as “important”, whereas the detailed view shows all symbols (normal view). This makes it possible to work with a less detailed version of the SDL diagrams.

By selecting the high-level view, only symbols which are either marked as “important”, or belong to one of the types selected in the Mark Types dialog, will be visible. Also, a tidy up operation will be performed, and the diagram will be read-only - all editing has to be done in the detailed view.

By selecting the detailed view, the diagram is reverted to the original, detailed view, where all symbols can be seen and edited.

Temporary Colors > Remove

Temporary colors are colors that are not saved in the SDL diagram. These colors are used by certain operations, such as SDL trace from SDL simulators and *Compare Diagrams* in the SDL editor, to highlight symbols of interest. Before doing a new operation that relies on color,

it might be useful to remove already existing temporary colors. This can either be done by using this menu choice or by closing down the SDL editor.

Temporary Colors > Make Permanent

Temporary colors are explained in *Temporary Colors > Remove*. This menu choice is used to convert temporary colors into permanent colors that can be saved in diagram files for future use.

Window Options

This menu choice issues a dialog where you set the options that affect the window properties.

- *OK* applies the options as defined in the dialog to the current window only.
- *All Windows* applies the options as defined in the dialog to all windows opened by the SDL Editor.
- *Tool Bar* determines whether the tool bar should be displayed or not.
- *Status Bar* determines whether the status bar should be displayed or not.
- *Symbol Menu* determines whether the symbol menu should be displayed or not.
- *Text Window* determines whether the text window should be visible or not.
- *Page Breaks* determines whether *physical page breaks*, with the appearance of dashed horizontal and vertical lines, should be displayed or not in the drawing area. These page breaks are defined by the print preferences; they show where the print utility will break the diagram into multiple printout pages.
- *Show Grid* determines whether the current symbol grid points are shown as small markers.

Diagram Options

This menu choice issues a dialog where you set the options that affect the editing properties applied on the current diagram.

Interaction and Flow Diagram Options

A dialog with the following options is displayed on interaction and flow diagrams.

- *Use Grid*

  This option determines whether or not the symbols that are added, resized or moved should adhere to the symbol grid or not. By default the symbol grid is active.

  By disabling the symbol grid, the SDL Editor will use the minimum grid of 5 * 5 mm.

- *Layout syntax check*

  This option determines whether the SDL Editor should adhere to the formal SDL syntax rules regarding symbols and the connection of symbols. Ideally the layout syntax check should always be on.

  – Turning syntax checking *off* allows you to insert any symbol displayed in the *symbol menu* into the drawing area. In this mode, symbols can be interconnected in any manner. Furthermore, the connector symbol will always be treated as an inconnector in this mode. Therefore the Analyzer will detect errors when trying to analyze the diagram. To avoid problems turn off the syntax checking only if you want to draw diagrams that never should be analyzed.

Note:

Turning the switch from off to on will **not** perform a retroactive syntax check for not allowed or interconnection of symbols. Only the objects that you add while syntax checking is enabled are checked.

- *Textual syntax check*

  This option determines whether the SDL Editor should perform a syntax check on all the texts in the diagram. Ideally the textual syntax check should always be on.

  – Turning syntax checking *off* disables the textual syntax check except for the kernel heading and the reference symbols which are always checked.

- *Additional Heading only on first page*

This option determines whether the SDL Editor should present the Additional Heading symbol on each page. When the option is on, only the first page in the diagram will show the Additional Heading symbol.

The diagrams options are also saved on file when the diagram is saved.

Overview Diagram Options

A dialog with the following options is displayed on *overview* diagrams.

- *Show line names*

  This option governs whether the names of lines (such as channels and signal routes) should be displayed or not.

- *Show signal lists*

  This option governs whether the signal lists associated to channels and signal routes should be displayed or not.

The diagrams options are also saved on file when the diagram is saved.

Editor Options

This menu choice issues a dialog where you can customize the behavior of the SDL Editor.

The options are controlled by toggle buttons. They are:

- *Always new Window*

  This option indicates whether or not a new window should be opened whenever you select the *New* or *Open* command or any command from the *Pages* menu.

  The default behavior is not to open a new window.

- *Sound*

  This option indicates whether or not improper actions in the SDL Editor, such as attempting to overlap symbols, should be brought to your attention by producing an alert sound.

  The default value for this option is on.

- *Show link endpoints*

This option indicates whether endpoint markers should be displayed for symbols having link endpoints. Regardless of the setting of this option, link endpoints are never shown when printed.

- *Use tab key for word completion*

  See "Complete Word" on page 2012.

- *Show hidden symbols*

  This option indicates whether hidden symbols should be displayed as a vertical line. If this option is selected hidden symbols will be displayed normally but filled with a grid pattern.

- *Use informal view*

  This option sets the editor in Informal mode. In informal mode the content of the symbols is substituted with the content of the attached comment symbol, if any. The comment symbols are hidden. Symbols without an attached comment symbol are displayed normally.

- *Show signal declaration*

  This option decides if the signal declaration including parameters should be shown in the message area when a signal name is selected by clicking on it in the drawing area. Turn this option off if you think it takes too long for the editor to find the signal declaration. There is a preference deciding the default value of this option: Editor*ShowSignalDeclaration.

Pages Menu

The *Pages* menu contains the following menu choices:

- *First*
- *<Page Name>*
- *Last*
- *Add*
- *Edit*
- *Edit Reference Page*

First

This menu choice opens the first page contained in the diagram. The first page is defined according to the order of appearance in the *Edit Pages* dialog. If the page is already opened, its window is displayed.

<Page Name>

Activating the *Page* menu presents up to four menu choices that consist of the names of the two pages that are sequentially right before and after the page you edit. If you edit the first page of the diagram, the next four sequential pages are shown. If you edit the last page of the diagram, the previous four pages are shown.

When you select one of these page names, that page is opened or restored in the SDL Editor. Use the *Edit* menu choice if you want open other pages.

Last

This menu choice opens the last page of a diagram. See "First" on page 2019 for more information.

Add

This menu choice is a shortcut for adding one page to the current diagram. The *Add Page* dialog is issued and when you click *OK* the new page is shown.

Edit

This menu choice opens a dialog where you can *Add*, *Rename*, *Move up*, *Move down*, *Clear*, *Cut*, *Copy* and *Paste* an SDL Page. See "Page Editing Functions" on page 2033.

Edit Reference Page

This menu choice opens (or, if already active, simply restores) the page in the parent diagram where the name of the current page is referred.

This menu choice is dimmed when the current page is one of the pages contained in the Organizer *Root Document* (in which case there is no parent diagram) or the diagram being edited is not known by the Organizer.

Diagrams Menu

The *Diagrams* menu records all diagrams and pages that are opened by the SDL Editor.

- *Back*

- *Forward*
- *<Diagram Name>*
- *List All*

Back

This menu choice opens the diagram that was previously visible in the same window.

Forward

This menu choice opens the diagram that was displayed in the window before you pressed the back button.

<Diagram Name>

The last edited page always goes to the top of the list, and subsequently moves the other diagrams and pages down a position. A maximum of 9 open pages can be shown. A tenth one will be put at the top of the list, but any subsequent opening of a diagram or page will only show the last 9 that have been opened. Another option – *List All* (at the bottom of the list) – is available to list all the open diagrams in the SDL Editor.

Each item in the menu provides information about the diagram type, its name, a slash (‘/’) followed by a page name, a hyphen and, possibly, the file it is stored on. A diagram that is preceded by an asterisk (‘*’) denotes that it has been modified during the SDL Editor session.

List All

This menu choice becomes available when a maximum of 9 open pages has been surpassed. When you select *List All* a dialog is issued containing all diagrams and pages that are currently open in the SDL Editor and you have the possibility to display them.

Window Menu

The *Window* menu contains the following menu choices:

- *New Window*
- *Close Window*
- *Grammar Help*
- *Signal Dictionary*
- *Class Information*

- *Entity Dictionary*
- *<Window Name>*
- *List All*

New Window

This command opens a new window containing a new view on the SDL page contained in the source window from where you selected this menu choice. You can edit the SDL page in any window.

Close Window

This option closes the open window, but, does **not** close the diagram. All but the last open window can be closed, the last one you must close from the *File* menu, possibly in conjunction with saving information (see "Close Diagram" on page 14 in chapter 1, *User Interface and Basic Operations*).

Grammar Help

This menu choice opens the *Grammar Help* window, see "Grammar Help and Signal Dictionary" on page 1971. Its purpose is to assist you in editing SDL textual elements that are correct according to the SDL grammar.

Each SDL Editor window has its associated Grammar Help window.

The SDL Editor tries to open a file with grammar help templates when opening the Grammar Help window (which file to open by default may be specified as an SDL Editor preference). If the file cannot be located, a dialog is issued where you can choose to select it manually. The filter in the file selection dialog will be set to `*.tpl`.

Signal Dictionary

This menu choice opens the *Signal Dictionary* window, see "Using the Signal Dictionary" on page 1983. It gives access to information about what signals are defined in an SDL hierarchy. Each SDL Editor window has its associated Signal Dictionary window.

Class Information

Opens the *Class Information* window. See "Class Information" on page 1942 for more information.

Entity Dictionary

Opens the Entity Dictionary window. See "The Entity Dictionary" on page 434 for more information.

<Window Name>

If more than one editor window is open the other windows are listed here. The behavior of this list will be similar with the diagrams list in the *Diagrams* menu. The only difference is that the menu items will not provide the diagram file information.

List All

This menu choice is available only if more than 9 editor windows are open, and has the same functionality as the *List All* menu command in the *Diagrams* menu.

Tools Menu

The *Tools* menu contains the following menu choices:

- *Show Organizer*
- *Link > Create*
- *Link > Create Endpoint*
- *Link > Traverse*
- *Link > Link Manager*
- *Link > Clear*
- *Link > Clear Endpoint*
- *Search*
- *Spelling > Comments*
- *Spelling > All Text*
- *Tidy Up*
- *Connect to Text Editor*
- *Navigate*
- *Show > Definition of X*
- *Show > Use of X*
- *Show > Definition or Use of X*
- *Show > Next (Definition or Use of) X*
- *Show > Definition of X in Index Viewer*
- *Show GR Reference*
- *Create Bookmark*
- *Compare Diagrams*
- *Merge Diagrams*

- *Add Differences*
- *Generate PR*

Show Organizer is described in "Show Organizer" on page 15 in chapter 1, *User Interface and Basic Operations* and the Link commands are described in "Link Commands in the Tools Menus" on page 442 in chapter 9, *Implinks and Endpoints*.

Search

This menu choice opens a dialog that allows you to search for a text in the current diagram or document in any editor. You can search many diagrams and documents at the same time with this menu choice.

For more information about searching, see "Search" on page 142 in chapter 2, *The Organizer* and "Searching and Replacing Text" on page 1962.

Spelling > Comments

Check the spelling of comments in the current diagram. For more information about the spelling operation, see "Spelling > Comments" on page 147 in chapter 2, *The Organizer*.

Spelling > All Text

Check the spelling of all text in the current diagram. For more information about the spelling operation, see "Spelling > Comments" on page 147 in chapter 2, *The Organizer*.

Tidy Up

This menu choice rearranges the graphical layout of the entire SDL diagram, using default layouting algorithms when calculating the location and size of graphical objects. Before the tidy up operation is started, a dialog appears where you can adjust parameters to the operation:

- *Start transition on new page.* Decides if a state symbol representing the beginning of a new transition should be placed on the same page as already placed symbols, or on a new page.
- *Use extra space after comment and text extension.* Decides if a symbol in a flow, after a symbol with an associated comment or text extension, should be moved below the associated symbol or not.

- *Format input and output text.* Decides if text in input and output symbols should be reformatted or not. If the text is reformatted, the signal name is placed in the symbol, while any parameters are placed in a text extension symbol.
- *Replace textual comments with comment symbols.*
- *Place comment symbols to the left.*
- *No text extension for state.* Decides if text extensions should be used or not if the state name does not fit in the state symbol.
- *No text extension for decision.* Decides if text extensions should be used or not if the decision text does not fit in the decision symbol.
- *Sort states and transitions.* Decides the order state symbols (More precise: state and input symbol combinations) will be presented in the resulting diagram.

Connect to Text Editor

This command issues an external text editor and creates a temporary file from the currently selected text. After this you can only edit the text from the external editor. The SDL Editor is updated every time the external text editor saves the temporary file. When you no longer edit the temporary file the editing control returns to the SDL Editor.

Which external text editor you are to use is defined by the preference SDT*TextEditor.

Navigate

This command navigates to another diagram or to another symbol within the current diagram, depending on the selected symbol. It is available for the following symbols:

- For a reference symbol it will show the diagram being referenced.
- For an instantiation symbol it will show the corresponding type diagram. If there is more than one diagram that matches the type name, a dialog will appear where you can select one of the diagrams.
- For a create request symbol the process diagram for the created process will be shown. If the diagram is ambiguous a selection dialog appears.

- For a procedure call symbol the procedure diagram will be shown. If the diagram is ambiguous a selection dialog appears.
- For a macro call symbol the macro definition will be shown.
- For a state symbol another state or nextstate symbol using the same state name in the same diagram will be shown. A selection dialog will appear if there are more than one occurrence of the name.
- For an inconnector symbol the corresponding outconnector symbol will be shown. If more than one outconnector exists a selection dialog appears.
- For an outconnector symbol the corresponding inconnector symbol will be shown.
- For a class symbol, another class symbol, using the same class name in the same diagram, will be shown. If there is more than one occurrence of the name, a select dialog is shown.

Double-clicking a symbol will have the same effect as using the *Navigate* command. This applies to all navigable symbols, except class symbols.

The *Show* Sub-menu

All menu choices in the *Show* sub-menu require a running index viewer loaded with an up-to-date cross reference file. You can get this for all SDL systems that passes through the SDL Analyzer, by pressing the *Generate Index* quick-button in the Organizer.

Show > Definition of X

This command takes the name of the word closest to the current cursor position as input. If the name represents an SDL entity listed in the index viewer, the SDL Editor will navigate to one of the definitions of that entity. Usually there is only one definition to show, but for states, each state symbol is considered to be a part of the definition and one of them is shown. If you invoke this command once more for the same state name, another state symbol is shown (if there are several).

Show > Use of X

This command takes the name of the word closest to the current cursor position as input. If the name represents an SDL entity listed in the in-

dex viewer, the SDL Editor will navigate to one of the uses of that entity. If you invoke this command once more for the same word, another use of that entity is shown (if there are several uses),

Show > Definition or Use of X

This command takes the name of the word closest to the current cursor position as input. If the name represents an SDL entity listed in the index viewer, a dialog is opened, allowing you to navigate to one of the definitions or uses of that SDL entity.

Show > Next (Definition or Use of) X

This command repeats the last *Show > Definition of X*, *Show > Use of X* or *Show > Definition or Use of X* command using the same word as last time as input.

Show > Definition of X in Index Viewer

This command takes the name of the word closest to the current cursor position as input. If the name represents an SDL entity listed in the index viewer, the index viewer tool is popped up and this entity is selected.

Show GR Reference

This command issues a message where the graphical SDT reference for the object you have currently selected is displayed.

The syntax of the graphical references used in the SDL Suite environments described in chapter 18, *SDT References*.

Create Bookmark

This command creates a bookmark in the Organizer for the object you have currently selected.

Compare Diagrams

With this menu choice you can compare the contents of two SDL diagrams. See “Comparing and Merging Diagrams” on page 2036.

Merge Diagrams

With this menu choice you can compare the contents of two SDL diagrams and create a new diagram by merging the two SDL diagrams. See "Comparing and Merging Diagrams" on page 2036.

Add Differences

With this menu choice you can merge two SDL diagram versions into one. The SDL diagram that is visible in the editor when the operation is invoked will be updated with information from the other version, for all differences. Symbols from the other diagram might be placed slightly to the left of the original place, to avoid overlapping symbols.

Differences are marked with temporary color, except for complete page differences when a complete page is missing in the other diagram. The reason for this is to support merging of a complete diagram (the SDL diagram in the editor) with diagram parts (containing a subset of all pages in the complete diagram) that might be slightly different.

In the *Add Differences* dialog, it is possible to specify the other diagram to compare with, either by specifying a file name or by specifying another editor buffer. The *Add Differences* dialog also makes it possible to specify the temporary colors to use for highlighting differences.

Generate PR

This command will generate SDL/PR/CIF for the current diagram. A dialog with the following options appears:

- *PR file*

  The name of the PR/CIF file to create.

- *Generate GR references*

  This option will generate GR references that can be used to trace the PR code back to the GR diagram.

- *Generate CIF*

  CIF is the standard defined in ITU recommendation Z.106 to be used when transferring SDL/GR diagrams preserving the graphical layout. With this option set, CIF comments will be generated together with the PR.

The *File* Menu of the Text Window

The *File* menu provides functions that transfer text from a file to the text window and vice-versa. The basic intention is to provide you the possibility to edit larger portions of text with a more suitable text editor (for instance signal definitions in text symbols). Another possibility to edit text externally is to use the *Connect to Text Editor* command in the *Tools* menu.

Import

Import imports the contents of a file into the text window and inserts the contents of the file at the text cursor position, possibly replacing selected text in the text window. In the file selection dialog, the filter is set to `*.txt` by default.

Export

Export exports the selected text to a file. If no text is selected in the text window, the entire text window contents will be exported to the file. In the file selection dialog, the filter is set to `*.txt` by default.

Menu Bar in Grammar Help Window and Signal Dictionary Window

These menu bars contains the following menus:

- *File Menu*
- *Edit Menu*
- *Select Menu*
- *Tools Menu*

File Menu

The *File* menu contains menu choices that access files that contain *SDL Grammar Help templates*.

These commands are useful only when requesting Grammar Help support.

Load

This command opens a file selection dialog, where you can select and load the file with grammar help definitions.

Grammar template files normally have the file extension `.tpl`. With the SDL Suite, a standard template file, `sdt.tpl`, is enclosed. The SDL Editor attempts to locate a `.tpl` file each time you invoke the *Load* command.

Any template definitions that are already loaded will be replaced by the contents of the selected grammar help definition file.

Merge

Merge extends the current loaded grammar definitions with the contents of a grammar help definition file.

This command issues a file selection dialog, in which you can select and add a set of custom templates to the basic set provided in the SDL Suite.

Any template definitions that are already loaded will be extended with the contents of the merged template definition file.

Edit Menu

The *Edit* menu provides two utility functions that you can use when copying text from the *Grammar* window or the *Signal Dictionary* window to the SDL Editor's text window.

Undo

You can revert changes with the *Undo* command.

Insert

This menu choice copies the entire contents of the *Grammar* field or the signal definition and copies it into the text window at the current I-beam cursor location. Selected text will thus be overwritten.

A shortcut for *Insert* is to double-click on the template name in the name field.

Replace

This command replaces the contents of the text window with the contents of the *grammar field*. This function is a shortcut for the following sequence:

- "*Select All, Clear* and *Insert*" **(Grammar Help)**

- "*Select All* and *Insert*" **(Signal Dictionary)**

Select Menu

The commands on the *Select* menu define what functionality the *Grammar Help* window and the *Signal Dictionary* window should provide.

Each of the options can be individually turned on and off. In addition, an *Options* menu choice (see "Options" on page 2032) allows you to enable and disable multiple options in one command only.

The options that are currently enabled are indicated by an asterisk ('*') preceding the corresponding menu choice.

When you invoke the Grammar Help, the *Grammar* option is enabled, while the remaining options are disabled.

These functions restrict or extend the scope of search for signals. The Signal Dictionary functionality can be extended to provide access to MSC Messages and an external signal library.

Grammar

This toggle option, when set to on, will enable the SDL Grammar Help function.

Up

This toggle option enables the *Up* option provided in the Signal Dictionary window. This option displays the SDL signals that are available when looking one level up in the SDL hierarchy.

This

Turning *This* on lists all signals that are used in the current diagram.

Down

This option displays the SDL signals that are available when looking one level down in the SDL hierarchy.

All

This option displays all signals that are defined and are visible according to the SDL scope rules, starting from the root document (see "Root

Document" on page 42 in chapter 2, *The Organizer*) in the SDL System Structure chapter.

MSC

This option displays all messages that are available in the Message Sequence Charts that are submitted as input to the Signal Dictionary function. Each message is mapped to an SDL signal, with its parameters mapped to SDL signal parameters.

An MSC is submitted as input to the Signal Dictionary if associated to an SDL diagram that is present in the Organizer's diagram structure.

External

This option displays all signals that have been imported from an external signal dictionary. Importing external signals is done through the Public Interface. See *"Load Definition File" on page 627 in chapter 11, The Public Interface*.

Options

Issues a dialog where you can turn on and off all options individually (see "Select Menu" on page 2031 for a description of the options).

The default options for the Signal Dictionary are *Up* and *Down*.

Tools Menu

The Tools menu provide various convenience functions.

Show Editor

This command displays the parent SDL Editor window.

Show Definition

An SDL Editor comes up showing the definition of the item which is selected in the signal list.

Page Editing Functions

When you select *Edit* from the *Pages* menu, the *Edit Pages* dialog will be opened. In this dialog, you can add, rename, clear, cut, copy and paste an SDL page. The items in the dialog will be described below:

The Page List

This list includes all SDL pages in the SDL diagram. The operations available in the dialog, are only possible to perform if a page is selected in this list.

Edit

This button opens the selected page in the SDL Editor.

Cut

This button removes the selected SDL page from the diagram and saves it in the clipboard buffer. The information in the Organizer that is dependent on this page, will also be removed.

If the page contains reference symbols and these have an underlying structure in the Organizer this structure will be restored when you paste the page in a new position. See "Cutting, Copying and Pasting Reference Symbols" on page 1917.

The button is dimmed if the object you have selected is not an SDL page.

Copy

This button copies the selected page to the clipboard buffer.

The button is dimmed if the object you have selected is not an SDL page.

Paste

This button pastes a previously cut or copied page into the current diagram.

The *Paste* button will be dimmed if:

- The clipboard buffer is empty.
- The current clipboard contents would lead to a syntax violation in the target diagram.

The SDL Editor checks that the contents of the page are syntactically correct. If required a warning will be issued. Then a new dialog is displayed, where you should assign the page a new name. You can specify:

- The new name of the page (two pages with the same name are not allowed within a diagram)
- Possibly, an autonumbered name (see "The Autonumbered Option" on page 2036)
- If the new page should be pasted before or after the current page

Clear

This button removes the selected SDL page from the diagram. A confirmation dialog will be issued before the page is removed, and the SDL Editor will automatically rename autonumbered pages.

Caution!

As stated in the dialog, *Clear* on a page cannot be undone.

If the page contains reference symbols and these symbols have a substructure, this substructure will be removed from the Organizer. As there is no undo for the *Clear Page* command, a warning will be issued and it is possible to keep the substructure as a new hierarchy instead.

Move up

If an SDL diagram page is selected and you click the *Move up* button, the page will be moved up.

Note:

The undo function in the Organizer and in the SDL Suite will have no effect on page moves. It is, however, easy to undo a page move operation by just moving the page back again.

Move down

If an SDL diagram page is selected and you click the *Move down* button, the page will be moved down.

> **Note:**
>
> The undo function in the Organizer and in the SDL Suite will have no effect on page moves. It is, however, easy to undo a page move operation by just moving the page back again.

Add

This button opens a dialog where you can change some settings before new page is created:

- If autonumbering is turned off, you may specify any pagename, which must be in keeping with SDL conventions. If two pages are given the same name X the names will automatically be renamed to X_1 and X_2. The enumeration character can be chosen by the Editor preference Page*EnumerationCharacter.
- If autonumbering is on (the default), the page is automatically named using the next available sequential number within the diagram (1, 2, etc).
- If the page is to be inserted before of after the current page.
- If you add a page to a process or process type diagram, you can select if the new page should be a graph page (the default) or a service interaction page.
- If you add a page to a block or block type diagram, you can select if the new page should be a block interaction page or a process interaction page.

New pages are listed in the same order that they were added.

Rename

This button opens a dialog where you can rename the selected SDL page. If the page is part of a block or block type diagram, you can also change the page type (process interaction page or block interaction page) in this dialog.

Autonumbered pages cannot be renamed, unless you turn the option *The Autonumbered Option* off first.

The *Autonumbered* Option

If the option *Autonumbered* is on, a numeric name (1, 2, etc) will be applied to the selected page. In a dialog, you can select to auto-number the selected page or all pages in the diagram.

The *Open This Page First* Option

If the option *Open This Page First* is on, the selected page will be the page that will be displayed by default when you open the diagram. Only one page at the time can have this option set.

Comparing and Merging Diagrams

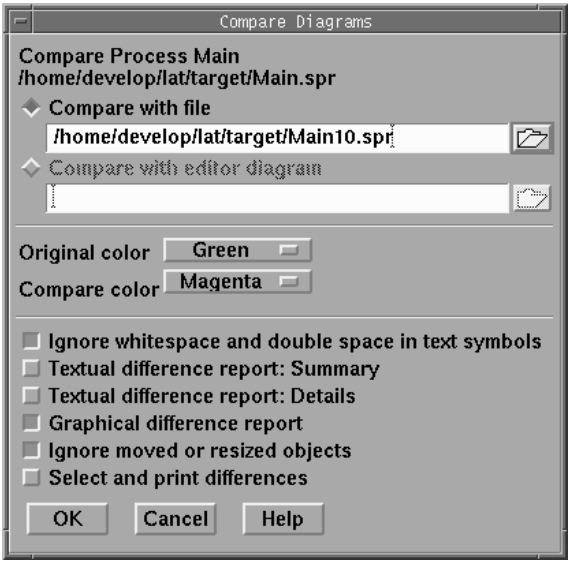

Figure 438: The Compare Diagrams dialog

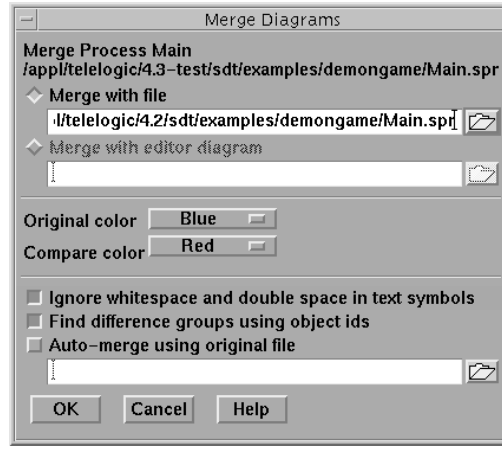

Figure 439 The Merge Diagrams dialog

When you select *Compare Diagrams* or *Merge Diagrams* from the *Tools* menu, a dialog will be opened where you can select the SDL diagram to compare with. (It is also possible to compare more than one diagram pair in one operation, but to do this you should use the corresponding menu choices in the Organizer. See "Compare > SDL Diagrams" on page 148 in chapter 2, *The Organizer* and "Merge > SDL Diagrams" on page 151 in chapter 2, *The Organizer*.

Specifying the Diagram to Compare With

There are two ways for specifying the diagram that should be compared with the currently displayed diagram:

- You may specify the file in the *Compare with file* field.
- You may specify another diagram already opened the SDL Editor in the *Compare with editor diagram* field. When you click the folder button, a dialog will be opened with a list of all diagrams opened in the SDL Editor (except for the currently displayed).

The option *Compare with editor diagram* has the two restrictions:

– It can only be used if more than one diagram is opened in the SDL Editor.

– The folder button can only be used if more than two diagrams are loaded into the SDL Editor.

Selecting the Report Type

In the Compare Diagrams dialog, there are six alternatives for reporting differences between diagrams: *Ignore white space and double space in text symbols*, *Textual Difference Report: Summary*, *Textual Difference Report: Details*, *Graphical Difference Report (with Merge Facility)* and *Select and Print Differences*.

The Merge Diagrams dialog does not allow you to get a textual difference report. Instead, you always get a graphical difference report and the only option available is *Auto-merge using original file*.

Ignore white space and double space in text symbols

When this option is on, differences caused by different usage of white space are ignored when comparing texts. One space character is considered equal to two space characters.

Textual Difference Report: Summary

This option is only available when comparing using the *Compare Diagrams* menu choice.

A summary of how many differences that has been found is presented in the Organizer log. The summary may look like this:

```
Comparing /home/lat/x.spr
     with /home/lat/y.spr
27 differences (16 symbols, 11 lines) :
  7 changed objects (7 symbols, 0 lines)
  13 removed objects (6 symbols, 7 lines)
  7 added objects (3 symbols, 4 lines)
```

When you read this report, notice the following:

- 27 is the total number of found differences in this diagram pair. This is the total of all changed, removed and added objects.

- An object is considered to be changed if you have moved or resized it, or if you have changed a text associated with the object.

If at least one of the two compared diagrams has more than one page, then a summary is also presented for each page pair. It may look like this:

```
Comparing /home/lat/version1/registeredcard.spt
     with /home/lat/version2/registeredcard.spt
5 differences (1 symbol, 4 lines) :
  1 changed object (1 symbol, 0 lines)
  2 removed objects (0 symbols, 2 lines)
  2 added objects (0 symbols, 2 lines)

Page details:

Page ValidateCard
5 differences (1 symbol, 4 lines) :
  1 changed object (1 symbol, 0 lines)
  2 removed objects (0 symbols, 2 lines)
  2 added objects (0 symbols, 2 lines)

Page RegisterMode
0 differences
```

Textual Difference Report: Details

This option is only available when comparing using the *Compare Diagrams* menu choice.

This option will print information about each found difference in the Organizer log. This makes it possible to navigate from the Organizer log to every found difference by using the *Show Error* operation in the Organizer log. See "Organizer Log Window" on page 183 in chapter 2, *The Organizer*.

The detailed textual difference report may look like this:

```
Comparing /home/lat/d1/db.sbk
     with /home/lat/d2/db.sbk

Comparing page 1

#SDTREF(SDL,/home/lat/d1/db.sbk(1),119(50,35))
ERROR This symbol has been changed...
#SDTREF(SDL,/home/lat/d2/db.sbk(1),119(50,40))
ERROR ...and now looks like this.

#SDTREF(SDL,/home/lat/d1/db.sbk(1),176(95,60))
ERROR This symbol has been removed.
```

```
#SDTREF(SDL,/home/lat/d2/db.sbk(1),182(60,60))
ERROR This line has been added.
```

Graphical Difference Report (with Merge Facility)

The merge facility is only available when merging with the *Merge Diagrams* menu choice, but you can get a graphical difference report both when comparing with the *Compare Diagrams* menu choice and when merging with the *Merge Diagrams* menu choice.

Two SDL Editor windows, named *Source 1* and *Source 2*, displaying the two diagram versions and their differences, and one dialog will be opened. For merge, there will be a third SDL Editor window, named *Result*, showing the merge result.

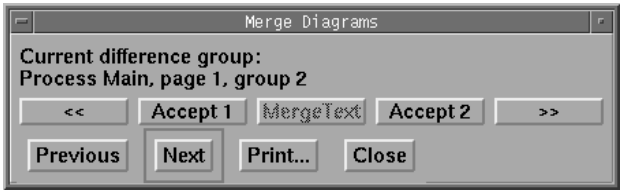

Figure 440: The Merge Diagrams dialog

The Compare Diagrams dialog is similar to the Merge Diagrams dialog. The difference is that the Compare Diagrams dialog is missing the first row of buttons. (“<<“, Accept1, Accept2 and “>>”.)

In the dialog that will be opened, you can:

– Navigate between difference groups with the *Next* and *Previous* buttons.

– (*Merge Diagrams* only.) Navigate between unresolved (not-yet merged) difference groups with the “<<“ and “>>” buttons.

– (*Merge Diagrams* only.) Do a merge, i.e. update the merge result diagram with information from the current difference group

and one of the compared diagram versions, with the *Accept1/Reject1* and *Accept2/Reject2* buttons.

- Compare or merge a text in a text symbol in the current difference group.
- Print the current difference found in the current page pair.

When the second compare dialog is closed, the editor windows are restored to how they appeared before the compare operation.

Comparing text in text symbols

When two text symbols differ the *CompareText* button will be available in the Compare Diagrams dialog and it will be possible to enter the Compare Text Symbols dialog.

The Compare Text Symbols dialog consists of two lists of text that are placed side by side with a "gutter" that will contain extra information about the differences. This gutter-information consist of:

- A "-" indicates that there is no corresponding line in the text compared to the other text.
- A "|" character indicates that this line differs in the two texts.

The current difference is indicated with a highlight. Buttons make it possible to navigate to *Previous* and *Next* difference item.

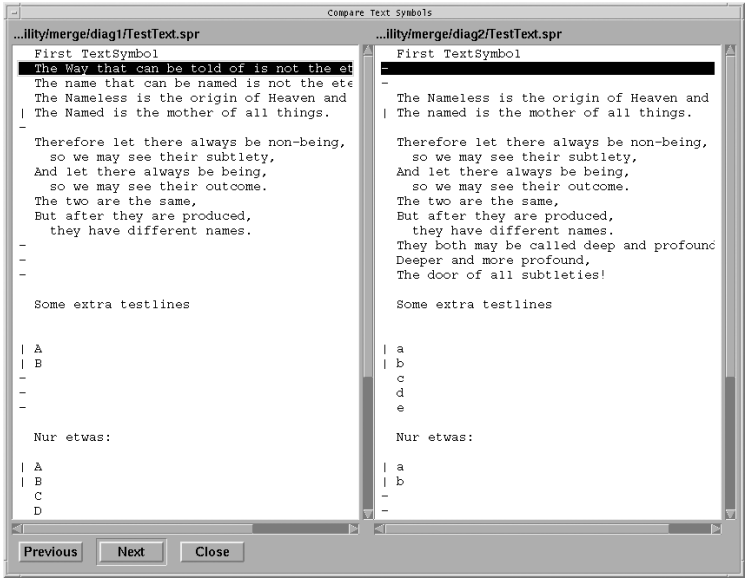

Figure 441: The Compare Text Symbols dialog

Merging text in text symbols

When manual merges are conducted the option to merge text symbols will always be available in the Merge Diagrams dialog. When merging a *MergeText* button is available as in the compare function. When a text symbol is selected there will be an option to select either symbol or merge the text in the symbols into a new symbol.

If the text merge is selected a Merge Text Symbols dialog is presented with three text lists, the two source texts and the result text. It is possible to navigate between the unresolved differences or between all differences.

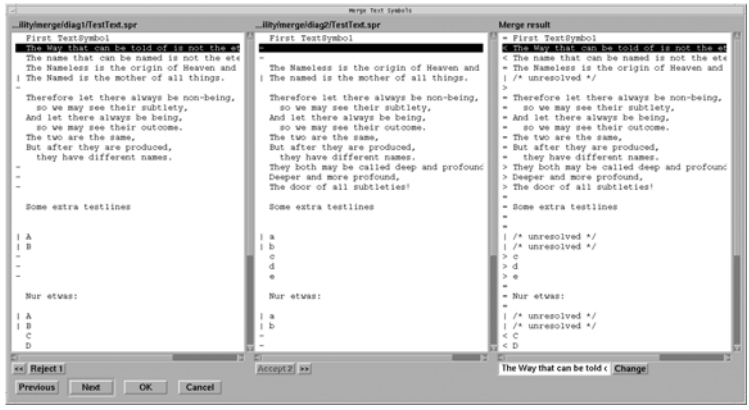

Figure 442: The Merge Text Symbols dialog

This works in the same way as in the normal merge. The buttons “<<“ and “>>” will jump between the unresolved differences and the *Previous* and *Next* buttons will jump between all differences.

The use of *Accept 1*/*Reject 1*, *Accept 2*/*Reject 2* buttons will select neither, either or both the texts for merge. The selections from the source files are presented in the result-list the gutter will show what version is selected. Additional symbols in the result list are:

- A “|” character indicates that this line differs in the two texts.
- A “=” character indicates that the selected text are equal in both versions.
- A “>” character indicates that the right text has been selected for merge.
- A “<” character indicates that the left text has been selected for merge.

It is also possible to edit the result line-by-line by selecting a line and edit it below the list. Clicking the *Change* button will replace the changed line in the result list.

Ignore moved or resized objects

If this option is on, the compare operation tries to ignore differences only caused by moved or resized symbols. You should only use this option if the two compared diagrams originates from the same diagram. (For instance, you have used Save as on the original diagram to get the second copy.) This option will not work well if you create two diagrams from scratch and compare them, because the operation uses object IDs to match moved or resized objects.

Select and Print Differences

If this option is on and there are differences, then a print dialog will pop up when the first dialog is closed. Only SDL diagram pages containing differences will be printed, and the differences will be highlighted with selection markers. If the same page containing differences can be found in both compared diagrams, then the two pages will be printed after each other, beginning with the page from the diagram that was visible in the editor when the compare operation was invoked.

Auto-merge using original file

This option is only available in the Merge Diagrams dialog. It allows you to specify the original diagram file that both the diagram versions that are compared originates from. If you specify the original diagram file, then the merge operation can auto-merge all non-conflicting changes for you. Note that if you give the wrong original diagram, then the auto-merge operation may merge the two versions in the wrong way. If you do not specify an original diagram, then the merge operation leaves all merging of differences to you.

Differences That Will Be Reported

When you use *Compare Diagrams* or *Merge Diagrams*, all visual object differences will be found:

- An object that has been moved, resized, removed, added or painted in a different color.
- A text, associated with an object, that has been changed

An object is considered to be moved if it has been moved relative to the upper left corner of the diagram frame. This means that if you move the frame, it will have no effect.

Diagrams are compared one page pair at a time. A page pair is one page from the original diagram and one page from the other diagram where both pages have the same name. If there is no page with the same name in the other diagram, then the complete page is considered to be a difference.

Difference Groups

Differing objects from the same page pair are grouped into *difference groups*. Two differing objects are placed in the same group if:

- The objects are from the same diagram and they are connected to each other. For instance, a flow line connected to a task symbol.
- The objects are from different diagrams and they would overlap if they were in the same diagram, that is, it would be impossible to place the two objects in the same diagram without changing the position within the diagram for one of them.
- The objects are from different diagrams and the difference operation can conclude that it is the same object that has been moved.

Color and the Current Difference Group

In the graphical difference report, all differing objects are given temporary background colors as specified in the initial dialog. As default, the color is green in the original diagram and magenta in the other diagram. Temporary colors are not saved in diagram files. How temporary colors are removed is described in "Temporary Colors > Remove" on page 2015.

The dialog that will be opened during the graphical difference report, allows you to navigate between difference groups using previous and next buttons. All objects in the current difference group are selected.

Normally, version 1 of the compared diagrams (the diagram that was in the SDL editor when the compare operation was invoked) is shown in a window in the top left corner of the screen. Version 2 (the diagram that was specified in the first compare dialog) is shown in the top right corner off the screen. For complete page differences (a difference where a page can not be found in the other diagram), the window that misses the page is hidden.

Note that it is possible to manually edit the compared diagrams while the compare operation is ongoing. This can be seen as a light-weight alternative to the full merge operation (described next).

Merging

During a merge operation, three windows are used in addition to the second merge dialog:

- The top left corner of the screen is used to show version 1 of the compared diagrams, in the editor window named *Source 1*. This is the diagram that was visible in the SDL editor window when the merge operation was invoked.
- The bottom left corner of the screen is used to show version 2 of the compared diagrams, in the editor window named *Source 2*. This is the diagram that was specified in the first merge dialog as the diagram to compare with.
- The right part of the screen is used to show the merge result diagram, in the editor window named *Result*. This is a new diagram that has been created from the two compared diagram versions.

The second Merge dialog does not only have previous and next buttons to navigate between differences. It does also have *Accept/Reject* buttons and “<<” (fast backward) / “>>” (fast forward) buttons.

- Pressing *Accept 1* (*2*) will add symbols to the merge result diagram. It is the symbols from version 1 (2) of the current difference group that will be added.
- Pressing *Reject 1* (*2*) will remove symbols from the merge result diagram. It is the symbols that can be found in version 1 (2) of the current difference group that will be removed.
- Pressing “<<” (fast backward) will navigate to the previous unresolved difference group. An unresolved difference group is a difference group where both version 1 and version 2 are not accepted.
- Pressing “>>” (fast forward) will navigate to the next unresolved difference group.

Note that it is possible to manually edit diagrams while a merge operation is ongoing. This can be useful if you want the merge result diagram to look different from both version 1 and version 2 of the compared diagrams.

When the second merge dialog is closed, the editor will ask you to save the merge result by displaying a save dialog above the window with the

merge result diagram buffer. When the save dialog is closed, the editor windows are restored to how they appeared before the merge operation was invoked.

GR to PR Conversion

It is possible to convert diagrams from SDL/GR to SDL/PR. In the conversion, SDL diagrams are translated from the binary files into PR files, possibly containing CIF information. All graphical symbols in that diagram will be replaced by their corresponding keywords and any text in the symbols will be copied to the output file. When possible, the definitions in the output file will appear in the same order as in the input.

The conversion is used by the SDL Analyzer as the first step in the analysis process, and also by the SDT2CIF Converter to convert to PR that preserve the graphical layout information. You can also convert to PR by the *Generate PR* command in the *Tools* menu, or by using the Public Interface (see "GRPR" on page 628 in chapter 11, *The Public Interface*).

The PR/CIF files produced by the SDL Suite fill various purposes:

- As a way to export information to other SDL tools
- As a temporary storage format that is used as input to the static and semantic analyzer
- As a format that is suitable for reading by the user. To produce this format, the PR file should be pretty printed.

Mapping between GR and PR

The following list defines the mapping between the GR and PR forms:

- In general, when symbols of the same type are converted, symbols are ordered first of all by the page ordering within the diagram. Within the same page symbols are ordered such that a symbol with a low y-coordinate (closer to the top) will be converted first. If two symbols have the same y-coordinate the symbol with the lowest x-coordinate is treated first.

Note:

The **order in which text symbols are converted may be of importance** when it comes to code generation issues. This is, in particular, applicable when using the SDL to C Compiler. Therefore, you should use one text symbol only for type definitions.

- When analyzing systems using macros, all macros are converted to PR before they are expanded. This restricts the usability of macros, for instance the number of inlets and outlets must be 0 or 1.
- A merge symbol (a flow line connected to another flow line) is translated to PR using join and label constructs. The labels introduced will be named *grst0*, *grst1*, and so on, starting on *grst0* at each diagram. In macro diagrams, the labeling is *grst0%MACROID*... If the label already exists in the GR diagram, the sequential number is incremental until the label is unique.
- A block diagram may contain a block substructure diagram without its frame and heading if the block diagram does not contain any definitions but the substructure. This rule is applied to all the pages in the block diagram that are of the block interaction type.
- When specifying a header in GR, it must be specified according to the PR syntax and the valid input signal set should be written into the heading symbol and not in a text symbol as specified by the GR syntax.
- References to graphical symbols, which will be used by the Analyzer in error messages, are stored in the PR file using SDL comments beginning with the character "#". It is therefore recommended that you do not write comments beginning with "#".
- To be able to perform a correct conversion of SDL/GR *Substructure* diagrams to SDL/PR, the enclosing diagram type, block/channel or block type, must be known. For a channel going to the environment, a name outside the frame must be a gate name, generating the `via` construct, if the enclosing diagram is a block type, and a channel name, generating `connect` statements, for other cases.

  If nothing is known about the enclosing diagram type, it is assumed that the diagram is a block.

  To resolve the ambiguity, a qualifier can be used in the kernel heading to determine the enclosing diagram type. Alternatively the An-

alyzer directive #BLOCKTYPE can be used to indicate that the enclosing diagram is a block type diagram. This directive should be added to the diagram kernel heading.

Differences when generating CIF

In general the PR generated as input to the analyzer will be the same as generated for CIF but for some constructs there are differences due to language limitations or to get a better error detection.

- The conversion of a graphical comment symbol differs dependent on if the translation is made to CIF or not. When converting to CIF, the PR generated is the `<comment>` PR construct; in other cases, including when performing Analysis, the graphical comment is converted to "/* text inside graphical comment symbol */".
- The SDL editor supports the possibility to place the comment symbol without connecting it to another symbol. When generating PR without CIF this comment will be converted to PR as described above. When generating CIF the CIF comment will be
  /* CIF Comment (500,100) Right */
  /* text in unconnected comment */
  This standalone nonstandard CIF construct will be recognized by the CIF2SDT application such that the original comment symbol will be restored in the diagram.
- In the SDL editor you can connect many comments to the same symbol. This is an extension to the SDL language. For this graphical construct there is no immediate translation to PR. When generating PR without CIF the comments are generated according to the note above and there will be no problems. However, when generating CIF the comment will be generated using the <comment> PR construct. As there only can be one <comment> to each symbol there is no direct possible translation in PR for many comments. In this case the extra comment symbols are handled as if they were unconnected to the symbol. This means that when regenerating a diagram from the CIF code, the diagram will not be exactly the same as the original diagram as the extra comments will now be unconnected.
- When generating non-CIF all unattached comments will be attached to a symbol that is closest to the comment. In this way the comment text will be generated as if the text belongs to this symbol.

- There is a difference also for graphical connections. If a channel C1 has a graphical connector to the outer channel outerC and another channel C2 also has a graphical connector to outerC, but the points where outerC is drawn is not the same, the conversion for CIF will contain two connect statements:

  ```
  /* CIF ... */
  connect outerC and C1;
  /* CIF ... */
  connect outerC and C2;
  ```

  This PR will produce a semantic error according to SDL-92, but will be correct when using SDL-96.

  When using non-CIF conversion, the two graphical connections will be combined into one statement, provided that the two texts specifying outerC are lexically the same, thus writing outerC in one text and out_\nerC in the other (\n is a newline) will not be treated as the same text. They are still considered the same if only the case differs.

  ```
  connect outerC and C1,C2;
  ```

- When PR is generated for a macrodefinition the macro inlet and macro outlet symbols will differ whether CIF is generated or not. As there are no corresponding PR to these symbols nothing will be generated when generating CIF except of course for the CIF statements itself. For non-CIF a note will generated indicating that these symbols are present in the diagram.

  ```
  /* Macro Inlet Symbol  */
  ```

  A task having no text or having only a note/comment is allowed in GR. The correct PR correspondence is the compound statement construct having an empty statement

  ```
  task { };
  ```

  As this PR will restrict the use of the simulator command Next-Symbol the PR generated for non-CIF is an empty informal text

  ```
  task '';
  ```

  For CIF the compound statement will be generated.

- CIF generation for the class symbol is not supported. The generation for non-CIF is described in "Class Information" on page 1942.

Error and Warning Message

This section contains messages that may be produced during the GR to PR conversion.

When the Public Interface performs the conversion from GR to PR, the messages will be displayed in the Organizer log. The reply message on the service will indicate that the conversion has been done and it will also contain the number of errors produced.

If the conversion for some reason fails, the reply message will contain a text stating the kind of problem that has occurred. See further the *GRPR* service in the Public Interface.

ERROR 5001 Unexpected end of flow

This message indicates that a symbol has been found that has no following flowline and according to the SDL syntax there must be one. In addition to the error message the following line is generated in the PR:

```
***** Unexpected end of flow *****
```

WARNING 5002 More than one line entering macro outlet

This message indicates that inside a macro there are more than one line entering the macro outlet symbol. This situation should be avoided as this can lead to syntax errors (which are hard to track) if this macro is expanded inside decision branches.

The easiest way to avoid this situation is to add a no-action task symbol with the text ‘’ and use this as the last symbol in the macro. Let all lines enter this task symbol and add a single line between this task and the macro outlet.

Chapter 43 Using the SDL Editor

Chapter

44

Symbols and Lines – Quick Reference

The following notations are included in the quick reference:

- **DP - Deployment Diagrams**
- **HMSC – High-level Message Sequence Charts**
- **MSC – Message Sequence Charts**
- **OM – Object Model**
- **SC – State Charts**
- **SDL – Specification and Description Language**

The quick reference contains all the symbols and lines in those diagrams in combination with a short explanation of when they may be used.

There is also a landscape oriented version of this document. It is called `symref.pdf` and is located in `/pdf/files` on the installation CD. If you want to make your own printout of the quick reference, that document is perhaps the most suitable.

Symbols and Lines in DP Diagrams

Symbols in DP Diagrams

Symbol	Name	Explanation
	Node	Is used to describe a run-time physical object that represents a computational resource.
	Component	Represents a physical, replacable part of a system that packages implementation.
	Thread	Represents an OS thread.
	Object	Represents an SDL entity (system, block or process).
	Text	Contains comments relevant for the diagram or build script information. Is not connected to any other symbol.

Lines in DP Diagrams

Line	Name	Explanation
	Association line	Defines an association between two node symbols. To create it, select one node symbol and drag the association line handle (a rectangle). To create a line breakpoint, click in the diagram background. To attach the association line to its final destination, click the border of the associated node symbol.
	Composite Aggregation line	Defines that the symbol connected to the simple line end is contained in the symbol connected to the diamond line end. To create it, select the container symbol and drag the aggregation line handle (a diamond). To create a line breakpoint, click in the diagram background. To attach the aggregation line to its final destination, click the border of the contained symbol.

Symbols and Lines in HMSC Diagrams

Symbols in HMSC Diagrams

Symbol	Name	Explanation
	Start	The start symbol in an HMSC diagram. Is followed by a condition, reference or a condition point symbol.
	Stop	The last symbol in an HMSC diagram.
	Condition	Represents a system or process state, or indicates that a certain condition is true. Contains the name of the represented state or condition.
	Reference	References another MSC or HMSC diagram in the same group of MSC diagrams. Contains the name of the other diagram.
	Connection point	Splits or joins lines. One to many, many to one, or many to many.
	Text	Contains comments relevant for the diagram. Is not connected to any other symbol.

Lines in HMSC Diagrams

Line	Name	Explanation
	HMSC line	Defines how symbols can be traversed. Starts below the from-symbol and ends above the to-symbol. From-symbols can be start, condition, reference and connection point. To-symbols can be stop, condition, reference and connection point. To create the line, select a start, condition, reference or connection point symbol (a from symbol), and drag the line handle. To create a line endpoint, click in the diagram background. To attach the line to its final destination, click the symbol border.

Symbols and Lines in MSC Diagrams

Symbols in MSC Diagrams

Symbol	Name	Explanation
	Text	Contains comments relevant for the diagram. Is not connected to any other symbol.
	Comment	Contains comments relevant for a part of the diagram. Is connected to a symbol, a message sending or a message reception.
	Instance head	Represents an instance of something that can communicate by sending and receiving messages. The “start symbol” for a created or an already existing instance.
	Instance end	Used for graphically ending an instance axis without terminating the represented instance.
	Message	Represents a signal sending from one instance to another. Is connected to at least one instance axis. Usually connected to an instance axis in both ends.
	Condition	Represents a system or process state, or indicates that a certain condition is true. Contains a name of the represented state or condition. Is initially connected to one instance axis, but should often be connected to all.
	Timer	Represents the use of a timer in an instance. Is connected to an instance axis. One symbol represents both a timer set and either a timeout or a reset.
	Action	Is a kind of text symbol and is connected to an instance axis. Describes something that is happening in the instance.
	Create process	Describes the creation of an instance. The arrow should go from an instance axis (the creator) to an instance head (the creator instance). The instance head is created when the create process symbol is initially laid out.
	Process stop	Terminates an instance. The instance ceases to exist. Is connected to an instance axis.

Symbol	Name	Explanation
	Coregion	Creates a part of an instance axis where the order of received and sent signals is undefined. Is connected to an instance axis.
	MSC reference	References another MSC or HMSC diagram in the same group of MSC diagrams. Contains the name of the other diagram. Is initially connected to one instance axis, but can be connected to several.
	Inline expression	Is used for specification of alternative or optional parts (that is, message sending sequences) which are contained in the symbol. Is initially connected to one instance axis, but should most likely be connected to several.
	Inline expression separator	Creates a new partition in an inline expression symbol. Initially, the inline expression symbol only contains one partition.

Lines in MSC Diagrams

Line	Name	Explanation
	Message	Is used for defining a message sending and/or a message reception. Is at least connected to one instance axis, but is usually connected to an instance axis in both ends. Create it from the symbol menu.
	Create process line	Is used for defining the creation of an instance. The arrow should go from an instance axis (the creator) to an instance head (the created instance). Create the process line from the symbol menu. When the create process arrow is initially laid out, the instance head is created.

Line	Name	Explanation
	Comment line	Associates a comment symbol with another symbol. To create it, select the comment symbol and drag the line handle to another symbol. Note that it is also possible to attach the comment symbol to a message sending or a message reception, by dragging the line handle to a connection point between a message and an instance axis.

Symbols and Lines in OM Diagrams

Symbols in OM Diagrams

Symbol	Name	Explanation
	Class	Specifies a class. Contains three sections: Name, attributes and operations.
	Object	Specifies an object instantiated from a class. Contains two sections: Name and attribute values
	Text	Contains comments relevant for the diagram. Not connected to any other symbol.

Lines in OM Diagrams

Line	Name	Explanation
	Generalization line	Defines that the class connected to the simple line end inherits from the class connected to the triangle line end. To create it, select the class symbol to inherit from and drag the generalization line handle (a triangle). To create a line break point, click in the diagram background. To attach the generalization line to its final destination, click the border of the inheriting class symbol.
	Aggregation line	Defines that the class connected to the simple line end is contained in the class connected to the diamond line end. To create it, select the container class symbol and drag the aggregation line handle (a diamond). To create a line breakpoint, click in the diagram background. To attach the aggregation line to its final destination, click the border of the contained class symbol.

Line	Name	Explanation
	Association line	Defines an association between two class symbols. To create it, select one class symbol and drag the association line handle (a rectangle). To create a line breakpoint, click in the diagram background. To attach the association line to its final destination, click the border of the associated class symbol.
	Link class line	Defines a class connected to an association line or an aggregation line. To create it, select an association or an aggregation line and drag the link class handle. The class symbol is created at the same time. There can only be one class symbol connected to one association or aggregation line.

Symbols and Lines in SC Diagrams

Symbols in SC Diagrams

Symbol	Name	Explanation
	State	Represents a state in a state machine. May contain sub states when hierarchical state machines are specified. Is connected to other states via transition lines.
	Start	The start symbol on a level in a state chart. Is followed by a transition to a state symbol.
	Termination	Terminates a state machine. The state machine ceases to exist.
	Text	Contains comments relevant for the diagram. Is not connected to any other symbol.

Lines in SC Diagrams

Line	Name	Explanation
	Transition line	Defines a transition between two states. Is also used for defining the start transition and the last transition, by connecting a state symbol with either a start symbol or a termination symbol. To create it, select the start symbol or a state symbol and drag the transition line handle. To create a line breakpoint, click in the diagram background. To attach the transition line to its final destination, click the border of a state or termination symbol.

Symbols and Lines in SDL Diagrams

Symbols in Both SDL Structure and Behavior Diagrams

Symbol	Name	Explanation
	Class	Defines a newtype. Contains three sections: Name, attributes and operators.

Symbols in SDL Structure Diagrams

Symbol	Name	Explanation
	Text	Declares SDL entities such as signals and data types.
	Comment	Contains comments in the diagram. Is attached to other symbols.
	Text extension	Is attached to other symbols. Used if the text in another symbol is too large for the symbol. Put the last part of the text or the complete text in the text extension symbol.
	Block reference	References a block diagram in a system, system type, substructure, block or block type diagram. Also used for instantiation of a block type.
	Process reference	References a process diagram in a block or block type diagram. Is also used for instantiation of a process type
	Block substructure reference	References a substructure diagram from a block or block type diagram.[a]
	Service reference	References a service diagram in a process or process type diagram, from a service interaction page. Also used for instantiation of a service type.

Symbol	Name	Explanation
	Procedure reference	References a procedure diagram from any other diagram.
	System type reference	References a system type diagram from a package diagram.
	Block type reference	References a block type diagram from a package, system, system type, block or block type diagram.
	Process type reference	References a process type diagram from a package, system, system type, block or block type diagram.
	Service type reference	References a service type diagram from a package, system, system type, block, block type, process or process type diagram.
	Operator reference	References an operator diagram from any other diagram.
	Gate	Defines a gate in a block type, process type or service type diagram. Is attached to the diagram frame.

a. Not often used, because “block A in block C” is a commonly used shorthand for the more syntactically correct “block A in substructure B in block C”.

Symbols in SDL Behavior Diagrams 1(2)

Symbol	Name	Explanation
	State	Defines a state or terminates a transition in an already defined state. Is followed by an input, save continuous signal or priority output signal.
	Input	Receives a signal. Always preceded by a state symbol. Together, they define the start of a transition. Is followed by the behavior of the transition.
	Save	Saves signals from being discarded when being received in the current state (that does not handle the signal). Always preceded by a state symbol. Is not followed by any symbols.

Symbol	Name	Explanation
	Output	Sends a signal from a transition
	In/out connector	**Out connector:** A jump/join/goto symbol that finishes the definition of a transition on one page, if there is not enough space. Is always associated via a name with an in connector that continues the definition. **In connector:** The label symbol that is followed by the rest of the transition.
	Procedure call	Calls a procedure that does not return a value from a transition. (A value returning procedure is called from a task symbol.)
	Create request	Creates an instance of a process in a transition
	Enabling condition/ continuous signal	**Enabling condition:** Is preceded by an input symbol. Contains a boolean expression that decides if the transition below it should be taken or not. **Continuous signal:** Is preceded by a state symbol. Is followed by the behavior of a transition. Contains a boolean expression that is continuously evaluated while in the state. The following transition is taken when the expression evaluates to true.
	Priority input	Specifies that this signal reception has higher priority than normal signal reception in the same state. Primarily intended to give signals between services in the same process higher priority than other signals. Not often used.
	Procedure start	The start symbol in a procedure diagram. Is followed by the behavior of the start transition.
	Procedure return	The symbol in a procedure diagram that finishes the execution of the procedure and returns to the procedure caller.
	Procedure reference	References a procedure diagram from any other diagram.
	Gate	Defines a gate in a block type, process type or service type diagram. Is attached to the diagram frame.

Symbols in SDL Behavior Diagrams 2(2)

Symbol	Name	Explanation
	Text	Declares the SDL entities such as variables, timers and types.
	Comment	Contains comments in the diagram. Is attached to other symbols.
	Text extension	Is attached to other symbols. Used if the text in a symbol is too large for the symbol. Put the last part of the text or the complete text in the text extension symbol.
	Decision	Specifies alternative paths in the behavior part of a transition. Contains an expression. Each path is labeled with an answer that should match the expression for the path to be taken.
	Task	Is used for writing textual code in the behavior part of a transition. Contains for example variable assignments, for-loops and calls of value returning procedures.
	Macro call	Calls a macro diagram in the behavior part of a transition. Macros are a depreciated feature of SDL, consider using procedures or diagram inheritance instead.
	Transition option	Specifies alternative paths in the behavior part of a transition. Similar to a decision symbol, but the expression must be built up of constants and (external) synonyms that can be evaluated once before execution of the system starts. Not often used.
	Start	Starts the execution of the current diagram instance in a process, process type, service or service type diagram. Is followed by the definition of the behavior of the start transition.
	Stop	Stops the execution of the current diagram instance in a process, process type, service or service type diagram.
	Macro inlet	The start symbol in a macro diagram. Macros are a depreciated feature of SDL, consider using procedures or diagram inheritance instead.

Symbol	Name	Explanation
	Macro outlet	The end symbol in a macro diagram. Macros are a depreciated feature of SDL, consider using procedures or diagram inheritance instead.
	Operator reference	References an operator diagram from any other diagram.

Lines in Both SDL Structure and Behavior Diagrams

Line	Name	Explanation
	Comment line	Associates a comment symbol with another symbol. To create it, select the comment symbol and drag the line handle to another symbol.
	Text extension line	Associates a text extension symbol with another symbol. To create it, select the text extension symbol and drag the line handle to another symbol.
	Gate line	Defines a gate in a block type, process type or service type diagram. To create it, select it from the symbol menu and attach it to the diagram frame.
	Aggregation line	Defines that the class connected to the simple line end is contained in the class connected to the diamond line end. To create it, select the container class symbol and drag the aggregation line handle (a diamond). To create a line breakpoint, click in the diagram background. To attach the aggregation line to its final destination, click the border of the contained class symbol.
	Association line	Defines an association between two class symbols, can be unidirected or bidirected. To create it, select one class symbol and drag the association line handle (a rectangle). To create a line breakpoint, click in the diagram background. To attach the association line to its final destination, click the border of the associated class symbol.

Lines in SDL Structure Diagrams Only

Line	Name	Explanation
	Channel	Defines a part of a communication path for signals, either between two blocks or between one block and the environment (i.e. the diagram frame). To create it, select a block symbol and drag the line handle. To make line breakpoints, click in the diagram background. To attach the line to its final destination (either another block or the diagram frame), click the symbol border. After creation, the channel can be reversed or made bidirectional. The arrow is movable and an arrow at the end of the channel indicates that the channel does not delay signals being sent.
	Signal route	Similar to a channel. The differences are that a signal route connects to processes and services instead of blocks, and that a signal route arrow cannot be moved around.
	Create line	Defines that the process where the create line starts, can create instances of the process where the create line ends. The create line is optional. To create it, select the process symbol and drag the create line handle. To make line breakpoints, click in the diagram background. To attach the create line to its final destination, click the symbol border.

Line in SDL Behavior Diagrams Only

Line	Name	Explanation
	Flow line	Defines the order that symbols are executed in. Starts at the bottom of a symbol and ends at the top of another symbol. To create it, select a symbol that can be followed by other symbols and drag the flow line handle. To make line breakpoints, click in the diagram background. To attach the flow line to its final destination, click the symbol border. Note that two symbols can only be connected with a flow line if the SDL syntax rules allow it.

Chapter

45 *The SDL Type Viewer*

The Type Viewer shows SDL-92 types and type instances in the current system and how they relate to each other.

This chapter contains a reference manual to the Type Viewer; the functionality it provides, its menus, windows and symbols.

Objects and Windows

Objects and Attributes

An object in the Type Viewer is either a type or an instance of a type. Both of these may be referred to as a *type* in the Type Viewer and in this chapter. For each type object, the following attributes can be presented:

- A graphical *symbol* to identify the type of diagram. The symbols are identical to the icons used in the Organizer's Main window (see "Icon Types" on page 51 in chapter 2, *The Organizer*). The symbol is always shown.
- The *type identifier*, in the form <virtuality> <diagram type> <object type>, where:
  - <virtuality> may be either Virtual, Redefined or Finalized
  - <diagram type> may be either System, Block, Service or Process
  - <object type> may be either Type or Instance
- The *name* of the type or instance
- The complete *qualifier*, in text form.

You can hide or show each of the last three text items. By default, the type identifier and the type name is shown.

You can open an SDL Editor by double clicking on a symbol in the Type Viewer. If a type symbol is double clicked, an SDL Editor is opened with that type diagram. If an instance symbol is double clicked, an SDL Editor is opened with the diagram that contains the instance.

Type Viewer Windows

The Type Viewer has two windows, the list window and the Tree window, which present the type information in the system in two different ways. The main window lists the type objects without showing inheritance or redefinition relations between them, whereas the Tree window shows such relations for a type object in a tree form. Both windows can

display all of the object attributes above, but in somewhat different ways.

The Main window is opened when the Type Viewer is started, whereas the Tree window is not opened initially. The general characteristics of these windows are described in chapter 1, *User Interface and Basic Operations*.

Updating the Type Viewer

When the Type Viewer is started, it extracts type information from the current system. If, for any reason, there are problems extracting type information, you are warned in a dialog and details can be found in the Organizer log window. You may update the information in the Type Viewer at any time, with the *Update* command.

The Type Viewer obtains the information about what types are defined in the SDL scope from the Information Server. The Information Server updates its contents **each time an SDL diagram is saved**. When the diagram is saved, the Analyzer is invoked and produces a mirrored image which is an SDL/PR description of the SDL/GR diagram. That information is then loaded into the Information Server which serves the Type Viewer with information upon request. All of this is done automatically without the user having to bother about performing any actions.

Error Reporting

> **Note:**
>
> In order to extract signal information from a diagram, the diagram needs to be syntactically correct in the sense that SDL/PR code can be generated from the SDL/GR diagram without encountering errors.

Any errors are appended to the Organizer log window. For a reference to error messages that may be produced by the Information Server, see *"Information Server Error Messages" on page 912 in chapter 17, The Information Server*.

Main Window

The Drawing Area

The main window's drawing area contains a simple line-oriented list of all types in the current SDL system. No inheritance or redefinition relations are shown. The object attributes are listed in the following way (see Figure 443):

Icon Type identifier Type name
<< Qualifier >>

The qualifier is displayed within double angle brackets on a single text line, with slashes separating the path items.

In the list, the type objects are sorted alphabetically according to the diagram type, object type and type name, i.e. all objects of the same diagram type are grouped together.

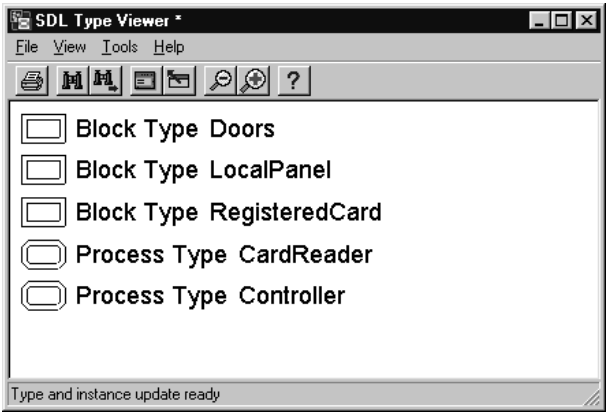

Figure 443: Main window

When you select a type or instance in the main window, the Tree window is updated and displays the relation trees that contain the selected type/instance. If the Tree window has not been opened earlier in the same Type Viewer session, the Tree window is opened automatically.

The Menu Bar

File Menu

The *File* menu contains the following menu choices:

- *Update*
- *Print*
  (See *"Printing from the SDL Suite" on page 315 in chapter 5, Printing Documents and Diagrams*.)
- *Exit*
  (See "Exit" on page 15 in chapter 1, *User Interface and Basic Operations*.)

Update

Updates the type list in the main window and the type trees in the Tree window, according to the possibly changed SDL diagrams (see "Updating the Type Viewer" on page 2071).

This command should be used whenever changes that might have an impact on the type inheritance are applied to any of the SDL diagrams contained in the diagram structure.

View Menu

The View menu contains the following menu choices:

- *Window Options*
- *List Options*
- *Symbol Options*
- *Set Scale*

Window Options

Sets options for which parts of the main window to show. The dialog controls whether to show the tool bar and the status bar.

List Options

Sets options for which symbols to include in the list in the main window. The dialog controls whether to show *Instance symbols* (type symbols are always shown).

Symbol Options

Sets options for which attributes to show for each type object in the list in the main window. The dialog controls whether to show the *Qualifier*, the *Type* identifier, and the *Name* of the types and instances.

Set Scale

Issues a dialog where the scale for the main window may be set.

Tools Menu

The Tools menu contains the following menu choices:

- *Show Organizer*
  (See "Show Organizer" on page 15 in chapter 1, *User Interface and Basic Operations*.)

- *Search*
- *Search Again*
- *Show in Editor*
- *Show Type Trees*

Search

Searches for a visible text in the type list shown in the Main window.

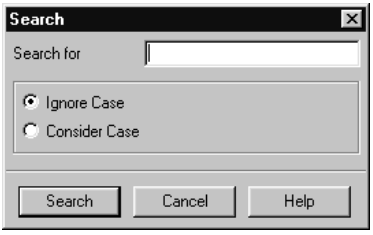

Figure 444: The Search dialog

- *Search for*

  Specifies the text string to search for. As a special case, a GR Reference obtained from for instance an editor may also be specified.

- *Ignore Case, Consider Case*

These options toggles between a case insensitive and a case sensitive search.

- *Search*

  Starts the search and closes the dialog. The first symbol containing the text is selected. The search starts from the selected symbol, if any, or from the first symbol in the list.

If the search reaches the end of the list, you are asked whether to continue the search from the top of the list or not.

If the text cannot be found among the visible information, you are informed in a confirmation dialog.

Search Again

Searches again for the same text as in the latest search. The behavior is the same as described in "Search" on page 2074.

Show in Editor

Shows the selected type or instance in an SDL Editor. If a type symbol is selected, an SDL Editor is opened with that type diagram. If an instance symbol is selected, an SDL Editor is opened with the diagram that contains the instance.

Show Type Trees

Opens or raises the Tree window. The type or instance selected in the Main window becomes selected in the Tree window.

Popup Menus

The following tables lists the menu choices in the Main window popup menus and a reference to the corresponding menu choice in the menu bar.

On the Main Window Background

Search	“Search” on page 2074.
Search Again	“Search Again” on page 2075.
Show Type Trees	“Show Type Trees” on page 2075.

On a Symbol in the Main Window

Search	“Search” on page 2074.
Search Again	“Search Again” on page 2075.
Show in Editor	“Show in Editor” on page 2075.
Show Type Trees	“Show Type Trees” on page 2075.

Keyboard Accelerators

Apart from the general keyboard accelerators, the following accelerator can be used in the main window:

Accelerator	Reference to corresponding command
`Ctrl+E`	“Show in Editor” on page 2075

Tree Window

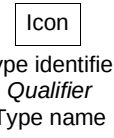
The Drawing Area

The Tree window's drawing area visualizes inheritance and redefinition relations between types by presenting the types and instances in a tree form. There are two types of trees displayed in the Tree window:

- A *Redefinition tree* shows virtual types, specializations based on redefinition of the virtual types, and all instances of these types.
- An *Inheritance tree* shows types, specializations based on inheritance and adding properties to the types, and all instances of these types.

The two trees for a certain type are often, but not always, identical. The Type Viewer supports you by checking if they are identical; if so, they are shown as one tree. When the Inheritance and Redefinition trees are different, both are shown separately. Each tree has a header identifying which type of tree it is.

The object attributes are listed vertically in the trees in the following way (see Figure 445):



The qualifier is displayed in italics in a multi-line form, with each path item on a separate line. No angle brackets or slashes are used.

In the tree, the type objects with the same parent are placed from left to right alphabetically according to the diagram type and object type.

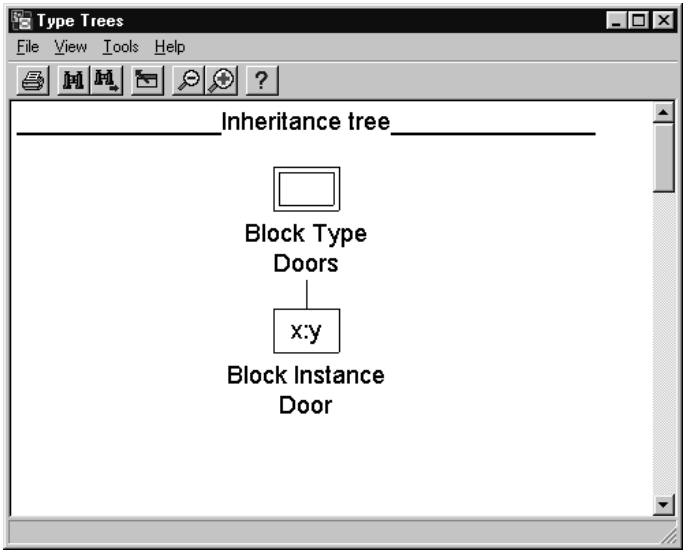


Figure 445: Tree window

The Tree window is updated when the selection in the Main window is changed. The Tree window is updated to show the Inheritance and Redefinition trees in the system that contain the type/instance that is selected in the Main window. The first occurrence of that type/instance also becomes selected in the Tree window.

It is possible to view all Inheritance and Redefinition trees in the current system at once in the Tree window (see "Show All Trees" on page 2080). The trees are lined up vertically in the same drawing area.

The Menu Bar

File Menu

The *File* menu contains the following menu choices:

- *Print*
  (See *"Printing from the SDL Suite" on page 315 in chapter 5, Printing Documents and Diagrams*.)
- *Close*
  (See "Close" on page 14 in chapter 1, *User Interface and Basic Operations*.)

View Menu

The View menu contains the following menu choices:

- *Expand*
- *Expand Substructure*
- *Expand All*
- *Collapse*
- *Window Options*
- *Tree Options*
- *Symbol Options*
- *Show All Trees*
- *Set Scale*

Expand

Expands the selected object one level down.

Expand Substructure

Expands the selected object as much as possible.

Expand All

Expands all visible trees as much as possible.

Collapse

Collapses the selected object, i.e. hides all child objects. If there is no selected object, the menu choice is named *Collapse All*. *Collapse All* collapses all trees in the window.

Window Options

Sets options for which parts of the Tree window to show. The dialog controls whether to show the tool bar and the status bar.

Tree Options

Sets options for which symbols to include in the trees in the Tree window. The dialog controls whether to show instance symbols (Type symbols are always shown).

Symbol Options

Sets options for which attributes to show for each symbol in the trees in the Tree window. The dialog controls whether to show the *Qualifier*, the *Type* identifier, and the *Name* of the types and instances.

Show All Trees

Shows type trees for all types in the system.

Set Scale

Issues a dialog where the scale for the Tree window may be set.

Tools Menu

The Tools menu contains the following menu choices:

- *Show Organizer*
  (See "Show Organizer" on page 15 in chapter 1, *User Interface and Basic Operations*.)

- *Search*
- *Search Again*
- *Show in Editor*
- *Show Type Viewer*

Search

Searches for a text in the type trees shown in the Tree window.

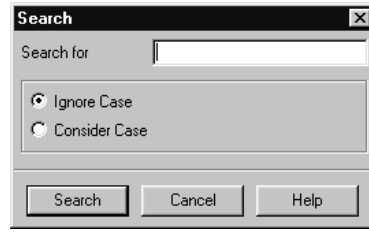

Figure 446: The Search dialog

- *Search for*

  Specifies the text string to search for. As a special case, a GR Reference obtained from for instance an editor may also be specified.

- *Ignore Case, Consider Case*

  These options toggles between a case insensitive and a case sensitive search.

- *Search*

  Starts the search and closes the dialog. The first symbol containing the text is selected. The search starts from the selected symbol, if any, or from the first symbol in the first tree.

If the search reaches the end of the trees, you are asked whether to continue the search from the first tree.

If the text cannot be found, you are informed in a confirmation dialog.

Search Again

Searches again for the same text as in the latest search. The behavior is the same as described in "Search" on page 2080.

Show in Editor

Shows the selected type or instance in an SDL Editor. If a type symbol is selected, an SDL Editor is opened with that type diagram. If an instance symbol is selected, an SDL Editor is opened with the diagram that contains the instance.

Show Type Viewer

Raises the Type Viewer's Main window.

Popup Menus

The following tables lists the menu choices in the Tree window popup menus and a reference to the corresponding menu choice in the menu bar.

On the Tree Window Background

Search	"Search" on page 2080.
Search Again	"Search Again" on page 2081.
Show All Trees	"Show All Trees" on page 2080.
Show Type Viewer	"Show Type Viewer" on page 2082.
Expand All	"Expand All" on page 2079.
Collapse All	Collapse all top objects in all trees.

On a Symbol in the Tree Window

Search	"Search" on page 2080.
Search Again	"Search Again" on page 2081.
Show in Editor	"Show in Editor" on page 2081.
Show All Trees	"Show All Trees" on page 2080.
Show Type Viewer	"Show Type Viewer" on page 2082.
Expand	"Expand" on page 2079.
Expand Substructure	"Expand Substructure" on page 2079.
Collapse	"Collapse" on page 2079.

Keyboard Accelerators

Apart from the general keyboard accelerators, the following accelerator can be used in the Tree window:

Accelerator	Reference to corresponding command
Ctrl+E	“Show in Editor” on page 2081

Chapter 45 The SDL Type Viewer

Chapter

46 *The SDL Index Viewer*

The Index Viewer shows all definitions of SDL entities in a system and where they are used. The Index Viewer uses cross reference files produced by the Analyzer.

In previous versions of SDL Suite, the Message Sequence Chart Editor could also produce listings of definitions and references from an MSC. These older listings are also supported by the Index Viewer.

This chapter contains a reference manual to the Index Viewer; the functionality it provides, its menus, windows and symbols.

Entities and Windows

Definitions and Uses

SDL

The SDL Analyzer has the ability to generate files containing SDL cross references. See the Analyzer command described in *"Set-Xref" on page 2496 in chapter 54, The SDL Analyzer*, and the Organizer's Analyzer option described in "Generate a cross reference file" on page 116 in chapter 2, *The Organizer*. These files use a textual format that is human readable; the purpose of the Index Viewer is to provide a means to take advantage of this information in the graphical environment. SDL icons are used when displaying the contents of the files in a graphical way.

MSC

In previous versions, the Message Sequence Chart Editor featured the generation of MSC cross references. These entities had properties that were similar to SDL cross references. Where possible, a direct mapping from MSC to the corresponding SDL concept were made. A few concepts were added so that all information of interest could be extracted from an MSC.

MSC icons identify the various MSC entities graphically, and are supported for backward compatibility reasons.

SDL Icons

Each type of SDL entity has a unique name and icon used in the Index Viewer. The different SDL diagram types use the same icon and type name as in the Organizer's Main window. For other types of entities, the following icons and names are used:

Icon	Name
	OPERATOR
	PACKAGE_INTERFACE
	CHANNEL

Icon	Name
	SIGNALROUTE
	GATE
	INPUT
	OUTPUT
	CONNECTION
	CREATE
	TASK
	SIGNAL
	SIGNALLIST
	GENERATOR
	FPAR; PROCESS_PARAM, PROCEDURE_PARAM (actual param.)
	STATE
	NEXTSTATE
	TIMER
	LABEL (in-connector, out-connector)
	INSTANTIATION
	SET
	USE
	INHERITS
	JOIN
	STATE_LIST
	ATLEAST
	DECISION

Icon	Name
	SAVE
	DCL; VARIABLE
	NEWTYPE; SYNTYPE; SORT
	SYNONYM
	RESET
	IMPORT; IMPORT_DEF (i.e. Imported)
	LITERAL
	VIEW; VIEW_DEF (i.e. Viewed)
	REMOTE_PROCEDURE
	REMOTE_VARIABLE
	SIGNALSET
	ACTIVE
	TRANS_OPTION (i.e. transition option)
	EXPORT
	ENAB_COND (i.e. enabling condition)
	CONT_SIGNAL (i.e. continuous signal)
	NUMBER_INST (i.e. number of instances)
	EXPORTED_PROCEDURE
	(PROCEDURE) CALL
	REFERENCE
	FIELD
	Unknown symbol type. Used for diagrams when the type of the diagram for some reason could not be determined.

MSC Icons

Each type of MSC entity has a unique name and icon used in the Index Viewer. The MSC diagram uses the same icon as in the Organizer's Main window. For other types of entities, the following icons and names are used:

Icon	Name
	CONDITION
	CREATE of instance
	INPUT of message
	INSTANCE head
	OUTPUT of message
	RESET of timer
	SET of timer
	STOP of process
	TIMEOUT (expire of timer)
	Unknown symbol type. Used for diagrams when the type of the diagram for some reason could not be determined.

Index Viewer Window

All entities defined in the system are listed in alphabetical order in the Index Viewer window. The entities are sorted alphabetically according to either name, or type and name. For each entity, there may be a list of uses of the entity. The general characteristics of the window is described in chapter 1, *User Interface and Basic Operations*.

The Drawing Area

The window contains a list of all definitions of entities in the current SDL system or the current MSC diagram. The first line in the list gives the name of the current cross reference file.

For each entity, the following information is presented:

- An icon identifying the type of entity (see "SDL Icons" on page 2086 and "MSC Icons" on page 2089)
- The name and type of the entity.
- A reference to the diagram the entity definition is located in.
- The number of definitions with an asterisk in front, if more than one definition of the entity exists (in SDL diagrams, it is only states that can have multiple places of definition for one entity).
- The number of cross references found (only for SDL entities; not applicable to MSC entities)

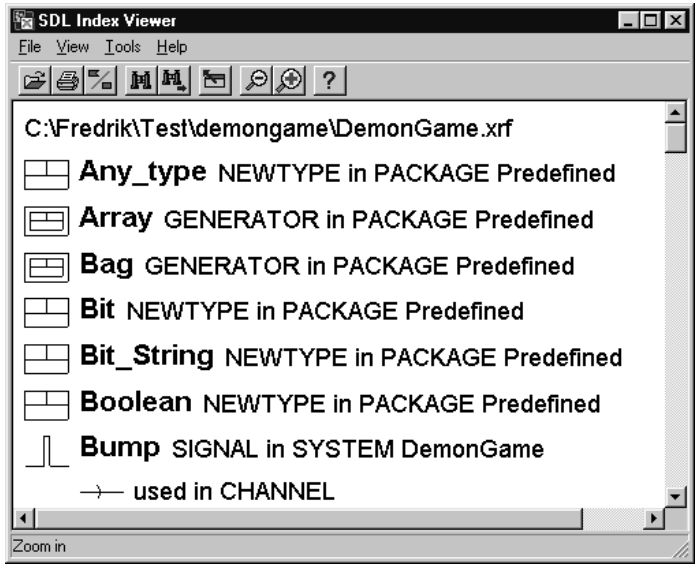

Figure 447: The Index Viewer window

To double click on a defined entity in the window is the same operation as *Show Definition* in the *Tools* menu (see "Show Definition" on page 2097). If there are several definitions associated with the entity, one of them is selected. If you double click again, another definition is selected. The list of definitions associated with the entity is traversed in a circular pattern.

To double click on a use in the window is the same operation as *Show Use* in the *Tools* menu (see "Show Use" on page 2098). If there are several uses associated with the symbol, one of them is selected. If you double click again, another use is selected. The list of uses associated with the reference symbol is traversed in a circular pattern.

Fast Search

There is a fast search operation available when the Index Viewer drawing area has the input focus. Just start typing on the keyboard, and the list of entities will be searched from the top. The first matching entity will be selected.

Note that the fast search operation will only match if what you type matches the beginning of the text for an entity. For instance: If you type “Ga”, you will find the entity *Game_On* if the entities are sorted with name first, while you will not find it if you type “On”. The normal *Search* operation does not have this restriction.

The search string used by the fast search operation will be reset whenever any other operation than the fast search operation is performed. For instance, if you have typed “Ga” and the index viewer has found the entity *Game_On*, and you select another entity and start typing again, then the search string used for the search operation will not contain the initial “Ga” characters (and the fast search operation will start searching from the top of the list).

It is possible to use the delete character to correct any spelling mistakes. You can see what you have typed in the message area. Matched characters are shown in non-capital letters, while unmatched are shown in capital letters.

The Menu Bar

File Menu

The *File* menu contains the following menu choices:

- *Open*
  (See “Open” on page 9 in chapter 1, *User Interface and Basic Operations*.)
- *Print*
  (See *“Printing from the SDL Suite” on page 315 in chapter 5, Printing Documents and Diagrams*.)
- *Exit*
  (See “Exit” on page 15 in chapter 1, *User Interface and Basic Operations*.)

View Menu

The *View* menu contains the following menu choices:

- *Window Options*
- *Index Options*
- *Filter Types*

- *Filter Uses*
- *Filter Diagrams*
- *Set Scale*

Window Options

Sets options for which parts of the Main window to show. The dialog controls whether to show the tool bar and the status bar.

Index Options

Determines the appearance of each entity in the window.

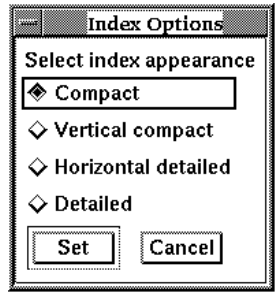

Figure 448: The Index Options dialog

The following alternatives are available:

- Compact:

  T timer in process Demon 3 uses

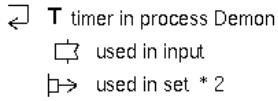
- Vertical Compact:

  T timer in process Demon
  3 uses

- Horizontal Detailed:

  T timer in process Demon used in input used in set * 2

- Detailed:



Filter Types

Determines which entity types to show/hide in the entity list. A dialog is opened with a sorted list of all entity types found in the current cross reference file:

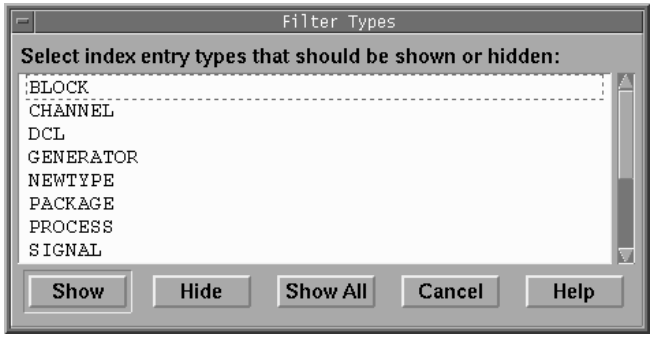


Figure 449: The Filter Types dialog

The figure shows some entity types for an SDL system. See "MSC Icons" on page 2089 for a list of MSC entities.

- *Show*

  Shows entities in the Index Viewer window that have a type that is selected in the dialog. Entities with other types are hidden.

- *Hide*

  Hides entities in the Index Viewer window that have a type that is selected in the dialog. Entities with other types are shown.

- *Show All*

  Shows entities of all types in the Index Viewer window.

An SDT preference, *FilterTypes* can be set to an initial list of entities to show or hide whenever the Index Viewer is opened. Another SDT preference, *ShowSelectedTypes*, determines if the mentioned types should

be shown or hidden. See "FilterTypes" on page 283 in chapter 3, *The Preference Manager*.

Filter Uses

Determines which uses to show/hide. The dialog works in the same way as the dialog for *Filter Types*. The associated SDT preferences are named *FilterUses* and *ShowSelectedUses*.

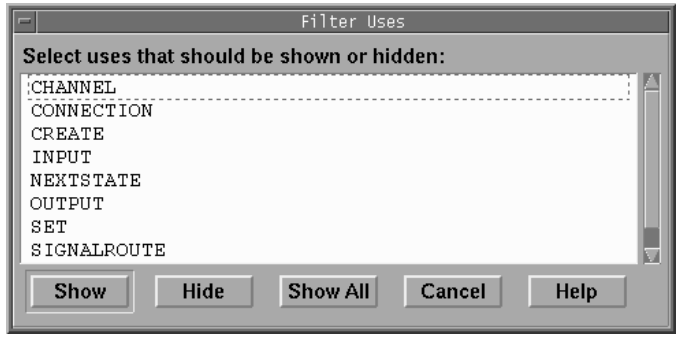

Figure 450: The Filter Uses dialog

Filter Diagrams

Hide/show entities based on which diagram they are defined in. The dialog works in the same way as the dialog for *Filter Types*. The most common use of this operation is to hide definitions from the SDL predefined package. The associated SDT preferences are named *FilterDiagrams* and *ShowSelectedDiagrams*.

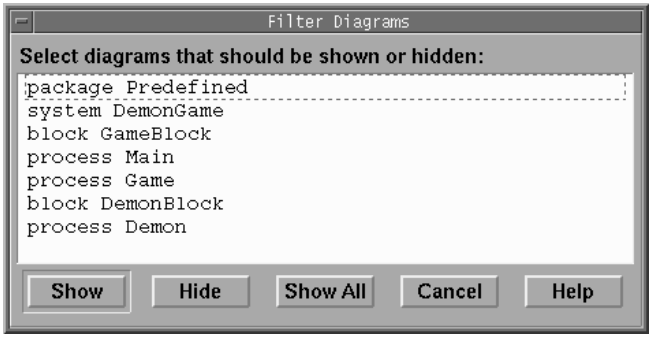

Figure 451: The Filter Diagrams dialog

Set Scale

Issues a dialog where the scale for the Tree window may be set.

Tools Menu

The Tools menu contains the following menu choices:

- *Show Organizer*
  (See "Show Organizer" on page 15 in chapter 1, *User Interface and Basic Operations*.)

- *Search*
- *Search Again*
- *Show Definition*
- *Show Use*

Search

Searches for a visible text in the entity list shown in the Main window.

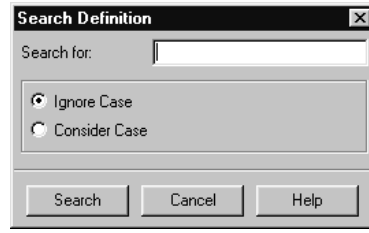

Figure 452: The Search dialog

- *Search for*

  Specifies the text string to search for. As a special case, a GR Reference obtained from for instance an editor may also be specified.

- *Ignore Case, Consider Case*

  These options toggles between a case insensitive and a case sensitive search.

- *Search*

  Starts the search and closes the dialog. The first symbol containing the text is selected. The search starts from the selected symbol, if any, or from the first symbol in the first tree.

If the search reaches the end of the trees, you are asked whether to continue the search from the first tree.

If the text cannot be found among the visible information, you are informed in a confirmation dialog.

Search Again

Searches again for the same text as in the latest search. The behavior is the same as described in "Search" on page 2096.

Show Definition

Opens an editor containing the specified definition of the entity selected in the entity list. The diagram symbol containing the definition becomes selected in the editor.

The name and behavior of this menu choice depends on the number of existing definitions for the selected entity:

- If only one definition exists, that definition is shown in the editor.
- If more than one definition exists, a separate menu choice is available for the first 9 definitions: *Show Definition 1*, *Show Definition 2*, etc. The specified definition is shown in the editor.
- If more than 9 definitions exist, an additional menu choice *Show Definition*... is available. This menu choice opens a dialog in which the number of the definition can be specified.

Show Use

Opens an editor, showing the selected use of an entity. The Show Use operation works in the same way as the *Show Definition* operation.

Popup Menus

The following tables lists the menu choices in the window's popup menus and a reference to the corresponding menu choice in the menu bar.

On the Window Background

Search	"Search" on page 2096.
Search Again	"Search Again" on page 2097.

On an Entity in the Window

Search	"Search" on page 2096.
Search Again	"Search Again" on page 2097.
Show Definition	"Show Definition" on page 2097. The same menu choice variations apply.

Keyboard Accelerators

Apart from the general keyboard accelerators, the following accelerator can be used in the main window:

Accelerator	Reference to corresponding command
`Ctrl+E`	"Show Definition" on page 2097

Quick Buttons

The following quick button is special to the Index Viewer window. The general quick buttons are described in "General Quick-Buttons" on page 24 in chapter 1, *User Interface and Basic Operations*.

Toggle Order
Switches the entity sort order between *name* and *type and name*.

Chapter 46 The SDL Index Viewer

Chapter

47

The SDL Coverage Viewer

The Coverage Viewer shows the coverage of a simulation or validation in the terms of executed transitions or symbols in the system. The information used by the Coverage Viewer can be stored in a coverage file with the file extension `.cov`.

Coverage files can be generated by the SDL Simulator and the SDL Explorer.

This chapter contains a reference manual to the Coverage Viewer; the functionality it provides, its menus, windows and symbols.

Coverage Viewer Windows

The Coverage Viewer has two windows, the Main window and the Coverage Details window. The Main window graphically shows the simulation or validation coverage of transitions or symbols in a tree corresponding to the system structure. The Coverage Details window shows a more detailed coverage chart for a node in the tree.

The Main window is opened when the Coverage Viewer is started, whereas the Coverage Details window is not opened initially. The general characteristics of these windows are described in chapter 1, *User Interface and Basic Operations*.

The Main Window

The Main window shows a graphical tree representing the diagram structure of the simulated or validated system. The tree can either present *Transition Coverage* or *Symbol Coverage*; the mode is controlled by a user option. When the Coverage Viewer first opens a coverage file, the preference *ShowTransitions* is used to determine the default mode.

At the top of the drawing area, above the root of the tree, is a text identifying the type of coverage tree (transition/coverage) and the name of the current coverage file.

In the tree, the different SDL diagram types use the same icons as in the Organizer's main window. For an explanation of all other icons, see "SDL Icons" on page 2086 in chapter 46, *The SDL Index Viewer*.

Transition Coverage

When the tree shows transition coverage, the lowest level in the tree consists of transitions, represented by a small SDL input symbol. Both states and transitions are visible below the process and procedure diagrams in the tree structure. The start transitions are treated as all other transitions, even though they are represented in the tree by an SDL start symbol.

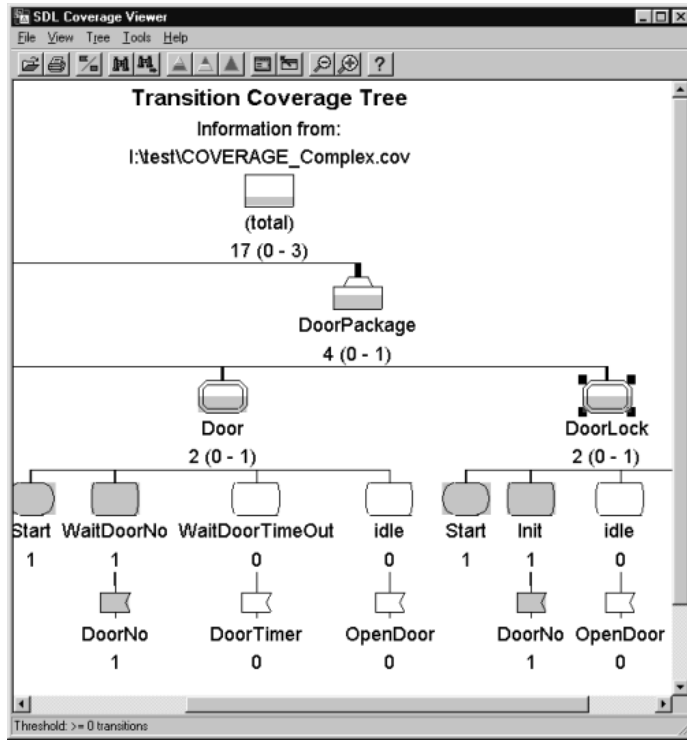

Figure 453: Transition coverage in the Main window

Symbol Coverage

When the tree shows symbol coverage, the lowest level in the tree consists of symbols corresponding to SDL symbols found in flow diagrams.

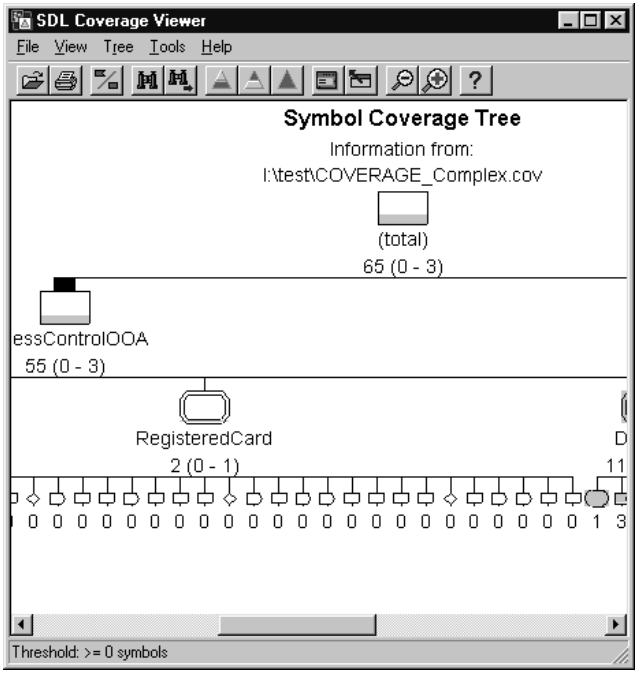

Figure 454: Symbol coverage in the Main window

Nodes

Each node in the tree consists of three parts:

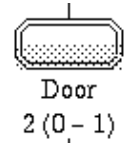

Figure 455: A coverage node

- A graphical symbol indicating the type of node, either:
  - In SDL systems containing packages, an extra root node named “(total)” is introduced, showing the grand total for the system and all packages
  - An SDL diagram (for instance, Figure 455 shows a process type symbol)
  - An SDL state
  - A transition (start transition or input of signal/timer)
  - Any symbol that can be found in SDL flow diagrams

  The graphical notation uses the same symbols as in SDL, where applicable. See also “SDL Icons” on page 2086 in chapter 46, *The SDL Index Viewer*.
- The name of the node is presented as text below the symbol (in Figure 455, the name of the process type is “Door”). An exception to this is the symbols at the lowest level in a symbol coverage tree. These symbols are shown without a name.
- The number of executed transitions/symbols associated with the node is presented below the name. For symbols above the lowest level of the tree, a range is also shown indicating the number of times the least and most executed transition/symbol below the node

has been executed. The process type symbol in Figure 455 reads "2 (0 - 1)" which means that:

- Two transitions/symbols have been executed.
- The least frequently executed transition / symbol in process type Door has been executed zero times.
- The most frequently executed transition / symbol in process type Door has been executed once.

Line Thickness

The number of executed transitions/symbols shown below the node symbol also controls the thickness of the vertical line connecting the node with its parent node.

The line thickness thus gives a visual clue about how much the different branches of the tree have been executed, expressed as a relative number. The thicker the line, the more the tree branch has been executed.

Filling Level

In each node symbol, the number of transitions/symbols that have been executed at least once in relation to the total number of transitions/symbols in that node is also displayed. This is done by filling the node symbol with a gray pattern, showing the percentage level (number of executed divided by total number).

The higher the filling level, the more transitions/symbols have been executed. Figure 455 for instance shows that 50% of the total number of transitions/symbols have been executed.

Dashed Nodes

The visibility condition determines if nodes should be shown or not. A node that should not be shown according to the visibility condition can be visible anyway because a child node is shown. To indicate that a visible node does not match the visibility condition, the node is drawn with a dashed line.

The Visibility Condition

When the Coverage Viewer first opens a coverage file, every node in the coverage tree is shown. You can hide and show nodes in two ways, either via the expand/collapse mechanism (see "View Menu" on page 2110), or via the visibility condition.

By using the visibility condition, you can control which nodes should be visible or not. Only those nodes that meet the visibility condition are shown in the tree, and you cannot use the expand mechanism to see nodes that do not meet the visibility condition.

The visibility condition is a threshold value for the number of times a transition/symbol is executed. It is specified with the *Set Visibility* menu choice in the *Tree* menu (see "Set Visibility" on page 2112). It can also be changed by quick buttons, as well as the *Increase Tree* and *Decrease Tree* menu choices in the *Tree* menu.

A node in a fully expanded tree is visible either if:

- The number of executed transitions/symbols associated with the node meets the visibility condition.
- At least one of the underlying nodes is visible.

The symbol of a node that meets the second condition but not the first one becomes dashed to indicate that the node itself does not meet the visibility condition.

Single and Double Clicks

When you select a node in the main window, the Coverage Details window is updated and displays the coverage chart for the selected node. The Coverage Details window must be opened by the *Show Details* menu choice in the *Tools* menu.

To double-click on a symbol in the main window opens an SDL Editor with a diagram that corresponds to the selected symbol. See "Show in Editor" on page 2115 for more information.

Quick Buttons

The following quick buttons are special to the Main window. The general quick buttons are described in "General Quick-Buttons" on page 24 in chapter 1, *User Interface and Basic Operations*.

Coverage Type
Switches between a transition coverage tree and a symbol coverage tree in the Main window.

Show Bottom
Changes the appearance of the coverage tree to show only those transitions/symbols that have been executed the **least** number of times, i.e. having a number of executions exactly equal to the **lowest** number of available executions. This command changes the visibility condition.

Show Top
Changes the appearance of the coverage tree to show only those transitions/symbols that have been executed the **most** number of times, i.e. having a number of executions exactly equal to the **highest** number of available executions. This command changes the visibility condition.

Show Whole Tree
Changes the appearance of the coverage tree to show all transitions/symbols. The visibility condition is reset to zero or more (>=0).

Show Details Window
Pops up (opens/raises) the Coverage Details window.

The Menu Bar

File Menu

The *File* menu contains the following menu choices:

- *Open*
  (See "Open" on page 9 in chapter 1, *User Interface and Basic Operations*.)
- *Open Directory*
- *Merge*
- *Save*
  (See "Save" on page 11 in chapter 1, *User Interface and Basic Operations*.)
- *Print*
  (See *"Printing from the SDL Suite" on page 315 in chapter 5, Printing Documents and Diagrams*.)
- *Exit*
  (See "Exit" on page 15 in chapter 1, *User Interface and Basic Operations*.)

Open Directory

This menu choice is used to merge information from all coverage files (`*.cov`) in one directory.

> **Note:**
> It is only possible to merge coverage files created from the same SDL system, i.e. the *Open Directory* operation will fail if there are coverage files from different SDL systems in the same directory.

A directory selection dialog is opened. The first coverage file in the specified directory is opened, and all other coverage files in the specified directory are merged. The resulting coverage information is presented in the main coverage window.

Merge

Reads an additional coverage file about the same system and merges the coverage information in it with the current coverage information. A File Selection Dialog is opened with the file filter set to `*.cov`. The contents of the main window is augmented by the additional information read from the selected file.

It is not possible to merge coverage files with another system.

View Menu

The View menu contains the following menu choices:

- *Expand*
- *Expand Substructure*
- *Expand All*
- *Collapse*
- *Window Options*
- *Set Scale*

Expand

Expands the selected node one level down.

Expand Substructure

Expands the selected node as much as possible.

Expand All

Expands all nodes as much as possible.

Collapse

Collapses the selected node, i.e. hides all child objects. This menu choice is named *Collapse All* if no node is selected. Invoking the *Collapse All* menu choice collapses the top node.

Window Options

Sets options for which parts of the Main window to show. The dialog controls whether to show the tool bar and the status bar.

Set Scale

Issues a dialog where the scale for the main window may be set.

Tree Menu

The Tree menu contains the following menu choices:

- *Tree Options*
- *Symbol Options*
- *Line Options*
- *Increase Tree*
- *Decrease Tree*
- *Set Visibility*

Tree Options

Sets options for which type of coverage tree to show in the main window. The dialog controls whether to show either:

– *Transition Coverage*
– *Symbol Coverage*

Symbol Options

Sets options for how to show execution numbers for the nodes in the coverage tree. The dialog controls whether to show the numbers for

– *Every node*,
– the *Bottom nodes* only, or
– *Do not show numbers* at all.

Line Options

Sets options for controlling the line thickness of the nodes in the coverage tree.

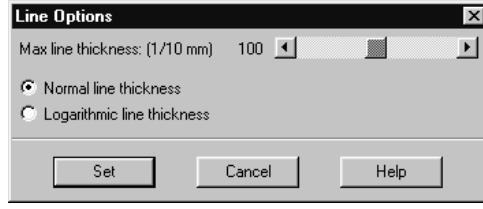

Figure 456: The Line Options dialog

- *Normal line thickness*
- *Logarithmic line thickness*

  The dialog controls whether to show *Normal line thickness* or *Logarithmic line thickness*, i.e. the thickness is proportional either to the executed number of transitions/symbols, or to the logarithm of the same number.

- *Max line thickness*

  With a slide bar, you may also specify the *Max line thickness*, measured in 1/10 mm. The possible range of values is 1–200. The default is 60, which is the thickness of the line connecting the top node of the tree.

Increase Tree

Shows more of the coverage tree by calculating a *visibility threshold* (see "The Visibility Condition" on page 2107) that makes at least one more symbol become visible.

Decrease Tree

Shows less of the coverage tree by calculating a *visibility threshold* (see "The Visibility Condition" on page 2107) that makes at least one more symbol become hidden.

Set Visibility

Sets options to control the visibility condition of the coverage tree (see "The Visibility Condition" on page 2107).

Figure 457: The Set Visibility dialog

The dialog controls:

- *Threshold*

  The value which may be set with the slide bar,

- *Show symbols executed >= threshold*
- *Show symbols executed <= threshold*

  The option whether to make nodes visible that are executed more than or less than the threshold value.

Tools Menu

The Tools menu contains the following menu choices:

- *Show Organizer*
  (See "Show Organizer" on page 15 in chapter 1, *User Interface and Basic Operations*.)

- *Search*
- *Search Again*
- *Show Coverage*
- *Show in Editor*
- *Show Details*

Search

Searches for a visible node name in the coverage tree shown in the Main window.

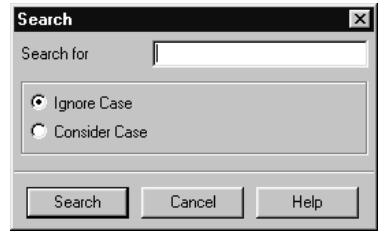

Figure 458: The Search dialog

- *Search for*

  Specifies the text string to search for. As a special case, a GR Reference obtained from for instance an editor may also be specified.

- *Ignore Case, Consider Case*

  These options toggles between a case insensitive and a case sensitive search.

- *Search*

  Starts the search and closes the dialog. The first symbol containing the text is selected. The search starts from the selected symbol, if any, or from the first symbol in the tree.

If the search reaches the end of the tree, you are asked whether to continue the search from the first node.

If the text cannot be found among the visible information, you are informed in a confirmation dialog.

Search Again

Searches again for the same text as in the latest search. The behavior is the same as described in "Search" on page 2113 above.

Show Coverage

Opens an SDL Editor for all the transitions/symbols that meet a certain threshold condition in the tree below the selected symbol. The diagram symbols corresponding to the transitions/symbols become selected in the SDL Editor.

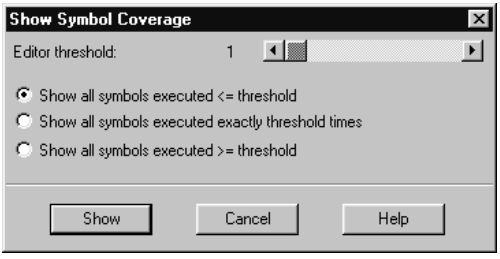

Figure 459: The Show Coverage dialog

The dialog controls the *Editor threshold* value with a slide bar, as well as whether to show transitions/symbols that are executed, either:

- less than
- equal to
- more than

the threshold value.

The *Show* button displays all diagram pages containing transitions or symbols that meet the threshold condition, one page at a time, with a confirmation dialog between each page.

Transitions (represented by the input symbol) or symbols matching the threshold condition are selected and colored with a temporary background color. The temporary background color can be removed with SDL editor > View > Temporary Colors > Remove. The temporary background color is also removed when the diagram is unloaded from the editor.

There is a *No Dialog* button in the confirmation dialog that can be used to avoid displaying the confirmation dialog for each page with symbols to show.

Note:

The editor threshold condition specified in this dialog does not affect the visibility condition. It only controls which transitions/symbols to show in an SDL Editor.

Show in Editor

Opens an SDL Editor with a diagram that corresponds to the selected symbol. If the selected symbol is located in a process or procedure diagram, the corresponding diagram symbol becomes selected in the diagram. Only applicable on transition/symbol icons at the lowest level in the tree, including start states.

Show Details

Opens or raises the Coverage Details window, showing a coverage chart for the selected node.

Popup Menus

The following tables lists the menu choices in the main window popup menus and a reference to the corresponding menu choice in the menu bar, or the corresponding quick button.

On the Main Window Background

Show Bottom	“Show Bottom” on page 2108.
Show Top	“Show Top” on page 2108.
Show Whole Tree	“Show Whole Tree” on page 2108.
Show Details	“Show Details” on page 2115.
Expand All	“Expand All” on page 2110.
Collapse All	Collapses the whole tree, i.e. only the top node becomes visible.

On a Node in the Coverage Tree

Show in Editor	“Show in Editor” on page 2115.
Expand	“Expand” on page 2110.
Expand Substructure	“Expand Substructure” on page 2110.
Collapse	“Collapse” on page 2110.

Keyboard Accelerators

Apart from the general keyboard accelerators, the following accelerator can be used in the main window:

Accelerator	**Reference to corresponding command**
`Ctrl+E`	“Show in Editor” on page 2115

Coverage Details Window

The Coverage Details window presents more detailed coverage information for the node selected in the Main window. It contains a coverage chart for transitions or symbols, depending on what type of tree is shown in the main window. Above the chart is a text identifying:

- The type of coverage chart
- The type and name of the node
- The total number of executed transitions/symbols.
- The number of covered transitions/symbols.
- The number of not covered transitions/symbols.

The Coverage Details window is updated when the selection in the Main window is changed. The Coverage Details window is updated to show the coverage chart for the node selected in the Main window.

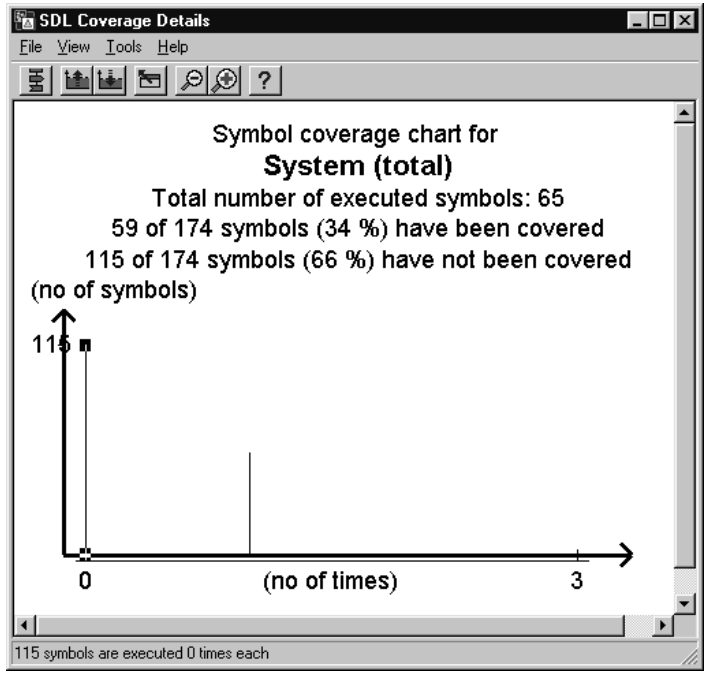

Figure 460: Coverage Details window

The Coverage Chart

The coverage chart shows how many transitions/symbols in the node that have been executed a certain number of times:

- The horizontal axis denotes the number of times a transition/symbol is executed; the range of the axis is the same as the range shown for the node in the Main window.
- The vertical axis denotes the number of transitions/symbols that has been executed a specific number of times; the range of the axis cannot generally be determined from the values shown for the node in the Main window.

For each value along the horizontal axis (no of times), a vertical bar shows how many transitions/symbols have been executed that specific number of times. The vertical axis scale is adjusted to include the highest vertical bar, but this can be changed by using the *Chart Options* menu choice in the *View* menu (see "Chart Options" on page 2120), or the quick buttons.

The left most bar is automatically selected when a new coverage chart is displayed. The selection can be moved by using the left and right arrow keys. Double clicking on a bar in the chart executes the *Show in Editor* command, see "Show in Editor" on page 2120.

Just below the horizontal axis is the *visibility line*. It underlines the bars that correspond to the visible nodes in the coverage tree in the Main window. "Visible" in this case means visible according to the visibility condition. Nodes that are hidden by collapsing a parent node are still regarded as visible in this context.

Quick Buttons

The following quick buttons are special to the Coverage Details window. The general quick buttons are described in "General Quick-Buttons" on page 24 in chapter 1, *User Interface and Basic Operations*.

Show in Editor
Corresponds to the description in "Show in Editor" on page 2120.

Increase Vertical Scale
Increases the vertical scale of the coverage chart by decreasing the value of the upper range of the vertical axis. Those bars that "overflows" the range of the vertical axis are shown with an up arrow at the top of the bars to indicate that the bars in reality are higher.

Decrease Vertical Scale
Decreases the vertical scale of the coverage chart by increasing the value of the upper range of the vertical axis. The reverse of the *Increase Vertical Scale* quick button above.

Show Coverage Tree
Pops up the Coverage Viewer's main window (the Coverage Tree window).

The Menu Bar

File Menu

The *File* menu contains the following menu choices:

- *Print*
  (See *"Printing from the SDL Suite" on page 315 in chapter 5, Printing Documents and Diagrams*.)
- *Close*
  (See "Close" on page 14 in chapter 1, *User Interface and Basic Operations*.)

View Menu

The *View* menu contains the following menu choices:

- *Window Options*
- *Chart Options*
- *Set Scale*

Window Options

Sets options for which parts of the Coverage Details window to show. The dialog controls whether to show the tool bar and the status bar.

Chart Options

Sets options controlling the appearance of the coverage chart.

The dialog controls the value of the upper limit of the vertical axis in the chart and whether to:

- *Show visibility line*
- *Hide Visibility line*

Set Scale

Issues a dialog where the scale for the Coverage Details window may be set.

Tools Menu

The *Tools* menu contains the following menu choices:

- *Show in Editor*
- *Show Coverage Tree*

Show in Editor

Opens an SDL Editor for all the transitions/symbols of the selected vertical bar in the coverage chart. The diagram symbols corresponding to the transitions/symbols become selected in the SDL Editor.

A confirmation dialog is displayed between each diagram page.

Show Coverage Tree

Raises the Coverage Viewer's main window.

Popup Menu

The following table lists the menu choices in the Coverage Details window popup menu and a reference to the corresponding menu choice in the menu bar.

Show Coverage Tree	“Show Coverage Tree” on page 2120.

Keyboard Accelerators

Apart from the general keyboard accelerators, the following accelerators can be used in the Coverage Details window:

Accelerator	**Reference to corresponding command**
`Ctrl+E`	“Show in Editor” on page 2120

Chapter 47 The SDL Coverage Viewer

Chapter

48

Complexity Measurements

Complexity measurements can be generated as a means to analyze the characteristics of a system.

General

It is possible to generate a number of complexity measurements when running the tool. The generated measurements are provided as raw data in a text file with comma as delimiter between fields. Viewing and manipulating this data can be performed using a spreadsheet tool.

The information in the complexity file can be used in many ways, for example:

- A project leader can obtain overall information about how a system evolves, by comparing different complexity files.
- By identifying the "most complex" parts of a system, a project leader can get help about how to allocate both development and test resources.

The Complexity File

The complexity file will have the name `<system name>.csv` and will be generated at the same time and in the same place as the `.xref` file (the target directory).

The `.csv` format is a "standard" spreadsheet format containing comma separated values. Many spreadsheet tools recognize this format, to read the file properly the list separator in the regional setting has to be "," (comma).

In some countries ";" (semicolon) is used as separator. If the separator is a semicolon the file should be imported as a text file, so the separator can be explicitly specified.

Generating the complexity file

The complexity file is generated during the analysis phase according to the following setup:

1. In the Analyzer dialog, select **Semantic Analysis** and click **Details.**
2. In the dialog displayed, select **Generate a complexity measurement file** and enter a file name.

Other ways of generating a complexity file

There are alternate ways of generating a complexity file:

- The environment variable SDT_COMPLEXITY_INFO can be set to generate a complexity file. In that case it is a prerequisite that an .xrf (cross references file) also has to be generated.

  As the calculation of the execution paths (see "Execution Paths" on page 2128) is the most complex seen from the implementation side and at the same time is the calculation that might take some time, this calculation can be turned off by setting the environment variable SDT_NO_COMPLEXITY_PATH_INFO. The figures for this field in the file will then be 0. The recommendation, however, is to leave this calculation turned on, until something seems to go wrong.

- The Analyzer commands *Set-ComplexityMeasurement* and *ComplexityMeasurement-File* can be used for creating a complexity file.

  See "Set-ComplexityMeasurement" on page 2486 in chapter 54, *The SDL Analyzer* and "ComplexityMeasurement-File" on page 2478 in chapter 54, *The SDL Analyzer* for more information.

Complexity File Contents

There is one line in the file for each:

- System, System Type, Package
- Block, Block Type, Block Substructure
- Process, Process Type
- Service, Service Type
- Procedure (not simple procedures, >= 2 states or >= 50 symbols)

Each line contains first the *declaration level*. This is 1 for the system and for packages. Units defined in the system have level 2 and so on.

The lines then include the *entity class* and the *name of the unit*, followed by some complexity numbers. The complexity numbers are given both for the unit itself (local) and for the unit including all its subunits (total).

The lines are sorted so that all subunits are placed **before** the unit where they are defined.

Complexity Numbers

Declarations

This is the number of declarations in the unit. The following entity classes contribute to the declaration count:

- System, System Type
- Block, Block Instance, Block Type, Block Substructure
- Channel, Signal Route, Gate
- Process, Process Instance, Process Type
- Service, Service Instance, Service Type
- Procedure, Operator (user defined), Remote Procedure, Remote Variable
- Sort, Syntype, Generator, Synonym
- Variable, View, Formal Parameter
- Signal, Timer, Signal List

States

This number gives the number of distinct states in the unit. The start symbol is not counted as a state.

This number does not correspond to the number of graphical state symbols, as the same state can be mentioned in several graphical state symbols and as many states can be mentioned in the same graphical state symbols.

Transitions

This number gives the number of transitions defined in the unit. The start transition is considered as a transition. A transition starts with the symbol after a start, input, enabling condition, or continuous signal symbol, and ends with a nextstate, stop, return, or join symbol.

This means for example that the transition starting with a task in the following is counted as one transition:

```
state a,b,c;
  input s1,s2,s3;
    task ....;
    ....;
    nextstate c;
```

Symbols

This is the number of symbols in the transitions in the unit. State, start, input, continuous signal, and enabling conditions are not counted. More precisely the following symbols are counted:

- task
- create
- call
- output
- set
- reset
- decision
- nextstate
- stop
- return
- join

A compound statement in a task or defining an operator or procedure is counted as one symbol.

The count is not directly connected to the graphical symbols, but rather to the syntactical entities. A task is, for example, counted as one symbol independently how it is divided between a task symbol, a text extension, and a comment symbol.

Statements

This is an extension of the count of symbols. Each of the following is also counted individually:

- Assignments in a task
- Signals sent in an output
- Timers handled in a set or reset
- Variables exported in an export
- Statements in a compound statement

Execution Paths

This is the number of possible different paths to go from a transition start (start, input, continuous signal) to a transition end (stop, nextstate, return). This figure is not completely correct but will in most cases give a good estimate.

The following details should be noted:

- Break and Continue statements in compound statements are ignored.
- Loops (joins leading backwards and for statements) are considered to be executed one time.

Maximum Statement Depth

This figure gives the statement depth, that is the nesting of statements. In graphs it is the decision symbol that contributes, while in compound statements it is the compound statement, the if statement, the decision statement, and the for statement that contribute.

Chapter

49 *The SDL Simulator*

This chapter is a reference to the simulator user interface.

For a guide to how to use the simulator, see chapter 50, *Simulating a System*.

The Simulator Monitor

A simulator generated by the SDL Suite consists of two main parts; the application itself (the simulated SDL system), and an interactive monitor system. The monitor system is the interface between the user and the simulated system. For more information on the structure of a simulator and the features of the simulator monitor, see "Structure of a Simulator" on page 2234 in chapter 50, *Simulating a System*.

Monitor User Interfaces

Two different user interfaces are provided for the simulator monitor, a textual and a graphical.

The textual interface only allows commands to be entered from the keyboard, using the syntax described in the section "Syntax of Monitor Commands" on page 2132.

The graphical interface still allows commands to be entered from the keyboard in the same way, but also provides buttons, menus and dialogs for easy access to commands and other features.

The textual interface is invoked by executing the generated simulator directly from the operating system prompt. This is called running a simulator in *textual mode*. When started, the simulator responds with the following text:

```
Welcome to SDL SIMULATOR. Simulating system <system>

Command :
```

Another prompt may appear if the SDL system contains external synonyms. For more information, see "Supplying Values of External Synonyms" on page 2240 in chapter 50, *Simulating a System*.

> **Note:**
>
> Before a simulator can be run in textual mode **on UNIX**, a command file must be executed from the operating system prompt. The file is called `telelogic.sou` or `telelogic.profile` and is located in the binary directory that is included in the user's path.
> For csh-compatible shells: **`source <bin dir>/telelogic.sou`**
> For sh-compatible shells: **`. <bin dir>/telelogic.profile`**

The graphical interface, known as the *Simulator UI*, runs in a separate window. It is started from the Organizer by selecting *SDL > Simulator UI* from the *Tools* menu. The Simulator UI is described in "Graphical User Interface" on page 2199.

If a file called `siminit.com` exists in the current directory an implicit Include-File command will be done on this file at startup.

Activating the Monitor

Commands can be issued to the interactive monitor system when it becomes active. The simulator's monitor system becomes active:

- When the simulator is started.
- When the last command was Next-Transition or Next-Visible-Transition and the transitions initiated by this command have completed.
- When the last command was Next-Symbol or Step-Symbol and one SDL symbol has been executed.
- When the last command was Next-Statement or Step-Statement and one SDL statement has been executed.
- When the last command was Finish and the currently executing procedure has returned.
- When the last command was Proceed-Until and the value of the simulation time is, for the first time, equal to the time given as a parameter to the command.
- When the last command was Proceed-To-Timer and all transitions up to the next timer output have been executed.
- Immediately before a transition matching a transition breakpoint set by the command Breakpoint-Transition.
- Immediately before a symbol matching a symbol breakpoint set by the command Breakpoint-At.
- Immediately after an output symbol that contains an output matching an output breakpoint set by the command Breakpoint-Output.

- Immediately after a symbol or assignment statement where a variable is changed matching a variable breakpoint set by the command Breakpoint-Variable.
- When there is no transition that can be executed, that is, the system is completely inactive. (**On UNIX**, if no environment is present and the command Go-Forever was issued.)
- Immediately after a symbol that included an SDL semantic error.
- In the Simulator UI, when the *Break* button is clicked in the *Execute* button module; in textual mode, when `<Return>` is pressed during the output of trace information. The interactive monitor then becomes active directly after the current symbol has been executed.

Note:

No other characters may be typed before `<Return>` **is pressed**.

Syntax of Monitor Commands

The monitor system waits for commands from the user by issuing the following prompt:

```
Command :
```

The syntax to be used for the commands and their parameters are described in the following.

Command Names

A command name may be abbreviated by giving sufficient characters to distinguish it from other command names. A special character, the hyphen (-), is used to separate command names into distinct parts. Any part may be abbreviated as long as the command name does not become ambiguous.

Consider, as an example, the command name List-Process. The command name may be typed **`List-P`** or **`L-P`**. However, if only **`List`** is typed, the monitor system will respond with the message

```
Command was ambiguous, it might be an abbreviation
of:
```

followed by a list of all commands starting with “List,” since the command cannot be distinguished from, for example, the commands List-Ready-Queue and List-Timer.

There is no distinction made between upper and lower case letters when matching command names.

Parameters

Command parameters are separated by one or several spaces, carriage returns or tabs. A colon is also accepted between a process name and an instance number, when a PId value is required. If the parameter list following a command name is not complete the interactive monitor system will ask for the missing parameters by prompting with the type of the expected parameters.

Parameters may be abbreviated as long as the parameter value does not become ambiguous. There is no distinction made between upper and lower case letters.

> **Note:**
>
> The SDL keywords **Sender**, **Parent**, **Self** and **Offspring** may **not be abbreviated**.

Underscores in SDL Names

Command parameters that are SDL names may also be abbreviated, as long as the abbreviation is unique. The underscore character ‘_’ is used to separate names into distinct parts in the same way as the hyphen character (-) is used with command names. If a name is equal to the first part of another name, as for example Wait and Wait_For_Me, then any abbreviation of Wait is ambiguous. However, if all characters of the shorter name are given (Wait in this example), this is considered as an exact match and the short name will be selected.

The abbreviation facility means that the introduction of underscores in SDL names simplifies simulation. If, for example, you were considering if two signals should be named GenerateOn and GenerateOff or if they should be named Generate_On and Generate_Off, the last alternative is preferable for simulations, as the abbreviations G_On and G_Off are likely to be unique.

Matching of Parameters

When a (possibly abbreviated) parameter name is entered and is to be matched with an unabbreviated name, only names in the entity class of interest are considered. That is, if the monitor expects a process name as parameter, only the names denoting process types will be part of the search for the full name.

Signal names and timer names are in the same entity class; process formal parameters and process variables are in the same entity class; each other type of name (process, procedure, state, block,...) is in an entity class of its own.

Knowledge of previous parameters is used to narrow the search for a given parameter name. Consider for example the command Output-Via, which takes two parameters, a signal and a channel. The channel name is then only searched for among the channels the given signal can be sent via.

Qualifiers

Names can still cause problems, if, for example, there are two process types with the same name in two different blocks, or if the system and a block contain signal definitions with the same name.

In the first situation the process name will always be ambiguous and in the second case the system's signal will always be used. To solve cases like this, qualifiers with the same syntax as in SDL can be used. To reach a process P defined in block B in system S, the following notations can be used:

```
System S / Block B P
<<System S / Block B>> P
```

The words "system," "block," "process," "procedure," and "substructure" in the qualifier **may not be abbreviated**, while all names of, for example, blocks and processes may be abbreviated according to the usual rules. It is only necessary to give those parts of the qualifier that make the qualifier path unique (this is an extension of the qualifier concept in SDL). The slash (/) in a qualifier may be omitted and replaced by one or more spaces. The angle brackets that are part of the qualifier when printed may be omitted when entering the qualifier.

Default Parameters

Some command parameters may be omitted, indicating a default value for the parameter. To accept a default parameter value at the prompt, just press <Return>.

If the parameter is given on the same line as the command name and/or other parameters, type a hyphen '-' to indicate a default parameter value.

Example 324: Default Parameters in Simulator Command

Consider as an example the command Breakpoint-Transition, which takes at least eight parameters. To specify default values for all parameters, except the first and fourth parameter:

```
Breakpoint-Transition P - - State1 - - - -
```

Signal and Timer Parameters

When the parameters of a signal instance or a timer instance are to be entered, the interactive monitor system will ask for the parameters one by one, in the same way as for command parameters. The parameters can also be entered directly after the signal or timer name, possibly enclosed by parenthesis.

Example 325: Signal and Timer Parameters in Simulator Command

```
Signal name : S
Parameter 1 (Integer) : 3
Parameter 2 (Boolean) : true
```

The same specification could also be given as:

```
Signal name : S 3 true
```

or as:

```
Signal name : S (3 true)
```

When entering signal parameters it is not necessary to give all parameter values. By entering '-' at the parameter's position, the parameter is given a "null" value (i.e. the computer's memory for the value is set to 0). By entering ')', the rest of the parameters are given "null" values.

Example 326: Signal Parameters in Simulator Command

```
Signal name : S -, true
```

will give the first parameter a “null” value.

```
Signal name : S (3, -)
```

will give the second parameter a “null” value. Could also be given as:

```
Signal name : S (3)
```

Errors in Commands

If an error in a command name or in one of its parameters is detected, an error message is printed and the execution of the command is interrupted, that is, a command is either executed completely or not at all. **On UNIX**, this is the only way to cancel a command that has been entered, when not using the simulator’s graphical user interface.

Context-Sensitive Help

By typing a question mark (‘?’), a context-sensitive help is obtained. The monitor will respond to a ‘?’ by giving a list of all allowed values at the current position, or by a type name, when it is not suitable to enumerate the values. After the presentation of the list, the input can be continued.

If no default value exists for the requested parameter, the list of all allowed values is also printed if the user simply presses `<Return>` at the prompt. In these cases, there is no need to type ‘?’.

Input and Output of Data Types

The syntax of literals of the predefined data types is in most cases obvious and follows the SDL definition of literals. There are, however, some extensions that are described below. As an option, it is also possible to use the ASN.1 syntax for values. On input the monitor system can manage both value notations, while there are commands in the monitor to select the type of output to be produced (SDL-Value-Notation and ASN1-Value-Notation).

Integer, Natural Values

The format of integers conforms exactly with the SDL and the ASN.1 standard, that is, an integer consists of a sequence of digits, possibly preceded by a '+' or '-'. However, with the command Define-Integer-Output-Mode it is possible to define the base of integers on output (decimal, hexadecimal, octal), which also affects how they may be entered. Hexadecimal values are preceded with "0x", and octal values are preceded with '0' (a zero).

Boolean Values

Boolean values are entered (and printed) as `true` and `false`, using upper or lower case letters. Abbreviation is allowed on input. In ASN.1 mode the value is printed in capital letters (`TRUE`, `FALSE`).

Real Values

The SDL literal syntax of real values has been extended to include the E-notation for exponents, in the same way as in many programming languages.

Example 327: Real Values in SDL Syntax ----------

The real number $1.4527 * 10^{24}$ can be written `1.4527E24`

The real number $4.46 * 10^{-4}$ can be written `4.46E-4`

The syntax for real values in ASN.1 is easiest described by an example:

Example 328: Real Values in ASN.1 Syntax ––––––––––––––––––––

```
{mantissa 23456, base 10, exponent -3}
```

This is the value 23.456.

Time, Duration Values

The format for Time and Duration values follows the SDL standards, i.e. real values without E-notation, with one extension. On input time values can either be absolute or relative to NOW. If the time value is given without a sign an absolute time value is assumed, while if a plus or minus sign precedes the value, a value relative to NOW is assumed.

Example 329: Time Values in SDL Syntax ––––––––––––––––––––

`123.5` is interpreted as 123.5

`+5.5` is interpreted as NOW + 5.5

`-8.0` is interpreted as NOW - 8.0

Character Values

Character values are entered and printed according to the SDL standard, including the literals for the non-printable characters.

Example 330: Character Values in SDL Syntax ––––––––––––––––––

```
'a', '3', '''', ' ', NUL, DEL
```

On input, the quotes may be omitted for all characters except ‘ ’ (space) and ‘[‘. A ‘should be entered as ‘’’.

Charstring Values

Charstring values can be entered and printed according to the SDL standard, that is, a single quote (’) followed by a number of characters followed by a single quote. Any quote (’) within a charstring has to be given twice. On output a non-printable character within a charstring is

printed as a single quote followed by the character literal followed by a single quote.

The ASN.1 syntax for Charstring is similar to the SDL syntax. The delimiter character ‘ (single quote) is however replaced by the character “ (double quote).

Example 331: Charstring Values in SDL Syntax ––––––––––––––––––

`''`	An empty string
`'abc'`	A string of three characters
`'a'NUL'c'`	The second character is NUL

––

PId Values

Apart from the value null, which is a valid PId value, a PId value consists of two parts, the name of the process type and an instance number, which is an integer greater than 0.

The first process instance of a process type that is created will have instance number 1, the second that is created will have instance number 2, and so on. The syntax is Name:No, where Name is the process name and No is the instance number.

On input the process name and the instance number may, as an alternative, be separated by one or more spaces, if the command parameter is a PId value. In the same circumstances the instance number is not necessary (and will not be prompted for) if there is only one process instance of the process type. If, however, the command parameter is a unit that might be a process type or a process instance, only a colon (‘:’) is allowed between the process name and the instance number and the colon must follow directly after the process type name. Examples of such situations are the unit parameter in Set-Trace and Signal-Log.

On output a PId value may be followed by a plus sign (‘+’), which indicates that the process instance is dead; that is, has executed a stop action. The plus sign is chosen as it is reminiscent of the ‘†’ character.

Bit

The Bit sort contains two values, 0 and 1. This syntax is used for input and output.

Bit_String

For Bit_String values the following syntax is used:

```
'0110'B
```

The characters between the two single quotes must be 0 or 1. On input the syntax for Octet_String, see below, can also be used.

Octet

The syntax used for an octet value is two HEX digits. Examples:

```
00   46   F2   a1   CC
```

The characters 0-9, a-f, and A-F are allowed.

Octet_String

The syntax for Octet_String is the following

```
'3A6F'H
```

Each pair of two HEX values in the string is treated as an Octet value. If there is an odd number of characters an extra 0 is inserted last in the string.

Object_Identifier

The sort Object_Identifier is in SDL treated as a String(Natural). This means that the syntax, in case SDL value notation is used, will be:

```
(. 2, 3, 11 .)
```

On input the items in the list should be separated by a comma and/or spaces - tabs. If ASN.1 value notation has been selected, the syntax will be:

```
{ 2 3 11 }
```

On input the items in the list should be separated by a comma and/or spaces - tabs.

Enumerated Values

Types that in SDL are defined as an enumeration of possible values can be entered and printed using the literals of the SDL data type definition. On input, the literals can be abbreviated as long as they are unique.

STRUCT Values

A struct value is entered and printed as the two characters "(." followed by a list of components followed by the two characters ".)". The components should, on input, be separated by a comma and/or a number of spaces (or carriage returns or tabs). Example:

```
(. 23, true, 'a' .)
```

If ASN.1 syntax is used, the component names will also be present. Example:

```
{ Comp1 2, Comp2 TRUE, Comp3 'a' }
```

On input the components using ASN.1 syntax may come in any order. Components not given any value will have the value 0, whatever that means for the data type.

On input the components using ASN.1 syntax may come in any order.

Optional components that are not present, will not be printed. In SDL syntax that means an empty position between two commas.

#UNION Values

A #UNION value uses, in SDL value notation, the same syntax as a struct value. However, only the tag value and the active component is printed. In ASN.1 value notation, #UNION values use the Choice value syntax described below.

Choice Values

The syntax for a choice value is `ComponentName:ComponentValue`. If, for example, a choice contains a component C1 of type integer, then

```
C1:11
```

is a valid choice value.

#UNIONC Values

The syntax for a #UNIONC value is ! `ComponentName ComponentValue` or -> `ComponentName ComponentValue`. If, for example, a #UNIONC contains a component C1 of type integer, then

```
! C1 11
```

is a valid #UNIONC value. However, this syntax will not be used when printing, since the value contains no tag and hence it is not possible to know which component to use.

Array Values

An array value is entered and printed as “(:” followed by a list of components followed by a “:)”. The components should, on input, be separated by a comma and/or a number of spaces (or carriage returns or tabs). Note that there should also be a space between the last component and the terminating “:)”. In ASN.1 syntax, ‘{’ and ‘}’ are used as delimiters.

There are two syntaxes for array components depending on the implementation that the SDL to C Compiler has selected for the array implementation. This selection is described in *“Array” on page 2671 in chapter 56, The Cadvanced/Cbasic SDL to C Compiler*. These easiest way to determine which syntax to use on input is to look at a variable of the array sort.

- If an array is a simple array (i.e. index type is a simple type with one range condition and a limited range), the SDL syntax for an array value is according to the following example:

  ```
  (: 1, 10, 23, 2, 11 :)
  ```

  If ASN.1 value notation is selected, replace “(:” and “:)” by ‘{’ and ‘}’.

- If the array is a general array, the a syntax according to the following example should be used:

  ```
  (: (others:2), (10:3), (11:4) :)
  ```

  This would mean that for index 10 the value is 3, for index 11 the value is 4, and for all other indexes the value is 2. On input the commas, the parenthesis, and the colons in the components may be replaced by one or more spaces (or carriage returns or tabs).

For simple arrays the second syntax is also accepted. If the first syntax is used for simple arrays it is not mandatory to enter all values for the array components; by entering ":)" or "}" the rest of the components are set to a "null" value (i.e. the computer's memory for the value is set to 0).

String Values

A string value starts with "(." and ends with ".)". The components of the string is then enumerated, separated with commas. Example:

```
(. 1, 3, 6, 37 .)
```

On input the commas can be replaced by one or more spaces (or carriage returns or tabs). In ASN.1 syntax, '{' and '}' are used as delimiters instead of "(." and ".)".

Powerset Values

A powerset value starts with a '[' and ends with a ']'. The elements in the powerset is then enumerated, separated with commas. Example:

```
[ 1, 3, 6, 37 ]
```

On input the commas can be replaced by one or more spaces (or carriage returns or tabs).

Bag Values

A bag value starts with a '{' and ends with a '}'. The elements in the bag is then enumerated, separated with commas. Example:

```
{ 1, 3, 6, 37 }
```

On input the commas can be replaced by one or more spaces (or carriage returns or tabs). If the same value occurs more than once, then this value is in SDL syntax not enumerated several times. Instead, the number of occurrences is indicated after the value. Example

```
{ 1, 3:4, 6:2, 37 }
```

This is identical to

```
{ 1, 3, 3, 3, 3, 6, 6, 37 }
```

In ASN.1 syntax, each member is given explicitly according to the last example. On input items are separated by comma and/or one or more

spaces. It is also allowed to mention the same value several times, with or without a number of items each time.

Ref Values

There are two possible syntaxes for Ref values. Either the pointer address as a HEX value, or the value of the data area referenced by the pointer. The value Null is printed as `Null` in both syntaxes. In the monitor system two commands are available to determine the syntax to be used (REF-Address-Notation and REF-Value-Notation). On input both syntaxes are allowed independently of what syntax that has been selected.

Example of the address notation:

```
HEX(23A20020)
```

In the value notation the keyword `new()` is used to indicate a reference to a value. If, for example, the following data types are available in SDL

```
newtype Str struct
  data integer;
  next StrRef;
endnewtype;

newtype StrRef Ref(Str)
endnewtype;
```

then a value of the StrRef type can look like the examples below:

```
Null
new( (. 1, Null .) )
new( (. 1, new( (. 2, Null .) ) .) )
```

The last example is a linked list with two elements. To handle recursive data structures, e.g. graphs, a special syntax is used: `old n`, where `n` is an integer. Example:

```
new( (. 1, new( (. 2, old 1 .) ) .) )
```

The notation `old 1` in the example above means a reference to the same data area as the first `new()` notation refers to. So here we have two structs with next pointers referring to the other struct value. `Old n` would refer to the n:th `new()` seen from the left of the expression.

The same applies for Own and ORef values.

Monitor Commands

This section provides an alphabetical listing of all available commands in the simulator monitor. Simulator UI commands are described in "SimUI Commands" on page 2225.

@ (Keyboard Polling)

Parameters:

(None)

The monitor will repeatedly look at the keyboard for a carriage return, indicating an immediate break in the execution of the current transition. Using the command @, this facility can be turned off. Each time the command @ is entered the monitor toggles between having the keyboard polling for carriage return on and off. At start up keyboard polling is on.

> **Note:**
>
> **No other characters** may be typed together with the carriage return. If some other characters are typed by mistake, please delete them before typing the carriage return.

To turn keyboard polling off is useful in some situations, for example if a user wants to paste a sequence of commands into the monitor. If the sequence contains an empty line this might cause an unwanted interrupt.

? (Interactive Context Sensitive Help)

Parameters:

(None)

The monitor will respond to a '?' (question mark) by giving a list of all allowed values at the current position, or by a type name, when it is not suitable to enumerate the values. After the presentation of the list, the input can be continued.

Typing '?' at the prompt level gives a list of all available commands, after which a command can be entered. For further help, see the command Help.

ASN1-Value-Notation

Parameters:

(None)

The value notation used in all outputs of values is set to ASN.1 value notation. See also the command SDL-Value-Notation.

Assign-Value

Parameters:

```
[ '(' <PId value> ')' ]
<Variable name> <Optional component selection>
<New value>
```

The new value is assigned to the specified variable in the process instance, service instance, or procedure given by the current scope. Sender, Offspring, and Parent may also be changed in this way, but their names may not be abbreviated.

It is, in a similar way as for the command Examine-Variable, possible to handle components in structured variables (struct, strings, array, and Ref) by appending the struct component name or a valid array index before the value to be assigned. Nested structs and arrays can be handled by entering a list of index values and struct component names.

If a PId is given within parenthesis the scope is temporarily changed to this process instance instead.

Breakpoint-At

Parameters:

```
<SDT reference> <Optional breakpoint commands>
```

A breakpoint is defined at the symbol specified by the SDT reference. If the execution reaches the symbol, the monitor becomes active immediately before that symbol. SDT references may be obtained by using the *Show GR Reference* command in an SDL Editor, see "Show GR Reference" on page 2027 in chapter 43, *Using the SDL Editor*.

The <Optional breakpoint commands> parameter can be used to give monitor commands that should be executed when the breakpoint is triggered. Monitor commands should be separated by `" ; "`, i.e. space semicolon space.

Breakpoint-Output

Parameters:

```
<Signal name>
<Receiver process name> <Receiver instance number>
<Sender process name> <Sender instance number>
<Counter>
<Optional breakpoint commands>
```

A breakpoint is activated and a breakpoint condition is defined. If a breakpoint condition is matched by an output, the monitor becomes active immediately after the symbol containing the output. The breakpoint condition defines one or several outputs and is specified by the parameters. Any of the parameters may be omitted, which implies that any value will match the missing fields in the breakpoint condition. Initially no breakpoints are active.

The <Counter> parameter is used to indicate how many times the breakpoint condition should be true before the monitor should become active. Default value for this parameter is 1, which means that the monitor should be activated each time the breakpoint condition is true.

The <Optional breakpoint commands> parameter can be used to give monitor commands that should be executed when the breakpoint is triggered. Monitor commands should be separated by `" ; "`, i.e. space semicolon space.

Breakpoint-Transition

Parameters:

```
<Process name> <Instance number> <Service name>
<State name> <Signal name> <Sender process name>
<Sender instance number> <Counter>
<Optional breakpoint commands>
```

A breakpoint is activated and a breakpoint condition is defined. If a breakpoint condition is matched by a transition, the monitor becomes active immediately before that transition is started. The breakpoint condition matches one or several transitions and is specified by the parameters. Any of the parameters may be omitted, which implies that any value will match the missing fields in the breakpoint condition. Initially no breakpoints are active.

The <Counter> parameter is used to indicate how many times the breakpoint condition should be true before the monitor should become active. Default value for this parameter is 1, which means that the monitor should be activated each time the breakpoint condition is true.

The <Optional breakpoint commands> parameter can be used to give monitor commands that should be executed when the breakpoint is triggered. Monitor commands should be separated by `" ; "`, i.e. space semicolon space.

Breakpoint-Variable

Parameters:

```
<Variable name> <Optional breakpoint commands>
```

A breakpoint is defined on the specified variable in the process instance given by the current scope. If the variable's value is changed, the monitor becomes active immediately after the symbol or assignment statement where the value is changed. The value is only checked between symbols and between assignment statements in tasks.

The breakpoint is also triggered when the variable no longer exists, i.e. the PId containing the variable is stopped or the procedure containing the variable has reached its end. In this case, the breakpoint is automatically removed.

The <Optional breakpoint commands> parameter can be used to give monitor commands that should be executed when the breakpoint is triggered. Monitor commands should be separated by `" ; "`, i.e. space semicolon space.

Call-Env

Parameters:

```
(None)
```

The Call-Env command performs one call of the function `InEnv`. See the command Start-Env for more details.

> **Note:**
>
> This command and the commands Start-Env and Stop-Env are only available when the SDL to C Compiler is used to generate applications.

Call-SDL-Env

Parameters:

```
(None)
```

The command makes one call to the function that looks for incoming signals from the SDL Suite communication mechanism. This means that all signals that have come to the simulator will be sent to their appropriate receiving process instances. See the command Start-SDL-Env for more details.

Cd

Parameters:

```
<Directory>
```

Change the current working directory to the specified directory.

Clear-Coverage-Table

Parameters:

```
(None)
```

This command is used to reset the coverage table to 0 in all positions, which means restart counting coverage from now.

Close-Signal-Log

Parameters:

```
<Entry number>
```

Stops the signal log with the specified entry number and closes the corresponding log file; see the command Signal-Log for more details. Entry numbers assigned by the command List-Signal-Log should be used.

Command-Log-Off

Parameters:

```
(None)
```

The command log facility is turned off; see the command Command-Log-On for details.

Command-Log-On

Parameters:

```
<Optional file name>
```

The command enables logging of all the commands given in the monitor. The first time the command is entered a file name for the log file has to be given as parameter. After that any further Command-Log-On commands, without a file name, will append more information to the previous log file, while a Command-Log-On command with a file name will close the old log file and start using a new file with the specified name.

Initially the command log facility is turned off. It can be turned off explicitly by using the command Command-Log-Off.

The generated log file is directly possible to use as a file in the command Include-File. It will, however, contain exactly the commands given in the session, even those that were not executed due to command errors.

The concluding Command-Log-Off command will also be part of the log file.

Connect-To-Editor

Parameters:

```
(None)
```

This command will create a new *Breakpoints* menu in the SDL Editor and tell the SDL Editor to show all graphical breakpoints. If no SDL Editor is opened, the menu will appear when an SDL Editor is opened the next time. The commands given in the new menu will only be handled in those simulations that are connected. See also the Disconnect-Editor command.

Create

Parameters:

```
<Process name> <Parent's PId value>
<Process parameters>
```

A process instance of the specified process type is created. If the parent PId is not equal to null, Offspring is set in the specified parent instance. If the number of instances of the specified process type is greater than or equal to the maximum number of concurrent instances, the user has to verify the create action.

Define-Continue-Mode

Parameters:

```
"On" | "Off"
```

Defines whether the execution of the simulation shall continue after a command is given. The default is “Off”.

Define-Integer-Output-Mode

Parameters:

```
"dec" | "hex" | "oct"
```

Defines whether integer values are printed in decimal, hexadecimal or octal format. In hexadecimal format the output is preceded with “0x”, in octal format the output is preceded with ‘0’ (a zero).

On input: if the format is set to hexadecimal or octal, the string determines the base as follows: After an optional leading sign a leading zero indicates octal conversion, and a leading “0x” hexadecimal conversion. Otherwise, decimal conversion is used.

The default is “dec”, and no input conversion is performed.

Define-MSC-Trace-Channels

Parameters:

```
"On" | "Off"
```

Defines whether the env instance should be split into one instance for each channel connected to env in the MSC trace. The default is “Off”.

Detailed-Exa-Var

Parameters:

```
(None)
```

When printing structs containing components with default value, these values are explicitly printed after this command is given.

Disconnect-Editor

Parameters:

```
(None)
```

This command will remove the connection to the SDL Editor. If this simulation is the only connected to the SDL Editor, it will also remove the *Breakpoints* menu in the SDL Editor. See also the Connect-To-Editor command.

Display-Array-With-Index

Parameters:

```
"On" | "Off"
```

When Display-Array-With-Index is On and you examine an array, the value of the array element is printed with its index. Index is added before the value of the array element. The default is “Off”.

Down

Parameters:

```
<Optional service name>
```

Moves the scope one step down in the procedure call stack. If the current scope is a process containing services, one of the services should be specified. See also the commands Stack, Set-Scope and Up.

Examine-PId

Parameters:

```
[ '(' <PId value> ')' ]
```

Information about the process instance given by the current scope is printed (see the Set-Scope command for an explanation of scope). This information contains the current values of Parent, Offspring, Sender and a list of all currently active procedure calls made by the process instance (the stack). The list starts with the latest procedure call and ends with the process instance itself. If the process contains services, these services will be listed, each with its own procedure call stack.

If a PId is given within parenthesis information about this process instance is printed instead.

Examine-Signal-Instance

Parameters:

```
<Entry number>
```

The parameters of the signal instance at the position equal to entry number in the input port of the process instance given by the current scope are printed (see the Set-Scope command for an explanation of scope). The entry number is the number associated with the signal instance when the command List-Input-Port is used.

Examine-Timer-Instance

Parameters:

```
<Entry number>
```

The parameters of the specified timer instance are printed. The entry number is the number associated with the timer when the List-Timer command is used.

Examine-Variable

Parameters:

```
[ '(' <PId value> ')' ]
<Optional variable name>
<Optional component selection>
```

The value of the specified variable or formal parameter in the current scope is printed (see the Set-Scope command for an explanation of scope). Variable names may be abbreviated. If no variable name is given, all variable and formal parameter values of the process instance given by the current scope are printed. Sender, Offspring, Self, and Parent may also be examined in this way. Their names, however, may not be abbreviated and they are not included in the list of all variables.

Note:

If a variable is exported, both its current value and its exported value are printed.

It is possible to examine only a component of a struct, string or array variable, by appending the struct component name or a valid array index value as an additional parameter. The component selection can handle structs and arrays within structs and arrays to any depth by giving a list component selection parameters. SDL syntax with '!' and "( )" as well as just spaces, can be used to separate the names and the index values.

It is also possible to print a range of an array by giving "FromIndex: To-Index" after an array name. Note that the space before the ':' is required if FromIndex is a name (enumeration literal), and that no further component selection is possible after a range specification.

To see the possible components that are available in the variable, the variable name must be appended by a space and a '?' on input. A list of components or a type name is then given, after which the input can be continued. After a component name, it is possible to append a '?' again to list possible sub components.

To print the value of the data referenced by a Ref pointer it is possible to use the SDL syntax, i.e. the "*>" notation. If, for example, `Iref` is a Ref(Integer) variable then `Iref*>` is the integer referenced by this pointer. If `Sref` is a Ref of a struct, then `Sref*> ! Comp1` is the Comp1 component in the referenced struct. The sequence `*> !` can in the monitor be replaced by `->` (as for example in C).

If a PId is given within parenthesis the scope is temporarily changed to this process instance instead.

Exit

Parameters:

`(None)`

The simulation is terminated. If the command is abbreviated the monitor asks for confirmation. This is the same command as Quit.

Finish

Parameters:

`(None)`

This command will execute the currently executing procedure up to and including its return, i.e. it will finish this procedure. The execution will also be interrupted at the end of the transition. In a process, Finish will behave just like the command Next-Transition.

Go

Parameters:

(None)

The execution of the simulation is resumed. The execution will continue until one of the conditions listed in "Activating the Monitor" on page 2131 becomes true. To stop the execution of transitions, press <Return> (and only this key). The interactive monitor will then become active when the execution of the current SDL symbol is completed.

This command has to be used with care in the interactive monitor, as it might result in executing the simulation program "forever" (if none of the conditions for activating the monitor becomes true). In a catastrophic situation (e.g. an endless loop within an SDL symbol) it is possible to terminate the program by using the way to stop the execution of a program defined in the operating system (<Ctrl+C> **on UNIX**).

Go-Forever

Parameters:

(None)

The command Go-Forever behaves, in most situations, in the same way as the command Go.

For Go-Forever to behave differently than Go, there has to be an environment to the SDL system that can send signals to the SDL system (communicating simulations or environment functions). When the command Go is issued and the SDL system becomes completely idle (no possible transition and no active timer) the monitor becomes active again and is entered. If Go-Forever was used instead of Go, the monitor is not entered in this case; instead the simulation continues to wait for external stimulus. This feature is valuable when a simulation communicates with other simulations or applications.

Help

Parameters:

<Optional command name>

Issuing the Help command without a parameter will print all the available commands. If a command name is given as parameter, this command will be explained.

Include-File

Parameters:

```
<File name>
```

This command provides the possibility to execute a sequence of monitor commands stored in a text file. The Include-File facility can be useful for including, for example, an initialization sequence or a complete test case. It is allowed to use Include-File in an included sequence of commands; up to five nested levels of include files can be handled.

This command also provides the possibility to perform script calling with variable substitution.

In a script file it is possible to refer to variables using $1, $2, ... , $99. The numbered variables refer to the arguments (actual values) given when calling a script using the command Include-File.

Unix shell script expressions like $0, $#, $? and $* are not available to be given as variable references in script files. Letters are not used as reference variables. For example $a, $1b, $ac are not available to be used as reference variables.

The actual values will be given as parameters in the Include-File command after script-file name. It is possible to pass up to 99 actual values. The numbered variables will be substituted by the actual values during execution of commands in the script files.

Arguments should be separated by spaces. $1 will be substituted by arg1, $2 will be substituted by arg2, $3 will be substituted by arg3, and $4 will be substituted by arg4 and so on.

If there is an argument missing, the corresponding reference variable will not get a value, it is up to the user to provide the correct arguments when using the Include-File command.

List-Breakpoints

Parameters:

```
(None)
```

All active breakpoints are listed. Each breakpoint is assigned an entry number that can be used in the Remove-All-Breakpoints and Show-Breakpoint commands.

List-GR-Trace-Values

Parameters:

```
(None)
```

The values of all currently defined GR traces are listed. The list contains the trace unit type (system, block, process, PId), the unit name, and the GR trace value (both numeric and a textual explanation). See also the commands Set-GR-Trace and Reset-GR-Trace.

List-Input-Port

Parameters:

```
[ '(' <PId value> ')' ]
```

A list of all signal instances in the input port of the process instance given by the current scope is printed (see the Set-Scope command for an explanation of scope). For each signal instance an entry number, the signal type, and the sending process instance is given. A '*' before the entry number indicates that the corresponding signal instance is the signal instance that will be consumed in the next transition performed by the process instance. The entry number can be used in the commands Examine-Signal-Instance, Rearrange-Input-Port and Remove-Signal-Instance.

If a PId is given within parenthesis information about this process instance is printed instead.

List-MSC-Log

Parameters:

```
(None)
```

This command returns the current status of the MSC log (off / interactive / batch). See also the commands Start-Interactive-MSC-Log, Start-Batch-MSC-Log and Stop-MSC-Log.

List-MSC-Trace-Values

Parameters:

```
(None)
```

This command returns the current status for the MSC trace parameters. The list contains the trace unit type (system, block, process, PId), the

unit name, and the MSC trace value (both numeric and a textual explanation). See also the commands Set-MSC-Trace and Reset-MSC-Trace.

List-Process

Parameters:

```
<Optional process name>
```

A list of all process instances associated with the specified process type is produced. If no process name is specified all process instances in the system are listed. The list will contain the same details as described for the List-Ready-Queue command.

List-Ready-Queue

Parameters:

```
(None)
```

A list is produced containing the process instances in the ready queue, i.e., those instances that have received a signal that can cause an immediate transition, but that have not yet had the opportunity to execute this transition to its end. If the process contains services, the currently active service is also listed. If a process/service instance has active procedure calls, the current executing procedure instance is also listed. For each instance in the list the following information is given:

1. An entry number (process instances only).
2. An identification of the process/service/procedure instance.
3. The name of its current state. If the state name is followed by a '*', then the process/service/procedure is currently executing a transition starting from this state.
4. The number of signal instances in the input port of the process instance.
5. The signal name of the signal instance that will cause (or has caused) the transition by the process instance. This signal instance is marked with a '*' before the entry number, if the command List-Input-Port is issued. If the transition has started the signal is no longer in the input port.

The process instance, the state, and the signal instance determine uniquely the transition that will be executed by the process instance when it gets permission to do so.

The entry number can be used in the command Rearrange-Ready-Queue.

List-Signal-Log

Parameters:

```
(None)
```

Print information about the currently active signal log; see the command Signal-Log for more details. Each log is assigned an entry number which can be used in subsequent Close-Signal-Log commands.

List-Timer

Parameters:

```
(None)
```

A list of all currently active timers is produced. For each timer, its corresponding process instance and associated time is given. An entry number will also be part of the list, which can be used in the command Examine-Timer-Instance.

List-Trace-Values

Parameters:

```
(None)
```

The values of all currently defined traces are listed. The list contains the trace unit type (system, block, process, PId), the unit name and the trace value (both numeric and a textual explanation). See also the commands Set-Trace and Reset-Trace.

Log-Off

Parameters:

```
(None)
```

The command Log-Off turns off the interaction log facility, which is described in the command Log-On.

Log-On

Parameters:

```
<Optional file name>
```

The command Log-On takes an optional file name as a parameter and enables logging of all the interaction between a simulation program and the user that is visible on the screen. The first time the command is entered, a file name for the log file has to be given as parameter. After that any further Log-On commands, without a file name, will append more

information to the previous log file, while a Log-On with a file name will close the old log file and start using a new file with the specified file name.

Initially the interaction log facility is turned off. It can be turned off explicitly by using the command Log-Off.

News

Parameters:

```
(None)
```

The News command summarizes the changes in the textual monitor user interface from previous releases.

Next-Statement

Parameters:

```
<Optional number of statements>
```

This command is used to step statement for statement through SDL transitions. A statement is the same as a symbol, except that a task symbol may contain several assignment statements; compare with the Next-Symbol command.

Next-Statement steps over procedure calls, i.e. all actions in the procedure will be executed and the monitor will be entered again when the statement after the procedure call is reached; compare with the Step-Statement command.

After making the step(s) the monitor is entered, making it possible to, for example, examine the temporary status of the actual process instance.

> **Note:**
>
> The right hand side of an assignment may contain a value returning procedure call.

Next-Symbol

Parameters:

```
<Optional number of symbols>
```

This command is used to step symbol for symbol through SDL transitions. A symbol may contain several statements; compare with the Next-Statement command.

Next-Symbol steps over procedure calls, i.e. all actions in the procedure will be executed and the monitor will be entered again when the symbol after the procedure call is reached; compare with the Step-Symbol command.

Using the optional integer parameter, a specified number of symbols can be stepped through. Next-Symbol will, however, never step from within one transition into another transition.

After making the step(s) the monitor is entered, making it possible to, for example, examine the temporary status of the actual process instance.

Note:

Join is not considered a symbol by this command.

To determine how far a transition has been executed, the commands Show-Next-Symbol and Show-Previous-Symbol, together with trace printouts and GR traces can be used. The last trace printout is from the last executed symbol (if it has caused a printout, which depends on the trace level), while the symbol next to be executed is selected by the GR trace, if GR trace is on.

Next-Transition

Parameters:

```
(None)
```

The next transition is executed. If real time is used and the next transition is a timer output scheduled in the future (more than a second from now), the command Next-Transition will wait one second, after which the monitor is entered again.

Executing a Next-Transition command within a transition will execute the remaining part of the transition.

Next-Visible-Transition

Parameters:

```
(None)
```

A number of transitions are executed up to and including the next transition with a trace value > 0. For a timer output transition, it is the trace value for the corresponding process instance that is considered.

This command should be used with care in the interactive monitor, as it might result in executing the simulation program “forever” (if no transition with trace>0 is ever executed). To stop the execution of transitions, press `<Return>`. The interactive monitor will then become active when the execution of the current SDL symbol is completed.

Nextstate

Parameters:

```
<State name>
```

The state of the process/service/procedure instance given by the current scope is changed (see the Set-Scope command for an explanation of scope). This command implies that all actions in a nextstate are performed, i.e. recalculation of enabling conditions and continuous signals, and searching for a signal to be received according to the input and save sets. As a consequence the ready queue for process instances may change.

Now

Parameters:

```
(None)
```

The current value of the simulation time is printed.

Output-From-Env

Parameters:

```
-
```

The command will list all signals possible to send into the system, together with receiver. If the signal contains parameters, an empty parenthesis pair will be added after the signal name. Only signals that will trigger a transition directly will be listed. So signals causing an immediate null transition or signals that will be saved are not listed.

By just giving Output-From-Env in the Simulator UI, the possible choices will be given in a dialogue and by selecting one of the signals it is sent into the system. If the signal contains parameters they will be given "null" values.

Output-Internal

Parameters:

```
<Signal name> <Signal parameters>
<Receiver's PId value> <Sender's PId value>
```

The command is used to simulate an output of an internal signal instance between two process instances in the system. The parameter <Sender's PId value> may also denote "env:1". No check is made to ensure that a path of signal routes and channels exists. The monitor responds with either of the three messages below.

```
Signal <name> is not in valid input signal set of
process <name>
```

The signal was not in the valid input signal set of the receiver and can thus not be handled by the receiver. The signal was immediately discarded.

```
Signal <name> was sent to <receiver> from <sender>
```

The signal instance was successfully sent and was placed in the input port of the receiver.

```
Signal <name> caused an immediate null transition
```

The receiving process instance is currently waiting in a state where the specified signal type neither may cause an input operation, nor is saved. The signal instance is immediately discarded (in SDL this is called a null transition, i.e a transition with no actions, leading back to the same state).

Output-None

Parameters:

```
<PId value> <Optional service name>
```

The command is used to send a signal "none" to the specified process instance. If the process instance contains services, one of the services should to be specified as well. The none signal is used to indicate that a spontaneous transition should be initiated in the current state.

Output-To

Parameters:

```
<Signal name> <Signal parameters>
<Receiver's PId value>
```

The command is used to send a signal from the environment of the system to a process instance in the system. It will be checked that a path of channels and signal routes exists from the environment to the specified process instance.

The monitor will respond with either of the messages described below, or by an error message if no path existed.

```
Signal <name> was sent to <receiver> from <sender>
```

The signal instance was successfully sent and is placed into the input port of the receiver.

```
Signal <name> caused an immediate null transition.
```

The receiving process instance is currently waiting in a state where the specified signal type neither may cause an input operation, nor is saved. The signal instance is immediately discarded (in SDL this is called a null transition, a transition with no actions, leading back to the same state).

Output-Via

Parameters:

```
<Signal name> <Signal parameters>
<Optional channel name>
```

The command is used to send a signal from the environment of the system to a process instance in the system via the specified channel. If no channel is given, it is assumed that any channel from the environment to the system may be selected. It will be checked that there exists one process instance that can receive the signal, according to the rules of outputs in SDL.

The monitor will respond with either of the messages below, or by an error message if the number of possible receivers is not equal to one.

```
Signal <name> was sent to <receiver> from <sender>
```

The signal instance was successfully sent and is placed into the input port of the receiver.

```
Signal <name> caused an immediate null transition.
```

The receiving process instance is currently waiting in a state where the specified signal type neither may cause an input operation, nor is saved. The signal instance is immediately discarded (in SDL this is called a null transition, a transition with no actions, leading back to the same state).

Print-Coverage-Table

Parameters:

```
<File name>
```

This command can be used to obtain test coverage information and profiling information. Each time the command is issued a coverage file, with the name specified as parameter, is produced in the work directory

containing the relevant information. The coverage file always reflects the situation from the start of the simulation. To study the information in the coverage file, it can be opened in the Coverage Viewer; see chapter 47, *The SDL Coverage Viewer*.

> **Note:**
>
> The specified file is always overwritten, i.e. there is no confirmation message if an existing file is specified.

The generated file consists of two sections, first a summary with profiling information, containing the number of transitions and the number of symbols executed by each process type. Secondly the file contains detailed information about how many times each symbol and each state - input combination is executed.

Example 332: Profiling Information in Coverage File ––––––––––––––

```
*************** PROFILING INFORMATION **************

2  System DemonGame : Transitions = 13, Symbols = 40
3  Block GameBlock
4  Process Main : Transitions = 3 (23%),
                  Symbols = 10 (25%), MaxQ = 2
4  Process Game : Transitions = 6 (46%),
                  Symbols = 15 (37%), MaxQ = 2
3  Block DemonBlock
4  Process Demon : Transitions = 4 (30%),
                  Symbols = 15 (37%), MaxQ = 1
```

––

This information in Example 332 should be interpreted in the following way:

- As *transitions*, the number of executed input symbols + continuous signal symbols + start symbols are counted.
- As *symbols*, the number of executed process symbols (task, output, decision, set, reset, call, export, stop, return, create, nextstate, input, continuous signal, start) are counted.
- The number of transitions and the number of executed symbols are, as shown in the example above, presented both for the system (total for all processes) and for each process type. The relative numbers for the processes are, of course, relative to the numbers for the system.

- *MaxQ* is the maximum input port queue length for any instance of the process type. Note that start up signals, used to implement create, and continuous signals are counted as signals in MaxQ.
- The numbers at the beginning of each line are the scope level of the that unit. This can be used to determine if, for example, a procedure is defined within or after another procedure.

Note:

To be true, profiling information **execution time** ought to be measured instead of the number of transitions and number of executed symbols, but this information is still very valuable for getting a feeling for the load distribution.

Example 333: Coverage Table in Coverage File ——————————

```
************** COVERAGE TABLE DETAILS **************

2 System DemonGame

3 Block GameBlock

4 Process Main
  1 : Start  #SDTREF(SDL,main.spr(1),131(30,10),1)
  1 : Game_Off  Newgame  #SDTREF(SDL,main.spr(1),137
  1 : Game_On  Endgame  #SDTREF(SDL,main.spr(1),119(
  --------------------
  1 START : #SDTREF(SDL,main.spr(1),131(30,10),1)
  1 INPUT : #SDTREF(SDL,main.spr(1),137(31,44),1)
  1 INPUT : #SDTREF(SDL,main.spr(1),119(56,44),1)
  1 NEXTSTATE : #SDTREF(SDL,main.spr(1),134(34,29),1)
  1 CREATE : #SDTREF(SDL,main.spr(1),140(37,59),1)
  1 TASK : #SDTREF(SDL,main.spr(1),143(34,72),1)
  1 NEXTSTATE : #SDTREF(SDL,main.spr(1),146(35,89),1)
  1 OUTPUT : #SDTREF(SDL,main.spr(1),122(56,59),1)
  1 TASK : #SDTREF(SDL,main.spr(1),125(60,72),1)
  1 NEXTSTATE : #SDTREF(SDL,main.spr(1),128(59,89),1)
```

————————————————————————————————————

For each process type two types of information are given, separated by a line of hyphens:

- The first part contains information about the start transition and each relevant state-input combination: the number of times executed and a GR or PR reference to the associated process symbol. Continuous signals are counted as a separate input.

- The second part contains information about each process symbol: the number of times it has been executed, the type of symbol, and a GR or PR Reference to the symbol.

To identify the process symbols, the command *Show GR Reference* command in the SDL Editor's *Tools* menu can be used for the printed GR references. (See "Show GR Reference" on page 2027 in chapter 43, *Using the SDL Editor*.)

Proceed-To-Timer

Parameters:

```
(None)
```

This command will execute all transitions up to but not including the next timer output. The timer output will not be executed even if it is the next transition.

Proceed-Until

Parameters:

```
<Time value>
```

The execution of the simulation is resumed. The monitor will become active when the value of the simulation time first becomes equal to the time value given as parameter.

Note that relative time values can be given using the '+' sign. Entering "+5.0" as parameter is interpreted as the time value NOW+5.0. See also "Input and Output of Data Types" on page 2137.

Quit

Parameters:

```
(None)
```

The simulation is terminated. If the command is abbreviated the monitor asks for confirmation. This is the same command as Exit.

Rearrange-Input-Port

Parameters:

```
<Entry number> <New entry number>
```

This command is used to change the order of signal instances in the input port of the process instance given by the current scope (see the Set-Scope command for an explanation of scope).

The entry number parameters refer to the numbers assigned by the command List-Input-Port. The signal instance with entry number equal to the first parameter will be moved to a position where it in a subsequent List-Input-Port command will be assigned the entry number given as the second parameter.

Rearrange-Ready-Queue

Parameters:

```
<Entry number> <New entry number>
```

This command is used to change the order in which transitions by process instances are executed. The entry number parameters refer to the entry numbers assigned by the command List-Ready-Queue. The process instance with entry number equal to the first parameter will be moved to a position where it in a subsequent List-Ready-Queue command will be assigned the entry number given as the second parameter.

The Rearrange-Ready-Queue command should be used with care when process priorities are used. The ready queue is then sorted in priority order (see also "Scheduling" on page 2647 in chapter 56, *The Cadvanced/Cbasic SDL to C Compiler*), which means that a rearrangement might disturb this order. Such a disturbance does not harm, except when a new process should be inserted into the ready queue. In this situation the insert point might not be the proper one. The following insert algorithm is used: Search from the end of the ready queue until a process with higher or equal priority (lower or equal priority value) is found, then insert the new process after the found process. If no process with higher or equal priority is found, then insert the new process first in the ready queue.

REF-Address-Notation

Parameters:

```
(None)
```

REF values (pointers introduced using the generator Ref) are printed as addresses, using the HEX value for the address. The Null value is printed as `Null`. On input, both this syntax and the Value-Notation (see command REF-Value-Notation) can be used.

The same applies for Own and ORef values.

REF-Value-Notation

Parameters:

(None)

REF values (pointers introduced using the generator Ref) are printed as NEW(<the value the pointer refers to>). This is the default syntax for REF values. It means that complete lists or graphs will be printed. Example:

```
NEW( (. 1, NEW( (. 2, Null .) ) .) )
```

To avoid problems in cyclic graphs a special syntax is used if a pointer refers to an address already presented in the output. OLD n, where n is a digit, means a reference to the n:th NEW in the printed value. Example:

```
NEW( (. 1, NEW( (. 2, OLD 1 .) ) .) )
```

The Null value is printed as Null. On input both this syntax and the Address-Notation (see command REF-Address-Notation) can be used.

The same applies for Own and ORef values.

Remove-All-Breakpoints

Parameters:

(None)

This command removes all breakpoints.

Remove-At

Parameters:

<SDT reference>

This command removes all breakpoints at the symbol specified by the SDT reference.

Remove-Breakpoint

Parameters:

<Entry number>

This command removes the breakpoint with the specified entry number. The entry number given by List-Breakpoints should be used.

Remove-Signal-Instance

Parameters:

<Entry number>

The signal instance with the given entry number in the input port of the process instance given by the current scope is removed (see the Set-Scope command for an explanation of scope). The entry number given by List-Input-Port should be used. If this signal was selected for the next transition, the process instance will execute an implicit next-state action.

> **Note:**
>
> Entry numbers are just positions in the input port. The removal of a signal changes the entry numbers of the remaining signals.

Reset-GR-Trace

Parameters:

```
<Optional unit name>
```

The GR trace value of the given unit is reset to undefined. If no unit is specified the GR trace value of the system is reset to undefined. As there always has to be a GR trace value defined for the system, Reset-GR-Trace on the system is considered to be equal to setting the GR trace value to 0. For more information about optional unit names, see the command Set-Trace.

Reset-MSC-Trace

Parameters:

```
<Optional unit name>
```

The MSC trace value of the given unit is reset to undefined. If no unit is specified the MSC trace value of the system is reset to undefined. As there always has to be a MSC trace value defined for the system, Reset-MSC-Trace on the system is considered to be equal to setting the trace value to 0. For more information about optional unit names, see the command Set-MSC-Trace.

Reset-Timer

Parameters:

```
<Timer name> <Timer parameters>
```

The result of the command is exactly the same as if the process instance given by the current scope had executed a reset action. If the reset action causes a timer signal to be removed and this signal was selected for the next transition, the process instance will execute an implicit nextstate action.

Reset-Trace

Parameters:

```
<Optional unit name>
```

The trace value of the given unit is reset to undefined. If no unit is specified the trace value of the system is reset to undefined. As there always has to be a trace value defined for the system, Reset-Trace on the system is considered to be equal to setting the trace value to 0. For more information about optional unit names, see the command Set-Trace.

Restore-State

Parameters:

```
<File name>
```

This command will restore the state of the current simulation to a state given in a file created with the Save-State command. The file name is given as parameter.

The write and read functions for the sorts are used to save and restore the variable values. So if a user has added a sort via the ADT directive, these write and read functions must be consistent.

It is recommended to restart the simulator before giving the Restore-State command. The command is not allowed when the execution is within a transition.

If the SDL system contains the Any construct, the sequence of random numbers will not be the same after the restore.

Only the sdl execution state is restored, no monitor settings are restored. E.g. Show-Previous-Symbol, Show-Next-Symbol does not work directly after a restore. The MSC trace is not restored. Coverage is not restored either.

The ADT package pidlist.pr is not supported, since the PId synonyms that are initialized are not valid after the restore.

Extern C and C++ variables will not be saved and restored since the simulator has no knowledge of them.

Charstar, Voidstar and Voidstarstar variables are not handled.

Since all variables are saved, dangling Ref and ORef variables will cause problems.

Scope

Parameters:

```
(None)
```

This command prints the current scope. See the command Set-Scope for a description of scope.

SDL-Value-Notation

Parameters:

```
(None)
```

The value notation used in all outputs of values is set to SDL value notation. This is the default value notation. See also the command ASN1-Value-Notation.

Save-Breakpoints

Parameters:

```
<File name>
```

This command will save all breakpoints in a file, with the name specified as parameter (in the work directory). It is written as a text file with commands, so the breakpoints can be restored with the Include-File command.

Save-State

Parameters:

```
<File name>
```

This command will save the state of the current simulation in a file, with the name specified as parameter (in the work directory). It is written as a text file with special commands, so the state can be restored with the Restore-State command.

Set-GR-Trace

Parameters:

```
<Optional unit name> <Trace value>
```

The GR trace value is assigned to the specified unit (system, block, process, or process instance). If no unit is specified the GR trace value is assigned to the system. The initial GR trace value of the system is 0, i.e. no GR trace, while it is undefined for all other units. For more information about optional unit names, see the command Set-Trace.

For a description of the possible GR trace values, see "GR Traces" on page 2186.

Set-MSC-Trace

Parameters:

```
<Optional unit name> <Trace value>
```

This command enables the trace of SDL events that take place during the simulation and which can be transformed into events in a Message Sequence Chart. Typically, the events that can be transformed are sending and consumption of signals, and creation and termination of processes.

> **Note:**
>
> Setting the MSC trace value with this command **does not** start the actual logging of MSC events. To do this, the command Start-Interactive-MSC-Log or Start-Batch-MSC-Log is used.

The scope of the trace can be delimited by specifying an optional unit name and a trace value. The general considerations for specifying the unit name for the command Set-Trace are also applicable for Set-MSC-Trace.

Optional Unit Name

- The trace value is assigned to the specified unit (system, block, process, or process instance).
- When specifying a unit name, the scope of trace affects **all process instances** contained in the **underlying SDL structure**.
- Initially, the scope of trace is set on the entire SDL system. So, by default, all events will generate Message Sequence Chart traces. If the unit name is omitted, the trace value is assigned to the system.

Trace Value

- Specifying a trace value of 0 means no trace for the currently specified unit name.
- Specifying a trace value of 1 means trace only if both involved units have a trace value greater than 0.
- Specifying a trace value of 2 means always trace, independent of the trace value of the other involved unit.
- Specifying a trace value of 3 means trace on the block level.

The initial MSC trace value of the system is 1. For more information on MSC trace values, see "Message Sequence Chart Traces" on page 2187.

> **Note:**
>
> Once the logging of Message Sequence Chart traces has been started (using any of the commands Start-Interactive-MSC-Log or Start-Batch-MSC-Log) **modifying the scope of trace may cause unpredictable results**, such as Message Sequence Charts with an unexpected appearance.

Set-Scope

Parameters:

```
<PId value> <Optional service name>
```

This command sets the scope to the specified process, at the bottom procedure call. If the process contains services, one of the services can be given as parameter to the command. A scope is a reference to a process instance, a reference to a service instance if the process contains services, and possibly a reference to a procedure instance called from this process/service. The scope is used for a number of other commands for examining and changing the local properties of a process instance. The scope is automatically set by the execution commands, when entering the monitor, to the next process in turn to execute.

The command Scope prints out the current scope; i.e. the name of the process instance and possibly the service instance and the called procedure instance. See also the commands Stack, Define-MSC-Trace-Channels and Up.

Set-Timer

Parameters:

```
<Timer name> <Timer parameters> <Time value>
```

The result of the command is exactly the same as if the process instance given by the current scope had executed a set action. If the set action causes a timer signal to be removed and this signal was selected for the next transition, the process instance will execute an implicit nextstate action.

Set-Trace

Parameters:

```
<Optional unit name> <Trace value>
```

The trace value is assigned to the specified unit (system, block, process, or process instance). If no unit is specified the trace value is assigned to the system. The initial trace value for the system is 4, while it is undefined for all other units. For a description of the possible trace values, see "Trace Limit Table" on page 2184.

There might, in some cases, be problems in identifying a specific unit. If more than one unit in the system match the, possibly abbreviated, unit name, the first unit found when searched from the system level will be assigned. To make sure the correct unit is assigned, the unit's diagram type, e.g. "process" (unabbreviated), can be introduced before the unit name. If there still are problems, for instance due to the fact that there are several processes with the same name, a qualifier should be inserted immediately before the unit name. An example can be found in "Specifying Unit Names" on page 2254 in chapter 50, *Simulating a System*.

To specify a PId value, a colon and an instance number must follow directly after the process name; see also "Input and Output of Data Types" on page 2137.

Show-Breakpoint

Parameters:

```
<Entry number>
```

This command is only applicable for symbol breakpoints defined with the command Breakpoint-At. The breakpoint with the specified entry number is listed, and the symbol with the breakpoint will be selected in an SDL Editor showing the source GR document. The entry number given by List-Breakpoints should be used.

Show-C-Line-Number

Parameters:

```
(None)
```

This command prints the `.c` file name and line number where the execution of the current SDL transition is suspended. The Text Editor is opened with the cursor positioned on that line in the C source file. The given line number will reference a statement with the following structure:

```
XBETWEEN_SYMBOLS(...)
```

The case label just following this statement is the place where the execution will be resumed when an execute command is given in the monitor.

The Show-C-Line-Number command is mainly thought to be used when the execution is interrupted within an SDL transition. If the command is issued between two transitions, the `XBETWEEN_SYMBOLS` statement immediately before the last Nextstate or Stop operation will be referenced in the printout, together with a warning that this is not the current position.

> **Note:**
>
> Changes made in the monitor, as for example Rearrange-Ready-Queue, will not affect the printout by this command.

Show-Coverage-Viewer

Parameters:

`(None)`

This command starts the Coverage Viewer tool with the current test coverage loaded.

Show-Next-Symbol

Parameters:

`(None)`

The symbol in turn to be executed will be selected in an SDL Editor showing the source GR document. If the simulation is not connected to the SDL Suite or the SDL source document is in SDL/PR, a GR symbol reference or a PR reference will instead be displayed on the screen. The details about GR symbol references are presented in "Dynamic Errors" on page 2190. A PR reference is a file name and a line number. See also "Syntax" on page 917 in chapter 18, *SDT References*.

Note that between the execution of two transitions, i.e. after a Nextstate or Stop operation, no next symbol can be shown. Note also that changes made in the monitor, as for example changing the ready queue using the command Rearrange-Ready-Queue, will not affect the symbol selected by Show-Next-Symbol.

This command uses the same mechanisms to select symbols in the SDL Editor as the GR trace facility, so the same general characteristics as presented in "GR Traces" on page 2186 are also valid for this command.

Show-Previous-Symbol

Parameters:

```
(None)
```

The last executed symbol will be selected in an SDL Editor displaying the source GR document. If the simulation is not connected to the SDL Suite or the SDL source document is in SDL/PR, then a GR symbol reference or a PR reference will instead be displayed on the screen. See the command Show-Next-Symbol for more information.

Show-Versions

Parameters:

```
(None)
```

The versions of the SDL to C Compiler and the runtime kernel that generated the currently executing program are presented.

Signal-Log

Parameters:

```
<Unit name> <File name>
```

Starts logging of signals to a specified file. See also the commands Close-Signal-Log and List-Signal-Log.

The unit name parameter should be either a channel, a signal route, a system, a block, a process type, or a process instance.

- If the unit is a channel or a signal route then all signals sent through the channel or signal route will be logged on the specified file.
- If the unit is a process type or a process instance then all signals sent to or from any instance of the process type or to or from the specified process instance will be logged.
- If the unit is a block or a system then all signals that have relevance for the block or system will be logged, i.e. signals sent within the block or system or signals sent to or from the block or system.

Note that the process “env” is a legal unit in the Signal-Log command. By specifying “env” as unit parameter, the signal interface between the system and the environment is logged. For more information about the unit name parameter, see the command Set-Trace.

Stack

Parameters:

`(None)`

The procedure call stack for the PId/service defined by the scope is printed. For each entry in the stack, the type of instance (procedure/process/service), the instance name and the current state is printed. See also the commands Set-Scope, Define-MSC-Trace-Channels and Up.

Start-Batch-MSC-Log

Parameters:

`<Symbol level> <File name>`

This command starts the logging of SDL events which can be translated into the corresponding MSC events in a log file (see "Mapping Between SDL and MSC" on page 2187). See also the commands Start-Interactive-MSC-Log and Stop-MSC-Log.

The results will be stored in a log file, whose contents are specific for this purpose. That log file can later on be read by a Message Sequence Chart Editor, where its contents are interpreted as a Message Sequence Chart and displayed as such.

The symbol level parameter determines if states and actions should be included in the MSC log. For a description of the possible symbol level values, see "Level of Symbol Logging" on page 2188.

The file name parameter to this command can be any valid file name, although it is recommended to use a file name with the suffix `.mpr`, since this is the default suffix used when reading a log file into a Message Sequence Chart Editor.

Start-Env

Parameters:

`(None)`

When the SDL to C Compiler is used to generate applications, interface functions towards the environment of the SDL system must be provided. The `InEnv` function, which is used to enter signals into the SDL system, is frequently called from the main loop in the process scheduler. During debugging, the polling of the `InEnv` function can turned on and turned off.

The Start-Env command turns on the polling of `InEnv`. At start up of the program polling is turned off. See also the commands Stop-Env and Call-Env.

> **Note:**
>
> This command and the commands Stop-Env and Call-Env are only available when the SDL to C Compiler is used to generate applications.

Start-Interactive-MSC-Log

Parameters:

```
<Symbol level>
```

This command starts the logging of SDL events which can be translated into the corresponding MSC events in a Message Sequence Chart Editor (see "Mapping Between SDL and MSC" on page 2187). See also the commands Start-Batch-MSC-Log and Stop-MSC-Log.

The symbol level parameter determines if states and actions should be included in the MSC log. For a description of the possible symbol level values, see "Level of Symbol Logging" on page 2188.

When the command is issued, the following takes place:

1. An instance of the Message Sequence Chart Editor is started. Each currently existing (SDL) process instance is displayed as an instance, with its instance head and its instance axis.
2. Following the execution of the simulation, each SDL event which is possible to map to an MSC event and which is within the scope of MSC trace which is currently defined will automatically be displayed in the MSC Editor. Each event will cause the insertion point in the MSC Editor to be moved downwards with one step, which provides a feeling of absolute order between events.

Some drawing conventions and default layouting algorithms are used when drawing the automatically generated Message Sequence Chart. These conventions are described in *"Drawing Conventions" on page 1727 in chapter 39, Using Diagram Editors*.

Start-SDL-Env

Parameters:

```
(None)
```

A simulator can communicate with other simulations using SDL signals and the SDL Suite communication mechanism. Signals sent to the environment in one simulation can enter as signals from the environment in another simulator.

This command is used to tell a simulator to start sending signals that are designated to the environment via the SDL Suite communication mechanism and to start looking for incoming signals (polling) from the SDL Suite communication mechanism. See also the commands Stop-SDL-Env and Call-SDL-Env.

This facility is at program start up turned off, and should only be turned on when a simulator should be able to communicate with other simulators (or applications).

> **Note:**
> The command must be given in **both communicating simulators**.

Start-ITEX-Com

Parameters:

`(None)`

This command starts the communication with the TTCN Suite.

Stop-ITEX-Com

Parameters:

`(None)`

This command stops the communication with the TTCN Suite.

Start-SimUI

Parameters:

`(None)`

This command starts a Simulator UI and connects the running simulator to it. After this it is only possible to give commands in the UI.

Start-UI

Parameters:

`(None)`

This command attempts to start the program `sdtenv` in the start directory. The started program is assumed to connect itself to the SDL Suite communication mechanism and can then communicate with the simulation program.

Note:

The command Start-SDL-Env should be given in the simulation program to make it communicate.

Step-Statement

Parameters:

```
<Optional number of statements>
```

This command is used to step statement for statement through SDL transitions. A statement is the same as a symbol, except that a task symbol may contain several assignment statements; compare with the command Step-Symbol.

Step-Statement will step into procedure calls; compare with the Next-Statement command.

After making the step(s) the monitor is entered, making it possible to, for example, examine the temporary status of the actual process instance.

Note:

The right hand side of an assignment may contain a value returning procedure call.

Step-Symbol

Parameters:

```
<Optional number of symbols>
```

This command is used to step symbol for symbol through SDL transitions. A symbol may contain several statements; compare with the Step-Statement command.

Step-Symbol will step into procedure calls; compare with the Next-Symbol command.

Using the optional parameter, a specified number of symbols can be stepped through. Step-Symbol will, however, never step from within one transition into another transition.

After making the step(s) the monitor is entered, making it possible to, for example, examine the temporary status of the actual process instance.

Note:

Join is not considered a symbol by this command.

Stop

Parameters:

```
<PId value> <Optional service name>
```

The specified process instance is stopped. If the process contains services, then either the process can be stopped by giving no service parameter, or one of the services can be stopped. The result of the command is exactly the same as if the process instance or service instance had executed a stop action.

Stop-Env

Parameters:

```
(None)
```

This command turns off the polling of the InEnv function; see the Start-Env command for more details.

Note:

This command and the commands Start-Env and Call-Env are only available when the SDL to C Compiler is used to generate applications.

Stop-MSC-Log

Parameters:

```
(None)
```

This command stops the logging of Message Sequence Chart events (in interactive mode as well as in batch mode). In the case of a batch mode logging, the log file will be closed. See the commands Start-Interactive-MSC-Log and Start-Batch-MSC-Log for more details.

Following this command, it is possible to log the rest of the session on a new file.

Stop-SDL-Env

Parameters:

```
(None)
```

The command turns off the communication mechanism described for the Start-SDL-Env command.

Up

Parameters:

(None)

Moves the scope one step up in the procedure call stack. Up from a service leads to the process containing the service. See also the commands Set-Scope, Stack and Define-MSC-Trace-Channels.

Traces

When a process instance executes actions within a transition, trace information describing the current action might be printed on the screen. The amount of information printed can be selected using the trace commands in the monitor system. A typical trace from a transition containing a few actions is given below.

```
*** TRANSITION START
*      PId    : Demon:1
*      State  : Generate
*      Input  : T
*      Sender : Demon:1
*      Now    : 1.0000
*   OUTPUT of Bump to Game:1
*   SET on timer T at 2.0000
*** NEXTSTATE  Generate
```

The transitions can also be traced in the GR source diagrams. This is discussed in detail under "GR Traces" on page 2186.

Transition Trace

A trace value, which is a non-negative integer, can be assigned to process instances, to process types, blocks, and to the system. The commands associated with traces are Set-Trace, Reset-Trace and List-Trace-Values.

When a process instance starts a transition, the trace value that governs the amount of trace to be printed is computed according to the following algorithm:

1. If a trace value is defined for the process instance executing the transition, that value is used.
2. If not, and a trace value is defined for the process type, that value is used.
3. Otherwise, if a trace value is defined for the block enclosing the process, that value is used.
4. If still no trace value is found, the block structure is followed outwards until a unit is reached which has a trace value defined. The system will always have a trace value.

The hereby computed value is compared with the trace limit for each action executed during the transition. The trace information is printed only

if the trace value is greater or equal to the trace limit for the action. Trace information at trace level 1 is treated specially, see below.

In the table below the trace limits for all the information that can be part of a trace is presented.

Note:

The **trace messages** are **produced** when **actions** defined in the SDL diagrams are **executed**. These messages are not used when monitor commands like Set-Timer, Nextstate, or Stop are entered.

Trace Limit Table

Action	Trace limit
Transition start	2
Parameters of signal in input	6
Output to environment, signal name and receiver	1 (see below)
Output, signal name and receiver	3
Output caused immediate null transition	5
Parameters of signal in output	6
Task	4
Decision, value of expression in decision	4
Procedure start, procedure return	3
Parameters to procedures	6
Create, successful or unsuccessful	3
Parameters to create	6
Set, timer name, time	3
Time less than Now in set, changed to Now	5
Parameters in set	6
Set caused an implicit reset action	5

Action	Trace limit
Reset, timer name	3
Reset caused timer or signal to be removed	5
Parameters to reset	6
Output of timer signal, timer name, receiver, time	2
Output of timer signal caused a null transition	5
Parameters to timer signal	6
Nextstate, state name	3
Null transitions at a nextstate	5
Parameters to signals in null transitions at nextstate	6
Stop	3
Signals discarded at stop	5
Parameters to signals discarded at stop	6
Timers discarded at stop	5
Parameters to timers discarded at stop	6
Export	4

The trace limit table can be summarized as follows:

Trace Limit Table Summary	
0	No trace
1	Trace of signals to environment (environment as seen from the specified unit)
2	Trace of transition start and timer outputs
3	As 2 + trace of important SDL actions
4	As 3 + trace of other SDL actions as well
5	As 4 + result of actions (example: discarded signals)
6	As 5 + Parameters of signals, timers, create actions

Trace information at trace level 1, i.e. trace of signals sent to the environment of the specified unit, is treated in a special way. This information is not printed if the trace value is greater than 1, instead the normal trace of outputs is used.

GR Traces

GR trace is a way to follow the execution of transitions in the GR source diagrams by selecting SDL symbols. It should normally only be used for a small number of processes to limit the amount of information displayed. The GR trace value determines to what degree the execution will be traced, i.e. how often SDL symbols will be selected in the GR diagrams (see below). After a nextstate or stop operation, i.e. between two transitions, the nextstate or stop symbol is still selected.

The commands associated with GR traces are Set-GR-Trace, Reset-GR-Trace and List-GR-Trace-Values.

The GR tracing will take place in a single SDL Editor window, which will show the appropriate GR diagram as the execution progresses. If no SDL Editor is opened, a new editor is started.

Three trace values are possible:

- 0 - No GR trace.
- 1 - When the monitor is entered next, show the next symbol to be executed. No symbols are selected during execution when the monitor is inactive. Thus, the SDL Editor window may not show the diagram containing the symbol currently executed.
- 2 - Follow the execution and show each symbol as it is executed. If the execution is continued into another diagram, this diagram is loaded into the SDL Editor window.

Message Sequence Chart Traces

The commands associated with MSC traces are Set-MSC-Trace, Reset-MSC-Trace and List-MSC-Trace-Values.

Mapping Between SDL and MSC

When executing an SDL system, some of the SDL events can be transformed into a corresponding symbol in a Message Sequence Chart. The mapping rules which govern how SDL events are transformed into MSC symbols, lines and textual elements are described in "Mapping Between SDL and MSC" on page 1726 in chapter 39, *Using Diagram Editors*.

The ITU definition of the MSC language introduces the *instance* concept. An instance is mapped to any instance of an SDL process.

Scope of Trace for Generation of Message Sequence Charts

The scope of MSC trace is the process instances that have a calculated MSC trace value > 0.

Assume that we have set the scope of MSC trace to a part of the SDL system, for instance a block and the underlying structure in terms of processes. When an event takes place in the SDL system, one of three possible situations is possible. Let us assume for the sake of simplicity that the event is the sending of a signal from one process to another process. The three cases and their behavior are as follows:

- First case: The two units (the sending process and the receiving process) are both within the scope of MSC trace. It is easy to transform this into the sending and consuming of a message, and the result will be a trace in a Message Sequence Chart.
- Second case: None of the units is in the scope of MSC trace. This will not result in any trace in a Message Sequence Chart.
- Third case: One and (one only) of the units is in the scope of MSC trace. This case is slightly more complicated. Sending and receiving messages to and from units may be of interest outside the scope of trace.

  The concept *conditional trace* is introduced: A conditional trace will indicate that a message has been sent or received, and that the

receiver or sender is beyond the scope of trace. See also "The Void Instance" on page 1730 in chapter 39, *Using Diagram Editors*.

The MSC trace levels 1 and 2 are used to specify if conditional trace should be presented or not; see the table below. MSC trace level 3 specifies a block level trace.

MSC Trace for Sender	MSC Trace for Receiver	Result
0	0	No trace
	1	No trace
	2	Conditional trace
1	0	No trace
	1	Trace
	2	Trace
2	0	Conditional trace
	1	Trace
	2	Trace

Level of Symbol Logging

The *symbol level* determines the amount of information that should be part of the MSC log. Three symbol levels are possible:

- 0 - Events for signals and timers plus create and stop.
- 1 - As level 0, plus condition symbols for each nextstate.
- 2 - As level 1, plus action symbols for task, decision, call, and return.

Signal Parameter Length

When using MSC trace it is possible to set a maximum parameter trace length by using the environment variable `SDTMSCMAXPARAMLENGTH`.

This can improve performance on simulations using large signal parameters that otherwise could cause the MSC editor to work slowly.

If a parameter exceeds the maximum length it will be truncated to the maximum length with an ending "..." to indicate that the parameter has been truncated.

After the ending "..." there can be possible ending parenthesis, apostrophes or quotes to match initial ones in order to make the signal parameter syntactically correct.

Initial Trace Values

At the start of a simulation, the trace values, the GR trace values and the MSC trace values for all units except the system are undefined. The system trace is 4, the system GR trace is 0, and the system MSC trace is 1.

Dynamic Errors

Violations of the dynamic rules of SDL will cause dynamic errors during the execution of a simulation program. A dynamic error is presented to the user on the screen as an error message. See the example below.

Example 334: Dynamic Error Printout

```
Warning in SDL Output of signal Bump
Signal sent to NULL, signal discarded
Sender: Demon:1
TRANSITION
  Process         : Demon:1
  State           : Generate
  Input           : T
  Symbol          :
#SDTREF(SDL,/usr/tom/demon.spr(1),122(30,55),1)
TRACE BACK
  Process         : Demon
  Block           : DemonBlock
  System          : Demongame
```

The symbol reference given in the `TRANSITION` message should be interpreted as follows:

Item	Text in Example 334	Interpretation
1	`SDL`	Reference to SDL/GR object
2	`/usr/tom/demon.spr`	Reference to the file
3	`(1)`	Page name
4	`122`	The object identity (an unique number assigned by the SDL Editor)
5	`30`	The x-coordinate of the object in mm. The origin of coordinates is the upper left corner of the page.
6	`55`	The y-coordinate of the object in mm
7	`1`	Line number within symbol

By entering the monitor command Show-Previous-Symbol, the symbol that caused the error is displayed.

For more information on references, see chapter 18, *SDT References*.

Dynamic Errors Found by a Simulation Program

```
Error in SDL array index in sort <sort>:
<value> is out of range.
```

Violation of the index range given in an array.

```
Error in assignment in sort <sort>:
<value> is out of range.
```

Violation of the range conditions given in a syntype.

```
Error in SDL Decision: Value is <value>
Entering decision error state
```

The value of the expression in the decision did not match any of the possibilities (answers).

```
Error in SDL Import. Attempt to import from NULL

Error in SDL Import. Attempt to import from stopped
process instance

Error in SDL Import. Attempt to import from the
environment

Error in SDL Import. No process exports this
variable

Error in SDL Import. The specified process does not
export this variable
```

Error in an import statement. Supplementary information about remote variable and exporting processes is also given.

```
Warning in SDL Output of signal <signal>.
No path to receiver, signal discarded
```

An attempt was made to output a signal to a PId expression. There exists, however, no path of channels and signal routes between the sender and the receiver that can convey the signal.

```
Warning in SDL Output of signal <signal>.
No possible receiver found, signal discarded
```

An attempt was made to output a signal without specifying a to PId expression. When all paths or all paths mentioned in a via clause had been examined no possible receiver was found.

```
Warning in SDL Output of signal <signal>.
Signal sent to NULL, signal discarded
```

An attempt was made to output a signal to a PId expression that was null.

```
Warning in SDL Output of signal <signal>.
Signal sent to stopped process instance
```

An attempt was made to output a signal to a PId expression that referred to a process instance which has performed a stop action.

```
Error in SDL View. Attempt to view from NULL

Error in SDL View. Attempt to view from stopped
process instance

Error in SDL View. Attempt to view from the
environment

Error in SDL View: The specified process does not
reveal this variable

Error in SDL View: No process reveals this variable
```

Error in a view statement. Supplementary information about viewed variable and viewing process is also given.

```
Error in SDL Create: Process <process>
More static instances then maximum number of
instances.
```

Obvious!

```
Illegal #UNION tag value for assignment to component
Name.
Tag value is xxx.
```

Attempt to assign a value to a non-active UNION component.

```
Illegal #UNION tag value for access to component
Name.
Tag value is xxx.
```

Attempt to access a non-active UNION component.

```
Error when accessing component Name. Component is
not Present.
```

Attempt to access a non-active optional struct component.

```
Component Name is not active.Present is xxx.
```

Attempt to access a non-active choice component.

```
Dereferencing of NULL pointer.
Pointer assigned new data area at address: HEX(xxx)
```

Attempt to de-reference a Null pointer defined using the Ref generator.

```
User specified error: SDL error expression found
```

Error introduced by the user, by inserting the error expression defined in SDL.

Errors Found in Operators

The errors that can be found in operators defined in the predefined data types are listed below.

```
Error in SDL Operator: Extract! in sort Charstring,
Index out of bounds

Error in SDL Operator: Modify! in sort Charstring,
Character NUL not allowed.

Error in SDL Operator: MkString in sort Charstring,
Character NUL not allowed.

Error in SDL Operator: First in sort Charstring,
Charstring length is 0

Error in SDL Operator: Fix in sort Integer, Integer
overflow

Error in SDL Operator: Last in sort Charstring,
Charstring length is 0

Error in SDL Operator: Substring in sort Charstring,
Charstring length is 0

Error in SDL Operator: Substring in sort Charstring,
Length of substring < 0

Error in SDL Operator: Substring in sort Charstring,
Start index is <= 0

Error in SDL Operator: Substring in sort Charstring,
Start index + length of substring > length of
charstring

Error in SDL Operator: / in sort Integer, Attempt to
divide by 0.

Error in SDL Operator: / in sort Real, Attempt to
divide by 0.0.
```

```
Error in SDL Operator: Rem in sort Integer,
Second operand is 0

Error in SDL Operator: Mod in sort Integer,
Second operand is 0

Error in SDL Operator: Modify! in sort Bit_String,
Index out of bounds.

Error in SDL Operator: Extract! in sort Bit_String,
Index out of bounds.

Error in SDL Operator: First in sort Bit_String,
Bit_String length is zero.

Error in SDL Operator: Last in sort Bit_String,
Bit_String length is zero.

Error in SDL Operator: SubString in sort Bit_String,
Bit_String length is zero.

Error in SDL Operator: SubString in sort Bit_String,
Start is less than zero.

Error in SDL Operator: SubString in sort Bit_String,
SubLength is less than or equal to zero.

Error in SDL Operator: SubString in sort Bit_String,
Start + Substring length is greater than string
length.

Error in SDL Operator: BitStr in sort Bit_String,
Illegal character in Charstring (not 0 or 1).

Error in SDL Operator: HexStr in sort Bit_String,
Illegal character in Charstring (not digit or a-f).

Error in SDL Operator: Modify! in sort Octet,
Index out of bounds.

Error in SDL Operator: Extract! in sort Octet,
Index out of bounds.

Error in SDL Operator: Division in sort Octet,
Octet division with 0.

Error in SDL Operator: Mod operator in sort Octet,
Right operand is 0.

Error in SDL Operator: Rem operator in sort Octet,
Right operand is 0.

Error in SDL Operator: BitStr in sort Octet,
An Octet should consist of not more than 8
characters 0 or 1.
```

```
Error in SDL Operator: HexStr in sort Octet,
An Octet should consist of 2 HEX values.

Error in SDL Operator: HexStr in sort Octet,
Illegal character in Charstring (not digit or a-f).

Error in SDL Operator: Modify! in sort Octet_String,
Index out of bounds.

Error in SDL Operator: Extract! in sort
Octet_String,
Index out of bounds.

Error in SDL Operator: BitStr in sort Octet_String,
An Octet_String should consist of 0 and 1.

Error in SDL Operator: HexStr in sort Octet_String,
Illegal character in Charstring (not digit or a-f).
```

Apart from these error message each instantiation of generator String will introduce similar error messages as for the Charstring sort. Note that `Object_Identifier` is a predefined sort which is an instantiation of String.

Action on Dynamic Errors

After a dynamic error, the execution of the simulation program is continued until the current symbol is ended. The interactive monitor will then become active. The following actions will be taken:

- If the error was an output error the signal will not be sent.
- If the error was a decision error the process instance will immediately be placed in an *decision error state*. It can only be removed from this state by using the Nextstate command in the monitor. The input port will not be affected when the decision error state is entered. All signals sent to a process instance in a decision error state will be saved in the input port.
- If the error occurred during the creation of static process instances, i.e. the initial number of instances is greater that the maximum number of instances, an error message is given and the number of instances specified by initial number of instances are created.
- If the error occurred during an import or view action a data area of the correct size containing zero in all positions is returned.

- If the error was found in a range condition check during an assignment, the variable to the left of the assignment operator will be assigned the computed value, although it is out of bounds.
- If the error was found during a range check of an array index the index value will be changed to be the lowest value of the index type. This means that the corresponding C array will never be indexed out of its bounds.
- If the error occurred during selection of an optional component in a struct or when selecting a component in a #UNION or Choice, an error message is given and the operation is perform anyhow.
- If a Null pointer (Ref) is de-referenced, an new data area of correct size is allocated containing zeros. This data area is assigned to the pointer. After the error message the statement containing the de-referencing is performed.
- If the error occurred within an expression the operator that found the error returns a default value and the evaluation of the expression is continued. The default values returned depend on the result type of the operator and are given in section *"Default Values" on page 2674 in chapter 56, The Cadvanced/Cbasic SDL to C Compiler*.

Assertions

A user can define his own run-time errors or assertions. Basically the run-time library only provides an appropriate C function that can be called to print out an error message. This function is assumed to be used in #CODE directives in TASKs according to the following example:

Example 335: Assertion in C Code ----------

```
TASK  '' /*#CODE
#ifdef XASSERT
  if (#(I) < #(K))
    xAssertError("I is less than K");
#endif
*/ ;
```

The `xAssertError` function, which has the following prototype:

```
extern void xAssertError ( char *Descr )
```

takes a string describing the assertion as parameter and will produce an SDL run-time error similar to the normal run-time errors. The function is only available if the compilation switch XASSERT is defined. For the standard libraries this is true for all libraries except the *Application Library*.

Run-time Prompting

For some special SDL constructs, an SDL simulator is not able to continue executing without prompting the user for necessary input. The execution continues when the user has entered an allowed value.

Decision with Any

If an SDL DECISION is encountered with an ANY question, the user will be prompted which path to execute:

```
Decision with ANY
1 (go path)
1 ? (show path)
2 (go path)
2 ? (show path)
3 (go path)
3 ? (show path)
Enter path :
```

At this point, the user must enter a path value (integer) within the allowed range. If GR trace is enabled, the user may enter a path value followed by a '?' to see the corresponding path in an SDL Editor.

Informal Decision

If an SDL DECISION is encountered with informal text, the user will be prompted which path to execute:

```
Informal decision: 'Question1'
'answer1'  1
'answer2'  2
'ELSE'  3
Enter path :
```

At this point, the user must enter a path value (integer) within the allowed range. If GR trace is enabled, the user may enter a path value followed by a '?' to see the corresponding path in an SDL Editor.

Unimplemented Operator

If an expression is encountered involving an operator that is not implemented, the user will be prompted for the value to be returned depending on the parameters:

```
Operator op in sort s is called
Parameter 1: 50
Enter value(s) :
```

At this point, the user must enter a value in the resulting sort to be the returned value of the operator when called with the listed parameter values.

Graphical User Interface

This section describes the appearance and functionality of the graphical user interface to the simulator monitor (SimUI). Some user interface descriptions general to all tools can be found in chapter 1, *User Interface and Basic Operations*. These general descriptions are not repeated in this chapter.

Starting the SimUI

A new SimUI is started by selecting *SDL > Simulator UI* from the *Tools* menu in the Organizer. When the SimUI is started, a number of definition files are read, controlling the contents of the main window and some status windows. See "Definition Files" on page 2221 for more information.

No simulator is started automatically by the SimUI in this way. The user must start a simulator by selecting *Open* from the *File* menu, as stated in the text area of the main window, or by using the *Open* quick button.

A simple way to generate a simulator, start the SimUI and open the simulator is to click the *Simulate* quick button in the Organizer.

When a simulator is started, a file selection dialog may be opened if the SDL system contains external synonyms. For more information, see "Supplying Values of External Synonyms" on page 2240 in chapter 50, *Simulating a System*.

The Main Window

The main window provides a text area (which displays output from the monitor system), an input line (used for entering and displaying textual command line input to the monitor system and the SimUI) and a button area with button modules (with buttons for execution of monitor and SimUI commands).

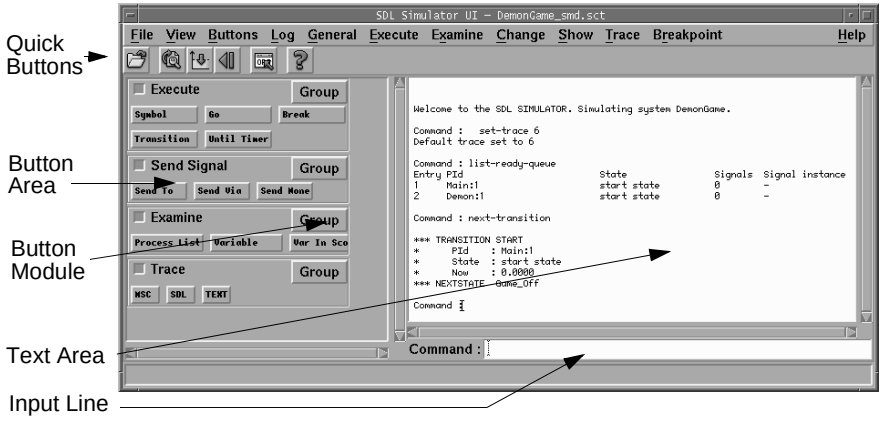

Figure 461: The main window

The Text Area

The *text area* displays all text output from the monitor system, including user prompts, error messages and command results.

Commands cannot be entered in this area, but a command given on the input line or through the use of the command buttons is echoed after the displayed prompt:

```
Command :
```

The Input Line

The *input line* is used for entering and editing commands from the keyboard. For information on available monitor commands, see "Monitor Commands" on page 2145. There are also special SimUI commands that are not sent on to the simulator monitor, see "SimUI Commands" on page 2225.

The 100 latest commands entered on the input line are saved in a history list. The history list can be traversed by using the `<Up>` and `<Down>` keys on the input line.

When `<Return>` is pressed anywhere on the input line, the complete string is saved in the history list and is moved to the text area. The command is then executed.

The input line also has an associated popup menu with the choices *Undo*, *Command*, *Save*, *Go to Source* and *Add to watchwindow*:

- Both *Undo* and *Command* open a dialog with all commands entered so far. In the *Undo* case, all the commands to redo can be selected, and the default is to redo all but the last one, which is equivalent to an Undo of the last command. In the *Command* case, only one of the commands to re-execute can be selected. For more information, see "Undo/Redo Commands" on page 2247 in chapter 50, *Simulating a System*.
- *Save* will save all monitor commands issued by the user so far to a command file. It opens a file selection dialog, in which the name of a command file is selected (**on UNIX** preferably with the suffix `.com`).
- *Go to Source* will go to the SDT reference selected in the text area.
- *Add to watchwindow* will add the variable selected in the text area to the watch window.

Parameter Dialogs

If a command entered on the input line requires additional user input (i.e. parameter values), the information will automatically be asked for in a dialog:

- Parameter values that are file names are selected in File Selection Dialogs.
- Parameter values of enumeration type are presented in lists, from which the value can be selected (see Figure 462).
- Other parameter values are prompted for in simple text input dialogs. In these dialogs, the button *Default value* will enter a "null" value for the parameter in the input field.

Each parameter dialog has an *OK* button for confirming the value and a *Cancel* button for cancelling the command altogether. Some parameters have a default value that does not have to be specified. In this case, an empty value or '-' is accepted for the default value.

Enumeration Type Parameter Dialogs

Additional functionality is available in the dialog for enumeration type parameters:

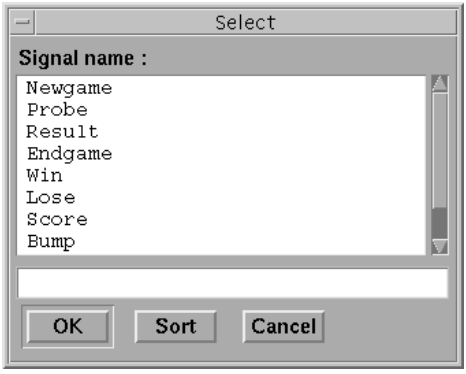

Figure 462: A typical selection dialog

In this dialog, the value can also be entered or edited on the text input line below the list in the dialog. The *Sort* button sorts all values in alphabetical order.

Name completion with the space character is provided. When you press `<Space>` after an initial string, the first value **starting with** the string will be selected (if any). Another `<Space>` will select the next value, etc. When there are no more matches, a space character will be added after the string you initially entered.

A slightly different name completion is provided with the '?' character. When you press '?' after an initial string, the first value **containing** the string will be selected (if any). Another '?' will select the next value. When there are no more matches, a '?' character will be added after the string you initially entered.

For those commands that take an optional variable component, the component must be entered on the text input line after the selected variable name, since it will not be asked for in a dialog. If a '?' is entered instead of a variable component, an additional dialog is opened in which the component can be selected. See the discussion of '?' in "Examine-Variable" on page 2152.

Signal Parameter Dialogs

If a command takes an output signal as parameter, and that signal have parameters, the signal parameters are asked for in a separate dialog. In this dialog, all parameters are listed with their default (“null”) values, and they can all be edited in the same dialog. For more information, see “Selecting Signal Parameters” on page 2246 in chapter 50, *Simulating a System*.

Quick Buttons

The simulator has the following quick buttons:

- **Open simulator**: Open an existing simulator executable file.
- **Restart simulator**: Restart the current simulator from the initial system state.
- **Rerun script**: Rerun last executed script.
- **Undo command(s)**: Undo one or more commands.
- **Show Organizer**: Show the Organizer main window.
- **Show Help**: Show help on Simulator user interface.

The Button Area

The *button area* is used for entering monitor or SimUI commands by clicking the left mouse button on a command button. Each button corresponds to a specific command. The buttons are divided into groups, roughly corresponding to the different types of commands listed in chapter 50, *Simulating a System*. Each group is shown as a *module* in the button area. Any number of button modules may reside in the button area. If the modules do not fit in the button area, a vertical scroll bar is added.

The definition of the buttons and button groups are stored in a *button definition file* (see “Definition Files” on page 2221). New buttons can be added and existing ones deleted or redefined by using the *Group* menu in a button module.

To examine a button’s definition without executing the command, the left mouse button is pressed on the button and the mouse pointer is

moved outside the button. The command definition then appears in the status bar, but the command is not executed.

If a button's definition contains parameters, the parameter values are prompted for in dialog boxes before the command is executed, in the same way as described for commands entered from the input line. See "Parameter Dialogs" on page 2201.

When no more parameter values are requested, the string shown on the input line saved in the history list and is moved to the text area. The command is then executed.

A Button Module

A *button module* looks like this:

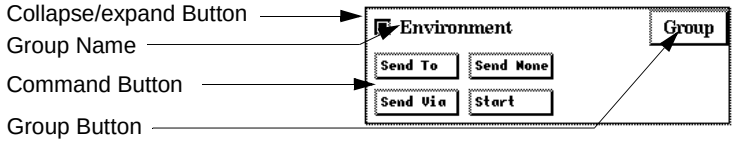

Figure 463: A button module

Each module consists of a title bar and a number of command buttons arranged in rows and columns. The title bar displays:

- A *collapse/expand* toggle button. Clicking on this button collapses the module so that only the title bar is visible, and expands the module back to its current size so that the buttons become visible.
- The *group name* of the button module.
- A *Group* button, providing a menu with commands affecting the buttons in the module.

The *Group* button contains the following menu items:

Add

This menu choice adds a new button to the button module. A dialog prompts for the button label and the command to be executed when the button is pressed. The new button is added to the end of the module. Several buttons may be added with the dialog by using the *Apply* button instead of the *OK* button.

For the syntax of a button definition, see the subsection "Button and Menu Definitions" on page 2222.

> **Note:**
>
> **On UNIX**, if several buttons have **the same button label**, it is always **the first button** found that will be deleted or modified, independently of the selection.

Edit

This menu choice edits the label and definition of a button. The button to edit is selected in a dialog. When a button has been selected, the label and definition can be edited using a dialog.

> **Note:**
>
> **On UNIX**, if several buttons have **the same button label**, it is always **the first button** found that will be edited, independently of the selection.

Delete

This menu choice deletes one or more buttons from the button module. The buttons to be deleted are selected in a dialog.

> **Note:**
>
> **On UNIX**, if several buttons have **the same button label**, it is always **the first button** found that will be deleted, independently of the selection.

Rename Group

This menu choice edits the name of the current button module in a dialog.

Delete Group

This menu choice deletes the current module from the button area. A dialog asks for confirmation.

The Default Button Modules

The following tables list the default buttons in the button modules and the corresponding monitor command. See "Monitor Commands" on page 2145 for more information.

> **Note:**
>
> The buttons in the button modules are specified in the button definition file. If the default button file is not used, the button modules may be different than described here. See "Button and Menu Definitions" on page 2222 for more information.

The *Execute* Module

Button	Monitor command
Symbol	Step-Symbol
Transition	Next-Transition
Go	Go
Until Timer	Proceed-To-Timer
Break	Pressing `<Return>`

The *Send Signal* Module

Button	Monitor command
Send To	Output-To
Send Via	Output-Via
Send None	Output-None

The *Examine* Module

Button	Monitor command
Process List	List-Process -
Variable	Examine-Variable (
Var In Scope	Examine-Variable

The *Trace* Module

Button	Monitor command
MSC	Start-Interactive-MSC-Log 1
SDL	Set-GR-Trace 1
TEXT	Set-Trace 6

The Menu Bar

This section describes the menu bar of the SimUI's main window and all the available menu choices. However, the *Help* menu is described in "Help Menu" on page 15 in chapter 1, *User Interface and Basic Operations*. Simulator commands are described in "Monitor Commands" on page 2145.

The menu bar contains the following menus:

- *File Menu*
- *View Menu*
- *Buttons Menu*
- *Log Menu*
- *General Menu*
- *Execute Menu*
- *Examine Menu*
- *Change Menu*
- *Show Menu*
- *Trace Menu*
- *Breakpoint Menu*
- *Help Menu*
  (See "Help Menu" on page 15 in chapter 1, *User Interface and Basic Operations*.)

File Menu

The File menu contains the following menu choices:

- *Open*
  (See "Open" on page 9 in chapter 1, *User Interface and Basic Operations*.)
- *Restart*
- *Exit*
  (See "Exit" on page 15 in chapter 1, *User Interface and Basic Operations*.)

Restart

Restart the currently opened simulator. After user confirmation, the currently running simulator is stopped, the *Watch* window is updated, and the text area is cleared from previously executed commands.

The command is dimmed if no simulator has been opened.

View Menu

The *View* menu contains the following menu choices:

- *Watch Window*
- *Command Window*
- *Open All*
- *Close All*
- *Clear Text Area*

Watch Window

Opens the Watch window displaying variable values in the simulation. If this window is already opened, the menu item is dimmed. See "Watch Window" on page 2219 for more information about this window.

Command Window

Opens the Command window in which arbitrary monitor commands will be executed. If this window is already opened, the menu item is dimmed. See "Command Window" on page 2216 for more information about this window.

Open All

Opens the Watch and Command windows.

Close All

Closes the Watch and Command windows.

Clear Text Area

Clears the text area in the main window without affecting the simulation.

Buttons Menu

The Buttons menu contains the following menu choices:

- *Load*
- *Append*
- *Save*
- *Save As*
- *Expand Groups*
- *Collapse Groups*
- *Add Group*

For more information on the SimUI's button definition file mentioned in the menu commands below, see "Definition Files" on page 2221.

Load

Reads in a new button definition file that overrides the current button definitions. All buttons and modules currently in the button area are deleted and replaced by the buttons and modules defined in the new file. A File Selection Dialog is opened for specifying the file to load.

Append

Appends the contents of a new button definition file into the current button definitions. Buttons with new labels are added to the button area, while buttons with already existing labels in the same module will be duplicated (possibly with different definitions). A File Selection Dialog is opened for specifying the file to append.

Save

Saves the current button and module definitions in the button definition file under its current file name.

Save As

Saves the current button and module definitions in a new button definition file. A File Selection Dialog is opened for specifying the new file name.

Expand Groups

Expands all modules in the button area.

Collapse Groups

Collapses all modules in the button area.

Add Group

Adds one or more new button module after the last module in the button area. A dialog box is opened for specifying the name of the new module. Several modules may be added with the dialog by using the *Apply* button instead of the *OK* button.

Log Menu

The *Log* menu manages three different log variants:

- The *input history* contains all textual commands sent to the SimUI.
- The *command history* contains all textual commands sent to the simulator.
- The *complete log* contains all textual output presented during a simulator session, this includes both user commands and simulator output.

The difference between the input history and the command history is that the SimUI processes commands before forwarding them to the simulator. The input history contains the raw user input, while the command history contains pure simulator commands. For instance:

- *Macros*: The input history contains

```
Output-to MySignal ($maxvalue) Main
```

while the command history contains

```
Output-to MySignal (37329) Main
```

- *Check*: This SimUI command, together with its expected output section, is saved in the input history but not in the command history.
- *Execute input script*: This SimUI command is saved in the input history, while the command history contains the executed commands.

The *Log* menu contains the following menu choices:

- *Save Input History*
- *Save Command History*
- *Clear Input History*
- *Clear Command History*
- *Start/Stop Complete Log*
- *Log Status*

Clear Input History

SimUI command: `clear-input-history`

Normally, the input history is cleared when the simulator is restarted. You use this menu choice to clear the input history without restarting the simulator.

Save Input History

SimUI command: `save-input-history`

A file selection dialog appears, where you specify the file to save the input history in. The default file extension for input history files, i.e. input scripts, is `*.cui`.

Clear Command History

SimUI command: `clear-command-history`

Normally, the command history is cleared when the simulator is restarted. You use this menu choice to clear the command history without restarting the simulator.

Save Command History

SimUI command: `save-command-history`

A File Selection Dialog appears, where you specify the file to save the command history in. The default file extension for command history files, i.e. command scripts, is `*.com`.

Start/Stop Complete Log

Start Complete Log starts the logging of complete monitor interaction, i.e. the complete contents of the text area will be logged to a file. A file selection dialog is opened for specifying the log file. If an already existing log file is selected, the user is asked whether to overwrite this file or to append the log to it.

Stop Complete Log stops the complete logging to the file. The appropriate menu choice is displayed depending upon the current state of the log.

Log Status

Displays the status of the command and complete logs in a dialog box. If a log is active, the name of the log file is shown.

Additional Simulator Menus

In addition to the standard SimUI menus, a few special simulator menus are included in the menu bar. The menu choices in these menus simply execute a monitor command, i.e. they are functionally equivalent to buttons in the button modules. If the monitor command requires parameters, they are prompted for using dialogs in the same way as the command buttons.

The following tables list the default menu choices and the corresponding monitor command. See "Monitor Commands" on page 2145 for more information.

> **Note:**
>
> The additional menus in the SimUI are specified in the button definition file. If the default button file is not used, the button modules may be different than described here. See "Button and Menu Definitions" on page 2222 for more information.

General Menu

Show	List-Breakpoints

Command Window

The *Command window* is an optionally visible window used for displaying the results of executed commands. The Command window is opened from the SimUI's *View* menu.

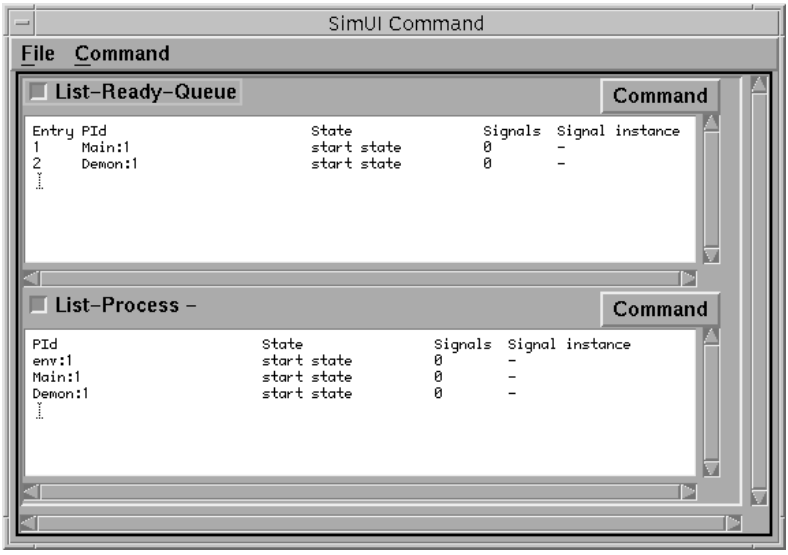

Figure 464: The Command window

The Command window is updated automatically whenever the monitor becomes active and after each monitor command. See "Activating the Monitor" on page 2131 for information on when the monitor becomes active. The window can also be updated manually with a menu command.

Any number of commands can be defined to be executed in the Command window. Each command is executed in a scrollable module in the window.

New commands can be added to the window and existing commands can be changed. The commands to execute are by default List-Process and List-Ready-Queue. The set of commands to execute are stored in a *command definition file* (see "Definition Files" on page 2221). The default command definition file can be changed with the Preference Manager.

Command Modules

A *command module* looks like this:

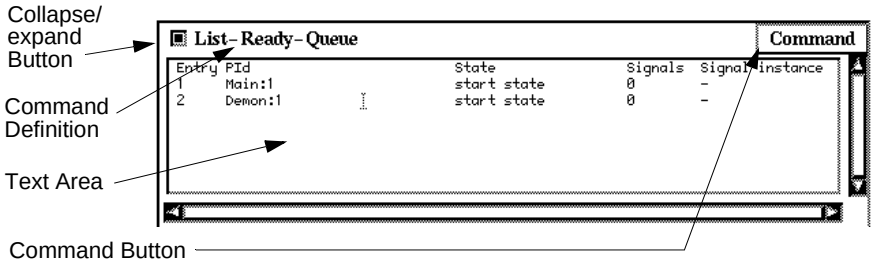

Figure 465: A command module

Each module consists of a *title bar* and a scrollable *text area* for the command output. The title bar displays:

- A *collapse/expand* toggle button. Clicking this button collapses the module so that only the title bar is visible, and expands the module back to its current size so that the text area becomes visible. When a module is expanded, the text area is automatically updated.
- The *command* that is executed.
- A *Command* button, providing a menu with commands affecting the module.

The *Command* button contains the following menu items:

Edit

Opens a dialog for editing the command executed.

Delete

Deletes the command and command module from the Command window.

Size

Sets the size of the text area. A dialog is opened where the number of text rows can be set using a slider.

File Menu

The File menu contains the following menu choices:

- *Load*
- *Append*
- *Save*
  (See "Save" on page 11 in chapter 1, *User Interface and Basic Operations*.)
- *Save As*
  (See "Save As" on page 12 in chapter 1, *User Interface and Basic Operations*.)
- *Close*
  (See "Close" on page 14 in chapter 1, *User Interface and Basic Operations*.)

Load

Reads in a new command definition file that overrides the current command definitions. All commands currently in the Command window are deleted and replaced by the commands defined in the new file. A File Selection Dialog is opened for specifying the file to load.

Append

Appends the contents of a new command definition file into the current command definitions. New commands are added to the command window, but already existing commands are not affected. A File Selection Dialog is opened for specifying the file to append.

> **Note:**
>
> Command names in a command definition file are **case sensitive**. If a command in an appended file already exists in the Command window, but with different case, the command will be duplicated.

Command Menu

The Command menu contains the following menu choices:

Command

Adds a new command to the Command window. A dialog box prompts for the new command. The new command module is added to the bottom of the window. For the syntax of a command definition, see "Command Definitions" on page 2223.

Update All

Updates all command modules by executing the defined commands.

Watch Window

The *Watch window* is an optionally visible window used for displaying values of variables defined in the currently running simulation. The Watch window is opened from the SimUI's *View* menu.

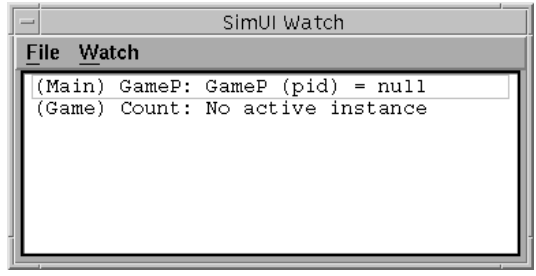

Figure 466: The Watch window

The Watch window is updated automatically after each monitor command. The window can also be updated manually with a menu command.

The variables to display are selected with a menu command. The set of selected variables are stored in a *variable definition file* (see "Definition Files" on page 2221).

File Menu

The File menu contains the following menu choices:

- *Load*
- *Append*
- *Save*
  (See "Save" on page 11 in chapter 1, *User Interface and Basic Operations*.)
- *Save As*
  (See "Save As" on page 12 in chapter 1, *User Interface and Basic Operations*.)
- *Close*
  (See "Close" on page 14 in chapter 1, *User Interface and Basic Operations*.)

Load

Reads in a new variable definition file that overrides the current variable definitions. All variables currently in the Watch window are deleted and replaced by the variables defined in the new file. A File Selection Dialog is opened for specifying the file to load.

Append

Appends new variable definitions to the current variable definitions file. The variables in the file are added to the Watch window. A File Selection Dialog is opened for specifying the file to merge. Duplicate variable definitions are permissible.

Watch Menu

The Watch menu contains the following menu choices:

- *Update All*
- *Add*
- *Edit*
- *Delete*
- *Delete All*

Update All

Updates the Watch window by showing the current value of all displayed variables.

Add

Adds one or more variables to the Watch window. A dialog is opened for specifying the variable to be added. For the syntax of a variable definition, see "Variable Definitions" on page 2224. Several modules may be added with the dialog by using the *Apply* button instead of the *OK* button.

Edit

Edits a variable specification in the Watch window. The variable whose specification is to be changed is selected in a dialog. When a variable has been selected, the specification can be edited using a dialog.

Delete

Deletes one or more variables from the Watch window. The variables to delete are selected in a dialog.

Delete All

Deletes all variables from the Watch window.

Definition Files

In the SimUI, the following types of information are stored on files:

- **Button definitions**

  i.e. definitions of button groups and button commands in the main window's button area.

- **Menu definitions**

  i.e. definitions of additional menus and menu commands in the main window's menu bar.

- **Command definitions**

  i.e. definitions of commands to be executed in the Command window.

- **Variable definitions**

  i.e. definitions of variables to display in the Watch window.

At start-up of the SimUI, the files to read are determined in the following way:

1. The file names are defined with the Preference Manager. If a file name is not defined there, the default file name `def.btns`, `def.cmds` and `def.vars` is used, respectively.

2. If the file names does not contain a directory path, the files are searched for in the following directories and the following order:

   – the current directory
   – the user's home directory
   – the installation directory

Once a file has been found, it is read and the contents of the corresponding window are set up. If a file cannot be found, the corresponding window area becomes empty.

Common File Syntax

Each of three text files can contain comment lines starting with the '#' character. Empty lines are not discarded.

> **Note:**
> When a file is read, **no checks are made upon the relevance** or correctness of the definitions contained in the file.

Button and Menu Definitions

The *button and menu definitions* are stored in a button definition file with the default extension `.btns`. The button definitions are divided into groups where each group defines a button module in the main window's button area, or a menu in the main window's menu bar.

Syntax

In the file, a button group has the following syntax:

```
:[COLLAPSED] <group name>
<button label>
<definition>
<button label>
<definition>
  . . .
```

The <group name> is the string shown in the title bar of the button module. If the group name is prefixed with the string `COLLAPSED`, the button module is initially collapsed. The <button label> is the label of the button in the button module. The <definition> is the monitor command that will be executed when the button is pressed. The syntax of a button definition is the same as when entering a command textually to the monitor.

A menu has the following syntax:

```
:MENU <menu name>
<menu choice>
<definition>
<menu choice>
<definition>
 . . .
```

The <menu name> is the name of the menu shown in the menu bar. The <menu choice> is the name of the menu choice in the menu. The <definition> is the monitor command that will be executed when the menu choice is selected.

In the monitor command definition, a '?' as parameter will not work, but a hyphen '-' can be used to signify the default value. Missing parameters at the end of the command will open dialogs for those parameters.

Defining Multiple Commands

In addition, a button definition may consist of several monitor commands, if they are separated by a space and a semicolon, i.e. ";". The commands are then executed immediately after each other.

Example 336: Multiple Commands in Simulator ––––––––––––––––––

```
next-transition ; out-via probe -
```

This button definition executes the next transition and then sends the signal Probe from the environment.

––

Command Definitions

The command definitions are stored in a command definition file with the default extension `.cmds`. Each command definition defines a command module in the Command window. The file has the following syntax:

```
<command>
<command>
   . . .
```

The <command> is the monitor command that will be executed in the command module. The syntax of a command definition is the same as when entering a command textually to the monitor. All parameter values must be specified explicitly or with the default value '-', i.e. '?' is not allowed, and no parameters may be missing. Command names are case sensitive.

> **Note:**
>
> Care should be taken when deciding what command to execute; commands belonging to the Execute group **should be avoided**.

Variable Definitions

The variable definitions are stored in a variable definition file with the default extension `.vars`. Each variable definition defines a variable to display in the Watch window. The file has the following syntax:

```
(<process>) <variable>
(<process>) <variable>
   . . .
```

The <process> is the name of the process, possibly augmented with an instance number separated with a space or colon. The <variable> is the name of the variable in that process. Names are **not** case sensitive.

Example 337: Variable Definitions in Simulator

```
(Main) Count
(game:1) guess
```

Macros

The SimUI has a built-in macro facility. A macro can represent a simulator command or a part of a simulator command. Even though SimUI macro commands are processed by the SimUI, it is possible to enter SimUI macro commands almost as if they were normal simulator commands:

- Type in the SimUI macro command. Note though, that SimUI commands cannot be abbreviated in the same way as simulator commands.
- Define a button or a menu for the SimUI macro command.

These commands are available for macros:

- Use **add-macro** to define a new macro:

  ```
  add-macro <macro name> <macro value>
  ```

  Example:

  ```
  add-macro maxvalue 37329
  ```

- Use **list-macros** to see all defined macros and their values:

  ```
  list-macros
  ```

  Example:

  ```
  Command: list-macros
  Number of macros defined: 1
  Macro name: maxvalue
  Macro value: 37329
  ```

- Use **$** to get the value of a defined macro:

  ```
  $<macro name>
  ```

  Example: The SimUI input:

  ```
  Output-to MySignal ($maxvalue) Main
  ```

  is sent to the simulator as

  ```
  Output-to MySignal (37329) Main
  ```

- Use **remove-macro** to remove an already defined macro:

  ```
  remove-macro <macro name>
  ```

  Example:

  ```
  remove-macro maxvalue
  ```

SimUI Commands

The SimUI examines entered textual commands before sending them to the simulator. If they are SimUI commands they are not sent to the simulator.

Here is a list of all SimUI commands and what they do:

- `add-macro`

  Adds a new SimUI macro. For details, see "Macros" on page 2224.

- `check`

  Tells the SimUI that the textual simulator output from the next command should be checked.

  – When commands are entered manually and a check command is issued, the SimUI saves the simulator output for the next command in an expected output section in the input history.

  – When commands are read from file by executing an input script, and a check command is encountered, the SimUI compares the simulator output for the next command with the expected output from the input script. The SimUI reports if the check passed or failed.

- `clear-command-history`

  Clears the simulator command history without restarting the simulator. This command is useful if you want to save a command history that does not start from the beginning of a simulator session.

- `clear-input-history`

  Clears the SimUI input history without restarting the simulator. This command is useful if you want to save an input history that does not start from the beginning of a simulator session.

- `execute-input-script`

  Executes the commands found in an input script, i.e. an input history saved to file.

  – If a relative file name is used, then it is interpreted as relative to the Organizer source directory.

  – If parameters are given as a space separated list after the file name, then these parameters can be accessed with $1, $2, ... in the called script. It is also possible to access the number of parameters with $# and the name of the calling script with $0.

- `list-macros`

Produces a list of all defined macros and their values. For more details, see "Macros" on page 2224.

- `remove-macro`

  Removes an already existing SimUI macro. For more details, see "Macros" on page 2224.

- `save-command-history <file name>`

  Saves the simulator command history in a command script file (`*.com`). If no <file name> is given, a file selection dialog appears, where you can specify a file name.

- `save-input-history`

  Saves the SimUI input history in an input script file (`*.cui`). If no <file name> is given, a file selection dialog appears, where you can specify a file name.

- `set-source`

  Saves an SDT reference so it is possible to navigate to the symbol in the MSC diagram that the following commands originated from. It is not intended for a user to enter, instead it is automatically generated by the MSC translator.

- `set-synonym-file <file name>`

  Sets the synonym file to use the next time the simulator is restarted from the simulator UI. If no <file name> is given, a file selection dialog appears, where you can specify a file name. Note that the synonym file can also be set from the menu choice SimUI>Change>Synonym File.

Regression Testing

By using the simulator for regression testing, it is possible to check that an enhanced version of an SDL system does not break the old functionality, that is still expected to work for the same SDL system.

With regression testing in the simulator, you can for instance:

- Send in signals and check that the correct signals are sent back out again.
- Check that a variable has the correct value at a specific moment.

The basic idea is to save and replay the input history, and check the textual simulator output for selected commands. An input history saved to a file is called an input script. A group of input scripts can be collected in the Organizer together with the SDL system. The Organizer provides the possibility to run a group of input scripts (or test cases). This results in a textual summary where it is easy to see any test case failures. To examine a test case failure in detail, it is possible to run a single test case with the SimUI command `execute-input-script` (see "SimUI Commands" on page 2225).

Note that it is also possible to express test cases with the MSC notation. MSC test cases are converted to input scripts before being run in the simulator.

Here is a small example, to see how it works:

Example 338 ----------

In System DemonGame (that is provided as an example in the SDL Suite installation), you can (after some initialization) send in a Result signal and expect to get a Score signal back.

To make a test case testing that we get a Score signal back:

1. Create a simulator for System DemonGame.
2. Execute the following simulator commands (you do not have to type in the comments):

```
- Output-To NewGame Main /* Send in signal NewGame
  to start a new game. */
- Next-Transition /* Execute the start transition
  for process Main. */
- Next-Transition /* Execute the start transition
  for process Demon. */
- Next-Transition /* Execute the transition receiv-
  ing signal NewGame and creating process Game */
- Output-To Result Game /* Send in a signal to get
  the current score. */
- break-output - env - - - - - - /* Set a breakpoint
  on signals sent to the environment. */
- Set-Trace System DemonGame 0 /* Minimize textual
  trace. */
- check /* Check the output from the next command. */
- go /* Execute as far as possible. The simulator
  will stop and report that the Score signal has been
  sent to the environment. */
```

3. The go command that we are checking produces the following textual simulator output:
   ```
   Breakpoint matched by output of Score
   ```
4. Save the input history in an input script, with the SimUI command `save-input-history`. The last part of the input script will look like this:

   ```
   check
   go
   expected-output start
   Breakpoint matched by output of Score
   expected-output end
   ```

5. Add a symbol for the input script in the Organizer, with *Edit > Add New*, plain text, do not show in editor.
6. Connect the symbol to the input script file with *Edit > Connect*.
7. Now, make a test: Deselect everything in the Organizer (to make sure that both the SDL system and the input script will be considered) and choose *Tools > Simulator Test*. After a dialog, a fresh simulator will be created and the test case run. The result is presented in the Organizer Log.
8. To force a test case failure:
   - Edit the test case (by double-clicking on the Organizer symbol to get a text editor) by changing the expected output to be something different.
   - Save the test case.
   - Repeat the above test.
   - If everything works as expected, the test case fails.
9. To examine the details of a test case failure:
   - Restart the simulator.
   - Execute the test case (input script) in the SimUI with the `execute-input-script` command.
   - If everything works as expected, the expected output from the go command did not match the actual output.

Mapping Instances to Different Environments

When generating test scripts (.CUI scripts) from MSCs, it is possible to select for which specific processes/blocks for which a cui script shall be generated if an MSC testcase describes several blocks.

Through an instance translation table, which is a plain text file in the Organizer with the extension `*.itt`, it is decided which instances in the MSC that should be regarded as environment. In this file it is for example stated that an instance A really is instance `env:2`.

```
Example *.itt file:
MyBlock env:2
MyProcess env:3
```

The name used for an instance in the MSC is placed first, followed by a space, and then comes the name of the environment instance to map the MSC instance to. Note that the only names that can be used for mapping are `env:2`, `env:3`, `env:4` etc. and that no numbers can be left out when mapping, i.e. it is not allowed to only use `env:2` and `env:4` without using `env:3`.

Whenever an MSC is converted to a CUI test script, the first found (or closest found) translation table from the Organizer is used and all instances in the file are translated according to the table in the file. All instances starting with `env` (after translation, if there is a translation file) are outside the system, and all other instances are assumed to be inside the system.

Order of execution

In the case where the MSCs used as test scripts only have one environment instance, the order of execution is the same order as messages are connected to the environment instance in.

To determine the order things are done in when several instances are converted to environment instances, the y-coordinate of the connection of messages to environment instances is used. If the y-coordinate of sending in message A is above the y-coordinate of sending in message B, then message A is sent before message B. If two connections have the same y-coordinate, then the x-coordinate is used to determine the order. The left most connection is done first.

Only messages connected to an environment instance in one end and a system instance in the other end are used to drive the simulation. Mes-

sages between environment instances and messages within the system are ignored.

For action symbols (that can contain ordinary simulator commands or shortcuts for ordinary simulator commands), the upper connection point to the environment instance is used for determining the order of doing things in.

It is also possible to test in an MSC test script if a service response message is returned to the same environment instance (representing a specific external process) that sent in the service request message, in the case where there are many environment instances. This is done with the *output-internal* simulator command that is generated by the MSC to CUI converter. An example:

```
output-internal SignalIn ProcessOne env:2
```

If the system responds to this message by sending back another message to sender, then the textual trace will contain information about what environment instance the signal was sent to:

```
* OUTPUT of SignalOut to env:2 from ProcessOne:1
```

In addition to the output-internal command, the create null env command is generated in the CUI script by the converter. This command will create the environments in the simulator that will be used for the instances that are mapped to an environment instance in the `.itt` file.

Note that when instances are mapped with an `.itt` file, process id mapping should not be used.

Restrictions

Restrictions on Monitor Input

The following restrictions apply to the monitor input:

- A parameter to a monitor command may not contain more than 5,000 characters.
- **On UNIX**, control characters of different types may terminate the simulation program. `<Ctrl+C>`, `<Ctrl+D>`, and `<Ctrl+Z>` are typical characters that might terminate a simulation program.

Restrictions on Dynamic Checks

There are a number of dynamic checks that are not performed at all or performed at the C level by the C runtime system. A C runtime error will of course lead to the simulation program being terminated. The following checks are not made at the SDL level.

- Several paths from a decision for a certain decision expression value. A simulation program will simply choose one of the existing paths.
- Overflow of integer and real values are checked at the C level if the actual C system performs these checks. (These checks are likely not to be performed.)

Chapter

50 *Simulating a System*

This chapters provides general information related to simulation in the SDL Suite and describes the actions you perform when simulating an SDL system.

For a reference to the simulator user interface, see *chapter 49, The SDL Simulator*.

Structure of a Simulator

In order to generate a simulator, the SDL to C Compiler is used. The simulators generated using the SDL to C Compiler consist of the following components:

- The Simulated System (the application itself)
- The Environment Process
- The Interactive Monitor System
- The Graphical User Interface (the Simulator UI).

Additional tools support graphical trace when executing a simulator:

- The SDL Editor
- The MSC Editor.

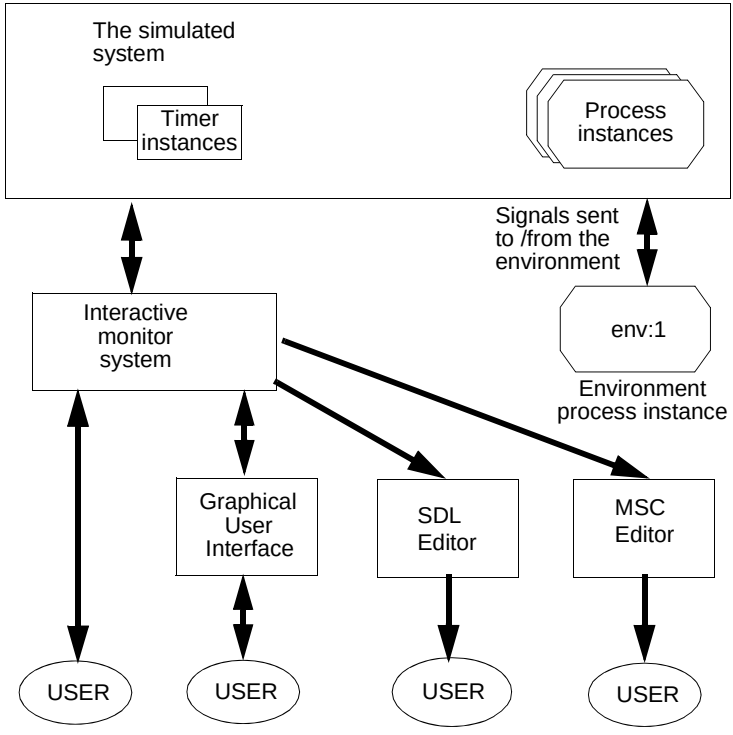

Figure 467: Structure of a running simulator

The Simulated System

The application is a representation in C code of the implementation of the SDL system. Having generated the application (that is, translated the SDL system into C code), the SDL to C compiler generates a make-file which contains instructions about how to compile and link the application together with the appropriate runtime library. A number of libraries are provided, which allow you to generate an application with the desired behavior. For instance, it is possible to have multiple simulators communicate with each other or communicate with an external application, provided that application has the facility to communicate through the Postmaster.

An executing simulation program contains a number of data objects that represent certain SDL objects in the system that is being simulated. Process instances, signal instances (signals that are waiting in the input port of a process instance), and timer instances (timers that are set, but that have not output their corresponding signal instance) are all examples of such objects. These objects, together with the process instance env:1, which represents the environment of the system, and the monitor system, constitute the simulation program (see Figure 467).

The process instances in the simulated system will execute transitions that consist of actions like tasks, decisions, outputs, procedure calls, and so on, according to the rules of SDL. It is assumed that a transition takes no time and that a signal instance is immediately placed in the input port of the receiver when an output operation occurs.

The Environment Process

The function of the environment process instance, env:1, is to be a receiver of signal instances sent from the system to the environment of the system. The input port of env:1 will always hold the last 20 signals sent to the environment.

The Interactive Monitor System

When generating a simulating application, a *monitor system* is included, the function of which is to allow the interaction between the application and the user via a command line user interface. The monitor system provides a functionality similar to high-level language debuggers, in which you can, for instance:

- view and modify objects defined in your SDL system,
- set breakpoints,
- control the execution,
- control the logging facilities,
- and so on...

The interactive monitor is the interface between the user and the simulated system. The monitor can be seen as an ordinary process instance, which, when executing a transition, accepts commands from the user.

One group of monitor commands terminate the current transition of the monitor, allow one or several other process instances to execute their transitions, and then start a new transition by the monitor.

The Graphical User Interface

A graphical user interface to the monitor system of a simulator, known as the *Simulator UI*, is also provided. It is a window-based tool which facilitates the use of the monitor system. It contains graphical components, such as buttons, menus, and scrollable lists, which make it easier to run the simulator in an intuitive way. Also, it is designed to minimize the required amount of user interaction.

> **Note:**
>
> Running the graphical user interface requires that the Cbasic SDL to C Compiler is present in your configuration.

When running the Simulator UI, the user has the option to take advantage of the graphical features which are provided, or to enter commands in a command line fashion in the same way as the textual interface.

Generating and Starting a Simulator

There are two ways to generate and start a simulator:

- A quick way in one single step, adequate for most situations
- A more complex way in several steps, giving you complete control of the generation and start process.

In the following, the more complex way will be described first, to give a full understanding of the process. The quick way is described in "Quick Start of a Simulator" on page 2239.

Generating a Simulator

A Simulator for an SDL system, or a part of an SDL system, consists of the C code generated by the SDL to C compiler together with a predefined run-time kernel. To start a Simulator, it is thus necessary to first generate an executable simulator. This is performed in the Organizer.

To generate an executable simulator:

1. Select a system, block, or process diagram in the Organizer.
2. Select *Make* from the *Generate* menu. The Make dialog is opened.
3. Turn on the options *Analyze & generate code* and *Makefile*.
4. From the *Standard kernel* option menu, select *Simulation*.
5. If you need to check the Analyzer options, click the *Analyze Options* button. In the dialog, set the options and click the *Set* button. For more information about these options, see "Analyzing Using Customized Options" on page 2618 in chapter 55, *Analyzing a System*.
6. Click the *Make* button.

   On UNIX, a simulator for the system is now generated in the current directory with the name `<system>_xxx.sct` (the `_xxx` suffix is platform specific).

   In Windows, a simulator for the system is now generated in the current directory with the name `<system>_xxx.exe` (the `_xxx` suffix is kernel and compiler specific).

   The Status Bar of the Organizer reports the progress of the generation; the last message should be "Compiler done."
7. Open the Organizer Log window from the *Tools* menu and check that no errors occurred and that a simulator was generated.
   - If errors were found, correct them and repeat the generation process. See "Locating and Correcting Analysis Errors" on page 2624 in chapter 55, *Analyzing a System*.
   - If no simulator was generated, repeat the generation process, but click the *Full Make* button in the Make dialog instead.

Starting a Simulator

An executable simulator can be run in two different modes; graphical mode and stand-alone mode (textual mode).

Graphical Mode

In graphical mode, the Simulator takes advantage of the graphical user interface and integration mechanism of the SDL Suite. A separate graphical user interface, the *Simulator UI*, is started, giving access to the monitor system through the use of menus, command buttons, etc.

To start a simulator in graphical mode:

1. Select *SDL > Simulator UI* from the Organizer's *Tools* menu. The graphical user interface of the Simulator is opened (see "The Graphical Interface" on page 2244).
2. Select *Open* from the Simulator UI's *File* menu. A File Selection Dialog is opened.

   – Alternatively, click the *Open* quick button in the tool bar.

3. In the dialog, select an executable simulator and click *OK*.

A welcome message is printed in the text area of the Simulator UI. The monitor system is now ready to accept commands. Please see "Supplying Values of External Synonyms" on page 2240 for some additional information that may affect the start-up.

Stand-Alone Mode (Textual Mode)

In stand-alone mode, the Simulator uses the input and output devices currently defined on your computer, which provide a textual, command line based user interface. A very limited graphical support is provided when running the Simulator in this mode.

To start a simulator in stand-alone mode, the generated simulator is executed directly from the OS prompt, e.g.

```
csh% ./system_sma.sct
```

A welcome message is printed on the terminal:

```
Welcome to SDL SIMULATOR. Simulating system <system>

Command :
```

The monitor system is now ready to accept commands. Please see "Supplying Values of External Synonyms" on page 2240 for some additional information that may affect the start-up.

> **Note:**
>
> **On UNIX**, before a simulator can be run in stand-alone mode, you must execute a command file from the operating system prompt. The file is called `telelogic.sou` or `telelogic.profile` and is located in the binary directory that is included in your `$path` variable.
> For csh-compatible shells: **`source <bin dir>/telelogic.sou`**
> For sh-compatible shells: **`. <bin dir>/telelogic.profile`**

Quick Start of a Simulator

A simulator can also be generated and automatically started in graphical mode in one single step.

To quick start a simulator, click the *Simulate* quick button in the Organizer's tool bar. The following things happen:

- A simulator is generated by using the simulator kernel that is specified in the Make dialog. (If no simulator kernel is specified, a default simulator kernel is used.)
- The graphical Simulator UI is started. If a Simulator UI with the same simulator name is already open, this UI is reused. If another Simulator UI is open, a dialog is opened where you can select to start a new UI, or to reuse one of the existing UI's.
- The generated simulator is started from the Simulator UI.

Restarting a Simulator

An executing simulator can be restarted from the beginning to reset its state completely:

- In graphical mode, select *Restart* from the Simulator UI's *File* menu. (This is the same as opening the same simulator again.) A confirmation dialog is opened.
- In stand-alone mode, the simulator has to be exited with the Exit command and then executed from the OS prompt again.

Supplying Values of External Synonyms

The SDL system for the simulator may contain external synonyms that do not have a corresponding macro definition (see "External Synonyms" on page 2650 in chapter 56, *The Cadvanced/Cbasic SDL to C Compiler*). In that case, you will be asked to supply the values of these synonyms, either by selecting a file with synonym definitions, or by entering each synonym value from the keyboard.

In stand-alone mode, the following prompt appears:

```
External synonym file :
```

Enter the name of a file containing synonym definitions, or press `<Return>` to be prompted for each synonym value.

In graphical mode, a file selection dialog is opened. Either select a file (`*.syn`) containing synonym definitions, or press *Cancel* to be prompted for each value in a separate dialog. In this dialog, the name and type of the synonym is shown together with an input text field. You can now do the following:

- Enter a value and click *OK*.
- Click *Default value* to get a "null" value for the synonym type entered in the input field. Accept or edit this value and click *OK*.
- Click *Cancel* to give the synonym a "null" value (without the possibility to edit the value).
- Click *Cancel all* to give the synonym and all following synonyms a "null" value.

If a synonym file is selected in the file selection dialog, this file is also used when the simulation is restarted. (If you want to use another synonym file you have to `set-synonym-file` simulator UI command.)

If you set the environment variable `SDTEXTSYNFILE` to a file before starting the SDL Suite, this file will automatically be used. If `SDTEXTSYNFILE` is set to "[[" all synonyms are given "null" values.

Note that the simulator lists all external synonyms that have been given values in another way than from a synonym file. This is done to make it easy to cut and paste information to a synonym file, for future use. An example:

```
The following external synonyms were not found in
```

```
synonym file
/home/lat/simulator.syn:

myThirdSynonym (integer)
```

The syntax of a synonym file is described in "Reading Values at Program Start up" on page 2651 in chapter 56, *The Cadvanced/Cbasic SDL to C Compiler*.

Actions on Simulator Start-up

When a simulator is started, the static process instances in the system are created, but their initial transitions are not executed.

If a file called `siminit.com` exists in the current directory an implicit Include-File command will be done on this file at startup.

Issuing Monitor Commands

Whenever the interactive monitor system becomes active, commands are accepted from the user. When running the simulator in stand-alone mode, commands can only be entered textually from a command prompt. When running the simulator in graphical mode, commands may be issued both textually and through the use of menus and buttons.

Activating the Monitor

The simulator's monitor system becomes active when the simulator is started, when the execution has reached a stop condition or a breakpoint, when the system is completely idle, when a semantic error occurs, or when the execution is manually stopped.

These conditions are listed in greater detail in *"Activating the Monitor" on page 2131 in chapter 49, The SDL Simulator*.

The Textual Interface

The commands to the monitor system consist of a command name and possibly one or more parameters to the command, separated by spaces or carriage return. The following general rules apply:

- All command names and parameter values are case insensitive. They may also be abbreviated, as long as they are unique. For in-

stance, the command List-Ready-Queue can be entered in any of the following ways:

```
List-Ready-Queue
list-ready
l-r-q
```

- If not all parameters to a command are given on the command line, the missing parameters will be prompted for. A parameter may be optional, in which case a default value always exists. Default values may also exist for required parameters.
- If you enter an unallowed value for a parameter, an error message is printed and the command is not executed. This is the only way to cancel a command that has been entered.

Getting Command Help

To get a simple list of all possible command names, enter a '?' at the command prompt. A command can then be entered after the list.

To get a list of all commands, grouped into different categories, use the command Help without parameters.

To get a list of all possible commands starting with a certain string, enter the string and hit <Return>. Unless the string was a complete command, all command names starting with the entered string are listed. The following example shows how to list all output commands:

```
Command : out
Command was ambiguous, it might be an abbreviation
of:
Output-To Output-Via Output-None Output-Internal
```

To get short help on a specific command, use the Help command and specify the command in question as a parameter, e.g.

```
Command : help help

Help <Optional command name>

Issuing the help command will print all the
available commands. If help is entered with a
command name, this command will be explained.
```

Entering Parameters

To get a list of possible parameter values, enter a '?' on the command line or when prompted for a missing parameter.

To specify a default value for a parameter, enter a '-' on the command line or when prompted for a missing parameter.

If a default value exists for a parameter, you may also hit `<Return>` when prompted for the parameter to accept the default value. However, if no default value exists, this will list the possible values and prompt for the parameter again.

Hint:

Before you are acquainted with the monitor commands and their parameters, it is generally a good idea to only enter the command names, without parameters. When prompted for parameters, use '?' to list possible values, and '-' to accept default values.

The Graphical Interface

The graphical Simulator UI is illustrated in the figure below:

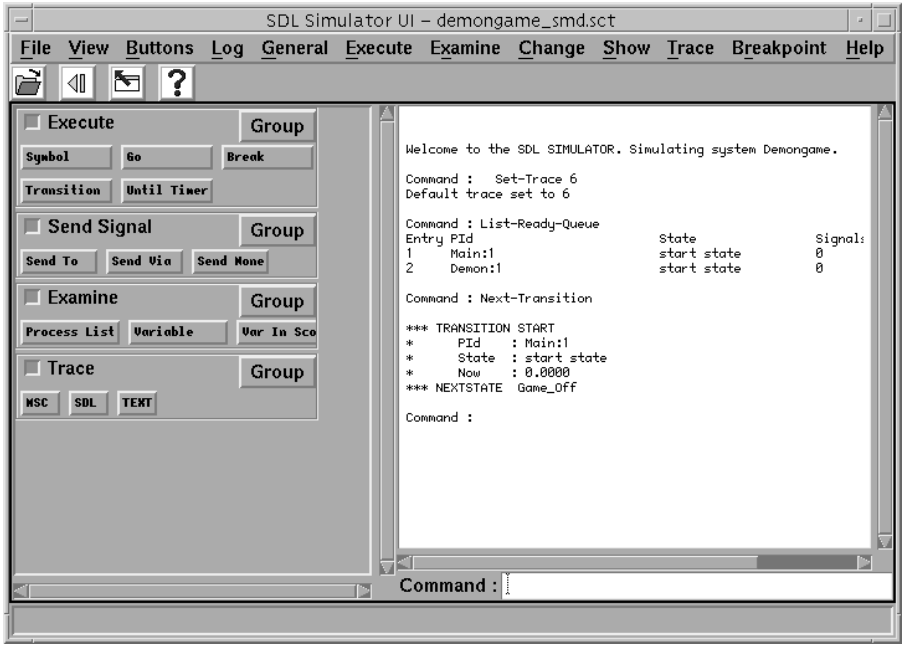

Figure 468: The Simulator UI

All input and output texts to and from the simulator monitor is displayed in the text area to the right.

Entering Commands Textually

To enter monitor commands textually:

1. Place and click the mouse pointer inside the *Command:* input field at the bottom right, below the text area.
2. Enter the command on the input line. The same syntax is used as when running in stand-alone mode; see "The Textual Interface" on page 2241. However, prompting for missing parameters are done by issuing dialogs, where the parameter value can be entered or select-

ed from a list of possible values. See "Selecting Parameters" on page 2245.

Monitor commands entered textually are saved in a *history list*. To re-execute a command in the history list:

1. Place the mouse pointer inside the input field.
2. Use the arrow keys `<Up>` and `<Down>` to display the commands that have been entered earlier.
3. Hit `<Return>` on the command line to re-execute the displayed command. You may edit the command before executing it.

Issuing Commands Using Buttons

The preferred way to issue monitor commands is by using the command buttons in the left area of the Simulator UI, or by using menu choices in the menu bar. Each button or menu choice correspond to a certain monitor command. The buttons are grouped into modules, corresponding to different categories and uses of the commands. The groups are similar to those listed when using the Help command in the textual interface.

To "preview" the command associated with a button or menu choice, without executing it:

1. Place the mouse pointer on the button or menu choice and press the mouse button. The name of the monitor command is displayed in the Status Bar at the very bottom of the Simulator UI.
2. Move the mouse pointer outside the button or menu and release the mouse button.

To execute a command, simply click on a button.

Selecting Parameters

Parameters to monitor commands are prompted for in dialogs (unless they have been specified on the command input line). If a parameter has a set of possible values, the list of values is presented from which you may select a value:

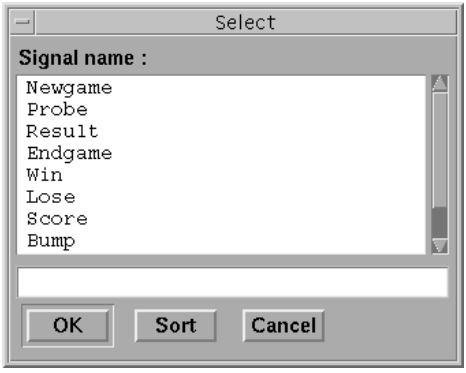

Figure 469: A typical parameter dialog

In this dialog, the values can be sorted alphabetically by clicking the *Sort* button. After having entered an initial string, you can also press `<Space>` to select the first value **starting with** this string, or press '?' to select the first value **containing** this string. Additional `<Space>` or '?' characters will select the next value, etc. When there are no more matches, a real space or '?' character will be added after the string you initially entered.

File parameters are prompted for in File Selection Dialogs. Other parameters, like integers, are prompted for in a simple text input dialog.

- To accept a selected or entered value, click *OK* in the dialog.
- To enter a "null" value for the parameter in the input field, click *Default value* (only available for some parameter types).
- To specify a possible default value, click *OK* without having selected or entered any value, or enter a '-' in the dialog's text input field.
- To cancel a command, click *Cancel* in any of the parameter dialogs, or enter an unallowed value in the dialog's text input field.

Selecting Signal Parameters

If a command parameter is an output signal and you select a signal which in turn have parameters, the signal parameters are asked for in a separate dialog. In this dialog, all parameters are listed with their default ("null") values:

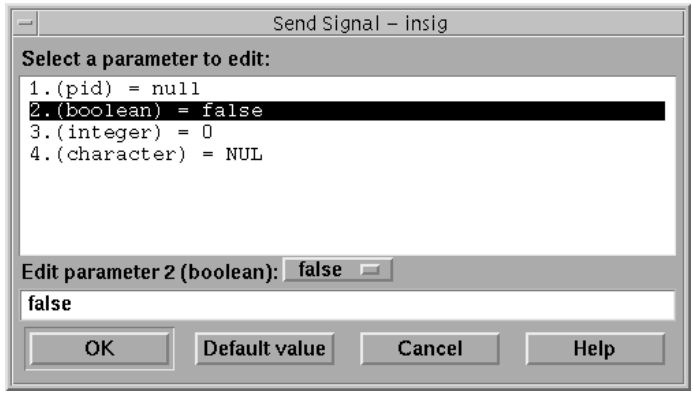

Figure 470: Editing signal parameters

To edit a signal parameter, you select the parameter and then edit the value displayed in the input field. If the parameter is of an enumerated type, the possible values can also be selected from the option menu just above the input field. By clicking *Default value*, the "null" value will be inserted in the input field. A changed parameter value is not updated in the parameter list until a parameter is selected in the list.

Click *OK* to accept all parameter values, and *Cancel* to abort the monitor command. The validity of the parameter values is not tested until you click the *OK* button.

Undo/Redo Commands

To undo a previous command, click the *Undo* quick button in the tool bar, or select *Undo* in the popup menu that is available in the text area. Then you get a dialog with all commands you have given so far. All commands are shown, even the ones entered using buttons or menu choices.

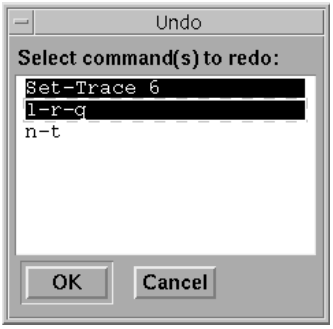

Figure 471: Undoing a command

Initially all commands except the last is selected. If you click *OK* the simulation is restarted and all the selected commands will be re-executed. By clicking on the commands in the dialog you can decide which commands you want to be re-executed in the restarted simulation.

Note:

The Undo function cannot handle to undo commands for setting or removing graphical breakpoints.

To redo a command in the current simulation, select *Command* in the popup menu in the text area. Then you also get a dialog with all commands you have given so far, in the same way as for *Undo*.

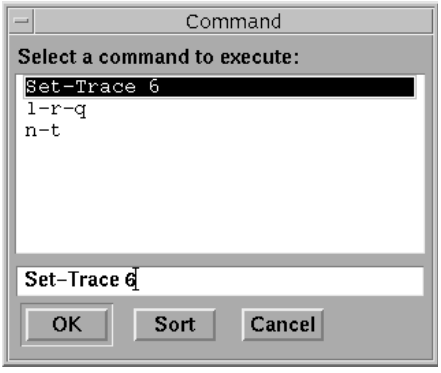

Figure 472: Redoing a command

After selecting one of the commands and clicking *OK* the command is executed. You can also change the command on the command line before clicking *OK*.

Customizing the Simulator UI

In the Simulator UI, you may change the contents and appearance of button modules and some additional windows. All these configurations are stored in a number of definition files, which are read at start-up of the Simulator UI. If you change any of the configurations, you are prompted to save them when you exit the Simulator UI.

Managing Command Buttons

You may wish to add your own command buttons for frequently used commands, or to change or delete existing command buttons. These operations are invoked from the *Group* menu in the button modules:

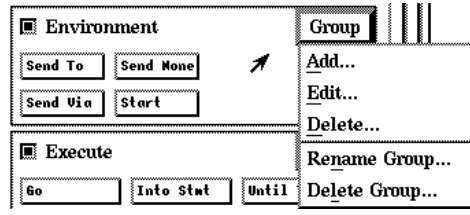

Figure 473: The Group menu

Adding a Button

To add a button to a module:

1. Select *Add* from the *Group* menu. A dialog is opened:

Figure 474: Adding a button

2. Enter a button label and a monitor command definition. The same syntax is used as when entering commands textually. If you omit a parameter value, it will be asked for in a parameter dialog when the command is executed.

3. Click *OK* to add the button and close the dialog. If you click *Apply*, the button is added and you can specify another button to add.

Note:

You cannot specify the location of the button in the module. It will be placed in the next available empty position.

Changing a Button

To change an existing button in a module:

1. Select *Edit* from the *Group* menu. A dialog is opened:

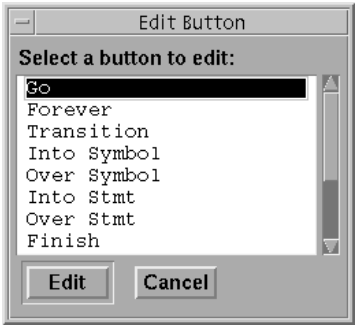

Figure 475: Selecting a button

2. Select the button to edit and click *OK*. A dialog similar to when adding a button is opened (see Figure 474).

3. Edit the button label and/or the command definition and click *OK*.

Deleting a Button

To delete an existing button in a module:

1. Select *Delete* from the *Group* menu. A dialog similar to when editing a button is opened (see Figure 475).
2. Select the button to delete and click *OK*. The button is deleted from the module and the remaining buttons are possibly re-arranged.

Managing Button Modules

In addition to the command buttons, you may also add, rename, delete and collapse/expand the button modules.

Collapsing and Expanding Modules

Modules may be collapsed and expanded to only show the command buttons of interest at the moment. A collapsed module hides all of its buttons and only displays the title bar:

Figure 476: A collapsed button module

To collapse and expand a module, click the toggle button to the left of the module name in the title bar.

To collapse and expand all modules, select *Collapse Groups* or *Expand Groups* in the *Buttons* menu.

Adding, Deleting and Renaming a Module

To add a new module to the bottom of the button module area, select *Add Group* in the *Buttons* menu. In the dialog, enter the module's name and click *OK*.

To delete a module, select *Delete Group* from the module's *Group* menu. In the confirmation dialog, click *OK*.

To rename a module, select *Rename Group* from the module's *Group* menu. In the dialog, enter a new name and click *OK*.

The Command and Watch Windows

In the Simulator UI, you can continuously view the internal status of the system by using the *Command* and *Watch* windows. These windows are opened from the *View* menu. They are both updated automatically whenever the monitor system becomes active.

The Command Window

In the Command window, you can execute a number of monitor commands automatically. The commands are executed in command modules, similar to button modules in the main window of the Simulator UI:

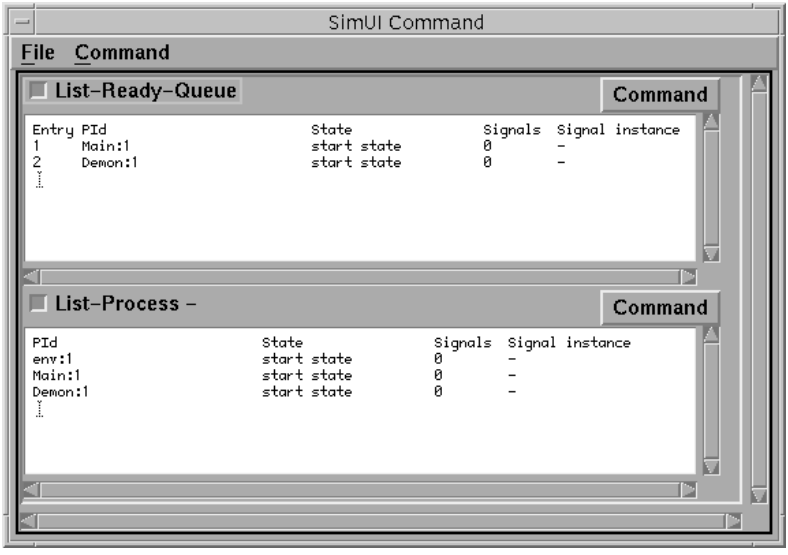

Figure 477: The Command window

By default, the commands List-Ready-Queue and List-Process are executed. You are advised to only use commands for examining the system, see "Examining the System" on page 2264.

The command modules are managed in the following ways:

- To add a command module, select *Command* from the *Command* menu in the menu bar. In the dialog, enter the monitor command to execute, including possible parameters.

- To change the command executed in a module, select *Edit* from the module's *Command* menu. In the dialog, enter a new command and click *OK*.
- To delete a command module, select *Delete* from the module's *Command* menu. No confirmation dialog is issued.
- To change the size of a module's text output area, select *Size* from the module's *Command* menu. In the dialog, use the slider to set the number of text lines to be visible.
- To collapse or expand a module, click the toggle button to the left of the module name in the title bar.

The Watch Window

In the Watch window, you can automatically monitor values of variables in the system. The variables are displayed on separate lines in the window:

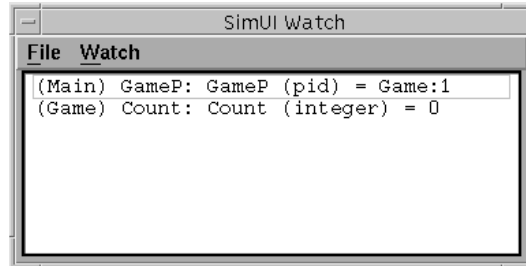

Figure 478: The Watch window

By default, the Watch window is empty. To add a variable, select *Add* from the *Watch* menu. In the dialog, enter the variable specification and click *OK*. A variable specification consists of the process instance name within parenthesis, followed by the variable name, e.g.
`(game:1) count`.

To change a variable specification, select *Edit* from the *Watch* menu. In the dialog, select the variable to edit and click *OK*. In the next dialog, you can edit the specification and click *OK*.

To delete a variable specification, select *Delete* from the *Watch* menu. In the dialog, select the variable to delete and click *OK*.

Tracing the Execution

When the SDL system is executing during simulation, you can obtain trace information of the execution. This makes it easier to follow the events that happen during execution.

There are three types of execution traces:

- *Textual Trace*, printed in the Simulator UI's text area, or on the terminal (in stand-alone mode)
- *GR Trace*, graphically illustrated by selecting SDL symbols in an SDL Editor
- *MSC Trace and Logging*, illustrated by drawing MSC events in an MSC Editor, or by saving the MSC events to a log file.

The amount of trace is determined by a trace value for each of the three trace types. The trace value controls the level of detail in the trace; the trace value 0 (zero) means no trace. Setting appropriate trace levels is often something you would like to do before the execution is started.

Apart from these continuous trace functions, there are also other possibilities to trace the execution. See "Other Tracing Functions" on page 2261.

Specifying Unit Names

Trace values can be assigned to different units of the SDL system; the system as a whole, blocks, process types, and process instances.

- When using the Simulator UI, you will be presented with a list of all units in the system, from which you may select the appropriate unit.
- When running the simulator stand-alone, you have to specify a unit, unless you want to set the trace for the system. In the trace commands described below, you may abbreviate the name of the unit. However, if several units match a unit name, the first unit found from the system level will be used. To make sure the correct unit is specified, the name can be prefixed with the diagram type or a qualifier.

Example 339: Specifying Trace Unit Names

```
System Demongame
   Block GameBlock
      Process Game
```

In this diagram structure, the unit name “Game” would refer to the block GameBlock. To specify the process Game instead, the unit could be expressed as “process Game” or “<<System Demongame / Block GameBlock>> Game”.

Determining the Scope of Trace

When a process instance executes a transition, or part of a transition, the trace value for the instance is found using the following algorithm:

1. If a trace value is defined for the process instance executing the transition, that value is used.
2. If not, and a trace value is defined for the process type, that value is used.
3. Otherwise, if a trace value is defined for the block enclosing the process, that value is used.
4. If still no trace value is found, the block structure is followed outwards until a unit is reached which has a trace value defined. The system always has a trace value defined.

For MSC trace the situation is slightly more complex; see “MSC Trace” on page 2259.

Textual Trace

Textual trace is printed for the transition or the SDL symbols that were last executed.

To quickly set the maximum textual trace level (6) for the system, click the *TEXT* button in the *Trace* module.

The general procedure to set the trace value for textual trace is:

1. Choose *Text Level* : *Set* in the *Trace* menu, or enter the command Set-Trace. The command takes two parameters, an optional unit name and the trace value.

2. Select or enter the name of the unit to set the trace for. If you do not specify a unit name, or the default name '-' is entered, the trace will be set for the whole system.

3. Select or enter a trace value between 0 and 6. The trace values are shortly described in the dialog, or after hitting `<Return>` in stand-alone mode. The following table explains them in more detail; for a full explanation, see *"Trace Limit Table" on page 2184 in chapter 49, The SDL Simulator*. The default textual trace value is 4 for the system.

Value	Trace Explanation and Examples
0	No trace
1	Trace of signals sent to the environment, as seen from the specified unit. This is useful if you only want to look at the external behavior of the unit. Example: `*  OUTPUT of Score from Game:1 to env:1` `*  Parameter(s) : -1`
2	Trace of transition start and timer outputs, i.e. what is causing the transition to occur. For transition starts, the process instance, initial state, input signal, sender process and value of Now is printed, e.g.: `*** TRANSITION START` `*  PId  : Demon:1` `*  State  : Generate` `*  Input  : T` `*  Sender : Demon:1` `*  Now  : 1.0000` For timer outputs, the timer name, receiver process and value of Now is printed, e.g.: `*** TIMER signal was sent` `*  Timer  : T` `*  Receiver : Demon:1` `*** Now  : 1.0000`

Value	Trace Explanation and Examples
3	As 2 + trace of important SDL actions, e.g. signal output, create, timer set and reset, nextstate and stop. Examples: `*  SET on timer T at 1.0000` `*  CREATE Game:1` `*  OUTPUT of Bump to Game:1` `*** NEXTSTATE  Generate`
4	As 3 + trace of other SDL actions as well, e.g. task, decision and export. Example: `*  ASSIGN  Count :=`
5	As 4 + result of actions, e.g. null transitions, implicit resets, and discarded signals.
6	As 5 + print of parameter values for signals, timers, create actions, etc. Examples: `*  ASSIGN  Count := 1` `*  OUTPUT of Score to env:1` `*  Parameter(s) : 1`

To list the textual trace values that are defined for the units in the system, choose *Trace Level : Show* in the *Trace* menu, or enter the command List-Trace-Values.

You can also reset the trace value for textual trace for a unit, i.e., set it to undefined. To do this, enter the command Reset-Trace and specify a unit (there is no button for this command).

GR Trace

GR trace will open an SDL Editor and continuously select the next SDL symbol to be executed in the corresponding process diagram. (See also "Tracing Simulations (Graphical Trace)" on page 1851 in chapter 43, *Using the SDL Editor*.)

To quickly set the GR trace level for the system to 1 (see below), click the *SDL* button in the *Trace* module.

The general procedure to set the trace value for GR trace is:

1. Choose *SDL Level : Set* in the *Trace* menu, or enter the command Set-GR-Trace. The command takes two parameters, an optional unit name and the trace value.
2. Select or enter the name of the unit to set the trace for. If you do not specify a unit name, or the default name '-' is entered, the trace will be set for the whole system.
3. Select or enter a trace value between 0 and 2. The trace values are shortly described in the dialog, or after hitting `<Return>` in stand-alone mode. The following table explains them in more detail. The default GR trace value is 0 for the system.

Value	Trace Explanation
0	No trace.
1	In an SDL Editor, show the next SDL symbol to be executed. This only happens when the monitor is activated the next time, i.e. when it becomes ready to accept a new command. No symbols are selected during execution when the monitor is inactive.
2	In an SDL Editor, follow the execution and show each SDL symbol as it is executed, until the monitor is activated again.

To list the GR trace values that are defined for the units in the system, choose *SDL Level : Show* in the *Trace* menu, or enter the command List-GR-Trace-Values.

You can also reset the trace value for GR trace for a unit, i.e., set it to undefined. To do this, enter the command Reset-GR-Trace and specify a unit (there is no button for this command).

MSC Trace and Logging

MSC trace will enable transformation of the SDL events that take place during execution into corresponding MSC events. Of course, not all SDL events are possible to transform into MSC events; typically, the events that can be transformed are sending and consumption of signals, setting and expiration of timers, and creation and termination of processes. By default, this transformation is enabled for the whole system.

The MSC events that are created by MSC trace can then be logged in two different ways:

- by opening an MSC Editor and continuously adding the events to an MSC diagram created for this purpose, or
- by continuously saving the events to a log file that later can be opened from an MSC Editor.

Therefore, setting the MSC trace value does not start the actual logging of MSC events in an MSC Editor or on file.

MSC Trace

To set the trace value for MSC trace:

1. Choose *MSC Level : Set* in the *Trace* menu, or enter the command Set-MSC-Trace. The command takes two parameters, an optional unit name and the trace value.
2. Select or enter the name of the unit to set the trace for. If you do not specify a unit name, or the default name '-' is entered, the trace will be set for the whole system.
3. Select or enter a trace value between 0 and 3. The trace values are shortly described in the dialog, or after hitting `<Return>` in stand-alone mode. The following table explains them in more detail; for a full explanation, see *"Message Sequence Chart Traces" on page 2187 in chapter 49, The SDL Simulator*. The default MSC trace value is 1 for the system.

Value	Trace Explanation
0	No trace.
1	For an MSC event that involves another unit, trace only if that unit's trace value is greater than 0.
2	For an MSC event that involves another unit, trace always, even if that unit's trace value is 0. Such an MSC event will be logged to interact with a special "void" instance in the MSC diagram.
3	Trace on block levels.

To list the MSC trace values that are defined for the units in the system, choose *MSC Level : Show* in the *Trace* menu, or enter the command List-MSC-Trace-Values.

You can also reset the trace value for MSC trace for a unit, i.e., set it to undefined. To do this, enter the command Reset-MSC-Trace and specify a unit (there is no button for this command).

Logging of MSC Events

To start the continuous logging of MSC events in an MSC Editor:

1. Choose *MSC Trace : Start* in the *Trace* menu, or enter the command Start-Interactive-MSC-Log. The command takes one parameter, a symbol level determining the amount of information that should be part of the MSC.
2. Select or enter a symbol level between 0 and 2 (see the table below).

   An MSC Editor is opened and the execution is then traced by adding MSC events to the created diagram. (See also "Tracing a Simulation in a Message Sequence Chart" on page 1725 in chapter 39, *Using Diagram Editors*.)

To quickly start the continuous logging of MSC events in an MSC Editor with symbol level 1, click the *MSC* button in the *Trace* module.

To start the continuous logging of MSC events in a log file:

1. Choose *MSC Trace : Start Batch* in the *Trace* menu, or enter the command Start-Batch-MSC-Log. The command takes two parameters, a symbol level and the name of the log file. The symbol level determines the amount of information that should be logged.
2. Select or enter a symbol level between 0 and 2 (see the table below).
3. Select or enter a log file name, preferably with the suffix `.mpr`.

When an MSC log is started, the amount of information that should be part of the log can be decided by giving the symbol level parameter an appropriate value, according to the table below:

Level	Information in MSC
0	Basic MSC, i.e. containing events for signals and timers plus create and stop.
1	Basic MSC extended with condition symbols for each next-state.
2	Basic MSC extended with condition symbols for each next-state and action symbols for task, decision, call, and return.

Note that you cannot have both types off logging enabled at the same time. To see what type of logging is enabled, enter the command List-MSC-Log (this command has no button).

To stop the logging, choose *MSC Trace : Stop* in the *Trace* menu, or enter the command Stop-MSC-Log. If you used logging to an MSC Editor, you should then save the trace from the editor. If you used logging to file, the file is automatically saved and closed.

Other Tracing Functions

Showing SDL Symbols

If you do not have GR trace enabled, it is still possible to show the next symbol to be executed in an SDL Editor. To do this, choose *Next Symbol* in the *Show* menu, or enter the command Show-Next-Symbol.

In a similar fashion, the last executed symbol can be shown in an SDL Editor. This will give you a correspondence between textual trace and the SDL Editor, since textual trace always is printed for the last executed symbols. To do this, choose *Prev Symbol* in the *Show* menu, or enter the command Show-Previous-Symbol.

Tracing Back to C Code

A trace-back to the generated C source code for the system is also possible. To show where in the C code the execution is at the moment, choose *C Line* in the *Show* menu, or enter the command Show-C-Line-Number. The file name and line number of the C source file is printed, and the C source file is opened in the Text Editor, positioned on the correct line.

Generating Coverage Information

To see how much of the SDL system you have covered during simulation, you can open the coverage information in a Coverage Viewer, and for instance examine which parts of the system that have not been executed during the simulation. To start the Coverage Viewer, choose *Coverage* in the *Show* menu, or enter the command Show-Coverage-Viewer.

Executing a Simulator

There are a number of monitor commands for executing one or more transitions in process instances, and for stepping symbol by symbol within a transition.

> **Note:**
>
> During execution, you may be prompted for input before the execution can continue. See *"Run-time Prompting" on page 2197 in chapter 49, The SDL Simulator* for more information.

Continuous Execution

To start executing the simulation program continuously, click the *Go* button in the *Execute* module, or enter the command Go. The execution continues until one of the conditions listed in "Activating the Monitor" on page 2241 becomes true, for instance when reaching a breakpoint. See also "Stopping the Execution" on page 2264.

> **Note:**
>
> The button *Forever*, corresponding to the command Go-Forever, behaves very similar to the above. The difference is that the monitor **does not** become active when the system is completely idle. This feature is valuable when communicating with other simulations or applications.

Executing Until a Condition

To execute until a certain point in time:

1. Choose *Until Time* in the *Execute* menu, or enter the command Proceed-Until. The command takes one parameter, the value of the simulation time when to stop executing.

2. Enter a time value, either an absolute value (without sign) or a value relative to Now (with a '+' sign). That is, "7.5" is an absolute time value, whereas "+7.5" is the time value Now+7.5.

To execute until, but not including, the next timer output, click the *Until Tim*er button in the *Execute* module, or enter the command Proceed-To-Timer.

Executing Transitions

To execute the next transition, or the remainder of the current transition, click the *Transition* button in the *Execute* module, or enter the command Next-Transition.

To execute a number of transitions until a transition with a textual trace value > 0 has been executed, choose *Until Trace* in the *Execute* menu, or enter the command Next-Visible-Transition. This is very valuable when you have set the trace value for some "uninteresting" parts of the system to 0, and you want to skip over those parts.

Single-Stepping Symbols or Statements

To execute only the next SDL symbol, choose *Over Symbol* in the *Execute* menu, or enter the command Next-Symbol. This may execute several statements, and will step over procedure calls.

To execute only the next SDL statement, choose *Over Stmt* in the *Execute* menu, or enter the command Next-Statement. This will step over procedure calls.

Executing Procedures

The only way to follow the execution into a procedure is to use the following single-stepping functions.

To execute only the next SDL symbol, and to step into possible procedure calls, click the *Symbol* button in the *Execute* module, or enter the command Step-Symbol. This may execute several statements.

To execute only the next SDL statement, and to step into possible procedure calls, choose *Into Stmt* in the *Execute* menu, or enter the command Step-Statement.

To execute a procedure up to and including its return, choose *Finish* in the *Execute* menu, or enter the command Finish. In a process, this command behaves exactly like Next-Transition.

Stopping the Execution

To stop the execution of transitions and symbols manually:

- In the Simulator UI, click the *Break* button in the *Execute* module.
- In stand-alone mode, press `<Return>` during printing of trace information (repeatedly, if necessary). No other characters may be typed before `<Return>` is pressed.

Caution!

There are some situations in which it is not possible to stop the execution in this way, for instance in an endless loop within an SDL symbol. The only way to stop the simulator in these situations is to terminate the simulation program from the operating system, for instance by pressing `<Ctrl+C>`, in which case all simulation results are lost.

Examining the System

In the Simulator, you can issue a number of monitor commands to examine the internal status of the system. Detailed information concerning processes, procedure calls, signals, timers, and variables can be requested. Using the Simulator UI, you may continuously view the internal status by using the Command and Watch windows; see "The Command and Watch Windows" on page 2252.

Current Process and Scope

Some of the commands used for examining the system operate on a specific process instance, the *current process*, identified by the current *scope*. A scope is a reference to a process instance, a reference to a service instance if the process contains services, and possibly a reference to a procedure instance called from this process/service (the *current procedure*). The scope is also used by some of the commands for modifying the system; see "Modifying the System" on page 2280.

The scope is automatically set by the execution commands, when entering the monitor, to the next process instance in turn to execute. You may change the scope if you would like to examine (or modify) another process, service or procedure instance. Changing the scope does not change the execution order of process instances. As soon as the execution continues again, the scope is reset to the next process instance in turn to execute.

The Process/service Scope

To print the current process/service scope enter the command Scope.

To set the current process/service scope:

1. Choose *Set Scope* in the *Examine* menu, or enter the command Set-Scope. This command takes one parameter, a process instance, and optionally if the process contains services, a second parameter which specifies a service name.
2. Select or enter the name of a process instance.
3. If the process instance contains services, select or enter the name of a service instance.

The scope is set to the specified process/service, at the bottom procedure call.

The Procedure Scope

To print the procedure call stack for the process/service instance defined by the current scope, choose *Call Stack* in the *Examine* menu, or enter the command Stack.

To change the procedure scope within the current process/service scope, you can move the scope one step up or down in the procedure call stack by entering the command Up or Define-MSC-Trace-Channels. Going up from a service leads to the process containing the service. To go down in a service within a process, select or enter the name of the service instance.

Printing the Simulation Time

To print the current value of the simulation time, in case it is not displayed by the textual trace, choose *Now* in the *Examine* menu, or enter the command Now.

Printing the Process Ready Queue

The ready queue is the queue of process instances that are ready to execute a transition, i.e., those instances that have received a signal that can cause an immediate transition, but that have not yet had the opportunity to execute this transition to its end.

To print an ordered list of the process instances in the ready queue, choose *Ready Q* in the *Examine* menu, or enter the command List-Ready-Queue. The list contains an entry number (queue position), the process instance, its current state, the number of signals in its input port, and the name of the signal that will cause the next transition. If a process instance has active procedure calls, the current executing procedure instance is also listed. If the state name is followed by a '*', then the process/procedure is currently executing a transition starting from this state.

The ready queue is by default printed in the Command window. It may look like this:

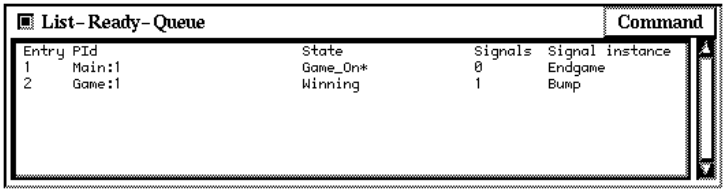

Figure 479: The ready queue in the Command window

Examining Process Instances

To list all active process instances of a certain process type:

1. Click the *Process List* button in the *Examine* module, or enter the command List-Process. The command takes one parameter, the name of the process type. (The button already has the parameter '-'.)

2. Select or enter a process type. If no process type is specified, or it is specified as '-', all active process instances in the system are listed. The list contains the same details as described for the process ready queue, above.

To print information about the current process instance, enter the command Examine-PId. The information contains the current values of Par-

ent, Offspring, Sender and a list of all currently active procedure calls made by the process instance (the stack). For more information on current process and procedure call stack, see "Current Process and Scope" on page 2264. An example of output is:

```
Parent    : null
Offspring : Game:1
Sender    : env:1

PId       Main:1
```

Examining Signal Instances

To list all signal instances in the input port of the current process instance, choose *Input Port* in the *Examine* menu, or enter the command List-Input-Port. The list contains an entry number (queue position), the signal type, and the sending process instance. If the entry number is prefixed by a '*', the signal instance is the one to be consumed in the next transition performed by the process instance. For more information on the current process, see "Current Process and Scope" on page 2264. An example of output is:

```
Input port of Game:1
Entry   Signal name          Sender
*1      Bump                 Demon:1
 2      GameOver             Main:1
```

To print the parameters of a signal instance in the input port of the current process instance:

1. Choose *Signal* in the *Examine* menu, or enter the command Examine-Signal-Instance. This command takes one parameter, an entry number in the input port.
2. Enter an entry number. To see what entry number is associated with the signal instance, list the input port as described above. An example of output is:

```
Signal name : Score
Parameter(s) : -1
```

Examining Timer Instances

To list all active timers in the system, choose *Timer List* in the *Examine* menu, or enter the command List-Timer. The list contains an entry number, the timer name, the corresponding process instance, and the associated time. An example of output is:

```
Entry   Timer name        PId                Time
1       T                 Demon:1            4.0000
```

To print the parameters of an active timer instance:

1. Enter the command Examine-Timer-Instance. This command takes one parameter, an entry number in the timer list.
2. Enter an entry number. To see what entry number is associated with the timer instance, list the active timers as described above. If only one timer is active, the entry number is not needed.

Examining Variables

To print the value of a variable or formal parameter in the current process or procedure:

1. Click the *Var In Scope* button in the *Examine* module, or enter the command Examine-Variable. This command takes two optional parameters, the name of the variable and a specification of a variable component.
2. Select or enter the name of a variable, possibly abbreviated. If no variable name is specified, all variables and formal parameters of the current process or procedure are printed.

   If a variable has several components (e.g. an array, struct or string) and it is specified without a component, the values of all components of the variable is printed (e.g. the complete array).

   – To print only a certain component, specify the component after the variable name. (In the Simulator UI, this must be done on the text input line in the dialog, after a variable name has been selected.)

   – To get a list of the possible components of a variable, enter a '?' after the variable name. (In the Simulator UI, this must be done on the text input line in the dialog, after a variable name has

been selected; another dialog is then opened, in which the component can be selected.)

More information on the input and output of SDL data types can be found in *"Input and Output of Data Types" on page 2137 in chapter 49, The SDL Simulator*.

To examine variables or formal parameters in any process, click the *Variable* button in the *Examine* module. In addition to the variable name and component (as described above), you will be prompted for the process name.

Managing Breakpoints

By setting breakpoints in the system, the execution of a simulator can be stopped and the monitor system activated at a certain point of interest. They can be used to trap certain SDL symbols, transitions, signal outputs, and variable changes.

Breakpoints are often used together with continuous execution to reach a certain state of the system (see "Continuous Execution" on page 2262). The monitor system becomes active when the breakpoint condition becomes true. Care should be taken when using continuous execution with breakpoints; if the breakpoint is never reached, the system may continue executing "forever."

Breakpoint Commands

When defining a breakpoint, you may specify one or more monitor commands to be executed after the breakpoint has been reached. In this way it is possible to, for instance, automatically print information about the system by using the examine commands. The monitor commands are specified using the same syntax as when entering them textually.

If you want to use several monitor commands, they have to be separated by spaces and semicolons. It is even possible to use the execution commands in this context to automatically continue the execution after a breakpoint has been reached. However, care should be taken to make sure the system does not end up executing "forever." An example of a combination of breakpoint commands may be:

```
Examine-PId ; Go
```

Setting a Symbol Breakpoint

Symbol breakpoints are set on a specific SDL symbol. Symbol breakpoints are checked **before** a symbol is executed, i.e., the symbol is not executed when the breakpoint is reached.

There are two ways to set a symbol breakpoint, either graphically by selecting the SDL symbol directly in the SDL Editor, or textually by specifying an SDT reference to the SDL symbol.

When a symbol breakpoint has been set, the breakpoint is indicated by a red “stop” sign placed at the SDL symbol in the SDL diagram.

To set a symbol breakpoint graphically using the SDL Editor:

1. If necessary, open an SDL Editor on the diagram containing the SDL symbol.
2. Choose *Connect sdle* in the *Breakpoint* menu in the Simulator UI, or enter the command Connect-To-Editor. A new menu *Breakpoints* now appear in the SDL Editor.
3. Select the symbol in the SDL Editor.
4. From the *Breakpoints* menu in the SDL Editor, choose one of the two *Set Breakpoint* commands. The first command opens a dialog to allow entering one or more optional breakpoint commands. The second command sets the breakpoint without any breakpoint command.

To set a symbol breakpoint textually using an SDT reference:

1. Choose *Symbol* in the *Breakpoint* menu, or enter the command Breakpoint-At. This command takes two parameters, a textual SDT reference to the SDL symbol and an optional breakpoint command.

Setting a Transition Breakpoint

Transition breakpoints are set on a transition, i.e. the combination of a process instance, state, signal and sender. Transition breakpoints are checked **before** a transition is executed, i.e., the transition is not executed when the breakpoint is reached.

To set a transition breakpoint:

1. Choose *Transition* in the *Breakpoint* menu, or enter the command Breakpoint-Transition. This command takes the following parameters: the process name and instance number, the name of a service, the state of the process/service, the signal, the sender's process name and instance number, a breakpoint counter, and an optional breakpoint command.

   Any of the parameters may be omitted or given the value '-', which means that any value will match that parameter. In this way, transition breakpoints can be matched by more than one transition.

2. Select or enter the name of the process in which the transition exists. If no process is specified, any process will match.

3. Enter the instance number of the process. If no instance number is specified, any instance of the process specified above will match.

4. Select or enter the name of the service of interest.

5. Select or enter the state of the process where the transition is executed from. If no state is specified, any state will match.

6. Select or enter the name of the signal that causes the transition. If no signal is specified, any signal will match.

7. Select or enter the name of the process sending the signal. If no process is specified, any sender process will match. Note that "env" may be entered for the environment process.

8. Enter the instance number of the sender process. If no instance number is specified, any instance of the process specified above will match.

9. Enter a breakpoint counter, i.e. how many times the breakpoint condition must be true before the execution is stopped. If no counter value is specified, the default value 1 is used.

10. Enter one or more optional breakpoint commands.

Setting an Output Breakpoint

Output breakpoints are set on a signal output, i.e. the combination of a signal, sender process and receiver process. Output breakpoints are checked immediately **after** a signal is sent.

To set an output breakpoint:

1. Choose *Output* in the *Breakpoint* menu, or enter the command Breakpoint-Output. This command takes the following parameters: the signal name, the sender's process name and instance number, the receiver's process name and instance number, a breakpoint counter, and an optional breakpoint command.

   Any of the parameters may be omitted or given the value '-', which means that any value will match that parameter. In this way, output breakpoints can be matched by more than one signal output.

2. Select or enter the name of the signal. If no signal is specified, any signal will match.

3. Select or enter the name of the process sending the signal. If no process is specified, any sender process will match. Note that "env" may be entered for the environment process.

4. Enter the instance number of the sender process. If no instance number is specified, any instance of the process specified above will match.

5. Select or enter the name of the process receiving the signal. If no process is specified, any receiver process will match. Note that "env" may be entered for the environment process.

6. Enter the instance number of the receiver process. If no instance number is specified, any instance of the process specified above will match.

7. Enter a breakpoint counter, i.e. how many times the breakpoint condition must be true before the execution is stopped. If no counter value is specified, the default value 1 is used.

8. Enter one or more optional breakpoint commands.

Setting a Variable Breakpoint

Variable breakpoints are set on a specific variable and are triggered whenever the value of the variable is changed. Variable breakpoints are checked **after** a variable assignment, i.e., the execution stops immediately after the symbol or assignment statement where the value was changed.

To set a breakpoint on a variable in the current process:

1. Choose *Variable* in the *Breakpoint* menu, or enter the command Breakpoint-Variable. This command takes two parameters: the variable name and an optional breakpoint command.
2. Select or enter a variable name in the current process.
3. Enter one or more optional breakpoint commands.

Listing and Removing Breakpoints

To list all defined breakpoints, choose *List* in the *Breakpoint* menu, or enter the command List-Breakpoints. The list contains an entry number and the break condition for each breakpoint, i.e. the values of the parameters specified when the breakpoint was defined. An omitted parameter value, where permitted, is listed as “any.”

A symbol breakpoint can be visualized by opening the SDL diagram and selecting the SDL symbol in an SDL Editor. To see where a specific symbol breakpoint has been defined:

1. Enter the command Show-Breakpoint (this command has no associated button or menu choice). This command takes one parameter, an entry number in the breakpoint list.
2. Enter an entry number. (To see what entry number is associated with the symbol breakpoint, list the breakpoints as described above.) The SDL symbol, pointed out by the SDT reference specified for the breakpoint, becomes selected in an SDL Editor.

To remove a defined breakpoint using the Simulator UI:

1. Choose *Remove* in the *Breakpoint* menu, or enter the command Remove-All-Breakpoints. This command takes one parameter, an entry number in the breakpoint list.
2. Enter an entry number. (To see what entry number is associated with the symbol breakpoint, list the breakpoints as described above.) The breakpoint is removed.

To remove all symbol breakpoints set on an SDL symbol:

1. If necessary, open an SDL Editor on the diagram containing the SDL symbol.
2. If the *Breakpoints* menu is not visible in the SDL Editor menu bar, choose *Connect sdle* in the *Breakpoint* menu in the Simulator UI, or enter the command Connect-To-Editor. The menu *Breakpoints* now appear in the SDL Editor.
3. Select a symbol with a red breakpoint symbol in the SDL Editor.
4. From the *Breakpoints* menu in the SDL Editor, choose the *Remove Breakpoint* command. All symbol breakpoints are removed.

To remove all defined breakpoints:

- Enter the command Remove-All-Breakpoints (this command has no associated button or menu choice). All defined breakpoints are now removed.

Sending Signals from the Environment

Usually, you have to send signals into the system to make something of interest happen, for instance when the system is completely idle. You can send signals directly to a process instance, or indirectly by specifying a channel.

Sending Signals to a Process

To send a signal from the environment to a certain process:

1. Click the *Send To* button in the *Send Signal* module, or enter the command Output-To. This command takes three parameters: the signal name, any signal parameters, and the process instance of the receiver.
2. Select or enter the name of the signal to send.
3. If the signal has parameters, set the values of the parameters in the dialog that is opened. Select a parameter in the list, enter/edit its value using the input line, or the option menu containing possible values (for enumeration type parameters). Click the *Default value* button to get a “null” value for the parameter.
4. Select or enter the name of a process instance to send the signal to.

   The Simulator tries to find a path of channels and signal routes to the receiver. If no path was found, an error message is printed. If a path was found, the signal is either successfully sent (and placed in the input port of the receiver), or is discarded (an immediate null transition occurred), i.e. the receiver is in a state that cannot receive or save the specified signal.

Sending Signals via a Channel

To send a signal from the environment via a channel:

1. Click the *Send Via* button in the *Send Signal* module, or enter the command Output-Via. This command takes three parameters: the signal name, any signal parameters, and an optional channel.
2. Select or enter the name of the signal to send.
3. If the signal has parameters, set the values of the parameters in the dialog that is opened. Select a parameter in the list, enter/edit its val-

ue using the input line, or the option menu containing possible values (for enumeration type parameters). Click the *Default value* button to get a "null" value for the parameter.

4. Select or enter the name of a channel to send the signal via. If no channel is specified, any channel from the environment may be used.

   The Simulator tries to find a single process instance that can receive the signal. If no or several possible receivers were found, an error message is printed. If a single receiver was found, the signal is either successfully sent (and placed in the input port of the receiver), or is discarded (an immediate null transition occurred), i.e. the receiver is in a state that cannot receive or save the specified signal.

Causing a Spontaneous Transition

To send a "none" signal to a process, i.e. to try to cause a spontaneous transition in the process:

1. Click the *Send None* button in the *Send Signal* module, or enter the command Output-None. This command takes one parameter: the process name. If the process contains services, it is also necessary to specify one of the services.

2. Select or enter the name of the process to send a "none" signal to. A message is printed, indicating whether a spontaneous transition occurred.

Logging the Execution

The following types of interaction during simulation can be logged to file:

- The commands issued by the user.
- The complete interaction with the user, i.e. commands issued and resulting print-outs. In other words, all texts visible in the Simulator UI's text area or in the terminal window.
- The signals sent to, from and via a unit in the system.

> **Note:**
> The logging of MSC events to file is described in "MSC Trace and Logging" on page 2258.

Logging Commands

To start logging of all issued monitor commands from now on:

1. Select *Start Command Log* from the *Log* menu, or enter the command Command-Log-On. This command takes one parameter, the name of the log file.
2. Select or enter a log file name; **on UNIX** preferably with the suffix `.com`.

To stop the logging, select *Stop Command Log* from the *Log* menu, or enter the command Command-Log-Off.

After logging has been stopped, it can be continued on the same log file, i.e. the existing log file is appended, or on a new log file.

To continue logging of monitor commands:

- If using the Simulator UI's menu commands, select *Start Command Log* from the *Log* menu. Select or enter the same file name as before, or a new file name.
  - If a new file name was specified, the logging is continued on the new file.
  - If the name of an existing log file was specified, a dialog is opened:

Figure 480: Continued logging on an existing file

Click *Append* to append the existing log file. Click *Create* to overwrite the existing log file.

- If using monitor commands, enter the command Command-Log-On, with or without a file name parameter.
  - If you do not specify any file name, the logging is continued on the same lag file as before.
  - If a file name is specified, the logging is continued on this file.

All monitor commands issued by the user so far in the Simulator UI session can also be saved on a command file, without starting continuos logging of commands. To do this, select *Save* from the popup menu on the input line and select a command file.

A command log file may later be read in and executed to repeat the same command session. To do this:

1. Choose *Script* in the *Execute* menu, or enter the command Include-File. This command takes one parameter: the name of a file containing monitor commands.
2. Select or enter the name of an existing command file. When the file has been specified, it is read and the commands in the file are executed exactly as they are stated in the file.

Logging the User Interaction

Complete logging of all user interaction works in the same way as logging of monitor commands, described above. The only difference is the name of the menu choices and commands. Either select *Start Complete Log* and *Stop Complete Log* from the *Log* menu, or enter the commands Log-On and Log-Off.

Logging Signal Interaction

The signals that are sent to, from or via a unit in the system can be logged on file. The signal log file will contain a line for each signal sent, including the simulation time, the name of the signal, the sender process instance and the receiver process instance. Values of signal parameters are also printed.

More than one signal log can be active at a time, each one in a separate log file.

To start a signal log:

1. Enter the command Signal-Log (this command has no associated button). This command takes two parameters: a unit in the system, and the name of a log file.
2. Select or enter a unit whose signals are to be logged. A unit can be one of the following:
   - A channel or signalroute. Signals sent through the channel or signalroute are logged.
   - A process type or process instance. Signals sent to and from any of the process instances are logged.
   - A block or a system. Signals sent within, to and from the system or block are logged.
   - The process “env.” In this way, the signal interface between the system and the environment is logged.
3. Select or enter a file name of the signal log file.

To list the active signal logs, enter the command List-Signal-Log (this command has no associated button). The list contains an entry number, the unit name and the log file name.

To stop a signal log:

1. Enter the command Close-Signal-Log (this command has no associated button). This command takes one parameter, an entry number in the signal log list.
2. Enter an entry number. To see what entry number is associated with the timer instance, list the active signal logs as described above. If only one signal log is active, the entry number is not needed.

Modifying the System

The are a number of commands that change the behavior of the simulated system. These commands are useful to make debugging easier. They can, for example, be used to recover from logical errors, or to put the system in a state that could be difficult to achieve otherwise.

Caution!

When these commands are used, **it is no longer the original system that is simulated**, as the commands modify the behavior of the system. It is completely up to the user to interpret the simulation and its relation to the original system.

Some of these commands operate on the current process. For more information on the current process, see "Current Process and Scope" on page 2264.

Sending an Internal Signal

To simulate the sending of an internal signal between two process instances:

1. Enter the command Output-Internal. This command takes the following parameters: the name of the signal, values of any signal parameters, receiver process instance, and sender process instance.
2. Select or enter the name of the signal to send.
3. If the signal has parameters, set the values of the parameters in the dialog that is opened. Select a parameter in the list, enter/edit its value using the input line, or the option menu containing possible values (for enumeration type parameters). Click the *Default value* button to get a "null" value for the parameter.
4. Select or enter the receiver process instance. Note that "env" may be entered for the environment process.
5. Select or enter the sender process instance. Note that "env" may be entered for the environment process.

The signal is put in the input port of the receiver process, if it is in the valid input signal set; otherwise, it is discarded. No checks are made whether a path exists between the sender and the receiver.

Changing the Process State

To change the state of the current process, service, or procedure:

1. Choose *State* in the *Change* menu, or enter the command Nextstate. This command takes one parameter: the name of the new state.
2. Select or enter the name of the state to go to.

Creating and Stopping Processes

To create a new process instance:

1. Choose *Create Process* in the *Change* menu, or enter the command Create. This command takes the following parameters: the process to create, the parent process instance, and any process parameters.
2. Select or enter the name of the process to create a new instance for.
3. Select or enter the parent process instance. “env” may be entered for the environment process, and “null” may also be entered.
4. If the process has parameters, enter the values of the parameters one by one.

   If the number of instances already is greater than or equal to the maximum number for this process type, you have to verify the create action. The following message appears:

   ```
   Attempt to create more than the max number of
   concurrent instances.
   Do you still want to create the instance :
   ```

5. Enter ‘y’ or ‘Y’ to create; all other answers cancels the create.

To stop a running process instance:

1. Choose *Stop Process* in the *Change* menu, or enter the command Stop. This command takes one parameter, the process instance to stop.
2. Select or enter the name of the process instance to stop.

Setting and Resetting Timers

To set a timer in the current process:

1. Choose *Set Timer* in the *Change* menu, or enter the command Set-Timer. This command takes the following parameters: the name of the timer, any timer parameters, and a time value.
2. Select or enter the name of a timer in the current process.
3. If the timer has parameters, enter the values of the parameters one by one.
4. Enter a time value when the timer is to expire, either an absolute value (without sign) or a value relative to Now (with a '+' sign). That is, "7.5" is an absolute time value, whereas "+7.5" is the time value Now+7.5.

To reset a timer in the current process:

1. Choose *Reset Timer* in the *Change* menu, or enter the command Reset-Timer. This command takes the following parameters: the name of the timer, and any timer parameters.
2. Select or enter the name of a timer in the current process.
3. If the timer has parameters, enter the values of the parameters one by one.

Changing a Variable

To change the value of a variable in the current process:

1. Choose *Variable* in the *Change* menu, or enter the command Assign-Value. This command takes the following parameters, the name of the variable, an optional specification of a variable component, and the new value.
2. Select or enter the name of a variable, possibly abbreviated.

   If a variable has several components (e.g. an array, struct or string) and it is specified without a component, the values of all components of the variable have to be specified (e.g. the complete array).

To assign a component only, the same rules as for examining a variable apply (see "Examining Variables" on page 2268):

- To assign only a certain component, specify the component after the variable name. (In the Simulator UI, this must be done on the text input line in the dialog, after a variable name has been selected.)
- To get a list of the possible components of a variable, enter a '?' after the variable name. (In the Simulator UI, this must be done on the text input line in the dialog, after a variable name has been selected; another dialog is then opened, in which the component can be selected.)

More information on the input and output of SDL data types can be found in *"Input and Output of Data Types" on page 2137 in chapter 49, The SDL Simulator*.

Changing the Input Port

To remove a signal instance in the input port of the current process:

1. Enter the command Remove-Signal-Instance. This command takes one parameter, an entry number in the input port.
2. Enter an entry number. To see what entry number is associated with the signal instance, list the input port as described in "Examining Signal Instances" on page 2267.

> **Note:**
>
> Entry numbers are just positions in the input port. The removal of a signal changes the entry numbers of the remaining signals.

To change the placing of a signal instance in the input port of the current process:

1. Choose *Input Port* in the *Change* menu, or enter the command Rearrange-Input-Port. This command takes two parameters, the current and new entry number in the input port.
2. Enter the current entry number of the signal instance. To see what entry number is associated with the signal instance, list the input port as described in "Examining Signal Instances" on page 2267.
3. Enter the new entry number of the signal instance. The current signal instance at this position will be moved down in the queue.

Rearranging the Ready Queue

You can change the order of process instances in the ready queue, i.e. the execution order of processes.

To change the placing of a process instance in the ready queue:

1. Choose *Ready Q* in the *Change* menu, or enter the command Rearrange-Ready-Queue. This command takes two parameters, the current and new entry number in the ready queue.
2. Enter the current entry number of the process instance. To see what entry number is associated with the process instance, list the ready queue as described in "Printing the Process Ready Queue" on page 2266.
3. Enter the new entry number of the process instance. The current process instance at this position will be moved down in the queue.

Exiting a Simulator

To exit a simulator, choose *Stop Sim* in the *Execute* menu, or enter the command Exit or Quit. If the command is abbreviated, you have to confirm the exit operation; the following message appears:

```
Do you really want to exit program :
```

Enter 'y' or 'Y' to exit; all other answers cancels the exit.

To exit the Simulator UI, select *Exit* from the *File* menu. If you have changed the configuration of the Simulator UI, you are asked whether to save these changes. See "Customizing the Simulator UI" on page 2249. If you save them under the default file names, they are read in and restored the next time the Simulator UI is started.

Chapter

51 *Remote Target Simulation*

This chapter describes how to run a simulator on a target and connect it to the SDL simulator interface (SimUI) on the host via TCP/IP communication.

Target Simulation

Overview

A simulator executable (called *simulator*) communicates with the SDL Suite tools, e.g. the SDL Simulator UI (SimUI), via the SDL Suite communication mechanism (the PostMaster). By using some special features it is possible to run the simulator on a target system (called *target*), while the SDL Suite tools and Postmaster run on a host system (called *host*) separate from the target. This set-up is known as *target simulation*. This gives the possibility to test a simulator in its correct environment and still get the trace and debug possibilities offered by the SDL Suite.

For instance, the target could be a VME147 bus system running VxWorks, and the host is a Sun workstation running SunOS 5. The simulator running on the target is built using a special library, instead of the ordinary simulator library containing the simulator kernel. The special library contains the kernel for a simulator on VxWorks, as well as a communication interface to the host. On the host, the simulator is replaced by a gateway executable (called *gateway*) that communicates with the simulator on the target over the TCP sockets connection. Figure 481 shows the set-up for target simulation.

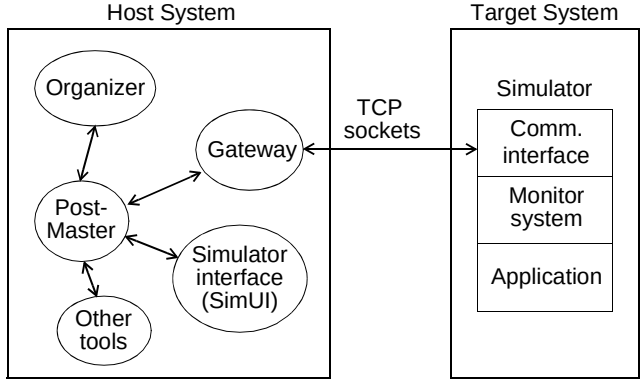

Figure 481: Target simulation set-up

Architecture

Simulators, as well as other executables communicating via the Postmaster, has a set of layers as shown in Figure 482, where the layers are represented by the files that implement them. All units (the Simulator, Postmaster and SimUI) are located on the same host machine.

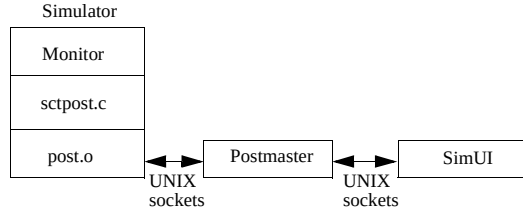

Figure 482: Architecture of an ordinary simulator

`sctpost.c`, `post.o` (`post64.o` for solaris 64-bit) and a few other files are then linked into the simulator kernel used for making the simulator.

The basic principle of this target simulation is to direct the communication between the simulator and the Postmaster over a TCP sockets connection. This re-direction must be transparent to the simulator and to the Postmaster.

To direct the messages between the Simulator Monitor and the Postmaster through the TCP sockets, a new layer, implemented in the file `tlayer.c`, is introduced between `sctpost.c` and `post.o` according to Figure 483.

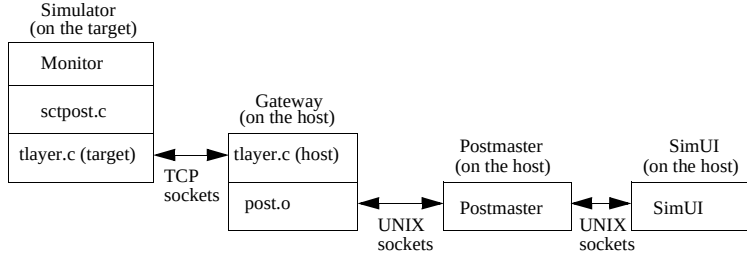

Figure 483: tlayer.c is introduced

For the target, `tlayer.c` emulates `post.o` (the same interface), and for the host, `tlayer.c` emulates `sctpost.c` (the same interface). (**In Windows NT** there are other communication mechanisms on host than UNIX sockets.)

The Configuration File and Simulator UI Command Extension

All configuration is made on host side in a file called `tarsim.cfg`. This file is searched by `host_smr.sct/host_smr.exe` in a directory specified by the environment variables (searched in this order):
Unix: `$TARSIMPATH, $PWD, $HOME, $sdtdir`.
Windows NT: the only searched variables are `%TARSIMPATH%`. You set the environment variable `%TARSIMPATH%` as described below.

1. Open the System Control Panel and select the *Environment* tab.
2. In the *Variable* field enter **`TARSIMPATH`**, and in the *Value* field enter the directory (including logical disk drive) where `tarsim.cfg` is located.
3. Press *Set* and close down the System Control Panel.

The syntax of `tarsim.cfg` is described below. In the delivery, a sample `tarsim.cfg` is supplied.

- All lines beginning with '#' (hash) are considered as comments and left unread.
- All lines after the optional command END are left unread, regardless of contents.
- All commands must be at the first position in a line.
- All commands and arguments are case insensitive, except arguments specifying files, etc.
- Separation between commands and arguments are any whitespace (i.e. space or tab).

Example 340: A sample `tarsim.cfg` ----------

```
# targsim.cfg, config file for simulating an SDT executable simulator
# on remote target with SDT SIMUI on a host.
#
# forces use of invalid IP addresses. gethostbyaddr on some networks
# returns an invalid hostent entry even if the address is usable.
# FORCEIP must come before any used IP address in TARGET or HOST
# default OFF
FORCEIP         ON
#
#SERVICE        IP-ADDRESS              PORT    NAME(optional)
TARGET          146.75.124.23           18000   targetcomputer
#HOST           111.22.33.55            17000   SDT-host
# Target must be specified, host not. Port number is default, target
# has 18000 defined in tlayer.h
#
# setting USETIMEOUT to OFF disables timeouts and makes it possible
# to suspend the target or halt it at a C debugger breakpoint
# default ON
USETIMEOUT      OFF
#
# communication between host and service, only TCP (default) or TTYA/B (n/a)
#           NOTE, only TCP in this version
#COM            TARGET                  TCP
#
# in debug mode signals can be logged on file (default = stderr)
# Note! stderr will not work on Windows NT.
#
#LOG            dummylog.tmp
#
# debug on/off must be set to 'on' to activate logging.
#
#debug          on      #default = OFF
#
# If SDL diagram files are in a different directory than is hardcoded
# into the simulator (which assumes they are in the source directory
# which was specified in SDT when it was generated), you can explicitly
# give the path to the SDL source files here.
# Note! absolute path from root, i.e. starting with /dir1/dir2/... etc.
# trailing directory (a / in the end) is optional.
# If you can not get symbol trace on SDL editor, the SDLpath need to be
# defined to where you have your SDL source files
# Note! this only works on a flat directory structure.
#
#SDLpath        /home/kod/sdl/demongame
#
end
#
after an "end" statement host stops reading, so you can write anything!
```

Tarsim Shell (UNIX only)

On UNIX, there is a very basic shell included in `host.sct`.

If you start `host.sct` without the target running, you will enter a shell where only the commands **INIT** (try contacting target again) and **EXIT** (quit session) are applicable. If you know your target is running and still

do not get contact, please check that the specified IP address and PORT of the target in `tarsim.cfg` are correct. PORT is for the target hard-coded in `tlayer.h`, the header file for `tlayer.c`.

During simulation you can enter the tarsim shell by entering a "**:**" (colon). You can only leave the simulation if the simulator is not running with **GO** or **FOREVER**. If so, first stop the simulation with the *Break* button.

After entering the "**:**" you will see a welcome text to the shell. You can enter the command **HELP** to see the full command set, or **STATUS** to see the current simulation setup. You exit the shell by entering **EXIT**.

> **Note:**
>
> Be sure you are still in the tarsim shell when entering EXIT, since it is the same command for exiting the simulation. You can see if you are in the shell by the fact that all text begin with a colon as the first character in the text window. There is a time-out in the shell, after one minute of inactivity you get back to the simulator again.

LOG and **DEBUG** has the same syntax and meaning as in `tarsim.cfg`.

Addresses like TARGET and HOST, as well as the COM and SDLPATH statements, cannot be changed from the shell.

An additional facility for the logging is **GREP**, which gives a possibility to filter out up to 5 strings that you want to log and skip the rest.

To clear all GREP's and log everything:

```
GREP    *
```

To add a string (this example looks for MSCE, i.e. signals to the MSC Editor):

```
GREP    MSCE
```

Strings are not case sensitive by default. To search for the **exact** string `MyPath/demo.sdt`, prefix it with '=':

```
GREP    =MyPath/demo.sdt
```

If you want to log everything **except**, for instance, signals to the SDL Editor you can use the prefix '!':

```
GREP     !SDLE
```

Note:

If you have GREP MSC active and then enter GREP !MSC, status will be changed of the previously entered argument, so you cannot enter two contradictions and have both active.

You can also combine the inverse and exact functions:

```
GREP     !=MyPath/demo.sdt
```

Up to five GREP arguments can be active simultaneously and each can be up to 25 characters long.

If the GREP buffer is full, empty the old with GREP *.

You can empty the buffer and enter new argument in one statement:

```
GREP      *       MSCE
```

Executing and Terminating the Tools

When the simulator and gateway have been started, the simulator can be controlled from the Simulator UI on the host in the same way as an ordinary simulator. Differences may be seen in execution performance and in the printing of log messages. Using *Open* in the *File* menu in the SimUI, you specify the simulator file `host.sct`. After you have chosen this file, `host.sct` will try to establish contact with the target, according to settings in `tarsim.cfg`. This file must be in the same directory as `host.sct`, and the SDL Suite should also be started from this directory. (Setting Source Directory in the Organizer does not help SimUI find the target simulation file dependencies.)

The simulator on the target can be stopped by typing `<Ctrl+C>` on the console. It is though recommended only to stop the target by pressing the *Exit* button in the SimUI. The `host.sct` will then, before it finishes, send a stop signal to the target, and give it a chance to close all open file descriptors for TCP sockets. If not, you can get a bind error if you try to restart the target simulator without rebooting the target system.

The gateway on the host is terminated by issuing the command *Exit* or *Quit* in the SimUI.

When the simulator and gateway have been started, the simulator can be controlled from the Simulator UI on the host in the same way as an ordinary simulator. Differences may be seen in execution performance and in the printing of log messages. Using *Open* in the *File* menu in the SimUI, you specify the simulator file `host_smr.sct`. After you have chosen this file, `host_smr.sct` will try to establish contact with target, according to settings in `tarsim.cfg`. This file must be in the same directory as `host_smr.sct`, and the SDL Suite should also be started from this directory. (Setting Source Directory in the Organizer does not help SimUI find the target simulation file dependencies).

The simulator on the target can be stopped by typing `<Ctrl+C>` on the console. It is though recommended only to stop the target by pressing the *Exit* button in the SimUI. The `host_smr.sct` will then, before it finishes, send a stop signal to the target, and give it a chance to close all open file descriptors for TCP sockets. If not, you can get a bind error if you try to restart the target simulator without rebooting the target system.

The gateway on the host is terminated by issuing the command Exit or Quit in the SimUI.

On Windows NT the host gateway is named `host_smr.exe`.

The gateway are prebuilt but if needed they can be built using the makefiles host_smr.mak available in the platform directories.

Known Problems

- Some targets must be rebooted after a crash, since the OS does not make `fclose` on open file descriptors upon kill. You will see the error message “bind (0x30)”, meaning that bind fails since the target port address is busy. However, since enhanced shutdown and bind methods has been introduced, the risk of this has been reduced.
- Sometimes the SimUI interface hangs with a clock cursor after several reboots. Try the following solutions in the specified order until it works:

  1. Press the *Break* button in the SimUI.
  2. Select *Restart* in the *File* menu and restart the file `host.sct`

3. If you still get no access to the SimUI, try `<Ctrl+O>` (shortcut for open file) to reopen the file.

4. Find `host.sct` in the process list (`ps -ef` on Solaris) and kill it. Try 2-3 again.

5. Kill `sdtsimui` in the same way and restart it from the Organizer.

- If you get no contact with the target the first time, check the `tarsim.cfg` configuration file. Correct any incorrect IP address or port to the target (port is default 18000 except on VxWorks/VME) and restart `host.sct` like in step 2 above. The target's port is hard-coded into the file `tlayer.h`.

- If you cannot establish connection on an IP address and you still can ping/telnet the same address, try to set the command `FORCEIP ON` before any `TARGET` statement in `tarsim.cfg`. This forces use of an IP address even if it is reported invalid by `gethostbyaddr()`.

- On a slow network connection you might lose connection with the MSC editor. It can be impossible to start it by pressing the MSC button in the Simulator User Interface, or you can get the message "Error writing MSC event". Other problems that can occur is that it is impossible to `BREAK` when you are running the simulation with `GO` or `GO-FOREVER`.
  The solution to all of these problems is to set the environment variable `sdt_rpctimeout` to `100`. You need to restart the SDL Suite after doing this.

- If simulation starts but crashes after starting the MSC trace you are running out of stack space in the target. There is two solutions. Add the compiler flags MAX_READ_LENGTH=500 and MAX_WRI_LENGTH=500 in the makefile when you build the target. The flags reduces the default buffer size used by the simulation kernel. You may need to adjust the value after size and complexity of your system.
  The second fix is to set the stack size for the SDL task when you start it. Most RTOS:s has stack size as a parameter to taskSpawn, t_create or corresponding. Suitable stack size for remote simulation is 30-50 kB. Default stack in many RTOS kernels is 20kB, which will only work for very small systems.

- When using large messages between the simulator UI and the target simulator the buffers used for these messages maybe too small. The default size is 6000 bytes. To increase the buffers the define `DEFAULTBUFSIZE` in the source file `tlayer.h` can be changed. Note that for this to take effect you need to rebuild the gateway as well as the simulator.

Source Code Files

Source code for the target contains the complete standard Master Library. The only difference is that `post.o` does not contain any Postmaster, but a TCP socket communication program.

Both host and target use the same `tlayer.c` file, with the compile flags `-DTARGET` and `-DHOST`, respectively. Also the flag `-DTCP` need to be specified in both ends to get TCP functionality.

All other files in `sctworld.o` needs the flags `-DTARGETSIM`, `-D/compiler/`, `-D/rtos/`, `-DSCTDEBCLCOM` and `-DXMAIN_NAME=sdlmain`.

Also recommended: `-DMAX_READ_LENGTH=500` `-DMAX_WRI_LENGTH=500`

See the specific integrations for the RTOS and compiler specific flags.

There is also special flags for the TCP connection. Supported flags are currently VXWORKS_SDT, PSPS_SDT and WINDOWS. Default is standard Unix/Posix.

The source file structure in `tlayer.c` is also documented in the top of `tlayer.c` in a comment.

To make the target you will need `tlayer.c` and `tcp.c`, along with the `.h` files which are supplied. A makefile is also provided.

Building a remote simulation project

In the remsim directory there is a subdirectory called SampleProject Into the `INCLUDE` directory copy *.`c` and *.`h` from the installation under `sdt/sdtdir/{ARCH}sdtdir/INCLUDE` and `sdt/sdtdir/remsim/source`. The makefiles are referring to this directory. You could of course change the makefiles to refer to the original installation if you

do not need any changes.
In the directory REMSIMKERNEL you have the file Makefile.m to build a new kernel and make.opt for compiler settings used by both final build and making the kernel.
comp.opt defines the syntax for the generated makefile.
In make.opt you could by setting sctLD, sctLDFLAGS and sctEXTENSION decide if you want to build the final executable or a library to link into the final target build.

You build the kernel in the REMSIMKERNEL directory. The sample makefiles will work under Sun/Solaris with a GCC compiler. You only need to change for your cross compiler environment. Make the kernel by typing:

```
make -f makefile.m
```

The result will be a prelinked kernel called sctworld.o.

When you perform a make, you need to choose the option “Generate Makefile and use template” and select env.tpm in the REMSIMKERNEL directory. This links in the template sctenv.c (which in the delivery does nothing). You also need to select “Use kernel in directory” and select REMSIMKERNEL.
Please note that this only sample code to give you ideas how you can build your own cross compilation environment.

Special Information about Windows NT

Compiling

Both target and host has been tested on Windows NT 4.0 and compiled with Microsoft Visual C++ 5.0 and 6.0.

In the directory sdt/sdtdir/remsim/wini386, makefiles for Microsoft compilers are stored. Normally you will probably not run the target under Windows NT; this is just for demo purposes. Edit the top of the makefile, variables ccbindir and sdtsource to the absolute paths of your compiler binaries and the SDL Suite installation. Make from the prompt like this:
Microsoft: nmake /f ms_target.mak

The host part is called host_smr.exe and is located into the SimUI the same way as on UNIX.

Both parts must be compiled as 32 bit console applications.

Non-supported Features

Due to the fact that there are no stdout or stderr when you run a Windows GUI application, together with the difficulties to determine the right directory to write to a file in, all debugging and logging facilities has been excluded. That means that the entries DEBUG, GREP and LOG in `tarsim.cfg` will be ignored. There is no extra Target Simulation Shell as on UNIX (which is not needed when you cannot do any message logging). None of this affects the target simulation as such.

Other Known Limitations

It is considerably slower to do a remote simulation in Windows NT than on UNIX, even with the same system, same options, and running target and host on the same machine. There are ways to speed up the simulation. Recommended is to give **`set-tr 0`** as the first command in SimUI. Then all textual tracing is stopped. Instead you can ask for the value of certain variables of interest. MSC trace and SDL trace works OK; MSC is the quicker of the two.

You can of course do a normal host simulation on the NT machine and then you have no limitations. Target simulation is not recommended to be used more than for the final fine tuning into the target environment.

It is especially important in Windows to use the option `SDLPATH` in `tarsim.cfg` if the target has been compiled on another system. The parser in `host.exe` can read NFS syntax “/path/” and will convert it to Windows/DOS syntax “\path\”. The thing that cannot be fixed automatically is the correct logical drive letter. Hence you can specify where your SDL source files are with:

```
SDLPATH D:\path\sdlsource
```

in `tarsim.cfg`. Of course the source files must be the same as the ones the target was compiled from.

Chapter

52 *The SDL Explorer*

This chapter is a reference to the SDL Explorer user interface and a reference for the terminology used in validation.

For a guide to how to use the SDL Explorer, see chapter 53, *Validating a System*.

The SDL Explorer Monitor

An SDL Explorer generated by the SDL Suite is similar to a simulator in that it contains an interactive monitor system. The explorer monitor looks and behaves very similar to the simulator monitor; the only real difference is the set of available commands.

Monitor User Interfaces

Two different user interfaces are provided for the explorer monitor, a textual and a graphical.

The textual interface only allows commands to be entered from the keyboard, in the same way as for the simulator monitor.

The graphical interface still allows commands to be entered from the keyboard in the same way, but also provides buttons, menus and dialogs for easy access to commands and other features.

The textual interface is invoked by executing the generated explorer directly from the operating system prompt. This is called running an explorer in *textual mode*. When started, the explorer responds with the following text:

```
Welcome to the SDL EXPLORER

Command :
```

Another prompt may appear if the SDL system contains external synonyms. For more information, see "Supplying Values of External Synonyms" on page 2396 in chapter 53, *Validating a System*.

> **Note:**
>
> Before an explorer can be run in textual mode **on UNIX**, a command file must be executed from the operating system prompt. The file is called `telelogic.sou` or `telelogic.profile` and is located in the binary directory that is included in the user's path.
> For csh-compatible shells: **`source <bin dir>/telelogic.sou`**
> For sh-compatible shells: **`. <bin dir>/telelogic.profile`**

The graphical interface, known as the *SDL Explorer UI*, runs in a separate window. It is started from the Organizer by selecting *SDL > Explorer UI* from the *Tools* menu. The graphical interface is basically the same as for the simulator monitor. However, some special windows and

menus have been added; see "Graphical User Interface" on page 2349 for more information.

Activating the Monitor

Commands can be issued to the interactive monitor system when it becomes active. The explorer's monitor system becomes active:

- When the explorer is started.
- When the last command was Next or Random-Down and the transitions initiated by this command have completed.
- When the last command was Bit-State-Exploration, Verify-MSC or Exhaustive-Exploration and the behavior tree down to the defined search depth has been fully explored.
- When the last command was Random-Walk and the defined number of repetitions have been executed.
- Immediately after a report with the report action Abort has been generated during automatic state space exploration.
- In the Explorer UI, when the *Break* button is clicked in the *Explore* button module; in textual mode, when `<Return>` is pressed during an automatic state space exploration.

Note:

No other characters may be typed before `<Return>` is pressed.

Monitor Commands

This section provides an alphabetical listing of all available commands in the SDL Explorer monitor. The syntax of commands and data type literals in the explorer monitor is the same as for the simulator monitor. Commands may be abbreviated, as well as most command parameters. All input to the monitor is case insensitive. For more information, see "Syntax of Monitor Commands" on page 2132 and "Input and Output of Data Types" on page 2137 in chapter 49, *The SDL Simulator*.

? (Interactive Context Sensitive Help)

Parameters:

```
(None)
```

The monitor will respond to a '?' (question mark) by giving a list of all allowed values at the current position, or by a type name, when it is not suitable to enumerate the values. After the presentation of the list, the input can be continued.

? (Command Execution)

Parameters:

```
<Command name>
```

Executes the monitor command given as a parameter. This is a convenience function for the Explorer UI. Entering '?' as parameter gives a list of all possible command names.

Assign-Value

Parameters:

```
[ '(' <PId value> ')' ]
<Variable name> <Optional component selection>
<New value>
```

The new value is assigned to the specified variable in the process instance, service instance, or procedure given by the current scope. Sender, Offspring, and Parent may also be changed in this way, but their names may not be abbreviated.

After the command is given, the root of the behavior tree is set to the current system state.

It is, in a similar way as for the command Examine-Variable, possible to handle components in structured variables (struct, strings, array, and Ref) by appending the struct component name or a valid array index be-

fore the value to be assigned. Nested structs and arrays can be handled by entering a list of index values and struct component names.

If a PId is given within parenthesis, the scope is temporarily changed to this process instance instead.

Bit-State-Exploration

Parameters:

`(None)`

Starts an automatic state space exploration from the current system state using the bit state space algorithm. When the exploration is started, the following information is printed:

- Search depth: The maximum search depth of the exploration. This can be set with the command Define-Bit-State-Depth.
- Hash table size: The size of the hash table used during bit state exploration. This can be set with the command Define-Bit-State-Hash-Table-Size.

The exploration will continue until either the complete state space to the defined depth is explored, `<Return>` is pressed from the command prompt, or the *Break* button is pressed in the graphical user interface. The system is then returned to the state it was in before the exploration was started.

If a bit state exploration already has been started, but has been stopped, this command asks if the exploration should continue from where it was stopped, or restart from the beginning again.

A status message is printed for every 20,000 transitions that are executed.

When the exploration is finished or stopped, the Report Viewer is by default opened (this can be changed with the command Define-Report-Viewer-Autopopup). The following statistics are also printed:

- No of reports: The number of reported situations that may be listed with the List-Reports command.
- Generated states: The total number of system states generated.
- Truncated paths: The number of times the exploration reached the maximum depth, causing the current execution path to be truncated.

- Unique system states: The number of generated system states that are not duplicated anywhere in the behavior tree.
- Size of hash table: The size of the hash table in bits and bytes.
- No of bits set in hash table: The number of bits actually used to represent the generated state space.
- Collision risk: The risk, in percent, of a collision occurring in the hash table for two different system states. This would cause an incorrect truncation of an execution path in a newly generated state.
- Max depth: The maximum number of levels in the behavior tree that have been reached during the exploration.
- Current depth: The level of the behavior tree reached at the moment when the exploration was stopped. If it is -1, the exploration was completed, i.e., the complete behavior tree down to the specified depth was explored. If it is > 0, the exploration may be continued from this level by issuing the command again.
- Min state size: The smallest number of bytes used to store a system state when computing hash values.
- Max state size: The largest number of bytes used to store a system state when computing hash values.
- Symbol coverage: The percentage of the symbols in the process graphs that have been executed at least once.

Bottom

Parameters:

```
(None)
```

Go down in the behavior tree to the end of the current path.

Cd

Parameters:

```
<Directory>
```

Change the current working directory to the specified directory.

Channel-Disable

Parameters:

```
<Channel> | '-'
```

Disables all test values defined for all signals using the given channel. '-' means *all channels*. Use Channel-Enable to start using them again. See also Signal-Disable. Test values for a signal are only used if both the signal and the channel that transports the signal are enabled. By default, all signals and channels are enabled.

Channel-Enable

Parameters:

```
<Channel> | '-'
```

Enables all test values defined for all signals using the given channel. '-' means *all channels*. See also Signal-Enable. Test values for a signal are only used if both the signal and the channel that transports the signal are enabled. By default, all signals and channels are enabled.

Clear-Autolink-Configuration

Parameters:

```
<Directory>
```

Clears the current Autolink configuration.

Clear-Constraint

Parameters:

```
<Constraint name> | '-'
```

Removes the constraint specified by the parameter. If '-' is given instead of a constraint name, all constraints are cleared.

Note: Only constraints that are not used by any generated test case can be cleared. Constraints used by one or more test cases are cleared automatically if the corresponding test cases are cleared.

Clear-Coverage-Table

Parameters:

```
(None)
```

Clears the test coverage information.

Clear-Generated-Test-Case

Parameters:

```
<Test case name> | '-'
```

Removes the generated test case specified by the parameter from memory. However, the corresponding MSC test case on disk is preserved. If '-' is given instead of a test case name, all generated test cases are

cleared. Alternatively, several test cases may be selected by a pattern enclosed in apostrophes. Such a pattern may include the special characters '*', '?', and '[...]' and is evaluated just as in a UNIX command shell.

Clear-Instance-Conversion

Parameters:

(None)

Clears all defined instance conversions. See also the command Define-Instance-Conversion.

Note that this command will not change an already loaded MSC.

Clear-MSC

Parameters:

(None)

Clears the currently loaded MSC and sets the current state to the current root of the behavior tree.

Clear-MSC-Test-Case

Parameters:

<File name> | '-'

Removes the MSC test case specified by the parameter from disk. If '-' is given instead of a file name, all test cases are cleared. Alternatively, several test cases may be selected by a pattern enclosed in apostrophes. Such a pattern may include the special characters '*', '?', and '[...]' and is evaluated just as in a UNIX command shell.

Clear-MSC-Test-Step

Parameters:

<File name> | '-'

Removes the MSC test case specified by the parameter from disk. If '-' is given instead of a file name, all test steps are cleared. Alternatively, several test steps may be selected by a pattern enclosed in apostrophes. Such a pattern may include the special characters '*', '?', and '[...]' and is evaluated just as in a UNIX command shell.

Clear-Observer

Parameters:

<Process type>

Defines all process instances of the given type to be usual SDL processes, not observer processes.

Clear-Parameter-Test-Values

Parameters:

```
( <Signal> | '-' ) ( <Parameter number> | '-' )
( <Value> | '-' )
```

The test value described by the value parameter is cleared for the signal parameter given as the parameter to the command. If the specified value parameter is '-', clears all test values for the signal parameter given as the parameter to the command. If '-' is given instead of the parameter number then the test values for all parameters of the signal are cleared. If '-' is given instead of the signal name then all test values for all parameters to all signals are cleared.

Regenerates the set of signals that can be sent from the environment during state space exploration.

Clear-Reports

Parameters:

```
(None)
```

Delete the current reports from the latest state space exploration.

Clear-Rule

Parameters:

```
(None)
```

The currently defined rule is deleted.

Clear-Signal-Definitions

Parameters:

```
<Signal> | '-'
```

Clears all currently defined test values for the signal given by the parameter. If '-' is given, the test values for all signals are cleared.

> **Note:**
>
> The signals cleared by this command may be regenerated if any of the commands for defining test values for sorts or parameters are used.

Clear-Test-Values

Parameters:

```
( <Sort> | '-' ) ( <Value> | '-' )
```

Clears all test values for the sort given as parameter. If the specified sort parameter is '-', all test values for all sorts will be cleared. If the value parameter is '-', all test values for the specified sort will be cleared.

Regenerates the set of signals that can be sent from the environment during state space exploration.

Command-Log-Off

Parameters:

```
(None)
```

The command log facility is turned off; see the command Command-Log-On for details.

Command-Log-On

Parameters:

```
<Optional file name>
```

The command enables logging of all the commands given in the monitor. The first time the command is entered a file name for the log file has to be given as parameter. After that any further Command-Log-On commands, without a file name, will append more information to the previous log file, while a Command-Log-On command with a file name will close the old log file and start using a new file with the specified name.

Initially the command log facility is turned off. It can be turned off explicitly by using the command Command-Log-Off.

The generated log file is directly possible to use as a file in the command Include-File. It will, however, contain exactly the commands given in the session, even those that were not executed due to command errors. The concluding Command-Log-Off command will also be part of the log file.

Continue-Until-Branch

Parameters:

```
<Optional node number>
```

First go to the system state node which is the child with the specified number to the current system state. Same as the Next command. Then go down as long as there is only one child, i.e. a branch is found.

Continue-Up-Until-Branch

Parameters:

`(None)`

Go up in the behavior tree as long as there is only one child, i.e. a branch is found.

Default-Options

Parameters:

`(None)`

Resets all options in the Explorer to their default values and clears all reports. It also sets the current state to the current root. Compare with the command Reset.

Define-Autolink-Configuration

Parameters:

`<Configuration>`

Defines an Autolink configuration which might consist of:

1. Rules for the handling of constraints and signal parameter values (naming, replacement and parameterization).
2. Rules for the arrangement of test cases (test suite structure).
3. Rules for declaring ASP and PDU types.
4. A rule for stripping signal definitions from constraints.
5. Functions used by the rules 1 and 2 above.

If any rule or function is already defined, Autolink prompts the user to decide whether to add the new rules or to clear the existing Autolink configuration. If Define-Autolink-Configuration is part of a command file, the existing configuration is always replaced.

Rules beginning with `TRANSLATE` are evaluated when a constraint is created during test case generation. A translation rule specifies the name and the parameters of a constraint for a given SDL signal. In addition, it allows to replace signal parameter values by wildcards in a constraint

declaration table (TTCN matching mechanism). Translation rules can also be used to introduce test suite parameters and constants.

Test suite structure rules are evaluated when a test suite is saved. A test suite structure rule specifies a test group reference for test cases and/or test steps.

The two rules for the mapping of SDL sorts and signals onto ASP/PDU types are evaluated when writing the TTCN MP file. The same applies to the `STRIP-SIGNALS` rule that tells Autolink to create a constraint for a (single) parameter of an SDL signal instead for the signal itself.

An Autolink configuration has to obey the syntax rules described in "Autolink Configuration Syntax" on page 2382.

For a detailed description of the semantics, see "Syntax and Semantics of the Autolink Configuration" on page 1471 in chapter 35, *TTCN Test Suite Generation*.

Define-Autolink-Depth

Parameters:

```
<Depth>
```

Sets the maximum depth of the state space exploration for test case generation to the given value. The default value is 1000.

Define-Autolink-Generation-Mode

Parameters:

```
"Partial-Ordering" | "Total-Ordering"
```

Determines the way Autolink analyzes an MSC test case during test generation. If set to "Partial-Ordering", the standard semantics of MSC is used whereas "Total-Ordering" lets Autolink evaluate incoming and outgoing messages in an MSC straight from top to bottom. Typically, "Partial-Ordering" results in a behavior tree with several leaves whereas "Total-Ordering" produces only one sequence of events. The default setting is "Partial-Ordering". Note: The total ordering interpretation is not supported by the Generate-Test-Case command.

Define-Autolink-Hash-Table-Size

Parameters:

```
<Size>
```

Sets the size of the hash table used for test case generation to `<Size>` bytes. The default value is 1,000,000 bytes.

Define-Autolink-State-Space-Options

Parameters:

```
"On" | "Off"
```

Determines whether Autolink sets its own default state space options before generating test cases. If “On’, the state space options are automatically set when Generate-Test-Case is invoked and reset to the previous options when the command is completed. The default value is “On”.

Note that in general, the Explorer’s default options are too strict to find all inconclusive events. Also be aware that for Autolink to work correctly, the priority of “Input from ENV” has to be higher than the priority of all other event classes, and the queues for all channels to the environment have to be activated.

Define-Bit-State-Depth

Parameters:

```
<Depth>
```

The parameter is the maximum depth of bit state exploration, i.e., the number of levels to be reached in the behavior tree. If this level is reached during the exploration, the current path is8 truncated and the exploration continues in another node of the behavior tree. The default value is 100.

Define-Bit-State-Hash-Table-Size

Parameters:

```
<Size in bytes>
```

Sets the size of the hash table used to represent the generated state space during bit state exploration. The default value is 1,000,000 bytes.

Define-Bit-State-Iteration-Step

Parameters:

```
<Step>
```

The Bit-State-Exploration algorithm includes a feature to automatically make a number of explorations with an increased depth for each exploration. The iteration continues until the search depth is greater than the maximum depth search as defined by Define-Bit-State-Depth command or one exploration terminates without any truncations.

This command activates the feature and defines how much the depth is increased for each iteration. If <Step> is set to 0 the iterative exploration

is deactivated, otherwise <Step> defines how much the maximum depth is increased for each exploration.

The default value is 0, i.e. the feature is not activated.

Define-Channel-Queue

Parameters:

```
<Channel name> ( "On" | "Off" )
```

Adds or removes a queue for the specified channel. If a queue is added for a channel, it implies that when a signal is sent that is transported on this channel, it will be put into the queue associated with the channel. By default no channels have queues.

Define-Concurrent-TTCN

Parameters:

```
"On" | "Off"
```

Defines whether TTCN test suites should be saved in concurrent TTCN format.

The default value is “off”.

> **Note:**
>
> Concurrent TTCN is not supported in combination with the “Local” or “Inline” TTCN test steps format. If an error message appears when trying to enable concurrent TTCN, first set the test steps format to “Global” with Define-TTCN-Test-Steps-Format.

Define-Condition-Check

Parameters:

```
"On" | "Off"
```

Defines whether conditions in an MSC should be used for synchronization purposes during MSC verification and test case generation. If condition check is turned on, then events below a global condition can only occur if all events on all instances above that condition have been processed; the condition becomes a synchronization point. If the condition is not global, then only the connected instances are synchronized. If condition check is turned off, then conditions in MSCs are ignored.

The default value is “off”.

Note:

If condition check is turned on, then the semantics of conditions is different from the semantics given in the ITU-T Recommendation Z.120!

Define-Constraint

Parameters:

```
<Constraint name> <Signal definition>
```

Defines a new constraint, which is automatically written to the test suite if the user enters the Save-Test-Suite command later.

Define-Exhaustive-Depth

Parameters:

```
<Depth>
```

The parameter defines the depth of the search when performing exhaustive exploration. The default value is 100.

Define-Global-Timer

Parameters:

```
"On" | "Off"
```

Defines whether a global timer should be added to TTCN test suites. If this option is enabled, the following things are done automatically:

- A declaration for a timer “T_Global” is generated with default duration “PIX_T_Global” and a unit “s” (seconds);
- A test suite parameter “PIX_T_Global” with type “INTEGER” is declared;
- A statement “START T_Global” is inserted at the beginning of each Test Case Dynamic Behaviour table; if concurrent TTCN output is enabled, a “START T_Global” is also inserted at the beginning of each top-level Test Step Dynamic Behaviour table for all parallel test components;
- A statement “CANCEL T_Global” is appended to every test sequence in each Test Case Dynamic Behaviour table; if concurrent TTCN output is enabled, a “CANCEL T_Global” is also added to the end of every test sequence in each top-level Test Step Dynamic Behaviour table of all parallel test components.

The default value is “on”.

Note:

It is recommended that the decision on using global timers is made before test case generation is started and that it is not changed later. Changing the option after the first test case has been generated may lead to unexpected results.

The name of the global timer cannot be changed. However, the default duration and unit may be defined with the Define-Timer-Declaration command. This should be done before the first test case is generated.

Define-Instance-Conversion

Parameters:

```
<From string> <To string>
```

Adds an entry into an instance conversion table. If a string contains spaces, it must be quoted.

When reading instances in an MSC diagram and the name textually match a <From string> in the conversion table, it will be replaced by the <To string>. This is useful if you want to verify some, but not all, instances in an MSC, in which case you can convert the unwanted instances to be considered as environment.

Note that this command will not change an already loaded MSC.

Define-Integer-Output-Mode

Parameters:

```
"dec" | "hex" | "oct"
```

Defines whether integer values are printed in decimal, hexadecimal or octal format. In hexadecimal format the output is preceded with “0x”, in octal format the output is preceded with ‘0’ (a zero).

On input: if the format is set to hexadecimal or octal, the string determines the base as follows: After an optional leading sign a leading zero indicates octal conversion, and a leading “0x” hexadecimal conversion. Otherwise, decimal conversion is used.

The default is “dec”, and no input conversion is performed.

Define-Max-Input-Port-Length

Parameters:

```
<Number>
```

The maximum length of the input port queues is defined. If this length is exceeded during state space exploration, a report is generated (see "Max Queue Length Exceeded" on page 2368). The default value is 3.

Define-Max-Instance

Parameters:

```
<Number>
```

Defines the maximum number of instances allowed for any particular process type. If this number is exceeded during state space exploration, a report is generated (see "Create Errors" on page 2367). The default value is 100.

Define-Max-Signal-Definitions

Parameters:

```
<No of signals>
```

This command defines the maximum no of signals that will be added to the list of signals from the environment for any particular signal. The default value is 10.

Define-Max-State-Size

Parameters:

```
<Size in bytes>
```

Sets the size of an internal array used to store each system state when computing the hash value for the system state. The default size is 100,000 bytes.

Define-Max-Test-Values

Parameters:

```
<No of text values>
```

This command defines the maximum no of test values that will be generated for a particular data type or signal parameter. The default value is 10.

Define-Max-Transition-Length

Parameters:

```
<Number>
```

The maximum number of SDL symbols allowed to be executed during the performance of a behavior tree transition is defined. If this number is exceeded during state space exploration, a report is generated (see "Transition Length Error" on page 2372). The default value is 1,000.

Define-MSC-Ignore-Parameters

Parameters:

```
"On" | "Off"
```

Defines whether the parameters of signals (and timers) will be ignored (i.e. set to default values) when reading MSC diagrams. The default is "Off".

Note that this command will not change an already loaded MSC.

Define-MSC-Search-Mode

Parameters:

```
"Verification" | "Violation"
```

Defines options for MSC verification depending on the purpose of the exploration. "Verification" mode should be used if the intention with the exploration is to verify all MSC alternatives. "Violation" mode should be used if the intention is to check if the SDL system can violate the MSC.

The difference between "Verification" and "Violation" mode is that in "Verification" mode the explorer will:

- synchronize on all MSC starts and start of inline expressions, and
- perform a separate MSC action to enter an MSC / inline expression.

The synchronization in "Verification" mode implies that the explorer will try to execute all events in one MSC before continuing with the events in a subsequent MSC. The special MSC action is executed when all events in one MSC has been executed and it is time to start with the subsequent MSC. Note that if there are more than one subsequent MSC (e.g. due to an HMSC alternative or an inline expression) each MSC action will select one of the MSCs. In the trace output (and in the Navigator) the MSC actions will be presented as "Enter MSC XXX" where XXX is the name of the MSC that the explorer will try to execute next.

A simple way to get hands-on experience with the difference between "Verification" and "Violation" mode is to load an MSC that includes alternatives (either an HMSC or an MSC with inline expressions) using the Load-MSC command. Then set up the MSC search mode and use the Navigator to manually explore the state space.

Note that in "Verification" mode the **par** operator is not supported.

The default search mode is "Violation" mode.

Define-MSC-Test-Cases-Directory

Parameters:

```
<Directory name> | '-'
```

Defines the directory in which the MSC test cases are stored. If '-' is provided instead of a directory name, the test cases directory becomes undefined.

Define-MSC-Test-Steps-Directory

Parameters:

```
<Directory name> | '-'
```

Defines the directory in which the MSC test steps are stored. If '-' is provided instead of a directory name, the test steps directory becomes undefined.

Define-MSC-Trace-Action

Parameters:

```
"On" | "Off"
```

This command defines whether actions like tasks, decisions, etc. are shown in the MSC trace. The default value is "Off".

Define-MSC-Trace-Autopopup

Parameters:

```
"On" | "Off"
```

This command defines whether an MSC Editor automatically will pop up and show an MSC trace when going to a report. The default value is "On".

Define-MSC-Trace-State

Parameters:

```
"On" | "Off"
```

This command defines if the SDL process graph states are shown in the MSC trace. If "On", a condition symbol will be shown in the MSC trace each time a process performs a nextstate. The default value is "On".

Define-MSC-Trace-Channels

Parameters:

```
"On" | "Off"
```

Defines whether the env instance should be split into one instance for each channel connected to env in the MSC trace. The default is "Off".

Define-MSC-Verification-Algorithm

Parameters:

```
"TreeSearch" | "BitState"
```

Defines the search algorithm that is used for MSC verification. Two options are available, the tree search algorithm and the bit state algorithm. The default is “BitState”.

Note that this command only defines what search algorithms that is used by the Verify-MSC command. It is possible to use other search algorithms, like Exhaustive-Exploration, by manually loading the MSC with the Load-MSC command and then starting the desired search algorithm.

Define-MSC-Verification-Depth

Parameters:

```
<Depth>
```

The parameter defines the depth of the search when performing MSC verification using the Verify-MSC command. The default value is 1,000.

Define-Observer

Parameters:

```
<Process type>
```

Defines all process instances of the given type to be observer processes.

Define-Parameter-Test-Value

Parameters:

```
<Signal> <Parameter number> <Value>
```

The parameter test value described by the command parameters is added to the current set of test values. The list of signals that can be sent from the environment is regenerated based on the new set of test values.

Define-Priorities

Parameters:

```
<Internal events> <Input from ENV> <Timeout events>
<Channel output> <Spontaneous transitions>
```

Defines the priorities for the different event classes. The priorities can be set individually to 1, 2, 3, 4 or 5. For more information about event classes and priorities, see “Event Priorities” on page 2467 in chapter 53, *Validating a System*.

The default priorities are:
- Internal events: 1
- Input from ENV: 2
- Timeout events: 2
- Channel outputs: 1
- Spontaneous transitions: 2

Note that the priorities of events processed in the explorer also is affected by the command "Define-Symbol-Time" on page 2320.

Define-Random-Walk-Depth

Parameters:

```
<Depth>
```

The parameter defines the depth of the search when performing random walk exploration. The default value is 100.

Define-Random-Walk-Repetitions

Parameters:

```
<No of repetitions>
```

The parameter defines the number of times the search is performed from the start state when performing random walk exploration. The default is 100.

Define-Report-Abort

Parameters:

```
<Report type> | '-'
```

Defines that the state space exploration will be aborted whenever a report of the specified type is generated.

The available report types are listed with the command Show-Options. They are also described in "Rules Checked During Exploration" on page 2366. If the parameter is specified as '-', all report types will be defined in the same way.

Define-Report-Continue

Parameters:

```
<Report type> | '-'
```

Defines that a state space exploration will continue past a state where a report of the specified type is generated. With this definition, the exploration of the behavior tree is not affected by a report being generated.

The available report types are listed with the command Show-Options. They are also described in "Rules Checked During Exploration" on page 2366. If the parameter is specified as '-', all report types will be defined in the same way.

Define-Report-Log

Parameters:

```
<Report type> ( "Off" | "One" | "All" )
```

Defines how many reports of a specified type will be stored in the list of found reports when they are encountered during state space exploration. Default for all report types is "One".

If "Off" is specified for a report type, reports of this type will not be stored, which implies for example that they will not be listed by the List-Reports command. However, the reports will be generated and the appropriate action taken as specified by the commands Define-Report-Abort, Define-Report-Continue and Define-Report-Prune.

If "One" is specified only one occurrence of each reported situation is stored.

If "All" is specified then all occurrences of a reported situation that have different execution paths is stored in the list.

The available report types are listed with the command Show-Options. They are also described in "Rules Checked During Exploration" on page 2366. If the parameter is specified as '-', all report types will be defined in the same way.

Define-Report-Prune

Parameters:

```
<Report type> | '-'
```

Defines that a state space exploration will not continue past a state where a report of the specified type is generated. Thus, the part of the behavior tree beneath the state will not be explored. Instead, the exploration will continue in the siblings or parents of the state. This is also known as "pruning" the behavior tree at the state. This is the default behavior for all report types.

The available report types are listed with the command Show-Options. They are also described in "Rules Checked During Exploration" on page 2366. If the parameter is specified as '-', all report types will be defined in the same way.

Define-Report-Viewer-Autopopup

Parameters:

```
"On" | "Off"
```

This command defines whether the Report Viewer automatically will pop up when an automatic exploration is finished. The default is “On”.

Define-Root

Parameters:

```
"Original" | "Current"
```

Defines the root of the behavior tree to be either the current system state or the original start state of the SDL system.

> **Note:**
>
> When the root is redefined, all paths, e.g. MSC traces or report paths, will start in the new root, not in the original start state.

Define-Rule

Parameters:

```
<User-defined rule>
```

A new rule is defined that will be checked during state space exploration.

Define-Scheduling

Parameters:

```
"All" | "First"
```

Defines which process instances in the ready queue are allowed to execute at each state. The parameter defines the scheduling as follows:

- `All`
  All process instances in the ready queue are allowed to execute at each state.
- `First`
  Only the first process instance in the ready queue is allowed to execute at each state.

The default is “First”.

Define-Signal

Parameters:

```
<Signal> <Optional parameter values>
```

A signal that is to be sent to the SDL system from the environment is defined. The signal is defined by its name and optionally the values of its parameters. Multiple Define-Signal commands may be used to define the same signal, but with different values for the parameters.

> **Note:**
>
> The signals defined by this command will be destroyed if the signals are regenerated, i.e., if any of the commands defining test values for sorts or signal parameters are used.

Define-Spontaneous-Transition-Progress

Parameters:

```
"On" | "Off"
```

Defines whether a spontaneous transition (input none) is considered as progress when performing non-progress loop check. Default is that spontaneous transition is considered to be progress, i.e. “On”. See “Non Progress Loop Error” on page 2372.

Define-Symbol-Time

Parameters:

```
"Zero" | "Undefined"
```

The time it takes to execute one symbol, e.g. an input, task or decision, in an SDL process is defined either to be zero or undefined. If it is set to zero, it is assumed that all actions performed by process instances take are infinitely fast compared to the timer values that are used in the system. If the symbol time is set to undefined, no assumption is made about how long time it takes for processes to execute symbols. Consider for example a situation where a process sets a timer with a duration 5 and then executes something that may take a long time, e.g. a long loop, and the sets a timer with duration 1. If symbol time is set to zero then the second timer will always expire first. If symbol timer is set to undefined then both timers can potentially expire first.

Note that when symbol time is set to zero, no timer will expire if an internal action is possible, even if internal and timer events have the same priority as set by the command Define-Priorities.

The default value of the symbol time options is “Zero”.

Define-Test-Value

Parameters:

```
<Sort> <Value>
```

The test value described by the parameters is added to the current set of test values. The list of signals that can be sent from the environment is regenerated based on the new set of test values.

> **Note:**
>
> When regenerating the set of signals, all signals that have been manually defined using the Define-Signal command will be lost.

Define-Timer-Check-Level

Parameters:

```
<Number>
```

The action taken during MSC verification when checking timer statements (set, reset and timeout) is defined. The possible values for the specified number are:

- 0: No checking of timer events is performed.
- 1: If a timer event exists in the MSC a matching timer event must exist in the explored SDL path, but a timer event in the explored SDL path is accepted even if there is no corresponding MSC timer event.
- 2: All timer events in the MSC must match a corresponding timer event in the explored SDL path, and vice versa.

The default value is 1.

Define-Timer-Declaration

Parameters:

```
<Timer name> <Duration> <Unit>
```

Creates or updates a TTCN timer declaration. Autolink distinguishes between implicit timer declarations, which are created from test description MSCs during test case generation, and explicit timer declarations, which are created with this command. Valid explicit declarations always override implicit ones. Existing explicit declarations cannot be updated.

The duration may be an integer value or a valid test suite parameter identifier. If a test suite parameter is specified, a declaration for this pa-

rameter is generated as well. If no valid duration is specified, the duration field in the declaration remains empty.

The unit must be a valid TTCN unit: “ps”, “ns”, “us”, “ms”, “s” or “min”. No declaration is made if an invalid unit is specified.

Note:

It is recommended that all timers appearing in MSC test cases and test steps are declared explicitly prior to test case generation.

Define-Timer-Progress

Parameters:

```
"On" | "Off"
```

Defines if the expiration of a timer is considered as progress when performing non-progress loop check. Default is that timer expiration is considered to be progress, i.e. “On”. See “Non Progress Loop Error” on page 2372.

Define-Transition

Parameters:

```
"SDL" | "Symbol-Sequence"
```

Defines the semantics and length of the transitions in the behavior tree. The parameter defines the transitions as follows:

- `SDL`
  The behavior tree transitions correspond to complete SDL process graph transitions.
- `Symbol-Sequence`
  The behavior tree transitions correspond to the longest sequence of SDL symbols that can be executed without any interaction with other process instances.

The default is “SDL”.

Define-Tree-Search-Depth

Parameters:

```
<Depth>
```

Defines the maximum search depth for tree search.

The default value is 100.

Define-TTCN-Compatibility

Parameters:

"Standard" | "ITEX"

Determines whether Autolink generates the declarations part of a TTCN test suite. If set to "Standard", Autolink creates declarations with ASN.1 data field names being constructed of the form "data type+parameter number" (e.g. "Integer2"). If set to "ITEX", no declarations are created. In this case, ASN.1 data field names used in constraint definitions are represented by '#' characters. This allows to merge the test suite with declarations generated by Link in the TTCN Suite. The default value is "Standard".

This command exists for backward compatibility reasons only.

Define-TTCN-Signal-Mapping

Parameters:

"ASP" | "PDU"

Determines whether SDL signals are mapped onto ASN.1 ASP constraints or ASN.1 PDU constraints. By default, signals are mapped onto ASPs. The setting of Define-TTCN-Signal-Mapping can be overruled for single signals by the use of the 'ASP-Types' and 'PDU-Types' commands in the Autolink configuration language (cf. Define-Autolink-Configuration).

Define-TTCN-Test-Steps-Format

Parameters:

"Global" | "Local" | "Inline"

Defines how test steps are written in a TTCN test suite. "Global" is the default value.

If set to "Global", each test step is saved in a separate behaviour description table. If a test step is used in more than one test case, then only one behaviour description table is generated.

If set to "Local", each test step is saved as a local tree in the behaviour table of the corresponding test case. If a test step is used several times in a single test case, then only one behaviour description is generated.

If set to "Inline", all test step trees are directly inserted into the test case descriptions.

Note that a test step which is used in several places may lead to trees with different inconclusive events or different verdicts. In this case, the test steps are stored in separate tables with unique names.

> **Note:**
>
> Test step formats “Local” and “Inline” are not supported in combination with concurrent TTCN. If an error message appears when trying to change the test steps format, first disable concurrent TTCN with Define-Concurrent-TTCN.

Define-Variable-Mode

Parameters:

```
<Process or Process Type> [ <Variable name> |
“Parent” | “Offspring” | “Sender” ]
[ “Compare” | “Skip” ]
```

This command defines how a specific variable is treated when comparing two system states during state space exploration. If the value for a variable is “Compare”, this variable will be taken into account when comparing two system states. If the value is “Skip”, this variable will not be taken into account, i.e. if the only difference between two system states is that values of variables in “Skip” mode differs, then the system states will be considered equal.

The purpose of the “Skip” mode for variables is to optimize the state space search. There are two different situations where this command can be used:

- All variables that is known to be constant during an exploration can be declared “Skip”.
- All variables that will not have an effect on the dynamic behavior of the system, i.e. that will not affect the path through a decision or the expression in an “output to”, can be declared “Skip”.

The benefit with constant variables in “Skip” mode is that the Explorer will ignore these variables when computing hash values. This can for large data structures like arrays mean that the performance of the explorer can be considerably improved.

Detailed-Exa-Var

Parameters:

```
(None)
```

When printing structs containing components with default value, these values are explicitly printed after this command is given.

Down

Parameters:

```
<Number of levels>
```

Go down the specified number of levels in the behavior tree, each time selecting the child of the current system state that is part of the current path. If the parameter is too large, Down will stop at the end of the current path.

Evaluate-Rule

Parameters:

```
(None)
```

The currently defined rule is evaluated with respect to the current system state. The command prints whether or not the rule is satisfied.

Examine-Channel-Signal

Parameters:

```
<Channel name> <Entry number>
```

The parameters of the signal instance at the position equal to the entry number in the queue of the specified channel are printed. The entry number is the number associated with the signal instance when the command List-Channel-Queue is used.

Examine-PId

Parameters:

```
(None)
```

Information about the process instance given by the current scope is printed (see the Set-Scope command for an explanation of scope). This information contains the current values of Parent, Offspring, Sender and a list of all currently active procedure calls made by the process instance. The list starts with the latest procedure call and ends with the process instance itself.

If the process instance contains service(s), information about all services is also printed.

Examine-Signal-Instance

Parameters:

```
<Entry number>
```

The parameters of the signal instance at the specified position in the input port of the process instance given by the current scope are printed (see the Set-Scope command for an explanation of scope). The entry number is the number associated with the signal instance when the command List-Input-Port is used.

Examine-Timer-Instance

Parameters:

```
<Entry number>
```

The parameters of the specified timer instance are printed. The entry number is the number associated with the timer when the List-Timer command is used.

Examine-Variable

Parameters:

```
[ '(' <PId value> ')' ]
<Optional variable name>
<Optional component selection>
```

The value of the specified variable or formal parameter in the current scope is printed (see the Set-Scope command for an explanation of scope). Variable names may be abbreviated. If no variable name is given, all variable and formal parameter values of the process instance given by the current scope are printed. Sender, Offspring, and Parent may also be examined in this way. Their names, however, may not be abbreviated and they are not included in the list of all variables.

> **Note:**
>
> If a variable is exported, both its current value and its exported value are printed.

It is possible to examine only a component of a struct, string or array variable, by appending the struct component name or a valid array index value as an additional parameter. The component selection can handle structs and arrays within structs and arrays to any depth by giving a list component selection parameters. SDL syntax with '!' and "( )" as well as just spaces, can be used to separate the names and the index values.

It is also possible to print a range of an array by giving “FromIndex : ToIndex” after an array name. Note that the space before the ‘:’ is required if FromIndex is a name (enumeration literal), and that no further component selection is possible after a range specification.

To see the possible components that are available in the variable, the variable name must be appended by a space and a ‘?’ on input. A list of components or a type name is then given, after which the input can be continued. After a component name, it is possible to append a ‘?’ again to list possible sub components.

To print the value of the data referenced by a Ref pointer it is possible to use the SDL syntax, i.e. the “*>” notation. If, for example, `Iref` is a Ref(Integer) variable, then `Iref*>` is the integer referenced by this pointer. If `Sref` is a Ref of a struct, then `Sref*> ! Comp1` is the Comp1 component in the referenced struct. The sequence `*> !` can in the monitor be replaced by `->` (as for example in C).

If a PId is given within parenthesis, the scope is temporarily changed to this process instance instead.

Exhaustive-Exploration

Parameters:

`(None)`

Starts an automatic state space exploration from the current system state, where the entire generated state space is stored in primary memory. This is only recommended for SDL systems with small state spaces.

The exploration will continue until either the complete state space to the defined depth is explored, `<Return>` is pressed from the command prompt, or the *Break* button is pressed in the graphical user interface. The system is then returned to its initial system state. The maximum depth of the exploration can be set with the command Define-Exhaustive-Depth.

If an exhaustive exploration already has been started, but has been stopped, this command asks if the exploration should continue from where it was stopped, or restart from the beginning again.

A status message is printed every 50,000 states that are generated. When the exploration is finished or stopped, the same information as for a bit state exploration is printed.

Exit

Parameters:

(None)

The executing explorer is terminated. If the command is abbreviated, the monitor asks for confirmation. If any of the Explorer options have been changed, the monitor will ask if the changed options should be saved. If so, the changed options are saved in a file `.valinit` **(on UNIX)**, or `valinit.com` **(in Windows)**, in the directory from where the SDL Suite was started. This file is automatically loaded the next time a Explorer is started from the same directory, thus restoring the previously saved options.

This is the same command as Quit.

Extract-Signal-Definitions-From-MSC

Parameters:

<Directory name> (<File name> | '-')

Extracts all signals from an MSC which are to be sent from the environment into the SDL system and adds them to the list of active signals. This command is only applicable to basic MSCs in textual format, i.e. to those MSCs stored with file extension `.mpr`. If '-' is given instead of a file name, signal definitions from all MSCs in the specified directory are extracted. Alternatively, several MSCs may be selected by a pattern enclosed in apostrophes. Such a pattern may include the special characters '`*`', '`?`', and '`[...]`' and is evaluated just as in a UNIX command shell.

Generate-Test-Case

Parameters:

<File name> | '-'

Starts the state space search algorithm which constructs an internal data structure for the MSC test case specified by the parameter. Additionally, constraints for all signals occurring in the test case are generated. At the end all constraints with identical signal definitions are merged.

If the command parameter is specified as '`-`', test cases are generated for all MSC test cases in the current test cases directory. Alternatively, several MSC test cases may be selected by a pattern enclosed in apostrophes. Such a pattern may include the special characters '`*`', '`?`', and '`[...]`' and is evaluated just as in a UNIX command shell.

If the previous generation of a test case has been interrupted, Autolink prompts the user to decide whether to continue the interrupted generation or to abort it. No file name is needed if the test case generation is to be continued.

Note that this command requires a TTCN Link license in addition to the Explorer license.

Goto-Path

Parameters:

```
<Path>
```

Go to the system state specified by the path. For details about paths, see the command Print-Path.

Goto-Report

Parameters:

```
<Report number>
```

Go to the state in the behavior tree where the report with the corresponding number has been found. The last behavior tree transition that was executed before the reported situation is printed, with the same information as for a full trace during simulation. The report number is the number associated with the report when the command List-Reports is used. If only one report exists, the report number is optional.

Help

Parameters:

```
<Optional command name>
```

Issuing the Help command without a parameter will print all the available commands. If a command name is given as parameter, this command will be explained.

Include-File

Parameters:

```
<File name>
```

This command provides the possibility to execute a sequence of monitor commands stored in a text file. The Include-File facility can be useful for including, for example, an initialization sequence or a complete test case. It is allowed to use Include-File in an included sequence of commands; up to five nested levels of include files can be handled.

List-Channel-Queue

Parameters:

```
<Channel name>
```

A list of all signal instances in the specified channel queue is printed. For each signal instance an entry number, the signal type, and the sending process instance is given. The entry number can be used in the command Examine-Channel-Signal.

List-Constraints

Parameters:

```
(None)
```

Lists all currently defined constraints.

List-Generated-Test-Cases

Parameters:

```
(None)
```

Lists all test cases which have been generated either by Generate-Test-Case or Translate-MSC-Into-Test-Case, or which have been loaded with the Load-Generated-Test-Cases command.

List-Input-Port

Parameters:

```
[ '(' <PId value> ')' ]
```

A list of all signal instances in the input port of the process instance given by the current scope is printed (see the Set-Scope command for an explanation of scope). For each signal instance an entry number, the signal type, and the sending process instance is given. A '*' before the entry number indicates that the corresponding signal instance is the signal instance that will be consumed in the next transition performed by the process instance. The entry number can be used in the command Examine-Signal-Instance.

If a PId is given within parenthesis information about this process instance is printed instead.

List-Instance-Conversion

Parameters:

```
(None)
```

Lists all defined instance conversions. See also the command Define-Instance-Conversion.

List-MSC-Test-Cases-And-Test-Steps

Parameters:

```
(None)
```

Lists all MSC test cases and test steps currently stored in the test cases and test steps directories.

List-Next

Parameters:

```
(None)
```

A list of the possible behavior tree transitions that can follow from the current system state is printed.

> **Note:**
>
> The number of possible transitions depends on the selected state space options.

List-Observers

Parameters:

```
(None)
```

List all process types which are defined to be observer processes.

List-Parameter-Test-Values

Parameters:

```
(None)
```

Lists all currently defined test values for signal parameters.

List-Process

Parameters:

```
<Optional process name>
```

A list of all process instances with the specified process name is printed. If no process name is specified all process instances in the system are listed. The list will contain the same details as described for the List-Ready-Queue command.

If the process contains services, information about the currently active service is also printed. To get information about all services use the Examine-PId command.

List-Ready-Queue

Parameters:

```
(None)
```

A list of process instances in the ready queue is printed. For more information, see the Simulator command "List-Ready-Queue" on page 2157 in chapter 49, *The SDL Simulator*.

List-Reports

Parameters:

```
(None)
```

All situations that have been reported during state space exploration are printed. For each report, the error or warning message describing the situation is printed, together with the depth in the behavior tree where it first occurred. Only one occurrence of each reported situation is printed; the one with the shortest path from the root of the behavior tree. The report numbers printed can be used in the command Goto-Report.

List-Signal-Definitions

Parameters:

```
(None)
```

A list of all currently defined signals is printed.

List-Test-Values

Parameters:

```
(None)
```

Lists all test values that currently are defined.

List-Timer

Parameters:

```
(None)
```

A list of all currently active timers is printed. For each timer, its corresponding process instance and associated time is given. An entry number will also be part of the list, which can be used in the command Examine-Timer-Instance.

Load-Constraints

Parameters:

```
<File name>
```

Loads all constraints stored in the file specified by the parameter. The suggested file extension is `.con`.

Load-Generated-Test-Cases

Parameters:

```
<File name>
```

Loads all generated test cases stored in the file specified by the parameter. The suggested file extension is `.gen`.

Load-MSC

Parameters:

```
<MSC file name>
```

The specified Message Sequence Chart is loaded into the Explorer. Loading an MSC always resets the state space and sets the current state to the root of the behavior tree.

Load-Signal-Definitions

Parameters:

```
<File name>
```

A command file with Define-Signal commands is loaded and the signals are defined. This command exists for backward compatibility reasons only.

Log-Off

Parameters:

```
(None)
```

The command Log-Off turns off the interaction log facility, which is described in the command Log-On.

Log-On

Parameters:

```
<Optional file name>
```

The command Log-On takes an optional file name as a parameter and enables logging of all the interaction between the Explorer and the user that is visible on the screen. The first time the command is entered, a file name for the log file has to be given as parameter. After that any further Log-On commands, without a file name, will append more information to the previous log file, while a Log-On with a file name will close the old log file and start using a new file with the specified file name.

Initially the interaction log facility is turned off. It can be turned off explicitly by using the command Log-Off.

Merge-Constraints

Parameters:

```
<First name> <Second name>
```

Merges the two constraints specified by the parameters. The resulting constraint has at least the formal parameters of the original constraints. If additional constraint parameters are necessary (e.g. when merging two constraints with signals S(1,1) and S(1,2)), Autolink prompts the user to enter a name for each new formal parameter. Merge-Constraints can only be applied to constraints with the same signal. The new constraint gets the name of the second constraint.

Merge-Report-File

Parameters:

```
<File name>
```

An existing report file is opened and the reports in it are added to the current reports.

MSC-Log-File

Parameters:

```
<File name>
```

A log file is produced containing information about the Message Sequence Chart for the trace from the root of the behavior tree to the current system state. This file can be opened in an MSC Editor; we recommend using a filename with the suffix `.mpr`, since that suffix is used as default.

MSC-Trace

Parameters:

```
(None)
```

An MSC Editor is opened, showing the Message Sequence Chart for the current execution path. The current state is shown in the MSC by the selection of some of the symbols. Whenever the current state and/or current path changes in the Explorer, the MSC will be updated.

If the MSC trace is already on, this command will turn it off.

New-Report-File

Parameters:

```
<File name>
```

A new report file for report storage is created. The current reports are deleted.

Next

Parameters:

```
<Transition number>
```

Go to a system state in the next level of the behavior tree, i.e. a child to the current system state. The parameter is the transition number given by the List-Next command.

Open-Report-File

Parameters:

```
<File name>
```

An existing report file is opened and the reports in it are loaded. The current reports are deleted.

Parameterize-Constraint

Parameters:

```
<Constraint name> <Replacement definition>
```

Replaces concrete values in a constraint with formal parameters. The replacement is defined by a sequence of pairs of a signal parameter number followed by the corresponding formal parameter name. The definition must be terminated with a 0.

Print-Autolink-Configuration

Parameters:

```
(None)
```

Displays the current Autolink configuration on the screen.

Print-Evaluated-Rule

Parameters:

```
(None)
```

The currently defined rule is printed with the values obtained from the last evaluation of the rule. The printed information is in the form of a so-called parse tree, and may require some knowledge of such structures to be interpreted correctly.

Print-File

Parameters:

```
<File name>
```

The content of the named text file is displayed on the screen.

Print-Generated-Test-Case

Parameters:

```
<Test case name> | '-'
```

Displays the internal representation of the generated test case specified by the parameter on the screen. If '-' is given instead of a test case name, all generated test cases are shown. Alternatively, several test cases may be selected by a pattern enclosed in apostrophes. Such a pattern may include the special characters '*', '?', and '[...]' and is evaluated just as in a UNIX command shell.

Print-MSC

Parameters:

```
(None)
```

A textual version of the currently loaded MSC is printed. The format is similar to the textual MSC format defined in ITU recommendation Z.120.

Print-Path

Parameters:

```
(None)
```

The path to the current system state is printed. A path is a sequence of integer numbers, terminated with a 0, describing how to get to the current system state. The first number indicates what transition to select from the root, the second number what transition to choose from this state, etc. To go to the state specified by a path, use the command Goto-Path.

Print-Report-File-Name

Parameters:

```
(None)
```

The name of the current report file is printed.

Print-Rule

Parameters:

```
(None)
```

The currently defined rule is printed.

Print-Trace

Parameters:

```
<Number of levels>
```

The textual trace leading to the current system state is printed. The same information as for a full trace during simulation is printed for each behavior tree transition. The parameter determines how many levels up the trace should start. For example, Print-Trace 10 will print the ten last transitions.

Quit

Parameters:

```
(None)
```

The executing explorer is terminated. If the command is abbreviated, the monitor asks for confirmation. If any of the Explorer options have been changed, the monitor will ask if the changed options should be saved. If so, the changed options are saved in the file `.valinit` **(on UNIX)**, or `valinit.com` **(in Windows)**, in the directory from where the SDL Suite was started. This file is automatically loaded the next time a Explorer is started from the same directory, thus restoring the previously saved options.

This is the same command as Exit.

Random-Down

Parameters:

```
<Number of levels>
```

Go down the specified number of levels in the behavior tree, each time selecting a random child of the current system state.

Random-Walk

Parameters:

```
(None)
```

This command will perform an automatic exploration of the state space from the current system state. Random walk is based on the idea that if more than one transition is possible in a particular system state, one of them will be chosen at random. When the exploration is started, the following information is printed:

- Search depth: The maximum depth to walk down. This can be set with the command Define-Random-Walk-Depth.

- Repetitions: The number of random walks to perform from the start state. This can be set with the command Define-Random-Walk-Repetitions.

The exploration will continue until either it is finished, `<Return>` is pressed from the command prompt, or the *Break* button is pressed in the graphical user interface. The system is then returned to the state it was in before the exploration was started.

When the exploration is finished or stopped, the Report Viewer is by default opened (this can be changed with the command Define-Report-Viewer-Autopopup). A few statistics are also printed; see the command Bit-State-Exploration for an explanation of these.

Rename-Constraint

Parameters:

`<Old name> <New name>`

Renames a constraint. If a constraint with the same "new" name but a different signal definition already exists, the user is prompted to choose between one of the following operations (which can be abbreviated):

- `Rename`: A different name can be chosen for the constraint.
- `Keep_old`: The definition of the renamed constraint is cleared. Any references from previously generated test cases to the renamed constraint are redirected to the old constraint.
- `Overwrite_old`: The definition of the old constraint is cleared. Any references from previously generated test cases to the old constraint are redirected to the renamed constraint.

Restriction: If one of the constraints contains formal parameters, then a different name must always be chosen for the renamed constraint. Rename-Constraint in combination with its options `Keep_old` and `Overwrite_old` allows to merge two constraints, e.g. if some signal parameters are irrelevant (see also the command Merge-Constraints and consider the use of `CONSTRAINT MATCH` ... statements in an Autolink configuration).

Reset

Parameters:

`(None)`

Resets the state of the Explorer to its initial state. This command resets all options and test values in the Explorer to their initial values and clears all reports, MSCs, and user-defined rules. It also sets the current state and the current root to the original start system state.

This command reads the `.valinit` **(on UNIX)**, or `valinit.com` **(in Windows)**, file (see the command Exit). It is equivalent to closing the Explorer and starting it again. Compare with the command Default-Options.

Save-As-Report-File

Parameters:

```
<File name>
```

The current reports are saved in a new file. The name of the current report file is set to the new file.

Save-Autolink-Configuration

Parameters:

```
<File name>
```

Saves the current Autolink configuration in a command file. The command name `Define-Autolink-Configuration` and the terminating `End` are written at the beginning and the end of the file in order to allow to reload the configuration with Include-File. The suggested file extension is `.com`.

Save-Constraint

Parameters:

```
( <Constraint name> | '-' ) <File name>
```

Saves the constraint in a file identified by `<File name>`. If '-' is given instead of a constraint name, all currently defined constraints are saved. The suggested file extension is `.con`.

Save-Coverage-Table

Parameters:

```
<File name>
```

Test coverage information is saved in the specified file. The test coverage table consists of two parts, a Profiling Information section, and a Coverage Table Details section. This is the same type of file as generated by the Simulator; for more detailed information about the file, see

"Print-Coverage-Table" on page 2163 in chapter 49, *The SDL Simulator*.

Save-Error-Reports-As-MSCs

Parameters:

```
(None)
```

Saves all reports (except those indicating an MSC verification) as MSCs in the target directory. The reports are stored as complete MSCs with file extension `.mpr`.

For each MSC a generic name consisting of the name of the currently loaded MSC (or "ErrorReport", if none is loaded), a four letter abbreviation of the error type and a sequence number is generated.

Save-Error-Reports-As-MSCs helps to find out what went wrong when running a batch job with a large number of MSC verifications.

Note: This command does not generate MSCs for MSC violation reports if the current MSC could be verified.

Save-Generated-Test-Case

Parameters:

```
( <Test case name> | '-' ) <File name>
```

Saves the generated test case in a file. If '-' is given instead of a test case name, all generated test cases which are currently stored in memory are saved. Alternatively, several test cases may be selected by a pattern enclosed in apostrophes. Such a pattern may include the special characters '`*`', '`?`', and '`[...]`' and is evaluated just as in a UNIX command shell.The suggested file extension is `.gen`.

This command allows to compute test cases in parallel on different machines and to merge them afterwards by using Load-Generated-Test-Cases.

Save-MSC-Test-Case

Parameters:

```
( <Test case name> | '*' )
```

Saves a test case as a system level Message Sequence Chart in the test cases directory (with file extension `.mpr`). The MSC contains a separate instance axis for each channel to the environment and another axis for the system. It comprises all signals sent to and from the environment for the trace from the root of the behavior tree to the current system

state. If '*' is given instead of a test case name, a generic test case name is generated.

Save-MSC-Test-Step

Parameters:

```
( <Test step name> | '*' )
```

Saves a test step as a system level Message Sequence Chart in the test steps directory (with file extension `.mpr`). The MSC contains a separate instance axis for each channel to the environment and another axis for the system. It comprises all signals sent to and from the environment for the trace from the root of the behavior tree to the current system state. If '*' is given instead of a test step name, a generic test step name is generated.

Save-Options

Parameters:

```
<File name>
```

Creates an Explorer command file with the name given as parameter. The file contains commands defining the options of the Explorer. If this file is loaded (using the command Include-File) the options will be restored to their saved values.

Save-Reports-as-MSC-Test-Cases

Parameters:

```
( <Report type> | '-' ) <Name prefix>
```

Saves all reports of a specified type as MSC test cases in the test cases directory (in system level MSC format; with file extension `.mpr`). The MSCs contain a separate instance axis for each channel to the environment and another axis for the system. For each MSC test case, a generic name is generated consisting of the name prefix, a four letter abbreviation of the report type and a five digit number. If '-' is provided instead of a report type, all current reports are saved.

Save-State-Space

Parameters:

```
<File name>
```

A Labelled Transition System (LTS) representing the generated state space is saved to a file. For a description of the file syntax, see section "State Space Files" on page 2384.

Note:

It is necessary to have executed an Exhaustive-Exploration command before the state space can be saved on a file.

Save-Test-Suite

Parameters:

```
<Test suite name> <File name>
```

Saves the generated test cases and all constraints in a test suite file in TTCN MP format. In addition, it generates the declarations part of the TTCN test suite. If the generation of a test case has been interrupted, Autolink prompts the user to decide whether to cancel the command or to abort the test case generation. The suggested file extension for the second parameter is `.mp`.

Note that this command requires a TTCN Link license in addition to the Explorer license.

Save-Test-Values

Parameters:

```
<File name>
```

A command file is generated containing Explorer commands that, if loaded with the Include-File command, will recreate the current test value definitions.

Scope

Parameters:

```
(None)
```

This command prints the current scope. See the command Set-Scope for a description of scope.

Scope-Down

Parameters:

```
<Optional service name>
```

Moves the scope one step down in the procedure call stack. If the current scope is a process containing services, one of the services should be specified. See also the commands Stack, Set-Scope and Scope-Up.

Scope-Up

Parameters:

```
(None)
```

Moves the scope one step up in the procedure call stack. Up from a service leads to the process containing the service. See also the commands Set-Scope, Stack and Scope-Down.

SDL-Trace

Parameters:

(None)

This command opens an SDL Editor that will show the transition leading to the current system state. Whenever the current system state changes in the Explorer, the SDL Editor will be updated.

If the SDL trace already is on, the command will turn it off.

Set-Application-All

Parameters:

(None)

The state space options of the Explorer are set to perform state space exploration according to the semantics of an application generated by the SDL Code Generator. No assumptions are made about the performance of the SDL system compared to timeout values or the performance of the environment.

This command sets the exploration mode factors by executing the following commands:

```
Define-Transition SDL
Define-Scheduling First
Define-Priorities 1 1 1 1 1
```

Set-Application-Internal

Parameters:

(None)

The state space options of the Explorer are set to perform state space exploration according to the semantics of an application generated by the SDL Code Generator. The assumption is made that the time it takes for the SDL system to perform internal actions is very small compared to timeout values and the response time of the environment.

This command sets the exploration mode factors by executing the following commands:

```
Define-Transition SDL
Define-Scheduling First
Define-Priorities 1 2 2 1 2
```

Set-Scope

Parameters:

```
<PId value> <Optional service name>
```

This command sets the scope to the specified process, at the bottom procedure call. If the process contains services, one of the services can be given as parameter to the command. A scope is a reference to a process instance, a reference to a service instance if the process contains services, and possibly a reference to a procedure instance called from this process/service. The scope is used for a number of other commands for examining the local properties of a process instance. The scope is automatically set to the process that executed in the transition leading to the current system state.

See also the commands Scope, Stack, Scope-Down and Scope-Up.

Set-Specification-All

Parameters:

```
(None)
```

The state space options of the Explorer are set to perform state space exploration according to the ITU semantics for SDL. No assumptions are made about the performance of the SDL system compared to timeout values, or the performance of the environment.

This command sets the exploration mode factors by executing the following commands:

```
Define-Transition Symbol-Sequence
Define-Scheduling All
Define-Priorities 1 1 1 1 1
```

Set-Specification-Internal

Parameters:

```
(None)
```

The state space options of the Explorer are set to perform state space exploration according to the ITU semantics for SDL. The assumption is made that the time it takes for the SDL system to perform internal actions is very small compared to timeout values and the response time of the environment.

This command sets the exploration mode factors by executing the following commands:

```
Define-Transition Symbol-Sequence
Define-Scheduling All
```

```
Define-Priorities 1 2 2 1 2
```

Show-Coverage-Viewer

Parameters:

(None)

This command starts the Coverage Viewer. The current test coverage is automatically loaded and a symbol coverage tree is presented. See chapter 47, *The SDL Coverage Viewer* for further description of the Coverage Viewer.

Show-Mode

Parameters:

(None)

This command displays a summary of the current execution mode and some other information about the current state of the SDL Explorer.

Show-Navigator

Parameters:

(None)

This command starts the Navigator tool to simplify interactive navigation in the behavior tree of the SDL system. See "The Navigator Tool" on page 2360 for more details.

Show-Options

Parameters:

(None)

The values of all options defined for the Explorer are printed, including the report action defined for each report type.

Show-Report-Viewer

Parameters:

(None)

This command starts the Report Viewer that presents a hierarchical view of all reports generated during state space explorations. See "The Report Viewer" on page 2363 for more details.

Show-Versions

Parameters:

(None)

The versions of the SDL to C Compiler and the runtime kernel that generated the currently executing program are presented.

Signal-Disable

Parameters:

```
<Signal> | '-'
```

Disables all test values defined for the given signal. '-' means *all signals*. Use Signal-Enable to start using them again. See also Channel-Disable. Test values for a signal are only used if both the signal and the channel that transports the signal are enabled. By default, all signals and channels are enabled.

Signal-Enable

Parameters:

```
<Signal> | '-'
```

Enables all test values defined for the given signal. '-' means *all signals*. See also Channel-Enable. Test values for a signal are only used if both the signal and the channel that transports the signal are enabled. By default, all signals and channels are enabled.

Signal-Reset

Parameters:

```
<Signal> | '-'
```

Removes all existing test values for the given signal, and defines a default set of test values instead, using the current test value settings for data types and signal parameters. '-' means *all signals*.

Stack

Parameters:

```
(None)
```

The procedure call stack for the PId/service defined by the scope is printed. For each entry in the stack, the type of instance (procedure/process/service), the instance name and the current state is printed. See also the commands Set-Scope, Scope-Down and Scope-Up.

Top

Parameters:

```
(None)
```

Go up in the behavior tree to the start of the current path (the root system state).

Translate-MSC-Into-Test-Case

Parameters:

```
( <File name> | '-' )
```

Translates an MSC into an internal test case data structure without performing a state space search. Additionally, constraints for all signals occurring in the test case are generated. At the end, all constraints with identical signal definitions are merged.

If the command parameter is specified as '-', all MSCs in the current test cases directory are transformed into test cases. Alternatively, several MSC test cases may be selected by a pattern enclosed in apostrophes. Such a pattern may include the special characters '*', '?', and '[...]' and is evaluated just as in a UNIX command shell.

Translate-MSC-Into-Test-Case does not require a fully specified SDL system. However, the signals used in the MSC must be defined in the SDL specification. Additionally, the channels between the SDL system and its environment have to be specified in order to find out which MSC instances relate to PCOs and which relate to the SDL system. Therefore, a direct translation cannot be applied to MSCs which consist of only a single instance axis for the environment.

Since the translation is done statically, it is not checked whether the MSC can in fact be verified. In addition, no inconclusive events are computed, unless they are stated explicitly by the use of an MSC exception expression.

Note that this command requires a TTCN Link license in addition to the Explorer license.

Tree-Search

Parameters:

```
(None)
```

Performs a tree search of the state space from the current system state. A tree search is an exploration where all possible combinations of actions are executed. The tree that is explored is exactly the same tree that can manually be inspected using the Navigator feature (or manual exploration using the Next / List-Next commands).

The depth of the tree search is bounded and is defined by the Define-Tree-Search-Depth command. The default depth is 100.

The command can be aborted by the user by pressing the *Break* button in the Explorer UI or any key if running the explorer from the command prompt.

Tree-Walk

Parameters:

```
<Timeout> <Coverage>
```

Performs an automatic exploration of the state space starting from the current system state. In contrast to Random-Walk, Tree-Walk is based on a deterministic algorithm that performs a sequence of tree searches with increasing depth starting at various states in the reachability graph. Tree Walk combines the advantages of both the depth-first and breadth-first search strategy - it is able to visit states located deep in the reachability graph and to find a short path to a particular state at the same time. Tree Walk is guided by a symbol coverage heuristic. Therefore it is particularly suitable for automatic test case generation.

Computation stops if either time exceeds <Timeout> (specified in minutes) or the targeted coverage (specified in percent) is reached. Alternatively, the exploration can be stopped at any time by pressing *Return* at the command prompt or by pressing the *Break* button if the graphical user interface is used.

Tree Walk creates a number of “TreeWalk” reports. These reports can be used for the generation of MSC test cases by applying command Save-Reports-as-MSC-Test-Cases.

Up

Parameters:

```
<Number of levels>
```

Go up the specified number of levels in the behavior tree. Up 1 goes to the parent state of the current system state. Up will stop at the root of the behavior tree (the start state) if the parameter is too large.

Verify-MSC

Parameters:

```
<MSC file>
```

This command will perform an automatic exploration from the current system state to search for all execution traces that are consistent with the MSC that is given as a parameter. The search algorithm is a variant of the bit state algorithm that is adapted to suite MSC verification. Before

the exploration is started, the root of the behavior tree is set to the current system state.

The file can either be an basic MSC file (`.msc`), a textual MSC file (`.mpr`) or a high-level MSC file (`.mrm`).

When the exploration is finished, the same information as for a bit state exploration is printed. In addition, a message is printed stating whether or not the MSC was verified, i.e. if an execution path was found that satisfied the MSC, and reports for MSC verification and MSC violation are generated.

If the MSC is a high-level MSC or it contains MSC reference expressions more that one MSC verification report can be generated. There will be one report for each sequence of 'leaf' MSCs that can be verified. For more information on criteria for MSC verification, see "MSC Verification Errors" on page 2373.

If the MSC was verified and exactly one MSC verification report was generated, the system state of the Explorer will be set up to the last system state in the path that satisfied the MSC. Otherwise, the system is returned to its initial state.

If the MSC contains MSC references the Explorer needs to match the logical MSC names in the MSC references with MSC file names. This is done according to the following algorithm:

1. If the Autolink test step directory is set, then the MSC file is assumed to be located in this directory and have the same name as the MSC with the suffix `.msc`, `.mpr` or `.mrm`.
2. The Explorer then checks if there is an MSC with the correct name in the same module in the Organizer as the parent MSC. If this is the case this MSC file is used.
3. If none of above applies then the Explorer checks if there is an MSC file in the same directory as the parent MSC with the correct name and with the suffix `.msc`, `.mpr` or `.mrm`. If this is the case this MSC file is used.

Graphical User Interface

This section describes the appearance and functionality of the graphical user interface to the explorer monitor (ExpUI). Some user interface descriptions general to all tools can be found in chapter 1, *User Interface*

and Basic Operations. These general descriptions are not repeated in this chapter.

> **Note:**
>
> The ExpUI looks and behaves very much like the SimUI, the graphical user interface to the simulator monitor. The differences are the set of available monitor commands and button modules, and a few additional menus and sub windows.

For an explanation of the Explorer main window, depicted in Figure 484, see "Graphical User Interface" on page 2199 in chapter 49, *The SDL Simulator*.

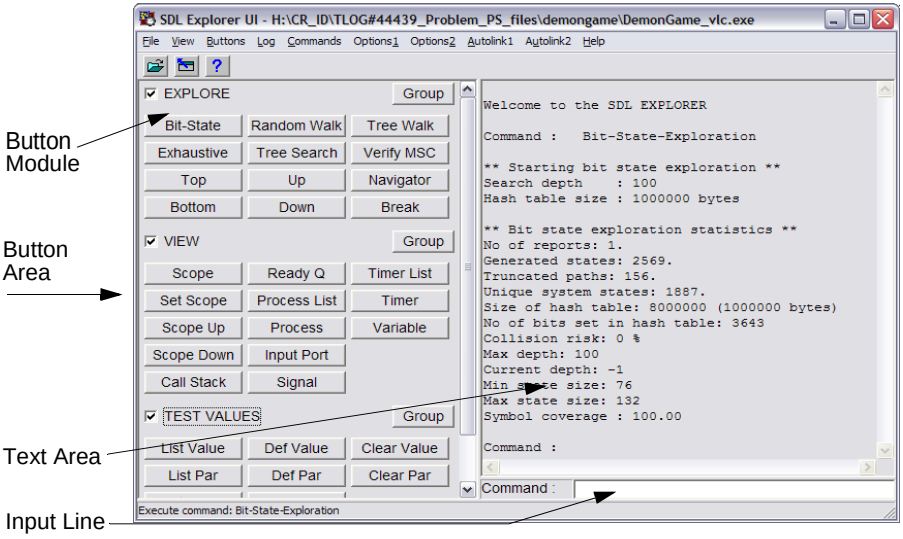

Figure 484: The main window

Starting the ExpUI

A new ExpUI is started by selecting *SDL > Explorer UI* from the *Tools* menu in the Organizer. When the ExpUI is started, a number of definition files are read, controlling the contents of the main window and some status windows. See "Definition Files" on page 2365 for more information.

No explorer is started automatically by the ExpUI in this way. The user must start an explorer by selecting *Open* from the *File* menu, as stated in the text area of the main window, or by using the *Open* quick button.

A simple way to generate an explorer, start the ExpUI and open the explorer is to click the *Explore* quick button in the Organizer.

When a simulator is started, a file selection dialog may be opened if the SDL system contains external synonyms. For more information, see "Supplying Values of External Synonyms" on page 2396 in chapter 53, *Validating a System*.

The Default Button Modules

The following tables list the default buttons in the button modules and the corresponding monitor command. See "Monitor Commands" on page 2300 for more information.

> **Note:**
>
> The buttons in the button modules are specified in the button definition file. If the default button file is not used, the button modules may be different than described here. See "Button and Menu Definitions" on page 2222 in chapter 49, *The SDL Simulator* for more information.

The *EXPLORE* Module

Button	Monitor command
Bit-State	Bit-State-Exploration
Exhaustive	Exhaustive-Exploration
Top	Top
Bottom	Bottom
Random Walk	Random-Walk
Tree Search	Tree-Search
Up	Up 1
Down	Down 1
Tree Walk	Tree-Walk
Verify MSC	Verify-MSC
Navigator	Show-Navigator
Break	Pressing `<Return>`

The *VIEW* Module

Button	Monitor command
Scope	Scope
Set Scope	Set-Scope
Scope Up	Scope-Up
Scope Down	Scope-Down
Call Stack	Stack
Ready Q	List-Ready-Queue
Process List	List-Process
Process	Examine-PId
Input Port	List-Input-Port
Signal	Examine-Signal-Instance

Button	Monitor command
Timer List	List-Timer
Timer	Examine-Timer-Instance
Variable	Examine-Variable

The *TEST VALUES* Module

Button	Monitor command
List Value	List-Test-Values
List Par	List-Parameter-Test-Values
List Signal	List-Signal-Definitions
Clear Signal	Clear-Signal-Definitions
Def Value	Define-Test-Value
Def Par	Define-Parameter-Test-Value
Def Signal	Define-Signal
Extract Sigs	Extract-Signal-Definitions-From-MSC
Clear Value	Clear-Test-Values
Clear Par	Clear-Parameter-Test-Values

The Menu Bar

This section describes the additional menus of the ExpUI's menu bar in comparison with the SimUI. The menus common to both the ExpUI and the SimUI is described in "The Menu Bar" on page 2207 in chapter 49, *The SDL Simulator*.

The menu bar contains the following menus:

- *File Menu*
  (See "File Menu" on page 2208 in chapter 49, *The SDL Simulator*.)
- *View Menu*
  (See "View Menu" on page 2208 in chapter 49, *The SDL Simulator*.)
- *Buttons Menu*
  (See "Buttons Menu" on page 2209 in chapter 49, *The SDL Simulator*.)
- *Log Menu*
  (See "Log Menu" on page 2210 in chapter 49, *The SDL Simulator*.)
- *Help Menu*
  (See "Help Menu" on page 15 in chapter 1, *User Interface and Basic Operations*.)
- *Commands Menu*
- *Options1 Menu*
- *Options2 Menu*
- Autolink1 Menu
- Autolink2 Menu

Additional SDL Explorer Menus

In addition to the standard SimUI menus, a few special explorer menus are included in the menu bar. The menu choices in these menus simply execute a monitor command, i.e. they are functionally equivalent to buttons in the button modules. If the monitor command requires parameters, they are prompted for using dialogs in the same way as the command buttons.

The following tables list the default menu choices and the corresponding monitor command. See "Monitor Commands" on page 2300 for more information.

> **Note:**
>
> The additional menus in the ExpUI are specified in the button definition file. If the default button file is not used, the additional menus may be different than described here. See "Button and Menu Definitions" on page 2222 in chapter 49, *The SDL Simulator* for more information.

Commands Menu

Menu choice	Monitor command
Toggle MSC Trace	MSC-Trace
Toggle SDL Trace	SDL-Trace
Show Report Viewer	Show-Report-Viewer
Show Coverage Viewer	Show-Coverage-Viewer
Show Navigator	Show-Navigator
Define Rule	Clear-Rule ; Define-Rule
Include Command Script	Include-File

Options1 Menu

The Command and Watch Windows

The Command window of the ExpUI is identical to the SimUI (see "Command Window" on page 2216 in chapter 49, *The SDL Simulator*). The only difference is that the default commands to execute are "List-Process -" and "Print-Trace 1". The set of commands to execute are stored in a *command definition file* (see "Definition Files" on page 2365). The default command definition file can be changed with the Preference Manager.

The Watch window of the ExpUI is identical to the SimUI (see "Watch Window" on page 2219 in chapter 49, *The SDL Simulator*).

The Navigator Tool

The Navigator is a separate tool in the ExpUI that is used for navigating in the behavior tree. It can be opened in the following ways:

- By issuing the monitor command Show-Navigator
- By selecting *Show Navigator* from the *Commands* menu.
- By clicking the *Navigator* button in the button area.

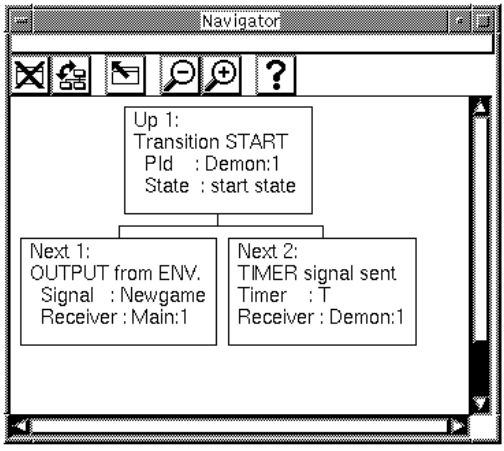

Figure 485: The Navigator window

The Navigator window consists of the tree area and the tool bar. There is no menu bar or status bar in the Navigator window.

Tree Area

The tree area of the Navigator window shows the structure of the behavior tree around the current system state. Each box, or node, represents a tree transition from one system state to another.

- The up node, always labelled *Up 1*, shows the tree transition leading to the current system state.
- The down nodes, labelled *Next 1*, *Next 2*, etc., show the possible tree transitions from the current system state. One of the down nodes may be labelled with three asterisks "***" to show which node is part of the current path, i.e., which part of the tree that already has been explored.

The text in the boxes contains the textual trace describing the tree transition. This may represent a complete or partial SDL process graph transition, depending on how the behavior tree is set up. The number of down nodes also depends on the structure of the behavior tree. This is determined by the state space options; see "State Space Options" on page 2466 in chapter 53, *Validating a System*.

Double-clicking a node in the Navigator executes the corresponding tree transition and moves one level up or down in the behavior tree. The current system state is changed and the Navigator window is updated to show the situation around the new system state.

> **Note:**
> Double-clicking a collapsed node (see below) **does not** expand the node; it always executes the corresponding transition.

The Navigator window is also updated whenever a monitor command is executed that changes the current system state.

Popup Menus

Each node in the node area has an associated popup menu.

Up 1	**On the up node:** Go up one level in the tree. This is the same as double-clicking the up node.
Up to top	**On the up node:** Go to the top of the behavior tree.

Continue Up	**On the up nodes**: Go up in the tree until more than one transition is possible (see Continue-Up-Until-Branch command).
Goto	**On the down nodes:** Go down this branch of the tree. This is the same as double-clicking the down node.
Continue	**On the down nodes:** Go down this branch of the tree until more than one transition is possible (see Continue-Until-Branch command).
Expand	Expand the collapsed node to show the down nodes. (Not applicable on a down node.)
Expand Substructure	The same as *Expand*.
Collapse	Collapse the node to hide the down nodes. A small triangle below the node shows that it is collapsed. (Not applicable on a down node.)

Quick Buttons

The following quick buttons are special to the Navigator tool. The general quick buttons are described in "General Quick-Buttons" on page 24 in chapter 1, *User Interface and Basic Operations*.

Close
Closes the Navigator tool.

Structure
Switches between a tree structure and a list structure in the node area.

Show Explorer UI
Raises the Explorer UI window.

The Report Viewer

The Report Viewer is a separate tool in the ExpUI that is used for examining the reports generated during an automatic state space exploration. It is opened in one of the following ways:

- Automatically when an automatic state space exploration has finished, unless the option Report Viewer Autopopup is off
- By issuing the monitor command Show-Report-Viewer
- By selecting *Show Report Viewer* from the *Commands* menu.

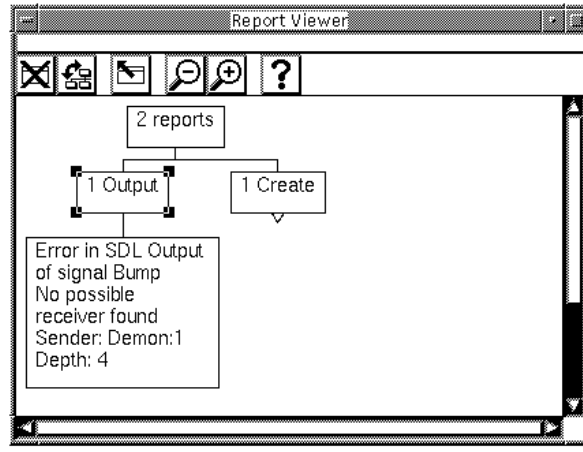

Figure 486: The Report Viewer

The Report Viewer window consists of the Report Area, containing Popup Menus, and the tool bar, containing Quick Buttons. There is no menu bar or status bar in the Report Viewer window.

Report Area

The report area of the Report Viewer shows the current reports from the latest state space exploration in the form of a report tree. The report tree contains three levels of nodes (see Figure 486):

- The top node shows how many reports there are. This node is always visible.

- The next level contains one node for each *report type*. The text shows the report type and how many reports of that type there are. When the Report Viewer is started, the report type nodes are shown, but they are collapsed (indicated by a small triangle below the node). For a list of possible report types, see "Rules Checked During Exploration" on page 2366.
- The bottom level contains one node for each actual report. The text shows the error or warning message, and the depth in the behavior tree where the report was generated. If the same report has been generated more than once, only one report is shown; the one generated at the lowest depth in the tree. When the Report Viewer is started, the report nodes are not visible.

Double-clicking a report node at the bottom level causes the Explorer to "go to" the report, i.e., go to the system state where the report was generated. The following things happen:

- The textual trace from the transition where the report was generated is printed in the text area of the main window.
- If the Navigator tool is opened, it is updated to show the transition where the report was generated and the error message.
- An MSC Editor is opened, showing the MSC trace from the start state to the state where the report was generated. The MSC Editor is not opened if the option MSC Trace Autopopup is off.

Double-clicking the top node or a report type node will expand or collapse the node, depending on its state. A collapsed node hides its underlying nodes and is indicated by a small triangle below the node.

Popup Menus

Goto	**Only on report nodes:** Go to the report. This is the same as double-clicking the report node.
Expand	Expand the collapsed node to show the nodes in the next level of the tree. This is the same as double-clicking the collapsed node (top node or report type node). (Not applicable on a report node.)

Expand Substructure	Expand the collapsed node to show all nodes on all levels below it. (Not applicable on a report node.)
Collapse	Collapse the node to hide all nodes on all levels below it. This is the same as double-clicking the node (top node or report type node). (Not applicable on a report node.)

Quick Buttons

The following quick buttons are special to the Report Viewer. The general quick buttons are described in "General Quick-Buttons" on page 24 in chapter 1, *User Interface and Basic Operations*.

Close
Closes the Report Viewer.

Structure
Switches between a tree structure and a list structure in the report area.

Show Explorer UI
Raises the Explorer UI window.

Definition Files

In the ExpUI, the syntax and contents of the definition files are the same as for the SimUI; see "Definition Files" on page 2221 in chapter 49, *The SDL Simulator*. The default file names for the definition files are `val_def.btns`, `val_def.cmds` and `val_def.vars`, respectively.

Rules Checked During Exploration

For each system state encountered during state space exploration, a number of rules are checked to detect errors or possible problems in the SDL system. If a rule is satisfied, a report is generated to the user.

The rules that are checked by the SDL Explorer are the same ones as checked and reported by the SDL Simulator, with a few additions and differences.

Apart from the predefined rules, an additional rule can be defined by the user of the explorer to check for other properties of the system states encountered. See "User-Defined Rules" on page 2376 for more information.

The rules are listed below, together with the reported error messages. The rules are grouped according to the corresponding report type, used in the Report Viewer in the Explorer. The names of the report types listed below are the ones to be used in the monitor commands that define the report actions.

Deadlock

Report Type: Deadlock

```
Deadlock
```

All processes instances are waiting for some other process instance to act, implying that none of the processes will execute. This is referred to as a deadlock.

Implicit Signal Consumption

Report Type: ImplSigCons

```
Warning: Implicit signal consumption of signal
<signal>
```

A signal was sent to a process that was not able to handle (or save) the signal in the current state, so it was implicitly consumed.

Create Errors

Report Type: Create

```
Error in SDL Create: Processtype <type>
More static instances than maximum number of
instances.
```

There are more static instances defined than the maximum allowed number of instances.

```
Warning in SDL Create: Processtype <type>
Unsuccessful create. Number of instances has reached
maximum number.
```

An attempt has been made to create a new instance of a process type of which there is already the maximum number of allowed instances active. The maximum number is either the value defined by the command Define-Max-Instance, or the value defined in the SDL diagram, whichever is smallest.

Output and Remote Procedure Call Errors

Report Type: Output

```
Error in SDL Output of signal <signal>
No valid receiver found
```

An attempt was made to output a signal to an invalid PId expression.

```
Error in SDL Output of signal <signal>
No path to receiver
```

An attempt was made to output a signal to a PId expression. There exists, however, no path of channels and signal routes between the sender and the receiver that can convey the signal.

```
Error in SDL Output of signal <signal>
No possible receiver found
```

An attempt was made to output a signal without specifying a PId expression. When all paths or all paths mentioned in a via clause had been examined no possible receiver was found.

```
Error in SDL Output of signal <signal>
Several possible receivers found
```

An attempt was made to output a signal without specifying a PId expression. When all paths or all paths mentioned in a via clause had been examined several possible receivers were found.

```
Error in SDL Output of signal <signal>
Signal sent to stopped process instance
```

An attempt was made to output a signal to a PId expression that referred to a process instance which has performed a stop action.

```
Error in SDL Output of signal <signal>
Signal sent to NULL
```

An attempt was made to output a signal to a PId expression that was null.

```
Error in SDL Output of signal <signal>
Illegal signal type in output TRANSFER
```

An attempt was made to output a signal with the TRANSFER directive that was not the same signal as in the preceding input.

```
Error in remote procedure call: <name>
More than one process provides the remote procedure
```

An attempt was made to call a remote procedure in a system state where there are more than one possible process instance that can provide the remote procedure.

```
Error in remote procedure call: <name>
No process provides the remote procedure
```

An attempt was made to call a remote procedure in a system state where there is no possible process instance that can provide the remote procedure.

Max Queue Length Exceeded

Report Type: MaxQueuelength

```
Error in SDL Output of signal <signal>
Max input port length exceeded
```

The length of the input port of the receiving process has exceeded the value defined by the monitor command Define-Max-Input-Port-Length.

```
Error in SDL Output of signal <signal>
Max channel queue length exceeded
```

The length of the queue of the receiving channel has exceeded the value defined by the monitor command Define-Max-Input-Port-Length.

```
Error in channel output. Max input port length
exceeded
```

The length of the input port of the receiving process has exceeded the value defined by the monitor command Define-Max-Input-Port-Length.

```
Error in channel output. Max channel queue length
exceeded
```

The length of the queue of the receiving channel has exceeded the value defined by the monitor command Define-Max-Input-Port-Length

Channel Output Errors

Report Type: ChannelOutput

In addition to the following messages, information about the channel, signal, sender and receiver is also displayed.

```
Error in channel output. No valid receiver found
```

An attempt was made to output a signal to an invalid PId expression.

```
Error in channel output. No path to receiver
```

An attempt was made to output a signal to a PId expression. There exists, however, no path of channels and signal routes between the sender and the receiver that can convey the signal.

```
Error in channel output. No possible receiver found
```

An attempt was made to output a signal without specifying a PId expression. When all paths or all paths mentioned in a via clause had been examined no possible receiver was found.

```
Error in channel output. Several possible receivers
found
```

An attempt was made to output a signal without specifying a PId expression. When all paths or all paths mentioned in a via clause had been examined several possible receivers were found.

```
Error in channel output. Signal sent to stopped
process instance
```

An attempt was made to output a signal to a PId expression that referred to a process instance which has performed a stop action.

```
Error in channel output. Signal sent to NULL
```

An attempt was made to output a signal to a PId expression that was null.

Operator Errors

Report Type: Operator

The errors that can be found in operators defined in the predefined data types are listed below.

```
Error in SDL Operator: Modify! in sort Charstring,
Index out of bounds

Error in SDL Operator: Extract! in sort Charstring,
Index out of bounds

Error in SDL Operator: MkString in sort Charstring,
character NUL not allowed

Error in SDL Operator: First in sort Charstring,
Charstring length is zero

Error in SDL Operator: Last in sort Charstring,
Charstring length is zero

Error in SDL Operator: Substring in sort Charstring,
Charstring length is 0

Error in SDL Operator: Substring in sort Charstring,
Sublength is less than or equal to zero

Error in SDL Operator: Substring in sort Charstring,
Start is less than or equal to zero

Error in SDL Operator: Substring in sort Charstring,
Start + Substring length is greater than string
length.

Error in SDL Operator: Division in sort Integer,
Integer division by 0.

Error in SDL Operator: Division in sort Real, Real
division by 0.

Error in SDL Operator: Fix in sort Integer
Integer overflow
Second operand is 0

Error in SDL Operator: Mod in sort Integer
Second operand is 0

Error in SDL Operator: Rem in sort Integer
Second operand is 0
```

Range Errors

Report Type: Subrange

```
Error in assignment in sort <sort>:
<value> out of range
```

A variable of a restricted syntype is assigned a value out of its range.

Index Error

Report Type: Index

```
Error in SDL array index in sort <sort>:
<value> out of range
```

An array index is out of range.

Decision Error

Report Type: Decision

```
Error in SDL Decision: Value is <value>:
Fatal error. Analysis is not continued below this
node
```

The value of the expression in the SDL decision did not match any of the possibilities (answers).

Import Errors

Report Type: Import

Error during execution of an import statement. Supplementary information about remote variables and exporting processes is also given.

```
Error in SDL Import. Attempt to import from the
environment

Error in SDL Import. Attempt to import from NULL

Error in SDL Import. Attempt to import from stopped
process instance

Error in SDL Import. Several processes exporting
this variable

Error in SDL Import. The specified process does not
export this variable

Error in SDL Import. No process exports this
variable

Error in SDL Import. More than one process exports
this variable
```

View Errors

Report Type: View

Error during execution of view statement. Supplementary information about viewed variables and revealing processes is also given.

```
Error in SDL View. Attempt to view from the
environment

Error in SDL View. Attempt to view from NULL

Error in SDL View. Attempt to view from stopped
process instance

Error in SDL View. More than one process instance
reveals the variable

Error in SDL View. The specified process does not
reveal the variable.

Error in SDL View. No process instance reveals this
variable
```

Transition Length Error

Report Type: MaxTransLen

```
Max transition length exceeded
```

The maximum number of SDL symbols executed in one behavior tree transition is more than the value defined by the monitor command Define-Max-Transition-Length.

Non Progress Loop Error

Report Type: Loop

```
Loop Detected.
```

The Explorer includes a mechanism for non-progress loop detection. A report will be generated if the Explorer during state space exploration finds a loop in the state space which does not contain any progress transition. A progress transition is defined as a transition that either:

- contains communication with the environment
- contains an assignment of the variable `xProgress` to 1 in user-defined C code
- includes a timer expiration (see "Timer Progress" on page 2470 in chapter 53, *Validating a System*)
- includes a spontaneous transition (see "Spontaneous Transition Progress" on page 2471 in chapter 53, *Validating a System*)

Assertion Errors

Report Type: Assertion

```
Assertion is false: <user-defined string>
```

A user-defined action in the SDL system has called the function `xAssertError`. See "Using Assertions" on page 2457 in chapter 53, *Validating a System* for more information.

User Defined Rule

Report Type: UserRule

```
User-defined rule satisfied
```

A user-defined rule is evaluated to true.

Observer Errors

Report Type: Observer

```
Observer violation
```

A process defined as an observer process has not been able to execute a transition.

MSC Verification Errors

Report Type: MSCVerification
Report Type: MSCViolation

```
MSC <MSC name> verified
MSC sequence: <MSC name list>

MSC <MSC name> violated
Event: <SDL Event>
```

The MSC verification report is given when a state space exploration has reached a state where the execution trace from the root of the behavior tree to the current state satisfies the loaded MSC. In this case, "satisfies" means that:

- The execution trace must include all events that exist in the MSC.
- The execution trace must not contain any observable event that is not part of the MSC.
- The sequence of observable events in the execution trace must be consistent with the partial ordering of the events that is defined by the MSC.

An event on the execution trace is considered to be “observable” if it is either

- an input or output of a signal that is sent between process instances that correspond to different MSC instances, or
- a create of a process instance that corresponds to a different MSC instance than the creating process instance, or
- a set, reset or input of a timer, depending on the value set by the command Define-Timer-Check-Level.

Note:

Two process instances can correspond to the same MSC instance if the MSC is a system or block level MSC.

The MSC violation report is given during state space exploration for each generated execution trace that either:

- includes an observable event that is not part of the loaded MSC, or
- contains a sequence of observable events that is not consistent with the partial ordering of events defined by the MSC.

REF Errors

Report Type: RefError

```
No reference to dynamically allocated memory of
sort: <Sort Name>
```

The list of dynamically allocated data areas that is maintained by the Explorer contains a data area that no SDL entity (like a variable, signal parameter etc.) references. This indicates a memory leak in the system.

```
No reference to dynamically allocated memory
```

The list of dynamically allocated data areas that is maintained by the Explorer contains a data area that no SDL entity (like a variable, signal parameter etc.) references. This indicates a memory leak in the system. The lack of <Sort Name> in this report indicates that this is a newly allocated data area and there has been no previous system state with a reference to this data area.

```
Referenced data area not found:
Variable <Variable name> in process <Process name>
```

A REF variable (or signal parameter, structure field etc.) has been found that references a data area that is not allocated. To avoid this report always set the REF variables to NULL after the data area has been released.

```
Dereferencing a NULL pointer of sort: <Sort Name>.
```

An expression `XX*>` has been evaluated where `XX` was NULL.

```
Calling UserMalloc with parameter NULL
Calling UserFree with parameter NULL
```

The `UserMalloc` or `UserFree` functions has been called with NULL as a parameter which is illegal.

```
Calling UserFree without dynamically allocated
memory
```

`UserFree` has been called with a parameter that is not a pointer to one of the data areas in the list of the dynamically allocated data areas.

User-Defined Rules

User-defined rules are used during state space exploration to check for properties of the system states encountered. If a system state is found for which a user-defined rule is true, this will be listed among the other reports when giving the List-Reports command. During an exploration more that one user defined rule report can be generated. There will be one report for each value assignment that can be made to a rule. The value assignments are the values printed by the Print-Evaluated-Rule command.

A rule essentially gives the possibility to define predicates that describe properties of one particular system state. A rule consists of a predicate (as described below) followed by a semicolon (';'). In a rule, all identifiers and reserved words can be abbreviated as long as they are unique.

Note:

Only one rule can be used at any moment. If more than one rule is needed, reformulate the rules as one rule, using the boolean operators described below.

Predicates

The following types of predicates exist:

- Quantifiers over process instances and signals in input ports.
- Boolean operator predicates such as "and", "not" and "or".
- Relational operator predicates such as "=" and ">".

Parenthesis are allowed to group predicates.

Quantifiers

The quantifiers listed below are used to define rule variables denoting process instances or signals. The rule variables can be used in process or signal functions described later in this section.

```
exists <RULE VARIABLE> [: <PROCESS TYPE>]
[ | <PREDICATE>]
```

This predicate is true if there exists a process instance (of the specified type) for which the specified predicate is true. Both the process type and the predicate can be excluded. If the process type is excluded all process

instances are checked. If the predicate is excluded it is considered to be true.

```
all <RULE VARIABLE> [ : <PROCESS TYPE>]
[ | <PREDICATE>]
```

This predicate is true for all process instances (of the specified type) for which the specified predicate is true. Both the process type and the predicate can be excluded. If the process type is excluded all process instances are checked. If the predicate is excluded it is considered to be true.

```
siexists <RULE VARIABLE> [ : <SIGNAL TYPE>]
[ -  <PROCESS INSTANCE>] [ |  <PREDICATE>]
```

This predicate is true if there exists a signal (of the specified type) in the input port of the specified process for which the specified predicate is true. If no signal type is specified, all signals are considered. If no process instance is specified the input ports of all process instances are considered. If no predicate is specified it is considered to be true. The specified process can be either a rule variable that has previously been defined in an `exists` or `all` predicate, or a process instance identifier (`<PROCESS TYPE>:<INSTANCE NO>`).

```
siall <RULE VARIABLE> [ :  <SIGNAL TYPE>]
[ - <PROCESS INSTANCE>] [ | <PREDICATE>]
```

This predicate is true for all signals (of the specified type) in the input port of the specified process for which the specified predicate is true. If no signal type is specified all signals are considered. If no process is specified the input ports of all process instances are considered. If no predicate is specified it is considered to be true. The specified process can be either a rule variable that has previously been defined in an `exists` or `all` predicate, or a process instance identifier (`<PROCESS TYPE>:<INSTANCE NO>`).

Boolean Operator Predicates

The following boolean operators are included (with the conventional interpretation):

```
not <PREDICATE>
<PREDICATE> and <PREDICATE>
<PREDICATE> or <PREDICATE>
```

The operators are listed in priority order, but the priority can be changed by using parenthesis.

Relational Operator Predicates

The following relational operator predicates exist:

```
<EXPRESSION> = <EXPRESSION>
<EXPRESSION> != <EXPRESSION>
<EXPRESSION> < <EXPRESSION>
<EXPRESSION> > <EXPRESSION>
<EXPRESSION> <= <EXPRESSION>
<EXPRESSION> >= <EXPRESSION>
```

The interpretation of these predicates is conventional. The operators are only applicable to data types for which they are defined.

Expressions

The expressions that are possible to use in relational operator predicates are of the following categories:

- Process functions: Extract values from process instances.
- Signal functions: Extract values from signals.
- Global functions: Examine global aspects of the system state.
- SDL literals: Conventional SDL constant values.

Process Functions

Most of the process functions must have a process instance as a parameter. This process instance can be either a rule variable that has previously been defined in an `exists` or `all` predicate, a process instance identifier (`<PROCESS TYPE>:<INSTANCE NO>`), or a function that returns a process instance, e.g. `sender` or `from`.

```
state( <PROCESS INSTANCE> )
```

Returns the current SDL state of the process instance.

```
type( <PROCESS INSTANCE> )
```

Returns the type of the process instance.

```
iplen( <PROCESS INSTANCE> )
```

Returns the length of the input port queue of the process instance.

```
sender( <PROCESS INSTANCE> )
```

Returns the value of the imperative operator sender (a process instance) for the process instance.

```
parent( <PROCESS INSTANCE> )
```

Returns the value of the imperative operator parent (a process instance) for the process instance.

```
offspring( <PROCESS INSTANCE> )
```

Returns the value of the imperative operator offspring (a process instance) for the process instance.

```
self( <PROCESS INSTANCE> )
```

Returns the value of the imperative operator self (a process instance) for the process instance.

```
signal( <PROCESS INSTANCE> )
```

Returns the signal that is to be consumed if the process instance is in an SDL state. Otherwise, if the process instance is in the middle of an SDL process graph transition, it returns the signal that was consumed in the last input statement.

```
<PROCESS INSTANCE> -> <VARIABLE NAME>
```

Returns the value of the specified variable. If `<PROCESS INSTANCE>` is a previously defined rule variable, the `exists` or `all` predicate that defined the rule variable must also include a process type specification.

```
<RULE VARIABLE>
```

Returns the process instance value of `<RULE VARIABLE>`, which must be a rule variable bound to a process instance in an `exists` or `all` predicate.

Signal Functions

Most of the signal functions must have a signal as a parameter. This signal can be either a rule variable that has previously been defined in an `siexists` or `siall` predicate, or a function that returns a signal, e.g. `signal`.

```
sitype( <SIGNAL> )
```

Returns the type of the signal.

```
to( <SIGNAL> )
```

Returns the process instance value of the receiver of the signal.

```
from( <SIGNAL> )
```

Gives the process instance value of the sender of the signal.

`<RULE VARIABLE> -> <PARAMETER NUMBER>`

Returns the value of the specified signal parameter. The `siexists` or `siall` predicate that defined the rule variable must also include a signal type specification.

`<RULE VARIABLE>`

Returns the signal value of `<RULE VARIABLE>`, which must be a rule variable bound to a signal in a `siexists` or `siall` predicate.

Global Functions

`maxlen( )`

Gives the length of the longest input port queue in the system.

`instno( [<PROCESS TYPE>] )`

Returns the number of instances of type `<PROCESS TYPE>`. If `<PROCESS TYPE>` is excluded the total number of process instances is returned.

`depth( )`

Gives the depth of the current system state in the behavior tree/state space.

SDL Literals

`<STATE ID>`

The name of an SDL state.

`<PROCESS TYPE>`

The name of a process type.

`<PROCESS INSTANCE>`

A process instance identifier of the format `<PROCESS TYPE>:<INSTANCE NO>`, e.g. Initiator:1.

`<SIGNAL TYPE>`

The name of a signal type.

`null`

SDL null process instance value

```
env
```

Returns the value of the process instance in the environment that is the sender of all signals sent from the environment of the SDL system.

```
<INTEGER LITERAL>
true
false

Autolink Configuration Syntax

An Autolink configuration is created with the command Define-Autolink-Configuration. The syntax of an Autolink configuration is expressed below in EBNF format.

```
<Start>          ::= "Define-Autolink-Configuration"
                     <Configuration>
                     "End"

<Configuration> ::= { <TransRule> | <TSStructureRule> |
                      <ASPTypesRule> | <PDUTypesRule> |
                       <StripSignalsRule> <Function> }*

<TransRule>    ::= "TRANSLATE"
                   [ "SIGNAL" ] <AlternativeListOfTerms>
                   <TransRuleIf>* [ <TransRuleNoIf> ]
                   "END"

<TransRuleIf> ::= "IF" <Conditions> "THEN"
                   <TransRuleNoIf> "END"

<TransRuleNoIf> ::= { "CONSTRAINT"
                      <TransRuleConstraint> |
                      "TESTSUITE"
                      <TransRuleTestSuite> }*

<TransRuleConstraint> ::= { "NAME" <Term> |
                            "PARS" <ParameterList1> |
                            "MATCH" <ParameterList1> }*

<TransRuleTestSuite>  ::= { "CONSTS" <ParameterList1> |
                            "PARS" <ParameterList2> }*

<ParameterList1> ::= <Parameter1> { "," <Parameter1> }*

<Parameter1>     ::= "$" <Number> [ "=" <Term> ]

<ParameterList2> ::= <Parameter2> { "," <Parameter2> }*

<Parameter2>     ::= "$" <Number> [ "=" <Term> ]
                     [ "/" <Term> ]

<TSStructureRule> ::= "PLACE" <AlternativeListOfTerms>
                      <TSStructureRuleIf>*
                      [ <TSStructureRuleNoIf> ]
                      "END"

<TSStructureRuleIf> ::= "IF" <Conditions> "THEN"
                        <TSStructureRuleNoIf> "END"

<TSStructureRuleNoIf> ::= "IN" <Term> { "/" <Term> }*

<ASPTypesRule>      ::= "ASP-TYPES"
```

```
                            <SequentialListOfTerms> "END"
<PDUTypesRule>          ::= "PDU-TYPES"
                            <SequentialListOfTerms> "END"
<StripSignalsRule>      ::= "STRIP-SIGNALS"
                            <SequentialListOfTerms> "END"
<Function>              ::= "FUNCTION" <Identifier>
                            <Mappings> "END"

<Mappings>              ::= <Mapping> { "|" <Mapping> }*

<Mapping>               ::= <Conditions> ":" <Term>

<Term>                  ::= <Atom> { "+" <Atom> }*

<Atom>                  ::= "$" <Number> | "@" <Number> |
                            <Text> | <Identifier> |
                            <FunctionCall>

<FunctionCall>          ::= <Identifier>
                            "(" <SequentialListOfTerms> ")"

<SequentialListOfTerms>     ::= <Term> { "," <Term> }*

<AlternativeListOfTerms>    ::= <Term> { "|" <Term> }*

<Conditions>            ::= <Condition> { "AND" <Condition> }*

<Condition>             ::= <Term> { "==" | "!=" } <Term> |
                            "TRUE"
```

For a detailed description of the semantics, see "Syntax and Semantics of the Autolink Configuration" on page 1471 in chapter 35, *TTCN Test Suite Generation*.

State Space Files

Using the command Save-State-Space, a Labelled Transition System (LTS) representing the state space generated during exhaustive exploration is saved to a file.

Syntax

The syntax of the generated LTS is (using BNF notation):

LTS	::=	‘START:’ StateId ‘LTS:’ TransList* ‘STATES:’ State*
TransList	::=	StateId ‘:’ Event ‘-’ [StateId] (‘,’ Event ‘-’ [StateId])* ‘;’
Event	::=	(Output | Input | Timeout | Internal)
Output	::=	‘o(’ Signal ‘,’ ‘"’ GraphRef ‘"’ ‘)’
Input	::=	‘i(’ Signal ‘,’ ‘"’ GraphRef ‘"’ ‘)’
Timeout	::=	‘t(’ Timer ‘)’
Internal	::=	‘x’
State	::=	‘*****’ StateId ‘*****’ Process*
Process	::=	ProcessName ‘:’ InstanceNo ‘State:’ StateName (VariableName ‘:’ Value)* ‘Input port:[’ Signal (‘,’ Signal)* ‘]’ ‘Timers:{’ Timer (‘,’ Timer)* ‘}’ Procedure*
Procedure	::=	‘Procedure’ ProcedureName ‘:’ ‘State:’ StateName (VariableName ‘:’ Value)*
Signal	::=	SignalName ‘(’ ParameterName (‘,’ ParameterName)* ‘)’
Timer	::=	TimerName ‘(’ ParameterName (‘,’ ParameterName)* ‘)’

Lexical Elements

The lexical elements used above are:

StateId	An integer denoting a system state.
GraphRef	A string denoting a graphical reference to an SDL diagram.

ProcessName	An id denoting a process type.
InstanceNo	An integer denoting a process instance.
StateName	An id denoting a state in an SDL process graph.
VariableName	An id denoting a process variable.
Value	A string denoting a value for a variable of any defined SDL type.
ProcedureName	An id denoting a procedure.
ParameterName	An id denoting a signal or timer parameter.

Example 341: A Generated LTS

A simple example of a generated LTS:

```
START:121
LTS:
2456:o(sig1(true,3),"5 P1 1 80 100")-43567;
43567:i(sig2(1),"5 P1 1 80 120")-2467,
      i(sig2(2),"5 P1 1 100 120")-98567;
121:x-2456;
2467:x-27645;
98567:x-27645;
27645:i(sig2(1),"5 P1 1 80 120")-2467,
      i(sig2(2),"5 P1 1 100 120")-98567;
STATES:
***** 121 *****
P1:1 State:idle Parent:null Offspring:null
Sender:null i:0 Input port:[ ] Timers:{ }
***** 2456 *****
P1:1 State:idle Parent:null Offspring:null
Sender:null i:5 Input port:[ ] Timers:{ }
***** 43567 *****
P1:1 State:s1 Parent:null Offspring:null Sender:null

***** 2467 *****
P1:1 State:s1 Parent:null Offspring:null Sender:null
i:1 Input port:[ ] Timers:{ }
***** 98567 *****
P1:1 State:s1 Parent:null Offspring:null Sender:null
i:2 Input port:[ ] Timers:{ }
***** 27645 *****
P1:1 State:s1 Parent:null Offspring:null Sender:ENV
i:5 Input port:[ ] Timers:{ }
```

Restrictions

Restrictions on the SDL System

The restrictions on the SDL system that can be validated with the SDL Explorer are basically the restrictions imposed by the SDL to C compilers. See "Restrictions" on page 2753 in chapter 56, *The Cadvanced/Cbasic SDL to C Compiler* for more information.

In addition to these general restrictions, the following restrictions are specific to the SDL Explorer:

- Time is not represented in the state space explored by the explorer. This makes the behavior of "Now" expressions special. In the SDL Explorer, "Now" will always return 0.
- If user-defined types with dynamic memory allocation are used, the type must be implemented as a pointer to a data area. A function for freeing the memory must also be supplied. For more information, see "More about Abstract Data Types" on page 2704 in chapter 56, *The Cadvanced/Cbasic SDL to C Compiler*.
- In some cases there will be problems when the name of an entity (system, block, process, channel) is identical to another entity. A conflict will for example appear when producing names for instances in MSC diagrams.

Restrictions on Monitor Input

There following restrictions apply to monitor input:

- A parameter to a monitor command may not contain more than 1,000 characters.
- **On UNIX**, control characters of different types may terminate the validation program. `<Ctrl+C>`, `<Ctrl+D>`, and `<Ctrl+Z>` are typical characters that might terminate a validation program.

Restrictions on Dynamic Checks

There are a number of dynamic checks that are not performed at all or performed at the C level by the C runtime system. A C runtime error

will of course lead to the validation program being terminated. The following check is not made at the SDL level.

- Overflow of integer and real values are checked at the C level if the actual C system performs these checks. (These checks are likely not to be performed.)

Chapter 52 The SDL Explorer

Chapter

53 *Validating a System*

This chapters provides general information related to validation in the SDL Suite and describes the actions you perform when validating an SDL system.

For a reference to the SDL Explorer user interface, see chapter 52, *The SDL Explorer*.

How to use Autolink, a part of the SDL Explorer, is described in "Using Autolink" on page 1431 in chapter 35, *TTCN Test Suite Generation*.

Introduction

Application Areas

The SDL Explorer is a tool intended to support engineers involved in development of specifications or designs using SDL. It is designed to give the engineers a possibility to increase the quality of their work and to automate time-consuming tasks. It is focused on the following major application areas in the development process:

- It provides an automated fault detection mechanism that checks the robustness of the application and finds inconsistencies and problems in an early stage of development. This is often referred to as *validating* an SDL system. See "Validating an SDL System" on page 2417.
- When verifying the system against requirements, the Explorer provides a possibility to perform automatic verification of the requirements expressed using the MSC (Message Sequence Chart) notation. See "Verifying an MSC" on page 2430.
- When designing safety-critical or complex systems the Explorer provides a possibility to test specific properties of the design. See "Using Observer Processes" on page 2437.
- When developing TTCN test cases, the Autolink feature of the Explorer can be used to create and use MSC test purposes and to generate TTCN test cases. See "Using Autolink" on page 1431 in chapter 35, *TTCN Test Suite Generation*.

Structure of an SDL Explorer

An executable explorer is built up in the same way as a simulator. See "Structure of a Simulator" on page 2234 in chapter 50, *Simulating a System* for more information.

The same interactive monitor system as for a simulator is used, but the set of available commands differ. The graphical user interface to the explorer monitor, the *Explorer UI*, works in the same way as the Simulator UI, but the set of available command buttons differ. For a description of some other differences, see "The SDL Explorer User Interface" on page 2398.

Underlying Principles and Terms

The SDL Explorer is based on a technique called *state space exploration*, which is a well-known technique for automatic analysis of distributed systems. All state space exploration tools for SDL are based on the idea of an automatic generation of the reachable state space for the SDL systems.

For readers interested in a more detailed description of the possibilities given by state space exploration for validation of distributed systems (focused on protocols), an excellent description is given in [17], see "References" on page 2472.

Behavior Trees

The SDL Explorer operates on structures known as *behavior trees* or reachability graphs. A behavior tree is a tree structure that represents the behavior of an SDL system.

The nodes of the tree represent SDL *system states*. A system state is defined by:

- The process instances that are active
- The variable values of these processes
- The SDL control flow state of the process instances
- Any procedure calls (with local variables etc.)
- Signals (with parameters) that are present in the queues of the system
- Active timers
- Etc.

The edges between the nodes in the tree represent atomic SDL events that transfers the SDL system from one system state to another. Therefore, the edges are also called *behavior tree transitions*. They can be individual SDL statements like tasks, inputs, outputs, etc. but also complete SDL transitions, depending on how the Explorer is configured.

The size and structure of the behavior tree can thus vary and is determined by a number of Explorer options. These options affect the number of system states generated for an SDL transition, and the number of possible behavior tree transitions from a state in the tree.

State Space Explorations

The set of all system states represented by the behavior tree is called the *state space* of the system. By moving around in the behavior tree, the behavior of the SDL system can be explored and the system states reached can be examined. This is known as *state space exploration*, and it can be performed both manually and automatically.

> **Note:**
>
> The “children” of a node in the behavior tree are not generated until a state space exploration actually reaches that node, i.e., the tree is not a static structure generated when a explorer is started.

For each system state reached during state space exploration, a number of *rules* are checked to detect errors or possible problems in the SDL system. If a rule is violated, a *report* is generated to the user. By investigating the report and the system state where it was generated, the cause of the error can be determined.

States and Paths

The original start state of the system is called the *system start state*. It is the system state where the static process instances have been created but their initial start transitions have not been executed.

The *current state* is the system state that currently is under investigation. It is changed when manually navigating in the behavior tree, or when going to the system state where a report has been generated. Initially, it is set to the system start state.

The *current root* of the behavior tree can be any system state. A number of Explorer commands and features use it as a starting point of operation. Initially, it is set up to the system start state, also known as the *original root* of the behavior tree. If it is redefined, it is not possible to reach a state above the current root in the behavior tree without resetting it back to the original root.

A *path* between two states in the behavior tree can be denoted by a sequence of integers, each one indicating which transition was used to get between two states in the path. The *current path* is a path that is set up when manually navigating in the behavior tree, or when going to the system state where a report has been generated. When set up, it is the path between the current root and the current state. The current path is

changed when the Explorer moves to a state that is not part of the current path, e.g. when manually navigating to a system state outside of the current path. However, moving up and down along the current path does not change it.

Generating and Starting an SDL Explorer

There are two ways to generate and start a explorer:

- A quick way in one single step, adequate for most situations
- A more complex way in several steps, giving you complete control of the generation and start process.

In the following, the more complex way will be described first, to give a full understanding of the process. The quick way is described in "Quick Start of an SDL Explorer" on page 2395.

Generating an Explorer

The Explorer is implemented as a precompiled run-time kernel to the SDL to C Compiler. To start an Explorer for an SDL system, or a part of an SDL system, it is thus necessary to first generate an executable explorer. This is done from the Organizer.

To generate an executable explorer:

1. Select a system, block, or process diagram in the Organizer.
2. Select *Make* from the *Generate* menu. The Make dialog is opened.
3. Turn on the options *Analyze & generate code* and *Makefile*.
4. From the *Standard kernel* option menu, select *Validation*.
5. If you need to check the Analyzer options, click the *Analyze Options* button. In the dialog, set the options and click the *Set* button. For more information about these options, see "Analyzing Using Customized Options" on page 2618 in chapter 55, *Analyzing a System*.

6. Click the *Make* button.

   An explorer for the system is now generated in the current directory with the name `<system>_xxx.val` **(on UNIX)**, or `<system>_xxx.exe` **(in Windows)**, where the `_xxx` suffix is platform or kernel/compiler specific. The Status Bar of the Organizer reports the progress of the generation; the last message should be "Compiler done."

7. Open the Organizer Log window from the *Tools* menu and check that no errors occurred and that an explorer was generated.
   - If errors were found, correct them and repeat the generation process. See "Locating and Correcting Analysis Errors" on page 2624 in chapter 55, *Analyzing a System*.
   - If no explorer was generated, repeat the generation process, but click the *Full Make* button in the Make dialog instead.

Starting an SDL Explorer

An executable explorer can be run in two different modes; graphical mode and stand-alone mode (textual mode).

Graphical Mode

In graphical mode, the Explorer takes advantage of the graphical user interface and integration mechanism of the SDL Suite. A separate graphical user interface, the *Explorer UI*, is started, giving access to the monitor system through the use of menus, command buttons, etc.

To start an explorer in graphical mode:

1. Select *SDL > Explorer UI* from the Organizer's *Tools* menu. The graphical user interface of the Explorer is opened (see "The Graphical Interface" on page 2398).
2. Select *Open* from the Explorer UI's *File* menu. A File Selection Dialog dialog is opened.

   - Alternatively, click the *Open* quick button in the tool bar.
3. In the dialog, locate and select an executable explorer and click *OK*.

A welcome message is printed in the text area of the Explorer UI. The monitor system is now ready to accept commands. Please see "Supplying Values of External Synonyms" on page 2396 for some additional information that may affect the start-up.

Stand-alone Mode (Textual Mode)

In stand-alone mode, the Explorer uses the input and output devices currently defined on your computer, which provide a textual, command line based user interface. A very limited graphical support is provided when running the Explorer in this mode.

To start an explorer in stand-alone mode, the generated explorer is executed directly from the OS prompt, e.g.

```
csh% ./system_vla.val
```

A welcome message is printed on the terminal:

```
Welcome to SDL EXPLORER

Command :
```

The monitor system is now ready to accept commands. Please see "Supplying Values of External Synonyms" on page 2396 for some additional information that may affect the start-up.

> **Note:**
>
> **On UNIX**, before an explorer can be run in stand-alone mode, you must execute a command file from the operating system prompt. The file is called `telelogic.sou` or `telelogic.profile` and is located in the binary directory that is included in your `$path` variable.
> For csh-compatible shells: **`source <bin.dir>/telelogic.sou`**
> For sh-compatible shells: **`. <bin.dir>/telelogic.profile`**

Quick Start of an SDL Explorer

An explorer can also be generated and automatically started in graphical mode in one single step.

To quick start an explorer, click the *Explore* quick button in the Organizer's tool bar. The following things happen:

- An explorer is generated by using the explorer kernel that is specified in the Make dialog. (If no explorer kernel is specified, a default explorer kernel is used.)

- The graphical Explorer UI is started. If an Explorer UI with the same explorer name is already open, this UI is reused. If another Explorer UI is open, a dialog is opened where you can select to start a new UI, or to reuse one of the existing UI's.
- The generated explorer is started from the Explorer UI.

It is possible to start an explorer for a part of an SDL system (a block or a process) by selecting the block/process and then clicking on the Explore button.

Restarting an SDL Explorer

An executing explorer can be restarted from the beginning to reset its state completely:

- In graphical mode, select *Restart* from the Explorer UI's *File* menu. (This is the same as opening the same explorer again.) A confirmation dialog is opened.
- In stand-alone mode, the explorer has to be exited with the Exit command and then executed from the OS prompt again.

Supplying Values of External Synonyms

The SDL system for the explorer may contain external synonyms that do not have a corresponding macro definition (see "External Synonyms" on page 2650 in chapter 56, *The Cadvanced/Cbasic SDL to C Compiler*). In that case, you will be asked to supply the values of these synonyms, either by selecting a file with synonym definitions or by entering each synonym value from the keyboard.

In stand-alone mode, the following prompt appears:

```
External synonym file :
```

Enter the name of a file containing synonym definitions, or press `<Return>` to be prompted for each synonym value.

In graphical mode, a file selection dialog is opened. Either select a file (`*.syn`) containing synonym definitions, or press *Cancel* to be prompted for each value in a separate dialog. In this dialog, the name and type of the synonym is shown together with an input text field. You can now do one of the following:

- Enter a value and click *OK*.
- Click *Default value* to get a “null” value for the synonym type entered in the input field. Accept or edit this value and click *OK*.
- Click *Cancel* to give the synonym a “null” value (without the possibility to edit the value).
- Click *Cancel all* to give the synonym and all following synonyms a “null” value.

If a synonym file is selected in the file selection dialog, this file is also used when the explorer is restarted. (If you by any chance want to use another synonym file you have to start a new Explorer UI.)

If you set the environment variable `SDTEXTSYNFILE` to a file before starting the SDL Suite, this file will automatically be used. If `SDTEXTSYNFILE` is set to “[[“ all synonyms are given “null” values.

The syntax of a synonym file is described in “Reading Values at Program Start up” on page 2651 in chapter 56, *The Cadvanced/Cbasic SDL to C Compiler*.

Actions on Explorer Start-up

When an explorer is started, the static process instances in the system are created, but their initial transitions are not executed.

In some cases when the Explorer is started, a message is printed that it is not possible to generate test values for all sorts and/or signal parameters. This has to do with the automatic test value generation mechanism that is used in the Explorer. It happens if there are signals coming from the environment of the SDL system that have parameters of a sort that the test value generation cannot handle. To overcome this, define some test values for the sort that the Explorer is complaining about. See “Defining Signals from the Environment” on page 2445 for more information.

The SDL Explorer User Interface

Monitor commands in the Explorer are issued in the same way as in the Simulator, since the same monitor system is used in both tools. Also, the Explorer UI works in the same way as the Simulator UI. Please see "Issuing Monitor Commands" on page 2241 for more information.

The Explorer UI can be customized in the same way as the Simulator UI. Please see "Customizing the Simulator UI" on page 2249 for more information.

However, there are a few differences between the user interface of the Explorer and the Simulator. These differences are described below.

Activating the Monitor

The explorer's monitor system becomes active when the explorer is started, when a transition executed during navigation has completed, when an automatic state space exploration has finished, when a report with Abort action has been generated, or when an automatic state space exploration is manually stopped.

These conditions are listed in greater detail in "Activating the Monitor" on page 2299 in chapter 52, *The SDL Explorer*.

The Graphical Interface

The graphical Explorer UI is illustrated in the figure below:

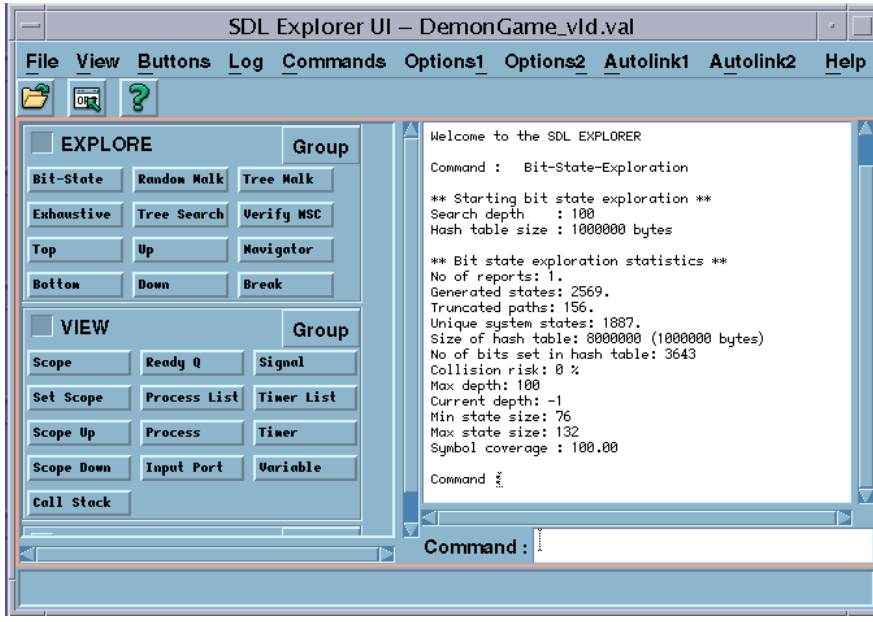

Figure 487: The Explorer UI

Since the set of available commands differ between the Simulator UI and the Explorer UI, the set of button modules and command buttons is also different. In addition, three extra menus are available in the menu bar: *Commands Menu*, *Options1 Menu* and *Options2 Menu*. The menu choices in these menus are similar to the command buttons in the sense that each of them correspond to a certain monitor command.

The Command and Watch Windows

The Command and Watch windows are also available in the Explorer UI. The difference compared to the Simulator UI is:

- In the Command window, the default commands that are executed are “List-Process -” and “Print-Trace 1”.

Navigating in the State Space

The SDL Explorer provides the possibility to interactively walk around in the behavior tree of an SDL system. This is also known as manually *navigating* in the state space. A dedicated graphical tool, the Navigator, is available in the Explorer to facilitate manual navigating. However, it is possible to use manual navigation without using the Navigator tool.

The Navigator is intended to be used in three different situations:

1. When learning how a state space exploration tool like the Explorer works, the Navigator is a convenient tool for interactively investigating the behavior tree of an SDL system.
2. When using automatic state space exploration, there is sometimes a need to start the exploration from a different starting point than the system start state of the SDL system. In this case, the Navigator can be used to walk to a suitable system state, from which the automatic exploration can be started.
3. When investigating a report generated during automatic exploration, the Navigator can be used to check the alternative behaviors that are possible on the path to the reported situation.

To open the Navigator tool, use one of the following methods:

- Select *Show Navigator* from the *Commands* menu.
- In the button module *Explore*, click the *Navigator* button.
- Enter the command Show-Navigator.

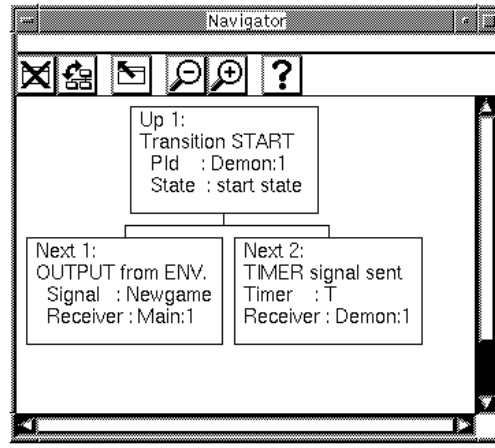

Figure 488: The Navigator

The boxes shown in the Navigator represent the behavior tree transitions leading to and from the current system state. They are labelled *Up 1* (for the transition leading to the current state) and *Next 1*, *Next 2*, etc. (for the transitions leading from the current state).

To close the Navigator, click the *Close* quick button in the tool bar.

Moving Up in the Behavior Tree

To move one level up in the behavior tree, use one of the following methods:

- In the Navigator, double-click the Up node, or select *Up 1* from the pop-up menu available on the Up node.
- In the button module *Explore*, click the *Up* button.
- Enter the command Tree-Walk 1.

To move more than one level up in the behavior tree at once:

- Enter the command Tree-Walk, followed by the number of levels to move up.

To move to the current root of the behavior tree, i.e. the top of the current path, use one of the following methods:

- In the Navigator, select *Up to top* from the pop-up menu available on the Up node.
- In the button module *Explore*, click the *Top* button.
- Enter the command Top.

Moving Down in the Behavior Tree

To see the possible Next nodes when the Navigator is not opened, enter the command List-Next. This gives a numbered list of all transitions leading from the current state.

To move one level down in the behavior tree, use one of the following methods:

- In the Navigator, double-click one of the Next nodes, or select *Goto* from the pop-up menu available on the Next nodes. This will follow the branch one step.
- Enter the command Next, followed by the number of the Next node, i.e. the number of the transition to execute.

To move more than one level down in the behavior tree at once:

- Enter the command Random-Down, followed by the number of levels to move down. For each level, a transition is chosen at random.
- Enter the command Continue-Until-Branch, or in the Navigator, select *Continue* from the popup menu available on the Next nodes. This will follow the branch several steps until there are more than one transition possible

Moving Along the Current Path

The *current path* can be seen as the path in the behavior tree that has been explored last. It is set up when going to a report (see "Going to a Report" on page 2416) and when interactively walking down the behavior tree.

The transitions making up the current path are labelled with three asterisks “***” in the nodes in the Navigator. However, no such marking is present when the transitions are listed with the List-Next command.

To move up along the current path, use the Up or Top commands as described in “Moving Up in the Behavior Tree” on page 2401 (above).

To move one level down along the current path, use one of the following methods:

- In the Navigator, double-click the Next node labelled with three asterisks “***”, or select *Goto* from the pop-up menu available on this node.
- In the button module *Explore*, click the *Down* button.
- Enter the command Down 1.

To move more than one level down along the current path at once, enter the command Down, followed by the number of levels to move down.

To move to the bottom of the current path, use one of the following methods:

- In the button module *Explore*, click the *Bottom* button.
- Enter the command Bottom.

Redefining the Current Root

The current root of the behavior tree is initially set up to the system start state. The current root is automatically redefined to the current state when using MSC verification (see “Verifying an MSC” on page 2430). It can also be redefined as an effect of changing explorer options (see “Affecting the State Space” on page 2459).

In addition, you can at any time redefine the current root to either the current state or back to the system start state. To do this, enter the command Define-Root. Select or enter *Current* to redefine the current root to the current state. Select or enter *Original* to redefine the current root to the system start state.

Going to a System State

When using the Explorer it is quite common that there is a need to go to a specific system state, for instance to be able to start an automatic state space exploration from this point. This section describe some possibilities to in an efficient way get to the wanted system state, called the *target state* below.

Using Manual Navigation

In many cases the simplest way is to use the Navigator tool or the navigation commands to interactively traverse the path to the target state. Manual navigation is described in "Navigating in the State Space" on page 2400.

Returning to an Already Reached State

It is possible to return to a state that has been reached in an earlier stage when using the Explorer. Three methods will be discussed:

- Using Path Commands
- Using the Command Log
- Using MSC Trace.

The benefit of the first two techniques is that the exact same target state will be reached. The drawback is that these techniques will not work as soon as either the SDL system or the state space options have been changed (see "State Space Options" on page 2466).

The benefit of the MSC technique is that it is less vulnerable to changes in the state space options or in the SDL system. The drawback is that the exact same target state may not be reached. We only know that the path to the reached system state will satisfy the generated MSC trace.

Using Path Commands

To go to the target state using path commands:

1. When in the target state, enter the command Print-Path. The path from the root state to the current state is printed. The path is a se-

quence of integers indicating which transitions must be chosen to get to the current state.

2. At a later stage, enter the command Goto-Path, followed by the path printed above.

Using the Command Log

To go to the target state using the command log:

1. Before navigating to the target state, select *Start Command Log* from the *Log* menu, or enter the command Command-Log-On. Specify a file name on which all subsequent monitor commands will be stored.
2. Navigate to the target state.
3. Select *Stop Command Log* from the *Log* menu, or enter the command Command-Log-Off. The command logging is stopped and the file is closed.
4. Return to the same state in which the command log was started.
5. Execute the commands stored in the file by selecting *Include Command Script* from the *Commands* menu, or enter the command Include-File. Select or specify the earlier file name.

Using MSC Trace

To go to the target state using MSC trace:

1. When in the target state, generate an MSC trace from the root state to the current state. Enter the command MSC-Log-File, followed by a file name.
2. Return to the root state by using the Top command.
3. Go to the end of the MSC trace by verifying the MSC. See "Verifying an MSC" on page 2430.

Using an MSC

If an MSC is created that describes the events leading to the target state, verifying this MSC gives a possibility to go to a system state that satisfies the MSC in an efficient way. It does not matter if the MSC is manually created, generated from the Simulator or from the Explorer itself (as discussed in "Using MSC Trace" on page 2405, above). However, the exact same target state may not be reached by this method. We only know that the path to the reached system state will satisfy the generated MSC trace.

Using a User-Defined Rule

If the target state can be described in terms of process states, variable values, etc., a convenient way to get to a state that satisfies the description is to use a user-defined rule (see "Using User-Defined Rules" on page 2455).

To go to a target state using a user-defined rule:

1. Define the rule describing the target state (see "Managing User-Defined Rules" on page 2456).
2. Define the report action for user-defined rules reports to be Abort (see "Report Action" on page 2464). This will cause an automatic exploration to stop as soon as a state is reached that satisfies the rule.
3. Start an automatic state space exploration (see "Using a Default Exploration" on page 2417).
4. Go to the state where the rule was satisfied and a report was generated (see "Going to a Report" on page 2416).

The benefit with this method is that it is fast and efficient, especially if the target state is on a considerable depth in the state space. The drawback is that sometimes there are shorter paths to the target state than the one that was automatically generated.

Tracing, Logging and Viewing Facilities

In the Explorer, the same kind of commands as in the Simulator are available for tracing the execution, logging the user interaction and examining the system. There are a few differences, described below.

Tracing the Execution

Textual Trace

In the Explorer, the same type of printed trace information is available for executed transitions as in the Simulator; see "Textual Trace" on page 2255. Unlike the Simulator, however, there is no command to start continuously printing the textual trace; instead, a command must be explicitly used whenever a trace is wanted.

- To print a textual trace for the transitions leading to the current state, enter the command Print-Trace, followed by the number of transitions to trace. That is, Print-Trace 1 prints the trace for the latest transition. The same information as for a full trace during simulation is printed.
- By default, the command Print-Trace 1 is executed in the Command window of the Explorer UI, i.e., a continuous trace is in practice available in graphical mode.

Graphical SDL Trace

Graphical trace of SDL symbols in the source GR diagrams is available. The graphical trace in the Explorer selects all symbols that were executed in the transition leading to the current state. This is different from the Simulator, where GR trace selects the **next** symbol to be executed.

- To enable or disable continuous graphical trace, enter the command SDL-Trace. This command toggles the graphical trace; the current state of the trace is printed after the command is executed. When the trace first is enabled, an SDL Editor is opened as soon as the next transition is executed.
- In the Explorer UI, the graphical trace can be controlled from the *Commands* menu. The command *Toggle SDL Trace* toggles the trace between enabled and disabled.

MSC Trace

MSC trace enables tracing of executed events in an MSC Editor. When the trace first is enabled, an MSC Editor is opened, showing the events executed up until the current state, and the current path is set up. After that, the trace is continuously updated in the MSC Editor as transitions are executed. This means that events are **added** when you navigate down the behavior tree, the selected event is **changed** when you navigate up, and the MSC is **redrawn** when you move outside the current path.

- To enable or disable continuous MSC trace, enter the command MSC-Trace. This command toggles the trace; the current state of the trace is printed after the command is executed.
- In the Explorer UI, the MSC trace can be controlled from the *Commands* menu. The command *Toggle MSC Trace* toggles the trace between enabled and disabled.

The MSC trace from the current root to the current state can also be saved on a log file, which later may be opened from an MSC Editor. To save such an MSC log, enter the command MSC-Log-File, followed by the file name. The MSC log file should be given the file extension `.mpr`.

Before an MSC trace is started, you may define what types of events that will be traced. See "MSC Trace Options" on page 2465 for more information.

Logging the User Interaction

The interaction between the user and the Explorer can be logged on file in exactly the same way as in the Simulator. See "Logging the User Interaction" on page 2278 in chapter 50, *Simulating a System* for more information.

Examining the System

The current state of the system can be examined in the same way as in the Simulator. The View commands available in the *View* module of the Explorer UI are generally the same ones as in the *View* module of the Simulator UI.

Current Process and Scope

Some of the commands used for examining the system operate on a specific process instance, the *current process*, identified by the current *scope*. A scope is a reference to a process instance, a reference to a service instance if the process contains services, and possibly a reference to a procedure instance called from this process/service (the *current procedure*).

The scope is automatically set by the explorer to the process instance that executed in the transition leading to the current system state. You may change the scope if you would like to examine another process, service or procedure instance.

- To print the current process/service scope, click the *Scope* button in the *View* module, or enter the command Scope.
- To set the current process/service scope:
  - Click the *Set Scope* button in the *View* module, or enter the command Set-Scope. This command takes one parameter, a process instance, and optionally if the process contains services, a second parameter which specifies a service name.
  - Select or enter the name of a process instance.
  - If the process instance contains services, select or enter the name of a service instance.
  - The scope is set to the specified process/service, at the bottom procedure call.
- To print the procedure call stack for the process/service instance defined by the current scope, click the *Call Stack* button in the *View* module, or enter the command Stack.
- To change the procedure scope within the current process/service scope, you can move the scope one step up or down in the procedure call stack. Click the *Up* or *Down* button in the *View* module, or enter the command Scope-Up or Scope-Down. Going up from a service leads to the process containing the service. To go down in a service within a process, select or enter the name of the service instance.

Commands to Examine the System

The available commands are shortly described below. See "Examining the System" on page 2264 in chapter 50, *Simulating a System* for more information.

- To list the process instances in the ready queue, enter the command List-Ready-Queue, or click the *Ready Q* button.
- To print overview information about process instances, enter the command List-Process, or click the *Process List* button.
- To examine a process instance, enter the command Examine-PId, or click the *Process* button. The process instance must be specified as the first parameter.
- To list all signal instances in the input port of a process instance, enter the command List-Input-Port, or click the *Input Port* button. The process instance must be specified as the first parameter.
- To examine a signal in the input port of a process instance, enter the command Examine-Signal-Instance, or click the *Signal* button. The process instance must be specified as the first parameter.
- To list all currently active timers, enter the command List-Timer, or click the *Timer List* button.
- To examine a timer instance, enter the command Examine-Timer-Instance, or click the *Timer* button.
- To examine a variable of a process instance, enter the command Examine-Variable, or click the *Variable* button. The process instance must be specified as the first parameter.

Performing Automatic State Space Explorations

This section describes how to perform an automatic state space exploration and how to examine the results. The application areas in which automatic state space exploration are used are further described in "Validating an SDL System" on page 2417, "Verifying an MSC" on page 2430, "Using Observer Processes" on page 2437 and "Using Autolink" on page 1431 in chapter 35, *TTCN Test Suite Generation*.

In the Explorer, three types of automatic state space explorations can be used, implemented as different algorithms:

- Bit state exploration, an efficient algorithm for reasonably large SDL systems.
- Random walk, a simple algorithm that can be used for very large SDL systems.
- Exhaustive exploration, an algorithm suited only for small SDL systems.

The characteristics of these algorithms are further described in "Configuring the SDL Explorer" on page 2458. They have the following in common:

- They start from the current system state, which means that you may have to navigate to a suitable start state before the exploration is started.
- They explore the state space down to a certain depth from the start state, to avoid exploring an infinite state space forever.

The performance and results of a state space exploration are also highly dependent on how the state space is configured. This is discussed in "State Space Options" on page 2466.

The most important monitor commands concerning state space explorations are available in the *Explore* module in the Explorer UI.

Executing an Exploration

The different types of explorations are started in the following way:

- To start a bit state exploration, enter the command Bit-State-Exploration, or click the *Bit-State* button.
- To start a random walk, enter the command Random-Walk, or click the *Random Walk* button.
- To start an exhaustive exploration, enter the command Exhaustive-Exploration (there is no button for this command).

> **Note:**
>
> The button *Verify MSC* starts a bit state exploration, configured to suit MSC verification. This is further described in "Verifying an MSC" on page 2430.

When the exploration is started, a message is printed stating the options used for this exploration type (see "Configuring the SDL Explorer" on page 2458):

```
** Starting bit state exploration **
Search depth    : 100
Hash table size : 1000000 bytes

** Starting exhaustive exploration **
Search depth : 100

** Starting random walk **
Depth       : 100
Repetitions : 100
```

By default, the exploration continues until it is finished, i.e., until the state space has been fully explored according to the exploration options. During the exploration, a status message is repeatedly printed after a certain number of transitions or states have been generated.

> **Note:**
>
> Depending on how an exploration is configured, it may take a considerable amount of time to finish!

To stop an exploration manually, click the *Break* button in the Explorer UI, or hit `<Return>` in stand-alone mode. A stopped exploration may

be continued by issuing the same exploration command again. You are then asked whether to continue the exploration from the state where it was stopped, or restart the exploration from the same start state as before.

When the exploration is finished or stopped, some exploration statistics are printed (see "Interpreting Exploration Statistics" on page 2413). By default, a tool called the *Report Viewer* is also opened (see "Examining Reports" on page 2414).

The Explorer always returns to the start state of the exploration when it is finished or stopped.

Rules Checked During Exploration

During state space exploration, a number of rules are checked to detect errors or possible problems in the SDL system. If a rule is satisfied, a report is generated to the user.

The rules are used to find design errors, typically caused by unexpected behaviors of the SDL system. Often the errors are caused by events happening at the same time in different parts of the system, for example when a signal is received from the environment of the system at the same time as a timer expires. So-called signal races are often part of the error situations that are found.

Apart from the predefined rules, an additional rule can be defined by the user to check for other properties of the system. See "Using User-Defined Rules" on page 2455 for more information.

Interpreting Exploration Statistics

The different exploration algorithms print somewhat different statistics. The important statistics to note are the following:

- `No of reports: x`
  The number of error situations found. How to investigate the reports are described in "Examining Reports" on page 2414.

- `Truncated paths: x`
  The number of times the exploration reached the maximum search depth. The execution path is at that stage truncated and the exploration continues in another state. If this value is greater than 0, parts

of the state space have not been explored. However, this is a normal situation for SDL systems with infinite state spaces.

- `Collision risk: x`
  For bit state explorations, the risk (in percent) for collisions in a hash table used to represent the generated system states (see "Bit State Exploration Options" on page 2460). This value should be **very** small, 0-1%; otherwise, the size of the hash table may have to be increased. If collisions occur, some execution paths may be truncated by mistake.

- `Current depth: x`
  The search depth reached at the moment the exploration was finished or stopped. If this value is -1, the exploration finished by itself. If the depth is greater than 0, the exploration was stopped. In this case, it may be continued from this depth, as described in "Executing an Exploration" on page 2412.

- `Symbol coverage: x`
  The percentage of the SDL symbols in the system that have been reached during the exploration. If this value is less than 100, parts of the system have not been explored.

What actions to take depending on the printed statistics is discussed in "Validating an SDL System" on page 2417.

Examining Reports

When an exploration has been performed, the reported error situations should be examined. A dedicated graphical tool, the Report Viewer, is available in the Explorer to facilitate the report examination. However, it is possible to examine the reports without using the Report Viewer.

The Report Viewer is by default automatically opened when an exploration has been performed. To open the Report Viewer manually, either select *Show Report Viewer* from the *Commands* menu, or enter the command Show-Report-Viewer.

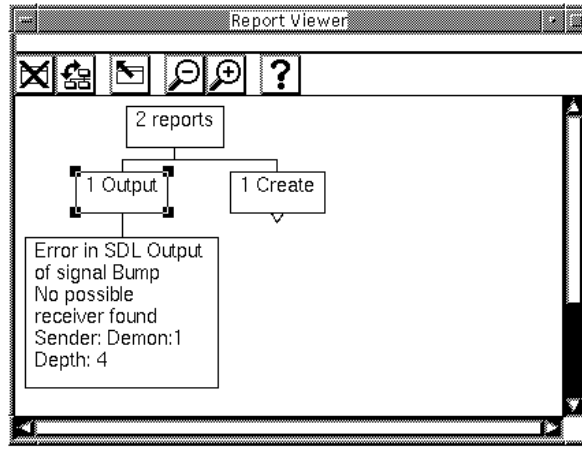

Figure 489: The Report Viewer

The nodes in the Report Viewer are structured in three levels and show, from top to bottom:

- The total number of generated reports
- The different types of reports (errors) and the number of reports of that type
- The actual reports with error message and trace information, and the exploration depth where the error was generated (this level of the tree is by default collapsed).

To close the Report Viewer, click the *Close* quick button in the tool bar.

To list the reports when the Report Viewer is not opened, enter the command List-Reports, which prints a numbered list of all reports.

Changing the Displayed Structure

Generally, to expand or collapse a node in the Report Viewer, double-click the node or select *Expand* or *Collapse* from the popup menu available on the nodes. This works for the top node and the report type nodes; for report nodes, see "Going to a Report" on page 2416 (below).

To show the whole report structure, select *Expand Substructure* from the popup menu available on the top node. To collapse the whole struc-

ture, select *Collapse* from the same pop-up menu, or double-click the expanded top node.

To switch between a tree structure and a list structure, click on the *Structure* quick button. The list structure makes it possible to easier see the different reports and report types when a large number of reports have been found.

Going to a Report

When "going to a report," the Explorer goes to the system state where the report was generated. You can then examine the reported situation further.

To go to a report using the Report Viewer:

1. Expand the report structure to show the desired report node.
2. Double-click the report node, or select *Goto* from the pop-up menu available on the report node.

To go to a report using monitor commands:

1. List the reports by entering the command List-Reports, and note the number of the desired report.
2. Enter the command Goto-Report, followed by the report number.

After going to a report, the Navigator tool is updated and the current path is set up. You can walk along the path to the error by using the Navigator; see "Moving Along the Current Path" on page 2402.

By default, an MSC Editor is also opened, showing the MSC trace from the current root to the state where the report was generated.

Validating an SDL System

This section describes how to use the automatic state space exploration facilities in the Explorer to look for inconsistencies and design errors in an SDL system. The idea is essentially to test the robustness of the application, the responses to unexpected situations. Essentially the validation is an attempt to answer questions like:

- What happens if a user does not press the buttons in the order assumed by the designer?
- What happens if the scheduling algorithm of the operating system that supports the application is changed?
- What happens if the environment happens to send an input to the system at the same time as a timer expires?

...and all other questions the designer never ever would imagine.

It is assumed that the SDL system is of moderate size and complexity; techniques for validating large SDL systems are described in "Validating Large Systems" on page 2422.

Using a Default Exploration

When you are to use the Explorer to try finding errors in a new SDL system for the first time, you are advised to start a bit state exploration using the default options.

To validate a system opened in the Explorer:

1. If you already have executed commands for the opened explorer, you should reset the explorer. Enter the command Reset, or click the *Reset* button in the *Explore* module. This is especially important if you earlier have loaded an MSC into the Explorer.
2. You should also make sure you use the default state space and exploration options. Enter the command Default-Options, or click the *Default* button in the *Explore* module.
3. Start a bit state exploration (see "Executing an Exploration" on page 2412). Let the exploration run for at least 10-20 minutes.
4. If the exploration has not finished by itself, stop it manually (see "Executing an Exploration" on page 2412). The Report Viewer is

opened and the exploration statistics is printed. Note especially what the symbol coverage is.

5. Use the Report Viewer to go to each of the reported situations (see "Examining Reports" on page 2414). Navigate along the current path to the report and use the tracing and viewing facilities to examine the report.

6. If you find errors in the system, you may decide to correct them immediately. In that case, generate a new explorer for the corrected system and rerun the validation, as described above. Otherwise, you should check if the validation is to be considered finished (see below).

Determining if the Validation is Finished

When all reports have been checked and the found errors possibly have been corrected, the next question arises: When are we finished validating the system? To answer this question, look at these aspects:

- What was the symbol coverage reported in the statistics after the automatic exploration?
- Did the exploration finish by itself or was it stopped by the user?

The following possibilities now exist:

1. The symbol coverage is 100% and the exploration finished by itself.

   All symbols have been executed and furthermore most orderings of the possible actions have been tested. In this case it is probably not worthwhile continuing the validation; you may consider it finished.

   However, not all orderings of possible actions have been tested, since the search may have been truncated, collisions may have occurred in the hash table, and more orderings are possible by configuring the state space exploration differently. If you want, you can change the explorer options and start a new exploration (see "Using Advanced Validation" on page 2421 and "Configuring the SDL Explorer" on page 2458).

2. The symbol coverage is 100% but the exploration was manually stopped.

In this case, it may still be worthwhile to continue the exploration until it finishes by itself. More reports may be generated, as there are still orderings of the possible actions that have not been executed.

3. The symbol coverage was less than 100%.

   Parts of the system have never been reached during the exploration. In this case, the validation cannot be considered finished, even if the exploration finished by itself. The reasons and possible solutions for low symbol coverage are discussed next.

Handling Low Symbol Coverage

If the symbol coverage after an exploration is 100%, all parts of the system have been executed at least once. If the symbol coverage is less than 100%, the possible reasons why parts of the state space have not been reached are listed below.

- The exploration was manually stopped before all symbols were reached.

  In this simple case, you should continue the exploration until it finishes by itself.

- The test values were inappropriate.

  Test values are used to define the set of possible signals from the environment. The automatically generated test values may not suit all SDL systems. This may for example cause the execution to never execute one branch of a decision statement. To overcome this problem, redefine the test values for the appropriate signal parameter. For more information on test values, see "Defining Signals from the Environment" on page 2445.

- The exploration was pruned after a report.

  In most cases the Explorer will *prune* the exploration of a particular path as soon as a report has been found, i.e., the exploration will not continue beneath the state in question. If you have examined such a report and has decided not to do anything about it, the Explorer will still prune the search when it finds the report the next time. To overcome this problem, change the report action for this particular report type from *prune* to *continue*. See "Configuring the SDL Explorer" on page 2458 for more information.

- Some parts of the system are, in fact, unreachable.

  If some parts of the SDL system are not reachable at all, it may be an indication that there is a design error in the system.

- There are problems with timer expirations.

  The explorer is by default configured in a way that tries to reduce the size of the state space. It will always try to execute internal actions (e.g. tasks, decisions, internal input and outputs) before any timers are allowed to expire. The assumption is that the system will always execute fast enough to ensure that no timers will expire (the timers may of course expire when waiting for input from the environment). To make a more complete test of this type of situation, see "Using Advanced Validation" on page 2421.

- The search depth was too small.

  The default search depth is 100. This may not be enough for some systems, e.g. a system with a very long initialization phase. In some cases, it is possible to overcome this problem simply by increasing the search depth (see "Configuring the SDL Explorer" on page 2458). However, the techniques discussed in "Validating Large Systems" on page 2422 are often more suitable.

- The state space is too big.

  Many SDL systems of reasonable complexity quite simply have state spaces that are too big; it is not possible to explore the entire state space in one exploration. Characteristic for this situation is a low symbol coverage, truncated paths, and either manually stopped exploration or a high (>10%) collision risk. This situation is discussed in "Validating Large Systems" on page 2422.

To find out which parts of the system that have not been reached, a tool called the Coverage Viewer is used. To start the Coverage Viewer, select *Show Coverage Viewer* from the *Commands* menu, or enter the command Show-Coverage-Viewer. If the symbol coverage was less than 100%, the Coverage Viewer will display a tree structure representing the parts of the system that have not been executed.

Using Advanced Validation

The default options for the state space exploration, in particular the options that define the structure of the state space, are optimized to give good results for a first validation of a system. They are intended first of all to test for internal inconsistencies in the SDL system and to get a good process graph coverage. This assumes a reasonably “nice” environment, i.e., the environment only sends signals when nothing can happen internally in the system.

This has the benefit of reducing the size of the state space while still preserving a good process graph coverage. The drawback is that some error situations are never detected. One particular class of errors that never will be detected using the default options can be characterized as signal races caused by signals sent from the environment, or timer expirations that happen at the same time. An example is a situation where a communication protocol ends up in an inconsistent system state when two connect requests are sent to the different access points at the same time.

To detect these types of errors it is necessary to change the options and perform a second set of explorations for the SDL system. The suitable settings of the options are called *advanced options.* When using these values for the options, the state space will get very large for most SDL systems. It is thus usually not possible to get a complete coverage of the state space, even if some of the techniques described in “Validating Large Systems” on page 2422 have been used. To anyway be able to get good results, the best strategy is to use the random walk algorithm when exploring the state space. See “Using Random Walk Exploration” on page 2428 for more information.

To set advanced options, click the *Advanced* button in the *Explore* module. In stand-alone mode, you have to enter a number of commands to achieve the same result; see “Setting Advanced Options” on page 2471 for information on which commands to use.

For a more in-depth explanation of the state space options, see “State Space Options” on page 2466.

Validating Large Systems

This section discusses various techniques that are useful when designing and validating large SDL systems. A large system is, in this context, a system that has a state space that is too large to be completely explored using one automatic state space exploration. The techniques are pragmatic and intended to give a reasonable chance of finding any errors even though the complete state space is not searched.

The following techniques are discussed:

- *Decomposed Exploration*
- *Using MSCs to Limit the Search*
- *More Efficient Bit-State Exploration*
- *Reducing the State Space Size*
- *Using Random Walk Exploration*
- *Incremental Validation*.

Decomposed Exploration

The idea when using decomposed explorations is to use a number of reasonably small explorations instead of one big exploration. Quite often the behavior of an SDL system can be divided into a number of “phases” or “features.” The idea is to explore each of these phases or features separately. The benefit with this approach is that it is a lot easier to explore the different phases separately than trying to explore the combination of all phases. The drawback is that errors that are caused by an interaction between different phases or features are not found. However, for large SDL systems it is sometimes the only possible method that at least can give a complete symbol coverage.

The process of finding which and how many partial explorations that are necessary is a combination of an iterative process and a planning issue where the possible features and phases that can be subject to a partial exploration are identified. If an incremental design process is used it is often possible to use the different iterations to guide the choice of partial explorations; compare with “Incremental Validation” on page 2429.

A common strategy used to find the needed partial explorations is essentially the following:

1. Start an exploration from the system start state.
2. Check all reports and correct the errors in the system. Generate a new explorer and make another exploration.
3. When all found reports have been fixed, check the symbol coverage. If the coverage is 100%, the validation is finished; otherwise, continue with the next step.
4. Use the Coverage Viewer to check which parts of the SDL system that need more testing.
5. Go to a suitable system state and start a new exploration from there.
6. Repeat the process until the symbol coverage is 100%.

There are two issues of this strategy:

- Where to start each partial exploration.
- How to limit each partial exploration.

Where to Start a Partial Exploration

The problem of identifying where to start a new exploration is of course system dependent and requires knowledge of the SDL system. The tool to use in this case is the Coverage Viewer, which shows exactly what parts of the SDL system that have been executed during the exploration and what parts have not been executed. Once a system state has been chosen the next issue is how to get there in the Explorer. There are number of possible ways to do this; see "Going to a System State" on page 2404.

How to Limit a Partial Exploration

The next problem is to limit each partial exploration to the intended part of the state space. There exists a number of factors which can be used to influence the extent of an exploration:

- The search depth
- The signals from the environment
- User-defined rules

The search depth is the simplest limiting factor to use. By reducing the search depth, e.g. to 10 or 20, the size of the exploration will of course be considerably reduced compared to the default depth of 100.

By changing the list of signals that can be sent from the environment it is possible to control which parts of the system that will be exercised by an exploration. For example, if we are interested in testing the data transfer phase of a connection-oriented protocol specification, a good strategy would be the following:

- Go to a system state where the connection is established.
- Define the signals from environment to be only the signals relevant for the data transfer, and start the exploration. For a description of how to define and remove signals from the list of signals that can be sent from the environment, see "Defining Signals from the Environment" on page 2445.

User-defined rules also give a possibility to limit the extent of an exploration. Define a rule that matches the system states where the exploration should be pruned and check that the report action for user-defined rules is to prune the search. For example, the rule `state(initiator:1)=idle` would prune the exploration whenever the initiator process entered the state *Idle*. User-defined rules are described in "Using User-Defined Rules" on page 2455.

Using MSCs to Limit the Search

Another possibility that sometimes is useful to control the exploration of the state space is to use MSCs to guide the exploration. This is particularly useful for SDL systems with a design that uses restrictions on the possible behavior of the environment of the system. It might, for example, be known that the signals A, B and C always will come in this order from the environment of the system. In this case it is not interesting to analyze what will happen if the signals will come in a different order.

An MSC can be loaded to guide the search by using the command Load-MSC. Once an MSC is loaded, both interactive navigation in the state space, e.g. by using the Navigator, and automatic exploration will only search the parts of the state space that correspond to the loaded MSC.

This means that if you want to go back to normal exploration, you have to clear the loaded MSC by using the commands Clear-MSC or Reset.

Note how the test values are used when an MSC is loaded. It is allowed to leave out parameters to messages in the MSC. If a parameter is left out on a signal from the environment, the test values are used to determine the parameter values that are actually sent to the system. This is a useful feature when using MSCs to limit the search. See section "Verifying an MSC" on page 2430 for more details.

Another useful hint when using MSCs is to always use system level MSCs to guide the state space exploration. A system level MSC will allow a larger part of the state space to be explored than a block or process level MSC.

An MSC loaded into the Explorer must comply with some requirements; see "Requirements for MSC Verification" on page 2436.

More Efficient Bit-State Exploration

The bit-state search uses a hash value based algorithm to store the state space that is traversed. Unfortunately the computation of hash values from a system state is an expensive operation and most of the execution time in a bit-state search is spent calculating hash values. The execution time for the hash algorithm is in most situations proportional to the size of each system state. The max and min system state size used by the hash algorithm is included in the statistics printed after each bit state search and should be checked if the search is slow. (See "Bit-State-Exploration" on page 2301).

If the size of a system state is big (> 10,000 bytes) the bit state execution of the explorer will be fairly slow. In these cases it might be worthwhile to try to optimize the performance by reducing the state size that the explorer uses when computing hash values. This can be done by informing the explorer to skip a number of variables when computing hash values. The explorer includes a command Define-Variable-Mode that is intended for this purpose. (See "Define-Variable-Mode" on page 2324.) For example the command:

```
define-variable-mode monitor subscrTab skip
```

will make the explorer skip all `subscrTab` variables in `monitor` processes.

A typical example of where this feature is useful is if the system includes a big array (or other big data structure) that is initialized at the start up of the system and that after the initialization is known to be con-

stant in the part of the state space that is explored. The correct way to take advantage of this in the explorer is to:

1. Go to a system state where the array is initialized. (See "Going to a System State" on page 2404 for more info about how to navigate in the state space.)
2. Redefine the root to the current state. (See "Define-Root" on page 2319.)
3. Change the mode of the table variable to "Skip".
4. Start the bit-state exploration.

Using this strategy it is possible to considerably increase the performance of the explorer.

Another situation where the variable mode can be changed to "Skip" is when there are variables in the system that is known not to have any influence on the dynamic behavior of the system. See "Variables Not Influencing the Dynamic Behavior" on page 2428.

Reducing the State Space Size

There is a number of ways to reduce the state space that is necessary to explore by using knowledge and assumptions about the SDL system. Usually this is based on the fact that the state space of an SDL system contains various "sub state spaces" that are equivalent except for some detail, which is not very interesting for the purpose of the validation. Some examples of such details are:

- The value of local variables
- The number of instances of process types
- The size of large data structures.
- Variables that do not influence the dynamic behavior.

Local Variable Values

An example of the way local variable values influence the size of the state space is the following: Consider a situation where a process contains an integer variable that counts the number of times a particular signal comes from the environment, and then replies with this number when requested to do so from the environment. It is obviously not espe-

cially interesting to try to investigate the behavior of the SDL system for all possible values of this local variable. Instead a reasonable set of values should be selected and the state space exploration guided by this selection.

A user-defined rule (see "Using User-Defined Rules" on page 2455) provides an efficient means to reduce the size of the state space by putting restrictions on variable values. In the example above a reasonable restriction might be that we only would like check what happens the first three times the variable is increased. A rule that expresses this is:

```
proc:1->var < 4;
```

Once this rule is defined and the report action for user-defined rule violation is set to Prune (which is the default), only the interesting parts of the state space are explored.

Number of Process Instances

Another issue is the number of process instances that are used for each process type. If the number is large and all of them do the same thing, for example by modeling different connections in a connection oriented protocol, it is probably not very useful to try to explore the combination of all instances. Instead, it is better to restrict the number of instances allowed in the exploration. This can be achieved with the command Define-Max-Instance (see "Maximum Number of Instances" on page 2470). If preferred, it is also possible to use a user-defined rule or an observer process to achieve the same result.

Size of Large Data Structures

A third area where the explorer performance is reduced is when large data structures, e.g. arrays, are used in the SDL system. A large data structure has two unfavorable effects on a state space exploration:

- The size of the reachable state space increases extremely rapidly as the size of the data structure increases.
- The efficiency of the bit state algorithm is decreased as the size of system states increase. Essentially the time to compute a new system state is linear to the size of the system states.

A good idea in this context is to, whenever possible, try to reduce the size of any large data structures in the SDL system before performing validation. Another possibility is to skip the variable when computing

hash values as described in "More Efficient Bit-State Exploration" on page 2425.

Variables Not Influencing the Dynamic Behavior

In many situations an SDL system contains a number of variables that does not have any impact on the dynamic behavior of the system. Essentially all variables that does not (directly or indirectly) have any influence on the path taken through a decision or the expression used when computing the receiver of a signal in output/RPC call will not influence the dynamic behavior of the system.

These variables can safely be ignored when performing a state space search. This can be accomplished by instructing the explorer to skip these variables using the Define-Variable-Mode command. (See "Define-Variable-Mode" on page 2324.) This will in many cases drastically reduce the size of the state space that the explorer needs to search and is an efficient way to improve the performance of the explorer.

Note that implicit variables like Sender/Parent/Offspring are also considered as variables in this respect. In particular Sender can be of interest to skip if it is not used, since it may change value every time a signal is received.

As an example, if Sender is not used in a process 'p' the following command will make the explorer ignore the Sender implicit variable when comparing two system states:

```
define-variable-mode p Sender skip
```

Using Random Walk Exploration

In some situations it is not possible to use the more elaborated techniques described in this section to cope with the problem of validating large SDL systems. The time and resources available for the validation may simply be too limited. A possible strategy to use when validating very large SDL systems is to use the random walk exploration strategy instead of the bit state algorithm.

The reason is that the random walk algorithm gives a possibility to get a partial exploration of the state space that is randomly chosen. Furthermore, the symbol coverage of the exploration is determined only by how long the exploration is allowed to run. The drawback with the algorithm is that if it is allowed to run for a long time, so that significant

parts of the state space already have been covered, there is no mechanism to avoid that already explored paths are explored once more.

How to start a random walk exploration is described in "Executing an Exploration" on page 2412. The random walk exploration algorithm is further described in "Random Walk Options" on page 2461.

The best way to get an idea of what has been tested when using random walk is to use the Coverage Viewer to check the symbol coverage. Even if this is not the same as the coverage of the system state space, it will show if there are large portions of the system that have not been reached by the exploration.

Incremental Validation

A common way to develop large SDL specifications and designs in practice is to use an incremental development strategy. First a base functionality is implemented and then various features are added in an incremental fashion. When this type of development process is used, a good way to plan the validation of the system is to let the different increments define the state space explorations that should be performed.

First a number of state space explorations are executed with different start states, and perhaps different test values. Together these explorations should give a good process graph coverage of the SDL system representing the base functionality.

For each increment that is added, a number of additional explorations is performed that will cover the new features in the SDL system.

It is also probably worthwhile to define command scripts that automatically can execute the various explorations that should be run to achieve a good process graph coverage. This makes it possible to run all of the various explorations in an straight-forward way for each new increment that is added to the system.

Verifying an MSC

MSC verification is one the major application areas for the SDL Explorer. This section describes how to use the Explorer to get started with MSC verification. It also gives some ideas of how to organize MSCs to be able to use common initialization MSCs and shows how to use batch files to achieve an efficient regression testing of an SDL system using MSC verification.

The first prerequisite for MSC verification is of course that we have an MSC that describes some desirable behavior that can be used to check the SDL system against. This MSC can be interactively created using the MSC Editor as part of a requirement analysis, but it is also possible to use MSCs created as execution traces in the SDL Simulator or the Explorer itself as input to the MSC verification.

It is worth noticing that the MSC does not have to be a process level MSC. It is possible to use MSCs where the MSC instances correspond to SDL blocks and systems, and even mixed MSCs where some instances correspond to processes and other to blocks.

There are some requirements on MSCs to be used for MSC verification; see "Requirements for MSC Verification" on page 2436.

The characteristics of the MSC verification algorithm is further described in "MSC Verification Options" on page 2462.

Basic MSC Verification

To verify an MSC for a system opened in the Explorer:

1. If necessary, go to a system state that corresponds to the start of the MSC to verify. If the MSC describes events from the start of the system, go to the system start state. You may have to reset the explorer first, especially if you already have an MSC loaded.
2. To start the MSC Verification, click the *Verify MSC* button in the *Explore* module, or enter the command Verify-MSC.
3. The MSC that you want to verify has to be specified. Either select it in the File Selection Dialog that appears (in graphical mode), or enter the name of the file on the command line (in stand-alone mode).

Note: Illegal characters in path name

Please note that verifying an MSC fails if the path name of the MSC contains "(" or ")".

4. A bit state exploration adapted to suit MSC verification is performed. After the exploration statistics, the result of the MSC verification is presented. If it was possible to find an execution trace that was consistent with the MSC, the text

   ```
   ** MSC <MSC name> verified **
   ```

   is printed, where <MSC name> is the name of the MSC that was checked. If it was not possible to find a consistent execution trace, the following text is printed:

   ```
   ** MSC <MSC name> NOT VERIFIED **
   ```

5. If the MSC was not verified, check the generated reports using the Report Viewer. There will be a number of "MSCViolation" reports. These reports identify the execution paths which violate the MSC, i.e., paths that contain events that are not part of the MSC. You may investigate these reports by using the method described in "Examining Reports" on page 2414.

6. If the MSC was successfully verified, there will be a "MSCVerification" report (there may also be a number of "MSCViolation" reports, but they can be discarded). You do not have to go to this report; the Explorer automatically goes to the state where the MSC was verified. This means that the current path is set up automatically.

7. To verify another MSC from the same start state, go to the top of the current path. It is now possible to directly start a new MSC verification, as described above (you do not have to reset the explorer).

Note:

When MSC verification is started, the current root of the behavior tree is redefined to the current state. This feature is used in the next section, "Verifying a Combination of MSCs Using High-Level MSCs" on page 2433. (It also means that you may have to reset the explorer to be able to reach the system start state again.)

Converting Instances Before Verification

Before an MSC is loaded into the Explorer for verification, it is possible to perform *instance conversion* of the MSC. Instance conversion will convert the name of an instance to another name.

This is useful if you want to verify some, but not all, instances in an MSC with an SDL system. For instance, you may have an MSC describing a complete system but an SDL system for only a part of the system. In this case, you can convert the not wanted instances to be considered as environment in the Explorer, without changing the MSC.

Note that if you have more than one instance representing the environment, the environment instances must be separated using channel names.

Instance conversion is performed before an MSC is loaded into the Explorer by entering the command "Define-Instance-Conversion FromString ToString" for each instance name to be converted. All instance conversions can be listed by entering the command List-Instance-Conversion, and all instance conversion can be cleared by entering the command Clear-Instance-Conversion.

Example 342 ----------

Consider an MSC with three process instances A, B and C. The SDL system specifies the behavior for instance A, but not for B or C. Before verifying the MSC, B can be converted to "channelB" and C to "channelC", where channelB is the existing SDL channel that will be used for communication between the existing A process and the non-existing process B, and channelC is the existing SDL channel that will be used for communication between the existing A process and the non-existing process C.

This is accomplished by entering the Explorer commands:

```
Define-Instance-Conversion B "channelB"
Define-Instance-Conversion C "channelC"
```

The MSC can now be verified.

Verifying a Combination of MSCs Using High-Level MSCs

The high-level MSC that are available in MSC'96 provide a very convenient possibility to describe how many small MSCs are combined to form a larger use case or scenario. The Explorer support verification of high-level MSCs.

As an example, consider a situation where we have an MSC "init" that will describe some initialization phase that is needed to set up the SDL system to some "connected" state from where two features are accessible. These features are described by the MSCs "datatrans" and "finish". If this would be a communication protocol, the "init" might be a connection establishment, and "datatrans" and "finish" successful data transfer and connection release. This situation could be described using the high-level MSC in Figure 490.

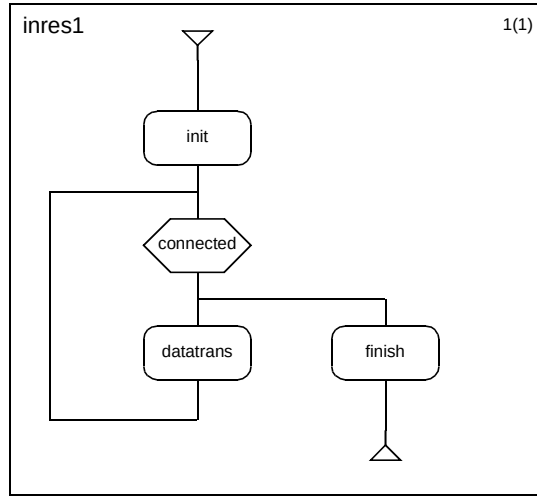

Figure 490 A high-level MSC

To check this combination of MSCs simply verify the "inres1" high-level MSC and the explorer will generate one MSC verification report for each sequence of "leaf MSCs" that can be verified. In this case there will be reports for "init, finish", "init, datatrans, finish", "init, datatrans, datatrans, finish", etc. until the max depth for MSC verification has been reached.

State of the SDL Explorer after MSC Verification

When an MSC verification has been done, the current state of the explorer is different depending on how many MSC verification reports has been found:

- If 0 or more than 1 MSC verification report has been generated the current state of the explorer is the system state where the MSC verification was started from.
- If exactly 1 MSC verification report was generated the current state is the state where this report was found.

This is in many cases useful when using MSCs to navigate to a specific system state, especially in combination with command scripts as described in the next section. Note that if the MSC that is verified is an "old style" MSC without high-level MSCs or MSC reference expressions then there will always be at most one MSC verification report and this type of MSCs is thus best when using MSCs for navigation.

Using Batch MSC Verification

An efficient test strategy when incrementally developing SDL systems is to use regression testing. A set of MSCs describe the requirements on the SDL system and new MSCs are incrementally added to the set when new features are implemented in the SDL system. Each time a new feature is implemented the resulting system should be tested against all the old MSCs as well as the new ones, to make sure that no new errors have been introduced.

To accomplish this using the Explorer the most efficient way is to use the command script facility in the Explorer. A command script is simply a text file containing a number of Explorer commands, usually one command per line. A command file can be loaded into the Explorer by selecting *Include Command Script* from the *Tools* menu, or by entering the command Include-File.

Example 343: Batch MSC Verification ––––––––––––––––––––––––––

A command script that when loaded will perform MSC verification for some requirements described as MSCs may look like:

```
log-on msc.log
verify-msc inres1.mrm
reset
verify-msc init2.msc
verify-msc inres2.mrm
quit
```

The command Log-On is used to store the output from the verification on the file `msc.log`.

––

Note in Example 343 how the MSC init2 was used to set up the start state for the verification of the high-level MSC inres2.

Verifying Message Parameters

When verifying an MSC, the parameters of the messages in the MSC can sometimes be crucial and need to be verified, and sometimes be unimportant for the behavior in question. To support this, the verification of MSCs in the Explorer allows three different levels of matching of message parameters:

- No parameters are given for the message.
- Only some of the parameters are given.
- All of the parameters are given.

If no parameters are given, all possible actual parameters are accepted. If the signal is sent from the environment to the system, the parameter values that are defined using the test value facility are used by the Explorer when exploring the state space of the system.

When only some of the parameters are to be given, only the given parameters are checked during the exploration. The notation used to show that a specific parameter should be ignored during the verification is to simply leave out this parameter in the parameter list. For example, if only the second and fifth parameter should be used during the verification the parameter list would be “,2,,,true” in the MSC. Trailing commas can be left out, so if a signal has five parameters and only the first

two are to be verified, the parameter list might be “1,2” which would ignore the last three parameters.

When only some of the parameters are given for a signal from the environment, the rest of the parameters are taken from the test value definitions when executing the signal output during state space exploration.

If all parameters are given, they are of course all checked.

Requirements for MSC Verification

The MSCs that can be loaded into the Explorer must comply with the following rules:

- It must be possible to map each MSC instance to either the environment, a channel to/from the environment, the entire SDL system, a block, or a process. This mapping is done by matching the name of the MSC instance with the names of the corresponding SDL entities. However, the name of an MSC instance can be changed before verification, see “Converting Instances Before Verification” on page 2432.
- PId values are not allowed as parameters to MSC messages from the environment of the SDL system. PId values are allowed on internal messages and messages to the environment, but the values are not checked during the exploration.
- If the MSC is on process level, only one static instance of each process type is allowed in the MSC. There is no limit to the number of dynamically created MSC instances.
- Only the following events/symbols are interpreted in an old-style MSC. All other events are ignored or will not be accepted by the Explorer.
  - input
  - output
  - set
  - reset
  - timeout
  - create
  - stop
  - global MSC reference symbol without substitution and gates
  - condition

Note:

Conditions are interpreted as a synchronization point if ***Define-Condition-Check*** is set to “on”, otherwise they are ignored. For more information, see ***“Synchronizing Test Events with Conditions” on page 1444 in chapter 35, TTCN Test Suite Generation***. Set, reset and timeout events on MSC instances representing SDL channels to the environment are only accepted by the Autolink test generation commands Generate-Test-Case and Translate-MSC-Into-Test-Case. For all other Explorer commands which load an MSC, timer events on environment instances are ignored and the Explorer generates a warning.

- Only the following symbols are allowed in a high level MSC:
  - start symbol
  - end symbol
  - MSC reference symbol without substitution and gates.
  - condition symbol (ignored during verification)
  - connection point.
- In MSC reference symbols it is allowed to use MSC reference expressions with the operators:
  - alt
  - par
  - seq
  - exc
  - opt
  - loop

Using Observer Processes

The purpose of an observer process is to make it possible to check more complex requirements on the SDL system than can be expressed using MSCs. The basic idea is to use SDL processes (called *observer processes*) to describe the requirements that is to be tested and then include these processes in the SDL system. Typical application areas include feature interaction analysis and safety-critical systems.

To be useful, the observer processes must be able to inspect the SDL system without interfering with it and also generate reports that convey the success or failure of whatever they are checking.

To accomplish this, three features are included in the Explorer:

- The observer process mechanism.

  By defining processes to be observer processes, the Explorer will start to execute in a two-step fashion. First, the rest of the SDL system will execute one transition, and then all observer processes will execute one transition and check the new system state.

- The assert mechanism.

  The assert mechanism enables the observer processes to generate reports during state space exploration. These reports will show up in the list of generated reports in the Report Viewer. The details of the assertion mechanism is discussed in "Using Assertions" on page 2457.

- The *Access* abstract data type.

  The purpose of the Access abstract data type is to give the observer processes a possibility to examine the internal states of the other processes in the system. Using the Access ADT it is possible to check variable values, contents of queues, etc., without any need to modify the observed processes. See "The Access Abstract Data Type" on page 2440 for more details.

A simple observer process is illustrated in Figure 491.

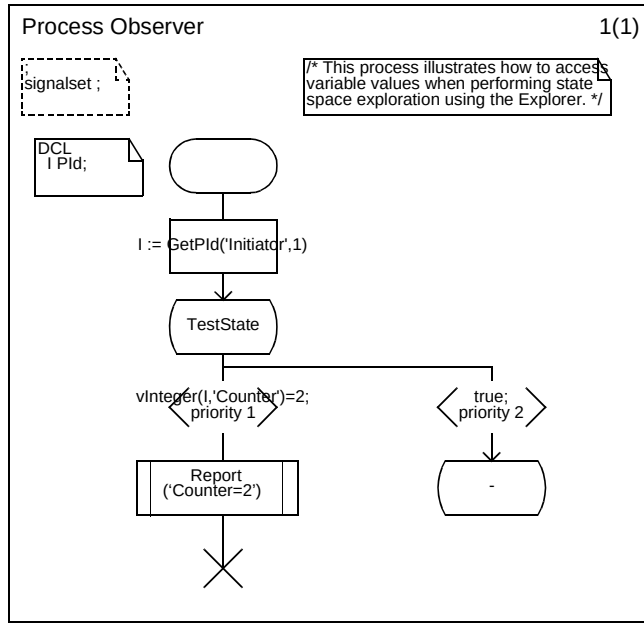

Figure 491: A simple observer process

This process will check if the variable Counter in the Initiator process ever becomes equal to 2.

Two characteristics for the observer processes are:

- the use of continuous signals with tests that use Access operator to check the internal state of other processes, and
- the use of assertions to report the result.

To use observer processes:

1. Create the observer processes in the SDL Editor. You should place the observer processes in a special block that you include in the diagram structure of the SDL system. In this block, you also need to specify an INCLUDE directive for the Access ADT:

   ```
   /*#INCLUDE 'access.pr' */
   ```

2. In the generated explorer, define each observer process by using the command Define-Observer, followed by the name of the process type. All instances of the process type will now become observer processes.

3. Perform a state space exploration. If an assertion defined in an observer process is satisfied, an "Assertion" report is generated. To simplify the observer processes, an "Observer" report will also be generated whenever there is an observer process that cannot execute.

In some cases the Observer reports are not convenient and they can then be turned off with the Define-Report-Continue (that will cause the exploration to continue past a reported situation) and the Define-Report-Log command (that can be used to turn off the logging a s specific report type, e.g. Observer reports)

The Access Abstract Data Type

The Access abstract data type is an ADT intended to be used together with observer processes to make it possible to access the internal state of other processes from an observer process. The ADT is defined in the file `access.pr` that resides in the `ADT` directory together with the rest of the ADTs supplied together with the SDL Suite. Unlike the rest of the ADTs the Access ADT is a special purpose ADT that only works with the Explorer kernel.

The Access ADT defines a number of SDL operators. The signatures of these operators are defined as follows:

```
GetPID : CharString, integer -> PId;
  /* Returns the PId value of a process instance

     par 1: the name of the process type
     par 2: instance number of the process instance
  */

ActivePID : integer -> PId;
  /* Return the PId of the process that executes.
     Returns NULL if no process executes.
     Observer processes are not taken into account.

     The integer parameter is a dummy parameter
     needed since operators must have parameters. */

GetState  : PId -> CharString;
  /* Returns the name of the current state of a
```

```
          process instance (or previous if the process
          is not in a state)

        par 1: the pid of the process instance */

GetNoOfInst: charstring -> integer;
   /* Returns the number of instances for a
      particular process type

      par 1: the name of the process type */

 terminated: PId -> boolean;
   /* Returns true if the process instance is
      terminated otherwise false

      par 1: The PId value of the process instance */

 GetProcedure: PId -> charstring;
   /* Returns the name of the procecure a process
      instance currently has called. If no procedure
      is called 'none' is returned

      par 1: The PId value of the process instance */

 InProcedure: PId, CharString -> boolean;
   /* Returns true if a process instance currently
      executes in a specific procedure, otherwise
      false

      par 1: The PId value of the process instance
      par 2: The name of the procedure */

 GetNoOfSignals: PID -> integer;
   /* Returns the number of signals currently in the
      input port of a process.

      par 1: The PId value of the process instance */

 GetSignalType: PId, integer -> charstring;
   /* Returns the name of the signal type for a
      signal in the input port of a process instance

      par 1: The PId value of the process instance.
      par 2: A number (>=1) identifying the signal */

 InQueue: PId, charstring -> boolean;
   /* Returns true if a process instance currently
      has a signal of a specific type in its input
      port queue

      par 1: The PId value of the process instance.
      par 2: The name of the signal type. */

 /* Variable access functions. These functions return
    a variable value that corresponds to one of the
```

```
    variables of a process instance as specified by
    the parameters.

      par 1: The PId value of the process instance.
      par 2: Variable name  */

v : PId, charstring -> integer;
vInteger : PId, charstring -> integer;
v : PId, charstring -> real;
vReal : PId, charstring -> real;
v : PId, charstring -> boolean;
vBoolean  : PId, charstring -> boolean;
v : PId, charstring -> Character;
vCharacter : PId, charstring -> Character;
v : PId, charstring -> Time;
vTime : PId, charstring -> Time;
v : PId, charstring -> Duration;
vDuration : PId, charstring -> Duration;
v  : PId, charstring -> Charstring;
vCharstring : PId, charstring -> Charstring;
v : PId, charstring -> PId;
vPId : PId, charstring -> PId;

EnvOutput : CharString -> Boolean;
  /* Returns true if the transition currently
     executing is caused by a signal from the
     environment with a specified name, otherwise
     false

     par 1: The name of the signal type */
```

The Access ADT also includes a utility procedure called *Report* that if called from an observer process will generate an Assertion report in the explorer. The procedure takes a charstring as parameter and this is the string that will be presented in the Assertion report.

An example of the usage of some of the operators is:

```
P := GetPId( 'Initiator', 1 ),
CS := GetState( P )
```

This example assigns the PId value of the first Initiator process to the PId variable P, and then assigns the name of the state of this process to the charstring variable CS.

An example of a statement that will access the variable value for one of the variables of another process instance is:

```
LocalVar := v(P,'Var')
```

In this example we assume that we have a PId variable `P` that identifies a process that has a variable `Var` of type for which a `v` operator is de-

fined. The statement will access the value of `Var` and assign it to the local variable `LocalVar`.

The operators for accessing the value of a variable are given in two versions for each predefined simple type: the `v` operator and the `vXXX` operator, where XXX is the name of the type. They are equivalent and the only time there is a need to use the `vXXX` operator is when it is not possible to resolve by context which of the `v` operators that is intended.

To access variables of sorts that are syntypes to the predefined simple types, the `v` operator for the corresponding predefined simple type can be used.

Accessing variable of structured types, enumeration types and user-defined types is a bit more complex. There are two possible ways to do it. Either define the `v` operator for the type in question, or use the **#CODE** operator and access the variable value using a C macro `XVV`.

Example 344: Structured Types in Observer Processes

Consider the following structure definition:

```
newtype MSDUType
  struct
    id IPDUType;
    num Sequencenumber;
    data ISDUType;
endnewtype MSDUType;
```

A `v` operator for this type can be defined as:

```
newtype MSDUTypeAccess
literals NotUsedMSDUTypeAccess;
operators
  v /*#NAME 'XVNAME(MSDUType)'*/ :
    PId, charstring -> MSDUType;
/*#ADT (H)
#TYPE
#define MSDUType #SDL(MSDUType)
*/
endnewtype MSDUTypeAccess;
```

Once this definition is in place, variable values for the complex data type can conveniently be accessed using the new `v` operator. Note also that it is possible to access the values of the fields of the structure in a simple way:

```
LocalVar := v(P,'MSDUVar')!id
```

If the type is one of the types passed as values, according to the table in "Parameter Passing to Operators" on page 2676 in chapter 56, *The Cadvanced/Cbasic SDL to C Compiler*, XVNAME should be substituted to XVNAME2.

However, if the values of the complex type only is accessed in a few places, it is possible to access them directly using the #CODE operator as illustrated in the following example:

```
LocalVar := #CODE('XVV(#SDL(P),"Var",#SDL(MyType))')
```

In this example we assume that we have a PId variable `P` that identifies a process that has a variable `Var` of type `MyType`. The statement will access the value of `Var` and assign it to the local variable `LocalVar`.

Defining Signals from the Environment

A problem common to all state space exploration techniques is related to the treatment of the environment of the SDL system under analysis. As an example, consider the situation during state space exploration where a signal with an integer parameter can be received from the environment. Since there is an infinite number of integer values, there will be an infinite number of successors of the current system state: one where the parameter value is 0, one where the parameter value is 1, etc.

This is obviously a situation that is not acceptable when performing state space exploration. The SDL Explorer allows three different strategies to avoid situations like this:

1. Create a closed system by specifying the environment of the system using SDL. This will solve the problem but introduces a new one; it is necessary to create an SDL model of the environment.

2. Specify the signals that can be sent from the environment to the system. This is a simple way to avoid the problem. By enumerating the signals with their parameters that the environment can send, a finite branching is guaranteed at each system state in the state space.

3. Use an MSC to guide the state space exploration. Since the MSC defines what signals the environment can send and their ordering, a limited part of the state space can be explored.

The second strategy is the most common and the test value feature of the Explorer is designed to make it easy to define the signals from the environment.

Test Values

When the Explorer is started a list of signals is automatically computed that will be used as the possible signals from the environment during state space exploration. The signal list is generated based on the concept of test values. Test values can be defined for data types and for signal parameters. When generating the signal list the Explorer checks for each signal that can come from the environment which test values are defined for its parameters (or for the parameter data types). It then generates one signal instance for each combination of test values for the parameters.

Each time the Explorer is in a state where input from the environment is possible during state space exploration, the list of signals defined by the test values is consulted.

The default test values for the simple data types are:

Data Type	Default Test Values
`Integer`	-55, 0, 55
`Boolean`	true, false
`Real`	-55, 0, 55
`Natural`	0, 55
`Character`	‘a’
`Charstring`	“test”
`Duration`	0
`Time`	0
`PId`	Environment PId
`Bit`	0, 1
`Octet`	00, FF
`Bit_string`	’01’B
`Octet_string`	’00FF’H

For other data types, test values are determined according to the following:

- Enumerated types: All values in the type
- Subranges of the predefined data types: All values in the range
- Structures: All combinations of the test values of the individual fields
- Arrays: All combinations of the test values of the component type.
- Ref types: NULL + pointers to the test values for whatever the Ref points to.
- Own types: NULL

- ORef types: NULL

Test Values Restrictions and Options

Two restrictions are posed on the computed test values:

- If the number of test values for a data type or signal parameter exceeds a maximum number, randomly chosen test values will be generated.
- If the number of signal instances for a particular signal type exceeds a maximum number, randomly chosen signal instances will be generated for this signal type.

Two commands exist for setting options related to the above restrictions:

- To define the maximum number of test values for any data type or signal parameter, enter the command Define-Max-Test-Values, followed by the number of test values. The default is 10.
- To define the maximum number of signal instances for any signal type, enter the command Define-Max-Signal-Definitions, followed by the number of signal instances. The default is 10.

Note:

These options affect the state space; see "Affecting the State Space" on page 2459.

Defining and Listing Test Values

The default test values are defined to be useful for a large number of applications, but they sometimes need to be modified. In some cases there are unnecessarily many test values and to enhance the performance of the state space exploration some test values can be cleared. In other cases the automatic test value generation cannot handle some of the data types used, so the test values must be manually defined.

Changing the test values are therefore only needed if you would like to fine-tune the behavior of the Explorer, or if the signals from the environment have parameters that are of a user-defined or unusual data type.

Note:

Changing test values affects the state space; see "Affecting the State Space" on page 2459.

Test values can be defined and cleared on three "levels": on data types, on individual signal parameters, and on signal instances. When test values are defined or cleared, the list of signals from the environment is regenerated. You are recommended to define test values either on data types and individual signal parameters, or on signal instances; do not combine both these methods.

The monitor commands concerning test values are available in the *Test Values* module in the Explorer UI.

Test Values for Data Types

The following commands operate on the test values for a data type (sort).

- To define a new test value for a sort, enter the command , or click the *Def Value* button. The parameters are the sort and the value. Example:

```
integer 20
```

- To list the new test values defined for all sorts, enter the command List-Test-Values, or click the *List Value* button.
- To clear all test values for a sort, enter the command Clear-Test-Values, or click the *Clear Value* button. As parameter, you either specify the sort, or '-' which means **all** sorts.

Test Values for Signal Parameters

The following commands operate on the test values for individual parameters to a signal.

- To define a new test value for a signal parameter, enter the command Define-Parameter-Test-Value, or click the *Def Par* button. The parameters are the signal, the ordinal number of the signal parameter, and the value. Example:

```
Define-Parameter-Test-Value Score 1 -5
```

- To list the new test values defined for all signal parameters, enter the command List-Parameter-Test-Values, or click the *List Par* button.
- To clear all test values for a signal parameter, enter the command Clear-Parameter-Test-Values, or click the *Clear Par* button. As parameter, you specify the signal and the ordinal number of the signal parameter. You may use '-' for the parameter number, which means **all** signal parameters, or just '-' for the signal, which means **all** signal parameters for **all** signals.

Test Values for Signal Instances

The following commands operate on the test values for a specific signal instance.

- To define a new set of test values for a signal instance, enter the command Define-Signal, or click the *Def Signal* button. The parameters are the signal and an optional set of values for the parameters. Multiple Define-Signal commands may be used to define several signal instances of the same signal type, but with different values. Example:

```
Define-Signal Test 10 'hello' true
Define-Signal Test -5 'bye'
```

Note:

The signals defined using this command are cleared when the signal list is regenerated, e.g. if a test value is defined for a sort or a signal parameter.

- The command Extract-Signal-Definitions-From-MSC analyzes basic MSCs in textual form (with suffix `.mpr`) and extracts all signals sent from the environment axes to the system axis. If a signal definition is found which does not already exist, it is added automatically by calling Define-Signal.
- To list all currently defined signal instances, enter the command List-Signal-Definitions, or click the *List Signal* button.
- To clear all test values for a signal type, enter the command Clear-Signal-Definitions, or click the *Clear Signal* button. As parameter, you specify the signal, or '-' which means **all** signals.

Saving Test Values

The current set of test values can be saved on file and later be recreated by reading in the file again. The file will contain monitor commands that recreates the saved set of test values and discards any other test values.

To save the test values, enter the command Save-Test-Values, followed by a file name. To read in the saved test values again, enter the command Include-File, followed by the file name.

Validating Systems That Use the Ref Generator

The Ref generator (see "The Ref Generator" on page 111 in chapter 2, *Data Types, in the SDL Suite 6.2 Methodology Guidelines*) is used to create pointer structures to be used in SDL systems. The Explorer supports the Ref generator, but imposes some restrictions on the usage of it due to the special requirements caused by state space exploration.

Variables that are defined to be Ref's to something can be used in two ways, either as a pointer to some other variable or as a pointer to a dynamically allocated memory area. Both ways of using Ref types are supported by the Explorer.

To handle dynamically allocated data areas the Explorer creates a special data structure as part of each system state. This data structure is a list of all data areas allocated by `Alloc` (the Ref operator that allocates a new data area) and data areas allocated in external C code (see "Validating Systems with External C Code" on page 2452). The list contains for each data area in addition to the area itself information about e.g. the sort of the data area and the size of the data area. Whenever the Explorer copies a system state, the list of dynamically allocated data areas is also copied and all Ref variables are set up corresponding to the new copy of the list.

Some restrictions/simplifications are needed when using Ref sorts in the Explorer:

- Variables may not be defined to be of the VoidStar or VoidStarStar sorts, since the Explorer needs to know the sort and size of what is pointed to. This is not known for VoidStar and VoidStarStar sorts.
- A simplification is made when comparing two system states for equivalence (both in exhaustive exploration and in the hash function used by bit state exploration): Two Ref variables are considered equivalent if the data they are pointing to are equivalent. This may in some cases prune the search in situations where it should not have been pruned. Note that equivalence tests in the SDL system works correctly, if two Ref variables are compared using '=' they are considered the same only if they contain the same pointer value.

Note that the handling of pointers in the Explorer introduces a significant overhead that unfortunately reduces the number of transitions per second that is executed by the Explorer.

When performing state space exploration, the Explorer checks the usage of Ref variables when copying system states and reports several different types of problems including:

- memory leaks, and
- pointers to released or never allocated memory.

For more information about the reports see "REF Errors" on page 2374 in chapter 52, *The SDL Explorer*.

Validating Systems with External C Code

the SDL Suite allows the usage of external C code together with an SDL system and this is also true for the Explorer. In many cases it is possible to directly use the Explorer on a system that uses external C code. However, due to the special requirements of state space exploration, some restrictions must hold for the external C code, and some modifications may have to be done to the external code to make it functions properly with the Explorer.

To be able to perform a state space exploration it must be possible for the Explorer to make a complete copy of a system state, including all data structures that are implemented directly in C code. The Explorer must also be able to modify each copy of a system state separately. This has some implications:

- variables defined in C code cannot be handled by the Explorer,
- C unions may not contain pointers, data types implemented by pointers (like the SDL types string and bag) or SDL PIds, and
- some restrictions on the usage of pointers are needed since the C pointers in SDL are treated like Ref types (see "Validating Systems That Use the Ref Generator" on page 2451).

If there are variables in C code, this will not be detected by the explorer. It may appear as if the Explorer works, but the variables defined in C code will not be copied when the Explorer copies a system state. When the value of a variable is changed by an action performed in one system

state, this value will change the value for all system states that the Explorer currently handles. This implies e.g. that when the Explorer backtracks during an automatic exploration to test more possible successors of a particular system state, the values of variables defined in C may be different from the values they had the previous time the system state was visited and the state space exploration will not be correct.

In order to be able to copy a system state, the Explorer must have exact information about the sort of all data areas in the system to be able to copy e.g. pointer-based data structures correctly. One consequence of this is that the Explorer cannot support the C union sort if the union may contain pointer-based sorts, since the Explorer cannot know the current sort of the union and thus cannot deduce whether to treat the union as a pointer or not. SDL PIds are also treated specially in the Explorer and can also not be part of a C union.

Pointers are frequently used in C code and when used together with the SDL Suite they are treated as the (nonstandard) SDL type Ref. The Explorer handles the Ref types in a particular way (see "Validating Systems That Use the Ref Generator" on page 2451) and the restrictions on variables of this sort also applies to the usage of C pointers in data type in external C code.

When using dynamic memory allocation in extern C code some special additions are needed for the Explorer to work properly. This is needed since the Explorer keeps a list of all dynamically allocated data areas as part of each system state. If an external C function allocates memory, the Explorer must be informed about the data area that was allocated, and the same holds when a C function releases memory. This is accomplished by calling two functions from the C code:

```
extern void UserMalloc (void *data);
extern void UserFree (void *data);
```

UserMalloc should be called when a data area has been allocated, and UserFree should be called immediately before the data area is released. Both functions should have a pointer to the data area as parameter.

The purpose of UserMalloc is to insert a new element into the list of dynamically allocated data areas that is maintained by the Explorer. Note that there is no need to tell the Explorer what sort of data was allocated or its size. This is handled automatically by the Explorer simply by finding the SDL entity (e.g. a variable) that points at the data area and assuming that the sort and size given by this entity is correct. If no SDL

entity can be found that points to the data area, this is considered to be an error and a Explorer report is generated.

The purpose of the UserFree function is to inform the Explorer that a data area has been released, and thus should be removed from the list of dynamically allocated data areas.

There exists a special C macro XVALIDATOR_LIB that can be used to check in external C files if the code is compiled together with the Explorer kernel. It is thus possible to only include the calls to UserMalloc/UserFree when the C code is compiled together with the Explorer using this macro, as in the following example:

```
...
v = malloc( 10 );
#ifdef XVALIDATOR_LIB
UserMalloc( (void *)v );
#endif
```

Using User-Defined Rules

In the Explorer, you may define a user-defined rule to be used during state space exploration to check for properties of the encountered system states. If a system state is found for which the user-defined rule is true, a report will be generated. Note that only one user-defined rule may be defined at a time.

Different Usages

There are three different situations in which a user-defined rule is useful:

- To verify properties of the SDL system.

  A user-defined rule describes properties of system states. By using an automatic state space exploration, it is thus possible to verify the existence of system states that satisfy the specified properties. If the state space is small enough to allow a complete exploration it is also possible to verify that the state space does not contain any system state with the specified property.

- To search for specific system states.

  A user-defined rule makes it possible to go to a specific system state in the state space without the need to use the navigating commands of the explorer monitor. By describing the desired state with a rule and using an automatic state space exploration, you can go directly to the report that satisfied the rule. In this case, the report action for the user-defined rule report should be set to Abort.

- To reduce the state space to be explored.

  For many SDL systems, the state space can be very large or even infinite, which makes it difficult to perform a state space exploration effectively. However, in many cases the state space contains large subspaces that for some reason are not interesting to explore. For instance, they may be equivalent to other parts of the state space except for the value of one particular variable. In such cases, a user-defined rule can be used to restrict the exploration by defining system states that are considered to be uninteresting. When such a state is encountered, the exploration is truncated and continued in another node.

Examples of Rules

An example of a rule that checks a system property is:

```
exists P:Proc | P->var=12;
```

which is true for all system states where there exists a process of type "Proc" with a variable "var" that is equal to 12.

A simple example of a rule that searches for a system state is:

```
state(initiator:1)=disconnected;
```

which is true for all system states where the process instance "initiator:1" is in the state "disconnected".

A more complex example of such a rule is:

```
state(Game:1)=Winning and
sitype(signal(Game:1))=Probe
```

which is true for all system states where the state of the process instance "Game:1" is equal to "Winning" and the type of signal to be consumed by the same process instance is "Probe".

An example of a rule that reduces the state space is:

```
(Game:1->Count > 2) or (Game:1->Count < -2)
```

which is true for all system states where the absolute value of the variable "Count" in the process instance "Game:1" is greater than 2.

For a full description of the features and syntax of user-defined rules, see "User-Defined Rules" on page 2376 in chapter 52, *The SDL Explorer*.

Managing User-Defined Rules

To define the user-defined rule, select *Define Rule* from the *Commands* menu, or enter the command Define-Rule, followed by the definition of the rule.

To clear the user-defined rule, enter the command Clear-Rule.

To print the definition of the current user-defined rule, enter the command Print-Rule.

To evaluate the user-defined rule in the current system state, i.e. to check whether the rule is satisfied, enter the command Evaluate-Rule.

Using Assertions

Like most other run-time libraries to the SDL to C Compiler, the Explorer library gives the user a possibility to define his own run-time errors or assertions. An assertion is a test that is performed at run-time, for example to check that the value of a specific variable is within the expected range. Assertions are described by introducing `#CODE` directives with calls to the C function `xAssertError` in a TASK. See the following example.

Example 345: Assertion in C Code ––––––––––––––––––––––––––

```
TASK '' /*#CODE
#ifdef XASSERT
  if (#(I) < #(K))
    xAssertError("I is less than K");
#endif
*/ ;
```

––

In the SDL Explorer, the assertions are checked during state space exploration. Whenever `xAssertError` is called during the execution of a transition, a report is generated. The advantage of using this way to define assertions, as opposed to using user-defined rules, is that in-line assertions are computed much more efficiently by the explorer than the user-defined rules.

The `xAssertError` function, which has the following prototype:

```
extern void xAssertError ( char *Descr )
```

takes a string describing the assertion as parameter and will produce an SDL run-time error similar to the normal run-time errors. The function is only available if the compilation switch XASSERT is defined. For the standard libraries this is true for all libraries except the Application Library.

Configuring the SDL Explorer

This section describe the various possibilities available to control the behavior of the Explorer using the options that can be defined for different features. The available options are grouped into a number of categories; each category and option will be described later in this section.

Managing Options

Each option can be set using a monitor command, usually named something similar to “Define-<option>”. Most options can also be set from the menus *Options1* and *Options2* in the Explorer UI. The monitor command and menu choice associated with an option is listed together with the description of the option.

If the options are changed during a session with the Explorer, you will be asked whether to save the options when you exit or restart the currently executing explorer. If you save the options, the new values will be stored in a file named `.valinit` **(on UNIX)**, or `valinit.com` **(in Windows)**, in the directory from where the SDL Suite was started. This file will automatically be loaded the next time the Explorer is started from the same directory, thus restoring the previous options.

Some monitor commands operate on all the options:

- To print a list of all options and their current values, select *Show Options* from either the *Options1* or *Options2* menu, or enter the command Show-Options. (A few of the options described here are not listed.)
- To set all options to their predefined default values, click the *Default* button in the *Explore* module, or enter the command Default-Options. Note that this also clears all reports.
- To set all options to their initial values, i.e. the values set when the explorer was started, click the *Reset* button in the *Explore* module, or enter the command Reset.

Note:

This command also resets the explorer completely and is equivalent to restarting the explorer from scratch. To just set the options to their initial values without resetting the explorer:

1. Set the options to their default values. See above.
2. Read in the file `.valinit` **(on UNIX)**, or `valinit.com` **(in Windows)**; see above. Select *Include Command Script* from the *Commands* menu, or enter the command Include-File.

Affecting the State Space

Some of the options affect, directly or indirectly, the size of the state space and the structure of the behavior tree. This can only be done while being in the current root of the behavior tree, since the whole structure of the tree may be affected. If such an option is changed when the explorer is **not** in the current root of the behavior tree, you have two choices: either to change the current system state back to the current root, or to redefine the current root to the current system state.

In this case, the following dialog is opened:

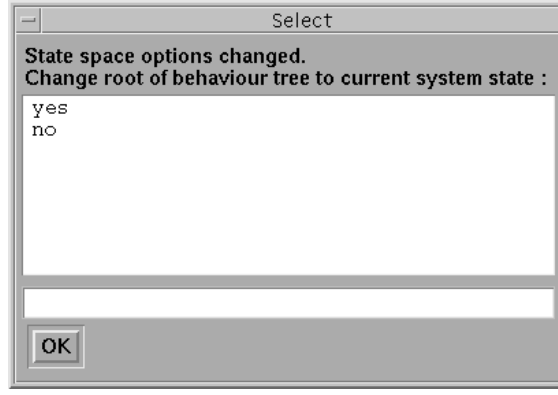

Figure 492: Changing the current root

To change the root to the current system state, select *yes* and click *OK*. (In stand-alone mode, enter **`yes`**)

To keep the current root and move back to it, select *no* and click *OK*. (In stand-alone mode, enter `no`)

> **Note:**
>
> It is **not** possible to cancel this operation, i.e. you **have to** either change the current root or the current system state.

Bit State Exploration Options

Bit state exploration is an efficient automatic state space exploration algorithm for reasonably large SDL systems (for a reference, see [17]). It performs a depth-first search through the state space and uses a bit array to store the states that has been traversed during the search.

Every time a new system state is generated during the search, two hash values are computed from the system state. The bit array is checked:

- If both of the positions indicated by the hash values are already set, the state is considered to have been previously visited. The search of this particular path in the state space is pruned, and the search backs up to a previous system state and continues elsewhere.
- If both of the positions are not set, the state is a new state that has not been previously visited. Both position in the bit array are then set and the search continues with the successor states.

Search Depth

The search depth is the maximum depth the Explorer will explore a particular execution path in the state space. When this depth is reached, the search is truncated and the search backs up to a previous system state.

- Default value: 100
- Command: Define-Bit-State-Depth
- Menu choice: *Options2: Bit-State: Depth*

Hash Table Size

The size of the bit array used as hash table is an important factor defining the behavior of the bit state exploration. The reason is that each time a new state is checked by comparing its hash values with previous hash values there is a risk for collision. The bigger the hash table is, the smaller the collision risk is.

- Default value: 1,000,000 (bytes)
- Command: Define-Bit-State-Hash-Table-Size
- Menu choice: *Options2: Bit-State: Hash Size*

Random Walk Options

Random walk is an automatic state space exploration algorithm that can be useful for very large SDL systems. It performs a depth-first search through the state space by selecting transitions to execute at random.

When the maximum search depth is reached during such a “random walk,” the search is restarted from the original state again and a new random walk is performed. However, there is no mechanism to avoid that already explored paths are explored once more, i.e. a system state may be visited a large number of times.

Search Depth

The search depth determines how many transitions will be executed before the search is pruned and restarted from the beginning again.

- Default value: 100
- Command: Define-Random-Walk-Depth
- Menu choice: *Options2: Random: Depth*

Repetitions

The number of times the random walk search will be repeated from the start state before the exploration is finished.

- Default value: 100
- Command: Define-Random-Walk-Repetitions
- Menu choice: *Options2: Random: Repetitions*

Exhaustive Exploration Options

Exhaustive exploration is an automatic state space exploration algorithm intended for small SDL systems where the requirements on correctness are very high.

The algorithm is a depth-first search through the state space similar to the bit state search, but there is no collision risk involved. The reason is that all traversed system states are stored in primary memory, so it is always possible to determine whether a newly generated system state has already been visited during the search.

The drawback with the algorithm is that very much primary memory is needed to be able to store all traversed states. This limits the complexity of the SDL systems the algorithm is applicable to.

Search Depth

The search depth is the maximum depth the Explorer will explore a particular execution path in the state space. When this depth is reached, the search is truncated and the search backs up to a previous system state.

- Default value: 100
- Command: Define-Exhaustive-Depth
- Menu choice: *Options2: Exhaustive: Depth*

MSC Verification Options

The MSC verification algorithm is a bit state exploration that is adapted to suit the needs of MSC verification:

- An MSC is always loaded to guide the search
- The search depth is different from the depth used during usual bit state exploration
- The search is aborted as soon as the MSC has been verified.

Search Depth

The maximum depth searched by the algorithm. The intention is that this depth always should be enough. If the MSC verification fails and the number of truncations is more than 0, this depth should be increased.

- Default value: 1,000
- Command: Define-MSC-Verification-Depth
- Menu choice: Not available

Timer Check Level

When verifying an MSC where there are timers in the MSC and/or in the SDL system, there is a choice of how to perform the matching between the timer events in the MSC and in the SDL system. The timer check level determines how this matching should be done:

- 0: No checking of timer events is performed.
- 1: If a timer event exists in the MSC a matching timer event must exist in the explored SDL path, but a timer event in the explored SDL path is accepted even if there is no corresponding MSC timer event.
- 2: All timer events in the MSC must match a corresponding timer event in the explored SDL path, and vice versa.

The choice must be determined by the style of MSC that is used.

This option affects the state space; see "Affecting the State Space" on page 2459.

- Default value: 1
- Command: Define-Timer-Check-Level
- Menu choice: *Options2: MSC: Timer check level*

Report Options

For each report type, you can define the action performed when the report is found and whether it should be reported to the user.

Report Action

The report action determines what action should be performed when a report situation is encountered while performing state space exploration. There are three possibilities:

- Continue: The search continues past the reported situation as if it never happened.
- Prune: The search is pruned and depending on the algorithm some appropriate action is taken. For example, when using bit state exploration, the search will back up one state and continue with the next alternative transition, as if max search depth was reached and the search truncated.
- Abort: The search is aborted and the command prompt displayed.

Note that for some report types, like Deadlock, the continue choice is impossible.

This option affects the state space; see "Affecting the State Space" on page 2459.

- Default value: Prune for all report types
- Commands: Define-Report-Continue, Define-Report-Prune and Define-Report-Abort
- Menu choices: *Options2: Report: Continue*, *Options2: Report: Prune* and *Options2: Report: Abort*

Report Log

The report log setting defines whether the report should be recorded in the list of generated reports. If the report log is set to Off for a particular report type, these reports will never show up in the report list. Note however that the report action still is performed, even though the report is not logged.

This option affects the state space; see "Affecting the State Space" on page 2459.

- Default value: On for all report types
- Command: Define-Report-Log
- Menu choice: *Options2: Report: Report log*

Report Viewer Autopopup

When an automatic state space exploration is finished, the Report Viewer is normally started automatically to present the found reports. In some cases this may be inconvenient, so there is a possibility to turn this feature off.

- Default value: On
- Command: Define-Report-Viewer-Autopopup
- Menu choice: *Options1: Report Viewer Auto Popup*

MSC Trace Options

When the Explorer performs an MSC trace, you can define what types of events that are traced.

Action Trace

By default, actions like tasks, decisions, etc. are not shown in the MSC trace. You may change this by setting action trace to On.

- Default value: Off
- Command: Define-MSC-Trace-Action
- Menu choice: Not available

State Trace

By default, changes in process states are shown in the MSC trace by adding a condition symbol. You may change this by setting state trace to Off.

- Default value: On
- Command: Define-MSC-Trace-State
- Menu choice: Not available

MSC Trace Autopopup

When you go to a report, an MSC Editor is normally started automatically to present the trace from the current root to the state where the report was generated. In some cases this may be inconvenient, so there is a possibility to turn this feature off.

- Default value: On
- Command: Define-MSC-Trace-Autopopup
- Menu choice: *Options1: MSC Trace Auto Popup*

State Space Options

The structure and size of the state space that can be generated for any given SDL system can be modified in a number of ways using the state space options. The default values are defined to make the state space as small as possible to make the Explorer immediately useful for as many applications as possible. This, however, also means that the search performed by the Explorer is fairly scarce compared to what is possible. Some error situations may thus be overlooked during the search if they only occur in a part of the state space that never is reached.

Since these options affect the state space, note the information in "Affecting the State Space" on page 2459.

Transition Type

There are two alternatives possible for the type of a behavior tree transition during state space exploration:

- It can be equal to a complete SDL process graph transition (the value "SDL" in the command)
- It can be a part of such an SDL transition (the value "Symbol-Sequence" in the command).

If it is equal to an SDL process graph transition, whenever such a transition is started, it is completed before anything else is allowed to happen. This implies that all process instances in all system states in the behavior tree will always be in an SDL process graph state.

If it is only a part of an SDL process graph transition, a transition in the behavior tree is considered to be a sequence of events that are local to the process instance, followed by a non-local event. Examples of local events are tasks and decisions; examples of non-local events are creates

and inputs/outputs of signals from/to other process instances. The idea of this alternative is to model the ITU semantics for SDL as closely as possible while still allowing optimized performance during state space exploration.

- Default value: SDL
- Command: Define-Transition
- Menu choice: *Options1: State Space: Transition*

Scheduling Algorithm

The scheduling algorithm defines which of the process instances in a system state will be allowed to execute. There are two possible alternatives:

- All of the process instances in the ready queue are allowed to execute (the value “All” in the command)
- Only the first process instance in the ready queue is allowed to execute (the value “First” in the command).

The ready queue is a queue containing all process instances that have received a signal that can cause an immediate transition, but that have not yet had the opportunity to execute this transition to its end.

If all process instances are allowed to execute, the semantics of ITU recommendation Z.100 are modeled. There will be one child node to the current node in the behavior tree for each process instance in the ready queue.

If only the first process instance is allowed to execute, the semantics of an application that has been generated by the SDL to C Compiler are modeled. There will only be one child node to the current node in the behavior tree, the first process instance in the ready queue.

- Default value: First
- Command: Define-Scheduling
- Menu choice: *Options1: State Space: Scheduling*

Event Priorities

The events that are represented in a behavior tree can be divided into five classes:

- Internal events: Events local to the processes in the system, e.g., tasks, decisions, inputs, outputs.
- Input from ENV: Reception of signals from the environment. The signal is put in the input port of a process instance or on a channel queue.
- Timeout events: Expiration of SDL timers. The timer signal is put in the input port of a process instance.
- Channel outputs: A signal is removed from a channel queue and put into another channel queue or the input port of a process instance
- Spontaneous transitions: A transition in a process caused by input of `none`.

To each of these event classes a priority of 1, 2, 3, 4 or 5 is assigned. These priorities are used during state space exploration to determine which transitions should be generated from each system state. The events with priority 1 are first considered. Only if no events with priority 1 are possible in the current state, the events with priority 2 are considered. Only if no events with priority 1 or 2 are possible in the current state are events with priority 3 considered, etc.

Note that also the setting of the symbol time option will have an impact on the events that will can be executed in each system state; see section "Transition Time" on page 2469.

The two most common ways of assigning priorities to event classes are:

- All event classes are assigned priority 1.
- Internal events and channel outputs are assigned priority 1, and external, timeout and spontaneous transition events are assigned priority 2 (the default).

The first alternative represents the situation where no assumptions can be made about the time scale for the different types of events. The second alternative represents a situation where the internal delays are very short compared to the timeout durations and execution speed of the environment.

- Default value: Priorities 1, 2, 2, 1, 2
- Command: Define-Priorities
- Menu choice: *Options1: State Space: Priorities*

Transition Time

A common simplification made in the analysis of SDL systems is to consider the time it takes for a process to execute a symbol, e.g. an action or output, to be zero. This time is of course never zero in a real system, but in many cases the time is very small compared to the timer durations in the system, and can be neglected when analyzing the system.

Consider for example a situation where a process sets a timer with a duration 5 and then executes something that may take a long time, e.g. a long loop, and then sets a timer with duration 1. If symbol time is assumed to be zero, the second timer will always expire first. If considered to be non-zero, any one of the timers can potentially expire first.

The explorer allows the user to choose whether to assume that the execution time for SDL symbols is zero or undefined using the Define-Symbol-Time command.

- Default value: Zero
- Command: Define-Symbol-Time
- Menu choice: *Options1: State Space: Symbol time*

Channel Queues

The Explorer allows queues to be attached to and removed from all channels in the SDL system. If a queue is added for a channel, it implies that when a signal is sent transported on this channel it will be put into the queue associated with the channel. Then there will be a separate transition in the state space that represents the forwarding of the signal to the receiver (or the next channel queue).

- Default: No channels have queues
- Command: Define-Channel-Queue
- Menu choice: *Options1: State Space: Channel queues*

Maximum Input Port Length

The length of the input port queues is not infinite in the Explorer, since in practice it is likely to be a design error if the queues grow forever. If the length of a queue exceeds the defined max length during state space exploration, a “MaxQueuelength” report is generated.

- Default value: 3
- Command: Define-Max-Input-Port-Length
- Menu choice: *Options1: State Space: Input port length*

Maximum Transition Length

To make it possible to detect infinite loops within a transition in the state space, the maximum number of SDL symbols allowed to be executed in one transition is defined. If this number is exceeded during state space exploration, a "MaxTransLen" report is generated.

- Default value: 1,000
- Command: Define-Max-Transition-Length
- Menu choice: *Options1: State Space: Transition length*

Maximum Number of Instances

To avoid infinite chains of create actions in the state space, the Explorer uses a max number of allowed process instances for any type. If this number is exceeded during state space exploration, a "Create" report is generated.

- Default value: 100
- Command: Define-Max-Instance
- Menu choice: *Options1: State Space: Max instance*

Maximum State Size

When the Explorer is exploring the state space, an internal buffer is used to store the system states. The size of this buffer defines the maximum size of the system states that the Explorer can handle.

- Default value: 100,000 (bytes)
- Command: Define-Max-State-Size
- Menu choice: *Options1: State Space: Max state size*

Timer Progress

One test that can be made with the Explorer is to look for non-progress loops, i.e. loops in the state space without any progress being made. The intention with this test is to look for situations where the SDL system is busy doing internal communication but to an outside observer looks dead.

This option defines if the expiration of a timer is considered as progress when performing non-progress loop checking. See also "Non Progress Loop Error" on page 2372 in chapter 52, *The SDL Explorer*.

- Default: On (timer expiration is considered to be progress)
- Command: Define-Timer-Progress
- Menu choice: *Options1: State Space: Timer progress*

Spontaneous Transition Progress

One test that can be made with the Explorer is to look for non-progress loops, i.e. loops in the state space without any progress being made. The intention with this test is to look for situations where the SDL system is busy doing internal communication but to an outside observer looks dead.

This option defines if a spontaneous transition is considered as progress when performing non-progress loop checking. See also "Non Progress Loop Error" on page 2372 in chapter 52, *The SDL Explorer*.

- Default: On (spontaneous transition is considered to be progress)
- Command: Define-Spontaneous-Transition-Progress
- Menu choice: Not available

Autolink Options

See section "Computing Test Cases" on page 1450 in chapter 35, *TTCN Test Suite Generation* for a discussion of the Autolink options.

Setting Advanced Options

Advanced options can be set for state space explorations to achieve a much larger state space than the default, thus allowing for special kind of errors to be detected. See "Using Advanced Validation" on page 2421 for more information.

To set advanced options, click the *Advanced* button in the *Explore* module. This executes the following set of commands:

```
Define-Scheduling All
Define-Priorities 1 1 1 1 1
Define-Max-Input-Port-Length 2
Define-Report-Log MaxQueuelength Off
```

The reasoning behind these settings are:

- The scheduling should be set to All, since we in this case are looking for signal races and a characteristic property of signal race conditions is that they are depending on the ordering of internal events.

- The priorities should be set to 1 for all types of events.
- To reduce the size of the state space, the maximum queue length should be set to a very small number. The reason is that when the environment is allowed to send signals to the system at any time, the queues that can receive signals from the environment will grow very rapidly.
- Since a lot of maximum queue length reports will be generated with these options, the report log for this report should be set to Off. Note also that the report action for this report should be Prune (which is the default).

Chapter

54 *The SDL Analyzer*

The SDL Analyzer's primary task is to check SDL-92 diagrams (extended as defined in "Compatibility with ITU SDL" on page 2 in chapter 1, *Compatibility Notes, in the Release Guide*) with respect to syntactic and semantic rules. The Analyzer accepts both SDL/GR and SDL/PR as input, and has the ability to transform SDL/GR diagrams to SDL/PR files and vice-versa.

This chapter is a reference to the Analyzer commands. Its limitations according to the Z.100 recommendation is found in "SDL Analyzer" on page 20 in chapter 1, *Compatibility Notes, in the Release Guide*.

For a guide to how to perform syntactic and semantic check on an SDL diagram structure, see chapter 55, *Analyzing a System*. This chapter also gives an overview of the Analyzer.

The Analyzer User Interfaces

The Analyzer Graphical UI

The Analyzer's graphical user interface is managed by the Organizer.

To start the Analyzer, select *Analyze* from the Organizer *Generate* menu or click the *Analyze* quick button. For more information, see "Analyze" on page 112 in chapter 2, *The Organizer* and "Quick Buttons" on page 180 in chapter 2, *The Organizer*.

The Analyzer's graphical user interface is further described in "Using the Analyzer" on page 2618 in chapter 55, *Analyzing a System*.

The Analyzer Batch UI

See *"Batch Facilities" on page 208 in chapter 2, The Organizer* for information on running the Analyzer non-interactively.

The Analyzer Command Line UI

The Analyzer also has a *command line mode,* when it is started from the OS outside the graphical environment of the SDL Suite. This is the user interface that is described in the remainder of this chapter.

Starting the Analyzer

The Analyzer is started in command line mode from the OS prompt with the command:

```
sdtsan [1]
```

When the Analyzer is started in command line mode, it responds with the prompt

```
SDL Analyzer
Command :
```

1. The directory where the SDL Suite binaries are stored is assumed to be included in the PATH variable. Otherwise, the complete directory path must be supplied.

Environment Variables

- SDTSAN_WARN_GATE

  By setting this to any value the analyzer will give warnings instead of errors for unconnected gates that should be connected. This option is only provided for backwards compatibility and should not be used if possible.

- SDTSAN_ASN1_ENUM_OP

  By setting this to any value the analyzer will pass the -e option to asn1util. This will create all operators for ASN.1 ENUMERATED types as defined in Z.105.

- SDTSAN_FILTER_USE

  By setting this to any value the analyzer will run the specified filter command specified in the analyzer options once before SDL package dependencies are resolved. This makes it possible for external filter scripts to exclude SDL package before make files are generated.

- SDTSAN_FILTER_ABORT

  By setting this to any value the analyzer will terminate it’s job at the first failing filter command.

- SDTSAN_INCLUDE_PATH

  Set this to a list of directories where the analyzer should look for include files. The separator is : on Unix and ; on Windows.

Syntax of Analyzer Commands

A command name may be abbreviated by giving sufficient characters to distinguish it from other command names. A hyphen (’-’) is used to separate command names into distinct parts.

Any part may be abbreviated as long as the command does not become ambiguous.

Parameters to commands are separated by one or several spaces. In case you omit a parameter of type “on/off”, the value currently defined will toggle between its “on” and “off” values.

In both command names and parameters there is no distinction made between upper and lower case letters.

> **Note:**
>
> **On UNIX** systems, distinction is made between upper case letters and lower case letters for file names.

Comments are indicated by the "#" character, and extend to the end of the line. Comments may only be preceded by white space.

Description of Analyzer Commands

In this section, the Analyzer commands are listed in alphabetical order, along with their parameters and a description.

! (shell escape)

Parameters:

```
<operating system command>
```

Escape to the shell to do command.

Add-Input

Parameters:

```
<Filespec>
```

Add a file to the list of files to be converted to PR. The file will be processed according to the setting of Input-Mode.

Analyze

Parameters:

```
(None)
```

This command orders the Analyzer to perform the passes according to the *Analyzer options* as they are defined.

> **Hint:**
>
> The current analysis options can be printed using the command *Show-Analyze-Options* (see "Show-Analyze-Options" on page 2497).

The order in which the passes are performed is:

1. *Conversion to PR*, if the input is C header, ASN.1 or SDL/GR diagrams.
2. *Macro expansion* (optional).
3. *Syntactic analysis* (optional).
4. *Pretty-printing* of a PR file (optional).
5. *PR to GR conversion* (optional). This pass converts an SDL/PR input file to SDL/GR diagrams, using the native format of the SDL Suite.
6. *Semantic analysis* (optional).
7. *Cross reference generation* (optional).

Note:

The Analyzer may need to be reset (using the *New* or *Clear* command) between subsequent *Analyze* commands, since the Analyzer keeps track of what passes have been performed in order to minimize analysis time.

ASN1-Coder-Name

Parameters:

```
<name>
```

The prefix of encode and decode functions for ASN.1 types. Default is BER.

ASN1-Keyword-File

Parameters:

```
<file>
```

Change keywords in files output by asn1util according to file. Default is no file, in this case the keywords in file asn1util_kwd.txt in the SDT installation is used.

Asn1Util

Parameters:

```
<options>
```

Invoke asn1util through the post master. Same options as the command line interface.

Cd

Parameters:

`<directory>`

Change current working directory to <directory>.

Clear

Parameters:

`(None)`

Force the Analyzer to perform all passes from scratch as defined in the Analyzer options on the previously selected input. See also the *New* command described in "New" on page 2484.

Coder-Buffer-In-Sdl

Parameters:

`Octet-String | Coder-Buf | Custom-Coder-Buf | None`

Pick representation of ASN.1 Buffer in SDL, None means no encoding available in SDL. Default is Octet-String. For more information see "Buffer Management System" on page 2850 in chapter 58, *ASN.1 En-coding and De-coding in the SDL Suite*.

ComplexityMeasurement-File

Parameters:

`[<file spec>]`

Specifies where the complexity measurements file is stored if the Set-ComplexityMeasurement command is set.

Default is `<system name>.csv`.

See chapter 48, *Complexity Measurements* for more information.

Component

Parameters:

`[<SDL qualifier>]`

Add a new item to a program. See *"Partitioning" on page 2641 in chapter 56, The Cadvanced/Cbasic SDL to C Compiler*.

Cpp2sdl

Parameters:

<options>

Invoke cpp2sdl through the post master. Same options as the command line interface.

Env-Header-Channel-Name

Parameters:

```
[<name>]
```

Configuration of channel names in environment header file (.ifc). %n is the name of the entity in SDL, %s is the name of the scope. Omit <name> to exclude the definitions completely from the file. Default is %n.

Env-Header-Literal-Name

Parameters:

```
[<name>]
```

Configuration of literal names in environment header file (.ifc). %n is the name of the entity in SDL, %s is the name of the scope. Omit <name> to exclude the definitions completely from the file. Default is %n.

Env-Header-Operators

Parameters:

```
[On/Off]
```

Configure if operators should be present in environment header file (.ifc). Default is On.

Env-Header-Signal-Name

Parameters:

```
[<name>]
```

Configuration of signal names in environment header file (.ifc). %n is the name of the entity in SDL, %s is the name of the scope. Omit <name> to exclude the definitions completely from the file. Default is %n.

Env-Header-Synonym-Name

Parameters:

```
[<name>]
```

Configuration of synonym names in environment header file (.ifc). %n is the name of the entity in SDL, %s is the name of the scope. Omit <name> to exclude the definitions completely from the file. Default is %n.

Env-Header-Type-Name

Parameters:

```
[<name>]
```

Configuration of type names in environment header file (.ifc). %n is the name of the entity in SDL, %s is the name of the scope. Type definitions are always present in the file. Default is %n.

Error-File

Parameters:

```
[<file spec>]
```

An optional file to store analyzer messages in. Default is no error file.

Exit

Parameters:

```
(None)
```

Terminates the Analyzer and returns you to the Operating System prompt.

Filter

Parameters:

```
[Command]
```

This command allows filtering or preprocessing files before they are read by the Analyzer. The command should be an executable file, preferably found in $PATH. The Analyzer appends three parameters to the supplied command. The first parameter is the name of the file, the second parameter tells what the Analyzer is about to do with the file, and the third is the Source Directory. Currently the following are available:

- **use** (before SDL package dependencies are resolved, this phase is only activated when the environment variable SDTSAN_FILTER_USE is set)
- **import** (before converting to SDL PR)
- **macro** (before macro expansion)
- **parse** (before syntax analysis)
- **include** (before syntax analysis)

The command is supposed to modify the file given in the parameter and leave the result in the same file. Note that the files passed are your original files.

Generate-Advanced-C

Parameters:

(None)

This command invokes the Cadvanced SDL to C Compiler, which will produce one / multiple C program(s), as well as a makefile. This C program is then compiled and linked in order to build up an executable application. The Cadvanced SDL to C Compiler uses the options which have been previously defined using the various Generate Options commands. See also Generate-Basic-C.

Generate-Basic-C

Parameters:

(None)

This command invokes the Cbasic SDL to C Compiler, which will produce one / multiple C program(s), as well as a makefile. This C program is then compiled and linked in order to build up an executable application. The Cbasic SDL to C Compiler uses the options which have been previously defined using the various Generate Options commands. This command cannot be used when building applications, but otherwise it is identical to Generate-Advanced-C.

Generate-Micro-C

Parameters:[1]

(None)

This command invokes the Cmicro SDL to C Compiler, which will produce one / multiple C program(s), as well as a makefile. This C program is then compiled and linked in order to build up an executable application. The Cmicro SDL to C Compiler uses the options which have been previously defined using the various Generate Options commands. See also Generate-Advanced-C.

GR-PR-File

Parameters:

[<file spec>]

This command specifies where the output of the conversion to PR pass is stored. Default is <infile>.pr.

1. The exact syntax is subject to change since the tool is still under development.

GR2PR

Parameters:

```
<GR-File> <PR-File>
```

The command converts the file designated by the file specifier `GR-File` to a textual (i.e. PR) description of the diagram, storing the results in the file designated by the file specifier `PR-File`.

The file `GR-File` should contain an SDL diagram stored in binary format.

Help

Parameters:

```
[Command]
```

The command issues on-line help for the Analyzer commands. Depending on if a command is specified or not, the following happens:

- By typing this command without parameters, the available commands are listed with their parameters. Control is then transferred to the Analyzer on-line help, where additional information about all commands is available. The on-line help prompt looks like this:

  ```
  Topic?
  ```

  – Typing a command name followed by `<Enter>` issues information about the command.

  – Typing `<Enter>` only, returns control to the Analyzer prompt.

- Typing the Help command followed by a command name, on-line for that command will be displayed. Control is then transferred to the Analyzer on-line help utility.

You can abbreviate any topic name, although ambiguous abbreviations result in all matches being displayed.

Include-Directory

Parameters:

```
[<directory>]
```

Where the analyzer looks for include files. An empty <directory> clears the list.Subsequent commands adds more directories to the list. Default is an empty list.

Include-File

Parameters:

```
<file spec>
```

Execute analyzer commands in <file spec>.

Include-Map

Parameters:

```
<logical name> <file spec>
```

Maps logical names to file names for graphical includes when converting graphical SDL (GR) to text (PR). This command should be preceded by commands to specify input mode to GR and a GR file. Subsequent commands adds more maps to the list. Default is an empty list.

Input-Mode

Parameters:

```
ASN.1 | C-Header | GR | PR
```

Select filter to convert input to PR. Default is PR.

Instance-File

Parameters:

```
[<file spec>]
```

Where the instance tree is stored. Default is `<system name>.ins`. See "SDL Instance Information" on page 2512 for more information.

Macro-PR-File

Parameters:

```
[<file spec>]
```

This command specifies where the output of the macro expander is stored. Default is `<infile>.prm`.

Make-File

Parameters:

```
[<file spec>]
```

Name of makefile. Default is `<system name>.m`.

Make-Template-File

Parameters:

```
[<file spec>]
```

Name of make template file. Default is no template.

New

Parameters:

```
(None)
```

This command initializes the Analyzer. Following the *New* command, you will need to specify an input to the Analyzer using the *Set-Input* command.

See also "Clear" on page 2478.

Operating-System

Parameters:

```
(None)
```

Creates a subprocess which returns you temporarily to the Operating System. Once you terminate this process, control is returned to the Analyzer.

Organizer-Object

Parameters:

```
Level Type Name File Sep SepName Selected [Depend]
```

Pass the Organizers info on a diagram to the Analyzer. This command is used by the Organizer.

Pretty-PR-File

Parameters:

```
<Filespec>
```

This command specifies where the output of the pretty printer is stored. Default is `<infile>.sdl`.

Program

Parameters:

```
[<name>]
```

Name of program built from components. See *"Partitioning" on page 2641 in chapter 56, The Cadvanced/Cbasic SDL to C Compiler*.

Quit

Parameters:

```
(None)
```

Synonym for exit.

SDL-Coder-Name

Parameters:

```
<name>
```

The prefix of encode and decode functions for SDL types. Default is ASCII.

SDL-Keyword-File

Parameters:

```
[<file spec>]
```

Produce a list of SDL keywords and SDT Ref in a file. Default is no list.

SDT-Ref

Parameters:

```
[<sdt ref>]
```

Use <sdt ref> in error messages from command parser overriding any other <sdt ref>.

SDT-SYSTEM-6.3

Parameters:

```
(None)
```

The Organizer uses this to make sure the right version of the analyzer is running.

Set-ASN1-Coder

Parameters:

```
[On/Off]
```

Generates encoder and decoder from ASN.1 modules (requires separate license).

Default is off.

Set-C-Compiler-Driver

Parameters:

```
[On/Off]
```

This option informs the SDL to C compilers if the SDL C Compiler Driver should be invoked. See chapter 60, *SDL C Compiler Driver (SC-CD)*.

Default is off.

Set-C-Plus-Plus

Parameters:

`[On/Off]`

SDL to C compilers generate code to be compiled with C++ compiler if on. Default is off.

Set-Case-Sensitive

Parameters:

`[On/Off]`

Case sensitive SDL names if On. Keywords must be all upper or lower case if on.

Default is off.

Set-Compile-Link

Parameters:

`[On/Off]`

This option informs the Code Generator (SDL to C compilers) whether the generated code should be compiled and linked automatically (by executing the generated makefile).

Default is on.

Set-ComplexityMeasurement

Parameters:

`[On/Off]`

This option will generate a complexity measurement file. Following the *Set-ComplexityMeasurement* command, you may specify a file name using the ComplexityMeasurement-File command.

Default is off.

See chapter 48, *Complexity Measurements* for more information.

Set-Echo

Parameters:

`[On/Off]`

This option will print (echo) all Analyzer commands as they are executed. Default is off.

Set-Env-Function

Parameters:

`[On/Off]`

This option informs the code generators (SDL to C compilers) if environment functions should be generated or not.

Default is off.

Set-Env-Header

Parameters:

`[On/Off]`

This option is applicable to the SDL to C compilers only. With this parameter turned on, a header file containing the definitions of the SDL system's interface to the environment is created. This file is identified by the `.ifc` file name extension.

Default is off.

Set-Error-Limit

Parameters:

`<Errorlimit>`

This command sets the limit of reported errors after which the Analyzer will stop its execution. Use 0 to turn off the limit.

Default is a limit of 30 diagnostics.

Set-Expand-Include

Parameters:

`[On/Off]`

This option specifies whether include directives should be handled and expanded when reading input files. See "Including PR Files" on page 2506.

Default is on.

Set-Expression-Limit

Parameters:

`<Depth>`

This command instructs the Analyzer to issue a warning when the semantic analyzer encounters an SDL expression which is at least *Depth* deep.

> **Note:**
>
> Deeply nested expressions may cause a **significant degradation of performance** when performing the semantic analysis pass. It is therefore recommended to break down complex expressions into multiple, less complex expressions.

Default is 0, meaning that no warnings will be issued.

Set-External-Type-Free-Function

Parameters:

```
[On/Off]
```

This option informs the code generators if GenericFree should be called for variables of externally defined types (of struct kind).

Default is on.

Set-File-Prefix

Parameters:

```
[<file name prefix>]
```

Prefix for files generated by the code generators. Default is no prefix.

Set-Full

Parameters:

```
[On/Off]
```

Redo everything if on. Default is off.

Set-Generate-All-Files

Parameters:

```
[On/Off]
```

Existing files will not be touched by C code generators if the new version is identical to the existing one and this option if Off. Default is On.

Set-Ignore-Hidden

Parameters:

```
[On/Off]
```

Decides if PR should be generated for hidden SDL symbols. Default is On.

Set-Implicit-Type-Conversion

Parameters:

`[On/Off]`

When this option is on, the Analyzer allows implicit type conversion of reference data types (generators Own, ORef, and Ref). Note that analyzing large expressions with this option on is slow. Default is off.

For more information, see "Implicit Type Conversions" on page 134 in chapter 3, *Using SDL Extensions, in the SDL Suite 6.2 Methodology Guidelines*.

Set-Input

Parameters:

`<Filespec>`

The Analyzer will use the file specified in filespec as input file. The file will be processed according to the setting of Input-Mode (see "Input-Mode" on page 2483). Use Add-Input to process a system stored in several files.

Set-Instance

Parameters:

`[On/Off]`

With this option on, a file containing the SDL instance tree will be generated. Default is off. See "SDL Instance Information" on page 2512 for more information.

Set-Kernel

Parameters:

`<Kernel>`

This option is applicable to the SDL to C compilers only. This option allows you to select the appropriate kernel with predefined runtime libraries. The makefile generated by the SDL to C compilers contains instructions which link the generated and compiled code with object modules of the selected library. The effect of this will be that the code which is generated by the SDL to C compilers will have different properties, reflecting the purpose of its usage (simulation, application generation, etc.). The allowed values of the parameter kernel vary from one configuration to another. The definitions are made in the file `sdtsct.knl`. The definitions for Cadvanced are made in the file `sdtsct.knl`, whereas the definitions for Cmicro are made in the file `scmsct.knl`.

The following values are recognized for Cadvanced:

Library	Application area
SCTADEBCOM	Simulation, simulated time
SCTADEBCLCOM	Simulation, real time
SCTAPERFSIM	Performance simulation
SCTAAPPLCLENV	Application
SCTADEBCLENV	Application debug (simulation with environment, only Cadvanced)
SCTAVALIDATOR	Validation
SCTATTCNLINK	TTCN link

The following values are recognized for Cmicro:

Library	Application area
SCMADEBCOM	SDL Target Tester and communication, no real time clock
SCMADEBCLCOM	SDL Target Tester, communication and real time clock
SCMADEBCLENVCOM	SDL Target Tester, communication, user's env and real time clock
SCMAAPPLCLENVMIN	Application with environment, clock, etc.
SCMAAPPLCLENV	Evaluation Kernel (no complex ADT; no SDL Target Tester)

Note:

The predefined kernels for Cmicro cannot be used with any C compiler. They require GCC 2.95.2 **on UNIX** or Microsoft Visual C++ 6.0 **in Windows**.

Set-Lower-Case

Parameters:

`[On/Off]`

SDL does not distinguish between lower case letters (a..z) and upper case letters (A..Z), but the high level programming language C does. With this parameter turned on, the names of, for instance, variables in the generated C code is written in lower case letters only. Otherwise, the case of an item in the SDL definition is used.

Default is off.

Set-Macro

Parameters:

`[On/Off]`

Turns on or off the macro expansion pass. This option must be turned on if your diagram contains references to macro(s).

Default is off.

Set-Make

Parameters:

`[On/Off]`

This command affects an option which enables or disables the generation of a makefile in conjunction with generation of C code.

Default is on.

Set-Modularity

Parameters:

`[Modularity]`

Allows to specify the modularity of the code generated by the code generators, e.g. the SDL to C compilers. This option affects how many files will be generated.

Three options for the parameter *Modularity* are available:

- *No* – One single code module is generated.
- *User* – User defined, according to the definitions in the Organizer. See "Edit Separation" on page 137 in chapter 2, *The Organizer*.
- *Full* – Multiple code modules will be generated.

Default value is *No*.

Set-Optional-Make-Operator

Parameters:

```
[On/Off]
```

Optional and default struct parameters are included in the make operator (invoked by (. .)) if On. Default is Off.

Set-Output

Parameters:

```
<Filespec>
```

Allows you to save the information generated by the Analyzer in files with a different name, using *Filespec* as the base name.

File name extensions are appended automatically by the Analyzer.

Set-Pr2Gr

Parameters:

```
[On/Off]
```

Turning this option on, the Analyzer will perform the PR to GR conversion pass. The steps are:

1. The Analyzer creates diagram files with temporary names.
2. The Analyzer lets the SDL Editor do tidy up on the diagram files.
3. The Organizer renames/moves diagram files according to its preference.

Step 3 is only performed when a PR to GR conversion is run from the Organizer. The request to put temporary files in the current working directory is ignored on the Windows platform (they end up in some temp directory).

Default is off.

Set-Predefined-XRef

Parameters:

```
[On/Off]
```

Include predefined data in SDL cross reference file if On. Default is Off.

Set-Prefix

Parameters:

`[Prefix]`

Allows you to specify what prefix the code generators add to SDL names in the generated code.

Possible values for the parameter *prefix* are:

- *No*
- *Entity*
- *Full*
- *Special*

Default is *Full*.

Set-Pretty

Parameters:

`[On/Off]`

Turning this switch on, a pretty printed PR file will be generated.

Default is off.

Set-References

Parameters:

`[On/Off]`

This option allows you to disable the verification that exactly one reference corresponds to each remote definition.

Default is on.

Set-SDL-Coder

Parameters:

`[On/Off]`

Generate encoder and decoder from SDL (requires separate license).

Default is off.

Set-Sdt-Ref

Parameters:

`[On/Off]`

Decides if SDT references should be included in the generated code as comments for easier navigation to its source. As default, SDT references in comments are included. Note that omitting SDT references in

comments by using this command is not supported by standard IBM Rational code generators.

Set-Semantic

Parameters:

`[On/Off]`

With this option turned on, the semantic check pass will be performed. Otherwise, the Analyzer will stop after the syntactic check.

Default is on.

See also "Optimizing a System to Reduce Analysis Time" on page 2621 in chapter 55, *Analyzing a System*.

Set-Signal-Number

Parameters:

`[On/Off]`

Code generators will generate a file with signal numbers if on.

Default is off

Set-Source

Parameters:

`[On/Off]`

This command informs the code generators whether to generate C code or not when a generate code command is given. The reason for disabling code generation is that you may want to produce a makefile only, without generating code.

Default is on.

Set-Synonym

Parameters:

`[On/Off]`

Decides if the specified synonym file should be used or not. Default is Off.

Set-Syntax

Parameters:

`[On/Off]`

This option turns on or off the syntax analysis pass.

Default is on.

Set-TAEX-Make

Parameters:

`[On/Off]`

This command controls the generation of a makefile for Targeting Expert in conjunction to generation of C code.

Default is off.

Set-Upcase-Keyword-Pretty

Parameters:

`[On/Off]`

Select between upper or lower case keywords in pretty printings.

Default is off (i.e. lower case letters).

Set-Warn-Else-Answer

Parameters:

`[On/Off]`

Print a message if a decision or transition option does not have an else answer and the Analyzer is unable to decide that it is not needed.

Default is on.

Set-Warn-Match-Answer

Parameters:

`[On/Off]`

Print a message if a decision or transition option does not have an answer for some value. The analyzer is not able to do this in all situations.

Default is on.

Set-Warn-Parameter-Mismatch

Parameters:

`[On/Off]`

Print a message if the types of the actual and formal parameters are implemented with different typedef, i.e. they may be of different size. This is only checked for functions that cannot handle length mismatch. No warning is given if the actual parameter is a literal.

Default is on.

Set-Warn-Optional-Parameter

Parameters:

`[On/Off]`

Print a message if an optional actual parameter is omitted.

Default is on.

Set-Warn-Output

Parameters:

`[On/Off]`

Print a warning message if an SDL signal output has a different semantic meaning between SDL 88 and 92.

Default is on.

> **Note:**
>
> This command is particularly useful when working with SDT 2.X diagrams in an SDT 3.X environment (SDT 2.X supports SDL-88, while SDT 3.X supports SDL-92).

Set-Warn-Parameter-Count

Parameters:

`[On/Off]`

Print a message if trailing actual parameters are omitted.

Default is on.

Set-Warn-Usage

Parameters:

`[On/Off]`

Print a message if an SDL definition is not used.

Default is off.

Set-Xref

Parameters:

`[On/Off]`

With this option on, a file containing *SDL Cross References* will be generated. See "SDL Cross-References" on page 2508.

Default is off.

Show-Analyze-Options

Parameters:

```
(None)
```

This command lists the current Analyzer options.

Show-Commands

Parameters:

```
(None)
```

Similar to *Help*. The commands are listed without the command parameters.

Show-Generate-Options

Parameters:

```
(None)
```

This command displays the code generator options as currently defined.

Show-License

Parameters:

```
(None)
```

This command returns information about:

- The total amount of software licenses
- How many licenses are currently in use, together with the user identification, the host name and the checkout time
- How many licenses are available

Show-Version

Parameters:

```
(None)
```

This command displays the version number of the Analyzer.

Source-Directory

Parameters:

```
[<directory>]
```

The analyzer looks for include files in this directory.

Default is current working directory.

Synonym-File

Parameters:

```
[<file spec>]
```

Specifies the synonym file (containing values of external synonyms). Default is no synonym file.

TAEX-Make-File

Parameters:

```
[<file spec>]
```

Name of makefile for Targeting Expert. See *Set-TAEX-Make*.

Target-Directory

Parameters:

```
[<directory>]
```

Specifies the directory where the code generators puts their files.

Default is current working directory.

Thread

Parameters:

```
<name> <stacksize> <stackprio> <maxqueuesize>
<maxmessize>
```

Use this command to distribute components of a program over several threads. Components following this command belongs to this thread. Parameters at the end may be omitted. Omitted parameters will use default values. The word default can be used to indicate that the default value is desired for a parameter. For more information see "Threaded Integration" on page 3303 in chapter 64, *Integration with Operating Systems*.

XRef-File

Parameters:

```
[<file spec>]
```

Specifies where the cross references are stored.

Default is `<infile>.xrf`.

Miscellaneous Analyzer Commands

The following commands can be used for instance in the case of malfunction or unexpected behavior. They are not described further within the scope of the user documentation.

zzMake-Options
Parameters:
(None)

zzSet-Access-Path-Tab
Parameters:
(None)

zzSet-Optimize
Parameters:
(None)

zzSet-Organizer-File
Parameters:
(None)

zzSet-Over-View
Parameters:
(None)

zzSet-SDT
Parameters:
(None)

zzSet-Verbose
Parameters:
(None)

zzSet-Warn-Oper-Usage
Parameters:
(None)

zzShow-Error
Parameters:
(None)

zzShow-Organizer
Parameters:
(None)

zzTransport
Parameters:
(None)

zzWrite-Name-List
Parameters:
(None)

zzWrite-Path
Parameters:
(None)

zzWrite-Pretty
Parameters:
(None)

zzWrite-Symbol
Parameters:
(None)

zzWrite-Syntax
Parameters:
(None)

Conversion to PR

During the first pass of the Analyzer, an SDL/PR file suitable for processing by the following passes (Macro Expansion or Syntax analysis) is produced. The resulting PR file is not intended to be read by the human, and is not formatted for that purpose. Conversion to PR is needed when input is not already in SDL/PR format, i.e, for SDL/GR diagrams, ASN.1 files, and C header files.

Several tools might be invoked through the PostMaster to perform the actual conversion:

- The SDL Editor to process SDL/GR. See "GR to PR Conversion" on page 2047 in chapter 43, *Using the SDL Editor*.
- The ASN.1 Utilities to process ASN.1. See "Translation of ASN.1 to SDL" on page 704 in chapter 13, *The ASN.1 Utilities*.
- The CPP2SDL Utility to process C/C++ header files. See "C/C++ to SDL Translation Rules" on page 785 in chapter 14, *The CPP2SDL Tool*.

Additional SDL/PR files may be copied into the output of this pass.

A number of checks are performed during this conversion pass. Many of these are actually syntactic in their nature. They may result in error messages; see "Error and Warning Messages" on page 2531.

The Macro Expander

A macro is a form of text substitution used in the SDL system definitions. In a macro definition, a collection of lexical units is defined. A macro call indicates where the text from the macro definition body is to be included. All macro calls must be expanded before further analysis of the system definition can be done.

> **Note:**
>
> **Macros may not contain any states.**
>
> **Diagrams referenced in PR form and macros only called in PR will not be converted. If a macro is called only in PR form, the macro definition must be in PR and placed in a diagram that will be converted.**

The name of the macro definition is visible in the whole system definition. A macro call may appear before its corresponding macro definition. A macro definition may contain macro calls, but not calls to itself, directly or indirectly.

A macro may use parameters, called formal parameters, in macro definitions and actual parameters in macro calls. There must be an equal number of formal parameters and actual parameters in corresponding macro definitions and macro calls. Using multiple formal parameters with the same name is not allowed.

When a character string is used as an actual parameter, the value of the character string will be used to replace the formal parameter in the macro body and not the character string itself.

The keyword *MACROID* may be used in a macro definition body only. The *MACROID* keyword will be replaced by a unique name at each expansion of the macro (that is, only one unique name is available at each expansion of a macro definition). New names can be constructed by concatenating names, parameters and *MACROID* using a percent sign (%) as a separator.

The reserved word *MACRODEFINITION* is not allowed inside a macro definition. The reserved words *MACROID* and *ENDMACRO* are only allowed inside a macro definition.

Macro expansion follows this order:

1. The name in the macro call is used to find the corresponding macro definition, and a copy of that macro definition is made.
2. In this copy, all occurrences of formal parameters are replaced by actual parameters. All occurrences of *MACROID* are replaced by a unique name. Also, all percent signs (%) separating names are removed.
3. Macro calls in the modified macro definition body are expanded.
4. The modified and expanded text is substituted for the macro call text in the system definition.

Implementation Details

The syntax checks made in the macro parser are entirely specific to macros since no other checks are possible until all macro calls are expanded. Some semantic checks are made during the expansion. These may produce error messages; see "Error and Warning Messages" on page 2531.

Example 346: Macro in SDL that Will Not Work

Constructs such as:

```
macro test('if par3 then',
           'if not par3 then',
           'k<0') ;
```

where the text `par3` in the first and second parameter strings is intended to be replaced by the third formal parameter in the macro definition will not work. This is because all formal parameters are replaced with actual parameters in a single step.

The reserved word *MACROID* is replaced by a unique name consisting of the string *"XMID"* and an integer. To assure system wide uniqueness the name is tested against all existing names in the system and the integer will be increased until the name is unique.

The Lexical and Syntactic Analyzer

The scanner (*lexical analyzer*) reads the input file and passes on lexical units to the parser. The parser checks the syntax and builds an internal representation (an abstract syntax tree) for the SDL specification.

The lexical and syntactic analysis may be performed not only on complete system definitions, but also on the following SDL units:

- *Block*
- *Process*
- *Substructure*
- *Service*
- *Procedure*
- *Package*

If no errors are found during the syntactic analysis, the syntax tree can be passed to the pretty-printer and, if the input is a system or package definition, to the semantic analyzer. For a description of the errors that can produced, see "Error and Warning Messages" on page 2531.

Separate Analysis

You may perform analysis on separate SDL units. The units that can be handled (other than system) are:

- *Block*
- *Process*
- *Substructure*
- *Service*
- *Procedure*
- *Package*

> **Note:**
>
> When performing separate analysis on a package, referred packages must be supplied as well.

If a unit is given without context, only syntactic checking can be performed. But, if the unit's placement in the system (that is, its context) is also given, both the syntactic checking and most of the semantic checking can be performed. The context of a unit is its enclosing scope units including the definitions that are not referenced, i.e. remote diagrams are excluded.

GR Input

In the Analyzer, the context is specified in the Organizer tree structure if the input is a GR diagram. The diagrams surrounding the diagram that is to be separately analyzed and the diagrams inside that diagram are translated to PR and analyzed. No errors will occur due to missing remote diagrams, except missing remote diagrams inside the separately analyzed diagram. See "Performing Syntax Check" on page 2620 in chapter 55, *Analyzing a System*.

PR Input

If the input is a PR file, there is no way to specify what part of the system to Analyze. Only syntax analysis is available on incomplete systems in PR form. See "Converting SDL/PR to SDL/GR" on page 2628 in chapter 55, *Analyzing a System*.

Including PR Files

The Analyzer allows the user to divide the SDL description into a number of separate PR files. (The macro expansion can, however, only handle one file at a time.) It may, for example, be convenient to have the system level data type definitions in a separate file. A separate file is included by adding an *include directive* to the SDL description.

Syntax of #INCLUDE Directives

The include directive is `#INCLUDE` followed by the name of the file which should be surrounded by single quotation marks. The directive should be placed in an SDL comment, directly after the comment start ("/*"), at the place where the file should be included.

- The first single quote must be preceded by at least one space. `<TAB>` characters are however not allowed.
- The second single quote may be followed by any number of spaces. `<TAB>` characters are however not allowed.

Example 347: #INCLUDE in Analyzer ----------

```
System Example;
/*#INCLUDE 'DataDefs.pr' */
/*#INCLUDE 'BlockA.pr' */
EndSystem Example;
```

Search Order for Included PR Files

The Analyzer will search for included SDL/PR files in the following order:

1. Any directory specified with Include-Directory command
2. Source directory
3. The current default directory
4. The directory designated by the environment variable `HOME`.
5. The directory designated by `$telelogic/sdt/include/ADT` **(on UNIX)**, or <*installation directory*>`\sdt\include\adt` **(in Windows)**
   (This directory contains a number of useful abstract data types in

SDL/PR that are included in the release. See chapter 62, *The ADT Library* for more information.)

The PR to GR Converter

General

The PR to GR Converter performs a conversion from SDL/PR files into SDL/GR diagrams. (It is also possible to input SDL/GR diagrams, which transforms them to new SDL/GR diagrams, applying default layouting algorithms.)

Conversion is done on a one-diagram-per-file basis, meaning that each generated GR diagram will be stored on one file. However, entering a PR file may generate multiple GR diagrams, depending on the contents of the PR file.

> **Note:**
>
> The PR to GR converter requires **syntactically correct** diagrams or PR files as input in order to function properly.
>
> Diagrams containing semantic errors will be converted, but, the **resulting** SDL/GR interpretation may be different from the SDL/PR representation.

Conversion Principles

The Analyzer passes which are performed are:

1. Macro expansion (if the PR input contains macro definitions).
2. Syntax analysis.
3. PR to GR conversion.
4. Then, graphical layouting is done by the SDL Editor.

Resulting files

The result from the PR to GR conversion is a number of SDL/GR binary files. Each diagram will be stored on one file.

To reconstruct the SDL diagram structure, the Organizer's command *Import SDL* should be used (see "Import SDL" on page 80 in chapter 2, *The Organizer*).

SDL Cross-References

The Analyzer has the ability to produce listings of SDL entities and references to these definitions. In one file, all *definitions* of entities in an SDL system will be gathered, along with cross references to these entities. Entities mainly used to indicate structure (such as system, block, substructure, process, procedure, and service), as well as entities defining objects (such as signals, variables and sorts) will be considered as definitions.

The file, which is described further below, is a plain text file.

> **Note:**
>
> The SDL Suite has support for graphical presentation of a cross-reference file, using an SDL-like graphical notation. To achieve this, you can use the Index Viewer. See chapter 46, *The SDL Index Viewer*.

Definitions and Cross References Files

The file name will be `<unitname>.xrf` for the *cross references file*, where <unitname> is the name of the SDL unit selected for analysis. Alternatively, the file name is to be supplied by the user when running the Analyzer from the Organizer.

If an SDL system is selected for analysis, all definitions and cross references are generated; while if case of a non-SDL system unit, definitions and cross references in the following units are generated:

- The unit itself
- All subunits to the selected unit
- All enclosing units (blocks and the system) of the selected unit

The following entities will be part of the files:

ACTIVE	ATLEAST

BLOCK	BLOCK SUBSTRUCTURE
CHANNEL	CHANNEL SUBSTRUCTURE
CONNECTION	CONTINUOUS SIGNAL
CREATE	DCL
DECISION	ENABLING CONDITION
EXPORT	EXPORTED_PROCEDURE
FORMAL PARAMETER	FPAR
GATE	GENERATOR
IMPORT	IMPORTED
IMPORTED VARIABLE	IN-CONNECTOR
INHERITS	INPUT
INSTANTIATION	JOIN
LITERAL	NEWTYPE
NEXTSTATE	NUMBER OF INSTANCES
OPERATOR	OUT-CONNECTOR
OUTPUT	PACKAGE_INTERFACE
PROCEDURE	PROCEDURE CALL
PROCEDURE PARAMETERS	PROCESS
PROCESS PARAMETERS	REMOTE PROCEDURE
REMOTE VARIABLE	RESET
SAVE	SERVICE
SET	SIGNAL
SIGNAL ROUTE	SIGNALLIST
SIGNALROUTE	SIGNALSET
SORT	STATE
STATE_LIST	SYNONYM
SYNTYPE	SYSTEM

TASK	TIMER
TRANSITION OPTION	USE
VARIABLE	VIEW
VIEWED	

Note:

No cross references will be generated for the predefined data types (INTEGER, NATURAL, CHARACTER, CHARSTRING, BOOLEAN, REAL, TIME, DURATION, PID) or for the predefined generators (ARRAY, STRING, POWERSET) as well as LITERALS and OPERATORS that are not part of the list above.

Syntax of Files

For each definition of any kind mentioned above the following information is generated:

```
ScopeLevel EntityType EntityName Reference
```

Explanation

- The number first on the line is the *scope level*. The system has level 1, any definition at the system level has scope level 2, and so on.
- Next on the line the *entity type* and *entity name* are given.
- Last there is an *SDT reference* to the place where the entity is defined. For more information on the format, see "Syntax" on page 917 in chapter 18, *SDT References*.

For each entity used to indicate structure (system, block, substructure, process, procedure, service) there is a header consisting of three additional lines, which should be considered as a comment to increase the readability.

Example 348: Reference in Analyzer Error

```
2  SIGNAL Bump \
SDTREF(SDL,/usr/tom/demongame.ssy(1),122(40,30),3)
```

Order of Definitions

The definitions are generated in pre-order (prefix walk in the tree formed by the definitions). This means that an entity is always followed by the entities defined within the entity. It also means that an entity at level N is defined in the first entity at level N-1 found when scanning upwards in the file.

Cross References

For each place where an entity is used, information about that cross reference is generated:

Example 349: Cross References ––––––––––––––––––––––––––––––

```
4  DCL Count \
#SDTREF(SDL,/usr/tom/game.spr(1),179(80,10),2)
     TASK \
#SDTREF(SDL,/usr/tom/game.spr(1),137(30,40),1)
     OUTPUT \
#SDTREF(SDL,/usr/tom/game.spr(1),128(80,55),2)
```

––

Cross references consist of a keyword, describing where the reference was found, and the SDL reference. In Example 349 on page 2511, the variable Count is referenced in a task symbol and in an output. All cross references for an entity are placed immediately after the line for the definition.

Note:

Entities used to indicate structure can also have cross references (procedure call, process create).

SDL Instance Information

The Analyzer supports the generation of a so-called instance information file, with the file extension `.ins`. This file contains various kinds of information about an SDL system. Similar to a cross reference file, it is a plain text file. The file syntax is described in detail in "File Syntax" on page 2513. The Analyzer invokes a tool called the Instance Generator to produce the instance information out of an analyzed SDL system.

The information that can be found in an instance information file helps to answer many questions. For example:

- How does a complex SDL-92 system look after instantiation of all types, i.e. when all inheritance hierarchies have been flattened out? Finding this information about the instance structure of a system directly from the SDL/PR file is a non-trivial task. Therefore, one of the main objectives behind the Instance Generator is to provide this "instance view" of a system.
- Which signals can be conveyed on a certain channel or signal route in a certain direction?
- What is the valid input signal set of a process?
- Which states does a process contain?
- Which transitions will take place if a certain signal is received by a process being in a certain state?
- Which output signals might be sent during a transition?
- Which procedures might get called during a transition?
- What is the set of possible nextstates after a transition?
- How shall a procedure be interpreted when called from a certain process?

The Instance Generator

The Analyzer provides two commands to use the Instance Generator from the command line user interface. These commands are described in "The Analyzer Command Line UI" on page 2474 but are repeated here for the sake of completeness.

Set-Instance

Parameters:

`[On/Off]`

This command sets an option that specifies whether an instance information file should be generated or not when the SDL system is analyzed. The option is by default off.

Instance-File

Parameters:

`<file spec>`

This command sets the name of the instance information file. The default filename is `<systemname>.ins`, where `<systemname>` is the name of the analyzed SDL system.

The Instance Generator can also be started from the Analyzer's graphical user interface. This is done in a way similar to how cross reference files are generated. In the Analyze dialog in the Organizer, you can check a button to make the Analyzer call the Instance Generator when the system has been analyzed. From this dialog it is also possible to set the name of the generated instance information file.

Note:

The Instance Generator is automatically invoked to produce the information needed by tools such as the State Matrix Viewer.

File Syntax

An instance information file consists of a *fileheader* followed by a list of *records*:

```
<fileheader>
<record>
<record>
...
<record>
```

The `<fileheader>` is a string telling which version of the Instance Generator that has generated the file. Each `<record>` describes an SDL entity according to the following format:

```
<level> <entity class> <name>
        <attribute> = <value>
        ...
        <attribute> = <value>
        .
```

The <level> is a number that tells at what depth in the "instance tree" the entity was found. For example, the system entity has level 1, a block entity in the system has level 2, a process entity in the block has level 3, and so on.

Attributes can be divided into three distinct **categories** depending on the format of their values:

1. A single value:

```
<attribute> = <single value>
```

2. A list of single values:

```
<attribute> = (
  <single value>
  <single value>
  ...
  <single value>
)
```

3. A list of pairs of single values:

```
<attribute> = (
  <single value> <single value
  <single value> <single value>
  ...
  <single value> <single value>
)
```

Sometimes an attribute is omitted from a record. This happens when the value of the attribute is an empty string or list.

The table below lists all entity classes for which information is generated in an instance information file. The attributes of the entities are also described, together with the category of the attributes (1, 2 or 3 according to above).

In the descriptions, the following terms are used:

- A *state-containing entity* is an entity that may contain states, i.e. a process, process instance, service, service instance or procedure.
- A *transition initiator* is an entity that can make a state-containing entity perform a transition from one state to another, i.e. a start, input, priority input, enabling condition or continuous signal.

Entity class	Attribute	Category	Description
BLOCK	InstRef	1	An SDT reference to the definition of this block.
	ConnectionOut	2	The names of the channels that are on the outside of this block.
	ConnectionIn	2	The names of the channels or signal-routes that are on the inside of this block.
BLOCK_INST	InstRef	1	An SDT reference to the definition of this block instance.
	TypeRef	2	SDT references to block type definitions. The first reference is to the block type from which this block instance is instantiated, followed by references to its supertypes all the way to the block type on top of the inheritance hierarchy.
CALLED_ PROCEDURE	InstRef	1	An SDT reference to the definition of this called procedure.
CHANNEL	InstRef	1	An SDT reference to the definition of this channel.
	SignalSet	3	The signals that are conveyed on this channel in the direction from the From-entity to the To-entity. Each signal is described by its name followed by an SDT reference to the definition of the signal.
	SignalSetRev	3	As SignalSet but for the signals that are conveyed in the opposite direction.

Entity class	Attribute	Category	Description
	From	1	The name of the block or block instance from which this channel starts. If the channel starts from the environment surrounding the system, system instance, block or block instance where this channel is located, this attribute is “env”.
	FromVia	1	This attribute is specified when the From-entity is a block instance, and is then the name of the gate of that block instance to which this channel is connected.
	To	1	The name of the block or block instance to which this channel leads. If the channel leads to the environment surrounding the system, system instance, block or block instance where this channel is located, this attribute is “env”.
	ToVia	1	This attribute is specified when the To-entity is a block instance, and is then the name of the gate of that block instance to which this channel is connected.
CHANNEL_SUBSTRUCTURE	InstRef	1	An SDT reference to the definition of this channel substructure.
CONTINUOUS_SIGNAL[a]	InstRef	1	An SDT reference to the definition of this continuous signal.
	InType	1	The name of the state-containing entity in which this continuous signal is defined.

Entity class	Attribute	Category	Description
	Outputs	3	The output signals that might be sent in the transition that is initiated by this continuous signal. Each signal is described by its name followed by an SDT reference to one of the output symbols in the transition that contains that name.
	Calls	3	The procedures that might get called in the transition that is initiated by this continuous signal. Each procedure is described by its name followed by an SDT reference to one of the symbols in the transition that contains a call to a procedure with that name. This name is also the name of a CALLED_ PROCEDURE entity that describes how the procedure look from the calling state-containing entity's point of view. This entity is normally placed immediately after the state information of the state-containing entity. However, when the state-containing entity is a procedure within another state-containing entity, it might be that the procedure has been called from another place in this surrounding state-containing entity. Then the CALLED_ PROCEDURE entity is not placed here also, since it is identical to the first one.
	NextStates	3	The states that might become the next-state after the transition that is initiated by this continuous signal. Each state is described by a name followed by an SDT reference to one of the state symbols that contains that name.

Entity class	Attribute	Cate-gory	Description
ENABLING_CONDITION	InstRef	1	See the description for CONTINUOUS_SIGNAL.
	InType	1	See the description for CONTINUOUS_SIGNAL.
	Outputs	3	See the description for CONTINUOUS_SIGNAL.
	Calls	3	See the description for CONTINUOUS_SIGNAL.
	NextStates	3	See the description for CONTINUOUS_SIGNAL.
GATE	InstRef	1	An SDT reference to the definition of this gate.
	SignalSet	3	The signals that are conveyed through this gate in to the block instance, process instance or service instance to which the gate belongs. Each signal is described by its name followed by an SDT reference to the definition of the signal.
	SignalSetRev	3	As SignalSet but for the signals that are conveyed in the opposite direction.
INPUT	InstRef	1	See the description for CONTINUOUS_SIGNAL.
	InType	1	See the description for CONTINUOUS_SIGNAL.
	Outputs	3	See the description for CONTINUOUS_SIGNAL.
	Calls	3	See the description for CONTINUOUS_SIGNAL.
	NextStates	3	See the description for CONTINUOUS_SIGNAL.

Entity class	Attribute	Category	Description
PRIORITY_INPUT	InstRef	1	See the description for CONTINUOUS_SIGNAL.
	InType	1	See the description for CONTINUOUS_SIGNAL.
	Outputs	3	See the description for CONTINUOUS_SIGNAL.
	Calls	3	See the description for CONTINUOUS_SIGNAL.
	NextStates	3	See the description for CONTINUOUS_SIGNAL.
PROCESS	InstRef	1	An SDT reference to the definition of this process.
	IniNoOfInst	1	The initial number of dynamic instances of this process.
	MaxNoOfInst	1	The maximum number of dynamic instances of this process. If this attribute is omitted it means that there is no upper limit on the number of dynamic instances.
	SignalSet	3	The signals that can be received by this process. This set of signals is commonly known as the valid input signal set of the process. Each signal is described by its name followed by an SDT reference to the definition of the signal.
	ConnectionOut	2	The names of the signalroutes that are on the outside of this process. Naturally, this attribute is only present when the process consists of services.

Entity class	Attribute	Category	Description
	ConnectionIn	2	The names of the signalroutes that are on the inside of this process. Naturally, this attribute is only present when the process consists of services.
PROCESS_INST	InstRef	1	An SDT reference to the definition of this process instance.
	TypeRef	2	SDT references to process type definitions. The first reference is to the process type from which this process instance is instantiated followed by references to its supertypes all the way to the process type on top of the inheritance hierarchy.
	IniNoOfInst	1	The initial number of dynamic instances of this process instance.
	MaxNoOfInst	1	The maximum number of dynamic instances of this process instance. If this attribute is omitted it means that there is no upper limit on the number of dynamic instances.
	SignalSet	3	The signals that can be received by this process instance. This set of signals is commonly known as the valid input signal set of the process instance. Each signal is described by its name followed by an SDT reference to the definition of the signal.
SAVE	InstRef	1	An SDT reference to the definition of this save.
	InType	1	The name of the state-containing entity in which this save is defined.
SERVICE	InstRef	1	An SDT reference to the definition of this service.

Entity class	Attribute	Category	Description
SERVICE_INST	InstRef	1	An SDT reference to the definition of this service instance.
	TypeRef	2	SDT references to service type definitions. The first reference is to the service type from which this service instance is instantiated followed by references to its supertypes all the way to the service type on top of the inheritance hierarchy.
SIGNALROUTE	InstRef	1	An SDT reference to the definition of this signalroute.
	SignalSet	3	The signals that are conveyed on this signalroute in the direction from the From-entity to the To-entity. Each signal is described by its name followed by an SDT reference to the definition of the signal.
	SignalSetRev	3	As SignalSet but for the signals that are conveyed in the opposite direction.
	From	1	The name of the process, process instance, service or service instance from which this signalroute starts. If the signalroute starts from the environment surrounding the block, block instance, process or process instance where this signalroute is located, this attribute is “env”.
	FromVia	1	This attribute is specified when the From-entity is a process instance or a service instance, and is then the name of the gate of that process instance or service instance to which this signalroute is connected.

Entity class	Attribute	Category	Description
	To	1	The name of the process, process instance, service or service instance to which this signalroute leads. If the signalroute leads to the environment surrounding the block, block instance, process or process instance where this signalroute is located, this attribute is “env”.
	ToVia	1	This attribute is specified when the To-entity is a process instance or a service instance, and is then the name of the gate of that process instance or service instance to which this signalroute is connected.
START[b]	InstRef	1	See the description for CONTINUOUS_SIGNAL.
	InType	1	See the description for CONTINUOUS_SIGNAL.
	Outputs	3	See the description for CONTINUOUS_SIGNAL.
	Calls	3	See the description for CONTINUOUS_SIGNAL.
	NextStates	3	See the description for CONTINUOUS_SIGNAL.
STATE	InstRef	2	SDT references to the state symbols in the state-containing entity that contain the name of this state. If the state-containing entity is a process type, service type or procedure, occurrences in the supertypes are also included.
SUBSTRUCTURE	ConnectionOut	2	The names of the channels that are on the outside of this substructure.

Entity class	Attribute	Cate-gory	Description
	ConnectionIn	2	The names of the channels or signal-routes that are on the inside of this sub-structure.
SYSTEM	InstRef	1	An SDT reference to the definition of this system.
SYSTEM_INST	InstRef	1	An SDT reference to the definition of this system instance.
	TypeRef	2	SDT references to system type definitions. The first reference is to the system type from which this system instance is instantiated followed by references to its supertypes all the way to the system type on top of the inheritance hierarchy.

a. The name of a CONTINUOUS_SIGNAL entity is set to the priority of the continuous signal. If no priority has been specified, maximum priority is assumed and the name is then set to “MAX_PRIO”.

b. The name of a START entity is always set to “Start”.

Information about the entities is generated in pre-order (prefix walk in the instance tree). This means that an entity is always followed by the entities defined within itself.

A formal and complete description of the general format of an instance information file would be rather complex, and is beyond the scope of this text. Instead, see Example 350:

Example 350: An instance information file

Consider the SDL system below:

```
System ExSystem;
  Signal Sig(Integer), Inp;
  channel ExChannel
    from ExBlock to env with Sig;
    from env to ExBlock with Inp;
  endchannel ExChannel;
  block ExBlock referenced;
endsystem ExSystem;

Block ExBlock;
  signalroute ExSignalRoute
    from ExProcess to env with Sig;
    from env to ExProcess with Inp;
  process ExProcess referenced;
  connect ExChannel and ExSignalRoute;
endblock ExBlock;

Process ExProcess;
  DCL Counter Integer;
  procedure ExProcedure referenced;
  start ;
    task Counter := 0;
    grst4:
  nextstate Wait;
  state Wait;
    input Inp;
    task {
      Counter := call ExProcedure(Counter);
    };
    output Sig(Counter);
    join grst4;
  endstate;
endprocess ExProcess;

Procedure ExProcedure;FPAR a Integer;RETURNS ret
Integer;
  start ;
  nextstate Idle;
  state Idle;
    input *;
    task {
      ret := a+1;
    };
    return ;
  endstate;
endprocedure ExProcedure;
```

The instance information file for this SDL system will look like this:

```
SDTINST V1.0
1  SYSTEM ExSystem
   InstRef = #SDTREF(TEXT,ExSystem.pr,1)
   .
2  CHANNEL ExChannel
   InstRef = #SDTREF(TEXT,ExSystem.pr,3)
   SignalSet = (
     Sig #SDTREF(TEXT,ExSystem.pr,2)
   )
   SignalSetRev = (
     Inp #SDTREF(TEXT,ExSystem.pr,2)
   )
   From = ExBlock
   To = env
   .
2  BLOCK ExBlock
   InstRef = #SDTREF(TEXT,ExSystem.pr,10)
   ConnectionOut = (
     ExChannel
   )
   ConnectionIn = (
     ExSignalRoute
   )
   .
3  SIGNALROUTE ExSignalRoute
   InstRef = #SDTREF(TEXT,ExSystem.pr,11)
   SignalSet = (
     Sig #SDTREF(TEXT,ExSystem.pr,2)
   )
   SignalSetRev = (
     Inp #SDTREF(TEXT,ExSystem.pr,2)
   )
   From = ExProcess
   To = env
   .
3  PROCESS ExProcess
   InstRef = #SDTREF(TEXT,ExSystem.pr,18)
   IniNoOfInst = 1
   SignalSet = (
     Inp #SDTREF(TEXT,ExSystem.pr,2)
   )
   .
4  START Start
   InstRef = #SDTREF(TEXT,ExSystem.pr,21)
   InType = ExProcess
   Nextstates = (
     Wait #SDTREF(TEXT,ExSystem.pr,24)
   )
   .
4  STATE Wait
   InstRef = (
     #SDTREF(TEXT,ExSystem.pr,25)
   )
   .
```

```
5  INPUT Inp
   InstRef = #SDTREF(TEXT,ExSystem.pr,26)
   InType = ExProcess
   Outputs = (
     Sig #SDTREF(TEXT,ExSystem.pr,30)
   )
   Calls = (
     ExProcedure #SDTREF(TEXT,ExSystem.pr,28)
   )
   Nextstates = (
     Wait #SDTREF(TEXT,ExSystem.pr,24)
   )
   .
4  CALLED_PROCEDURE ExProcedure
   InstRef = #SDTREF(TEXT,ExSystem.pr,20)
   .
5  START Start
   InstRef = #SDTREF(TEXT,ExSystem.pr,36)
   InType = ExProcedure
   Nextstates = (
     Idle #SDTREF(TEXT,ExSystem.pr,37)
   )
   .
5  STATE Idle
   InstRef = (
     #SDTREF(TEXT,ExSystem.pr,38)
   )
   .
6  INPUT Inp
   InstRef = #SDTREF(TEXT,ExSystem.pr,39)
   InType = ExProcedure
   Nextstates = (
     return #SDTREF(TEXT,ExSystem.pr,43)
   )
   .
```

Error Handling

Errors may be detected both during interaction with the user (command interpretation) and during analysis. Errors are displayed on the screen and optionally appended to an error file supplied by the user. When using the graphical UI, messages are directed to the Organizer log window.

Command Interpretation Errors

Errors that occur during command interpretation are errors due to:

- Illegal command parameters. See "Syntax of Analyzer Commands" on page 2475.
- Problems with accessing files on your computer system.

Diagnostics Issued During Analysis

Errors may be found during the various steps of the analysis. The different types of diagnostics and the format of the messages are described below. The messages are listed in "Error and Warning Messages" on page 2531 in chapter 54, *The SDL Analyzer*.

Diagnostic Types

Errors can be of the following types: warning, error, internal error, and information.

Warning

There are different types of warnings:

- Warnings that truncation has been performed, because the implementation limits have been exceeded.
- Warnings due to non implemented portions of the Analyzer.
- Warnings due to a badly designed SDL construction that is not essential for the interpretation.
- Warnings due to analysis actions that were not performed because the Analyzer could not recover from errors in previous analysis steps.

Error

One type of error is detected; violation of an SDL rule.

Internal Error

Internal errors due to malfunction of the Analyzer are detected. An internal error often has its roots in an SDL error from which the Analyzer did not recover properly.

Information

Often used to provide additional information to the other types of messages.

Diagnostic Format

Messages generally consist of the following parts:

- A reference to the source code that caused the diagnostic to be reported. See "Syntax" on page 917 in chapter 18, *SDT References*.
- The type of the diagnostic (ERROR / WARNING / INFO).
- A number identifying the diagnostic.
- A message describing the diagnostic.

Example of a Syntax Error

The message describing the error includes a text line where the illegal construct is indicated with a "?". If the trace back is common to many lexical or syntactic errors, the trace back will only occur after the last of these error messages.

The error also contains a reference to the source file.

Example 351: Syntax Error Produced by Analyzer ––––––––––––––––

```
#SDTREF(SDL,/usr/tom/game.spr(1),137(30,40),1,11)
ERROR 312 Syntax error in rule VARIABLE, symbol =
found but one of the following
expected:
!   (   :=
task Count=0 ;
          ?
```

––

The interpretation of the error message is that the Analyzer found the symbol "=" when it expected one of the symbols "!" (the field selector), "(" or ":=".

In the current example, the assignment statement can be found in position 11 the first line in the object with the ID 137 at position (30, 40) on page 3, on page 1 in the diagram stored on file `/usr/tom/game.spr`.

Example of a Semantic Error

The message describing the error includes, if possible, a line containing the error, with a "?" immediately preceding the SDL item that caused the error.

The error also contains a reference to the source file.

Example 352: Semantic Error Produced by Analyzer ––––––––––––––

```
#SDTREF(SDL,/usr/tom/game.spr(1),296(55,40),1)
ERROR 88 Undefined procedure
call ? ErrorHandler
```

––

The interpretation of this error message is that the procedure ErrorHandler is referred to but not is defined, and the call can be found in page 1 of the diagram stored on the on file `/usr/tom/game.spr`, in line 1 of the object with ID 296 and at position (55, 40).

Analyzer Files

When a diagram is being analyzed, a number of files are generated. The file names consist of the diagram name appended with a file name extension. The following file name extensions are used:

- `.pr`
  The SDL/PR, (also known as *phrasal representation*), of the SDL diagram. This file is generated by the conversion to PR pass. The purpose of this file is an intermediate format for the Analyzer. The format used in this file makes it not suitable to be read by the human.

- `.prm`
  After macros are expanded, the `.pr` file is used as input and expanded into a `.prm` file, which includes the SDL macros in an expanded form. The appearance of this file makes it not suitable to be read by the human.

- `.sdl`
  The pretty-printed SDL/PR file which is generated by the pretty-printer. This file uses a layout that is easy to read by the human.

- `.err`
  The error file containing the errors and warnings which were detected during the analysis.

- `.xrf`
  The files containing the listings of SDL definitions and cross-references.

- `.tsp`
  The file contains time stamp information from the last analysis.

- `.ins`
  The file containing instance information about the analyzed SDL system. Read more about the contents of this file in "SDL Instance Information" on page 2512.

- `predef.sdl`
  This file contains predefined SDL entities that the Analyzer needs access to in order to function properly. The file is found using the procedure in "Search Order for Included PR Files" on page 2506 with the directory `$sdtdir`.

Error and Warning Messages

This section contains a list of the Analyzer error and warning messages. Each message has a short explanation and, where applicable, a reference to the appropriate section of the recommendation Z.100, or to the formal definition. Z.100 is appended by the Formal Definition of SDL (Annex F.1-F.3) where a formal mathematical definition of the language is given.

Some messages contain a '%' followed by a number, which is used to indicate where information, specific to the error situation, will be included.

Some messages include a reference to the object that is the source of the diagnostic. These messages adhere to the format adopted in the SDL Suite. See chapter 18, *SDT References* for a reference to this format and for examples.

`INFO 0 Internal error: message %1 not found`

This message indicates an error in the implementation of the Analyzer. Please send a report to IBM Rational Customer Support, especially if the error can be reproduced as the only error message of an analysis. Contact information for IBM Rational Customer Support can be found in "How to Contact Customer Support" on page *iv in the Release Guide*.

`ERROR 1 Internal error`

This message indicates an error in the implementation of the Analyzer. Please send a report to IBM Rational Customer Support, especially if the error can be reproduced as the only error message of an analysis. Contact information for IBM Rational Customer Support can be found in "How to Contact Customer Support" on page *iv in the Release Guide*.

`ERROR 2 Cannot open file: %1`

This error message indicates that an error occurred when the Analyzer attempted to open a file. Modify, if necessary, the file protection and try to run the Analyzer again. If the error persists, contact IBM Rational Customer Support. Contact information for IBM Rational Customer Support can be found in "How to Contact Customer Support" on page *iv in the Release Guide*.

ERROR 3 Cannot close file: %1

This error message indicates that an error occurred when the Analyzer attempted to close a file. Modify, if necessary, the file protection and try to run the Analyzer again. If the error persists, contact IBM Rational Customer Support. Contact information for IBM Rational Customer Support can be found in "How to Contact Customer Support" on page *iv in the Release Guide*.

ERROR 4 Cannot delete file: %1

This error message indicates that an error occurred when the Analyzer attempted to delete a file. Modify, if necessary, the file protection and try to run the Analyzer again. If the error persists, contact IBM Rational Customer Support. Contact information for IBM Rational Customer Support can be found in "How to Contact Customer Support" on page *iv in the Release Guide*.

ERROR 5 Cannot rename file: %1 to %2

This error message indicates that an error occurred when the Analyzer attempted to rename a file. Modify, if necessary, the file protection and try to run the Analyzer again. If the error persists, contact IBM Rational Customer Support. Contact information for IBM Rational Customer Support can be found in "How to Contact Customer Support" on page *iv in the Release Guide*.

ERROR 6 Recursive definition of signal list %1

A signal list must not be based on itself, directly or indirectly.
(Z.100: 2.5.5)

ERROR 7 More than one %1 is visible in Packages

Several definitions with same name were found in a package. A qualifier might resolve the problem.
(Z.100: 2.4.1.2)

ERROR 8 Ending identifier (%2) must be equal to defining identifier (%1) in a referenced definition

When writing a definition, the name must be the same on the last row as on the first row.
(Z.100: 2.2.2)

ERROR 9 Referenced definitions are not unique (%1)

There are more than one definition which matches the reference.

You get this error if:

- You use the same diagram name for two different diagram references in one diagram.

To remove the error:

- Rename one of the referenced diagrams.

(Z.100: 2.4.1.3)

ERROR 10 Number of instances must be lexically equal in referenced process definition and process reference

(Z.100: 2.4.4)

ERROR 11 Different virtuality attributes in reference and referenced heading

(Z.100: 6.3.2)

ERROR 12 A referenced definition may not reference itself

It is not allowed to have a reference to itself in the reference definition.
(Z.100: 2.4.1.3)

ERROR 13 No referenced definition matches reference

A reference is found but not the corresponding definition.

You get this error if:

- You define a diagram as REFERENCED, but do not give a non-referenced definition of the diagram later.

To remove the error, either:

- Add a non-referenced diagram definition.
- Remove the diagram reference.

(Z.100: 2.4.1.3)

ERROR 14 Virtual start not allowed in operator definition

It is not allowed to have the start as virtual in an operator definition.

You get this error if:

- You use the keyword VIRTUAL for the start transition in an operator.

To remove the error:

- Remove the VIRTUAL keyword from the start transition.

(Z.100: 5.3.2)

INFO 15 Required item %1 is not connected to a file

The Organizer has ordered to analyze something depending on a diagram that is not connected to a file.

ERROR 16 Input %1 and output %2 should be different, aborting!

An Analyzer pass requires the input and output files to be different. Specify other input and/or output files.

ERROR 17 Definition name may not be qualified when not a referenced definition

A qualifier is only allowed on a definition if it is a referenced definition.

You get this error if:

- You use a qualifier when defining a diagram in place, i.e. without using the REFERENCED keyword.

To remove the error, either:

- Remove the qualifier.
- Use the keyword REFERENCED and move the definition of the child diagram out of the parent diagram.

(Z.100: 2.4.1.3)

ERROR 18 Referenced definition (%1) is not referenced in the Package definition

A reference to the definition (%1) is missing in the package definition. (Z.100: 2.4.1.3)

ERROR 19 Referenced definition (%1) is not referenced in the system definition

A reference to the definition (%1) is missing in the system definition.

You get this error if:

- You define a diagram outside the SDL system but do not reference it from the SDL system.

To remove the error, either:

- Introduce a reference construct in the SDL system to the diagram.
- Remove the unwanted diagram.

(Z.100: 2.4.1.3)

ERROR 20 Invalid separate analysis unit

It is not allowed to make a separate analysis of the unit selected. Start the analysis on the whole specification instead.

ERROR 21 Referenced substructure definition without name

It is not allowed to have a substructure without a name when referencing it or converting it to SDL/GR.
(Z.100: 3.2.2, 3.2.3)

ERROR 22 System definition may not occur as referenced definition to a system

Only system types may be referenced, not systems.
(Z.100: 2.4.1.3)

ERROR 23 Illegally placed process context parameter

A process context parameter is used where it is not allowed. Examples of bad use is in a system type or in a block type.
(Z.100: 6.2, 6.1.1.1, 6.1.1.2)

ERROR 24 Illegally placed procedure context parameter

A procedure context parameter is used where it is not allowed.
(Z.100: 6.2)

ERROR 25 Illegally placed signal context parameter

A signal context parameter is used where it is not allowed.
(Z.100: 6.2)

ERROR 26 Illegally placed timer context parameter

A timer context parameter is used where it is not allowed. For example in a system type, block type or service type.
(Z.100: 6.2, 6.1.1.1, 6.1.1.2, 6.1.1.4)

ERROR 27 Illegally placed variable context parameter

A variable context parameter is used where it is not allowed. For example in a system type or block type.
(Z.100: 6.2, 6.1.1.1, 6.1.1.2)

ERROR 28 Illegally placed synonym context parameter

A synonym context parameter is used where it is not allowed. For example in a signal.
(Z.100: 6.2, 2.5.4)

ERROR 29 Illegally placed remote procedure context parameter

A remote procedure context parameter is used where it is not allowed.
(Z.100: 6.2)

ERROR 30 Illegally placed remote variable context parameter

A remote variable context parameter is used where it is not allowed.
(Z.100: 6.2)

ERROR 31 Illegally placed sort context parameter

A sort context parameter is used where it is not allowed.
(Z.100: 6.2)

ERROR 32 Illegal redeclaration of name

All definitions in the same scope unit belonging to the same entity class must have different names, with some exceptions.

You get this error if:

- You use the same name as another item when declaring a new item.

To remove the error, either:

- Change one of the names in all appropriate places.
- Remove one of the declarations if the intention was to use the same variable.

(Z.100: 2.2.2)

ERROR 33 Illegally placed gate definition

A gate is defined where it is not allowed.
(Z.100: 6.1.4)

ERROR 34 %1 is not a time stamp file, will not save time stamps

On successful analysis the Analyzer saves info about this. Examine the file and rename or delete it to allow the Analyzer to save time stamps and possibly avoid unnecessary reanalysis in the future.

ERROR 35 Invalid regular interval

The character strings in a nameclass must be of length one and the first one smaller than the second.
(Z.100: 5.3.1.14)

ERROR 36 Integer literal expected

The name in the priority clause of a continuous signal must be an integer literal. This is also true for the name following a regular element in a name class literal.

You get this error if:

- You type something that is not an integer in a place where an integer is expected.

To remove the error:

- Replace the non-integer with an integer.

(Z.100: 4.11, 5.3.1.14)

ERROR 37 Invalid generator parameter %1

The actual generator parameter must match the type of the formal one.
(Z.100: 5.3.1.12.2)

ERROR 38 Illegal number of arguments

The number of actual parameters must be equal to the number of formal parameters when calling a procedure or creating a process. Similar rules apply for output, input and save of signals and timers.

ERROR 39 More than one default assignment; last from generator %1

A sort must not contain more than one default assignment. When instantiating many generators in a sort, only one of them may contain a default assignment.
(Z.100: 5.4.3.3)

ERROR 40 Recursive instantiation of generator %1

A generator definition must not instantiate itself, directly or indirectly.
(Z.100: 5.3.1.12.1)

ERROR 41 Undefined generator

Attempt to instantiate an undefined generator.
(Z.100: 5.3.1.12.2)

ERROR 42 No virtual definition %1 in super of enclosing definition

It is only allowed to redefine or finalize a definition if it is defined as virtual in the inherited type.

You get this error if:

- You are trying to redefine an entity that is not declared as VIRTUAL in the super type.

To remove the error, either:

- Make sure you are trying to redefine the correct entity.
- Make sure that there is a virtual entity to redefine in the super type.

(Z.100: 6.3.2)

ERROR 43 Ordering must not be defined more than once

All operator signatures in a sort must be different (ordering is shorthand for the relational operators).
(Z.100: 5.3.1.8)

ERROR 44 Name of formal parameter of class type must not equal name of generator %1

A generator must not have a formal parameter of class type with the same name as the generator definition.
(Z.100: 5.3.1.12.1)

ERROR 45 Formal generator parameters of classes literal and constant mixed

Literal and constant parameters must not have the same name.
(Z.100: 5.3.1.12.1)

ERROR 46 Only task, decision and transition option allowed in operator definition

You get this error if:

- You try to include signal sending in an operator.

To remove the error:

- Remove the signal sending.

(Z.100: 5.3.2)

ERROR 47 Only Join and Return allowed in operator definition

(Z.100: 5.3.2)

WARNING 48 Ending name (%1) in an asterisk state may lead to an error

The optional state name ending a state may be defined only if the state list is a single state name, in which case the ending state name should be that state name. The state list for an asterisk state is probably more than a single state name.
(Z.100: 2.6.3)

ERROR 49 A state with more than one state name in the state list cannot contain an ending name (%1)

The optional state name ending a state may be defined only if the state list is a single state name, in which case the ending state name should be that state name.
(Z.100: 2.6.3)

ERROR 50 Ending name (%2) must be equal to defining name (%1)

You get this error if:

- You use different names for a definition at the beginning and at the end of the same definition.

To remove the error, either:

- Change the name either at the beginning or at the end of the definition to get the same name in both places.
- Remove the optional name at the end.

(Z.100: 2.2.2, 2.6.3)

ERROR 51 Illegally placed virtuality

Virtual is used in a place where it is not allowed.

You get this error if:

- You use the keyword VIRTUAL for a transition that is not inside a type-based diagram.

To remove the error, either:

- Remove the VIRTUAL keyword from the transition.
- Make the diagram a type-based diagram.

ERROR 52 Illegally placed context parameter

The context parameter is placed where it is not allowed.
(Z.100: 6.2)

ERROR 53 Illegally placed virtuality constraint

The virtuality constraint is placed where it is not allowed.

You get this error if:

- You use the ATLEAST keyword for a type-based diagram that is not placed inside a type-based diagram.

To remove the error, either:

- Remove the ATLEAST construct.
- Move the type-based diagram with the ATLEAST construct to a type-based diagram.
- Make the diagram containing the type-based diagram with the ATLEAST construct a type-based diagram too.

ERROR 54 Illegally placed specialization

The specialization is placed where it is not allowed.

ERROR 55 Illegally placed instantiation

The instantiation is placed where it is not allowed.

ERROR 56 Packages can only contain type definitions

Systems, blocks, processes and services are not allowed, but their corresponding type are.
(Z.100: 2.4.1.2)

ERROR 57 Undefined package %1 in use clause

An used package is not defined. This error may also occur if you have two mutually dependent packages, which is not allowed. If you use ASN.1 modules or C headers, it may also occur if there are no dependency links between these and the SDL system.

You get this error if:

- You try to use a package that has not yet been declared.

To remove the error, either:

- Add a package definition named %1.
- Remove the use of the package.

ERROR 58 Illegally placed exported attribute

The exported attribute is placed where it is not allowed.

ERROR 59 Omitted actual context parameter

(Z.100: 6.2)

ERROR 60 Parameterized type %1 cannot be used as actual context parameter

A type with context parameters is not allowed to be used as an actual context parameter.
(Z.100: 6.2)

ERROR 61 Undefined actual context parameter

The actual context parameter is undefined or is not visible.
(Z.100: 6.2)

ERROR 62 Illegal number of actual context parameters (>)
(Z.100: 6.2)

ERROR 63 Illegal number of actual context parameters (<)
(Z.100: 6.2)

ERROR 64 Illegal number of actual context parameters (0)
(Z.100: 6.2)

ERROR 65 Formal context parameter %1 cannot be used as super type
It is not allowed to specialize a formal context parameter.
(Z.100: 6.2)

ERROR 66 Several matches
Resolution by context found several possible interpretations, use qualifiers to reduce the number of possibilities.
(Z.100: 2.2.2)

ERROR 67 No matching synonym or literal
You get this error if:

- You are using a synonym or literal of the wrong type. For instance, a constant expression of type integer may be required, but you supply a value of type real.

To remove the error, either:

- Replace the synonym or literal with a constant expression of the correct type.
- Define a synonym or literal of the correct type.

(Z.100: 2.2.2)

WARNING 68 Optional parameter of sort %1 omitted

A missing parameter may lead to uninitialized values, make sure it is not left out by mistake.

You get this warning if:

- You omit an IN parameter in a procedure call.

To remove the warning, either:

- Supply a constant value or a variable to the parameter in the procedure call.
- Remove the parameter from the procedure and from all calls to the procedure.

WARNING 69 Implicit remote variable, consider making it explicit

ERROR 70 Invalid import expression

The import identifier in an import expression is erroneous.

You get this error if:

- You use an integer where a boolean is expected.

To remove the error, either:

- Use a boolean value instead.
- Make the expected value an integer.

(Z.100: 4.13)

ERROR 71 Signal %1 is shadowed in connection

You get this error if:

- You have multiple declarations of a signal (same name) and two channels or signal routes that are connected uses different versions of a carried signal.

To remove the error, either:

- remove the inner declaration of the signal
- Rename one of the signals and determine which one the channels or signal routes in the connection should use.

ERROR 72 Invalid variable or attribute of variable

Reference to a nonexisting variable or a variable with illegal type or attribute from a view definition, a view expression or an export action.

You get this error either if:

- You EXPORT a variable that is not visible from the current scope.
- You EXPORT a variable that is not defined as EXPORTED.

To remove the error, either:

- Find the correct name of the variable you want to export.
- Make sure that the variable you want to export is defined as EXPORTED.

ERROR 73 Illegal use of parameterized signal

This message is output when context parameters are used in an SDL structure. Context parameters are not supported.

ERROR 74 Illegal use of parameterized sort

This message is output when context parameters are used in an SDL structure. Context parameters are not supported.

ERROR 75 Undefined timer

Use of an undefined timer in set, reset or active.

You get this error if:

- You are referring to a timer that has not been declared.

To remove the error, either:

- Declare the timer.
- Refer to an already existing timer instead.

(Z.100: 2.8)

ERROR 76 No range condition equals true in transition option

Exactly one of the branches out from a transition option must be true.

You get this error if:

- There is no alternative in a transition option that evaluates to true.

To remove the error, either:

- Change the condition for taking one of the alternatives to make sure that one alternative is always taken.
- Add a new alternative with a condition that evaluates to true.

(Z.100: 4.3.4)

ERROR 77 Undefined sort

A sort which is not defined is referenced.

You get this error if:

- You use a sort that has not been defined.

To remove the error, either:

- Use another sort that is already defined.
- Define the sort.

(Z.100: 2.2.2)

ERROR 78 Error not allowed where constant required

You get this error if:

- You use SDL keyword error in an expression required to be constant.

To remove the error:

- Replace the SDL keyword error with something else.

(Z.100: 5.3.9.1, 5.4.2.1)

ERROR 79 Variable expected

A variable was expected at this place.

You get this error either if:

- You use a constant value or an operator on the left side of the assignment.
- You give a constant value or the value of an operator instead of a variable as an actual parameter in a procedure call, when the corresponding formal parameter is an IN/OUT parameter.

To remove the error in the above cases, either:

- Use a variable on the left side of the assignment instead.
- Use a variable as an actual parameter in the procedure call instead.

You also get this error either if:

- You call a procedure using a constant as an actual in/out parameter.
- You call a procedure without specifying a parameter that is an in/out parameter.

To remove the error in the above cases, either:

- Change the constant or the not specified parameter to a variable of the correct type instead.
- Change the procedure to accept an in parameter instead of an in/out parameter.

(Z.100: 2.4.6)

ERROR 80 In parameter expected

An in parameter was expected according to the definition.

You get this error if:

- You are using an IN/OUT parameter in an imported procedure signature that should match an IN parameter in a remote procedure signature.

To remove the error, either:

- Change the imported procedure signature to use an IN parameter instead.
- Change the remote procedure signature to use an IN/OUT parameter instead.

ERROR 81 Unexpected parameter

The parameter should not be there according to the definition.

You get this error either if:

- You supply a parameter when you create a process that is not defined in an FPAR statement in the process definition.
- You add an extra parameter or return value to an imported procedure signature that should match a remote procedure signature.

To remove the error, either:

- Remove the extra parameter or return value.
- Add the extra parameter or return value to the definition of the called or created entity.

ERROR 82 Start transition required in instantiated type %1

An instantiated type must contain a start transition.

You get this error if:

- You try to instantiate a process type or a service type that has no start transition.

To remove the error, either:

- Instantiate a process type or a service type that has a start transition instead.
- Add a start transition to the process type or the service type.

ERROR 83 Start transition required in called procedure

You get this error if:

- You call a procedure that does not have a start transition.

To remove the error:

- Add a start transition to the procedure definition.

(Z.100: 2.4.6)

ERROR 84 Procedure call not allowed where constant required

You get this error if:

- You call a procedure in a place where a constant is required, such as in a variable or synonym definition.

To remove the error, either:

- Assign the variable a constant value in the variable definition.
- Assign the variable the return value of a procedure call in the start transition instead.

(Z.100: 5.3.1.9.1)

ERROR 85 Parameterized procedure cannot be called

(Z.100: 6.1.2)

ERROR 86 PId Expression or Process Identifier expected

An PId expression or a process identifier was expected at this place.

You get this error if:

- You supply a second parameter to import, but it is not a pid expression or a process identifier.

To remove the error, either:

- Change the second parameter to a pid expression or a process identifier.
- Remove the second parameter if it is not needed.

ERROR 87 Pid expression in procedure call only allowed for remote procedures

It is only allowed to have PId expressions in a procedure call if the procedure is a remote procedure.

You get this error if:

- You are using the TO keyword in a call to a procedure that is not remote and imported.

To remove the error, either:

- Remove the TO construct from the procedure call, if it is a normal procedure residing in this process.
- Make the procedure a REMOTE procedure in the other process, and declare the procedure as IMPORTED in this process.

(Z.100: 2.7.3, 4.14)

ERROR 88 Undefined procedure

Attempt to call an undefined procedure.

You get this error if:

- You call a procedure that is not defined or not visible from the current scope.

To remove the error, either:

- Make an existing procedure with the correct name visible from the current scope.
- Create an appropriate procedure if it does not exist.

(Z.100: 2.2.2, 2.7.3)

WARNING 89 Trailing parameter of sort %1 omitted

A missing parameter may lead to uninitialized values, make sure it is not left out by mistake.

ERROR 90 Two range conditions equals true in transition option

The branches out from a transition option must be mutually exclusive.

You get this error if:

- You have two alternatives in a transition option that are both evaluated to be true.

To remove the error, either:

- Change the condition for taking one of the alternatives to make sure that only one alternative is taken.
- Remove one of the alternatives that evaluated to true.

(Z.100: 4.3.4)

INFO 91 Location of the global definition previously mentioned

ERROR 92 Undefined remote variable

Attempt to use an undefined remote variable.

You get this error if:

- You use a remote variable that has not been defined.

To remove the error, either:

- Use another remote variable that is already defined
- Define the remote variable.

(Z.100: 4.13)

ERROR 93 Label expected on first item in free action

(Z.100: 2.6.7)

ERROR 94 Formal parameters required in operator definition

The operator definition must have formal parameters.

You get this error if:

- You have defined an operator that is missing a FPAR statement.

To remove the error:

- Introduce an FPAR statement in the definition of the operator.

(Z.100: 5.3.2)

ERROR 95 Recursive definition of parent sort %1 in syntype

A syntype must not be based on itself, directly or indirectly.

You get this error if:

- You define a syntype X that equals a syntype Y that equals syntype X.

To remove the error:

- Make sure that syntypes not equals each other in a circular chain, and that one syntype equals a non-syn-type.

(Z.100: 5.3.1.9)

INFO 96 Setlocale failed

The Analyzer failed to set the character handling part of the locale. It will remain in the default C locale.

ERROR 97 Undefined signallist

ERROR 98 New literal %1 must only occur once in literal renaming

All literals renamed in an inheritance must be given unique names.

You get this error if:

- You are declaring a newtype that inherits from another type, and renames two or more old literals to the same new name.

To remove the error:

- Make sure to use unique names for all renamed literals.

(Z.100: 5.3.1.11)

ERROR 99 Old literal %1 must only occur once in literal renaming

A literal must only be renamed once when inheriting.

You get this error if:

- You are renaming literals in a newtype that inherits from a super newtype, and the old literal names occur more than once in the list of renamings.

To remove the error:

- Make sure that the same old literal name only occurs once on the right side of the assignment in the list of renamings.

(Z.100: 5.3.1.11)

ERROR 100 Illegal redeclaration of operator signature

It is not allowed to have several operators with the same signature. This error may also occur if you use the same name twice in a sort with implicit operators, for example “structure”.

ERROR 101 Unexpected remote variable

Remote variable may not be used in [priority] input.

You get this error if:

- You are using a remote variable in a way that is not allowed, for instance as if it was a normal signal in an input construct.

To remove the error, either:

- Use the remote variable in a proper way instead: to update the value of the remote variable, use an IMPORT construct instead of trying to receive the value as if it was a signal.
- Change the remote variable to another more proper type for the intended use.

ERROR 102 Expression(s) in number of instances evaluates to error

(Z.100: 2.4.4)

ERROR 103 More than one sub signal is visible

You get this error if:

- You have two or more REFINED signals with the same name that is visible from the current place.

To remove the error:

- Rename (or remove) one of the REFINED signals, to get unique names.

(Z.100: 3.3)

ERROR 104 Undefined signal, timer, signallist, remote procedure or remote variable

No visible definition with proper entity kind found.
(Z.100: 2.2.2)

ERROR 105 Remote procedure definition missing

A definition of the remote procedure is missing.

You get this error if:

- You are referring to a procedure with an IMPORTED construct, but the procedure does not exist or is not defined as REMOTE.

To remove the error:

- Make sure there is a REMOTE definition of the procedure you are referring to in the IMPORTED construct.

ERROR 106 Recursive definition of synonym

The value of a synonym must not be based on itself, directly or indirectly.

ERROR 107 Gate must be connected

You get this error if:

- You instantiate a type without connecting all it’s gates.

To remove the error:

- Connect the gate.

(Z.100:6.1.4)

ERROR 108 Type mismatch for variable or formal parameter

ERROR 109 Signal refinement is not supported

ERROR 110 Only one varargs allowed

ERROR 111 Unexpected return value

The procedure has to be value returning to use return values.

ERROR 112 Return value expected

A value returning procedure must specify a return value.

You get this error if:

- You are returning from a procedure without specifying a return value, when the procedure is expected to return a value because of a RETURNS construct in the procedure heading.

To remove the error, either:

- Supply a return value in the RETURN construct.
- Remove the RETURNS construct from the procedure heading and remove any returned values from all RETURN constructs in the same procedure.

ERROR 113 Undefined state %1

A nextstate contains a name of a state which is not defined.
(Z.100: 2.6.7.2.1)

ERROR 114 Undefined label %1

Attempt to join an undefined label (connector).
(Z.100: 2.6.8.2.2)

ERROR 115 Open range does not match

A range condition does not match the actual context.
(Z.100: 5.3.1.9.1)

ERROR 116 Inherited operator %1 is not visible

Operators containing an exclamation cannot be inherited (and renamed).

You get this error if:

- You declare a newtype that inherits an operator that cannot be found in the current scope.

To remove the error in the above cases, either:

- Check that you are using the correct name for the operator.
- Declare the operator.

You also get this error if:

- You have a newtype that inherits from a super newtype, and you try to inherit an operator from the super newtype that does not exist.

To remove the error in the above case, either:

- Make sure that the name of the operator you wants to inherit is correct.
- Remove the name of the non-existing operator from the list of inherited operators.

(Z.100: 5.3.1.11)

ERROR 117 Old operator name %1 must only occur once in operator renaming

An operator must only be renamed once when inheriting.

You get this error if:

- You use the same name for the old operator name and the new operator name.

To remove the error:

- Use a new name instead of reusing the old name.

(Z.100: 5.3.1.11)

ERROR 118 New operator name %1 must only occur once in operator renaming

All operators renamed in an inheritance must be given unique names.

You get this error if:

- You use the same new operator name for several old operator names.

To remove the error:

- Make sure to use unique names for every new operator name.

(Z.100: 5.3.1.11)

ERROR 119 Inheritance for %1 is circular

You get this error if:

- You have created a circular chain of diagram inheritance.

To remove the error:

- Break the chain of circular inheritance by removing or changing the super diagram for one of the diagrams in the chain.

(Z.100: 6.3.1)

ERROR 120 Atleast constraint for %1 is circular

(Z.100: 6.3.2)

ERROR 121 Recursive sort inheritance

A sort must not inherit from itself, directly or indirectly.

You get this error if:

- You have created a circular chain of newtype inheritance.

To remove the error:

- Break the chain of circular inheritance by removing or changing the super newtype for one of the newtypes in the chain.

(Z.100: 5.3.1.11)

ERROR 122 Unexpected connect statement

A connect statement was not supposed to be found at this place.

INFO 123 %1 is one of the possible matches

ERROR 124 Signal expected in output

An output must contain at least one signal.

You get this error if:

- You are trying to send something from a process that is not a signal, such as a timer.

To remove the error, either:

- Change the name in the output construct to match a visible signal instead.
- Supply the value or variable that you were trying to send as a parameter to a signal.

(Z.100: 2.7.4)

ERROR 125 Undefined channel or signal route in output via

Identifiers used in a via clause of an output must be visible channels or signal routes.

You get this error if:

- You use a name of a non-existing channel or signal route after a VIA keyword in a signal sending.

To remove the error, either:

- Find a correct channel or signal route name and use that instead.
- Add the channel or signal route that you references in the VIA construct.
- Remove the VIA construct, if the VIA construct is not needed and the signal sending path can be determined uniquely anyway.

(Z.100: 2.7.4)

ERROR 126 Set with no time expression is only allowed for timers with default duration

It is only allowed to omit the time expression in set if there is a default duration specified for the timer.

You get this error if:

- You try to set a timer that does not have a default duration without specifying a duration in the SET construct.

To remove the error, either:

- Add a default duration to the timer definition:
  `TIMER myTimer:=10.`
- Specify a time in the SET construct: `SET(Now+10, myTimer).`

(Z.100: 2.8)

ERROR 127 Set must contain a time expression and a timer id

When using set you must specify when the timer should expire and which timer to set.
(Z.100: 2.8)

ERROR 128 Undefined process

Attempt to create an undefined process.

You get this error if:

- You are trying to create a process that has not been defined.

To remove the error, either:

- Check that you are using the correct name for the process that you want to create.
- Add a process definition of the process you want to create.
- Remove the process creation construct.

(Z.100: 2.2.2, 2.7.2)

ERROR 129 Created process must belong to the partition block %1

It is only allowed to create a dynamic instance of a process type if the process type definition is in the same block.

You get this error if:

- You try to create a process instance in another block than the block that the creating process resides in.

To remove the error:

- Make sure that the creating process and the process to be created resides in the same block diagram.
- Make sure that the creating process uses the correct name for the process to be created.

(Z.100: 2.7.2, FD)

ERROR 130 Remote procedure input and signal list input must not have parameters

It is not allowed to have parameters in a remote procedure input or when inputting a signal list.

You get this error if:

- You try to receive parameters by using a pair of parenthesis characters when referring to a remote procedure or a signal list in an INPUT construct.

To remove the error, either:

- Replace the remote procedure or the signal list with ordinary signals
- Remove the parameters and the associated pair of parenthesis characters.

(Z.100: 4.14)

WARNING 131 %1 : Signal not used in input or output

The defined signal has neither been used in an input nor in an output.

ERROR 132 Invalid procedure call

Expressions in Enabling condition and continuous signal must not contain procedure calls.

You get this error if:

- You are calling a procedure in an inappropriate place, such as in the expression related to a continuous signal.

To remove the error:

- Remove or move the procedure call from the inappropriate place.

ERROR 133 State name %1 in asterisk state list must be contained in other state lists

The state names used within the parenthesis (the exceptions) of an asterisk state must be defined somewhere in the enclosing body or the body of a supertype.

You get this error if:

- You include a name of a non-existing state in the list of exceptions after an asterisk (i.e. for all states) state.

To remove the error, either:

- Check that you are using the correct name for the state that should be excepted.
- Remove the unwanted exception.
- Introduce the missing state in your state machine.

(Z.100: 4.4)

ERROR 134 No state left to expand the asterisk with

The asterisk state list in the asterisk state includes all states in the enclosing process/procedure/service body.

You get this error if:

- You are using an asterisk (i.e. for all states) state that is representing zero states.

To remove the error, either:

- Make sure that you are not doing exceptions to the asterisk state for all states in the state machine.
- Replace the asterisk state with a normal state not using an asterisk.

(Z.100: 4.4)

ERROR 135 At least one state list must be different from asterisk

A process/procedure/service body cannot only contain asterisk states.

You get this error if:

- You only have asterisk states in the state machine.

To remove the error:

- Make sure that you have at least one non-asterisk state in the state machine.

(Z.100: 4.4)

ERROR 136 Several virtual continuous signals in a state with same or no priority

It is not possible to tell which transition would be affected by a redefinition.

You get this error if:

- You have several virtual continuous signals in the same state with the same priority.

To remove the error, either:

- Remove one of the virtual continuous signals.
- Give one of the virtual continuous signals another priority.

(Z.100: 6.3.3)

ERROR 137 Virtual continuous signal is virtual in super type with same or no priority

It is not possible to tell which transition would be affected by a redefinition.

You get this error if:

- You have a virtual continuous signal in both the sub type and the super type and the priority is the same or no priority is given.

To remove the error, either:

- Make the continuous signal in the sub type REDEFINED or FINALIZED instead of VIRTUAL.
- Give different priority to the continuous signal in the sub type than the priority in the super type.

(Z.100: 6.3.3)

ERROR 138 Redefined continuous signal is not virtual in super type with same or no priority

Cannot find the transition to redefine.

You get this error if:

- You redefine a continuous signal transition in a sub type and the same continuous signal transition cannot be found in a super type with the same priority.

To remove the error, either:

- If you intend to redefine an existing continuous signal, make sure the continuous signal you are redefining is starting from the same state and have the same priority.
- If you do not want to redefine an existing continuous signal, remove the REDEFINED or FINALIZED keyword.

(Z.100: 6.3.3)

ERROR 139 Filter exited with error code

A filter program terminated with a non zero exit code.

ERROR 140 External procedure not allowed

An external procedure cannot be mentioned in a <type expression>, in a <formal context parameter> or in an <atleast constraint>.

You get this error if:

- You try to use an external procedure where only a normal procedure is allowed.

To remove the error, either:

- Use a normal procedure instead of the external procedure.
- Make the external procedure a normal procedure.

ERROR 141 Number of block instances not allowed

Number of block instances may only be specified in typebased block definitions.
(Z.100: 6.1.3.3)

ERROR 142 No diagram to put definition in

It is not possible to convert something to a text symbol in SDL/GR without a surrounding diagram.

ERROR 143 Start is already defined in super type

It is not allowed to have more than one start transition and a start transition is already defined in the inherited type.

You get this error if:

- You redefine a transition from a super type without using the keyword REDEFINED or FINALIZED.

To correct the error, either:

- Use the keyword REDEFINED or FINALIZED for the redefined transition, if you intend to redefine the transition; make sure that the transition you redefine is either marked with VIRTUAL or REDEFINED.
- Remove the definition from the sub type if you do not intend to redefine it.

(Z.100: 2.6.2, 6.3)

ERROR 144 Start is defined as finalized in super type

It is not allowed to define the start transition as redefined, since it is defined as finalized in the inherited type.

You get this error if:

- You are trying to REDEFINE or FINALIZE the start transition in a sub type when it is declared as FINALIZED in a super type.

To remove the error, either:

- Change the start transition to VIRTUAL or REDEFINED in the closest super type where it is mentioned.
- Remove the start transition from the sub type if you did not intend to redefine the start transition.

(Z.100: 2.6.2, 6.3.3)

ERROR 145 Start is not defined as virtual in super

It is not allowed to define the start transition as redefined, since it is not defined as virtual in the inherited type.

You get this error if:

- You try to redefine the start transition in a sub type when the start transition is not defined as VIRTUAL in a super type.

To remove the error:

- Make the start transition VIRTUAL in the super type.

(Z.100: 2.6.2, 6.3.3)

ERROR 146 Multiple exits from state %2 with signal, timer or remote procedure %1

The signal, timer or remote procedure is contained in two inputs or one input and one save.

You get this error if:

- There are several ways to leave a state for the same signal, timer or remote procedure.

To remove the error:

- Remove enough ways to leave the state to make all remaining ways unique.

(Z.100: 2.6.3, 2.6.5)

ERROR 147 Virtual input %1 is already defined as input in state %2 in supertype

It is not allowed to define the input %1 as virtual, since it is already defined without virtual in the inherited type.

You get this error if:

- You are declaring a transition to be VIRTUAL in a sub type, when the transition is already VIRTUAL in the super type.

To remove the error:

- Use the keyword REDEFINED instead of VIRTUAL in the sub type.
- Make sure the transition is VIRTUAL in a super type.

(Z.100: 6.3.3)

ERROR 148 Redefined input %1 is not defined as virtual input in state %2 in supertype

It is not allowed to define the input %1 as redefined, since it is not defined with virtual in the inherited type.

You get this error if:

- You have a redefined transition in a sub type that does not exist in the super type.
- You have a redefined transition in a sub type that is not declared as virtual in the super type.

To remove the error, either:

- Make sure there is a matching virtual transition in the super type.
- Remove the REDEFINED keyword from the transition in the sub type.

(Z.100: 6.3.3)

ERROR 149 Redefined input %1 is defined as finalized input in state %2 in supertype

It is not allowed to define the input %1 as redefined, since it is defined as finalized in the inherited type.

You get this error if:

- You are trying to REDEFINE a transition that is marked as FINALIZED in a super type.

To remove the error, either:

- Change the transition from FINALIZED to REDEFINED in the super type.
- Make sure that you are redefining the correct transition.

(Z.100: 6.3.3)

ERROR 150 Redefined input %1 is defined as input in state %2 in supertype

It is not allowed to define the input %1 as redefined, since it is defined without virtual in the inherited type.

You get this error if:

- You define a transition as REDEFINED in a sub type, when the same transition in the super type is not VIRTUAL.

To remove the error, either:

- Make the transition in the super type VIRTUAL.
- Make sure that you are redefining the correct transition.

(Z.100: 6.3.3)

ERROR 151 Finalized input %1 is not defined as virtual input in state %2 in supertype

It is only allowed to define an input as finalized if it is a virtual defined input in a inherited type.

You get this error either if:

- You use the keyword REDEFINED or FINALIZED for a transition that is not declared VIRTUAL in a super type.
- There is no super type.

To remove the error, either:

- Make the transition in the super type VIRTUAL.
- Change the name in the sub type to match the correct transition in the super type
- Make sure the sub type inherits from the correct super type.

ERROR 152 Finalized input %1 is defined as finalized input in state %2 in supertype

It is not allowed to define the input %1 as finalized, since it is already defined as finalized in the inherited type.

You get this error if:

- You try to finalize a transition in a sub type that is already FINALIZED in a super type.

To remove the error, either:

- Change the keyword FINALIZED to REDEFINED in the super type.
- Make sure that you are trying to finalize the correct transition in the sub type.

(Z.100: 6.3.3)

ERROR 153 Signal %1 is already defined as input in state %2 in supertype

It is not allowed to have the same signal in more than one input to the same state. In this case there is already a input of the signal %1 in the type you inherit from.

You get this error if:

- You try to define a transition that already exists in a super type, without using the keyword REDEFINED or FINALIZED, or when the transition in the super type is not virtual.

To remove the error:

- Add the keyword REDEFINED or FINALIZED to the transition in the sub type.
- Make sure that the transition in the super type is VIRTUAL.

ERROR 154 A state (%1) cannot contain both asterisk input and asterisk save

It is not allowed to both have a asterisk input and a asterisk save to a state.

You get this error if:

- You have a state in your state machine that has both an asterisk input transition and an asterisk save.

To remove the error, either:

- Remove the asterisk save.
- remove the asterisk input transition.

(Z.100: 4.6, 4.7)

ERROR 155 A state (%1) may only contain one asterisk input

It is only allowed to have one asterisk input to a state.

You get this error if:

- You are having more than one asterisk input transition for the same state.

To remove the error:

- Remove all but one asterisk input transition for the same state.

(Z.100: 4.6)

ERROR 156 A state (%1) may only contain one asterisk save

It is only allowed to have one asterisk save to a state.

You get this error if:

- You have a state in your state machine that has more than one asterisk saves.

To remove the error:

- Reduce the number of asterisk saves for the transition to one (or zero).

(Z.100: 4.7)

ERROR 157 Valid input signal set must be specified (in process/service %1) when no signal routes or channels are specified in the enclosing block/process (%2)

If there are no signal routes or channels specified to the process/service. “Signalset” must be used inside the process/service extended heading to specify the valid input signal set.

You get this error if:

- You have a process or service that is not connected with the outer world via signal routes or channels, and you have not specified an input SIGNALSET.

To remove the error, either:

- Add signal routes and channels to connect the process to the outer world.
- Add a SIGNALSET construct to the process and indicate the signals the process can receive.

(Z.100: 2.5.2)

ERROR 158 Value returning procedure expected

A value returning procedure was expected at this place.

ERROR 159 Type mismatch: sort %2 does not match %1

You get this error if:

- You are using an integer where a boolean is expected. For instance, you are using an integer as a type for a parameter in an imported procedure signature that should match a boolean type parameter in a remote procedure signature.

To remove the error, either:

- Use a boolean instead.
- Change the expected type to be an integer instead.

ERROR 160 In/out parameter expected

An in/out parameter was expected according to the definition.

You get this error if:

- You are using an IN parameter in an imported procedure signature that should match an IN/OUT parameter in a remote procedure signature.

To remove the error, either:

- Change the imported procedure signature to use an IN/OUT parameter instead.
- Change the remote procedure signature to use an IN parameter instead.

ERROR 161 Missing parameter

A parameter is missing according to the definition.

You get this error if:

- You omit a parameter or return value from an imported procedure signature that should match a remote procedure signature.

To remove the error, either:

- Add the missing parameter or return value to the imported procedure signature.
- Remove the not wanted parameter or return value from the remote procedure signature.

ERROR 162 Virtual definitions only allowed in types

It is only allowed to use virtual in a type definition.

You get this error if:

- You have a virtual definition of a diagram in a normal diagram.

To remove the error:

- Remove the keyword virtual from the definition of the diagram.
- Make the diagram with the virtual definition a type-based diagram.

ERROR 163 Virtual definition %1 does not conform to its virtuality constraint

(Z.100: 6.3.2)

ERROR 164 Redefinition of %1 does not conform to the virtuality constraint

(Z.100: 6.3.2)

ERROR 165 A gate with addition of signals can only occur in subtypes

Adding in gate definition can only be used if the type is inherited from another type.

You get this error if:

- You are using the ADDING construct for a gate in a diagram that does not inherit from another diagram.

To remove the error, either:

- Remove the ADDING construct from the gate definition.
- Make the type-based diagram with the error inherit from another type-based diagram with an appropriate gate that you can use.

(Z.100: 6.1.4)

ERROR 166 Definition of %1 exists already in super type

An already defined gate cannot be defined again. If you want to add signals to an already existing gate, the word adding must be used.

You get this error if:

- You declare a gate in a type that inherits from another type that already has a gate with the same name.

To remove the error in the above case:

- Rename one of the gates to get two gates in the sub type.
- Use the keyword ADDING in the gate in the sub type if you want to redefine the gate in the super type from the sub type.

You also get this error if:

- You use the RETURNS construct in both the super procedure type and the sub procedure type.

To remove the error in the above case:

- Remove the RETURNS construct from the sub type.

You also get this error either if:

- You try to redefine a finalized procedure in a sub type.
- You try to define a procedure, that has already been defined as virtual in a super type, without using REDEFINED.

To remove the error in the above cases, either:

- Make sure that you are redefining the correct procedure.
- Make sure that you use the REDEFINED keyword in the sub type, if you intend to redefine a procedure.
- Change the name of the procedure in the sub type, if you do not intend to redefine any existing procedure.
- Change the finalized procedure in the super type to be a redefined procedure.

`ERROR 167 A gate with addition of signals must already be defined in a super type`

Adding in gate definition cannot be used when defining a new gate.

You get this error if:

- You declare a gate endpoint constraint with the keyword ADDING, but the gate is not already declared in any super type.

To remove the error, either:

- Make sure that the name of the gate with the ADDING keyword matches the name of a gate in a super type.
- Remove the ADDING keyword to get a new gate that does not depend on any gate in a super type.

(Z.100: 6.1.4)

ERROR 168 Two gate constraints may not use the same direction in gate %1

It is not allowed to have the same direction (in or out) in two gate constraints.

You get this error if:

- You have two gates in the same type-based diagram going in the same direction.

To remove the error, either:

- Reverse one of the gates.
- Merge the two gates, i.e. remove one of them, if they are intended to go in the same direction.

(Z.100: 6.1.4)

ERROR 169 Undefined type %1 in gate endpoint constraint

The endpoint constraint in the gate contains a undefined or not visible type.
(Z.100: 6.1.4)

ERROR 170 The two endpoint constraints of gate %1 is not consistent

The endpoint constraints, to and from, in the gate are not consistent.

You get this error if:

- You have two gate endpoint constraints in a type-based diagram that are going in the same direction.
- You have two gate endpoint constraints in a type-based diagram that are not referencing the same outer entity.

To remove the error:

- Make sure that the two gate endpoint constraints are going in different directions.
- Make sure that if you reference an outer type-based diagram, the same type-based diagram is referenced in both gate endpoint constraints.

(Z.100: 6.1.4)

ERROR 171 Undefined block, channel or signal route in connection

Identifiers used in a connection must be visible in the scope and of the above mentioned types.
(Z.100: 2.5.3, 3.2.3)

ERROR 172 Undefined block, process or service in path

The identifiers following the text “from” and “to” in channel and signal route definitions must be visible blocks, processes or services.
(Z.100: 2.5.1, 2.5.2)

ERROR 173 Selected diagram not in an SDL system

The context must be available when analyzing part of a system.

ERROR 174 Undefined type %1 in instance specification

The type must be defined and visible in the scope to be instantiated.

You get this error if:

- You refer to a type-based diagram that does not exist.

To remove the error, either:

- Refer to an existing type-based diagram instead.
- Create a matching type-based diagram.

ERROR 175 Undefined component %1/%2 in use clause

(Z.100: 2.4.1.2)

ERROR 176 Parameterized type %1 cannot be used as constraint type

It is not allowed to use a type with context parameters as a constraint type.
(Z.100: 6.3.2)

ERROR 177 Undefined type %1 in constraint specification

The type %1 used in the constraint specification is undefined or not visible.

ERROR 178 Substructure name in subtype and supertype must be the same

(Z.100: 6.3.1)

ERROR 179 Undefined type %1 in inheritance specification

A type which is inherited is not defined or not visible.

You get this error if:

- You in a signal declaration uses the keyword INHERITS and mention another signal that has not yet been defined.

To remove the error:

- Make sure the signal to inherit from is defined before the signal that inherits.

ERROR 180 Undefined type %1 in virtuality constraint

The type %1 used in the virtuality constraint is undefined or not visible.

You get this error if:

- You refer to a type-based diagram that does not exist in a virtuality constraint.

To remove the error, either:

- Use the name of an existing and matching type-based diagram instead.
- Create a matching type-based diagram.
- Remove the virtuality constraint.

ERROR 181 Environment must only appear in one connection

When a channel is partitioned and has the environment as one of its endpoints, the channel substructure must contain one and only one connection with environment.

You get this error if:

- You have more than one connect statement for a signal route or channel going to or from the environment.

To remove the error:

- Remove all but one connect statement going to or from the environment for the signal route or channel in question.

(Z.100: 3.2.3)

ERROR 182 The path %1 must only appear in one connection

It is not allowed to have the same channel or signalroute name mentioned in more than one connection.

You get this error if:

- You mention a signal route or a channel in two or more CONNECT statements in the same diagram.

To remove the error:

- Merge all CONNECT statements mentioning the same signal route or channel into one CONNECT statement.

(Z.100: 2.5.3, 3.2.2)

ERROR 183 All subsignals to the channel %1 must be included in the signal lists of the subchannels

In the connection between a channel and subchannels, each signal conveyed by the channel must either be conveyed by the subchannels or all of its subsignals must be conveyed by the subchannels.
(Z.100: 2.5.3, 3.3)

ERROR 184 Signal %1 must be included in the signal list of the inner paths

In a connection point, all signals in the outer paths must be conveyed by at least one of the inner paths.

You get this error if:

- You connect two signal routes or channels that do not allow the same set of signals to be sent in each direction.

To remove the error:

- Add or remove signals from the signal lists in the connected signal routes or channels to get matching signal lists.

(Z.100: 2.5.3, 3.3)

ERROR 185 Signal %1 must be included in the signal list of the outer paths %2

In a connection point, all signals in the inner paths must be conveyed by at least one of the outer paths.

You get this error if:

- You connect a signal route or channel to a signal route or channel one level up in the diagram hierarchy that does not include all signals of the signal route or channel in this diagram.

To remove the error, either:

- Add the signals you want to send to the appropriate signal lists in the diagrams outside this diagram.
- Remove the not wanted and troublesome signal from the signal list of the channel or signal route that is connected to the world outside this diagram.

(Z.100: 2.5.3, 3.3)

ERROR 186 In the implicit connection with %2 signal %1 is not included in any of the outgoing implicit signal routes

Each signal in the channels, directed out from the block, must be mentioned in at least one output in a process. See also *ERROR 187*.
(Z.100: 2.5.2, 2.5.3)

ERROR 187 In the implicit connection with %2 is signal %1 not included in any of the incoming implicit signal routes

When a block contains no signal routes, the signal route definitions and the connections are derived from the valid input signal sets and the outputs (of the processes in the block) and the channels connected to the block. (The same is valid for a service decomposition with no service signal routes.) Each signal in the channels, directed into the block, must be included in at least one valid input signal set.
(Z.100: 2.5.2, 2.5.3)

ERROR 188 Actual context parameter %1 does not conform to the fpar constraint

The actual context parameter is not correct according to the fpar constraint given for the formal context parameter.
(Z.100: 6.2)

ERROR 189 Actual context parameter %1 does not conform to the sort signature constraint

The actual context parameter is not correct according to the sort signature constraint given for the formal context parameter.
(Z.100: 6.2)

ERROR 190 Actual context parameter %1 does not conform to the atleast constraint

The actual context parameter is not correct according to the at least constraint given for the formal context parameter.
(Z.100: 6.2)

ERROR 191 Actual context parameter %1 does not conform to the process type constraint

The actual context parameter is not correct according to the process type constraint given for the formal context parameter.
(Z.100: 6.2)

ERROR 192 Actual context parameter %1 does not conform to the sort list constraint

The actual context parameter is not correct according to the sort list constraint given for the formal context parameter.
(Z.100: 6.2)

ERROR 193 Actual context parameter %1 does not conform to the signal set constraint

The actual context parameter is not correct according to the signal set constraint given for the formal context parameter.
(Z.100: 6.2)

ERROR 194 Block definition must contain process, block or substructure definition

A block definition must at least contain one process or a substructure.
(Z.100: 2.4.3)

ERROR 195 Block definition must contain process definition(s) when containing signal route definition(s)

A block definition cannot contain signal routes when no processes are defined.
(Z.100: 2.4.3)

ERROR 196 Block definition must contain process or block definition(s) when containing connection(s)

A block definition cannot contain connections when no processes are defined.
(Z.100: 2.4.3)

WARNING 197 Expansion of select definition is not yet implemented

The SDL concept select definition is not supported by the SDL Analyzer.

> **Caution!**
>
> A consequence of this is that the parts of your SDL system which are contained in the select definition will **not** be analyzed or be input to the SDL to C compilers.

ERROR 198 Substructure definition must contain at least one block definition

At least one block must be defined inside a substructure.

You get this error if:

- You have a substructure diagram that does not contain any block diagrams.

To remove the error, either:

- Add at least one block diagram with one or several processes to the substructure diagram.
- Instantiate a block type diagram in the substructure diagram.

(Z.100: 3.2.2)

ERROR 199 Gate only allowed in paths with instance of a type or env in a type

Gates are only allowed when connecting channels or signal routes to types.

You get this error if:

- You are using gates without using type-based diagrams.

To remove the error in the above case, either:

- Remove the reference to the gate.
- Make the current diagram type-based, if you want to have gates to connect to in the environment.
- Make referenced diagrams instances of type-based diagrams, if you want to have gates to connect to in reference symbols.

You also get this error if:

- You use the VIA keyword when declaring a signal route or a channel, that is not going to or coming from an instantiation of a type-based diagram, and that is not going to or coming from the environment in a type-based diagram.

To remove the error in the above case:

- Remove the VIA construct.

(Z.100: 6.1.4)

ERROR 200 Undefined gate

Use of an undefined gate in a channel or signal route definition.

You get this error if:

- You are referring to a gate that does not exist.

To remove the error, either:

- Remove the gate reference.
- Add the gate you are referencing.

ERROR 201 Connected to gate (%1) in wrong scope

(Z.100: 6.1.4)

ERROR 202 Connected instance %1 does not conform to the endpoint constraint of gate %2

The type of the instance %1 connected to gate %2 must be equal to or be a subtype of the endpoint constraint of gate %2.

ERROR 203 ENV does not conform to the endpoint constraint of gate %1

A gate with an endpoint constraint cannot be connected to the environment.

You get this error if:

- You have a gate endpoint constraint in the type you try to instantiate, and you connect the gate to an instance that is not of the same type (or a descendant of that type) as the one mentioned in the gate endpoint constraint.

To remove the error, either:

- Connect the gate to an instance of the same type (or a descendant of that type) as the one mentioned in the gate endpoint constraint.
- Remove or change the gate endpoint constraint.

ERROR 204 Signal %1 in path is not an incoming signal of %3 gate %2

The gate %2 of instance %3 must be defined to convey the incoming signal %1. Add the signal to the gate definition.

ERROR 205 Signal %1 in path is not an outgoing signal of %3 gate %2

The gate %2 of instance %3 must be defined to convey the outgoing signal %1. Add the signal to the gate definition.

ERROR 206 Via gate expected in env path with block type or process type

A channel or a signal route must be defined using “via <gate>” when connected to the environment in a block type or system type.

You get this error if:

- You declare a channel or a signal route in a type-based diagram going to or coming from the environment without using a VIA keyword to specify the gate to use.

To remove the error:

- Add a VIA keyword and mention the gate to use in the declaration of the signal route or channel.

ERROR 207 Via gate expected in path with typebased instance

Defining a channel or a signal route using “via <gate>” is only possible when the connected instance is type based and thus contain gates.

You get this error if:

- You declare a signal route or a channel going to or coming from an instantiation of a type-based diagram, without specifying the gate to connect to with a VIA keyword.

To correct the error:

- Add a VIA keyword and the name of the gate in the instantiated type-based diagram that you want to connect to.

ERROR 208 Endpoints of the path %1 must be different

A channel/signal route cannot connect a block/process/service with itself.

You get this error if:

- You specify the same endpoint for both ends of a signal route or channel.

To remove the error:

- Connect one of the ends of the signal route or channel to another endpoint.

(Z.100: 2.5.1, 2.5.2)

ERROR 209 Endpoint %1 of channel %2 must be a block or process

A channel must be connected to at least one block!

(Z.100: 2.5.1)

ERROR 210 Endpoint %1 of the path %2 must be locally defined

The endpoints of a channel/signal route must be defined in the same scope as the channel/signal route is defined.

You get this error if:

- You try to connect a signal route or channel to a diagram that is not visible from the current diagram.

To remove the error:

- Connect the signal route or channel to the environment or to a diagram one level below the current diagram. If necessary, create more signal routes or channels in other diagrams to reach the diagram you want to communicate with.

(Z.100: 2.5.1, 2.5.2)

ERROR 211 The second path must denote reverse direction of the first path in %1

In a bidirectional channel or signal route, the second path must be in the reverse direction of the first path.

You get this error if:

- The second FROM-TO-VIA-WITH construct is not going in exactly the reverse direction as compared to the first one.

To remove the error, either:

- Make sure that the same connection item is used after both FROM in the first construct and after TO in the second construct.
- Make sure that the same connection item is used after both TO in the first construct and after FROM in the second construct.

(Z.100: 2.5.1, 2.5.2)

ERROR 212 Endpoint %1 of signal route %2 must be a process or a service

A signal route must connect at least one process or service.
(Z.100: 2.5.2)

ERROR 213 Return not allowed here

You get this error if:

- You use the return construct in a process diagram.

To remove the error, either:

- Replace the return with a stop.
- Make the process diagram a procedure diagram.

(Z.100: 2.6.8.2.4)

ERROR 214 Process definition must contain either processbody or service decomposition

Syntax requirement.
(Z.100: 2.4.4)

ERROR 215 Process cannot contain timer definition when decomposed into services

(Z.100: 2.4.5)

ERROR 216 Revealed and exported variables only allowed in process and service

(Z.100: 2.4.6)

ERROR 217 Complete semantic analysis requires a system

(Z.100: 2.4.6)

ERROR 218 Procedure cannot contain stop

Syntax requirement.
(Z.100: 2.6.8.2.3)

ERROR 219 Undefined view

ERROR 220 Step expression requires a loop variable

It is not allowed to omit the variable indication from a for statement when having a step expression.

You get this error if:

- You have a for(x,y,z)-statement where x does not define a loop variable, but z uses a loop variable.

To remove the error, either:

- Define a loop variable in the for statement.
- Change the step expression to match the loop variable.

ERROR 221 Break without name or continue are only allowed within a loop

Break terminates a for loop and continue does the next iteration of a for loop. They can only be used in the context of for loops.

You get this error either if:

- You use a BREAK construct without a name outside a loop.
- You use a CONTINUE construct outside a loop.

To remove the error, either:

- Add a name after the break keyword that matches a label that you want to jump to.
- Remove the break or continue construct.
- Put the break or continue construct within a for loop.

ERROR 222 Variable used before it is defined

A variable may only be used in statements following its definition.

You get this error if:

- You use a variable before the declaration of the variable.

To remove the error, either:

- Move either the variable use or declaration to make sure that the variable declaration comes before the variable use.
- Make sure you are using the correct variable.

ERROR 223 A jump statement must be contained in a labeled statement with the given name

A jump statement is a more restrictive form of a join statement. The intent is to create less convoluted code.

You get this error if:

- You have a break construct to a label that is not visible from the break.

To remove the error:

- If the label and the break are on the same level, begin a pair of brackets after the label that contains the break.

ERROR 224 No receiver found

ERROR 225 Two services cannot have the same signal (%1) in their valid input signal set

The complete valid input signal sets of the service definitions within a process definition must be disjointed.
(Z.100: 2.4.5)

ERROR 226 Recursive package %1 in use clause

A package must not use itself.

You get this error if:

- There is a self-referential chain of uses of packages. For instance package A uses package B, and package B uses package A.

To remove the error:

- Break the self-referential chain of uses of packages by removing a USE statement in an appropriate place in the chain.

ERROR 227 Ending type keyword must match starting

A process type must be terminated with endprocess type and not just endprocess, and so on.

ERROR 228 Not Charstring sort and no proper operator (Length, ...)

ERROR 229 Service signal routes cannot be specified when no signal routes are specified in the enclosing block

(Z.100: 2.4.5)

ERROR 230 Service decomposition must contain at least one service definition

(Z.100: 2.4.4)

ERROR 231 No proper Length operator found

ERROR 232 Recursive include of file %1

The file is included recursively.

ERROR 233 Qualifier in component command not in SDL system

All parts (components) of a program must belong to the same system.

ERROR 234 More than one system

Can only analyze one system at a time.

ERROR 235 Code generation requires a system

Packages are not sufficient.

ERROR 236 Valid input signal set cannot contain a timer (%1)

You get this error if:

- You include a timer in the specification of the set of signals that a process can receive.

To remove the error:

- Remove the timer from the signal set construct.

(Z.100: 2.4.4, 2.4.5)

ERROR 237 Two signals (%1 and %2) in the complete valid input signal set are on different refinement levels of the same signal

(Z.100: 3.3)

ERROR 238 Two signals (%1 and %2) among the output-signals of the process are on different refinement levels of the same signal

(Z.100: 3.3)

ERROR 239 Signal %1 in save cannot be received

The signal is not included in the complete valid input signal set of the process/service.
(FD)

ERROR 240 Signal %1 in input cannot be received

The signal is not included in the complete valid input signal set of the process/service.

You get this error if:

- You try to receive a signal in an input, but you have not declared that anyone can send that signal to this process.

To remove the error, either:

- Check that you are trying to receive the correct signal.
- Make sure that the signal can be sent to this process via signal routes and channels, or by including the signal in a SIGNALSET construct for this process.

(FD)

ERROR 241 Error creating directory %1

A message from the operating system is following this and hopefully clarifies the problem.

ERROR 242 Signal %1 in priority input cannot be received

The signal is not included in the complete valid input signal set of the service.
(FD)

ERROR 243 Actual in/out param sort %1 does not match %2

The sort of actual and formal in/out parameters of procedures must be identical on the syntype level.

You get this error if:

- You call a procedure using a parameter that is not of the correct type.

To remove the error, either:

- Call the procedure with a parameter of the correct type.
- Change the procedure to accept a parameter of the wanted type.

ERROR 244 Call procedure from expression or supply variable parameter

A value returning procedure should be called from an expression.

You get this error if:

- You call a value-returning procedure from outside of an expression.

To remove the error, either:

- Call the value-returning procedure from an expression in a task instead.
- Call another, similar procedure that do not return a value.
- Force the procedure to not return a value.

WARNING 245 Trailing parameter of sort %1 omitted

ERROR 246 Last param of procedure called from expr is not in/out

Actual in/out procedure parameters may not be omitted.

You get this error if:

- You are calling a procedure in an expression, and the called procedure does not have a RETURNS statement.

To remove the error:

- Add a RETURNS statement to the procedure definition, and make sure the procedure returns a value of the correct type.

ERROR 247 Actual in/out param cannot be omitted

The actual parameter can be omitted if the formal is in.

You get this error if:

- You call a procedure without less actual parameters than all formal parameters declared for the procedure.

To correct the error, either:

- Add the missing actual parameters to match all formal parameters declared for the procedure.
- Remove any not wanted formal parameters from the declaration of the procedure.

WARNING 248 License %1 will expire in %2 days

This is a notification that some license will expire in the near future.

ERROR 249 Aborted by exit request

This indicate that the analyzer received a stop message

ERROR 250 Component and Thread commands requires a previous Program command

Issue a program command to set the name of the executable before adding threads or components to it.

ERROR 251 Change directory: %1: %2

An error occurred when changing default (working) directory.

ERROR 252 Get work dir: %1: %2

The analyzer failed to obtain current working directory.

ERROR 253 Connection with %1 is missing

Either a path is connected to a block/process but is not contained in a connection or a block is connected to a channel but is not contained in a connection in the channel substructure.
(Z.100: 2.5.3, 3.2.2, 3.2.3)

ERROR 254 Connection with environment is missing

When a channel is partitioned and has the environment as one of its endpoints, the channel substructure must contain a connection with the environment.

You get this error if:

- You omit a connect statement saying that a channel or signal route is connected to the environment, when the declaration of the channel or signal route indicates that it is connected to the environment.

To correct the error:

- Add a connect statement saying that the channel or signal route is connected to the environment.

(Z.100: 3.2.3)

ERROR 255 Transition must end with a terminator

If the terminator of a transition is omitted, then the last action in the transition must contain a terminating decision.
(Z.100: 2.6.4, 2.6.8.1)

ERROR 256 Post Master

A problem occurred when communicating with some other tool using the PostMaster.

WARNING 257 Statement not reached

SDL-92 allows dead code in transition. The warning is issued to notify the user of the dead code.

ERROR 258 Initial transition ends (directly or indirectly) with dash nextstate

A nextstate in the initial transition (of a process/ procedure/ service) must be specified with a state name.
(Z.100: 4.9)

ERROR 259 Ending name (%1) cannot be qualified (except for remote definitions)

You get this error if:

- You are using a qualifier when specifying the name of the diagram at the end of the diagram definition.

To remove the error:

- Remove the qualifier and keep just the name of the diagram.

(Z.100: 2.2.2)

ERROR 260 The outer channeldef must have the first connectionpoint (environment) as one of the endpoints

A channel substructure can only contain a connection with the environment if the partitioned channel is connected to the environment.
(Z.100: 3.2.3)

ERROR 261 Answers are not mutually exclusive

Exactly one answer in a decision must match the question. For instance, a boolean decision with more than 2 answers or 2 answers that are both true or both false will produce this message.

You get this error if:

- It is possible to take two or more paths after the decision for at least one given set of values.

To remove the error:

- Make sure that it is always only possible to take one path after the decision symbol.

ERROR 262 The outer channeldef must have the first connectionpoint (block) %1 as one of the endpoints

The block identifier in a connection in a channel substructure must identify one of the endpoints of the partitioned channel.
(Z.100: 3.2.3)

ERROR 263 One of the endpoints of path %1 must be the scope unit %2

A path that occurs as the first connection point in a connection, must be connected to the block/process that contains the connection.
(Z.100: 2.5.3, 3.2.2)

ERROR 264 The second connectionpoint %1 must be defined in the scope unit %2

A path occurring in the second part (i.e. the list of subpaths) in a connection must be locally defined.

You get this error if:

- You have a connection statement connecting an outer channel or signal route with a non-existing inner channel or signal route.

To remove the error:

- Change the name of the second connection point to match an existing inner signal route or channel.
- Add an inner signal route or channel with the correct name.

(Z.100: 2.5.3, 3.2.2)

ERROR 265 One of the endpoints of path %1 must be the environment

A path that occurs in the second part (i.e. the list of subpaths) of a connection must have the environment as one of its endpoints.

You get this error if:

- You use a signal route or a channel in a CONNECT statement, and the signal route or channel is not connected to the environment.

To remove the error, either:

- Check that the CONNECT statement is connecting the correct signal route or channel in this diagram.
- Change the signal route or channel in this diagram to go to the environment with one of its endpoints.
- Remove the connect statement.

(Z.100: 2.5.3, 3.2.2)

ERROR 266 System definition must contain at least one block or process definition

An SDL system must contain at least one block or process.

You get this error if:

- You have constructed an SDL system that does not contain any blocks or processes.

To remove the error, either:

- Add at least one block with one or several processes to your SDL system.
- Instantiate any existing block type diagrams.

(Z.100: 2.4.2)

WARNING 267 Optional parameter of sort %1 omitted

WARNING 268 Gate must be connected

ERROR 269 Expression evaluates to error

ERROR 270 Selected definition not allowed here

ERROR 271 All packages must either be before or after the system

The system should follow the package list according to SDL. For backwards compatibility the analyzer also accepts a package list after the system, but not both at the same time. In the Organizer this means that the icons for all packages used by a system should be above the system icon.

WARNING 272 No analysis is performed when the infile is empty

The SDL/PR input file cannot be empty.

WARNING 273 No semantic analysis is performed when the input is not a system or a package

Semantic analysis can only be performed on a system or a package.

ERROR 274 Compile and link exited with error code

The code generated by the SDL to C Compiler caused compile or link errors.

ERROR 275 Lost license

The connection to the license server is lost. You must wait until the Analyzer has regained access to the license server before resuming your work. If required, contact your system manager to get the problem solved.

ERROR 276 Cannot get license

No license was available when starting up Analyzer. You must wait until a license becomes available (which will occur when another user terminates his Analyzer).

ERROR 277 Cannot return license

The Analyzer could not return its license to the license pool. To return the license, you may need to stop and restart the license server.

INFO 278 Analyzer command could not be fully performed

The Analyzer did not perform all the passes that were ordered. The results from the Analyzer may not be what you expect. This message is output as a result from a syntactic or semantic error that in turn causes the remaining passes not to be executed.

ERROR 279 The number of block instances must be one or greater

The number of block instances in a multiple block instantiation must be greater than 0.

You get this error if:

- You instantiate a block type in a block reference symbol with a number of instances smaller than one.

To remove the error:

- Change the number of instances to one or more.

ERROR 280 Unreachable path %1 in VIA

The path %1 must be connected to the process instance.

You get this error if:

- You send a signal from a process and the static structure of the SDL system does not declare that you are allowed to send that signal the way you want.

To remove the error, either:

- Add signal routes and channels as needed (with your signal in the signal lists), to reach the wanted process or the environment.
- Remove the sending of that particular signal.

ERROR 281 Unreachable process instance set %1 in TO expr

There must be a path leading to the process instance set %1 from this process instance.

You get this error if:

- You send a signal from a process and the static structure of the SDL system does not declare that you are allowed to send that signal the way you want.

To remove the error, either:

- Add signal routes and channels as needed (with your signal in the signal lists), to reach the wanted process or the environment.
- Remove the sending of that particular signal.

WARNING 282 Several possible paths in VIA list

There are several paths that can convey the signal, one of them will be non deterministically chosen.

WARNING 283 Several possible paths

There are several paths that can convey the signal, one of the paths will be non deterministically chosen during execution.

WARNING 284 Set-Case-Sensitive should be the first command to the analyzer

ERROR 285 Hex string literal must have an even length

This applies to values for types that are strings of bytes.

ERROR 286 Bit string literal must have a length modulo 8

This applies to values for types that are strings of bytes.

ERROR 287 Literal must be one octet long

This applies to values for types that are one byte.

WARNING 288 No matching answer for %2

If a decision (or transition option) is executed with a question not covered by any answer it will be an error. (Z.100:2.7.5 and 4.3.4)

ERROR 289 Expression in transition option evaluates to error

One of the expressions in a transition option is erroneous.
(Z.100:4.3.4)

ERROR 290 External synonym not allowed

External synonyms are only allowed in a number of instances in process reference symbols and in heading symbols in process diagrams.

You get this error if:

- You use an external synonym in the condition for a transition option alternative.

To remove the error:

- Remove the external synonym from the condition for the transition option alternative in question.

ERROR 291 Range check failed

You get this error if:

- You specify a value not allowed for a syntype, like a negative value in a variable of sort Natural.

To remove the error, either:

- Change the value to one of the allowed ones.
- Change the syntype to allow the value.
- Use a different sort allowing the value.

(Z.100:5.3.1.9.1)

ERROR 292 Maximal number of instances equals zero

A process should have at least one instance.

You get this error if:

- You specify zero as the maximum number of instances.

To remove the error, either:

- Change the maximum number of instances to one or more.
- Remove the diagram with maximum number of instances set to zero.

(Z.100:2.4.4)

ERROR 293 Maximum number of instances is less than initial number

In the process instances definitions, the maximum number of instances must be greater or equal to the initial number.

You get this error if:

- You specify a maximum number of instances that is less than the initial number of instances.

To remove the error, either:

- Increase the maximum number of instances to at least the initial number of instances.
- Decrease the initial number of instances to less than or equal to the maximum number of instances.

(Z.100:2.4.4)

ERROR 294 Not allowed to change remote procedure in redefinition

(Z.100:2.4.6)

WARNING 295 Consider adding else answer

If a decision (or transition option) is executed with a question not covered by any answer it will be an error. (Z.100:2.7.5 and 4.3.4)

ERROR 296 Redefined or finalized procedure must be exported when base is

(Z.100:2.4.6)

INFO 297 Error limit reached, terminating

The number of diagnostics that the Analyzer has reported exceeds the value of the limit.

WARNING 298 Accumulated expression depth: %1 parts: %2 matches: %3

Semantic analysis of complex expression may cause long execution time. The execution time will increase in a fashion that is exponential rather than linear. If possible, try to reduce the complexity of expressions by breaking them down into multiple expressions.

WARNING 299 Expression depth: %1 parts: %2

See WARNING 298 Accumulated expression depth: %1 parts: %2 matches: %3 above.

ERROR 300 Command not found

The command that was input to the Analyzer's command interpreter was not recognized.

ERROR 301 Unexpected end of command: %1

The command that was input to the Analyzer does not contain all necessary parameters.

ERROR 302 Ambiguous command

The command that was input to the Analyzer's command interpreter was ambiguous. More characters need to be supplied to identify the command.

ERROR 303 Parameter expected

The command that was input to the Analyzer's command interpreter requires one or more parameters.

ERROR 304 Macro must not be part of a qualifier

A macro is not allowed to be part of a qualifier.

ERROR 305 Remote entity may only be exported once in a process

This applies to exported procedures and variables.

(Z.100:2.4.6 and 2.6.1.1)

ERROR 306 No input specified

There is no input set to the Analyzer using the set-input command.

WARNING 307 %1: unknown, line ignored!

The command line is ignored.

ERROR 308 More than one package match use statement

Use Modules to group systems together with their package lists to make package names unique within a module.

INFO 309 Location of the shadowed definition

ERROR 310 Selected item %1 is not connected to a file

The Organizer has ordered to analyze a diagram that is not connected to a file.

ERROR 311 Signal %1 found in opposite direction in connection

You get this error if:

- You connect two signal routes or channels where a signal is defined according to the signal lists to go in different directions on the inside and on the outside of the connection.

To remove the error:

- Reverse the direction of one of the signal routes or channels, at least for the signal that caused the error.

ERROR 312 Syntax error in rule %1, symbol %2 found but one of the following expected:

Syntax error!

ERROR 313 Syntax error, symbol %1 found but one of the following expected:

Syntax error!

ERROR 314 Lexical error in rule %1, symbol %2 found but one of the following expected:

Syntax error!

You get this error either if:

- You have typed a character or keyword that is not allowed in a CHARSTRINGLITERAL in a place where the syntax checker thinks there should be a CHARSTRINGLITERAL.
- You have used an SDL keyword as a name for a variable.

To remove the error in the above cases, either:

- Examine the pointed out character or keyword to see if it really belongs there.

- Try to find out why the syntax checker expects a CHARSTRING-LITERAL; did you intend to have a CHARSTRINGLITERAL there?.
- Rename any variable that you have given the same name as an SDL keyword.

You also get this error if:

- You have constructed a word or token out of single characters that does not match allowed word or tokens in SDL.

To remove the error in the above case:

- Check the word in question and replace any mistyped or misplaced characters.

ERROR 315 Lexical error, symbol %1 found but one of the following expected:

Syntax error!

ERROR 316 File %1 not found in environment variable %2 %3, check installation!

Check the installation. If the error persists, contact IBM Rational Customer Support. Contact information for IBM Rational Customer Support can be found in "How to Contact Customer Support" on page *iv in the Release Guide*.

ERROR 317 Outside connect item %1 is locally defined

You get this error if:

- Your connect statement mentions an inner channel or signal route instead of a channel or signal route outside the current diagram as the first connect item.

To correct the error, either:

- Swap places (if the second connect item is wrong too) on the inner and outer channel or signal route in the connect statement.
- If there is a name conflict with a locally defined item, then add a qualifier to the outer connect item.

WARNING 318 %1 : signal not used
The signal %1 should be used.

Here is a small explanation valid for all *<entity> not used* warning messages:

You get this error if:

- You declare an entity but do not use it.

To remove the error, either:

- Remove the declaration.
- Start using the entity.
- Rename the entity in the declaration to match a used entity of the same type that does not have a declaration.
- Change the type in the declaration to match a used entity with the same name but with a different type (that does not have a declaration).

WARNING 319 %1 : timer not used in input
The timer %1 should occur in an input.

WARNING 320 %1 : timer not used in set
The timer %1 should be set in the process.

WARNING 321 %1 : signallist not used
The signallist %1 should be used.

WARNING 322 %1 : variable not used
The variable %1 should be used.

WARNING 323 %1 : formal parameter not used
The formal parameter %1 should be used.

WARNING 324 %1 : synonym not used
The synonym %1 should be used.

WARNING 325 %1 : viewed variable not used
The viewed variable %1 should be used.

WARNING 326 %1 : remote variable not used
The remote variable %1 should be used.

WARNING 327 %1 : sort not used
The sort %1 should be used.

WARNING 328 %1 : generator not used
The generator %1 should be used.

WARNING 329 %1 : label not used
The label %1 should be used.

WARNING 330 %1 : system type not used
The system type %1 should be used.

WARNING 331 %1 : block type not used
The block type %1 should be used.

WARNING 332 %1 : process type not used
The process type %1 should be used.

WARNING 333 %1 : procedure not used
The procedure %1 should be used.

WARNING 334 %1 : package not used
The package %1 should be used.

ERROR 335
Reserved for future purpose.

ERROR 336 Input to Instance generator must be a system

ERROR 337 Operator diagram/definition not allowed where constant required

You get this error if:

- You call an operator in a place where a constant is required, for instance in a declaration of a variable.

To remove the error, either:

- Remove the operator call, and replace it with a constant if needed.
- Call a non operator definition operator.

WARNING 338 %1 : operator diagram/definition not used

WARNING 339 %1 : operator not used

WARNING 340 %1 : remote procedure not used

ERROR 341 No matching variable, formal parameter, synonym or literal

ERROR 342 Literal %1 in literal renaming is not defined in parent sort

ERROR 343 No matching field selection, array element access or prefix operator

ERROR 344 No matching quoted operator

You get this error if:

- You try to use a quoted operator with the wrong number of arguments or the wrong type of arguments.

To remove the error, either:

- Check that you are using two arguments for infix operators and one argument for monadic operators.
- Check that the operators you are using are of the correct type.

ERROR 345 No matching (. .)

ERROR 346 No visible variable or formal parameter with this name

ERROR 347 Type mismatch in component selection of variable or formal parameter

ERROR 348 No matching monadic operator

ERROR 349 No matching infix operator

INFO 350 %1 is one of the possible matching types

ERROR 351 No matching remote variable in variable definition

INFO 352 %1 is one of the visible definitions

WARNING 353 Type mismatch between actual and formal parameter

The types of the actual and formal parameters are implemented with different typedef, i.e. they may be of different size. Only checked for functions that cannot handle length mismatch.

ERROR 354

Reserved for future purpose.

ERROR 355 No matching remote variable in import definition

ERROR 356

Reserved for future purpose.

ERROR 357 No matching character string

ERROR 358 No matching choice primary

ERROR 359 Now not allowed where constant required

ERROR 360 No matching now expression

ERROR 361 Import expression not allowed where constant required

You get this error if:

- You use an import expression where a constant is required.

To remove the error:

- Replace the import expression with a constant.

ERROR 362 PId expression not allowed where constant required

You get this error if:

- You are using a pid expression where a constant is expected.

To remove the error:

- Replace the pid expression with a constant expression.

ERROR 363 No matching PId expression

You get this error if:

- You use a PId expression where a boolean value is expected.

To remove the error, either:

- Replace the PId expression with a boolean expression.
- Make the expected value to be of type PId.

ERROR 364 View expression not allowed where constant required

You get this error if:

- You are using a view expression where a constant expression is expected.

To remove the error:

- Replace the view expression with a constant expression.

ERROR 365 Timer active expression not allowed where constant required

ERROR 366 Any expression not allowed where constant required

ERROR 367 No matching dereferencing operator

ERROR 368 Data base error

An internal error occurred in the Analyzer. Please send a report to IBM Rational Customer Support. Contact information for IBM Rational Cus-

tomer Support can be found in "How to Contact Customer Support" on page *iv in the Release Guide*.

ERROR 369 No matching field selection

You get this error if:

- You try to access a field in a struct using a name that does not represent any field in the struct.
- You try to access a field in a struct whose sort does not match the one expected.

To remove the error:

- Make sure you are using the correct name to access a field in the struct.
- Add a field in the struct with the wanted name.
- If required, reference a conversion operator to have the field match the sort required.

ERROR 370 Type mismatch for procedure return value

ERROR 371 Type mismatch for variable, formal parameter, synonym or literal

You get this error if:

- You assign a variable a value of the wrong type.

To remove the error:

- Assign the value to a variable of the correct type instead.

ERROR 372 No visible variable, formal parameter, synonym, literal or operator with this name

You get this error if:

- You use the name of a variable, formal parameter, synonym, literal or operator that is not defined in the current scope.

To remove the error, either:

- Change the name to match a defined entity.
- Define the entity.

ERROR 373 No visible synonym or literal with this name

You get this error if:

- You refer to a synonym or a literal that cannot be seen from the current scope.

To remove the error, either:

- Correct the spelling mistake, if it was not meant to be a synonym or literal.
- Add a synonym or literal with the given name.

ERROR 374 Variable or formal parameter not allowed where constant required

You get this error if:

- You are using a variable or formal parameter in a place where a constant expression is expected.

To remove the error:

- Replace the variable or formal parameter with a constant expression.

ERROR 375 Type mismatch for synonym or literal

You get this error if:

- You use a boolean synonym or literal where an integer synonym or literal is expected.

To remove the error:

- Replace the boolean with an integer.

ERROR 376 Only one reference to each diagram allowed

Several diagrams connected to the same file.

ERROR 377 Keyword call required for procedure call

You get this error if:

- You are calling a value returning procedure without using the CALL keyword.

To remove the error:

- Add the CALL keyword before the procedure name in the expression.

ERROR 378 Several macrodefinitions have the same name %1

The name of a macro must be unique.

WARNING 379 Macrodefinition %1 was never called

The macro %1 should be used.

ERROR 380 Names separated by %, %1%%2, where neither is a formal parameter nor MACROID in macrodefinition %3

(Z.100: 4.2.1)

WARNING 381 Formal parameter %1 is never used in macrodefinition %2

The formal parameter %1 should be used in the macro definition

ERROR 382 The macrodefinition name is %1, but the endmacro name is %2

The names in the macro definition and the endmacro must be equal.

ERROR 383 Two formal parameters with the same name %1 in macrodefinition %2

Two formal parameters of a macro cannot have the same name.

ERROR 384 No matching macrodefinition found

The corresponding macro definition is missing.

ERROR 385 A macro may not call itself

A macro definition cannot be circular.

WARNING 386 No macro found

The system does not contain any macros or calls.

ERROR 387 Start transition expected

A process or procedure definition must begin with a start transition.

You get this error if:

- You define a process without defining a start transition.

To remove the error:

- Add a start transition to the process.

ERROR 388 Illegal redeclaration of operator definition

You get this error if:

- You declare an operator twice.

To remove the error, either:

- Rename one of the operators if they are different and you need them both.
- Remove one of the operator definitions.

(Z.100: 5.3.2)

ERROR 389 No matching operator signature found

The operator must be defined for this signature.

ERROR 390 This unexpected

The keyword this is only allowed in a procedure call, process create or “output to”.

You get this error if:

- You use the keyword THIS in normal diagrams.

To remove the error, either

- Remove or replace the keyword THIS.
- Convert the diagram to a type-based diagram.

ERROR 391 Context parameter %1 not allowed

(Z.100: 6.2)

ERROR 392 Call this invalidated by adding parameters to sub type

Call this cannot be used when formal parameters are added in the sub-type.

You get this error if:

- You use the keyword THIS in a procedure call and the called procedure is a super type to a sub type that adds parameters to be used in a procedure call.

To remove the error, either:

- Make both the sub type and the super type use the same set of parameters by declaring all parameters in the super type if you intend to call the sub type.
- Remove the THIS keyword if you intend not to call the sub type.

INFO 393 Instance path to the problem in previous message

This message provides additional information that may be used to locate the source of error in the previous message. This message may appear repeated times, depending on the depth of the SDL structure where the previous error is detected.

ERROR 394 Package Predefined expected, check installation

File *predef.sdl* does not contain the package Predefined. The error message appears only when you have altered the installation in an improper way.

ERROR 395 Type mismatch for view expression

You get this error if:

- You view a variable of the wrong type. For instance, you assign a variable of type boolean the value of a viewed variable of type integer.

To remove the error, either:

- Change the type either of the assigned variable or the viewed variable to match each other.
- View another variable instead, that has the correct type.
- Assign to another variable instead, that has the correct type.

ERROR 396 Viewed variable %1 is not revealed in block %2

The viewed variable must be declared as revealed in block %2.

ERROR 397 Context parameters are not supported

Context parameters are not implemented. Consider using an alternative approach.

WARNING 398 One line external formalism name expected on same line as alternative keyword

Syntax error! When using alternative the name of the alternative data formalism must occur on the same line as the alternative keyword.

ERROR 399 Type mismatch for timer active expression

You get this error if:

- You are using the result of the ACTIVE call as if it had another type than boolean.

To remove the error:

- Make sure you are using the result of the ACTIVE call as a boolean value.

ERROR 400 Type mismatch for any expression

Chapter

55 *Analyzing a System*

Analyzing a system means checking that its SDL description obeys the syntax and semantic rules as defined in the Z.100 recommendation (some syntax checking is performed by the SDL Editor at editing time).

The SDL Analyzer allows you to perform a complete syntactic and semantic check of an SDL system. This chapter describes the Analyzer and how you may use it to analyze an SDL system.

For a reference to the Analyzer commands and the Analyzer functionality and restrictions, see *chapter 54, The SDL Analyzer*.

General Description

The Analyzer's main task is to perform syntactic and semantic analysis of SDL-92 definitions and diagrams, and to serve as a front end to code generators. You may perform full syntactic and nearly full semantic analysis of complete system definitions.

Analysis of separate units (block, process, substructure, service, and procedure) is also supported. Syntactic analysis may be performed on a unit, while restricted semantic analysis of a unit may only be performed if the context of the unit is provided. The context is the enclosing units and their definitions (for a detailed description, see the section *"Separate Analysis" on page 2505 in chapter 54, The SDL Analyzer*).

The Analyzer works in a number of passes:

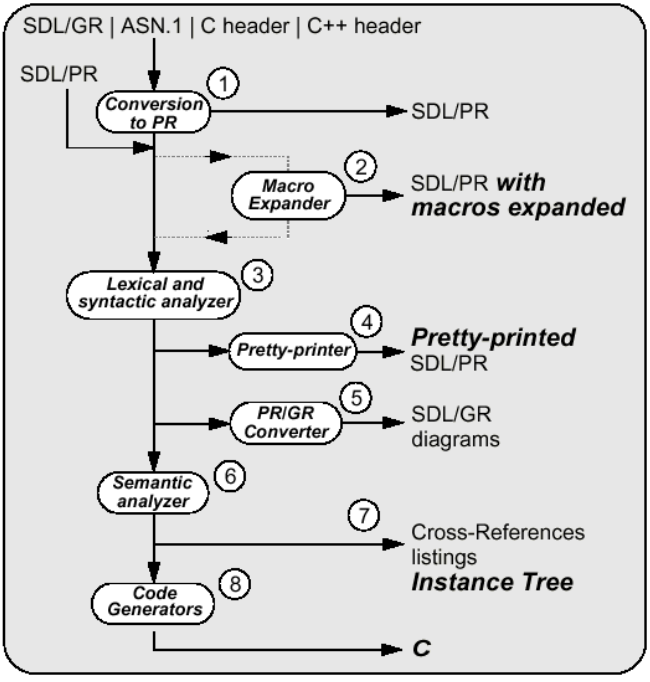

Figure 493: Analyzer passes

1. *Conversion to PR*. This pass is needed when input is not SDL/PR, i.e. for SDL/GR diagrams, ASN.1 files, C, and C++ header files. The result is a PR file with a "raw" layout, that is submitted as input to the next pass. This PR file is not intended to be read by the human. See *"Conversion to PR" on page 2501 in chapter 54, The SDL Analyzer* for a more thorough description.

2. *Macro expansion.* This pass is needed when input contains references to macros (which need to be expanded). The result is a PR file where SDL macros are expanded. See *"The Macro Expander" on page 2502 in chapter 54, The SDL Analyzer* for a more complete description of the Macro Expander.

3. *Lexical and syntactic analysis.* This pass checks that the input follows the SDL definition with respect to syntactic rules. During this pass, the Analyzer builds an abstract syntax tree that is used by the following passes. See *"The Lexical and Syntactic Analyzer" on page 2504 in chapter 54, The SDL Analyzer* for a more thorough description.

4. *Pretty-printing*. This optional pass uses the pretty-printer to produce an SDL/PR file with a nice layout, easy to read and understand by the human. The pretty-printed PR file contains the original SDL specification formatted according to specific layout rules.

5. *PR to GR conversion.* The input PR files are translated to SDL/GR diagrams, that you may open in the SDL Editor. This pass allows you to for instance import PR files from other tools supporting SDL. See also section *"The PR to GR Converter" on page 2507 in chapter 54, The SDL Analyzer*.

6. *Semantic analysis.* During this pass, the Analyzer checks that your SDL diagrams obey the static semantic rules as defined in the Z.100 recommendation. During this pass, the Analyzer builds and uses a symbol table, which can also be used later by the Code Generators. The semantic analysis is likely to be the "bottleneck" when analyzing a system. See "Optimizing a System to Reduce Analysis Time" on page 2621.

7. After the semantic analysis pass, you may optionally generate:
   - *cross-references* listings of SDL entities; where they are defined in an SDL system, and where they are used (referred). The result from this pass is a file which contents may be displayed graphically in the Index Viewer. See chapter 46, *The SDL Index Viewer* for more information.
   - *instance tree* information about the SDL system. The result from this pass is an instance information file consisting of records that describe the SDL entities that are present in the system after instantiation of all types. The file is a plain text file with a simple format. See *"File Syntax" on page 2513 in chapter 54, The SDL Analyzer* for more information.

8. If your configuration includes a Code Generator[1] you may include:
   - A *C Code Generation* pass, in order to generate a C description of your SDL system. This C code is then compiled and linked to generate a simulator, an explorer or an application. The SDL to C Compiler is available as a Cbasic and as a Cadvanced code generator.
   - A *Cmicro Code Generation* pass. The generated C code is optimized with respect to memory requirements, making it suitable for generating applications for systems with limited resources.

Analyzer Input and Output

The input to the Analyzer consists of SDL-92 specifications, that is, SDL/GR diagrams that are stored using the storage format of the SDL Suite, or SDL/PR files, or a combination of both.

The output consists mainly of PR files, error and warning messages. These messages are presented on the screen in a log window and may be stored on file. See "Error and Warning Messages" on page 2531 in chapter 54, *The SDL Analyzer* for a description of these messages.

It is also possible to obtain a pretty printed SDL/PR file of the input and to transform SDL/PR files into SDL/GR diagrams.

1. Although technically built into the Analyzer binary executable (sdtsan), the Code Generators are additional optional tools that are licensed separately.

The Analyzer User Interfaces

The Analyzer provides the following user interfaces.

Graphical UI

When started from the Organizer with the *Analyze* command, the Analyzer takes advantage of the graphical user interface and integration mechanism of the SDL Suite.

For instance:

- Graphical references between source documents and error reports is supported, which facilitates locating and correcting errors in the source SDL diagrams.
- An SDL-Make facility, managed by the Organizer, controls the Analyzer and brings down the analysis work that needs to be done.
- On-line help on analysis diagnostics is available (provided the prerequisites for the on-line help are satisfied).

Batch UI

Suitable for running the Analyzer non-interactively. See "Batch Facilities" on page 208 in chapter 2, *The Organizer*.

Command-Line UI

Suitable for working on the file level with detailed control. See "The Analyzer Command Line UI" on page 2474 in chapter 54, *The SDL Analyzer*.

Using the Analyzer

This section describes how you operate the Analyzer from the Organizer. We will discuss topics related to the various ways you may analyze an SDL structure. With the SDL Suite, you may for instance perform syntax check on an SDL structure or check an entire SDL system with respect to the semantic rules.

Analyzing Using Default Options

To analyze an SDL structure using default options:

1. In the Organizer, select the root node for the subtree that is the subject to be input to the Analyzer.

2. Click the quick button for Analyze. The Organizer first checks if there are any unsaved diagrams; if any, the Organizer will prompt you to save these before analyzing them (since the Analyzer operates on the latest saved copy of a diagram).

3. The Organizer determines what diagrams need to be analyzed and what passes need to be run, by looking at the time the diagrams were saved on file and by monitoring the Analyzer's work.

   – To perform an analysis, you may either "touch" the SDL diagram files or force the Analyzer by clicking the *Full Analyze* button (see Figure 494).

4. The analysis job is submitted the to the Analyzer, using the options as they are currently defined in the Analyzer options dialog (see Figure 494 on page 2619).

5. From now on, the status bar reads "Analyzer working". When done, the status bar will read "Analyzer ready".

Analyzing Using Customized Options

To analyze an SDL structure with customized options:

1. In the Organizer, select the root node for the subtree that is the subject to be input to the Analyzer.

2. From the Organizer's *Generate* menu, select the *Analyze* command. The Analyzer Options dialog is displayed.

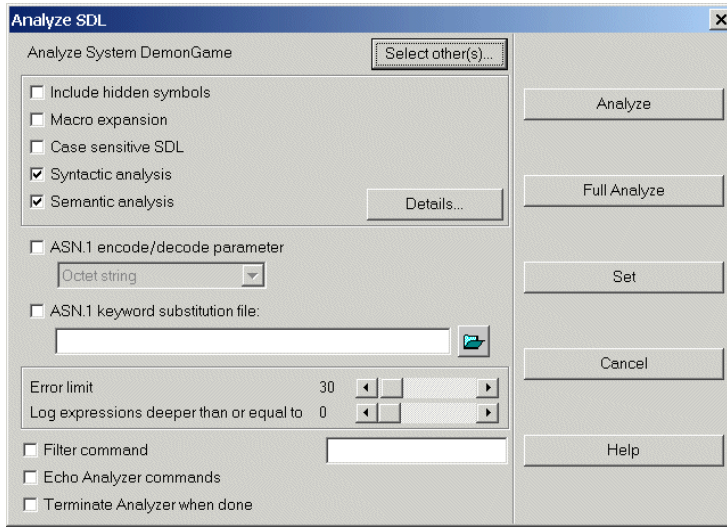

Figure 494: The Analyzer dialog

3. Adjust, if required, some of the Analyzer options to their required values. These options govern what passes should be performed by the Analyzer, see Figure 493 on page 2614, and what output should be produced by the Analyzer. (The code generation pass options are however not controlled from this dialog.)

4. Click the *Analyze* button. First, the Organizer checks if there are any unsaved diagrams; if any, the Organizer will prompt you to save these before analyzing them (since the Analyzer operates on the latest saved copy of a diagram).

5. The Organizer determines what diagrams need to be analyzed and what passes need to be run, by looking at the time the diagrams were saved on file and by monitoring the Analyzer's work.

   – To perform an analysis, you may either "touch" the SDL diagram files or force the Analyzer by clicking the *Full Analyze* button.

6. The Analyzer is initialized and starts executing (this is indicated in the Organizer status bar which now reads "Analyzer working").

7. When the Analyzer has analyzed the input as specified in the options, the Organizer status bar reads “Analyzer ready”. The results of the analysis are reported in the Organizer log window.

Performing Syntax Check

1. If the input contains SDL macros, you should expand these before proceeding with the syntax analysis in the resulting SDL/PR file.
   – Turn the *Macro expansion* button on to order expansion of SDL macros.
2. Turn the *Syntactic analysis* button on to include the syntax checking pass.
3. Click the *Analyze* button.

Performing Semantic Check

Turn the *Semantic analysis* button on to include the semantic check pass. This option cannot be turned on unless the *Syntactic analysis* pass is enabled. The semantic checker may be set up with by a number of options, each one individually activated by a toggle button.

Note: Optimizing a System to Reduce Analysis Time

There are two components that, to a large extent, affect the performance of the "resolution by context" in the semantic analysis pass:

- The depth of the expressions, because all possible combinations must be tried.
- The size of the system, because the context is all the visible identifiers.

Deeply nested expressions may cause a **significant** degradation of performance when performing the semantic analysis pass. It is therefore recommended to break down complex expressions into multiple, less complex expressions. *Checking for Deep Expressions* (see below) can assist you doing this.

If it is an option to modify your system, it might be worthwhile to go through all synonyms, newtypes and syntypes at the system level and move them as far as possible down the system structure. This makes the context visible to every expression smaller and reduces the time spent in "resolution by context". (Doing the same thing at lower levels will also improve performance, but not as much as on higher levels.) The Index Viewer might be useful in accomplishing this.

Checking Output Semantics

The *Check output semantics* option controls whether to issue warnings when SDL signal sendings, where the semantics is different in SDL-88 and in SDL-92, are detected. These warnings are particularly valuable when the input consists of SDL diagram that were designed in SDL-88 (for instance with SDT 2.X).

Detecting Not Used Definitions

The *Check unused definitions* option, when turned on, orders the Analyzer to report definitions that are not used (for instance variables that are declared but neither written or read).

Checking Optional Parameters

The *Check optional parameters* option controls whether to issue warnings when an optional parameter is omitted from a procedure call, an output, a create request, or an input. Note that in/out parameters are not

optional. An omitted parameter is indicated by empty parenthesis or a comma. See also *Checking Trailing Parameters*, below.

Checking Trailing Parameters

The *Check trailing parameters* option controls whether to issue warnings when the number of actual parameters is not equal to the number of formal parameters in a procedure call, an output, a create request, or an input. See also *Checking Optional Parameters*, above.

Checking Unique References

When the *Check references* option is activated, the Analyzer will check that each remote definition is referred only once. Turn this button off to disable this check.

Checking Missing Else Answer

The *Check missing else answers* option controls whether to issue warnings when an else part is expected but does not exist among the branches in a decision or transition option statement.

Checking Missing Answer Values

The *Check missing answer values* option controls whether to issue warnings when there are values not covered by any of the branches in a decision or transition option statement.

Checking Parameter Mismatch

The *Check parameter mismatch* option controls whether to issue warnings when the types of the actual and formal parameters are implemented with different typedef, i.e. they may be of different size. This is only checked for functions that cannot handle length mismatch.

Externel types should call GenericFree

The *External types should call GenericFree* option controls whether to generate code to call GenericFree for variables of externally defined types. Note this is a codegenerator option.

Allowing Implicit Type Conversions

The option *Allow implicit type conversion* controls whether implicit type conversions of reference data types (generators Own, ORef, and

Ref) are allowed. For more information, see "Implicit Type Conversions" on page 134 in chapter 3, *Using SDL Extensions, in the SDL Suite 6.2 Methodology Guidelines*.

> **Note:**
> Analyzing large expressions with this option on is slow.

Generating a Cross Reference File

Turn the *Generate a cross reference file* option on to have the Analyzer generate a file with a list of definitions and references to SDL entities, as an supplementary result from the semantic pass. You may also want to specify another file name than the suggested one. The contents of this file may be read and visualized graphically with the Index Viewer.

Generating a Complexity Measurement file

Turn the *Generate a complexity measurement file* option on to have the Analyzer generate a file containing characteristics of the system. You may change the file name in the field below. See chapter 48, *Complexity Measurements* for more information.

Generating an Instance Information File

Turn the *Generate an instance information file* on to have the Analyzer generate a file with instance information about the analyzed system. The name of the file can be set in the field below. The file is produced after the semantic pass. Read more about the contents of an instance information file in *"SDL Instance Information" on page 2512 in chapter 54, The SDL Analyzer*.

Checking for Deep Expressions

Adjust the *Expression depth* parameter to specify the depth limit that the Analyzer should check for when evaluating expressions. Expressions which depth exceed the specified limit will be reported. Where possible, try to break down deep expressions since they require advanced calculations and slow down the Analyzer.

Specifying the Error Limit

Adjust the *Error limit* parameter to an adequate value (drag the slider for coarse adjustments, click left or right on the bar for fine adjust-

ments). The Analyzer will stop its execution once this error limit has been reached.

Using a Filter

With the *Filter command* files can be filtered or preprocessed before they are read by the Analyzer. The specified executable file will be called with two arguments: the file to be processed by the Analyzer, and the Analyzer pass to be executed (import, macro, or parse). Try a simple OS command and look in the Organizer log to find out exactly how it is called.

Tracing the Analyzer Execution

You can trace the execution of the Analyzer by turning on the option *Echo Analyzer commands*. All Analyzer commands are then printed in the Organizer Log as they are executed.

Terminating the Analyzer Process

Turn on the option *Terminate Analyzer when done* if you want the Analyzer process to terminate after analysis is done. Otherwise, the Analyzer process is left running in the background.

Locating and Correcting Analysis Errors

The results of the Analyzer are appended to the Organizer Log Window. (You may save the window contents on any file at any time). The results of the last run are also saved on a file with the predefined name `analyzer.err`

The SDL Suite provides a nice feature for displaying the source of an analysis error:

1. Locate the Organizer log (select *Organizer Log* if required).
2. Select the error (or warning) message by dragging the mouse.

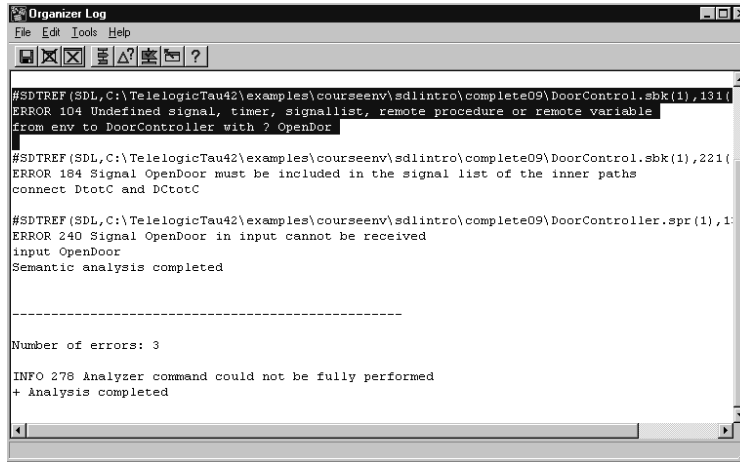

Figure 495: Selecting an error message

– The selection must contain at least the line starting with the text #SDTREF (for more information on the format of references, see chapter 18, *SDT References*).

3. Select the menu choice *Show Error* from the *Tools* menu.

4. The symbol where the error has been detected is displayed in an SDL Editor window. When the reference also contains a line and a column reference, the text cursor is placed on the line and column of text where the error was detected.

5. If you need additional explanations to understand the error message, select *Help on Error* from the *Tools* menu.

Producing a Pretty-Printed SDL/PR File

You may produce a pretty-printed PR file with the Analyzer, with a single command. The layout used by this PR makes it easy to read by the human. You may either submit SDL diagrams or SDL/PR files as input to the pretty-printer.

To be able to pretty-print SDL/PR, the SDL Suite requires that the input must be syntactically correct. If the input does not fulfill this requirement, the SDL Suite will however produce a PR file with a “raw” layout. This file is used by the SDL Suite as a temporary file and it does not address the human reader.

1. In the Organizer, select the root node of the SDL structure to be pretty-printed.
2. From the Generate menu, select *Convert to PR/MP*. The *Convert to PR* dialog is displayed:

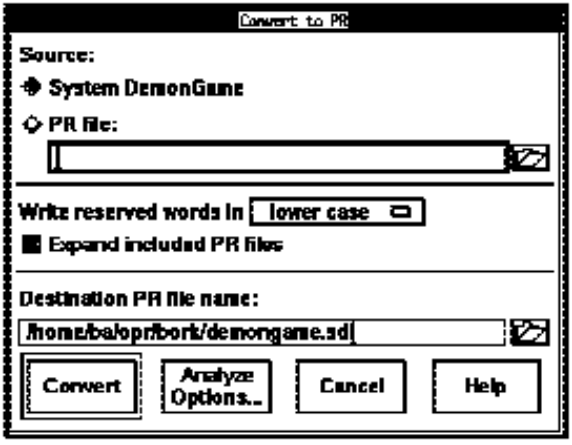

Figure 496: The Convert to PR dialog

3. Adjust, if required, the conversion options:
   – You may specify a PR file as alternative input. (The default input is the SDL structure designated by the object selected in the

Organizer.) To do this, type in the name of a file into the *PR file* text field.

- You may order the Analyzer to capitalize SDL reserved words or not; select the appropriate option from the *Write reserved words in* option menu.
- If the SDL structure contains #INCLUDE references to SDL/PR files, you may want to expand these and include them in the resulting pretty-printed PR file. Turn the *Expand included PR files* button on to order expansion of included PR files.

4. An output file where the resulting SDL/PR code will be stored is suggested. You may specify any other file to store the results on in the *Destination PR file name* text field.
5. If the input contains SDL macros, you may want to expand these in the resulting SDL/PR file.
   - Click the *Analyze Options* button to gain access to the *Analyzer options* dialog, where you turn the *Macro expansion* button on and click the *Set* button.
6. Click the *Convert* button to close the dialog and have the Analyzer start the conversion to SDL/PR.

Converting SDL/PR to SDL/GR

You may convert SDL/PR files to SDL/GR diagrams, storing them on files using the native format of the SDL Suite. Once converted, these SDL descriptions may be managed, edited and printed by the graphical tools of the SDL Suite just as if they were created using the SDL Suite.

To convert an SDL/PR file to SDL/GR diagrams:

1. From the Organizer, *Generate* menu, select *Convert to GR*. A dialog is displayed:

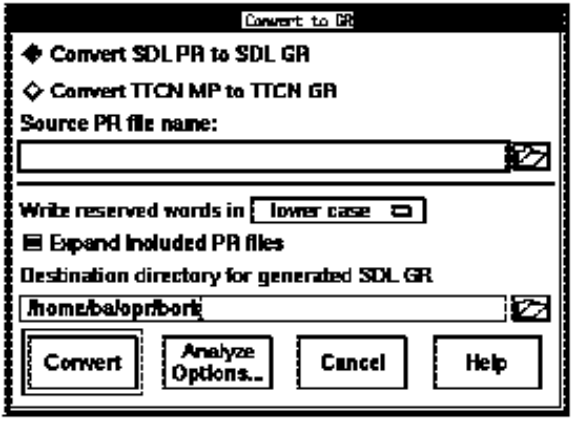

Figure 497: The Convert PR to GR dialog

2. Specify the PR file to convert from. You may either type the file specifier or click the folder button to issue a File Selection Dialog.

3. Specify the destination directory, where to store the results of the conversion. You may either type the name of a directory or click the folder button to issue a directory selection dialog.

4. You may specify other options:

   – Whether to capitalize SDL reserved words or not, by selecting the corresponding option from the option menu.

   – Whether to expand any included PR files or not (PR files are included using a #INCLUDE directive inside an SDL comment statement).

5. If required, click the *Analyze Options* button to modify the Analyze options (typically, you may need to turn the *Macro Expansion* option on). Close the *Analyze Options dialog* with the Set button (see Figure 494 on page 2619).

6. Click the *Convert* button to order the conversion. The Organizer's status bar reads "Analyzer ready" when the conversion is completed.

   – Each diagram that is specified (or included and expanded) in the source PR file is transformed to one file. These files are assigned default file names (see "Save in file" on page 63 in chapter 2, *The Organizer*).

   – The generated diagrams are assigned a layout by the SDL Editor.

   – Error and warning messages, if any, are appended to the Organizer log window.

7. To look at the resulting diagrams, you may either open the resulting files in the SDL Editor.

   – Alternatively, identify the root diagram file that has been produced. (You may need to look at the input SDL/PR file to determine what file to look for.) Then, import this file into the Organizer, with *Import SDL* from the *File* menu. Specify the root diagram file as *Root document*.

Chapter 55 Analyzing a System

Chapter

56

The Cadvanced/Cbasic SDL to C Compiler

The Cadvanced/Cbasic SDL to C Compiler translates your SDL system into a C program that you can compile and link together with a runtime library to form an executable program such as a simulator, an explorer or, in the case of Cadvanced, an application.

This chapter is a reference manual to the Cadvanced/Cbasic SDL to C Compiler. There are also a number of other chapters related to code generation:

- **In *chapter 49, The SDL Simulator*, you will find a reference to the simulation facilities in the SDL Suite. In chapter 50, *Simulating a System*, you will find a user's guide to the simulator.**
- **In *chapter 52, The SDL Explorer*, you will find a reference to the validation facilities in the SDL Suite. In chapter 53, *Validating a System*, you will find a user's guide to the SDL Explorer.**
- **In chapter 57, *Building an Application*, you may read about how to generate applications for host and target environments.**
- **In chapter 61, *The Master Library*, you will find information about how to customize your own libraries for a specific purpose, such as application generation for target computers. The chapter also describes the structure of the generated C code and the internal data structures in the generated C code.**
- **In chapter 62, *The ADT Library*, you will find a reference to the library of abstract data types that is distributed with the SDL Suite and that you may use in your systems designed in SDL. Some examples of use are also available.**
- **In chapter 63, *The Performance Library*, you may read about how to generate and run simulators which are specially adapted for the area of performance simulation.**

Introduction

Application Areas for the Cadvanced/Cbasic SDL to C Compiler

There are a number of application areas for the Cadvanced/Cbasic SDL to C Compiler, for example:

- Functional simulation and debugging of protocol specifications
- Debugging of system designs described in SDL
- Generation of applications, including embedded system applications with real time characteristics
- Performance simulations
- Simulation of the behavior behind a user interface prototype

In this part of the manual, the general behavior of the code generator and its application for simulation and debugging are discussed. The possibility to generate simulators is described in chapter 49, *The SDL Simulator*.

Functional Simulation and Debugging

During the validation of a specification or design of an application expressed in ITU SDL, you can use the Cadvanced/Cbasic SDL to C Compiler as a tool for simulation to help you understand and debug the behavior of a system description. (See *chapter 49, The SDL Simulator*.)

Errors arising from two different areas have to be considered in the validation process. In the language domain, errors due to illegal or illogical usage of the language concepts might be introduced into the specification; while in the problem domain, logical errors might be introduced.

With traditional computer program development, most illegal uses of language concepts are found by compilers or by run-time systems. Examples are syntax errors, missing declarations, division by zero, or indexing an array out of its bounds.

In the problem domain, however, the only feasible ways of detecting logical errors in non-trivial programs are testing and proofreading. When it comes to specifications in SDL, language domain errors can be

detected by using the SDL Analyzer, which can be seen as a compiler without a code generation facility (see *chapter 54, The SDL Analyzer*). To detect problem domain errors, testing by simulating the specification is the main procedure available. Please see also chapter 52, *The SDL Explorer*.

The specification of a protocol in SDL, for instance, specifies a signal interface by giving a hypothetical implementation of the components in the protocol. This strategy immediately brings up two different purposes for simulating the behavior of a system specification: to understand the external view and to understand the internal view.

In the external view, the signal interface is of concern, while the internal behavior of the system specification (the behavior of the processes in the system) is of little or no interest. In the internal view, the internal behavior of the system specification is of concern, while the external signal interface is simply seen as part of the internal behavior.

A simulation of the internal behavior of a system specification constitutes an important part of the validation of the specification, both as a debugging tool and as a means to increase the understanding of the dynamic behavior of the specification. A designer of a system might use this kind of simulation to understand the specification better.

The ability to simulate and debug applications generated by the code generator at an SDL level is a very important feature towards achieving the correct overall behavior of the application. The debugging facilities provided by the SDL Suite have much in common with interactive debuggers for ordinary programming languages. The debugging is performed on a host computer.

Another application of the code generator as a simulator generator, is of course in SDL education, where simulation, especially of the internal behavior of a system specification, can serve as a powerful way of clarifying the semantics of SDL concepts.

Performance Simulation

The Cadvanced/Cbasic SDL to C Compiler can be used for performance simulations. You describe the performance model of the actual system using SDL. This model can be translated to a simulation and executed. By introducing measurements of interesting data, such as queue lengths, delays, and so on, into the SDL model, it is possible to gather statistical data during the execution of the simulation. In chapter 63, *The*

Performance Library, you can find a description of the performance simulation facilities.

To simplify this kind of simulation, a number of SDL abstract data types and their implementations have been developed, where, for example, random number generation and handling of queues are supported. Please see chapter 62, *The ADT Library*.

Validation

The SDL Explorer uses the code produced by the Cadvanced/Cbasic SDL to C Compiler to form a program suitable for validation of an SDL system. The Explorer uses state space exploration and can be used to:

- Find run time errors
- Verify MSCs against the SDL system
- Verify user defined rules

The Explorer is described in *chapter 52, The SDL Explorer*.

Communicating Simulations

You can specify that a generated C program should be able to communicate over the *PostMaster*, which is the mechanism used for communication between the SDL Suite tools. Signals sent from the SDL system (the generated program) to the environment and signals coming to the SDL system from the environment can be handled. This facility makes it, for example, possible to develop simulation programs for two communicating systems, execute them using the SDL Suite and obtain communication between the systems.

As a generated C program does not know what it communicates with, it can of course communicate with any type of application, as long as the application is connected to the *PostMaster* (the communication medium) and sends signals according to the defined format. How to achieve this is described in *chapter 12, Using the Public Interface*.

A very interesting group of such applications are user interfaces. By connecting a user interface and an SDL simulation you can achieve several things: You can, for example, build well-designed application oriented user interfaces that present what is going on in a simulation, or you can in a simple way define the logic behavior behind a user interface during its prototyping phase.

Overview of the Cadvanced/Cbasic SDL to C Compiler

To facilitate the validation of SDL specifications or descriptions, the SDL Analyzer contains an SDL parser, an SDL semantic checker, and the Cadvanced/Cbasic SDL to C Compiler.

Creating a C Program

To obtain an executable program that behaves according to an SDL description, you enter the SDL description into the SDL Analyzer, which contains the Cadvanced/Cbasic SDL to C Compiler. If the SDL description is syntactically and semantically correct, a C program is generated. You then compile this program using an ordinary C compiler and link it with a predefined SDL run-time library to form an executable program. See Figure 499.

As indicated above, the C code generation facility contains two components:

- The SDL to C Compiler, which can be seen as a back-end to the SDL Analyzer. This component generates a C program.
- Predefined and precompiled C units, which implement an **SDL runtime library** and the command line user interface of a simulator, that is, a **monitor system**. The run-time library also includes a **communication mechanism** which makes it possible to trace the execution of SDL transitions in the SDL Editor. There are several versions of the library that are suitable to different application areas for the generated C code, see "Libraries" on page 2770 in chapter 57, *Building an Application*.

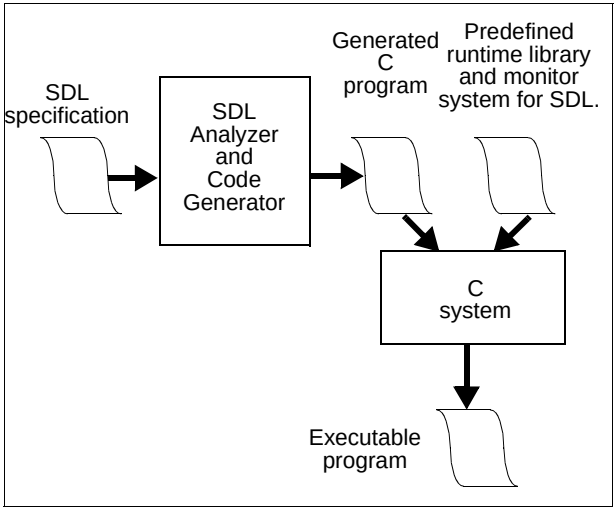

Figure 499: The production of an executable program

Executing a C Program as a Simulator

The generated C program uses an internal data representation of the SDL objects in the system, for example process instances and signal instances. The process instances will execute transitions in a quasi-parallel manner. During a transition, SDL actions such as tasks, decisions and signal outputs are executed according to the semantics of SDL.

You interact, using SDL terminology, with the simulator through a monitor system, which contains a number of commands to:

- Control the execution of transitions.
- Examine the status of objects in the system.
- Turn log facilities on and off.
- Affect the system by, for example, sending signal instances from the environment to the system.

Contents of This Chapter

You can find more details on creating and executing a C program in the following sections:

- In "Generating a C Program" on page 2638, the process of generating a C program is described.
- In "Abstract Data Types" on page 2656, implementation aspects especially concerning abstract data types, are described.
- In "Directives to the Cadvanced/Cbasic SDL to C Compiler" on page 2720, possibilities to give additional information to the Cadvanced/Cbasic SDL to C Compiler are discussed.
- The section "Using Cadvanced/Cbasic SDL to C Compiler to Generate C++" on page 2749, contains considerations on class definitions as C++ code and the utilization of the classes as C++ code in SDL tasks.
- In "Restrictions" on page 2753, the Cadvanced/Cbasic SDL to C Compiler restrictions are covered.

Generating a C Program

A generated C program can be used for several things, for example as a simulator, as an explorer, or as an application with the behavior defined by the translated SDL system. The process of generation of simulators, explorers, or applications, see below, is started in the Organizer, in the make dialog (see "Make" on page 120 in chapter 2, *The Organizer*) or by the quick buttons for simulation and validation (see "Quick Buttons" on page 180 in chapter 2, *The Organizer*).

The SDL Analyzer, which contains the C code generation facility, can also be started as a stand-alone tool. For more information about this possibility please see "The Analyzer Command Line UI" on page 2474 in chapter 54, *The SDL Analyzer*.

Process of Generating a C Program

There are four steps that must be performed to start the execution of, for example, a simulator:

1. The SDL Analyzer and its built-in Cadvanced/Cbasic SDL to C Compiler create a program expressed in C source code.
2. The generated C file (or files) is compiled.
3. The compiled file (or files) is linked together with a predefined library.
4. The executable program that is created in the link operation is started.

This process has been automated and requires no user knowledge about compiling or linking of programs. The process is initiated in the Organizer using the quick buttons for simulation and validation, or by using the *Make* dialog.

A C program can only be generated for an SDL system. The C code that constitutes the program can, however, be generated on multiple files, which means that a local change in, for example, a block diagram only requires a regeneration and recompilation of the code for that unit. The object files, (the compiled versions of the C files) for the other unchanged units can then be used in the link operation to form a new executable program. This feature in automatically used by the make facility and the quick buttons, to minimize the amount of work and thus the turn-around time, for the process from a change in the SDL system to a new simulator (for example).

The separation of the C code for an SDL system can be decided by the user. The *Edit Separation* command from the *Generate* menu is used for that purpose, see "Edit Separation" on page 137 in chapter 2, *The Organizer*. The effect on the generated file structure and some guidelines of how to use separation can be found in the section "Selecting File Structure for Generated Code – Directive #SEPARATE" on page 2721.

Executing a C Program

The generated C programs can in principle be compiled as either a simulator, an explorer, or an application. Generated applications have no further connection with the SDL Suite and are executed as any other application.

A generated simulator or explorer can however be started in two different ways:

- From the *Simulator Graphical User Interface*, which is started from the Organizer with the *SDL > Simulator UI* command and provides a graphical interface with buttons and menus and of course full connection to other SDL Suite tools. See *"Graphical User Interface" on page 2199 in chapter 49, The SDL Simulator* for more information.
- From an OS shell, just like any other executable program. The user then invokes a *command line monitor* system. If the Organizer is running when starting a simulator or explorer, the program will connect itself to the SDL Suite. If the Organizer is not running or the simulator/explorer is started with the program parameter `-nosdt`, the program will not connect itself to the SDL Suite.

The SDL Unit for Which Code is Generated

The first time a C program is generated for a system, the complete system will be selected for analysis and C code generation. After that only the unit (*system* or *block*) that is changed will be selected. Note that the lowest level of possible regeneration object is a block. That block may not be a block type, or be part of a block type or system type. The reason that a process cannot be generated without regenerating the enclosing block, is that internal process information about, for example, formal parameters are used to generate code for other processes within the same block.

- Only complete C files can be generated. If, for example, the user has specified that a *block* and a *sub-block* should be generated on the

same file, it is not possible to regenerate code only for the sub-block.

- If the file structure is changed (by, for example, changes in the *Edit Separation* command or in the #SEPARATE directives), then the complete system is regenerated.

Errors During Code Generation

Errors that may occur during code generation are internal errors. That is, errors due to not yet implemented features of SDL, and errors related to problems with opened or closed operations of files.

An error message starts with an SDT references and is followed by a description of the error, including a error number. Example:

```
ERROR 884 Not implemented: Signal refinement
```

Features

Partitioning

General Ideas

The partitioning concept is a way to divide one SDL system into several applications. As a special case this means also that it is possible to simulate and validate selected parts of a system. You should note the difference between partitioning and separation. The partitioning feature is a way to select the parts of an SDL system which should be handled, while the separation feature is a way to select the file structure for the generated files.

To select a partition (or a program) it is, in simple cases, possible to use selections in the Organizer, and in more general cases possible to work with *build scripts*, i.e. text files containing commands to the Analyzer (the syntax used when running the Analyzer stand-alone). The restriction in the Organizer view is that only one selection can be handled and that instantiation of OO types cannot be selected. In a build script on the other hand, several component commands can be used to select several parts of a system. As the component command takes an SDL qualifier as a parameter, instantiations can also easily be selected.

Using Selections in the Organizer

To start with the simple case when one block or process should be simulated, this is easy to perform directly from the Organizer: Select the proper block or process and press the *Simulate* button (or go via *Make* dialog).

> **Note:**
>
> If you already have generated a simulation from the Organizer, and want to generate a new one with other options or with another selection, you should perform a Full Make, as changes in options or selection is not handled by the build process. Otherwise compilation or link errors might be the result of the build process.

Only the system, a block or a process can be selected for simulation. Types, including procedures, are only definitions and are not executable objects, while services depend on its enclosing process and cannot be

simulated on its own because of these dependencies. Block and process instantiations can be simulated, but only using build scripts, as such objects cannot be selected in the Organizer. The discussion above is of course also valid for generation of explorers and applications.

Unconnected Diagrams

As another special case, there might be unconnected diagrams in the Organizer, i.e. objects not bound to a file. If such an object is a block, process, or a procedure, C code can anyhow be generated resulting in, for example, a Simulator or Explorer.

- If a block is unconnected, this is treated as an implicit partitioning excluding this block.
- If a process is unconnected, this is treated as an implicit partitioning excluding this process. If other processes try to “create” such a process, this will become a null-action just indicated in the textual trace. In an application, such a create action will cause a compilation error.
- If a procedure is unconnected, any call to this procedure is just indicated in the textual trace. In an application such a procedure call will cause a compilation error.

Build Scripts

In general cases, build scripts should be used to specify the build process. Using such a file there are a number of features that can be used.

- It is possible to generate code for several partitions, using independent options and potentially different code generators for different parts of the system, all in one build process.
- Each partition can consist of several objects, and objects might be instantiations.

There are two Analyzer commands, see *“Description of Analyzer Commands” on page 2476 in chapter 54, The SDL Analyzer*, that are of major interest for specifying a partition. First we have the Program command, which takes a name as parameter. Second we have the Component command, which takes a qualifier as a parameter. The Program command gives the start of a partitioning specification, while the Component command is used to select an SDL component that should be

part of the partitioning. A partition specification can of course contain a number of components. The Component command is very similar to a selection in the Organizer when running directly from the Organizer.

A program section in a build script typically starts with a Program command and ends with a Generate command.

Example 353: Build script ––––––––––––––––––––––––––––––––––

```
program MyExample
component system example/block b1
component system example/block b2/process p22
target-directory /home/jk/example/target
set-env-header on
set-modularity user
generate-advanced-c
```

In Windows, the target-directory command could, for example, be:

```
target-directory c:\example\target
```

––

The example above means that a program containing the implementation of the complete block b1 and the process p22 in block b2 is generated with the Cadvanced SDL to C Compiler. The modularity is user defined and a system header file (`.ifc` file) will also be generated.

Code from the code generators will be placed in a subdirectory with the name given in the Program command, to the directory given by target directory. If this subdirectory does not exist it will be created.

> **Note:**
>
> You should always include a target-directory command in a build script, as otherwise the target directory will depend on where the SDL Suite is started!

In the example above the generated C code can be found in the directory `/home/jk/example/target/MyExample`
(**In Windows** `c:\example\target\MyExample`).

In the example below three programs are generated for three different partitionings, also using different code generators.

Example 354: Build script with several programs ––––––––––––––––––

```
target-directory /home/jk/example/target

program MyExample
component system example/block b1
component system example/block b2/process p22
set-env-header on
set-modularity user
set-kernel SCTDEBCOM
generate-advanced-c

program MyExample1
component system example/block b2/process p21
generate-micro-c

program MyExample2
component system example/block b3
set-modularity no
generate-chipsy-chill
```

––

Analyzer commands that are of the type “set up an option” can be placed outside of the Program commands. The options actually used at the generate commands, are the options set up after executing all the commands up to the generate command. All the possibilities in the Make dialog and the Analyze dialog in the Organizer are also provided as commands in the Analyzer. Please see *“The Analyzer Command Line UI” on page 2474 in chapter 54, The SDL Analyzer*, for a list of all commands.

> **Note:**
>
> When build scripts are used, all features in the Analyzer will have its hard coded defaults, if it is not set in the build script. Preferences and your settings in the Organizer are ignored. The default values are given in *“The Analyzer Command Line UI” on page 2474 in chapter 54, The SDL Analyzer*, or you can start a stand-alone analyzer (sdtsan) directly in an OS shell and issue the commands Show-Analyze-Options and Show-Generate-Options.

See also “SDL Make” on page 121 in chapter 2, *The Organizer*, for handling of build scripts in the Organizer.

Behavior of Generated Partitioning

The basic idea is to redirect all channel going to objects not part of the current partitioning to the environment. This operation is performed by the code generator at code generation time. This means that all signals sent between objects in the partitioning and objects outside the partitioning, will be seen as signals to or from the environment. This is true everywhere, in simulations, validations, applications, in generated environment header files (.ifc files), and in generated environment functions.

Generation of Support Files

The Cadvanced/Cbasic SDL to C Compiler can generate a number of support files, together with the ordinary `.c`, `.h`, and makefiles. These files are

- System header file (`.ifc`)
- Skeleton to environment functions (`_env.c`)
- Signal number file (`.hs`)
- Coder/decoder framework files (`_cod.c`, `_cod.h`)

The generation of these files can be selected in the Organizer Make dialog, or as an Analyzer command, depending on which interface is used. The details on the system header files and the environment function can be found in "The Environment Functions" on page 2774, while the signal number file can be used to assign numbers to all signals in the system. Signal number files are most used in connection with OS integrations.

Implementation

In this section some implementation details are presented, that can be useful for understanding how a generated simulation or application behaves. Abstract data types are treated in the next section.

Time

A generated C program can be executed in two modes with respect to the treatment of time:

- *Simulated time*
- *Real time*

Simulated Time

Using simulated time, which is the most useful mode for simulations, means that the time in the simulation has no connection with the wall clock. Instead the *discrete event simulation* technique is used. This technique is based on the idea that the current value for the simulation time (Now in SDL) is equal to the time at which the currently executing event is scheduled. After one event is finished, the simulation time is increased to the time when the next event is scheduled and this event is started. Events in SDL will be process transitions, timer outputs, and signals sent to the system from the environment. As an example, the use of the discrete event simulation technique means that if the next event is a timer output scheduled one hour from now, and the next transition is allowed to execute, the timer output will occur immediately. The simulation time will be increased by one hour, but the user does not have to wait one hour.

Real Time

If real time is used, then there will be a connection between the clock in the executing program and the wall clock. In the example above the user would have to wait one hour until the timer output took place. To implement real time a clock function provided by the operating system is used. Not all systems are suitable to simulate in this way. The time scale in the system ought to be seconds or maybe minutes, not milliseconds and not hours.

At program start up the system time, SDL Now, is zero. The system clock is stopped during the time the program spends in the monitor system.

Note:

The C standard function `time` used as real time clock returns the time in seconds. It does not handle parts of seconds. The implementation of the clock can be changed by re-implementing the function SDL_Clock in `sctos.c`.

Scheduling

The process instances in the simulated system will execute transitions that consist of actions like tasks, decisions, outputs, procedure calls, etc., according to the rules of SDL. It is assumed that a transition takes no time and that a signal instance is immediately placed in the input port of the receiver when an output operation occurs.

A transition is always executed without any interrupts, if the user does not manually rearrange the ready queue using an appropriate command provided by the monitor system (Rearrange-Ready-Queue). It is possible to execute a few SDL symbols in one transition and then to re-arrange the ready queue and execute another transition. The interrupted transition can afterwards be executed to its end.

A quasi-parallel strategy for selecting transitions to be executed is thus the basic scheduling mechanism. SDL does not in itself define an execution strategy so the selected strategy is therefore an allowed, but not the only, possible strategy for execution.

As a consequence of the execution strategy, a generated simulator is not directly suited for simulation of “timing effects”, that is, situations where the time or order of actions in different process instances is of vital importance.

Example 355: Scheduling ––––––––––––––––––––––––––––––––––

An example of such a situation is: Suppose a process instance A outputs two signal instances during the same transition, one to process instance B and one to process instance C. During the corresponding transitions of B and C, a signal instance is sent to process instance D.

If the behavior of the system is dependent on the order in which the signal instances are received in the input port of D, this is a hazard situation

where the execution speed of process instances and the delay of signals in channels will determine the behavior. The way to handle such a situation would be to manually decide the order in which transitions should be executed.

As the Cadvanced SDL to C Compiler is also intended to generate applications, process priority has been introduced as an additional feature. For more information about how to assign priorities to processes see sub-section "Assigning Priorities – Directive #PRIO" on page 2739.

The Ready Queue

The ready queue is a queue containing all process instances which have received a signal that can cause a transition, but which have not yet completed that transition. The ready queue is ordered firstly according to the priority and secondly according to insert time, that is a process which will be inserted last among the processes with the same priority, but before all processes with lower priority (high priority value = low priority). A process will never be inserted before the process currently executing, as pre-emptive scheduling is not used. In more detail:

- If a process outputs a signal to another process, which immediately can receive the signal, the receiving process will be inserted into the ready queue last among the processes with the same priority, but never before the currently executing process.
- If the processes currently executing a nextstate immediately can continue to execute another transition, it will be inserted into the ready queue last among the processes with the same priority. This means that it can remain as first process in the ready queue, but it can also be re-inserted somewhere else.
- If the receiving process at a timer output immediately can execute a transition as response to the received signal, the process will be inserted into the ready queue last among the processes with the same priority. This means that it can be inserted anywhere in the queue.

Enabling Conditions and Continuous Signals

Enabling conditions and continuous signals are additional concepts in SDL. The model for these concepts use repetitive signal sending, to have the expressions recalculated repeatedly. This model is not suitable during simulation, and definitely not acceptable in an application. We

have therefore used an implementation strategy closer to the described behavior of the concepts, rather than the model used to define the concepts.

Implementation Strategy

First we distinguish between those enabling conditions and continuous signals that are dynamic and those that are static, that is containing expressions that can or cannot change their value when the corresponding process is waiting in the state. The expression in a dynamic enabling condition or continuous signal contains some part that can change its value, even though the process does not execute any statements. Or, put more precisely, it contains at least one import, view, or reference to Now.

Static enabling conditions or continuous signals do not provide any problems or any execution overhead, except that the corresponding expressions have to be calculated at nextstate operations. Dynamic enabling conditions or continuous signals, however, have to repeatedly be recalculated. The strategy selected for these expressions is to recalculate them after each transition or timer output performed by any process (and additionally also before the monitor is entered within a transition). In other words, each process waiting in a state containing a dynamic enabling condition or continuous signal executes an implicit nextstate operation between each transition or timer output performed by other processes.

Synonyms

Synonyms

An SDL synonym is implemented either as a C macro (`#define`) or as a C variable. To be translated to a macro the expression defining the value of the synonym must be:

- Of one of the predefined SDL sorts (Integer, Real etc.).
- Possible to calculate at analyze time, i.e. it may only contain literals and operators defined in the predefined SDL sorts and other synonyms which are possible to calculate at analyze time.

All other synonyms are implemented as variables given their values at program start up.

The reason for raising this question is because it is relevant to the implementation of arrays and powersets. There are two different implementations for each of these concepts, see "Array" on page 2671 and "Powerset" on page 2672. An array in SDL can either be translated to an array in C or to a linked list in C. A powerset can either be translated to a bit array in C or to a linked list. The translation method is selected by looking at the index type. If the index type is a syntype with one limited range, the array and bit array scheme is used, otherwise the linked list is used.

If a synonym translated to a variable is used in a range condition of a syntype and the syntype is used as an index sort in an array or powerset instantiation, the linked list scheme is used to implement the array or powerset. The reason for this is that the length of the array cannot depend on a variable in C.

External Synonyms

External synonyms can be used to parameterize an SDL system and thereby also a generated program. The values that should be used for the external synonyms can either be read by the generated program during start up, or included as macro definitions into the generated code. The Cadvanced/Cbasic SDL to C Compiler can handle both these cases – it is not necessary to select which way should be used for each synonym until the program is compiled.

Using a Macro Definition

To use a macro definition in C to specify the value of an external synonym, perform the following steps:

1. Write the macro definitions on a file.

   Example 356: Macro Definition ----------

   ```
   #define synonym1 value1
   #define synonym2 value2
   ```

   The synonym names are the SDL names (without any prefixes) and with any character not in letters, digits or underscore removed.

2. Introduce the following `#CODE` directive at the system level among the SDL definitions of, for example, synonyms, sorts, and signals but before any use of the synonyms.

Example 357: #CODE Directive

```
/*#CODE
#TYPE
#include "filename"
*/
```

If this structure is used, the value of an external synonym can be changed merely by changing the corresponding macro definition and recompiling the system.

> **Note:**
> When an application is created, macro definitions should be used for all external synonyms, as the function for reading synonym values stored on file is not available. (See below.)

Reading Values at Program Start up

The other way to supply the values of the external synonyms is to read the values at program start up. If there are any external synonyms that do not have a corresponding macro definition, it is possible to choose between supplying the values of the remaining external synonyms from the keyboard or to use a file containing the values.

When the application is started, the following prompt appears:

```
External synonym file :
```

- Press `<Return>` to indicate that the values should be read from the terminal.
- Or type the name of a file that contains the values and press `<Return>`.

If the user chooses to read the values from the terminal, he will be prompted for each value. In the other case the user should have created a file containing the external synonym names and their corresponding value according the following example:

Example 358: Values at Program Startup

```
synonym1 value1
synonym2 value2
```

The synonyms may be defined in any order.

Evaluation of Include Expressions

A synonym value can be followed by a simulator only comment:

```
mySynonym myValue /*SIMULATOR_ONLY*/
```

This value will not be used when evaluating include expressions.

This value will only used by the simulator when simulating the system.

Import – Export

These concepts are not implemented with the full semantics according to the model in the SDL recommendation. The model says that an imported value should be obtained using a signal interchange between the importer and exporter.

In the Cadvanced/Cbasic SDL to C Compiler we use a model where the imported value is directly obtained from the exporter, which of course makes the import operation much faster. However, the scheduling effect of the signal interchange is lost, as well as the change of SENDER in the involved processes. If these effects are important for an application, remote procedure calls can be used instead, see below.

Remote Procedure Calls

Remote procedure calls (RPC) have much in common with import/export, except that instead of obtaining one value, RPCs give the opportunity to execute a procedure in the exporting process. In the Cadvanced/Cbasic SDL to C Compiler, the model described in the SDL recommendation is used in detail to implement RPCs.

This means that a remote procedure call is translated to:

output of pCALL signal with all parameters.
nextstate in pWAIT, i.e. a implicit wait state.
input of pREPLY signal with all IN/OUT parameters.

In the exporting process there will be implicit transitions where the pCALL signal can be handled.

input pCALL.
call remote procedure with parameters from pCALL.
output pREPLY with the IN/OUT parameters.
nextstate -

For more details about this model, please see the SDL recommendation.

Procedure Calls and Operator Calls

In SDL-92 value returning procedures (and remote procedures) are introduced. This means that an SDL procedure can be called within an expression. In the Cadvanced/Cbasic SDL to C Compiler such procedure calls are implemented according to the model in the SDL recommendation, that is by inserting an extra CALL just before the statement containing the value returning procedure call. The result from the call is stored in an anonymous variable, which is then used in the expression.

Example 359: Procedure Call ----------

```
TASK i := (call p(1)) + (call Q(i,k));
```

is translated to:

```
CALL p(1, Temp1);
CALL q(i, k , Temp2);
TASK i := Temp1 + Temp2;
```

Note:

The value returning procedure calls are transformed to ordinary calls, by adding a new IN/OUT parameter for the procedure result, last in the call.

Operators which are defined using operator diagrams, are according the models in the SDL recommendation, treated exactly as value returning procedure.

External Procedures And Operators

External procedures is a extension to SDL introduced in SDL-96. An external procedure is defined in a text symbol as a procedure heading:

```
procedure test; fpar a integer; returns integer;
external;
```

Instead of giving an implementation for the procedure the keyword external is inserted. The purpose of external procedures in SDL are to specify the existence of procedures without giving their implementation.

The Cadvanced/Cbasic SDL to C Compiler will generate no code for an external procedure declaration and will translate a call to such a procedure to an ordinary C function call. It is then up to the user to provide

the C implementation of this function. Note that the code generator will in the generated function call use the name of the external procedure as it is. No prefix is inserted in this case, just as for external synonyms.

External operators are handled in the same way as external procedures. The name of the external operator is used in C just as it is. A quoted operator will cause an infix operator to be generated, while operators with ordinary names will cause C function calls to be generated.

Any

There are two different applications of any. It is possible to write

```
any(SortName)
```

within an expression, or to write just

```
any
```

in a decision. The second case, with any in a decision, is implemented in the following way:

- Simulator:

  A question in the monitor giving the user a possibility to select the path to follow.

- Explorer:

  The explorer sees this as an non-deterministic choice and selects all possible paths.

- Applications:

  Should not be used!

The first case, the any(SortName) within an expression, is implemented using a random number generator to draw a random number of the given type.

> **Note:**
>
> any(Sort) where Sort is a syntype is only implemented if the syntype contains at most one range condition which is of the form a:b, that is one limited range. If it is a syntype of a real type, e.g. Real or Time, with a range condition it is not implemented.

If any(SortName) is used for a sort violating the note above, there will be a C compilation error on the symbol ANY_SortNameWithPrefix.

This means that a user can implement any for such sorts himself by defining a C macro with this name, that implements any for the given sort. Such a macro should be inserted in the #TYPE section of a #ADT directive in the syntype.

Calculation of Receiver in Outputs

The Cadvanced/Cbasic SDL to C Compiler contains an algorithm that calculates the receiving process instance set, for outputs without TO, considering channels, signal routes, connection points, and via list. There are however a few restrictions for the algorithm:

- Outputs in process types, or in processes in block types or system types **cannot** be handled. The reason is that the same output might lead to different receivers in different instantiation.
- Paths (channels - signal routes) that lead into other units that are separate (see "Edit Separation" on page 137 in chapter 2, *The Organizer*) **cannot** be followed by the algorithm, as that would violate the separate generation scheme.
- Outputs in global procedures **cannot** be handled, as the receiver depends on the caller of the procedure.

This algorithm means that for an ordinary SDL-88 system, that is not generated using separate units, no information about the channels and signal routes are needed to direct signal to the correct receiver. For more information about the possible optimizations in applications, please see the compilation switch XOPTCHAN and the ADT PidLit ("The Data Type PIdLit" on page 3258 in chapter 62, *The ADT Library*). Please note that XOPTCHAN and PidLit is almost impossible to use if the SDL system contains system types, block types, or process types.

Abstract Data Types

This section is a reference to the abstract data types. The following topics will be discussed:

- We will have a look at the implementation of the predefined data types in SDL, see "SDL Predefined Types" on page 2658. We then discuss how user-defined abstract data types are translated, see "Translation of Sorts" on page 2665.
- Next implementation of operators and the possibility to include hand-coded C functions as implementation of the operators is presented, see "Implementation of User Defined Operators" on page 2679.
- Last, in "More about Abstract Data Types" on page 2704, we discuss more details about operators and the possibilities to include a hand-coded type definition in C to represent the SDL sort.

Removing un-used SDL Operators

When implementing an SDL system, you do not always use all available SDL operators. The Cbasic/Cadvanced SDL to C Compiler removes the declarations of unused operators, thus minimizing the code size of the generated application. Unused operators that are removed are:

- operators in predefined data types, for example substring, concatenate, length in the newtype Charstring, etc.
- operators defined in the predefined generators String, Array, Powerset, Bag
- special operators (and help functions) like assign, equal, default, make, extract, modify, free

The Cbasic/Cadvanced SDL to C Compiler performs the following steps to optimize the code:

1. Every C function that implements an operator is surrounded by an `#ifndef` definition.

Example 360 The `#ifndef` definition ––––––––––––––––––––––

```
#ifndef XNOUSE_AND_BIT_STRING
  /* function implementing the operator */
```

```
#endif
```

2. During the code generation, the usage of the operators in the translated SDL transitions is recorded.
3. The interdependencies between different operators are updated. For instance, an equal operator for a struct type may depend on equal operators for all its component types.
4. For each operator that is found to be unused, a `#define` definition is generated that removes the code for that operator. All the defines are placed in a file called *sdl_cfg.h.*

Example 361 The `#define` command

```
#define XNOUSE_AND_BIT_STRING
```

> **Note:**
> Even though the code size of the generated application is reduced, the code size of the generated C code is increased.

Manual override

In order to handle cases where operators are used invisibly from the Cbasic/Cadvanced SDL to C Compiler, for example in inline C code, you can manually override the automatic configuration of the unused operators.

In the code generation process, the Targeting Expert always generates a manual configuration file called `sct_mcf.h`. In this file you can list the unused operators that you have decided to include in the application. This is done by un-defining the previous definitions made in the `sdl_cfg.h` file.

The `sct_mcf.h` can be edited directly from Targeting Expert. Select **Edit Configuration Header File** from the **Edit** menu to open the file.

Example 362 The `#undef` command in the `sct_mcf.h` file

```
#ifdef XNOUSE_AND_BIT_STRING
#undef XNOUSE_AND_BIT_STRING
#endif
```

One section of the sct_mcf.h file, is dedicated for the manual edits. This section is marked with the text:

```
/* BEGIN User Code */
/*   END User Code */
```

The manual edits must be inserted between these to lines otherwise they will be deleted, as the sct_mcf.h file is re-generated each time you generate code. The information about the unused operators available in the sdl_cfg.h file is imported to the sct_mcf.h file. This allows you to quickly see which operators that are unused.

SDL Predefined Types

Mapping Table

Below is a table which summarizes the mapping rules between SDL and C, concerning the predefined types in SDL and their operators. Note that many of the operators are in C defined as macros, and expanded by the C preprocessor to simple operators in C.

SDL name/operator	C name/expression/operator
Boolean	SDL_Boolean
False, True	SDL_False, SDL_True
not	xNot_SDL_Boolean
and	xAnd_SDL_Boolean
or	xOr_SDL_Boolean
xor	xXor_SDL_Boolean
=>	xImpl_SDL_Boolean
=, /=	yEqF_SDL_Boolean, yNEqF_SDL_Boolean

SDL name/operator	C name/expression/operator
Character	SDL_Character
NUL SOH ...	SDL_NUL SDL_SOH ... (for all unprintable characters)
'a' 'b' ...	'a' 'b' ... (for all printable characters except ' and \)
'''', '\'	'\'', '\\'
chr	xChr_SDL_Character
num	xNum_SDL_Character
<, <=, >, >=	xLT_SDL_Character, xLE_SDL_Character, xGT_SDL_Character, xGE_SDL_Character
=, /=	xEqF_SDL_Character, xNEqF_SDL_Character
Charstring	SDL_Charstring
'aa'	SDL_CHARSTRING_LIT("Laa","aa")
mkstring	xMkString_SDL_Charstring
length	xLength_SDL_Charstring
first	xFirst_SDL_Charstring
last	xLast_SDL_Charstring
//	xConcat_SDL_Charstring
substring	xSubString_SDL_Charstring
=, /=	yEqF_SDL_Charstring, yNEqF_SDL_Charstring

SDL name/operator	C name/expression/operator
Integer	SDL_Integer
0, 1 etc.	SDL_INTEGER_LIT(0), SDL_INTEGER_LIT(1) etc.
+	xPlus_SDL_Integer
- (monodic, dyadic)	xMonMinus_SDL_Integer, xMinus_SDL_Integer
*	xMult_SDL_Integer
/	xDiv_SDL_Integer
mod	xMod_SDL_Integer
rem	xRem_SDL_Integer
float	xFloat_SDL_Integer
fix	xFix_SDL_Integer
<, <=, >, >=	xLT_SDL_Integer, xLE_SDL_Integer, xGT_SDL_Integer, xGE_SDL_Integer
=, /=	yEqF_SDL_Integer, yNEqF_SDL_Integer
Natural	SDL_Natural
Real	SDL_Real
12.45, ...	SDL_REAL_LIT(12.45, 12, 450000000)
- (monodic, dyadic)	xMonMinus_SDL_Real, xMinus_SDL_Real
+	xPlus_SDL_Real
*	xMult_SDL_Real
/	xDiv_SDL_Real
<, <=, >, >=	xLT_SDL_Real, xLE_SDL_Real, xGT_SDL_Real, xGE_SDL_Real
=, /=	yEqF_SDL_Real, yNEqF_SDL_Real

SDL name/operator	C name/expression/operator
Pid	SDL_PId
Null	SDL_NULL
=, /=	yEqF_SDL_PId, yNEqF_SDL_PId
Duration	SDL_Duration
23.45	SDL_DURATION_LIT(23.45, 23, 450000000)
+	xPlus_SDL_Duration
- (monodic)	xMonMinus_SDL_Duration
- (dyadic)	xMinus_SDL_Duration
* (Duration * Real) * (Real * Duration)	xMult_SDL_Duration, xMultRD_SDL_Duration
/	xDiv_SDL_Duration
<, <=, >, >=	xLT_SDL_Duration, xLE_SDL_Duration, xGT_SDL_Duration, xGE_SDL_Duration
=, /=	yEqF_SDL_Duration, yNEqF_SDL_Duration
Time	SDL_Time
23.45	SDL_TIME_LIT(23.45, 23, 450000000)
+ (Time + Duration) + (Duration + Time)	xPlus_SDL_Time, xPlusDT_SDL_Time
- (result: Time)	xMinusT_SDL_Time
- (result: Duration)	xMinusD_SDL_Time
<, <=, >, >=	xLT_SDL_Time, xLE_SDL_Time, xGT_SDL_Time, xGE_SDL_Time
=, /=	yEqF_SDL_Time, yNEqF_SDL_Time
IA5String	SDL_IA5String
NumericString	SDL_NumericString
VisibleString	SDL_VisibleString
PrintableString	SDL_PrintableString

SDL name/operator	C name/expression/operator
Bit	SDL_Bit
not	xNot_SDL_Bit
and	xAnd_SDL_Bit
or	xOr_SDL_Bit
xor	xXor_SDL_Bit
=>	xImpl_SDL_Bit
=, /=	yEq_SDL_Bit, yNEq_SDL_Bit
Bit_string	SDL_Bit_String
not	xNot_SDL_Bit_String
and	xAnd_SDL_Bit_String
or	xOr_SDL_Bit_String
xor	xXor_SDL_Bit_String
=>	xImpl_SDL_Bit_String
mkstring	xMkString_SDL_Bit_String
length	xLength_SDL_Bit_String
first	xFirst_SDL_Bit_String
last	xLast_SDL_Bit_String
//	xConcat_SDL_Bit_String
substring	xSubString_SDL_Bit_String
bitstr	xBitStr_SDL_Bit_String
hexstr	xHexStr_SDL_Bit_String
=, /=	yEq_SDL_Bit_String, yNEq_SDL_Bit_String

SDL name/operator	C name/expression/operator
Octet	SDL_Octet
not	xNot_SDL_Octet
and	xAnd_SDL_Octet
or	xOr_SDL_Octet
xor	xXor_SDL_Octet
=>	xImpl_SDL_Octet
shiftl	xShiftL_SDL_Octet
shiftr	xShiftR_SDL_Octet
+	xPlus_SDL_Octet
-	xMinus_SDL_Octet
*	xMult_SDL_Octet
i2o	xI2O_SDL_Octet
o2i	xO2I_SDL_Octet
/	xDiv_SDL_Octet
mod	xMod_SDL_Octet
rem	xRem_SDL_Octet
bitstr	xBitStr_SDL_Octet
hexstr	xHexStr_SDL_Octet
<, <=, >, >=	yLT_SDL_Octet, yLE_SDL_Octet, yGT_SDL_Octet, yGE_SDL_Octet
=, /=	yEq_SDL_Octet, yNEq_SDL_Octet

SDL name/operator	C name/expression/operator
Octet_string	SDL_Octet_String
mkstring	xMkString_SDL_Octet_String
length	xLength_SDL_Octet_String
first	xFirst_SDL_Octet_String
last	xLast_SDL_Octet_String
//	xConcat_SDL_Octet_String
substring	xSubString_SDL_Octet_String
bitstr	xBitStr_SDL_Octet_String
hexstr	xHexStr_SDL_Octet_String
bit_string	xBit_String_SDL_Octet_String
hex_string	xHex_String_SDL_Octet_String
=, /=	yEq_SDL_Octet_String, yNEq_SDL_Octet_String
Object_identifier	SDL_Object_Identifier
mkstring	xMkString_SDL_Object_Identifier
length	xLength_SDL_Object_Identifier
first	xFirst_SDL_Object_Identifier
last	xLast_SDL_Object_Identifier
//	xConcat_SDL_Object_Identifier
substring	xSubString_SDL_Object_Identifier
=, /=	yEq_SDL_Object_Identifier, yNEq_SDL_Object_Identifier
NULL (sort)	SDL_Null
NULL (literal)	SDL_NullValue
=, /=	yEq_SDL_Null, yNEq_SDL_Null

C Definitions

We will here discuss the types and macros supplied by the runtime library in the Cadvanced/Cbasic SDL to C Compiler for the predefined types in SDL. These macros and extern definitions for functions can be found in the file `sctpred.h`, except for the Pid sort which is handled in the file `scttypes.h`.

> **Note:**
>
> For more information about the Charstring sort, see the section "Handling of the Charstring Sort" on page 2688.

Translation of Sorts

The following data types are handled by the Cadvanced/Cbasic SDL to C Compiler:

- *Predefined Types*
- *Enumeration Type*
- *Struct*
- *Choice*
- *Array*
- *String*
- *Powerset*
- *Bag*
- *Ref, Own, Oref*
- *Syntypes*
- *Inheritance*

Predefined Types

All the predefined data types (Integer, Natural, Boolean, Character, Charstring, Real, Time, Duration, Pid, Bit, Bit_string, Octet, Octet_string, Object_identifier, IA5String, NumericString, PrintableString, and VisibleString) are completely handled. The name of these types in the generated C code will be SDL_Integer, SDL_Natural, SDL_Boolean, and so on. The translation rules for these types and their operators are discussed in more detail in the "SDL Predefined Types" on page 2658.

Enumeration Type

A sort which is not a struct and does not contain any inheritance or generator instantiation, but which contains a literal list, is seen as an enumeration type. See the example below. Such a type is translated to **int**, together with a list of defines where the literals are defined as 0, 1, 2, and so on. As in all examples in this sub-section, the prefixes, which are added to names when they are translated to C, are not shown. The prefixes are added to make sure that no name conflicts occur in the generated program. For more information about prefixes see "Names and Prefixes in Generated Code" on page 2735.

Example 363: Enumeration Type

```
NEWTYPE EnumType
  LITERALS Lit1, Lit2, Lit3;
ENDNEWTYPE;
```

is translated to:

```
typedef XENUM_TYPE EnumType;
#define Lit1 0
#define Lit2 1
#define Lit3 2
```

Where the macro `XENUM_TYPE` is defined in sctpred.c as:

```
#ifndef XENUM_TYPE
#define XENUM_TYPE int
#endif
```

This means that all enum types will be int types, except if the macro `XENUM_TYPE` is redefined by the user (to `unsigned char` for example). An enum type with 256 or more values will always be of type int and will not be affected by the macro `XENUM_TYPE`.

Struct

An SDL struct is translated to a struct in C, as can be seen in the example below.

Example 364: Struct

```
NEWTYPE Str STRUCT
  a Integer;
  b Boolean;
  c Real;
ENDNEWTYPE;
```

is translated to:

```
typedef struct {
  SDL_Integer a;
  SDL_Boolean b;
  SDL_Real c;
} Str;
```

All the properties of a struct in SDL are preserved in the C code.

The predefined operators extract! and modify! are implemented as component selections in the struct in the same way as in SDL, that is, if S is a variable of type Str, then S!a in SDL is translated to S.a in C.

The predefined operator make!, which is a constructor of a struct value, is implemented by generating a Make function in C. This means that the expression "(. 12, true, 0.22 .)" in SDL is in principle translated to the C function call Make(12, true, 0.22).

The components of a struct may be of any sort that the code generator can handle. A component may, however, not directly or indirectly refer to the struct sort itself. As an example the sort Str above may not have a component of sort Str. In such a case the translation to a C struct would not any longer be valid.

There are some extensions to SDL that are handled by the code generator. It is possible to define bit fields, i.e, to define the size of components (as in C) and to have optional components and components with initial values (as in ASN.1). Examples are shown below.

Example 365: Struct with bit fields

```
NEWTYPE str STRUCT
  a Integer : 4;
  b Integer : 4;
            : 0;
  c UnsignedInt : 2;
  d Integer;
ENDNEWTYPE;
```

is translated to:

```
typedef struct str_s {
    SDL_Integer  a : 4;
    SDL_Integer  b : 4;
    int : 0;
    UnsignedInt  c : 2;
    SDL_Integer  d;
```

```
} str;
```

Note that only Integer and UnsignedInt should be used in bit field components.

Example 366: Struct

```
NEWTYPE str STRUCT
  a, b integer;
  c    Boolean OPTIONAL;
  d    str2 OPTIONAL;
  e    Charstring := 'telelogic';
  f    arr3 := (. 11 .);
ENDNEWTYPE;
```

is translated to:

```
typedef struct str_s {
    SDL_Integer  a;
    SDL_Integer  b;
    SDL_Boolean  c;
    SDL_Boolean  cPresent;
    str2  d;
    SDL_Boolean  dPresent;
    SDL_Charstring  e;
    SDL_Boolean  ePresent;
    arr3  f;
    SDL_Boolean  fPresent;
} str;
```

Both optional components and components with initial values have a Present flag. This is according to ASN.1 and the translation of ASN.1 to SDL defined in Z.105. The present flag for a component with initial value is true if the component contains its default value otherwise false (the Present flag is used to determine code for some ASN.1 encoding scheme). The present flag for an optional component is false until the component is assigned a value. In SDL the present flags can only be accessed through operators and cannot be changed.

Union

Please see also the CHOICE concept presented below, as it usually provides a better and more secure solution to the same kind of problems.

Using the directive #UNION (see example below) it is possible to tell the Cadvanced/Cbasic SDL to C Compiler to generate a union according to the following example:

Example 367: Union ----------

```
NEWTYPE Str /*#UNION*/ STRUCT
  tag integer;
  a integer;
  b Boolean;
  c real;
ENDNEWTYPE;
```

is translated to:

```
typedef struct {
  SDL_Integer tag;
  union {
    SDL_Integer a;
    SDL_Boolean b;
    SDL_Real c;
  } U;
} Str;
```

The first component in the struct is assumed to be a tag value indicating which of the union components that are active. The tag should either be integer or an enumeration type. Tag value 0 or first enumeration literal is used to indicate that the first of the remaining components are active, and so on. On the SDL level a #UNION struct should be handled just like any other struct. It is up to the code generator to generate the correct code for operations on the struct, like assignment, test for equality, component selection, and so on.

> **Note:**
>
> It is completely up to the user to make certain that only valid components in a #UNION struct are accessed. During simulation, however, tests are inserted to ensure that only valid components are accessed.

UnionC

By using the directive #UNIONC according to the example below, it is possible to tell the Cadvanced/Cbasic SDL to C Compiler to generate a true C union.

Example 368: UnionC ----------

```
NEWTYPE Str /*#UNIONC*/ STRUCT
  a integer;
  b Boolean;
  c real;
ENDNEWTYPE;
```

is translated to:

```
typedef union {
  SDL_Integer a;
  SDL_Boolean b;
  SDL_Real c;
} Str;
```

Note:

The #UNIONC directive is not recommended for use as the Cadvanced/Cbasic SDL to C Compiler cannot give any support for checking the validity of component selection. Both the #UNION directive and the CHOICE concept discussed below are much better.

Note also that pointer types, including Charstrings are not allowed in #UNIONC structs, as it is not possible to know when to allocate and deallocate memory for such components.

Choice

Choice, which is an SDL extension originating from the needs when translating ASN.1 to SDL and which is included in SDL-2000, can be used to express a union with implicit tag.

Example 369: Choice ----------

```
NEWTYPE Str CHOICE
  a integer;
  b Boolean;
  c real;
ENDNEWTYPE;
```

is translated to:

```
typedef enum {a, b, c} StrPresent;
typedef struct {
  StrPresent Present;
  union {
    SDL_Integer a;
    SDL_Boolean b;
    SDL_Real c;
  } U;
} Str;
```

The component Present, which is the tag field, and its type (`StrPresent` in the example above) are both available in SDL. The Present component can in SDL be accessed, but not changed, through:

- component selection, i.e. by `Variable!Present`, i.e. it is possible to for example test: `V!Present = a`
- the operators aPresent, bPresent, or cPresent, which returns true or false depending on if the component is active or not.

The Present component is automatically set by the code generator when a component in the choice is given a value.

Note that during simulations and validations, it is automatically tested that a component “is present” when an attempt is made to access the component. A run-time error is issued if this is not the case.

Array

Instantiations of the predefined generator array can be handled by the code generator with the following restriction: The component and index sort may be any sorts that the code generator can handle, but may not directly or indirectly refer to the array type itself (see also the previous paragraph on struct).

If the index sort is a discrete sort, with one closed interval of values, that is of the following sorts:

- Character
- Boolean
- Octet
- Bit
- A sort that is considered as an enumeration type
- Syntypes of integer, character, Boolean, Octet, Bit, and enumeration types. The subtypes may only have one range condition that specifies a closed interval of values,

then the SDL array is translated to a struct containing an element which is an array in C.

If the index sort is **not** one of the sort in the enumeration above, the SDL array is translated to a linked list. The list head contains the default value for all possible indexes, while the list elements contain value pairs, (index_value, component_value), for each index having a component value not equal to the default value.

Example 370: Array ––

```
SYNTYPE Syn = integer
  CONSTANTS 0:10
```

```
ENDSYNTYPE;

NEWTYPE Arr ARRAY(Syn, real)
ENDNEWTYPE;
```

is translated to:

```
typedef SDL_Integer Syn;
typedef struct {
 SDL_Real A[11];
} Arr;
```

All the properties of an array in SDL are preserved in the C code.

The predefined operators extract! and modify! are implemented as component selection of the array in C in the same way as in SDL, so if AVar is a variable of type Arr, and Index is a valid index expression, then `AVar(Index)` in SDL is translated to `AVar.A[Index]` in C. In the case of a link list implementation of the array, component selection is made through function calls.

The predefined operator make!, which is a constructor of an array value, is implemented by generic Make function in C.

String

Instantiations of the predefined generator string can be handled by the code generator with the following restriction: The component sort may be any sorts that the code generator can handle, but may not directly or indirectly refer to the string type itself.

There are two translation schemes for Strings. The directive #STRING decide whether the string should be translated to linked list or to an array. For the #STRING directive please see "Alternative Implementations of the String Generator – Directive #STRING" on page 2746.

Strings are translated to linked list containing one element for each element in the string value. Operations and component selection in string sorts are fully supported.

Powerset

Instantiations of the predefined generator powerset can be handled by the code generator with the following restriction: The component sort may be any sorts that the code generator can handle, but may not directly or indirectly refer to the powerset type itself.

There are two translation schemes for powersets. If the component sort fulfills the conditions for index sorts mentioned in the subsection about arrays above ("Array" on page 2671), an array of 32-bit integers are used. Each bit will be used to represent a certain element whether it is a member of the powerset or not. If this is not the case, a linked list of all elements that are member of the set, is used to represent the powerset. All the available operations defined for Powersets in SDL are supported.

Bag

The Bag generator, which is introduced in SDL in Z.105, i.e. in the mapping from ASN.1 to SDL, is similar to powerset. However, it is possible to have several elements with the same value in a bag. A bag is always translated into a linked list, with one element for each value that is a member of the bag. Each element contains the value and the number of occurrences of this value.

Ref, Own, Oref

These generators represent pointers with different properties. They are all translated to pointers in C.

Syntypes

Syntypes may be defined for any sort that the code generator can handle, giving a new name for the sort and possibly a new default value for variables of the sort. Range conditions that restrict the allowed range of values are also allowed.

A syntype is translated to a type equal to the parent type using typedef. The check that a variable of a syntype is only assigned legal values is implemented in a test function that is generated together with the type definition. An attempt to assign an illegal value to such a variable will be reported as an SDL dynamic error. If the syntype is can be used as index sort in an array and the generated type in C would become an array, there will also be a test function that can be used to check that an index value is within its range in an array component selection.

Example 371: Syntypes ––––––––––––––––––––––––––––––––––––

```
SYNTYPE Syn = integer
  CONSTANTS 0:10
ENDSYNTYPE;

SYNTYPE Syn2 = integer
```

```
  CONSTANTS <0, =2, >=10
ENDSYNTYPE;

SYNTYPE Arr1 = Arr
  DEFAULT (. 2.0 .);
ENDSYNTYPE;
/* Arr defined above */
```

is translated to:

```
typedef SDL_Integer Syn;
typedef SDL_Integer Syn2;
typedef Arr Arr1;
```

Inheritance

A type that inherits another type is translated to a type equal to the parent type using a typedef.

Default Values

Default values are fully supported for all sorts that the code generator can handle, both if a default value is given in a sort definition and if an initial value is given in a variable definition (DCL).

Default values will also be assigned to all variables and components which do not have a default value specified in SDL. The reason for this is to avoid handling undefined variables in C, which might give serious problems and unexpected behavior of an executing program. The values selected by the code generator in such a case can be found below.

Note:

This is a deviation from SDL-92. It means that the generated program does not handle the value undefined for any type.

If no default value is given in the sort and no start value is given in the data definition (DCL) for a variable, the variable will be set to 0 by using a memset to 0.

Operators

In SDL-92, it is possible to define the behavior of operators in ADTs directly in SDL, using operator diagrams or operator implementations in SDL textual form. Such operators are translated to C by the Cadvanced/Cbasic SDL to C Compiler, and none of what is said below is

valid for such an operator. It is also possible to specify that an operator is external. In this case the code generator assumes that a C function with the name used in SDL exists and translates calls to the external operator directly to calls to the C function.

A user defined operator in an SDL sort definition, which is not defined by an operator diagram, is translated to a C function which asks the user for the result of the operation. At a call of an operator, the user is supplied with information describing what the operator and the sort are called, and given information about the parameter values. You are then requested to answer with the result value. If you press <Return> at the prompt for the result, the default value of the actual result type is returned. If the operator does not have a result type, no question is asked.

Example 372: Operator

```
Operator Op in sort S is called.
Parameter 1: true
Parameter 2: 10
Enter value (integer) : 12
```

assuming that newtype S contains an operator

```
Op: Boolean, Integer -> Integer;
```

More about operator implementation, both parameter passing and how to include implementations written in C can be found in the next two sections.

Literals

In sorts that are translated to enumeration types in C, literals are obviously handled by the code generator. In sorts that are not enumeration types, literals are treated as operators without parameters and are handled in exactly the same way as user defined operators.

> **Note:**
> The Cadvanced/Cbasic SDL to C Compiler does not permit naming of literals using name class literals or character strings.

Axioms and Literal Mappings

Axioms and literal mapping are allowed by the code generator in sorts, but are completely ignored.

Parameter Passing to Operators

For performance reasons the data types in SDL have been divide in two groups, simple, small types that are passed as values and structured, larger types that are passed as references (addresses).

Types passed as addresses (structured types)
Bit_string
Octet_string
Object_identifier
Struct types (including #UNION, #UNIONC)
Choice types
Instantiations of generator Powerset
Instantiations of generator Bag
Instantiations of generator Array
Instantiations of generator String
Instantiations of generator Carray
Syntypes of a type in this list
Types that inherit a type in this list

Table 1: Types Passed as Addresses

Types passed as values (simple types)
Integer
Real
Natural
Boolean
Character
Time
Duration
PId
Charstring
Bit
Octet
IA5String
NumericString
PrintableString
VisibleString
NULL
Enumeration types
Instantiations of generator Ref, Own, ORef
Syntypes of a type in this list
Types that inherit a type in this list

Table 2: Types Passed as Values

Note:

For types represented as pointers (Charstring, including its syntypes, Ref, Own, ORef), the pointers, not the addresses of the pointers, are passed as parameters.

The parameter passing for operators implemented in C works as follows (for Cmicro the mechanism described below is also used for operator diagrams and procedures):

In parameters:

- Passed as a value in C if the type is in the list “Passed as value”. This means that the parameter type in C is the same type as in SDL.
- Passed as an address in C if the type is in the list “Passed as address”. This means that the C parameter is (SDL_type *) if the type in SDL is SDL_type.

In/Out parameters:

Parameters are always passed as addresses, i.e the C parameter is (SDL_type *) if the type in SDL is SDL_type.

Operator result:

- If the result type is in the list “Passed as value”, the C function result type will be the same as in SDL.
- If the result type is in the list “Passed as address”, two things are changed. Firstly, the C result type will be (SDL_type *), i.e the result will be an address. Secondly, an extra parameter is inserted last in the C function. This parameter is also of type (SDL_type *) and is used as a location to store the result of the function. At an operator call, a “dummy” variable should be passed as the actual parameter. The C function can then use this to store the result of the operator and should return the variable again as result.

Example 373: ––

Assume that struct1 is a newtype struct in SDL.

```
operators
 X : integer, in/out integer -> integer;
 Y : struct1, in/out struct1 -> struct1;
```

The C prototypes for these operators are:

```
SDL_Integer X (SDL_Integer, SDL_Integer *);
struct1 * Y (struct1 *, struct1 *, struct1 *);
```

The example implementations are:

```
SDL_Integer X
  (SDL_Integer Param1, SDL_Integer *Param2)
```

```
{
  *Param2 = *Param2+Param1;
  return *Param2;
}

struct1 * Y (struct1 *Param1,
             struct1 *Param2,
             struct1 *Result)
{
  /* implementation assuming struct1 to contain
     two integers */
  (*Param2).comp1 = (*Param2).comp1+(*Param1).comp1;
  (*Param2).comp2 = (*Param2).comp2+(*Param1).comp2;
  *Result = *Param2;
  return Result;
    /* always return the last, extra, parameter */
}
```

Note: VERY IMPORTANT

As IN parameters are passed as addresses for structured types, changing such a parameter inside the operator might have undesired effects. A variable passed as actual parameter is then also changed. If you want to change the formal parameter copy it first to a operator local variable.

For Cadvanced/Cbasic this rule applies to operators implemented in C. For Cmicro this rule also applies to operators and procedures defined in SDL.

Implementation of User Defined Operators

Including Implementations of Operators

In a previous subsection, the default behavior of the Cadvanced/Cbasic SDL to C Compiler concerning operators (not defined in operator diagrams) and literals were described. If you do not specify otherwise interactive functions are generated, which, in each case, will ask you for the operator result or literal value. This is a fast way of getting started, but you will probably find it tedious in the long run, especially if you are using abstract data types extensively. To cope with this problem and to make it possible to generate applications, the code generator offers a possibility to include implementations written in C of the operator and

literal functions. This possibility can be used as an alternative to operator diagrams or operators defined using SDL textual form, where the operator is defined directly in SDL.

When the choice between an implementation in SDL or in C is to be made there are a few things to consider:

- There is always problems when mixing languages, for example how are C names for SDL entities constructed.
- Checking of SDL is performed by the SDL Analyzer, which will find problems much earlier than the C compiler checking C code. Also pointing to the error will be more accurate in SDL.
- SDL implementations will be more portable and might benefit from future improvements in the SDL Compiler.
- The risk for backward compatibility problems in future releases of the SDL Suite will be less for an SDL implementation.
- However, a C implementation might be more efficient or you might already have a corresponding C function.

So it is not obvious if SDL or C implementations should be used. However, we recommend SDL if there are no specific reasons for using C. Note also that the SDL extension described in "Grammar for the Algorithmic Extensions" on page 146 in chapter 3, *Using SDL Extensions, in the SDL Suite 6.2 Methodology Guidelines* could be very useful when writing implementations in SDL.

It is possible to choose between two alternatives to implement operators and literal functions:

- Q (question)
  This is the default value and specifies that the code generator should generate the interactive routines describe above.
- B (body)
  This specifies that the code generator should generate the heading of the operator and literal functions, while the user must supply the bodies of the functions.

Note:

The C functions are divided into a function heading (extern or static declaration) and a function body.

An example of a function heading (extern declaration) is:

Example 374: Implementing an Operator

```
extern SDL_Integer Max
  (SDL_Integer Para1,
   SDL_Integer Para2);
```

while the corresponding function body is:

```
SDL_Integer Max
  (SDL_Integer Para1,
   SDL_Integer Para2)
{
 if (Para1 > Para2)
   return Para1;
 return Para2;
}
```

The main reason for this division of functions into heading and body is the separate compilation scheme used in C. If, for example, an abstract data type is defined in a system and used in a process in the system, and the process is generated on a separate file, then there has to be a module interface file (a `.h` file) for the system containing the external interface (types, extern declarations of functions and so on). The interface file should then be included in the file generated for the process.

Even if separate compilation is not used, the division of functions into heading and body is useful. By having static declarations of the functions, the order in which functions must be defined is relaxed. If static declarations were not used, a function could only call the functions that are defined textually before the actual function.

To select the way the Cadvanced/Cbasic SDL to C Compiler should generate code for operators and literals, code generator directives are used. A code generator directive is an SDL comment with the first characters equal to '#', followed by a sequence of letters identifying the directive. In this case the letters are ADT (for Abstract Data Type) and OP (for operator). An ADT directive and a OP directive should thus look like:

```
/*#ADT */ /*#OP */
```

The text is not case sensitive.

OP directives are recognized at two different positions in an abstract data type:

- Directly after the name of a literal
- Directly after the semicolon ending the definition of an operator.

ADT directives are recognized immediately before the reserved word ENDNEWTYPE (or ENDSYNTYPE).

Example 375: Implementing an Operator (#ADT) ––––––––––––––––

```
NEWTYPE Str STRUCT
  a integer;
  b Boolean;
  c real;
ADDING
LITERALS
  Lit1 /*#OP */,
  Lit2 /*#OP */;
OPERATORS
  Op1 :Str,integer -> Str; /*#OP */
  Op2 :Str,Boolean -> Str; /*#OP */
/*#ADT */
ENDNEWTYPE;
```

––

At each of the positions after a literal name or operator definition, there is a possibility to specify how this literal or operator should be implemented. In the directive immediately before ENDNEWTYPE the default implementation technique can be given. When the code generator determines how to generate code for a literal or an operator, it first looks for an OP directive after the literal name or operator definition. If no such directive is found it looks for a directive immediately before ENDNEWTYPE. If no ADT directive is found here, the generation technique Q (question) is assumed. For Cmicro, Q is not used, so the default is B.

An OP or ADT directive specifying a generation technique should have the following structure:

```
/*#OP (B) */ /*#ADT (B) */
```

The letter between the parentheses should be either Q (question) or B (body). The interpretation of Q and B was explained earlier. If B has been specified for any operators or literals, then the C code for these functions must be supplied by the user. This code should be placed in the #BODY section in the ADT directive, according to the following example:

Example 376: Implementing an Operator (#ADT) ––––––––––––––––

```
/*#ADT (B)
#BODY
C code, representing bodies of functions
```

```
*/
```

The section name, i.e #BODY, must be given on a line of its own and must have the # character in the first position of the line. Upper case and lower case letters are as usual considered to be equal. If the section is empty, the section name can also be removed.

Note:

The Cadvanced/Cbasic SDL to C Compiler will **not check the consistency** between the specification of implementation techniques and the actual code included in the body section. This check is, together with checking the C code for syntactic and semantic errors, **left to the C compiler**.

Unfortunately it is not possible to have C comments within the code that is included in a #ADT directive, as SDL and C use the same symbols for start and end of comments. If a C comment is included, the SDL Analyzer will consider the end of the C comment as the end of the SDL comment. Instead a C macro called COMMENT can be used according to the examples below. Note that there might be some compiler dependent restriction of the character set allowed within the COMMENT macro. For example, the character ';' might not be allowed.

Example 377: Comment in ADT

```
COMMENT(This is a comment)
COMMENT(These comments may not contain commas \
        and should have a backslash at each \
        line break)
COMMENT((By having double parenthesis, any text
         can be entered into the comments. Some
         compilers might not allow everything.))
```

The function headings representing literals and operators are determined by their corresponding definition in SDL. The number of parameters, their types, the result type of the function and function name are all defined in SDL. In the example above, where the struct Str is defined, there are two literals (Lit1 and Lit2) and two operators (Op1: Str, integer –> Str; and Op2: Str, Boolean –> Str;). The type Str will be passed as an address, so the parameter passing rules described previously have to be applied. The function heading of the corresponding C functions should be:

Example 378: Implementing an Operator ––––––––––––––––––––––

```
extern Str* Lit1 (Str*);
extern Str* Lit2 (Str*);
extern Str* Op1 (Str*, SDL_Integer, Str*);
extern Str* Op2 (Str*, SDL_Boolean, Str*);
```

––

The function bodies, which should be supplied by the user if B is specified in the OP or ADT directive, are ordinary C functions.

Example 379: Implementing an Operator ––––––––––––––––––––––

```
Str* Lit1 (Str* Result)
{
 Result->a = 2;
 Result->b = false;
 Result->c = 10.0;
 return Result;
}

Str* Op1 (Str* P1, SDL_Integer P2, Str* Result),
{
  *Result = *P1;
  Result->a = P1->a + P2;
  return Result;
}
```

––

Before it is possible to give a complete example of an abstract data type with implementation of its operators supplied as C functions, it is necessary to look at the problem of names. When a name of some object in SDL is translated to C, a suitable sequence of characters, a prefix, is added to the SDL name, to make the name unique in the C program, see also "Names and Prefixes in Generated Code" on page 2735. This strategy is selected in the Cadvanced/Cbasic SDL to C Compiler to avoid name conflicts in the generated code, but it makes it also impossible to predict the full name of, for example, a type or a function, in the generated program. To handle this problem the user can tell the code generator to translate a name in the C code in the same way as SDL names are otherwise translated. This is specified by enclosing the SDL name between '#(' and ')' in the C code. The two functions in the previous example and their headings would then become:

Example 380: Including SDL name in C Code ––––––––––––––––––

```
extern #(Str)* #(Lit1) (#(Str)*);
extern #(Str)* #(Op1) (#(Str)*, SDL_Integer,
                       #(Str)*);
```

```
#(Str)* #(Lit1) (#(Str)* Result)
{
 Result->a = 2;
 Result->b = false;
 Result->c = 10.0;
 return Result;
}

#(Str)* Op1 (#(Str)* P1, SDL_Integer P2,
             #(Str)* Result),
{
  *Result = *P1;
  Result->a = P1->a + P2;
  return Result;
}
```

This facility to access an SDL name in C code is described in more detail in the section "Accessing SDL Names in C Code – Directive #SDL" on page 2725. A few observations concerning the example above might be appropriate:

1. The predefined sorts in SDL, that is for example integer, natural, Boolean have the names SDL_Integer, SDL_Natural, SDL_Boolean, and so on in the generated code. These types should not be enclosed between '#(' and ')'.

2. The component names of a struct are unchanged in the struct implementation in C, which means that struct components should not be enclosed between '#(' and ')' either.

Two Examples of ADTs

We now give two complete examples of abstract data types.

Example 381: ADT Example----------

```
NEWTYPE Str STRUCT
  a Integer;
  b Boolean;
  c Real;
  ADDING LITERALS
    Lit1;
  OPERATORS
    Op1 : Str, Integer -> Str;
    Op2 : Str, Boolean -> Str;
/*#ADT (B)
#BODY
#(Str)* #(Lit1) (#(Str)* Result)
```

```
{
  Result->a = 2;
  Result->b = SDL_False;
  Result->c = 10.0;
  return Result;
}

#(Str)* #(Op1) (#(Str)* P1, SDL_Integer P2,
                #(Str)* Result)
{
  *Result = *P1;
  Result->a = P1->a + P2;
  return Result;
}

#(Str)* #(Op2) (#(Str)* P1, SDL_Boolean P2,
                #(Str)* Result)
{
  if (P2)
    *Result = *P1;
  else
    (void)#(Lit1)(Result);
  return Result;
}
*/
ENDNEWTYPE;
```

The example above should be compared with the same example written in SDL. Note that the literal in the previous example is replaced with an operator without parameters. The algorithmic extensions described in "Grammar for the Algorithmic Extensions" on page 146 in chapter 3, *Using SDL Extensions, in the SDL Suite 6.2 Methodology Guidelines* is also used as they provide a powerful way to write textual algorithms.

Example 382: ADT Example in pure SDL

```
NEWTYPE Str STRUCT
  a Integer;
  b Boolean;
  c Real;
  OPERATORS
    Lit1 : -> Str;
    Op1 : Str, Integer -> Str;
    Op2 : Str, Boolean -> Str;
OPERATOR Lit1 RETURNS Str
{
   RETURN (. 2, false, 10.0 .);
}
OPERATOR Op1 FPAR P1 Str, P2 Integer RETURNS Str
{
   DCL Result Str;
   Result := P1;
```

```
    Result!a := P1!a + P2;
    RETURN Result;
}
OPERATOR Op2 FPAR P1 Str, P2 Boolean RETURNS Str
{
  IF (P2)
    RETURN P1;
  RETURN Lit1;
}
ENDNEWTYPE;
```

Example 383: ADT Example

```
SYNTYPE Index = Integer CONSTANTS 1:10
ENDSYNTYPE,

NEWTYPE A Array(Index, Integer)
  ADDING LITERALS
    Zero /*#OP (B) */;
  OPERATORS
    Add : A, A -> A; /*#OP (B) */
    Sum : A -> Integer;
/*#ADT()
#BODY
#(A)* #(Zero) (#(A)* Result)
{
  SDL_Integer i = 0;
  GenericMakeArray(Result,
    (tSDLTypeInfo *)&ySDL_#(A), &i);
  return Result;
}

#(A)* #(Add) (#(A)* P1, #(A)* P2, #(A)* Result)
{
  int I;
  for (I = 1; I<=10; I++)
    Result->A[I] = P1->A[I] + P2->A[I];
  return Result;
}
*/
ENDNEWTYPE;
```

Note that no body is supplied for the operator Sum as the default implementation strategy for operators, which should be used for Sum, is Q (question). The `GenericMakeArray` function used to implement the literal is a generic function that constructs array values. The details for this function will be described later in this section.

For more information about the functions and types (supplied by the runtime library in the Cadvanced/Cbasic SDL to C Compiler and con-

tained in generated code) that can be useful when implementing operators in C, see "SDL Predefined Types" on page 2658, and last in "More about Abstract Data Types" on page 2704.

Error Situations in Operators

In the C function used to implement operators (and literals) it is possible to define error situations and handle them as ordinary SDL run-time errors. The C library function xSDLOpError, with the following prototype:

```
extern void xSDLOpError(
  char *OpName,
  char *ErrText )
```

can be used for this purpose.

Example 384: Error Handler in Operator

Example of use:

```
  if ( strlen(C) <= 1 ) {
#ifdef XECSOP
    xSDLOpError("First in sort Charstring",
                "Charstring length is zero." );
#endif
    return SDL_NUL;
  } else
    return C[1];
```

This is a simplified version of the test in the function for the operator First in the sort Charstring. Here the error situation is when we try to access the first character in a charstring of length 0. In this case the xSDLOpError is called and a default value is returned (NUL). By including the xSDLOpError call between `#ifdef XECSOP - #endif` the function is only called to report the error if error checks are turned on. The first parameter to xSDLOpError should identify the operator and the sort, while the second parameter should describe the error.

Handling of the Charstring Sort

The SDL sort Charstring is implemented as char * in C.

Note:

This means that the value NUL (ASCII character 0) **cannot** be part of a Charstring, as this value is used as string terminator in C (this is checked by the library functions for Charstring).

The code generator and the library functions for the Charstring operators use the first character (index 0) in the C string to indicate the status of the string. If the first character is:

- 'V'
  the string is assigned to an SDL variable and may not be changed in any way.
- 'L'
  the string is a C char * literal, and may of course not be changed.
- 'T'
  the string is a temporary result from a function returning a Charstring. This memory should either be assigned to an SDL variable or returned to the pool of free memory.

All the library functions for Charstrings handle memory in an appropriate way. A user only has to take the extra character in to account, when Charstrings are handled in C. Any Charstring function parameters having a 'T' as first character must be handled according to the discussion above. A function that returns a Charstring and that creates new temporary memory to store the result, should assign the value 'T' to the first character in the Charstring.

As pointers and dynamic memory are used to implement Charstrings, it is necessary to be careful when Charstrings are handled in C code, which we show in two examples.

Example 385: Equal Test on Charstring Sort

If the `C` operator `==` is used to check if two charstrings are equal, then the actual test that is performed is to see if the two pointer values to the data areas representing the characters in the string are equal.

To check if the characters in the charstrings are equal the equal function should be used:

```
yEqF_SDL_Charstring
```

Example 386: Assignment on Charstring Sort

If the C assignment operator, =, is used to assign the value of one charstring variable (C1) to another charstring variable (C2), then two things will go wrong:

1. The memory used to represent the old value of C1 is lost and can never be reused.
2. C1 and C2 now refer to the same memory area, which means that if one of the variables is changed the other will also be changed. This leads to unpredictable behavior of the program.

The correct way to handle assignment of charstrings is to use the routine:

```
yAssF_SDL_Charstring
```

The problems mentioned above can of course also occur if a struct or array containing charstring components (or subcomponents) is handled carelessly. It is, for example, necessary to use the generic equal and assign functions to perform equal test and assignment.

To avoid problems one should be aware that Charstring is implemented as char * in C and take the consequences thereof. There are a number of help functions (that implement the operators for the Charstring sort) supplied in the runtime library that might be helpful when handling Charstrings. See "SDL Predefined Types" on page 2658).

Other Types Containing Pointers

The principal discussion about Charstrings in the previous section is also relevant for all other types containing pointers. Such types are:

- Bit_string
- Octet_string
- Object_identifier
- Strings (not #STRING)
- General Arrays
- General Powersets
- Bags

All these types contain a boolean component, IsAssigned, that gives the status of the data area. IsAssigned serves the same purpose as the first extra character in a Charstring and has to be treated in a similar way.

- IsAssigned equal to false means that this data area is a temporary result from a function returning the data type. This memory should either be assigned to an SDL variable or returned to the pool of free memory.
- IsAssigned equal to true means that this value is assigned to a variable and may not be changed in any way. It can also mean that the value is part of (i.e. is assigned to) a larger data structure.

External Properties

As an alternative to the #ADT directive, which is a comment, the external properties clause in a newtype can be used as container for this information. See the following example:

Example 387: External Properties in a Newtype ––––––––––––––––––

```
NEWTYPE Str STRUCT
  a integer;
  b Boolean;
  c real;
  ADDING LITERALS
    Lit;
  OPERATORS
    Op1 : Str, integer -> Str;
    Op2 : Str, Boolean -> Str;

ALTERNATIVE C;
#ADT (B)
#BODY
 some appropriate C code
ENDALTERNATIVE;

ENDNEWTYPE;
```

––

The #ADT directive, without the /* */ can be placed between ALTERNATIVE C; and ENDALTERNATIVE.

Note:

According to the syntax of SDL, if you have an external properties clause (i.e. alternative - endalternative), you **cannot**, in the same newtype, **have operator diagrams**, axioms, or literal mappings.

More about Operators

For an operator in an abstract data type, not only B (body) or Q (question) may be specified. The following choices are available:

- Q (question)
  This is the default value and specifies that the code generator should generate the interactive routines describe above.
- B (body)
  This specifies that the code generator should generate the heading of the operator or literal function, while the user should supply the body of the function.
- H (heading)
  This specifies that the code generator should neither generate the heading nor the body of the operator or literal function. The user is assumed to supply the necessary code.
- S (standard)
  This is used to indicate that a standard function or operator is available in the target language, which should be used as implementation of the SDL operator (literal). No function heading or function body is generated. In expressions where such an operator is used, no prefix is added to the SDL name during the translation, but the SDL name is used as it is (if no #NAME directive is present).
- P (prefix) or
  I (infix)
  where P is the default value. These letters are used to indicate if the operator should be used as a function or an operator:
  - As an operator: `a+1  a==4  -a`
  - Or as a function call: `sin(a) power(a, 3)`

Note:

As C does not include the possibility to have user defined operators, I (infix) is only adequate together with S (standard).

For each operator one of the letters B, Q, H, S and one of the letters P, I should be supplied, either in a #OP directive, or in a #ADT directive, or as the defaults Q and P; for literals P and I have no meaning.

The purpose of S is straight forward and easy to understand, but H might require some explanation. H means that the code generator will not gen-

erate any code for the operator, which leaves the user with a number of possibilities:

- By not including any code for an operator, the user may skip the code for an unused operator.
- There might already exist external declarations for a number of operators in a `.h` file that should be used instead of the generated headings.

Example 388: Using S (Standard Function or Operator) ––––––––––

Example of usage of S (standard)

```
"+" : integer, real -> real; /*#OP (SI) */
sin : real -> real; /*#OP (SP) */
```

An SDL expression using these operators:

`sin(a + 7.0)` will be translated to: `sin(zh723_a + 7.0)`

––

These examples show how standard functions in the target language can be directly utilized in abstract data types. In C, it is often easiest to use #OP(HP) for such special cases, and implement the operator in the #HEADING section as a C macro transforming the call to the appropriate syntax.

Generic Functions

Type Info Nodes

A generic function can perform a certain task for several different types. To be able to write generic functions, type-specific information for the types must be made available. This type of information could be, for instance, size of the type, component types for structured types and component offsets. This information is provided by the *type info nodes*.

A type info node is a struct that contains information that defines the type. Each type has a corresponding type info node. Each type info node contains two sections. The first section contains a sequence of general components that is identical for all type info nodes. The second section is an individual type-specific sequence of components that defines each unique type.

Every newtype or syntype introduced in SDL will be described by a type info node in the generated C code. For the predefined data types the following type info nodes can be found in `sctpred.h` and `sctpred.c`:

```
extern tSDLTypeInfo ySDL_SDL_Integer;
extern tSDLTypeInfo ySDL_SDL_Real;
extern tSDLTypeInfo ySDL_SDL_Natural;
extern tSDLTypeInfo ySDL_SDL_Boolean;
extern tSDLTypeInfo ySDL_SDL_Character;
extern tSDLTypeInfo ySDL_SDL_Time;
extern tSDLTypeInfo ySDL_SDL_Duration;
extern tSDLTypeInfo ySDL_SDL_PId;
extern tSDLTypeInfo ySDL_SDL_Charstring;
extern tSDLTypeInfo ySDL_SDL_Bit;
extern tSDLTypeInfo ySDL_SDL_Bit_String;
extern tSDLTypeInfo ySDL_SDL_Octet;
extern tSDLTypeInfo ySDL_SDL_Octet_String;
extern tSDLTypeInfo ySDL_SDL_IA5String;
extern tSDLTypeInfo ySDL_SDL_NumericString;
extern tSDLTypeInfo ySDL_SDL_PrintableString;
extern tSDLTypeInfo ySDL_SDL_VisibleString;
extern tSDLTypeInfo ySDL_SDL_Null;
extern tSDLGenListInfo ySDL_SDL_Object_Identifier;
```

For a user-defined type the type info node will have the name

```
ySDL_#(TypeName)
```

Generic Assignment Functions

Each type in SDL has access to an assignment macro `yAssF_typename`. Examples for type Boolean and for a user-defined type A:

```
#define yAssF_SDL_Boolean(V,E,A)  (V = E)

#define yAssF_A(V,E,A)  yAss_A(&(V),E,A)
#define yAss_A(Addr,Expr,AssName) \
   (void)GenericAssignSort(Addr,Expr,AssName,
                           (tSDLTypeInfo *)&ySDL_A)
```

This macro is used in the generated code (and in the kernel) at each location where an assignment should take place. The three macro parameters are:

- **V**: the variable on the left hand side
- **E**: the expression on the right hand side
- **A**: an integer giving the properties of the assignment

This macro will either become an assignment statement in C or a call of an assignment function. An assignment statement will be used if assignment is allowed according to C for the current type and if it has the correct semantics comparing with assignment in SDL.

If assignment is not possible to use, the assign macro will become a call to an assignment function. The basic generic assignment function can be found in `sctpred.c` and `sctpred.h`:

```
extern void * GenericAssignSort(void *, void *,
   int, tSDLTypeInfo *);
```

where:

- The first parameter is the address of the variable on the left hand side.
- The second parameter is the address of the expression on the right hand side.
- The third parameter is the properties of the assignment
- The fourth parameter is the type info node for the actual type.

GenericAssignSort returns the address passed as the first parameter.

The GenericAssignSort function performs three tasks:

1. The old value on the left hand side variable is released, if that is specified in properties of the assignment and if the value contains any pointers.
2. The value is copied from the expression to the variable. If possible this is performed by the function memcpy, otherwise special code depending on the kind of type is executed.
3. The IsAssigned flags are set up for the variable according to the properties of the assignment.

Special treatment of Charstring and instantiations of the Own generator has made it necessary to introduce specific wrapper functions that in their turn call GenericAssignSort for these types:

```
extern void xAss_SDL_Charstring (SDL_Charstring *,
   SDL_Charstring, int);
extern void * GenOwn_Assign (void *, void *, int,
   tSDLTypeInfo *);
```

An GenericAssignSort function must consider the following questions in order to handle the objects correctly.

How should one copy the object?

This is very important because performing the wrong action will lead to memory leaks or access errors. Three different possibilities exist:

- **AC**: always copy the referenced object.
- **AR**: always copy the pointer, i.e reusing the referenced object.
- **MR**: copy pointer if the object is temporary **or** copy object if not temporary.

What should be the status of the new object?

This is a preparation for the next operation on this object so the correct decision can be made according to the first question. Two different possibilities exists:

- **ASS**: an object should become assigned if it is assigned to a variable and needs to be copied in future assignments, i.e corresponds to the values ‘V’ and ‘L’ for the first character in a C- string representing the Charstring sort. A typical case is a normal assignment statement in SDL.
- **TMP**: an object should become temporary if it is not assigned to any persistent variable and therefore should not be copied in subsequent assignments, i.e corresponds to the value ‘T’ for the first character in a C-string representing the Charstring sort. A typical case is a result value from an operator.

What should be done with the old value referenced by the left hand side variable?

Normally free should be performed on the value, as otherwise there would be a memory leak. However, when initializing a variable, no free ought to be performed, as free might be called on a random address. Two different possibilities exists:

  - **FR**: free old value.
  - **NF**: do not free old value.

The third assignment property parameter in the GenericAssignSort function should be given a value according to the ideas given above, preferably using the macros indicated.

```
#define XASS_AC_ASS_FR  (int)25
#define XASS_MR_ASS_FR  (int)26
#define XASS_AR_ASS_FR  (int)28

#define XASS_AC_TMP_FR  (int)17
#define XASS_MR_TMP_FR  (int)18
#define XASS_AR_TMP_FR  (int)20

#define XASS_AC_ASS_NF  (int)9
#define XASS_MR_ASS_NF  (int)10
#define XASS_AR_ASS_NF  (int)12

#define XASS_AC_TMP_NF  (int)1
#define XASS_MR_TMP_NF  (int)2
#define XASS_AR_TMP_NF  (int)4
```

The macro names above are all of the form XASS_1_2_3, where the abbreviations placed at 1, 2, and 3 should be read:

- 1 = AC: always copy
- 1 = MR: may reuse (take pointer if temporary object)
- 1 = AR: always reuse (take pointer)
- 2 = ASS: new object assigned to “variable”
- 2 = TMP: new object temporary
- 3 = FR: call free for old value referred to by variable
- 3 = NF: do not call free for old value

The distinction between all these assignment possibility is only of interest when handling types using or containing pointers.

Generic Equal Functions

Each type in SDL has access to an equal macro `yEqF_typename` and an not equal macro `yNEqF_typename`. Examples for type Boolean and for a user-defined type A:

```
#define yEqF_SDL_Boolean(E1,E2)   ((E1) == (E2))
#define yNEqF_SDL_Boolean(E1,E2)  ((E1) != (E2))

#define yEqF_z3_A(Expr1,Expr2)  yEq_z3_A(Expr1,Expr2)
#define yNEqF_z3_A(Expr1,Expr2)  ( ! yEq_z3_A(Expr1,Expr2) )
#define yEq_z3_A(Expr1,Expr2) \
  GenericEqualSort((void *)Expr1,(void *)Expr2, \
                   (tSDLTypeInfo *)&ySDL_z3_A)
```

These macros are used in the generated code (and in the kernel) at each location where equality tests are needed. The parameters to the equal and not equal macro are the two expressions that should be tested.

If C equal or not equal are not possible to use, the equal macros will become calls to an equal function. The basic generic equal function can be found in `sctpred.h` and `sctpred.h`:

```
extern SDL_Boolean GenericEqualSort(void *, void *,
   tSDLTypeInfo *);
```

where:

- the first two parameters are the addresses to the two expressions to be tested
- the third parameter is the type info node for the actual type.

Special treatment of Charstring and instantiations of the Own generator has made it necessary to introduce specific wrapper functions that in turn calls GenericEqualSort for these types:

```
extern SDL_Boolean xEq_SDL_Charstring
   (SDL_Charstring, SDL_Charstring);
extern SDL_Boolean GenOwn_Equal (void *, void *,
    tSDLTypeInfo *);
```

Generic Free Functions

Each type in SDL that is implemented as a pointer, or that contains a pointer that references to memory that is automatically handled (in principle all pointers except Ref pointers), has access to a corresponding `yFree_typename` function or macro. In the generic function model, this is always a macro.

```
#define yFree_SDL_Charstring(P)  xFree_SDL_Charstring(P)
#define xFree_SDL_Charstring(P) \
   GenericFreeSort(P,(tSDLTypeInfo *)&ySDL_SDL_Charstring)

#define yFree_A(P) \
   GenericFreeSort(P,(tSDLTypeInfo *)&ySDL_A)
```

The yFree macro will always be translated to a call to the function GenericFreeSort.

```
extern void GenericFreeSort (void **, tSDLTypeInfo *);
```

This function takes the address of a variable and a type info node and releases the dynamic memory used by this value contained in the variable.

Generic Make Functions

There are four generic functions constructing values of structured types:

```
extern void * GenericMakeStruct (void *, tSDLTypeInfo *, ...);
extern void * GenericMakeChoice (void *, tSDLTypeInfo *,
   int, void *);
extern void * GenericMakeOwnRef (tSDLTypeInfo *, void *);
extern void * GenericMakeArray  (void *, tSDLTypeInfo *,
   void *);
```

GenericMakeStruct: According to SDL, the Make operator is only available for the struct type. However, in the SDL Suite the Make operator, and thus the GenericMakeStruct function, is also available for the Object_identifier type and the instantiations of the generators string, powerset, and bag.

- The void * parameter is the address of a variable where the result should be placed. This value is also returned.
- The tSDLTypeInfo * parameter is the address to the type info node for the type to be created.
- "..." denotes a list of addresses to the values for the components in the struct. All parameters must be passed as addresses (void *) regardless if the component type should be passed as an address or as a value. The only exceptions are the types represented as pointers themselves (Charstring, Ref, Own, ORef, and syntypes of these types), where the pointers are passed, not the addresses of the pointers. In case of an optional field or a field with an initial value, a '0' or '1' is passed to indicate if a value for the component is present or not. If '1' is passed the value follows as next parameter. If '0' is passed no value is present in the actual parameter list.

GenericMakeChoice: This function is used for choice types.

- The first void * parameter is the address of a variable where the result should be placed. This value is also returned.
- The tSDLTypeInfo * parameter is the address to the type info node for the type to be created.
- The int parameter decides which choice component that is present.

- The last void * parameter is the address of the value.

GenericMakeOwnRef: This function is used for instantiations of generators Own and Ref.

- The tSDLTypeInfo * parameter is the address to the type info node for the type to be created.
- The void * parameter is the address to the value that should be assigned to the memory allocated by this function.

GenericMakeArray: This function is used for instantiations of the generators Array, Carray, and GArray.

- The first void * parameter is the address of a variable where the result should be placed. This value is also returned.
- The tSDLTypeInfo * parameter is the address to the type info node for the type to be created.
- The last void * parameter is the address to the value that should be assigned to all components of the array.

Generic Function for Operators in Pre-defined Generators

The generic function for the operators in the pre-defined generators follow the general rules for operators with a few exceptions:

- a type info node is needed as a parameter, as the C function can handle all instantiations of a certain generator.
- parameters of generator parameter types (component and index types for example) must in many cases be passed as addresses, as the properties of these types are not known.

General array

```
extern void * GenGArray_Extract (xGArray_Type *, void *,
   tSDLGArrayInfo *);
extern void * GenGArray_Modify  (xGArray_Type *, void *,
   tSDLGArrayInfo *);
```

- Parameter 1: The array
- Parameter 2: The index value passed as an address

- Parameter 3: The type info node
- Result: The address of the component

Powerset

Generic functions available for powersets with a simple component type. The powerset is represented a sequences of bits (unsigned char[Appropriate_Length]).

```
#define GenPow_Empty(SDLInfo,Result) \
   memset((void *)Result,0,(SDLInfo)->SortSize)
extern SDL_Boolean GenPow_In (int, xPowerset_Type *,
   tSDLPowersetInfo *);
extern void * GenPow_Incl (int, xPowerset_Type *,
   tSDLPowersetInfo *, xPowerset_Type *);
extern void * GenPow_Del (int, xPowerset_Type *,
   tSDLPowersetInfo *, xPowerset_Type *);
extern void GenPow_Incl2 (int, xPowerset_Type *,
   tSDLPowersetInfo *);
extern void GenPow_Del2 (int, xPowerset_Type *,
   tSDLPowersetInfo *);
extern SDL_Boolean GenPow_LT (xPowerset_Type *,
   xPowerset_Type *, tSDLPowersetInfo *);
extern SDL_Boolean GenPow_LE (xPowerset_Type *,
   xPowerset_Type *, tSDLPowersetInfo *);
extern void * GenPow_And (xPowerset_Type *, xPowerset_Type *,
   tSDLPowersetInfo *, xPowerset_Type *);
extern void * GenPow_Or (xPowerset_Type *, xPowerset_Type *,
   tSDLPowersetInfo *, xPowerset_Type *);
extern SDL_Integer GenPow_Length (xPowerset_Type *,
   tSDLPowersetInfo *);
extern int GenPow_Take (xPowerset_Type *, tSDLPowersetInfo *);
extern int GenPow_Take2 (xPowerset_Type *, SDL_Integer,
   tSDLPowersetInfo *);
```

- **Parameter of type int in GenPow_In, GenPow_Incl, GenPow_Del, GenPow_Incl2, GenPow_Del2**: A component value.
- **Result of type int in GenPow_Take, GenPow_Take2**: A component value.
- **Parameters of type tSDLPowersetInfo ***: The type info node.
- **Parameters of type xPowerset_Type * after the type info node**: The address where the result should be stored. This address is returned by the function.
- **Other xPowerset_Type * parameters**: Powerset in parameters.

Bag and General Powerset

The following generic functions are available for bags and powersets with complex component type. These types are represented as linked lists in C.

```
#define GenBag_Empty(SDLInfo,Result) \
   memset((void *)Result,0,(SDLInfo)->SortSize)
extern void * GenBag_Makebag (void *, tSDLGenListInfo *,
   xBag_Type *);
extern SDL_Boolean GenBag_In (void *, xBag_Type *,
   tSDLGenListInfo *);
extern void * GenBag_Incl (void *, xBag_Type *,
   tSDLGenListInfo *, xBag_Type *);
extern void * GenBag_Del (void *, xBag_Type *,
   tSDLGenListInfo *, xBag_Type *);
extern void GenBag_Incl2 (void *, xBag_Type *,
   tSDLGenListInfo *);
extern void GenBag_Del2 (void *, xBag_Type *,
   tSDLGenListInfo *);
extern SDL_Boolean GenBag_LT (xBag_Type *, xBag_Type *,
   tSDLGenListInfo *);
extern SDL_Boolean GenBag_LE (xBag_Type *, xBag_Type *,
   tSDLGenListInfo *);
extern void * GenBag_And (xBag_Type *, xBag_Type *,
   tSDLGenListInfo *, xBag_Type *);
extern void * GenBag_Or(xBag_Type *, xBag_Type *,
   tSDLGenListInfo *, xBag_Type *);
extern SDL_Integer GenBag_Length (xBag_Type *,
   tSDLGenListInfo *);
extern void * GenBag_Take (xBag_Type *, tSDLGenListInfo *,
   void *);
extern void * GenBag_Take2 (xBag_Type *, SDL_Integer,
   tSDLGenListInfo *, void *);
```

- **Parameter of type int in GenBag_Makebag, GenBag_In, GenBag_Incl, GenBag_Del, GenBag_Incl2, GenBag_Del2**: The address of the component value.
- **Result of type int in GenBag_Take, GenBag_Take2**: The address of the component value.
- **Parameters of type tSDLGenListInfo ***: The type info node.
- **Parameters of type xBag_Type * after the type info node**: The address where the result should be stored. This address is returned by the function.
- **Parameters of type void * after the type info node**: The address where the result should be stored. This address is returned by the function.
- **Other xBag_Type * parameters**: Bag/Powerset in parameters.

String

The following Generic functions are available for String instantiations. A String is implemented as a linked list.

```
#define GenString_Emptystring(SDLInfo,Result) \
   memset((void *)Result,0,(SDLInfo)->SortSize)
extern void * GenString_MkString (void *, tSDLGenListInfo *,
   xString_Type *);
extern SDL_Integer GenString_Length (xString_Type *,
   tSDLGenListInfo *);
extern void * GenString_First (xString_Type *,
   tSDLGenListInfo *, void *);
extern void * GenString_Last (xString_Type *,
   tSDLGenListInfo *, void *);
extern void * GenString_Concat (xString_Type *,
   xString_Type *, tSDLGenListInfo *, xString_Type *);
extern void * GenString_SubString (xString_Type *,
   SDL_Integer, SDL_Integer, tSDLGenListInfo *,
   xString_Type *);
extern void GenString_Append (xString_Type *, void *,
   tSDLGenListInfo *);
extern void * GenString_Extract (xString_Type *, SDL_Integer,
   tSDLGenListInfo *);
```

- **Parameter of type void * in GenString_MkString, GenString_Append**: Address of component value.
- **Parameter of type void * or xString_Type * after type info node**: The address where the result should be stored. This address is returned by the function.
- **Parameters of type tSDLGenListInfo ***: The type info node.
- **Other parameters**: According to SDL definition of parameters.

Limited String

Generic functions available for limited strings, i.e. strings with #STRING directive giving a max size of the string. These strings are implemented as an array in C.

```
#define GenLString_Emptystring(SDLInfo,Result) \
   memset((void *)Result,0,(SDLInfo)->SortSize)
extern void * GenLString_MkString (void *, tSDLLStringInfo *,
   xLString_Type *);
#define GenLString_Length(ST,SDLInfo) (ST)->Length
extern void * GenLString_First (xLString_Type *,
   tSDLLStringInfo *, void *);
extern void * GenLString_Last (xLString_Type *,
   tSDLLStringInfo *, void *);
extern void * GenLString_Concat (xLString_Type *,
   xLString_Type *, tSDLLStringInfo *, xLString_Type *);
extern void * GenLString_SubString (xLString_Type *,
   SDL_Integer, SDL_Integer, tSDLLStringInfo *,
   xLString_Type *);
extern void GenLString_Append (xLString_Type *, void *,
```

```
   tSDLLStringInfo *);
extern void * GenLString_Extract (xLString_Type *,
   SDL_Integer, tSDLLStringInfo *);
```

- **Parameter of type void * in GenLString_MkString, GenString_Append**: Address of component value.
- **Parameter of type void * or xLString_Type * after type info node**: The address where the result should be stored. This address is returned by the function.
- **Parameters of type tSDLLStringInfo ***: The type info node.
- **Other parameters**: According to SDL definition of parameters.

More about Abstract Data Types

Including Type Definitions

> **Note:**
>
> Use the features presented in this section with care. The features were developed early in the SDL Suite history. Now in principle every data type in C can be expressed in SDL as well. Therefore, the recommended method is to write the types in SDL or to translate C types to SDL using the cpp2sdl tool.
>
> History has also shown that it has been difficult to keep full backward compatibility for these features and at the same time improve the performance of the generated code. This of course comes from that these features is highly dependent on the way code is generated.

In this subsection, the inclusion of a type definition in the target language for an abstract data type will be described. When this facility is used, it is necessary to specify how to perform assignment, test for equal, assign default values, and so on, as it is not possible to generate when the type definition is not known (not generated). All this information is given in the #ADT directive, which has the following structure:

```
/*#ADT
  (T(x) A(x) E(x) F(x) K(x) X(x) M(x) W(x) R(x)
   xy 'file name')
#TYPE
C code
#HEADING
C code
#BODY
```

```
C code
*/
```

where each x on the first line should be replaced by one of the characters B, H, Q, S, or G. Replace y by P or I. The interpretation of these characters is similar to the their interpretation for operators.

B	Body
H	Heading
Q	Question
S	Standard
G	Generate
P	Prefix
I	Infix

The reason why G (generate) is not allowed for operators or literals is of course that it would mean to generate the implementation of the operators from the axioms, which is, at least in the general case, an impossible task. For an operator defined in an operator diagram, G is assumed independently of what the user specifies.

The specifications, given in ADT directives, of how to generate code for type definition, assignment, test for equal, default values, and free function should be interpreted according to the table below.

Type Definition

First the actual type definition. The entry - should be interpreted as if no specification is given for T.

Type	Interpretation
T(G)	Generate type definition from SDL sort
T(B)	Do not generate type definition. Assume the type should be “passed as value” to operators
T(BV)	Do not generate type definition. Assume the type should be “passed as address” to operators

Type	Interpretation
T	Same as T(B)
-	Same as T(G)

Assignment

It is possible to select how assignments should be performed for values of the type. Note that all generated assignments will be of the form:

```
yAssF_#(SortName)(....);
```

The yAssF_#(SortName) is a macro either implemented as assignment or as a call to the yAss_#(SortName) function (if such function is to be used), i.e as:

```
#define yAssF_#(S)(V,E,A) V = E
#define yAssF_#(S)(V,E,A) yAss_#(S)(&(V),E,A)
```

Type	Interpretation
A(B)	Use and generate heading, but not body, of yAss_#(S)
A(H)	Use, but generate no code for yAss_#(S)
A(G)	• If the type definition **is** generated: – Use = if possible. – Otherwise use the GenericAssignSort function • If type definition **is not** generated (T, T(B)): – Use =
A(S)	Use =
A	Same as A(B)
-	Same as A(G)

If you define your own assign function, it must be implemented as a function, as the address of the function will be stored (in the type info node for the data type) so GenericAssignSort can call it to handle sub-components of this type. An assign function has the following heading:

```
void yAss_#(SortName)
  (#(SortName) *yVar,
   #(SortName) *yExpr,
   int          AssType)
```

It should assign the value passed as second parameter to the variable passed as first parameter. If the type that is to be assigned contains any pointers the assign function is a bit complicated to write in order to avoid access errors and memory leaks. See the discussion about the AssType parameter to GenericAssignSort in "Generic Assignment Functions" on page 2694.

There is one special case when two assign functions are needed. When the user has decided to write his own assign function and at the same time the type should be passed as value, a second assign function should be added:

```
void yAss2_#(Sortname)
  (#(Sortname) *yVar,
   #(Sortname)  yExpr,
   int   AssType)
```

The difference is that the `yAss2` function takes a value as second parameter, not an address. In generated code the yAss2 function will be used for direct assignment of this type (assignment statements, parameter assignments in input, output, set and so on). The `yAss` function will be called from `GenericAssignSort` to handle assignments of this type, when it is a component of a larger structured type (for example component in struct, array or string).

Equal Test

It is possible to select how test for equality should be performed for values of the type. Note that all generated equal tests will be of the form:

```
yEqF_#(SortName)(....);
```

The yEqF_#(SortName) is a macro either implemented as C equal or as a call to the yEq_#(SortName) function (if such function is to be used), i.e as:

```
#define yEqF_#(S)(E1,E2) E1 == E2
#define yEqF_#(S)(E1,E2) yEq_#(S)(E1,E2)
```

The /= operator is represented by the macro

```
#define yNEqF_#(S)(E1,E2) (! yEqF_#(S)(E1,E2) ).
```

Type	Method
E(B)	Use and generate heading, but not body, of yEq_#(S)
E(H)	Use but generate no code for `yEq_#(S)`
E(G)	• If the type definition **is** generated: – Use `==` if possible – Otherwise use the GenericEqualSort function. • If the type definition **is not** generated – Use `==`
E(S)	Use `==`
E(Q)	Use and generate an equal function that asks for the result of the test (same as Q for operators).
E	Same as E(B)
-	Same as E(G)

If you define your own equal function, it must be implemented as a function, as the address of the function will be stored (in the type info node for the data type) so GenericEqualSort can call it to handle sub-components of this type. An equal function has the following heading:

```
SDL_Boolean yEq_#(SortName)
  (#(SortName) *yExpr1,
   #(SortName) *yExpr2);
```

It should return `true` or `false` depending on if the two values passed as parameters are equal or not. If the parameters contain pointers it might be necessary to free these values, please see the discussion on general parameters to operators in"Other Types Containing Pointers" on page 2690.

Just as for assignment there is a special case when two equal functions are needed. If the user has decided to write his own equal function and at the same time the type should be passed as value, a second equal function should be added:

```
SDL_Boolean yEq2_#(Sortname)
  (#(Sortname) yExpr1,
   #(Sortname) yExpr2)
```

The difference is that the parameters are passed as values instead of as addresses. The `yEq` function will be called from the `GenericEqual-`

`Sort` function to handle when this type is a component in a structured type, while the `yEq2` function is used for direct equal test between values of this type.

Free of Dynamic Memory

This section describes how dynamic memory (if used for the type) will be released for reuse when it is no longer needed.

Type	Interpretation
F(B)	Generate heading, but no body of the free function `yFree_#(SortName)`.
F(H)	Generate neither heading nor body of the free function.
F(S)	Use the function `GenericFreeSort`
F	Same as F(B)
-	Do not use free function.

If you define your own free function, it must be implemented as a function, as the address of the function will be stored (in the type info node for the data type) so GenericFreeSort can call it to handle subcomponents of this type. A free function should have the following prototype

```
void yFree_#(SortName) (void **yVar)
```

The function should take the address to a pointer, return the allocated memory to the pool of available memory and assign 0 to the pointer.

Extract! and Modify!

This entry specifies how component selection (struct components, array components for example) should be performed. In SDL a component can be selected in two ways:

```
Variable ! Component
Variable (Index)
```

An Extract operation can be generated in four ways:

```
Variable.Component       used for struct and #UNIONC
Variable.U.Component     used for #UNION and choice
Variable.A(Index)        used for array
yExtr_SortName(Variable,Expr)
```

The last version, the Extract function, is used for all other cases.

Type	Interpretation
X(B)	Use Extract function
X(G)	Use component selection according to table above.
X	Same as X(B)
-	Same as X(G)

A Modify operation can in the same way be generated in four ways:

```
Variable.Component       used for struct and #UNIONC
Variable.U.Component     used for #UNION and choice
Variable.A(Index)        used for array
(* yAddr_SortName((&Variable), Expr))
```

The last version, the Addr function, is used for all other cases.

Type	Interpretation
M(B)	Use Addr function
M(G)	Use component selection according to table above.
M	Same as M(B)
-	Same as M(G)

Read and Write Function

The write function is used by the monitor system to write values of the type.

Type	Interpretation
W(B)	Generate heading but not the body of a write function.
W(H)	Generate neither heading nor body of a write function, but assume that the user has provided such a function.
W(S)	Values of this type are to be printed as a HEX string. No write function is assumed to be present.
W	Same as W(B)

Type	Interpretation
-	Same as W(S)

The read function is used by the monitor system to read values of the type.

Type	Interpretation
R(B)	Generate heading but not the body of a read function.
R(H)	Generate neither heading nor body of a read function, but assume that the user has provided such a function.
R(S)	Values of this type are to be read as a HEX string. No read function is assumed to be present.
R	Same as R(B)
-	Same as R(S)

In order to examine variable values for variables that are of a sort that is implemented in C, i.e. has #ADT(T) in its ADT directive, it is necessary to implement a write function. Otherwise the value can only be presented as a HEX string. Note that the run-time kernel can automatically handle all SDL sorts for which the code generator generates the C type definition. A write function should look like:

```
extern char * yWri_SortName (void * Value)
```

Given the address of a value of the type SortName, this function should return a char *, i.e. a character string, containing the value represented in a printable form. This character string is the string that will be printed by the monitor, when it needs to print a value of this type. To implement the write function it is not uncommon that a static char array is needed.

Note:

The following two considerations when it comes to write and read functions:

- The read and write functions and any help variables and help functions are surrounded by

```
#ifdef XREADANDWRITEF
#endif
```

This section can be removed if read and write functions are not needed.

- The string format used to represent value of a type should be the same in the read and the write function. **Otherwise communicating simulations will not work** if this type is passed as parameter between the systems.

The function xWriteSort, which is part of the run-time kernel can be useful when implementing Write functions.

```
extern char * xWriteSort (
  void        *In_Addr,
  xSortIdNode  SortNode);
```

The xWriteSort function takes the address of a value to be printed, and a pointer to a xSortIdNode and returns the given value as a string. This function is typically useful if the sort we are implementing a write function for contains one or several components of sorts defined in SDL.

Read Function

In order to assign new values to variables that are of a sort that is implemented in C, i.e. has #ADT(T) in its ADT directive, it is necessary to implement a read function. Otherwise the value can only be read as a HEX string. Note that the run-time kernel can automatically handle all SDL sorts for which the code generator generates the C type definition. A read function should look like:

```
extern int yRead_SortName (void * Result)
```

A read function is given an address to store the value that is read. It should return 1 if the read operation was successful. Otherwise, 0 should be returned and `Result` should be unchanged.

There are some suitable functions in the run-time kernel which can help you when you are implementing a read function. Basically the function xScanToken described below is a tokenizer that transforms sequences of characters to tokens. This function returns tokens according to the following enum type:

```
typedef enum {
  xxId,               /* identifiers, numbers   */
  xxString,           /* SDL Charstring literal */
  xxSlash,            /* /  */
  xxColon,            /* :  */
  xxMinus,            /* -  */
```

```
  xxPlus,              /* +  */
  xxStar,              /* *  */
  xxComma,             /* ,  */
  xxSemicolon,         /* ;  */
  xxArrowHead,         /* ^  */
  xxLPar,              /* (  */
  xxRPar,              /* )  */
  xxLParDot,           /* (. */
  xxRParDot,           /* .) */
  xxLParColon,         /* (: */
  xxRParColon,         /* :) */
  xxDot,               /* .  */
  xxLBracket,          /* [  */
  xxRBracket,          /* ]  */
  xxLCurlyBracket,     /* {  */
  xxRCurlyBracket,     /* }  */
  xxAt,                /* @  */
  xxQuaStart,          /* << */
  xxQuaEnd,            /* >> */
  xxLT,                /* <  */
  xxLE,                /* <= */
  xxGT,                /* >  */
  xxGE,                /* >= */
  xxEQ,                /* =  */
  xxNE,                /* /= */
  xxQuestionMark,      /* ?  */
  xx2QuestionMark,     /* ?? */
  xxExclMark,          /* !  */
  xxSystem,            /* system       */
  xxPackage,           /* package      */
  xxBlock,             /* block        */
  xxProcess,           /* process      */
  xxProcedure,         /* procedure    */
  xxOperator,          /* operator     */
  xxSubstructure,      /* substructure */
  xxChannel,           /* channel      */
  xxSignalroute,       /* signalroute  */
  xxType,              /* type         */
  xxNull,              /* null         */
  xxEnv,               /* env          */
  xxSelf,              /* self         */
  xxParent,            /* parent       */
  xxOffspring,         /* offspring    */
  xxSender,            /* sender       */
  xxEoln,              /* end of line */
  xxEOF,               /* end of file */
  xxErrorToken         /* used to indicate error */
} xxToken;
```

Function xScanToken

The function xScanToken:

```
extern xxToken xScanToken ( char * strVar);
```

reads the next token from input (stdin or Simulator UI) and returns the type of the next token as function result. If the token is xxId or xxString the strVar parameter will contain the identifier, number, or string. The size of the char[] parameter passed as actual parameter should be large enough to store the possible values. If some other token was found, no information is stored in `strVar`.

xUngetToken

Sometimes it is necessary to look-ahead to determine how to handle the current token. Using the function xUngetToken below it is possible return one token to the input. Note that both parameters must have the values obtained from xScanToken.

```
extern void xUngetToken (
  xxToken Token,
  char  * strVar);
```

The functions below can also be useful while implementing Read function. xPromptQuestionMark is suitable to obtain prompt in a similar way as for SDL defined sorts, while xReadOneParameter can be used to read element for element in a list, separated by commas and terminated either by ".)" or "]". The function xReadSort is similar to xWriteSort and can be used to read a component in the treated sort.

xPromptQuestionMark

```
extern xxToken xPromptQuestionMark (
  char  * Prompt,
  char  * QuestionPrompt,
  char  * strVar);
```

The function result and the parameter strVar behave in the same way as for the function xScanToken (see above). The parameter Prompt is the prompt that should be used. This string has to start with a ' ', i.e. a space. To conform with other built-in read function, the Prompt parameter should be: "(SortName) : " (note the ending space colon space). The QuestionPrompt parameter should either be identical to the Prompt parameter, or be null, i.e. (char *)0. If QuestionPrompt is null, the xPromptQuestionMark function will return xxEoln if a end-of-line is found. If QuestionPrompt is not null, the xPromptQuestionMark function will print the QuestionPrompt, and continue to read. Normally QuestionPrompt should be equal to Prompt in a simple data type, while it should be null in a structured data type.

Example 389: ADT Example, Byte Type ––––––––––––––––––––––––

This example is taken from the ADT byte (see "Abstract Data Type for Byte" on page 3254 in chapter 62, *The ADT Library*). The byte type should be read and printed using HEX format.

```
#ifdef XREADANDWRITEF
static char yCTmp[20];

extern int yRead_byte( void  *Result )
{
  unsigned temp;
  xxToken Token;

  Token = xPromptQuestionMark(" (byte) : ",
     " (byte) : ", yCTmp);

  if (Token==xxId && sscanf(yCTmp, "%X", &temp)>=1) {
    *(byte *)Result = (byte)temp;
    return 1;
  }
  xPrintString("Illegal byte value\n");
  return 0;
}

extern char *yWri_byte( void  * C)
{
  sprintf(yCTmp, "%0.2X", *(byte *)C);
  return yCTmp;
}
#endif
```

––

Example 390: ADT Example, Struct Write Functions ––––––––––––

This is an example of how the read and write functions for a struct with two components can look. The monitor system can handle reading of writing of struct values automatically, so please see this just as an example.

```
newtype struct1 /*#NAME 'struct1' */ struct
  a,b Integer;

/*#ADT(W)
#BODY
#ifdef XREADANDWRITEF
static char CTemp[500];

char * yWri_struct1 (void *In_Addr)
{
  strcpy(CTemp, "(. ");
```

```
  strcat(CTemp, xWriteSort((void *)
    (&((struct1 *)In_Addr)->a), xSrtN_SDL_Integer) );
  strcat(CTemp, ", ");
  strcat(CTemp, xWriteSort((void *)
    (&((struct1 *)In_Addr)->b), xSrtN_SDL_Integer) );
  strcat(CTemp, " .)");
  return CTemp;
}
#endif
*/
endnewtype;
```

More about #ADT

When generate is specified for a function, the code generator might decide not to generate the heading of the function, as in some cases it is not needed.

All code that is not generated is assumed to be included by the user in the #TYPE, #HEADING and #BODY sections in the #ADT directive.

Another name for an assign function, equal function and so on may be used, by including the desired name within quotes together with the generation options in the #ADT directive.

If, for example, the name of a certain assign function should be AssX, this can be obtained by specifying: A(B 'AssX') for the assign function. This name will then be used throughout the generated code, both in generated declaration and at the places where the function is called. The name should be last in the specification for the actual function.

An include statement may be generated together with or replacing the type definition by giving a file name within quotes last in the specification part of the #ADT directive, immediately before the first section with code.

Example 391: Including a File in ADT

If the directive

```
/*#ADT (T(B) A(S) E(S) 'file name') */
```

is used, the following include statement will be generated:

```
#include "file name"
```

Note:

Turning off the generation of the objects contained in the include file must be performed by the user.

Directive #REF

Note:

This directive is provided only for backward compatibility. The SDL Suite now supports in/out parameters for operators, which serves exactly the same purpose. In/out parameter is an SDL-2000 extension and is supported also in operator diagrams.

The directive #REF can be used to specify that the **address**, **not the value**, of a variable should be passed as parameter to an ADT operator, as it is defined in SDL. This feature cannot be used for operators defined in operator diagrams (the directive will be ignored for such operators).

The #REF directive is used as shown in the example below.

Example 392: Including a File in ADT

```
operators
  eq1 : Integer, Integer -> Integer;
  eq2 : Integer/*#REF*/, Integer/*#REF*/ -> Integer;
```

The headings for these two operator will become in ANSI-C syntax (ignoring prefixes)

```
extern SDL_Integer eq1 (SDL_Integer P1,
                        SDL_Integer P2);
extern SDL_Integer eq2 (SDL_Integer *P1,
                        SDL_Integer *P2);
```

This feature can be used to optimize parameter passing to operators. The directive, however, also imposes the restriction that the actual parameters must be a variable or a formal parameter (see Example 393 below). This is checked by the code generator. A #REF directive does not in any way effect the way a operator call should be implemented in SDL. It is the responsibility of the code generator to generate the proper actual parameters in C.

Example 393: Including a File in ADT ––––––––––––––––––––––––––

With the ADT in the previous example the following operator call is valid:

```
eq1(sVar, (. 1, 2, 3, 4 .) )
```

The same call of `eq2` would not be valid as the second parameter is not a variable or a formal parameter.

––

Generators

The Cadvanced/Cbasic SDL to C Compiler handles all the predefined generators in SDL, i.e. Array, String, Powerset, and Bag. It is also possible for a user to write his own generators and instantiate them in newtypes. However, the behavior of a user defined generator has to be specified completely by the user. This is performed in a somewhat extended #ADT directive placed just before the endgenerator keyword. These extensions are described below.

There are three additional sections in the directive, apart from #TYPE, #HEADING, and #BODY. These are #INSTTYPE, #INSTHEADING, and #INSTBODY. The inline C code in #TYPE, #HEADING, and #BODY is placed at the point of the generator, i.e. it is generated once. The contents of #INSTTYPE, #INSTHEADING, and #INSTBODY is inserted at each instantiation of the generator, i.e. in each newtype defined using the generator.

In the #INSTTYPE, #INSTHEADING, and #INSTBODY it is possible to use # followed by a number to access the information given in the generator instantiation:

- #0 means the name of the newtype in the instantiation
- #1 and ##1 is the first actual generator parameter
- #2 and ##2 is the second actual generator parameter
- and so on.

#1 and ##1 are equal, except when the corresponding actual generator parameter is a struct (or union). In that case, assuming the SDL struct:

```
newtype aaa struct
  a, b integer;
endnewtype;
```

which will be generated as

```
typedef struct aaa_s {
  SDL_Integer a;
  SDL_Integer b;
} aaa;
```

#1 will become `struct aaa_s` (or `union aaa_s` if a union), while ##1 will become `aaa`.

Example 394: Example of User Defined Generator ––––––––––––––––

```
GENERATOR Ref (TYPE Itemsort)
  LITERALS
    Null;                              /*#OP(S)*/
  OPERATORS
    Ref2VStar : Ref -> VoidStar;       /*#OP(HP)*/
  DEFAULT Null;
/*#ADT()
#INSTTYPE
typedef #1 *#0;
#INSTHEADING
#define #(Null)()        0
#define #(Ref2VStar)(P) ((#(VoidStar))P)
*/
ENDGENERATOR Ref;
```

––

Note the usage of #INSTTYPE and #INSTHEADING in the example above. The code in these section will be inserted in each newtype defined with this generator. For example, in a newtype:

```
NEWTYPE p Ref(Integer)
ENDNEWTYPE;
```

The #INSTTYPE section will become:

```
typedef SDL_Integer *p;
```

Directives to the Cadvanced/Cbasic SDL to C Compiler

Syntax of Directives

The Cadvanced/Cbasic SDL to C Compiler recognizes a number of directives given mainly in SDL comments. The #ADT, #OP, #UNION, and #REF directives used in abstract data types are examples of such directives. The directives #ADT and #OP were described in the section "Implementation of User Defined Operators" on page 2679, "Union" on page 2668, and "Directive #REF" on page 2717, in connection with abstract data types and are not further discussed here.

A directive has the general structure:

1. The start of comment character: /*
2. A '#' character.
3. The directive name.
4. Possible directive parameters given in free syntax. That is, spaces and carriage returns are allowed here.
5. The end of comment characters */.

Upper and lower case letters are considered to be equal in directive names.

Example 395: #OP Directive

Take as an example the directive:

```
/*#OP (B) */.
```

This comment will be recognized as a directive only if no other character is inserted in the sequence `/*#OP`. After this part, spaces and carriage returns may be inserted freely.

Selecting File Structure for Generated Code – Directive #SEPARATE

The purpose of the separate generation feature is to specify the file structure of the generated program. Both the division of the system into a number of files and the actual file names can be specified. There are two ways this information can be given.

- Normally this information is set up in the Organizer, using the *Edit Separation* command, see "Edit Separation" on page 137 in chapter 2, *The Organizer*. Here file names for the generated files can also be specified. In the *Make* dialog in the Organizer (see "Make" on page 120 in chapter 2, *The Organizer*) it is possible to select full separate generation, user-defined separate generation, or no separate generation.

- For an SDL/PR file that is used as input when running the SDL Analyzer as a stand-alone tool, the same information can be entered by #SEPARATE directives directly introduced in the SDL program. Full separate generation, user-defined separate generation, or no separate generation can be set up in the command interface of a stand-alone Analyzer, see *"Set-Modularity" on page 2491 in chapter 54, The SDL Analyzer*.

The Cadvanced/Cbasic SDL to C Compiler can generate a separate file for:

- system (always separate)
- package (always separate)
- system type
- block
- block type
- process
- process type
- service
- service type
- procedure

Note:

Instantiations cannot be separated, i.e. an instance of a block type cannot be generated on a file of its own.

If #SEPARATE directives are used, they should be placed directly after the first semicolon in the system, block, process, or procedure heading; see the following example.

Example 396: #SEPARATE Directive ----------

```
system S; /*#SEPARATE 'filename' */
block B; /*#SEPARATE */
process type P1 inherits PType; /*#SEPARATE */
process P2 (1, ); /*#SEPARATE */
procedure Q; /*#SEPARATE */
```

In the example above the two versions of separate directive, with or without file name, are shown. As can be seen a file name should be enclosed between quotes. The code generator will append appropriate extensions to this name when it generates code.

If no file name is given in the directive, the name of the system, block, process, or procedure will be used to obtain a file name. In such case the file name becomes the name of the unit with the appropriate extension (`.c .h`) depending on contents. The file name is stripped from characters that are not letters, digits or underscores.

The possibility to set up full, user-defined, or no separation in the Organizer's *Make* dialog and in the user interface of a stand-alone Analyzer (see *"The Analyzer Command Line UI" on page 2474 in chapter 54, The SDL Analyzer*), can be used, in simple manner, to select certain default separation schemes. This setting will be interpreted in the following way:

- *No* separation.
  The system and each package will be generated on a separate file.
- *User defined* separation.
  The system, each package, and each unit that the user has specified as separate will become a separate file.
- *Full* separation.
  The system, each package, each block, block type, process, process type, service, and service type will become a separate file. Note that even in this case a procedure is separate only if the user has specified it as separate.

Independently if *No*, *User defined*, or *Full* separation has be selected, the code generator will use the file name specified in the *Edit Separa-*

tion dialog or the #SEPARATE directive, for a file that is to be generated.

An Example of the Usage of the Separate Feature

In the following example a system structure and the #SEPARATE directives are given. The same information can easily be set up in the Organizer as well. This example is then used to show the generated file structure depending on selected generation option.

Example 397: #SEPARATE Directive ––––––––––––––––––––––––––

```
system S; /*#SEPARATE 'Sfile' */
  block B1; /*#SEPARATE */
    process P11; /*#SEPARATE 'P11file' */
    process P12;
  block B2;
    process P21;
    process P22; /*#SEPARATE */
```

Note that #SEPARATE directives can only be used in SDL/PR files. Normally this information is given in the Organizer.

––

Applying Full Separate Generation

If *Full* separate generation is selected then the following files will be generated:

Sfile.c	Sfile.h
B1.c	B1.h
P11file.c	
P12.c	
B2.c	B2.h
P21.c	
P22.c	

The `.c` files contain the C code for the corresponding SDL unit and the `.h` files contain the module interfaces.

Applying Separate Generation

If *User defined* separate generation is selected then the following files will be generated:

`Sfile.c`	`Sfile.h`	Contains code for units S, B2, P21
`B1.c`	`B1.h`	Contains code for units B1, P12
`P11file.c`		Contains code for unit P11
`P22.c`		Contains code for unit P22

The user defined separate generation option thus makes it possible for a user to completely decide the file structure for the generated code. The comments on files and extensions given above are, of course, also valid in this case.

Applying No Separate Generation

If the separation option *No* is selected, only the following file will be generated:

`Sfile.c`		Contains code for all units

The comments on files and extensions earlier are valid even here.

Guidelines

Generally a system should be divided into manageable pieces of code. That is, for a **large system full separate generation** should be used, while for a **small system no separate generation** ought to be used. The possibility to regenerate and recompile only parts of a system usually compensate for the overhead in generating and compiling several files for a large system.

> **Note:**
>
> A file name has to be specified, in the Organizer *Edit Separation* command, see "Edit Separation" on page 137 in chapter 2, *The Organizer*, or in the #SEPARATE directive, if two units in the system have the same name in SDL and should both be generated on separate files, otherwise the same file name will be used for both units.

Accessing SDL Names in C Code – Directive #SDL

When writing C code that is to be included in a generated program it is often necessary to refer to names of objects defined in SDL. The name of an SDL object is, however, transformed when it is translated to C. A prefix, which is a sequence of characters, is added to the SDL name to make the C name unique in the C program. Furthermore, all characters in SDL name which are not allowed in a C name are removed. The prefixes are calculated by looking at the structure of definitions in the actual scope and in all scopes above. This means that adding a declaration at the system level might change all prefixes in blocks and processes contained in the system. As a consequence it is almost impossible to know the prefix of an object in advance.

To be able to write C code and use the name of SDL objects in that code, the Cadvanced/Cbasic SDL to C Compiler provides the directive #SDL which is used in C code to translate an SDL name to the corresponding C name.

The syntax of the #SDL directive is as follows:

```
#SDL (SDL name)
```

or

```
#SDL (SDL name, entity class name)
```

There is also a short form for the directive. No characters are allowed between the # character and the left parentheses in this form:

```
#(SDL name)
```

or

```
#(SDL name, entity class name)
```

Replace `SDL name` with the name of an object in the SDL definition and `entity class name` by any of the following identifiers (upper and lower case letters are considered to be equal):

block blockinst blocksubst blocktype channel channelsubst connect formalpar gate generator label literal newtype	operator package predef procedure process processinst processtype remoteprd remotevar service serviceinst servicetype	signal signallist signalroute sort (= newtype) state synonym syntype system systemtype timer variable view

This list contains all entity classes, which means that not all of the entries are relevant for practical use. When a #SDL directive is found in included C code, the code generator first identifies what SDL object is referred to and then replaces the directive by the C name for that object. The search for the SDL object starts in the current scope (the scope where the C code is included), and follows the scope hierarchy outward to the system definition, until an appropriate SDL object is found. An appropriate SDL name is considered to be found if it has the specified name and is in the specified entity class. If no entity class name is given the search is performed for all entity classes.

Note:

In types, especially in block types, #SDL should be used with care. The reason is that some of the objects in a block type are generated for each instantiation of the block. A #SDL directive on such an object might lead to overloading of names in C. Sensitive objects are processes, process instantiations, signal routes, channels, remote definitions.

The table in the subsection "SDL Predefined Types" on page 2658 gives the direct translation between an SDL name and the corresponding C name or expression. For these names the #SDL directive should not be used.

Escaping # in inline C code

In inline C code # is in some circumstances used for a special meaning.

```
#(name)
#SDL(name)
#0, #1, ..., #9
```

```
##0, ##1, ..., ##9
```

The above constructs are all replaced by the C name for some appropriate unit defined in the source. In all other cases a # will just represent a #. However there are some rare situations when some of the translation rules above makes it impossible to include the intended C code. In format strings it is, for example, possible to have a # followed by a digit. To facilitate this it is possible to escape a # and override the translation rules above.

A sequence of three #, that is ###, will always be copied as one #. The reason for three # is that two # is already used by the translation rules given above.

Example 398: Use of ### in inline code ––––––––––––––––––––––––

Consider the following construction.

```
###1
```

will become:

```
#1
```

––

Including C Code in Task – Directive #CODE

The user's own C code may be included in tasks by using the #CODE directive. This directive has the following syntax:

```
/*#CODE
C code that should
be included in
generated code */
```

Type the directive name on the first line and the C code **on the following lines** up to the end of comment symbol. Note that text on the same line as the #CODE directive are not handled.

A #CODE directive can be placed:

- Immediately preceding or just following the comma that separates two assignment statements or informal texts
- After the last assignment statement or informal text
- Immediately after the ending semicolon (;) of a task (this position is only available in SDL/PR).

The C code in the directives is textually included in the generated code at the position of the directive. If, for example, a code directive is placed between two assignment statements, the code in the directive is inserted between the translated version of the assignment statements.

> **Note:**
>
> The Cadvanced/Cbasic SDL to C Compiler handles the C code in directives as text and performs **no check that the code is valid C code**.

The code directive is included as a facility in the code generator to provide experienced users an escape possibility to the target language C. This increases the application range of the code generator.

An example of a possible use of the code directive is: An algorithm for some computation, which in the SDL description is only indicated as a task with an informal text, could be implemented in C. In this case the directive #SDL described in the previous subsection will probably become useful to access variables and formal parameters defined in SDL. See also the section on "Escaping # in inline C code" on page 2726.

Some general hints on how to write C code that can be included into a simulation program, especially when charstrings or sorts containing charstrings as components are used, can be found in the last part of the section "Implementation of User Defined Operators" on page 2679.

Unfortunately it is not possible to have C comments within the code that is included in any directive, as SDL and C use the same symbols for start and end of comments. See also Example 377 on page 2683 which illustrates the possibility to use the C macro COMMENT.

#CODE directives in compound statements

#CODE directives are recognized after a semicolon that ends a statement of one of the following kinds:

- Output statement
- Create statement
- Set statement
- Reset statement
- Export statement
- Return statement
- Call statement
- Assignment statement
- Break statement
- Continue statement
- Empty statement

Example 399 ----------

```
{
  ;  /*#CODE
       #(i) = #(i)+1; */
  i := i+2;  /*#CODE
       #(i) = #(i)+3; */
}
```

This example contains first an empty statement followed by a directive and then an assignment followed by a directive. The empty statement can, as above, be used to insert #CODE directives at places that otherwise would not be possible, like at the beginning of a compound statement or directly after a compound statement.

Note that the code in the #CODE directive is associated to the statement just before the directive and is included in the scope of that statement.

Example 400 ----------

```
{
  if (true)
    i := i+4; /*#CODE
       #(i) = #(i)+5; */
}
```

In this case the code in the directive is included in the “if-part” of the if statement, just like the assignment it is associated with. This will be treated as:

```
  if (true) {
    i := i+4;
    i := i+5;
  }
```

To put the code directly after the if statement the following structure, with an empty statement after the if statement, can be used:

```
{
  if (true)
    i := i+4;
  ; /*#CODE
       #(i) = #(i)+5; */
}
```

Including C Declarations – Directive #CODE

The #CODE directive can also be used to include C declarations; for example types, variables, functions, #define, and #include in the declaration parts of the C program. This version of the code directive has the following structure:

```
/*#CODE
#TYPE
C code containing:
Types and variables
#HEADING
C code containing:
Extern or static declarations of functions
#BODY
C code containing:
Bodies of functions
*/
```

The separation of functions into `HEADING` and `BODY` sections serves the same purpose as in the #ADT directive, see “Implementation of User Defined Operators” on page 2679.

Code directives to include C declarations may, generally speaking, be placed immediately after a semicolon that ends a declaration in SDL. More precisely it is allowed to place a #CODE directive after the semicolon that ends:

- A heading of a system, block, substructure, process, procedure
- The formal parameters of a process or procedure
- The definition of a block, process, procedure
- The definition of a channel, signal route, signal, signal list, newtype, syntype, synonym, generator, connection, valid input signal set, variable, view, import, timer, remote variable, remote procedure

In the following small PR example the allowed positions are marked with an * followed by a number.

Example 401: #CODE Directive ----------

```
system s; *1
  signal s1, s2(integer); *2
  channel c1 from env to b1
    with s1, s2; *3
  newtype n
    ...
  endnewtype n; *4
  block b1; *5
    signalroute sr1 from env to p1
      with s1, s2; *6
    connect c1 with sr1; *7
    process p1 (1,1); *8
      signalset s1, s2; *9
      dcl a n; *10
      start;
        ...
      state ...;
        ...
    endprocess p1; *11
  endblock b1; *12
endsystem s1;
```

A code directive is considered to belong to the unit where it is defined and the declarations within the directive are thus placed among the other C declaration for that unit. In the example above, directives at positions 1, 2, 3, 4, 12 belong to system s, directives at positions 5,6,7,11 belong to block b1, while directives at positions 8, 9, 10 belong to process p1. Only one code directive may be placed at each available position.

Note:

A variable declared in a #CODE directive that belongs to a process will be shared between the process instances of the process instance set. Such a variable should only be used to represent some common property of all the process instances. To have a variable that is local to a process instance, the variable should be defined in SDL using DCL.

In the generated code the type sections are included in the order of appearance in SDL. However, the type sections are also sensitive for their relative position comparing with SDL sort definitions. This means that the order of the type definitions in the system in the example above will be as follows:

1. Type sections in 1, 2, 3
2. Type generated for newtype n
3. Type sections in 4, 12

As the Cadvanced/Cbasic SDL to C Compiler will generate the SDL sorts in the correct order, definition before usage, in C, the full algorithm is as follows.

- Step through all definitions in SDL in the order of appearance and include:
  - the type section of #CODE directives and #ADT directives.
  - generate typedef for a sort that have no reference to some other not yet generated sort.
- Step through all sorts that have not been generated, checking whether each sort references some other sort that has not been generated. If a sort does not reference some other un-generated sort, it requires typedef generation.
- Repeat the previous step until all sorts have been generated, or until no more sorts can be generated. If sorts remain not generated at this step a recursive dependency has been detected.

The heading sections are placed in the order of their appearance in SDL. This applies to the body sections as well. All body sections will be placed after the sequence of heading sections and the heading section will be placed after all the type definitions. The SDL declarations made in the corresponding unit are available in the code directives and can as usual be reached using the #SDL directive. All declarations made in

code directives are of course available in code directives in tasks in the corresponding unit or in its subunits.

The general hints on how to write C code that fits into a generated C program given in the section "Implementation of User Defined Operators" on page 2679 and in the section "Accessing SDL Names in C Code – Directive #SDL" on page 2725 are also applicable here.

Including C Code in SDL Expressions – Operator #CODE

For each sort defined in an SDL system, both predefined and user defined, the Cadvanced/Cbasic SDL to C Compiler includes an operator #CODE with the following signature:

```
#CODE : Charstring -> S;
```

where S is replaced by the sort name. This operator or rather these operators make it possible to access variables and functions defined in C using the #CODE directive in SDL expressions and still have syntactically and semantically correct SDL expressions.

During code generation, the code generator will just copy the Charstring parameter at the place of the #CODE operator.

Example 402: #CODE Directive ––––––––––––––––––––––––––––––

Suppose that `x` and `y` are SDL variables, which are translated to `z72_x` and `z73_y`, that `a` and `b` are C variables, and `f` is a C function defined in #CODE directives.

SDL expression	C expression
`x + #CODE('a')`	`z72_x + a`
`x + #CODE('a*b')`	`z72_x + a*b`
`x*#CODE('(a+b)')*y`	`z72_x*(a+b)* z73_y`
`#CODE('f(a,#SDL(x))')`	`f(a, z72_x)`

––

Within the Charstring parameter of a #CODE operator the #SDL directive is available in the same way as in other included C code. This is also shown in the last of the examples above.

As there is one #CODE operator for each sort in the system, it is sometimes necessary to qualify the operator with a sort name to make it possible for the SDL Analyzer to resolve which operator that has been used. If, for example, the question and all answers in a decision are given as applications of #CODE operators, then it is not possible to determine the type for the decision. One of the #CODE operators should then be qualified with a sort name to resolve the conflict.

Example 403: Code Directive

```
DECISION #CODE('a');
    (#CODE('1')) : TASK ...;
    (#CODE('2')) : TASK ...;
ENDDECISION;
```

In this case the sort of the decision cannot be resolved. To overcome this problem the question could be written as

```
DECISION TYPE integer #CODE('a');
```

Names and Prefixes in Generated Code

When an SDL name is translated to an identifier in C, a prefix is normally added to the name given in SDL. This prefix is used to prevent name conflicts in the generated code, as SDL has other scope rules than C and also allow different objects defined in the same scope to have the same name, if the objects are of different entity classes. It is, for example, allowed in SDL to have a sort, a variable and a procedure with the same name defined in a process. So the purpose of the prefixes is to make each translated SDL name to a unique name in the C program.

A generated name for an SDL object contains four parts in the following order:

1. The character “z”
2. A sequence of characters that make the name unique. If the object is part of a package, the package name will appear in this sequence.
3. An underscore “_”
4. The SDL name stripped from characters not allowed in C identifiers

Sequence of Characters

A C identifier may contain letters, digits, and underscore “_” and must start with a letter.

The sequence of characters that make the name unique is determined by the position of the declaration in structure of declarations in the system:

- Each declaration on a level is given a number: 0, 1, 2,..., 9, a, b,..., z.

- If the number of declaration on a level is greater than 36, the sequence is: 00, 10, 20, .., 90, a0, .., z0, 01, 11, 21, .., 91, a1, .., z1, ..., 0z, 1z, 2z, .., 9z, az, .., zz.
- If the number of declarations is greater than 36 * 36 then three character sequences are used, and so on.

The total sequence making a name unique is now constructed from the "declaration numbers" for the unit and its parents, that is the units in which it is defined, starting from the top.

If, for example, a sort is defined as the 5th declaration in a block that in turn is the 12th declaration in the system, then the total sequence will be b4 (if not more than 36 declarations are present on any of the two levels).

Example 404: Generated Names in Code ––––––––––––––––––––––

Examples of generated names:

SDL Name	Position of the Declaration	Generated Name
S1	10th declaration in the system	z9_S1
Var2	3rd declaration in the process, which is the 5th declaration in the block, which is the 15th declaration is system	ze42_Var2

––

There will also be other generated names using the prefixes. If, for example, a sort MySort is translated to za2c_MySort, then the equal function connected to this type (if it exists) will be called yEq_za2c_MySort.

Prefixes

> **Note:**
>
> If the OO diagram types in SDL-92 are used (system type, block type, process type), **full prefix should always be used**, as the OO concepts in itself most likely mean the name conflicts will be introduced in C.

This strategy for naming objects in the generated code should be used in all normal situations, as it guarantees that no name conflicts occur. The Cadvanced/Cbasic SDL to C Compiler offers, however, possibilities to change this strategy. In the *Make* dialog in the Organizer (see "Make" on page 120 in chapter 2, *The Organizer*) and in the user interface an Analyzer running stand-alone (see *"The Analyzer Command Line UI" on page 2474 in chapter 54, The SDL Analyzer*), it is possible to select one of the following strategies: *full* prefix, *entity class* prefix, *no* prefix, or *special* prefix. Full prefix is default and is the strategy described above.

Entity Class Prefix

If entity class prefix is selected, then the prefix that is concatenated with the SDL name will be in accordance with the table below and depends only of the entity class of the object.

Entity class	Prefix	Entity class	Prefix
Block, block type, block instance	`blo`	Process, Process type, Process instance	`prs`
Block substructure	`bls`	Remote procedure	`rpc`
Channel	`cha`	Remote variable	`imp`
Channel substructure	`chs`	Service, Service type, Service instance	`ser`
Connection	`con`	Signal	`sig`
Formal parameter	`for`	Signal list	`sil`
Gate	`gat`	Signal route	`sir`
Generator	`gen`	Sort = Newtype	`sor`
Import	`imp`	State	`sta`
Label	`lab`	Syntype	`syt`
Literal	`lit`	Synonym	`syo`
Operator	`ope`	System, System type	`sys`
Package	`pac`	Timer	`tim`
Predef	`pre`	Variable	`var`
Procedure	`prd`	View	`vie`

Using entity class prefix means that the user must guarantee that no name conflict occurs. It also means, however, that the generated names are predictable and thus simplifies writing C code where the SDL names are used. It is only necessary to look for name conflicts within entity classes, for example not having two sorts with the same name. The entity class prefixes handle the case when two objects of different entity class have the same name. Note that the table above contains all entity classes. Not all of the items are actually used by the code generator.

No Prefix

The third alternative, no prefix, means of course that no prefixes are added to the SDL name. The name in the C program will then be the SDL name stripped form characters that are not allowed in C identifiers (everything except letters, digits, and underscore). In this case, the user must guarantee that no name conflict occurs and that the stripped name is allowed as a C identifier, that is, that it begins with a letter.

Special Prefix

In the fourth alternative, special prefix, full prefixes are used for all entity classes except variable, formal parameter, sort, and syntype. For these entity classes no prefix is used.

Conclusion

As was said in the beginning of this subsection, the user should have a good reason for selecting anything but the full prefix, as it could be very difficult to spot name conflicts. The C compiler will in some cases find a conflict, but may in other cases consider the program as legal and generate an executable program with a possibly unwanted behavior. The note above about OO concepts is also a strong argument for full prefix.

Case Sensitivity

Another aspect concerning identifiers is that SDL is case insensitive, while C is case sensitive. The Cadvanced/Cbasic SDL to C Compiler has two translation schemes for identifiers, one is to use the capitalization used in the declaration of the object of concern (default), and one is to use lower case identifiers. The translation scheme is selected in the *Make* dialog in the Organizer (see "Make" on page 120 in chapter 2, *The Organizer*) or in the user interface of the Analyzer, when it is executed stand-alone (*"The Analyzer Command Line UI" on page 2474 in chapter 54, The SDL Analyzer*).

Specifying Names in Generated Code – Directive #NAME

If you wish to decide the name of an object in generated code yourself you can use the #NAME directive. Place the directive directly after the name in the declaration of the object. It should contain the desired name to be used in the generated code within quotes.

Example 405: #NAME Directive

```
NEWTYPE S /*#NAME 'S' */ STRUCT
  a integer;
  b Boolean;
  ADDING OPERATORS
    Op /*#NAME 'OtherName' */ :
      S, S -> Boolean;
ENDNEWTYPE;
```

The name defined in a #NAME directive will be used everywhere that the SDL name is used in the generated code, with two exceptions:

- In the monitor system the SDL names will be used in the communication with the user.
- The name of the files for generated code are not affected by the usage of #NAME directives.

There are, however, some restrictions on where #NAME directives can be placed. Some objects in, for example, a block type are generated in each instantiation of the block type. If a name directive is placed at such an object, the name will probably be overloaded in C, resulting in a C compilation error. The sensitive objects are processes, process instantiations, signal routes, channels, remote variables, and remote procedures.

Assigning Priorities – Directive #PRIO

Priorities can be assigned to processes and process instantiations using the directive #PRIO. The process priorities will affect the scheduling of processes in the ready queue, see "Time" on page 2646. A priority is a positive integer, where low value means high priority. #PRIO directives can be placed directly after the process heading in the definition of the actual process or **last in the reference symbol** (in SDL/GR).

Example 406: #PRIO Directive in process headings ––––––––––––– .

```
Process P1; /*#PRIO 3 */
Process P2(1,1); /*#PRIO 5 */

Process P3 : P3Type; /*#PRIO 3 */
Process P4(1,1) : P4Type; /*#PRIO 5 */
```

––

Processes that do not contain any priority directive will have the default priority 100.

Initialization – Directive #MAIN

The #MAIN directive is used to include initialization code that should be executed before any process transitions are started. The directive should be placed in the system definition directly after the system heading.

In a System diagram the comment with the #MAIN directive should be placed in the additional heading symbol, see "The Additional Heading Symbol" on page 1883 in chapter 43, *Using the SDL Editor*.

Example 407: #MAIN Directive––––––––––––––––––––––––––––––

```
System S;
/*#MAIN
C code for initialization */
```

––

The #MAIN directive has exactly the same structure as the #CODE directive for including code in tasks. The included code will, however, be placed last in the yInit function, after the initialization of the internal structure, but before any transitions are executed.

Modifying Outputs – Directive #EXTSIG, #ALT, #TRANSFER

The purpose of these directives is to modify the standard behavior of an SDL output. The #EXTSIG directive can be used to build applications with the SDL Suite run-time library. The directives #ALT and #TRANSFER are only useful together with other real-time operating systems.

The directive #EXTSIG is used to replace the code for an SDL output with any appropriate in-line C code. This is an optimization and an al-

ternative to the OutEnv function (see chapter 57, *Building an Application*). The #EXTSIG directive can be specified:

- Last in an output symbol (in PR just before the ';').
- Just before the ',' or ';' ending the definition of a signal.

In the first case the #EXTSIG is valid for the signal(s) sent in the output symbol, and in the second case for all outputs of the defined signal.

Example 408: #EXTSIG Directive ----------

```
signal
  Signal1          /*#EXTSIG */,
  Signal2(integer) /*#EXTSIG */;

output Signal3 To Sender /*#EXTSIG */;
```

For each output of a signal with a #EXTSIG directive (in either way described above) the following code is generated:

```
#ifndef EXT_SignalName
  "the normal implementation of an output"
#else
  EXT_SignalName(
    SignalName, ySigN_SignalNameWithPrefix,
    ToExpression, SignalParameters)
#endif
```

where SignalName is the name of the signal in SDL. The parameter ToExpression is a translated version of the SDL expression after TO in the output. If no TO expression is given in the output, this parameter will be xNotDefPId. The entry SignalParameters will be replaced by the list of signal parameter values given in the output.

The intention of this code is to give the user the possibility of introducing a macro with the same name as the signal, where the implementation of the output is expanded to in-line code. By just having a compilation switch which selects if this macro is visible or not, the same generated code can be used both for simulation and for highly optimized applications. An appropriate switch is probably XENV, which governs the normal way of connecting an SDL system to the environment.

Example 409: #CODE Directive ––––––––––––––––––––––––––––––

The following #CODE directive can be included in a text symbol in the system diagram (assuming a signal called SigName with one parameter).

```
/*#CODE
#TYPE
#ifdef XENV
#define EXT_SigName(Name, IdNode, ToExpr, Param1) \
   suitable macro code
#endif
*/
```

––

The other two directives, #ALT and #TRANSFER, can be used together with appropriate real-time operating systems, to have two different interpretations of an output (internal or external output for example) and to specify that a received signal should be immediately retransmitted (#TRANSFER). These kinds of features are not uncommon in real-time operating systems, and can be modeled and simulated by the Cadvanced/Cbasic SDL to C Compiler using these directives. Both these directives should be placed last in the output symbol.

The presence of an #ALT directive will be reflected in the generated code in the way described below.

- If no directive is used, the following macros will be present in generated code for sending a signal:
  - SDL_2OUTPUT: used when the receiver is known.
  - SDL_2OUTPUT_NO_TO: used when the receiver has to be calculated during runtime.
  - SDL_2OUTPUT_COMPUTED_TO: used when the receiver is calculated during code generation.
- If an #ALT directive is given these macros are replaced by:
  - SDL_ALT2OUTPUT
  - SDL_ALT2OUTPUT_NO_TO
  - SDL_ALT2OUTPUT_COMPUTED_TO

In the Master Library, the macros with and without ALT are expanded identically. In an OS integration they might be handled differently to implement two classes of signal sending.

The presence of a #TRANSFER directive indicates that a signal should be directly retransmitted to some other receiver. This can of course be

performed in SDL by an input-output, but then it is necessary to create a new signal and copy the contents of the received signal to the new signal. Using the #TRANSFER directive this copying can be avoided.

In generated code the macros

- ALLOC_SIGNAL
- ALLOC_SIGNAL_PAR

are generated to allocate the data area for a new signal. If a #TRANSFER directive is present in the output statement, these macros are replaced by:

- TRANSFER_SIGNAL
- TRANSFER_SIGNAL_PAR

Note:

In the master library #TRANSFER will still be implemented as a signal copy. It may be possible in an OS integration to avoid the copying if the OS supports such actions.

Normally the #TRANSFER directive should be used in the following way:

```
INPUT signal1(,,,);
OUTPUT signal1(,,,) /*#TRANSFER*/;
```

That is, receive none of the signal parameters in the input and retransmit the signal unchanged. If you want to receive, for example, the second parameter (in variable Var1) and retransmit the signal unchanged except for parameter 3, that should have a new value (73), the following code can be used:

```
INPUT signal1(,Var1,,);
OUTPUT signal1(,,73,) /*#TRANSFER*/;
```

Linking with Other Object Files – Directive #WITH

> **Note:**
>
> This feature is only valid for SDL/PR as input, when the Analyzer is executed stand-alone. Similar features are available in the Organizer's *Make* dialog among the *Generate makefile* options, see "Generate makefile" on page 123 in chapter 2, *The Organizer*.

You can tell the Cadvanced/Cbasic SDL to C Compiler that a number of user defined and precompiled units should be linked together with a generated simulation program. You do this in a #WITH directive that should be placed in the system definition directly after the system heading.

Example 410: #WITH Directive

```
System S; /*#WITH 'file1.o' 'file2.o' */
```

Within the #WITH directive the object files that are to be part in the link operation should be given between quotes, as in the example above. These files will be included in the definition of the link operation in the generated `.m` file.

The make file will, however, not include any definition of how to compile the corresponding source files, as it is impossible for the code generator to know the compilation options or even what compiler the user wants. A user that knows how to interface routines in other languages in a C program, can with this knowledge and the #WITH directive link modules written in another language together with the generated program.

> **Note:**
>
> The #WITH directive will only affect the generated make file. There will be no change in the generated C code when a #WITH directive is introduced.

Naming Tasks in Trace Output – Directive #ID

To simplify the identification of a TASK in a trace printout, the Cadvanced/Cbasic SDL to C Compiler uses the variable on the left hand side of the first assignment statement or the first informal text in the task symbol. A user that is not satisfied with this can name the tasks using #ID directives. An ID directive should contain the character string that is to be used as identification in trace printouts.

Example 411: #ID Directive ––––––––––––––––––––––––––––––––––

```
/*#ID 'Identification of task' */
```

––

The code generator will use the first ID directive it finds in a TASK (if any). An ID directive may be placed:

- First in the task (in PR that is just after the keyword TASK)
- Immediately before or just after a comma separating two assignments or two informal texts
- Last in a task (in PR that is just before the semicolon)
- Directly after the semicolon (this position is only available in SDL/PR).

Directive #C, #SYNT, #SYNTNN, #ASN1

These directives are used to pass information from the tools generating SDL from other languages, for example for C (a `.h` file) or ASN.1.

The #C and the #ASN.1 directive will be inserted after the semicolon ending the package definition or after the package name.

```
package asn1_module; /*#ASN.1 'Module_Name' */
package asn1_module /*#ASN.1 'Module_Name' */;
```

The #ASN.1 directive contains the ASN.1 module name and the #C directive contains the name of the originating `.h` file.

The #SYNT directive and its special form the #SYNTNN directive are used in a package generated from C, to indicate which SDL sorts that are synthesized, i.e. which sorts that where needed in SDL but do not have a name and definition in C. As the originating `.h` file is included in the generated code (with a #include), no typedefs should be generated for the non-#SYNT sorts, while typedefs have to be generated for the synthesized sorts. The #SYNT directive is inserted directly after the name of the newtype or syntype.

Alternative Implementations of the String Generator – Directive #STRING

An instantiation of the string generator can be translated to either a linked list or an array when implemented in C. The #STRING directive is used to determine which translation method to select. The directive should be inserted in a NEWTYPE definition, directly after the string name, when defining a new string data type.

If the #STRING directive is not included in the NEWTYPE definition, the string is implemented as a linked list. This is the default translation method. However, just adding the directive to the NEWTYPE definition is not enough to implement the string as an array. The length of the array must also be defined. This can be done either by using a directive parameter or by using a size constraint in the NEWTYPE definition of the string generator. How this is done is presented in the examples below.

Linked List Implementations

The following examples show how to translate an instantiation of the string generator to a linked list.

Example 412: No #STRING Directive

```
NEWTYPE Example_String
    string(integer, empty)
    constants size (0:10)
ENDNEWTYPE;
```

If the #STRING directive is missing from the NEWTYPE definition, the string will be implemented as a linked list. The length of the list is unlimited, unless a size constraints is defined. In this case the length of the string is within the range of 0 and 10.

Example 413: #STRING Directive without Limited String Size

```
NEWTYPE Example_String /*#STRING */
    string(integer, empty)
ENDNEWTYPE;
```

In this example the string is also implemented as a linked list. The reason for this is that we have not defined a maximum length of the string.

Example 414: #STRING Directive with Parameter Value 0 ––––––––––

```
NEWTYPE Example_String /*#STRING 0*/
    string(integer, empty)
    constants size (0:10)
ENDNEWTYPE;
```

If the parameter value of the #STRING directive is 0, the directive is ignored. Therefore the string will be implemented as a linked list. The size constant will still decide the length of the string.

This example, however, shows how to gradually migrate from a linked list implementation to an array implementation. By just changing the parameter value to anything larger than 0, this NEWTYPE definition creates an array implementation.

––

Array Implementations

The following examples show how to translate an instantiation of the string generator to an array.

Example 415: #STRING Directive with Limited String Size ––––––––

```
NEWTYPE Example_String /*#STRING */
    string(integer, empty)
    constants size (0:10)
ENDNEWTYPE;
```

In this case the string is implemented as an array with the maximum length of 10.

––

Example 416: #STRING Directive with Parameter Value ––––––––––

```
NEWTYPE Example_String /*#STRING 100*/
    string(integer, empty)
    constants size (0:10)
ENDNEWTYPE;
```

In this example the string will be implemented as an array with the length of 100. The parameter value in the #STRING directive overrides the size constant, which in this case is redundant.

––

Size constraint

The size constraint is decided by adding a constant in the NEWTYPE definition. The following declarations are valid when defining a maximum size of the string:

```
constants size (a:b)
constants size (a)
constants size (=a)
constants size (<a)
constants size (<=a)
```

Differences between the Implementations Methods

The different implementation methods affect the behavior and performance of the generated code. The following general statements apply to the methods:

- The performance of the array implementation is usually better than that of the linked list implementation.
- If the number of string values are equal to or close to the maximum string length, the array implementation is smaller.
- If the number of string values are substantially smaller than the maximum string length, the linked list requires less memory.
- The linked list requires memory allocation, while the array does not.

Selecting implementation Methods

It is of course hard to advice which method to select, but the following recommendations apply:

- If the string size is not known, use the linked list.
- If the number of string values is substantially smaller than the maximum string length, use the linked list if speed is not very important.
- If the maximum length is not large or the number of string values are almost equal to the maximum length, use the array.

Using Cadvanced/Cbasic SDL to C Compiler to Generate C++

General

The C code in the Master Library and the C code generated by the Cadvanced/Cbasic SDL to C Compiler is in the common subset of C and C++, and will thus compile both as a C program and as a C++ program. There is one special feature in the code generator concerning C++ when it comes to abstract data types and the possibility to match a C++ class and an SDL data type. Otherwise all the features for including C code, directive #ADT, directive #CODE (see "Abstract Data Types" on page 2656 and "Accessing SDL Names in C Code – Directive #SDL" on page 2725), and so on, are directly applicable for C++ as well. The #CODE directives make it possible to include class definitions as C++ code and the utilization of the classes as C++ code in SDL tasks.

Example 417: Using C++ Classes ––––––––––––––––––––––––––––

CODE directive containing declarations (see "Including C Declarations – Directive #CODE" on page 2730) which should be placed among the SDL declarations:

```
/*#CODE
#HEADING
class TEST {
public:
  void putvar(int avar, int bvar)
    {a = avar; b = bvar;}
  int  geta()
    {return a;}
  int  getb()
    {return b;}
private:
  int a,b;
} TESTvar;
*/
```

Example of usage of the class in a CODE directive in a TASK (see "Including C Code in Task – Directive #CODE" on page 2728).

```
TASK '' /*#CODE
          TESTvar.putvar(#(I), #(I)+10); */;
```

Example of usage of the class in a CODE operators in expressions (see "Including C Code in SDL Expressions – Operator #CODE" on page 2734).

```
OUTPUT Score(
  #CODE('TESTvar.geta()'),
  #CODE('TESTvar.getb()'),
  #CODE('#(TClass)->getVar()')
);
```

Connection Between C++ Classes and SDL

To obtain a close connection between a C++ class and SDL, an abstract data type in SDL can be used; see below.

If you have a C++ class (from a class library or developed specifically for the project), then the following correspondence rules can be used to map the class on an abstract data type.

C++	SDL
Class definition	Abstract data type definition
Class instance pointer	Process variable
Member functions	Operators
new, delete	Operators

Example 418: SDL and C++ Class

Suppose we have a C++ class with the following interface (`.h` file):

```
class TestClass {
public :
  TestClass (int);
  TestClass ();
  ~TestClass ();
  int updateVar(int);
  int getVar();
private :
  int v;
};
```

then the following abstract data type can be used to represent the class (in the example the NAME directive, see "Specifying Names in Generated Code – Directive #NAME" on page 2739, is used to instruct the Cadvanced/Cbasic SDL to C Compiler which name to use in C for particular SDL objects):

```
NEWTYPE TestClass     /*#NAME 'TestClassPtr' */

  LITERALS
```

```
    newTestClass      /*#NAME 'new1TestClass' */
    ;

  OPERATORS
    newTestClass      /*#NAME 'new2TestClass' */
      : integer -> TestClass;

    deleteTestClass   /*#NAME 'deleteTestClass' */
      : TestClass -> TestClass;

    updateVar         /*#NAME 'updateVar' */
      : TestClass, integer -> integer;  /*#OP(HC) */

    getVar            /*#NAME 'getVar' */
      : TestClass -> integer;           /*#OP(HC) */

/*#ADT(T A(S) E(S) D(H) H P)

#TYPE
#include "TestClass.h"
typedef TestClass * TestClassPtr;
COMMENT((NOTE! SDL data type TestClass is
        pointer to C++ class TestClass))

#HEADING
#define yDef_TestClassPtr(p)  *(p) = 0
#define new1TestClass()   new TestClass()
#define new2TestClass(P)  new TestClass(P)

extern TestClassPtr deleteTestClass
  (TestClassPtr);

#BODY
extern TestClassPtr deleteTestClass
  (TestClassPtr P)
{
  delete P;
  return (TestClassPtr)0;
}
*/
ENDNEWTYPE;
```

Note that the #ADT specification means that no code will be generated for the abstract data type. The abstract data type can utilized in the following way:

```
DCL
  TClass TestClass,
  I      Integer;

TASK TClass := newTestClass;
TASK TClass := newTestClass(2);
TASK I := updateVar(TClass, I);
TASK I := getVar(TClass);
```

```
TASK TClass := deleteTestClass(TClass);
```

The only feature that is not described before is the C option in the #OP directive. C (class) is an alternative to I (infix) and P (prefix), and specifies that the operator call should be translated to a member function call of a C++ member function. #OP(C) means that an operator call

```
F(a, b, c)
```

is translated to

```
a->F(b, c)
```

Note:

This means that each operator mapped on class member function should have the class instance pointer as first parameter.

Restrictions

SDL Restrictions

The Cadvanced/Cbasic SDL to C Compiler handles the majority of SDL concepts according to the definition of SDL-92. There are however a number of restrictions that are discussed in this section.

Analyzer Restrictions

The restrictions in the SDL Analyzer are, of course, also valid in the Cadvanced/Cbasic SDL to C Compiler. For more information see "SDL Analyzer" on page 20 in chapter 1, *Compatibility Notes, in the Release Guide*.

Cadvanced/Cbasic SDL to C Compiler Restrictions

The Cadvanced/Cbasic SDL to C Compiler introduces more severe restrictions on the allowed set of SDL concepts than the Analyzer. For more information, see "Cadvanced SDL to C Compiler" on page 24 in chapter 1, *Compatibility Notes, in the Release Guide*.

Migration Guide for Generic Functions

General

This section provides help to migrate a system using old-style code generation for operators to the new Generic Function style.

Introduction

The basic idea of the generic function approach is to decrease the number of generated help functions and functions for operators in predefined generators. This is accomplished by generating generic functions that can be re-used by different types.

This means, for instance, that only one assignment function is created. This function, however, can be used by all types. In the old-style method, one assignment function was created for each type. For operators in predefined generators, there is now **one single** length function calculating the length of **all** string generator instantiations.

In order to implement the generic functions, the parameter passing mechanisms have been changed. In principle, a generic function cannot take a value as parameter, it must receive a pointer to the value. This approach has a positive effect on the performance. However, the generic function approach introduces incompatibility problems if your existing system calls generated functions from inline C-code. If this is the case, the function calls must be changed.

If you need to migrate an SDL system created with the old-style code generation, you must solve the incompatibility issue.

References to Information

Generic Functions

The major source of information regarding generic functions is "Abstract Data Types" on page 2656, which contains a number of sections discussing different aspects of data types and operators:

- "Translation of Sorts" on page 2665 describes how different SDL types are translated to C.

- "Parameter Passing to Operators" on page 2676 discusses the general parameter passing principles for operators and literal functions. This section also lists which types that are passed as values and which types that are passed as addresses.
- "Implementation of User Defined Operators" on page 2679 describes how to include your own implementation in C for an operator.
- "Generic Functions" on page 2693 introduces you to the type info node concept and describes the general operators assign, equal, free, etc.
- "Generic Function for Operators in Pre-defined Generators" on page 2700 describes the operators in the predefined generators.
- "More about Abstract Data Types" on page 2704 comprises information on how to change the implementation of a data type.

SDL Data Types

Information on SDL data types and operators, seen from the SDL point of view, is available in "Using SDL Data Types" on page 42 in chapter 2, *Data Types, in the SDL Suite 6.2 Methodology Guidelines*. Although this section does not discuss the use of generic functions, it provides the framework for SDL data types and operators. In some circumstances it might be better to rewrite a data type or operator in SDL, than to fix the problems in C. A number of extensions and improvements have been included in the support for data types.

Type Info Nodes

For more information on the contents of the type info nodes, please see "Type Info Nodes" on page 3053 in chapter 61, *The Master Library, in the User´s Manual*. This section does not cover migration aspects, but provides implementation details for an interested reader.

Migrating Strategy

Overview

The common problems that might occur when migrating a system from the old-style operator implementation to the generic functions implementation can be divided into two groups:

- Some user-defined SDL operators have changed their prototypes in C. This means that user-provided implementations of the operators have to be changed and that calls to such operators directly from C have to be changed.
- Predefined operators like assignment, equal test, make, and so on, as well as operators in predefined generators might have changed their prototypes in C, which means that calls to such operators directly in C have to be changed. Also types where the implementation of assignment, equal and similar operators are changed by a #ADT directive, might have to be updated.

The first of these problems is fairly straight forward to fix, while the second might be more complex.

Step 1: Identifying Migration Problems

Before continuing with the migration instructions, check if your SDL systems are affected by any incompatibility problems.

1. Find an SDL system that compiles without errors in a previous version of the SDL Suite (with the old-style operator implementations)
2. Open it in the new version of SDL Suite.
3. Compile it and see if you get any compilations errors.

If your compilation errors are similar to the errors in Example 419 on page 2756 you can assume that you have a migration problem.

Example 419: Compilation Errors ––––––––––––––––––––––––––

The compilation error in this example originates from the GNU compiler, gcc. It gives a fairly good feeling of what kind of errors you can expect.

```
file.c:50825: conflicting types for `yAss_example'
file.c:50844: conflicting types for `yEq_example'
file.c:51496: conflicting types for `op1'
file.c:211376: too many arguments to function `op1'
file.c:211376: cannot convert to a pointer type
file.c:6042: incompatible type for argument 2 of
`GenericAssignSort'
file.c:6081: incompatible type for argument 2 of
`op1'
```

––

Step 2: Locating the Compatibility Problems

Note:

Before you try to investigate and correct any error from the list of C compilation errors, you should perform this step. The reason is that many of the errors will point at the wrong place so correcting them might introduce errors rather than correcting anything.

The Cadvanced, Cbasic, and Cmicro SDL to C compilers allows you to find the operators and literals that should be updated. By setting the environment variable `SDT_COMP_WARN` the code generators will produce a file called `compatibility.warn` in the target directory, while generating code for the system. In the first section of this file all operators and literals that might have to be changed are listed.

Example 420: Contents of `compatibility.warn`

```
LITERAL NewDb  C-name: z0V0_NewDb
  <<SYSTEM accesscontrolooa>>
  #SDTREF(TEXT,file.sdl,57,12)
  Literal function result passed as address

OPERATOR ValidateCard  C-name: z0V1_ValidateCard
  <<SYSTEM accesscontrolooa/TYPE CardDbType>>
  #SDTREF(TEXT,file.sdl,59,5)
  Parameter 2 passed as address
    Used in DIRECTIVE at #SDTREF(TEXT,file.sdl,62)
    Used in DIRECTIVE at #SDTREF(TEXT,file.sdl,62)
```

This example shows one literal and one operator that have to be updated:

- The first line contains the name of the operator/literal in SDL and in C.
- The second line contains an appropriate qualifier, that gives information on where in the system the item is defined.
- The third line is the SDT reference to the operator/literal. This can be used in the Organizer's *Goto Source* feature to show where the SDL source is located.
- The following lines indicate where changes are needed. Each line states that the result or a parameter is passed as an address. This means that previously this item was passed as a value, but now it

should be passed as an address. A complete list of types that must be changed can be found in "Mapping Table" on page 2658.

- Last, a number of cross references might be found. These show places where the operator is called from inline C using an #SDL directive. These calls might have to be updated.

Step 3: Updating Operators and Literals

For each operator or literal that is listed in the file `compatibility.warn`, perform the instructions presented in this section.

> **Note:**
> Literals should be treated as operators without parameters.

Updating the Headers

The headers of the corresponding C functions must be updated. If you have specified #OP(B), the header is generated and thus already correct, but if you have specified #OP(H), you have included the header in C probably in the #HEADING section in the #ADT directive for the type.

1. For each parameter that should be passed as an address, add a '*' after the corresponding type name in C.
2. If the result should be passed as an address, add a '*' after the result type in C, and add an extra parameter with the same C type as the updated function result, last among the parameters.

When this step has been performed for all types, the C compilation errors will be reliable again.

Example 421: Headers ----------

```
extern str lit1 (void);
extern str op1 (str, SDL_Integer);
```

Assume `str` is the type that should be passed as an address. The results of both functions and the first parameter of `op1` are mentioned in the `compatibility.warn` file. The heading should be updated to:

```
extern str* lit1 (str*);
extern str* op1 (str*, SDL_Integer, str*);
```

Updating Parameter Specifications

The parameter specification and result in the function implementation must be updated to match the heading. The function implementation is probably in the #BODY section in the #ADT directive of the type.

Example 422: Parameter Specifications (continued from Example 421)

```
str lit1 (void)
{ .... }
str op1 (str P1, SDL_Integer P2)
{ .... }
```

should be changed to:

```
str* lit1 (str* Result)
{ .... }
str* op1 (str* P1, SDL_Integer P2, str* Result);
{ .... }
```

Updating Operator/Literal Functions

The implementation of the operator/literal functions must be updated to reflect the change in parameters.

Example 423: Operator/Literal Functions (continued from Example 422) ----------

In the function `op1` every occurrence of:

`P1` should be replaced by `(*P1)`

Special cases where other changes might be more appropriate:

`&P1` should be replaced by `P1`
`P1.abc` should be replaced by `P1->abc`

The new Result parameter must be assigned the result value of the function and the function must end with a return statement.

Example 424: Return Parameter ----------

```
return Result;
```

It is not unusual that the function contains a local variable used for calculating the result. Normally this variable is no longer needed.

While updating the implementation of the function, information from the next section on, for example, assign and equal function might be valuable.

Note:

Check that parameters that are passed as addresses are NOT CHANGED within the function. If that is the case, copy the value to a local variable first, and work with that variable.

Update Calls to Functions

The calls to the changed functions must be updated. Calls made from SDL cause no problems as the SDL compilers produce the correct code. Only calls made directly from inline C code may have to be updated. The operator list in the file `compatibility.warn` contains cross-references to the inline C code where the operator is called using an `#SDL` directive.

Note:

Operator calls in C without the `#SDL` directive, are not listed in `compatibility.warn`. These calls can only be found via the compiler error list.

For parameters that has changed parameter passing mechanism from pass as value to pass as address you should perform one of the following tasks:

- If the actual parameter is a variable (or something it is possible to take the address of), add a '&', before the variable.
- If the actual parameter is a call to a function, then probably this function has changed its prototype so that it now returns an address. In that case nothing needs to be performed. In other cases proceed to the next possibility.
- If none of the situation above is appropriate, insert a new function local variable of the parameter type, assign the value of the actual parameter to this variable, and insert the address of the variable as actual parameter.

Implementation Hint

> **Note:**
> The following information is not required for the migration of the system, but can be used to improve the performance of the system.

When updating the operators, it might be worth investigating the available features in the SDL Suite, including extensions for operators, in/out parameters, no parameters, no result, etc.

One not too uncommon situation is when a value is passed as an in parameter, then changed by the operator and returned as result value. In every operator call, the same variable is used as both the actual parameter and the receiver of the result. To improve speed of the application, the operator, could be changed to an operator without result and using in/out parameters.

If you perform a change like this, remember to use the cross-reference tool to find all places where the operator is used.

Step 4: Updating typedefs

Overview

Another area where backward incompatibility problems might be present is when the `typedef` is changed in an #ADT directive, especially if the assign, equal, or free functions are changed as well. In the second section of the file `compatibility.warn` all types changing the typedef and at least one of assign, equal, or free functions are listed.

Example 425: Typedef Change ––––––––––––––––––––––––––––––

```
NEWTYPE example  C-name:zDZ_example
  <<SYSTEM mysystem>>
  #SDTREF(TEXT,file.sdl,3096,9)
    Pass as Value  #ADT(T(B)A(B)E(B)F(B))
```

––

The example should be interpreted like this:

- The first line contains the name of the newtype in SDL and in C.
- The second line contains an appropriate qualifier that gives information on where in the system the newtype is defined.

- The third line is the SDT reference to the newtype. This can be used in the Organizer's "goto source" feature to locate the SDL source code.
- The fourth line contains either "Pass as Value" or "Pass as Address", depending on the property of the newtype, followed by the interpretation of the #ADT directive.

As the #ADT directive can be used in many different ways, it is impossible to describe a general method how to correct any problems. The type list in the `compatibility.warn` file indicates what newtypes that have highest probability to cause problems. It is recommended that you go through the listed newtypes and review them given the information in the following sections.

You also have to find and in some cases correct the places where the functions discussed below are called. The compiler error list is the main source of information for this task. Please see "Locating Source Code" on page 2765 if you have problems locating the corresponding SDL source listed in a C compilation error message.

Assignment Functions

For all types passed as addresses, the differences between the old-style, and the new generic assignment functions are:

- The old functions pass the value of the right-hand side expression as the second parameter, while the new pass the address of the right-hand side expression.
- The old functions returns void, but the generic functions return the first parameter, i.e. the address of variable.
- It is now required that the assignment function must be a function (it cannot be a macro), as the address of the function is stored in the type info node for the newtype.

Example 426: The Assignment Function ––––––––––––––––––––––

The prototype for an old assign function would be:

```
void yAss_typename (typename*, typename, int)
```

The prototype for a new assign function should be:

```
typename* yAss_typename (typename*, typename*, int)
```

The body of the assignment function must be updated for these changes.

If assignment for a type passed as an address is used in inline C code, one of the following tasks must be performed:

- If the expression parameter is a variable, a '&', should be added before the variable.
- If the expression is an SDL operator call, a change is normally not needed, as the operator in the generic function model will return the address of a value, not the value itself (for types passed as address).
- You might want to add (void) before the yAss call to tell the compiler that you want to ignore the result.

For more information please see "Generic Assignment Functions" on page 2694.

Equal Functions

For all types passed as addresses, the differences between the old and the new generic equal functions are:

- The old functions pass the values of the two expression, while the new generic equal functions pass the addresses of the expressions.
- It is now required that the equal function must be a function (it cannot be a macro), as the address of the function is stored in the type info node for the newtype.

Example 427: The Equal Function ----------

The prototype for an old equal function would be:

```
SDL_Boolean yEq_typename (typename, typename)
```

The prototype for a new equal function should be:

```
SDL_Boolean yEq_typename (typename*, typename*)
```

The body of the equal function must be updated for these changes.

If equal for a type passed as an address is used in inline C code, perform the same tasks as presented for the assignment function.

For more information please see "Generic Equal Functions" on page 2697.

Free Functions

The `yFree_typename` function is backward compatible. However, it is now required that the equal function must be a function (it cannot be a macro), as the address of the function is stored in the type info node for the newtype.

For more information please see "Generic Free Functions" on page 2698.

Default Functions

The `yDef_typename` macro or function from the non-generic mode is no longer used or generated. Initialization of SDL variables are performed as follows:

- if the variable has an initial value given in the declaration, the variable is assigned this value, using an assignment statement.
- else if the type of the variable has a default value, the variables are assigned this value, using an assignment statement.
- else the variable is set to 0 using memset. If 0 is not an appropriate initial value, the function GenericDefault is called to initialize the variable. Examples of types where 0 is not an appropriate value are structs with components with initial values, Object_identifiers, Strings, general Powersets, Bags and general Arrays.

As yDef functions/macros do not exist in Generic mode, all usage in inline C code must be changed. There are several possibilities. First, decide if assigning a default value is really necessary. If it is necessary, then some of the following principle solutions might be used:

- memset to 0
- ```
  GenericDefault(&variable,
                 (tSDLTypeInfo *)&ySDL_typename)
  ```
- ```
  yAss_typename(variable, expression,
                XASS_MR_ASS_NF)
  ```
- direct C assignment, if possible

Make Functions

The `yMake_typename` function from the non-generic mode is no longer used or generated. All calls in inline code to yMake functions must be replaced by calls to proper GenericMake functions as described in "Generic Make Functions" on page 2699.

> **Note:**
>
> yMake functions pass component values as values, while GenericMake functions pass component values as addresses

Operators in Predefined Generators

The operators in predefined generators have got new generic implementations. All the available generic implementations are listed in "Generic Function for Operators in Pre-defined Generators" on page 2700. Macros that support the old operators names and translate them to the generic functions are generated. If you get compilation errors in such a call you should compare the call with the macro and the generic function, to see if there are any differences in the parameter passing principle.

Locating Source Code

A typical error message from a C compiler lists a file name, a line number, and a description of the error. To locate the corresponding SDL source code perform the following:

1. In a text editor, open the file that is listed in the error message
2. Go to the given line number.
3. Search upwards for an SDT reference, that is, a C comment starting with:

   ```
   /*#SDTREF(
   ```

Copy the SDT reference and paste it into the *Goto Source* feature in the Organizer. The Organizer will show you where the C code originated from.

Chapter 56 The Cadvanced/Cbasic SDL to C Compiler

Chapter

57 *Building an Application*

This chapter describes how you can use the Cadvanced SDL to C Compiler to generate applications and especially how to design the environment functions. These functions allows you connect the SDL system with the environment of the system.

You should read *chapter 56, The Cadvanced/Cbasic SDL to C Compiler* before reading this chapter to understand the general behavior of the Cadvanced SDL to C Compiler. Much of what you need to know to generate an application may be found there, and that information is not repeated here.

Introduction

The Basic Idea

An application generated with the Cadvanced SDL to C Compiler can be viewed as having three parts:

- The SDL system
- The physical environment of the system
- The environment functions, where you connect the SDL system with the environment of the system

In the SDL system process transitions are executed in priority order, signals are sent from one process to another initiating new transitions, timer signals are sent, and so on. These are examples of internal actions that only affect the execution of the SDL system. An SDL system communicates with its environment by sending signals to the environment and by receiving signals from the environment.

The physical environment of an application consists of an operating system, a file system, the hardware, a network of computers, and so on. In this world other actions than just signal sending are required. Examples of actions that an application wants to perform are:

- To read or to write on a file
- To send or receive messages over a network
- To respond on interrupts
- To read and to write information on hardware ports or on sockets

Note:

The entities in the C Code Generator framework, and especially those that use memory allocation, mutexes, semaphores and other synchronization features (implicitly or explicitly) should not be used in interrupt routines, signal handlers or in any similar functions. Depending on the underlying operating system such use may corrupt the application.

The environment functions are the place where the two worlds, the SDL system and the physical environment, meet. Here signals sent from the SDL system to the environment can induce all kinds of events in the physical environment, and events in the environment might cause signals to be sent into the SDL system. You have to provide the environ-

ment functions, as the Cadvanced SDL to C Compiler has no knowledge of the actions that should be performed.

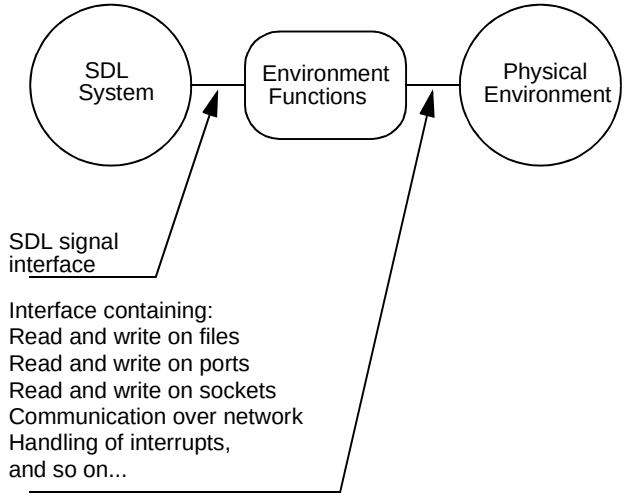

Figure 500: Structure of an application

In a distributed system an application might consist of several communicating SDL systems. Each SDL system will become one executable program. It might execute either as an operating system process, communicating with other operating system processes, or it might execute in a processor of its own, communicating over a network with other processors. There may, of course, also be combinations of these cases. Let us for the sake of simplicity call the operating system processes or processors for nodes communicating over a network. In the case of communicating operating system (OS) processes, the network will be the facilities for process communication provided by the OS.

There are no problems in building an application consisting of several nodes communicating over a network using the Cadvanced SDL to C Compiler. However, you have to implement the communication between the nodes in the environment functions.

Note:

All nodes in a network do not need to be programs generated by the *Cadvanced SDL to C Compiler* from SDL systems. As long as a node can communicate with other nodes, it might be implemented using any technique.

The PId values (references to process instances), are a problem in a distributed world containing several communicating SDL systems. We still want, for example, "Output To Sender" to work, even if Sender refers to a process instance in another SDL system. To cope with this kind of problem, a global node number has been introduced as a component in a PId value. The global node number, which is a unique integer value assigned to each node, identifies the node where the current process instance resides, while the other component in the PId value is a local identification of the process instance within the node (SDL system).

The partitioning of an application into an SDL system and the environment functions has additional advantages. It separates **external actions** into the **logical decision** to perform the action (the decision to send a signal to the environment) and the **implementation details** of the action (treating the signal in the environment functions). This kind of separation reduces the complexity of the problem and allows separate testing. It also allows parallel development of the logic (the SDL system) and the interface towards the environment (the environment functions). When the signal interface between the SDL system and its environment is settled, it is possible to continue both the activities in parallel.

Libraries

Two libraries, *Application* and *ApplicationDebug*, are provided to generate applications. Both use real time (see *"Time" on page 2646 in chapter 56, The Cadvanced/Cbasic SDL to C Compiler* and perform calls to environment functions (see section "The Environment Functions" on page 2774). The difference is that *ApplicationDebug* includes the monitor system while *Application* does not include the monitor system.

When an application is developed, it is usually appropriate to first simulate and debug the SDL system or systems without its environment. One of the libraries *Simulation* or *RealTimeSimulation* may then be used. You first simulate each SDL system on its own and can then simulate the systems together (if you have communicating systems) using

the facility of communicating simulations. After that you probably want to debug the application with the environment functions. This may be performed with the library *ApplicationDebug*. You may then generate the application with the library *Application*.

The library *Validation* allows you to build explorers from the code generated by the Cadvanced SDL to C Compiler. An Explorer has a user interface and executing principles that are similar to a Simulator. The technical approach is however different; an Explorer is based on a technique called *state space exploration* and operates on structures called *behavior trees*. Its purpose is to validate an SDL system in order to find errors and to verify its consistency against Message Sequence Charts.

Reference Section

Representation of Signals and Processes

In this first section, the representation of signals and processes is presented. The symbol table, which is a representation of the static structure of the system, will also be discussed. The information given here will be used in the next part of this section where the environment functions, which should be provided by the user, are described.

Types Representing Signals

A signal is represented by **a C struct** containing **general information** about the signal followed by the **parameters** carried by the signal.

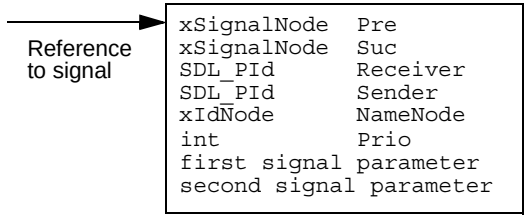

Figure 501: Data structure representing a signal

A general typedef `xSignalRec` for a signal without parameters and for a pointer to such a signal, `xSignalNode`, are given below. These types may be found in the file `scttypes.h`. These types may be used for type casting of any signal to access the general components.

```
typedef struct xSignalRec *xSignalNode;
typedef struct xSignalRec {
  xSignalNode Pre;
  xSignalNode Suc;
  SDL_PId     Receiver;
  SDL_PId     Sender;
  xIdNode     NameNode;
  int         Prio;
} xSignalRec;
```

A `xSignalRec` contains the following components:

- `Pre` and `Suc`. These components are used to link the signal in the input port list of the receiving process instance. The input port is implemented as a double linked list. When a signal has been consumed and the information contained in the signal is no longer needed, the signal will be returned to an avail list to be re-used in future outputs. The component `Suc` is used to link the signal into the avail list, while `Pre` will be `(xSignalNode)0` as long as the signal is in the avail list.
- `Receiver`. The receiving process instance.
- `Sender`. The sending process instance.
- `NameNode`. This component is a pointer to the node in the symbol table that represents the signal type. The symbol table is a tree with information about the SDL system and contains, among other things, one node for each signal type that is defined within the SDL system.
- `Prio`. This component represents the priority of the signal and is used in connection with continuous signals.

In the generated code there will be types to represent the parameters of the signals according to the following example:

Example 428: Generated C Code for Signal Definition ––––––––––––

Assume the following signal definitions in SDL:

```
SIGNAL
 S1(Integer),
 S2,
 S3(Integer, Boolean, OwnType);
```

then the C code below will be generated:

```
typedef struct {
  SIGNAL_VARS
  SDL_Integer Param1;
```

```
} yPDef_z0f_S1;
typedef yPDef_z0f_S1 *yPDP_z0f_S1;

typedef struct {
  SIGNAL_VARS
  SDL_Integer Param1;
  SDL_Boolean Param2;
  z09_OwnType Param3;
} yPDef_z0h_S3;
typedef yPDef_z0h_S3 *yPDP_z0h_S3;
```

where `SIGNAL_VARS` is a macro defined in `scttypes.h` that is expanded to the common components in a signal struct.

For each signal with parameters there are two generated types, a struct type and a pointer type. The struct type contains one component for each parameter in the signal definition and the components will be named `Param1`, `Param2` and so on. The components will be placed in the same order in the struct as the parameters are placed in the signal definition.

> **Note:**
> There are no generated types for a signal without parameters.

Types Representing Processes

A PId value is a struct consisting of two components, a **global node number**, which is an integer (see also "Function xGlobalNodeNumber" on page 2795 and "The Basic Idea" on page 2768) and a **local PId value**, which is a pointer.

```
typedef xLocalPIdRec *xLocalPIdNode;

typedef struct {
  int GlobalNodeNr;
  xLocalPIdNode LocalPId;
} SDL_PId;
```

The global node number identifies the SDL system that the process instance belongs to, while the local PId value identifies the process instance within the system. The local PId pointer value should not be referenced outside the SDL system where it is defined.

By introducing a global node number in the PId values, these values are possible to interpret throughout an application consisting of several

SDL systems. You can also define your own PId values in non-SDL defined parts of the application and still use communication with signals.

The variable `SDL_NULL`, which represents a null value for PIds and which is defined in the runtime library and available through the file `scttypes.h`, contains zero in both the global node number and the local PId component. Note that the global node number should be greater than zero in all PId values except `SDL_NULL`.

The Symbol Table

The symbol table is a tree built up during the initialization phase in the execution of the generated program and contains information about the **static structure of the SDL system**. The symbol table contains, for example, nodes which represent signal types, blocks, channels, process types, and procedures. The C type that are used to represent for example signals in the symbol table is given below.

```
typedef struct xSignalIdStruct *xSignalIdNode;
typedef struct xSignalIdStruct {
 /* components */
} xSignalIdRec;
```

It is the nodes that represent the signal types, for signals sent to and from the environment of the SDL system, that are of major interest in connection with the environment functions. For each signal type there will be a symbol table node. That node may be referenced using the name `ySigN_` followed by the signal name with prefix. Such references may be used in, for example, `xOutEnv` to find the signal type of the signal passed as parameter.

In some cases the symbol table nodes for channels from the environment to a block in the system are of interest to refer to. In a similar way as for signals such nodes may be referenced using the name `yChaN_` followed by the channel name with prefix.

The Environment Functions

An SDL system communicates with its environment by sending signals to the environment and by receiving signals from the environment. As no information about the environment is given in the SDL system, the Cadvanced SDL to C Compiler cannot generate the actions that should be performed when, for instance, a signal is sent to the environment. Instead you have to provide a function that performs this mapping be-

tween a signal sent to the environment and the actions that then should be performed. Examples of such actions are writing a bit pattern on a port, sending information over a network to another computer and sending information to another OS process using some OS primitive.

You should provide the following functions to represent the environment of the SDL system:

- `xInitEnv` and `xCloseEnv`, which are called during initialization and termination of the application
- `xOutEnv` which should treat signals sent to the environment
- `xInEnv` which should treat signals sent into the SDL system from the environment

There are two ways to get a skeleton for the env functions:

- You can copy the file `sctenv.c` from the directory *<installation directory>*`/sdt/sdtdir/`*<machine dependent dir>*`/INCLUDE`
  where <*machine dependent dir*> is for example `sunos5sdtdir` on SunOS 5 and `wini386` in Windows. (**In Windows**, `/` should be replaced by `\` in the path above.)
  This file also contains some trace mechanisms that may be used to trace the execution in a target computer. This trace can, however, only be used if you have the source code for the run-time library (included in the Cadvanced SDL to C Compiler) and can produce a new object library with the appropriate switches.
- You can generate a skeleton by using the *Generate environment functions* option in the Make dialog in the Organizer. In very simple cases you might obtain executable env functions by just tuning the macros in this generated file, but in the general case you must use it as a skeleton and edit it. Remember then to copy the file so that it is not overwritten when code is generated the next time.

An advantage with the generated env functions is that the SDL to C Compiler knows about the signal interface to be implemented in the env functions, and can therefore insert code or macros for all signals in the interface. To calculate this information is not that easy, especially if partitioning (generating code for a part of a system) is used.

Note:

A make template file is generated every time you generate an environment file. This file contains make information for the environment file and possibly for data encoding and decoding files. If you need to change this skeleton file, then remember to copy it so it is not overwritten next time an environment file is generated. The file can be used as make template in the Organizer's generate options. **Note that you may have to generate the file first, before you can select it in the Organizer.**

The env functions are thoroughly discussed below, but first we will introduce the *system interface header file* which considerably simplifies writing the environment functions.

System Interface Header File

The system interface header file contains code for objects that are defined in the system diagram. Included are all type definitions and other external definitions that are needed in order to implement external C code. These object definitions simplify the implementation of the environment functions. Therefore the system interface header file is also known the environment header file. This file is generated if:

- *Code* is generated for the complete system.
- The *Generate environment header file* option is selected in the *Make* dialog in the Organizer (see "Code Generation Options" on page 121 in chapter 2, *The Organizer*).

The default name of the generated interface header file is `<system_file_name>.ifc`.

The system interface header file, has the following structure:

- Macros for all synonyms that are translated to macros.
- All type definitions generated from newtypes and syntypes. This includes `#TYPE` and `#HEADING` sections in `#ADT` directives and in `#CODE` directives.
- External definitions of variables for all synonyms that are translated to variables.

- For each signal defined in the system diagram there will be an extern definition for the `xSignalIdRec` variable representing the signal.
- For each signal with parameters defined in the system diagram, there will be definitions of the types `yPDef_SignalName` and `yPDP_SignalName`, i.e. of the types used to represent a signal.
- For each remote procedure (that can be sent to or from the environment), code will be generated exactly as for two signals named `pCALL_procedurename` and `pREPLY_procedurename`.
- For each channel defined in the system diagram there will be extern definitions for the `xChannelIdRec` representing the channel.

Together with these definitions, macros that simplify the translation of SDL names to C names are also be generated.

Names of SDL Objects in C

Due to differences in naming rules in SDL and C, prefixing is used to make C identifiers unique (see section *"Names and Prefixes in Generated Code" on page 2735 in chapter 56, The Cadvanced/Cbasic SDL to C Compiler)*. These prefixes, however, may change when you update your SDL diagrams and cannot be predicted. Therefore you should not use the prefixed object names in the environment functions. Instead macros, generated in the system interface header file, assist you by mapping static names to the prefixed names. This means that you must regenerate the system interface header file each time you regenerate code for the system. The good part is that you do not have to make any changes in the environment functions, as the interface names are static.

Example 429: Macro in the system interface header file

If an SDL signal called Sig1 is defined in the system, the following macro is created:

```
extern XCONST struct xSignalIdStruct ySigR_z5_Sig1;
#ifndef Sig1
#define Sig1 (&ySigR_z5_Sig1)
#endif
```

This macro allows you to refer to the `xIdNode` by using the static name `Sig1` rather than the prefixed name, `ySigR_z5_Sig1`.

Macros generate static names for the following SDL types:

- Synonyms (both translated to macros and variables).
- Newtypes and Syntypes. If the newtype is translated to an enumeration type, all the literals are available directly in C using their SDL names.
- `xSignalIdNode` representing signals. (No `ySigN_` prefix).
- `xChannelIdNode` representing channels. (Use prefix `xIN_` or `xOUT_` to access the incoming or outgoing direction of the channel).
- The `yPDP_SignalName` pointer type. This type may be referred to using the name `yPDP_SignalName`, where `SignalName` is the SDL name.

Note:

You must always generate the system interface header file before editing or generating the environment functions.

Avoiding name clashes

In SDL it is allowed to give the same name to different objects. This is not allowed in C. For instance, in SDL you can give a signal and a Newtype the same name. In order to distinguish between the names in the system interface header file, you must define static unambiguous names. Using the *Env. Header File Generation* tab in the Targeting Expert, you can do this by using available general identifiers. The identifiers are:

- `%n` - This identifier is the SDL name
- `%s` - This identifier is the SDL name of the scope.
- `sdlobject` - In order to identify the type of object, you can type the object name as a prefix, e.g. signal, literal, etc.

Any combination of the identifiers can be used and they are all optional. However, in order to create a useful system interface header file, it is recommended that the `%n` identifier is always included. Leaving the field empty means that no objects of that type is included in the system interface header file at all.

Note:

If you select to include all objects and use the `%n` identifier only, the system interface header file will become compatible with earlier versions.

Example 430: Name Mapping in an system interface header file

If the signal `Signal1` is in the system `System2` you should type the following in the Signal field in the TAEX.

```
sig_%n_%s
```

The result in the system interface header file will be:

```
sig_Signal1_System2
```

This approach helps you to avoid name clashes in the ifc file. Literals, for example, are often given the same name when defined in different types. The following example shows how this can be solved.

Example 431: Avoiding Name Clashes

In an SDL system the following two newtypes are defined:

```
NewType s
   literals red, green

NewType t
   literals red, yellow
```

As the literal `red` appears in both newtypes, the C code cannot distinguish between them. However, by using the identifiers in the literals field,

```
lit_%n_%s
```

the literals are given the following names:

```
lit_red_s
lit_red_t
```

Thus we will avoid a possible name clash.

Structure of File for Environment Functions

The file containing the environment functions should have the following structure:

```
#include "scttypes.h"
#include "file with macros for external synonyms"
#include "systemfilename.ifc"

void xInitEnv XPP((void))
{
}

void xCloseEnv XPP((void))
{
}

#ifndef XNOPROTO
void xOutEnv (xSignalNode *S)
#else
void xOutEnv (S)
  xSignalNode *S;
#endif
{
}

#ifndef XNOPROTO
void xInEnv (SDL_Time Time_for_next_event)
#else
void xInEnv (Time_for_next_event)
  SDL_Time Time_for_next_event;
#endif
{
}

int xGlobalNodeNumber XPP((void))
{
}
```

The last function, `xGlobalNodeNumber`, will be discussed later, see "Function xGlobalNodeNumber" on page 2795. The usage of the macros `XPP` and `XNOPROTO` makes the code possible to compile both with compilers that can handle prototypes and with compilers that cannot. If you do not need this portability, you can reduce the complexity of the function headings somewhat. In the minor examples in the remaining part of this section, only versions with prototypes are shown.

Functions xInitEnv and xCloseEnv

There are two functions among the environment functions that handle initialization and termination of the environment. These functions, as well as the other environment functions, should be provided by the user.

```
void xInitEnv ( void );

void xCloseEnv ( void );
```

In the implementation of these functions you can place the appropriate code needed to initialize and terminate the software and the hardware. The function `xInitEnv` will be called during the start up of the program as first action, while the `xCloseEnv` will be called in the function `SDL_Halt`. Calling `SDL_Halt` is the appropriate way to terminate the program. The easiest way to call `SDL_Halt` is to include the call in a `#CODE` directive in a TASK. `SDL_Halt` is part of the runtime library and has the following definition:

```
void SDL_Halt ( void );
```

Note:

`xInitEnv` will be called before the SDL system is initialized, which means that no references to the SDL system are allowed in this function. To, for example, send signals into the system during the initialization phase, the `#MAIN` directive should be used (see "Initialization – Directive #MAIN" on page 2740 in chapter 56, *The Cadvanced/Cbasic SDL to C Compiler*). This directive code can be used after the initialization of the SDL system, but before any transitions are executed.

If you use the generated environment file, you could also define the symbols `XENV_INIT` and `XENV_CLOSE` to be the bodies of `xInitEnv` and `xCloseEnv`.

Function xOutEnv

Each time a signal is sent from the SDL system to the environment of the system, the function `xOutEnv` will be called.

```
void xOutEnv ( xSignalNode *S );
```

The `xOutEnv` function will have the current signal as parameter, so you have all the information contained in the signal at your disposal when you implement the actions that should be performed. The signal con-

tains the signal type, the sending and receiving process instance and the parameters of the signal. For more information about the types used to represent signals and processes, see section "Types Representing Signals" on page 2771 and "Types Representing Processes" on page 2773.

Note that the parameter of `xOutEnv` is an address to `xSignalNode`, that is, an address to a pointer to a struct representing the signal. The reason for this is that the signal that is given as parameter to `xOutEnv` should be returned to the pool of available memory before return is made from the `xOutEnv` function. This is made by calling the function `xReleaseSignal`, which takes an address to an `xSignalNode` as parameter, returns the signal to the pool of available memory, and assigns 0 to the `xSignalNode` parameter. Thus, there should be a call

```
xReleaseSignal(S);
```

before returning from `xOutEnv`. The `xReleaseSignal` function is defined as follows:

```
void xReleaseSignal ( xSignalNode *S );
```

In the generated environment skeleton file, the macro `RELEASE_SIGNAL` releases the signal as described above and returns from xOutEnv.

In the function `xOutEnv` you may use the information in the signal that is passed as parameters to the function. First it is usually suitable to determine the signal type of the signal. This is best performed by `if` statements containing expressions of the following form, assuming the use of the system interface header file and that the signal has the name `Sig1` in SDL:

```
(*S)->NameNode == Sig1
```

The above expression is captured in the macro `IF_OUT_SIGNAL` in the generated environment skeleton file.

Suitable expressions to reach the `Receiver`, the `Sender`, and the signal parameters are:

```
(*S)->Receiver
(*S)->Sender
((yPDP_Sig1)(*S)) -> Param1
((yPDP_Sig1)(*S)) -> Param2
```

(and so on)

Sender will always refer to the sending process instance, while Receiver is either a reference to a process in the environment or the value xEnv. xEnv is a PId value that refers to an environment process instance, which is used to represent the general concept of environment, without specifying an explicit process instance in the environment.

Note:

It is not possible to calculate the PId value for a process in the environment, the value has to be taken from an incoming signal (sender or signal parameter). This is the normal procedure in SDL to establish direct communication between two processes in the same SDL system.

Receiver will refer to the process xEnv if the PId expression in an output TO refers to xEnv, or if the signal was sent in an output without a TO clause and the environment was selected as receiver in the scan for receivers.

Remote procedure calls to or from the environment should in the environment functions be treated a two signals, a pCALL_procedurename and a pREPLY_procedurename signal.

Recommended Structure of the xOutEnv Function

You can, of course, write the xOutEnv function as you wish – the structure discussed below may be seen as an example – but also as a guideline of how to design xOutEnv functions.

Example 432: Structure of xOutEnv Function ----------

```
void xOutEnv ( xSignalNode *S )
{
 if ( (*S)->NameNode == Sig1 ) {
  /* perform appropriate actions */
  xReleaseSignal(S);
  return;
 }
 if ( (*S)->NameNode == Sig2 ){
  /* perform appropriate actions */
  xReleaseSignal(S);
  return;
 }
 /* and so on */
}
```

Function xInEnv

To make it possible to receive signals from the environment and to send them into the SDL system, the user provided function `xInEnv` is repeatedly called during the execution of the system (see section "Program Structure" on page 2796). During such a call you should scan the environment to see if anything has occurred which should trigger a signal to be sent to a process within the SDL system.

```
void xInEnv (SDL_Time Time_for_next_event);
```

To implement the sending of a signal into the SDL system, two functions are available: `xGetSignal`, which is used to obtain a data area suitable to represent the signal, and `SDL_Output`, which sends the signal to the specified receiver according to the semantic rules of SDL. These functions will be described later in this subsection.

The parameter `Time_for_next_event` will contain the time for the next event scheduled in the SDL system. The parameter will either be 0, which indicates that there is a transition (or a timer output) that can be executed immediately, or be greater than Now, indicating that the next event is a timer output scheduled at the specified time, or be a very large number, indicating that there is no scheduled action in the system, that is, the system is waiting for an external stimuli. This large value can be found in the variable `xSysD.xMaxTime`.

You should scan the environment, perform the current outputs, and return as fast as possible if Time has past `Time_for_next_event`.

If Time has not past `Time_for_next_event`, you have a choice to either return from the `xInEnv` function at once and have repeated calls of `xInEnv`, or stay in the `xInEnv` until something triggers a signal output (a signal sent to the SDL system) or until Time has past `Time_for_next_event`.

> **Note:**
>
> We recommend always to return from the `xInEnv` function as fast as possible to ensure that it will work appropriately together with the monitor (during debugging). **Otherwise**, the **keyboard polling**, that is, typing `<RETURN>` in order to interrupt the execution, **will not work**.

The function `xGetSignal`, which is one of the service functions suitable to use when a signal should be sent, returns a pointer to a data area

that represents a signal instance of the type specified by the first parameter.

```
xSignalNode xGetSignal
 ( xSignalIdNode SType,
   SDL_PId Receiver,
   SDL_PId Sender );
```

The components `Receiver` and `Sender` in the signal instance will also be given the values of the corresponding parameters.

- `SType`. This parameter should be a reference to the symbol table node that represents the current signal type. Using the *system interface header file*, such a symbol table node may be referenced using the signal name directly.
- `Receiver`. This parameter should either be a PId value for a process instance within the system, or the value `xNotDefPId`. The value `xNotDefPId` is used to indicate that the signal should be sent as an output without TO clause, while if a PId value is given the output, it is treated as an output with TO clause. Note that PId values for process instances in an SDL system cannot be calculated, but have to be captured from the information (sender or parameter) carried by signals coming from the system. This is the normal procedure in SDL to establish direct communication.
- `Sender`. Sender should either be a PId value representing a process instance in the environment of the current SDL system or the value `xEnv`. `xEnv` is a PId value that refers to an environment process instance, which is used to represent the general concept of the SDL environment, without specifying an explicit process instance in the environment.

The function `SDL_Output` takes a reference to a signal instance and outputs the signal according to the rules of SDL.

```
void SDL_Output
 ( xSignalNode S,
   xIdNode     ViaList[] );
```

- `S`. This parameter should be a reference to a signal instance with all components filled in.
- `ViaList`. This parameter is used to specify if a VIA clause is or is not part of the output statement. The value `(xIdNode *)0` (a null pointer), is used to represent that no VIA clause is present. For information about how to build a via list, please see below.

We now have enough information to be able to write the code to send a signal. Suppose we want to send a signal S1, without parameters, from `xEnv` into the system without an explicit receiver (without TO). The code will then be:

Example 433: C Code to Send a Signal to the Environment ––––––––

```
SDL_Output( xGetSignal(S1, xNotDefPId, xEnv),
  (xIdNode *)0 );
```

If S2, with two integer parameters, should be sent from `xEnv` to the process instance referenced by the variable P, the code will be:

```
xSignalNode OutputSignal; /* local variable */
...
OutputSignal = xGetSignal(S2, P, xEnv);
((yPDP_S2)OutputSignal)->Param1 = 1;
((yPDP_S2)OutputSignal)->Param2 = 2;
SDL_Output( OutputSignal, (xIdNode *)0 );
```

––

For the details of how to reference the parameters of a signal see the subsection "Types Representing Signals" on page 2771.

To introduce a via list in the output requires a variable, which should be an array of `xIdNode`, that contains references to the symbol table nodes representing the current channels (or signal routes) in the via list. In more detail, we need a variable

```
ViaList xIdNode[N];
```

where N should be replaced by the length of the longest via list we want to represent plus one. The components in the variable should then be given appropriate values, such that component 0 is a reference to the first channel (its symbol table node) in the via list, component 1 is a reference to the second channel, and so on. The last component with a reference to a channel must be followed by a component containing a null pointer (the value `(xIdNode)0`). Components after the null pointer will not be referenced. Below is an example of how to create a via list of two channels, C1 and C2.

Example 434: Via List of two Channels.

```
ViaList xIdNode[4];
/* longest via has length 3 */
...
/* this via has length 2 */
ViaList[0] = (xIdNode)xIN_C1;
ViaList[1] = (xIdNode)xIN_C2;
ViaList[2] = (xIdNode)0;
```

The variable `ViaList` may then be used as a `ViaList` parameter in a subsequent call to `SDL_Output`.

Guidelines for the xInEnv Function

It is more difficult to give a structure for the `xInEnv` function, than for the `xOutEnv` function discussed in the previous subsection. A `xInEnv` function will in principle consist of a number of `if` statements where the environment is investigated. When some information is found that means that a signal is to be sent to the SDL system, then the appropriate code to send a signal (see above) should be executed.

The structure given in the example below may serve as an idea of how to design the `xInEnv` function.

Example 435: Structure of xInEnv Function

```
void xInEnv (SDL_Time Time_for_next_event)
{
  xSignalNode S;

  if ( Sig1 should be sent to the system ) {
    SDL_Output (xGetSignal(Sig1, xNotDefPId,
      xEnv), (xIdNode *)0);
  }
  if ( Sig2 should be sent to the system ) {
    S = xGetSignal(Sig1, xNotDefPId, xEnv);
    ((xPDP_Sig2)S)->Param1 = 3;
    ((xPDP_Sig2)S)->Param2 = SDL_True;
    SDL_Output (S, (xIdNode *)0);
  }
  /* and so on */
}
```

This basic structure can be modified to suit your own needs. The if statements could, for example, be substituted for while statements. The signal types might be sorted in some “priority order” and a return can

be introduced last in the if statements. This means that only one signal is sent during a xInEnv call, which reduces the latency.

In the generated environments skeleton file, there are three macros defined to help with allocating and sending a signal;
IN_LOCAL_VARIABLES that declares a signal variable SignalIn,
IN_SIGNAL1 that calls xGetSignal and assigns it to SignalIn, and
IN_SIGNAL2 that calls SDL_Output for SignalIn.

The macros XENV_IN_START and XENV_IN_END can also be defined to be the top and bottom part of the xEnvIn function body.

Alternative to OutEnv - Directive #EXTSIG

To speed up an application it is sometimes possible to use the directive #EXTSIG instead of the xOutEnv function. The decision to use #EXTSIG or xOutEnv may be taken individually for each signal type.

The usage of the #EXTSIG directive is described in the section *"Modifying Outputs – Directive #EXTSIG, #ALT, #TRANSFER" on page 2740 in chapter 56, The Cadvanced/Cbasic SDL to C Compiler*. This information is not repeated here.

By using the #EXTSIG directive the following overhead can be avoided:

- Calling SDL_Output (the library function for outputs)
- SDL_Output determines that the signal is to be sent to the environment
- SDL_Output calls xOutEnv
- xOutEnv executes nested "if" statements to determine the signal type.

Including the Environment Functions in the SDL System Design

Apart from having the environment functions on a file of their own, it is of course possible to include these function directly into the system diagram in a #CODE directive.

Example 436: Including Environment Functions in SDL System ––––

```
/*#CODE
#BODY
```

```
... code for the environment functions ...
*/
```

In this case you cannot use the system interface header file, but instead you have all the necessary declarations already at your disposal, as the functions will be part of the SDL system. The only problem you will encounter is the prefixing of SDL names when they are translated to C. The `#SDL` directive should be used to handle this problem (or the `#NAME` directive), see sections "Accessing SDL Names in C Code – Directive #SDL" on page 2725 and "Specifying Names in Generated Code – Directive #NAME" on page 2739 in chapter 56, *The Cadvanced/Cbasic SDL to C Compiler*. The following table shows how to obtain C names for some SDL objects of interest:

```
#(Synonym name)
#(Newtype or syntype name)
ySigN_#(Signal name)
yPDP_#(Signal name)
yChaN_#(Channel name)
```

SDL Data Encoding and Decoding, ASCII coder

Communication between nodes often requires data encoding and decoding between node internal representations and a common format in a protocol buffer. The sending node writes information in the common format and the receiving node reads information from the common format. Data encoding is the transformation from a node internal representation into a common format and data decoding is the transformation from a common format into a node internal representation.

Supported common formats are:

- BER
- PER
- ASCII

BER (Basic Encoding Rules) is specified in ITU standard X.690 and PER (Packed Encoding Rules) is specified in ITU standard X.691. BER and PER are based on ASN.1 specifications of data types and can only be used for types specified in ASN.1 specifications. See chapter 58, *ASN.1 Encoding and De-coding in the SDL Suite* and chapter 8, *Tutorial: Using ASN.1 Data Types*.

ASCII is a format where the data is represented as ASCII characters. It is easy to read and analyze. The ASCII format is specified in appendix A.

Example 437 ASCII common format ––––––––––––––––––––––––––

```
newtype Person struct
    nm Charstring;
    nr Integer;
    fm Boolean;
endnewtype Person;

dcl boss Person := (.'Joe',5,false.);

ASCII format:{'Joe',5,F}
```

––

The ASCII coder uses the same buffer management and error management as the BER and PER coders, see chapter 58, *ASN.1 Encoding and De-coding in the SDL Suite*.

Type description nodes for SDL types

SDL data encoders and data decoders need information about types and signals, information that is stored in type descriptions nodes. Type description nodes for an SDL system are generated if the Generate SDL coder option is selected in the organizer, see chapter 2, *The Organizer*, or in the targeting expert, see chapter 59, *The Targeting Expert*. Declarations to access the type nodes are in the system interface header files and in a file with the name `<system_file_name>_cod.h`. Type nodes can be found in any generated c-file from a system or a package and also in the `<system_file_name>_cod.c` file.

A type description node for SDL is implemented as a static variable with the type information. The variable can be accessed by using the name ySDL_<type_name> or ySDL_<signal_name>, where <type_name> and <signal_name> are the names used in the interface header file. See "Names of SDL Objects in C" on page 2778 for more information.

––

Encoding signal and signal parameters into a buffer

You can use an encode function to encode signal parameters into a buffer. There is one encoding function for each common format. For ASCII,

it is accessed by using the macro ASCII_ENCODE. An encoding function has a buffer reference as the first parameter, a pointer to a type node as the second parameter and a pointer to the variable to encode as the third. The encoding function returns an integer value, which is 0 if the encoding was successful and error code if it was not. More details about encoding functions, the buffer reference, type nodes and error codes can be found in chapter 58, *ASN.1 Encoding and De-coding in the SDL Suite*.

Function declarations are in the file `"ascii/ascii.h"` `("ascii\ascii.h" on Windows platforms)` in the coder directory.

Example 438 ASCII encoding of signal parameters ––––––––––––––

```
In SDL:
SIGNAL Sig1(Integer,Person,Boolean);

In xOutEnv:
BufInitWriteMode(buf);
result = ASCII_ENCODE(buf,
              (tSDLTypeInfo *)&ySDL_Integer,
              (void *)&((yPDP_Sig1)(*S))->Param1));
if (result!=0) /* handle error */;
result = ASCII_ENCODE(buf,
              (tSDLTypeInfo *)&ySDL_Person
              (void *)&((yPDP_Sig1)(*S))->Param2));
if (result!=0) /* handle error */;
result = ASCII_ENCODE(buf,
              (tSDLTypeInfo *)&ySDL_Boolean
              (void *)&((yPDP_Sig1)(*S))->Param3));
if (result!=0) /* handle error */;
BufCloseWriteMode(buf);
```

Example 439 ASCII encoding of whole signal (all signal parameters)–

```
In SDL:
SIGNAL Sig1(Integer,Person,Boolean);

In xOutEnv:
BufInitWriteMode(buf);
result = ASCII_ENCODE(buf,
             (tSDLTypeInfo *)&ySDL_Sig1,
              (void *)(*S));
if (result!=0) /* handle error */;
BufCloseWriteMode(buf);
```

Note:

The names of the type nodes in the examples, the second parameter in ASCII_ENCODE, depend on the settings for generating system interface header files.

Decoding into signal parameters from a buffer

You can use a decode function to decode from a buffer into a signal parameter. There is one decoding function for each common format. For ASCII, it is accessed by using the macro ASCII_DECODE. A decode function has a buffer reference as the first parameter, a pointer to a type node as the second parameter and a pointer to the variable to decode as the third. The decoding function returns an integer value, which is 0 if the decoding was successful and an error code if it was not. More details about decoding functions, the buffer reference, type nodes and error codes can be found in chapter 58, *ASN.1 Encoding and De-coding in the SDL Suite*.

Function declarations are in the file `"ascii/ascii.h"` (`"ascii\ascii.h" on Windows platforms`) in the coder directory.

Example 440 ASCII decoding into signal parameters

```
In SDL:
SIGNAL Sig1(Integer,Person,Boolean);

In xInEnv:
BufInitReadMode(buf);
result = ASCII_DECODE(buf,
              (tSDLTypeInfo *)&ySDL_Integer,
              (void *)&((yPDP_Sig1)(S))->Param1));
if (result!=0) /* handle error */;
result = ASCII_DECODE(buf,
              (tSDLTypeInfo *)&ySDL_Person
              (void *)&((yPDP_Sig1)(S))->Param2));
if (result!=0) /* handle error */;
result = ASCII_DECODE(buf,
              (tSDLTypeInfo *)&ySDL_Boolean
              (void *)&((yPDP_Sig1)(S))->Param3));
if (result!=0) /* handle error */;
BufCloseReadMode(buf);
```

Example 441 ASCII decoding of whole signal (all signal parameters)

```
In SDL:
SIGNAL Sig1(Integer,Person,Boolean);
```

```
In xInEnv:
BufInitReadMode(buf);
result = ASCII_DECODE(buf,
              (tSDLTypeInfo *)&ySDL_Sig1,
              (void *)S);
if (result!=0) /* handle error */;
BufCloseReadMode(buf);
```

Note:

The names of the type nodes in the examples, the second parameter in ASCII_DECODE, depend on the settings for generating system interface header files.

Encoding and decoding signal identifier for ASCII encoding

When sending signals between nodes it is often important to put a signal identifier first in the buffer. The signal identifier must be a unique identifier of the signal in the distributed system. Decoding is then a two step process, first decode signal identifier and find signal information and second decode signal parameters.

You can use any representation of signal identifiers in the environment functions.

For SDL types there is a special signal id type node that supports character string signal ids. The type node can be used for ASCII encoding.

Example 442 Using signal identifier

```
In SDL:
SIGNAL Sig1(Integer);

In xOutEnv:
void xOutEnv ( xSignalNode *S )
{
 char * signalId;

 BufInitWriteMode(buf);
 if ( (*S)->NameNode == Sig1 ) {
   /* encode signal id into buffer */
   signalId="Sig1";
   result = ASCII_ENCODE(buf,
                         (tSDLInfo *)&ySDL_SignalId,
                         (void *)signalId);
   if (result!=0) /* handle error */;
   /* encode signal parameter */
   result =  ASCII_ENCODE(buf,
                     (tSDLTypeInfo *)&ySDL_Sig1,
```

```
                        (void *)(*S));
   if (result!=0) /* handle error */;

   /* send buffer using protocol*/

   /* release memory */

   xReleaseSignal(S);
   return;
 }
 BufCloseWriteMode(buf);
}

In xInEnv:
void xInEnv (SDL_Time Time_for_next_event) {
   char SId[100];

   BufInitReadMode(buf);
   /* decode signal id */
   result = ASCII_DECODE(buf,
                    (tSDLTypeInfo *)&ySDL_SignalId,
                     SId) );
   if (result!=0) /* handle error */;
   /* signal Sig1 in buffer */
   if ( strcmp(SId,"Sig1") ) {
      S=xGetSignal(Sig1,xNotDefPId, xEnv);
      result = ASCII_DECODE(buf,
                    (tSDLTypeInfo *)&ySDL_Sig1,
                     (void *)S);
      if (result!=0) /* handle error */;
      SDL_Output(S, (xIdNode *)0 );
   }
   BufCloseReadMode(buf);
}
```

Function xGlobalNodeNumber

You should also provide a function, `xGlobalNodeNumber`, with no parameters, which returns an integer that is unique for each executing system.

```
int xGlobalNodeNumber ( void )
```

The returned integer should be greater than zero and should be unique among the communicating SDL systems that constitutes an application. If the application consists of only one application then this number is of minor interest (it still has to be set). The global node number is used in PId values to identify the node (OS process / processor) that the process instance belongs to. PId values are thereby universally accessible and you may, for example, in a simple way make “Output To Sender” work

between processes in different SDL systems (OS processes / processors).

If you use the generated environment file you could also define `XENV_NODENUMBER` to be the wanted node number.

When an application consisting of several communicating SDL systems is designed, you have to map the global node number to the current OS process or processor, to be able to transmit signals addressed to non-local PIds to the correct OS process or processor. This will be part of the `xOutEnv` function.

Program Structure

The generated code will contain two important types of functions, the initialization functions and the PAD functions. The PAD functions implement the actions performed by processes during transitions. There will be one initialization function in each generated `.c` file. In the file that represents the system this function will have the name `yInit`. Each process in the system will be represented by a PAD function, which is called when a process instance of the current instance set is to execute a transition.

The example below shows the structure of the `main`, `MainInit`, and `MainLoop` functions.

Example 443: Start up structure ––––––––––––––––––––––––––––––

```
void main ( void )
{
 xMainInit();
 xMainLoop();
}

void xMainInit ( void )
{
  xInitEnv();
  Init of internal data structures in the
  runtime library;
  yInit();
}

void xMainLoop ( void )
{
  while (1) {
    xInEnv(...);
    if ( Timer output is possible )
      SDL_OutputTimerSignal();
    else if ( Process transition is possible )
```

```
        Call appropriate PAD function;
    }
}
```

The function `xMainLoop` contains an endless loop. The appropriate way to stop the execution of the program is to call the runtime library function `SDL_Halt`. The call of this C function should normally be included in an appropriate task, using the directive `#CODE`. `SDL_Halt` which has the following structure:

```
void SDL_Halt ( void )
{
  xCloseEnv();
  exit(0);
}
```

To complete this overview, which emphasizes the usage of the environment functions, we have to deal with the `xOutEnv` function. Within PAD functions, the runtime library function `SDL_Output` is called to implement outputs of signals. When `SDL_Output` identifies the receiver of a signal to be a process instance that is not part of the current SDL system, `SDL_Output` will call the `xOutEnv` function.

Dynamic Errors

In the library for applications SDL runtime errors will not be reported. The application will just perform some appropriate actions and continue to execute. These actions are in almost all cases the same as the actions at dynamic errors described in the "Dynamic Errors" on page 2190 in chapter 49, *The SDL Simulator*.

- **Output warnings**: If a signal is sent to NULL or to a stopped process instance, or if no receiver is found in an output without a "to" clause, the signal will not be sent, that is, the output statement is a null action. If a signal is sent to a process instance and there is no path between the sender and the receiver, the signal will be sent anyway (actually, no check will be performed).
- If the error was a **decision error**, that is, no path exists for the current decision value, the execution of the program will continue in an **unpredictable way**. To avoid these kind of problems you should always have else paths in decisions (if not all values in the current data type are covered in other paths).

- If the error occurred during an **import** or **view** action, a data area of the correct size containing zero in all positions is returned.
- **No checks** of **assignment** or **index out of range** will be performed. This means that if an array index is out of bounds, then the corresponding C array will be indexed out of its bounds.
- No checks when accessing struct, #UNION, or choice components are performed. No checks are performed when de-referencing a pointer value (Ref generator). These operations will just be executed.
- If the dynamic error occurred **within an SDL expression**, the operator that found the error will return a default value and the evaluation of the expression is continued. The default values returned depend on the result type of the operator and are given in the section "Default Values" on page 2674 in chapter 56, *The Cadvanced/Cbasic SDL to C Compiler*.

Example Section

In this section a complete example of an application is presented. The application is simple but it still contains most of the problems that arise when the Cadvanced SDL to C Compiler is used to generate applications. All source code for this example, together with the running application are delivered with the runtime libraries for application generation. **Note that the example is developed for SunOS 5. The example is not updated to use encoding and decoding support.**

The Example

We want to develop an application that consists of several communicating UNIX processes. Each UNIX process should also be connected to the keyboard and the screen. When a complete line is typed on the keyboard (when `<Return>` is pressed) in one of the UNIX processes, that line should be sent to and printed by all the UNIX processes, including the one where the line was entered. If a line starting with the character "." is entered in any UNIX process then all the UNIX processes should terminate immediately.

There are some observations we can make from this short description.

- Firstly, all the UNIX processes should behave exactly the same, which means that the behavior can be described in one SDL system

and one application can be generated. This application should be able to communicate with other instances of itself and should simultaneously be started in as many instances as we want communicating UNIX processes.

- Secondly, each UNIX process needs access to the terminal. To simplify the connection between a UNIX process and the terminal, we assume that each instance of the application is started from its own window (its own shell tool). In this way the underlying window manager will solve the problem of directing input typed on the keyboard to the correct application, as well as making it possible for you to distinguish between output from different applications.
- Thirdly, the UNIX processes have to be connected so they can communicate with each other. We have decided to use sockets as communication media, and to let the UNIX processes form a ring. This means that when a UNIX process receives a message containing a line, it should print the line and send the message on to the next UNIX process in the ring, if it did not itself originally send the line message.

The SDL System

The SDL system with a behavior as outlined above is very simple. It contains, for example, only one process. The system can receive three types of signals, TermInput from the terminal, and Message and Terminate from the SDL system that is the previous node in the ring. The system will respond by sending Display to the terminal and Message and Terminate to the SDL system next in the ring. The signals TermInput and Display take a line (which is read from the terminal or should be printed on the terminal) as parameter. The signal Message takes a line and a PId value (the original sender in the ring) as parameter, while the signal Terminate takes a PId value (the original sender in the ring) as parameter.

The diagrams for the SDL system may be found in “Appendix C: The SDL System” on page 2820. In the section “Where to Find the Example” on page 2807, references to where to find the source code for this example are given.

Simulating the Behavior

At this stage of the development of the application, when the SDL system is completed but the environment functions are not implemented, it is time to simulate the SDL system to debug it at the SDL level. The runtime library *Simulation* is appropriate in this case for simulation.

There are six cases that should be tested:

- If TermInput (with a line not starting with a period) is sent to the system, it should respond by sending a Message signal to the environment. The first parameter in this signal should be equal to the parameter in the received TermInput signal. The second parameter should be the PId value of the sending process.
- If TermInput (with a line starting with a period) is sent to the system, it should respond by sending a Terminate signal to the environment. The parameter should be the PId value of the sending process.
- If Message (with a PId parameter not equal to the receiving process) is sent to the system, it should respond by sending a copy of the Message signal to the environment. It should also send Display to the environment with the received line as parameter.
- If Message (with a PId parameter equal to the receiving process) is sent to the system, it should respond by just sending a Display signal to the environment with the received line as parameter.
- If Terminate (with a PId parameter not equal to the receiving process) is sent to the system, it should respond by sending a copy of the Terminate signal to the environment. The execution of the program should then terminate.
- If Terminate (with a PId parameter equal to the receiving process) is sent to the system, the program should just stop executing.

Let us now verify that the SDL system behaves according to this. In the two executions of the simulation shown below, the cases described above are tested in the same order as they are listed.

Example 444: Execution Trace of Generated Application
Start program `Phone.sim.sct`:

```
Command : set-trace 6
Default trace set to 6
```

```
Command : next-transition

*** TRANSITION START
*      PId    : PhonePr:1
*      State  : start state
*      Now    : 0.0000
*** NEXTSTATE  idle

Command : output-via
Signal name : TermInput
 Parameter 1 (charstring) : 'hello'
Channel name :
Signal TermInput was sent to PhonePr:1 from env:1
Process scope : PhonePr:1

Command : next-transition

*** TRANSITION START
*      PId    : PhonePr:1
*      State  : idle
*      Input  : TermInput
*      Sender : env:1
*      Now    : 0.0000
*      Parameter(s) : 'hello'
*   DECISION  Value: true
*   DECISION  Value: false
*   OUTPUT of Message to env:1
*      Parameter(s) : 'hello', PhonePr:1
*** NEXTSTATE  idle
Command : output-via TermInput '.' -
Signal TermInput was sent to PhonePr:1 from env:1
Process Scope : PhonePr:1

Command : next-transition

*** TRANSITION START
*      PId    : PhonePr:1
*      State  : idle
*      Input  : TermInput
*      Sender : env:1
*      Now    : 0.0000
*      Parameter(s) : '.'
*   DECISION  Value: true
*   DECISION  Value: true
*   OUTPUT of Terminate to env:1
*      Parameter(s) : PhonePr:1
*** NEXTSTATE  idle

Command : output-via Message
 Parameter 1 (charstring) : 'hello'
 Parameter 2 (pid) : env
Channel name :
Signal Message was sent to PhonePr:1 from env:1
Process scope : PhonePr:1
```

```
Command : next-transition

*** TRANSITION START
*       PId     : PhonePr:1
*       State   : idle
*       Input   : Message
*       Sender  : env:1
*       Now     : 0.0000
*       Parameter(s) : 'hello', env:1
*    DECISION  Value: false

Signal Terminate was sent to PhonePr:1 from env:1
Process scope : PhonePr:1

Command : next-transition

*** TRANSITION START
*       PId     : PhonePr:1
*       State   : idle
*       Input   : Terminate
*       Sender  : env:1
*       Now     : 0.0000
*       Parameter(s) : env:1
*    DECISION  Value: false
*    OUTPUT of Terminate to env:1
*       Parameter(s) : env:1
```

```
*   TASK  Halt
```

Example 445 ----------

Start program `Phone.sim.sct`:

```
Command : set-trace 6
Default trace set to 6

Command : next-transition

*** TRANSITION START
*       PId     : PhonePr:1
*       State   : start state
*       Now     : 0.0000
*** NEXTSTATE  idle

Command : output-via Terminate
 Parameter 1 (pid) : PhonePr:1
Channel name :
Signal Terminate was sent to PhonePr:1 from env:1
Process scope : PhonePr:1

Command : next-transition

*** TRANSITION START
*       PId     : PhonePr:1
*       State   : idle
*       Input   : Terminate
*       Sender  : env:1
*       Now     : 0.0000
*       Parameter(s) : PhonePr:1
*   DECISION  Value: true
*   TASK  Halt
```

By running the system with the SDL monitor, as in the examples above, you may debug the system at the SDL level. The overall behavior of the system can thus be tested.

It is possible to start two instances of the simulation and have the simulators communicate with each other. Then Message and Terminate signals sent to the environment in one of the simulations will appear as signals coming from the environment in the other.

> **Note:**
>
> Do not forget the monitor command Start-SDL-Env to make the simulation programs start communicating.

The Environment

In the environment functions we use the socket facility in UNIX to implement the communication between the executing programs. **In the current example, the implementation is developed for SunOS 5.**

To simplify the example we assume that each instance of the application is started in a window of its own (a shell tool window under for instance X Windows, where UNIX commands can be entered). This means that we will have no problems with the interpretation of `stdin` and `stdout` in the programs.

The name of the socket for incoming messages for a certain instance of the application will be the string “Phone” concatenated with the UNIX process number for the current program. The socket will be created in the directory `/tmp`. Each application instance will print this number during the initialization and will then ask for the process number of the application instance where it should send its messages. You have to enter these numbers in such a way as to form a ring among the applications.

The Environment Functions

The environment functions, which may be found in the file `PhoneEnv.c`, are shown in section “Appendix D: The Environment Functions” on page 2823. The file is developed according to the structure discussed in the previous part of this chapter and uses the system interface header file generated from the SDL system.

As the `PhoneEnv.c` file includes `scttypes.h` and uses some C macros, it should be compiled using the same compiler options as the C file for the SDL system. For information about how to extend the generated make file to handle also non-generated files, please see “Makefile Options” on page 123 in chapter 2, *The Organizer*.

In the code for the environment functions a number of UNIX functions are used. Their basic behavior is described below. For any details please see the UNIX manuals available from Sun Microsystems.

Function name	Functionality
`getpid`	Returns the UNIX process number for the current program.
`socket`	Returns a new, unnamed socket.

Function name	Functionality
`bind`	Binds a socket to a name in the file system.
`listen`	Starts listen for other programs trying to connect to this socket.
`connect`	Should be called by other programs that want to establish a connection to the current socket.
`accept`	Accepts a connection request.
`select`	Returns 1 if anything readable can be found in any of the specified file descriptors, where a file descriptor can represent a file, a socket, and the terminal (`stdin` and `stdout`).
`read, write`	Reads or writes on a file (a file descriptor).
`close`	Closes a file.
`unlink`	Removes a file.

If we now look at the code for the environment functions (see "Appendix D: The Environment Functions" on page 2823), we see that `xInitEnv` mainly performs the following actions:

- It creates two unnamed sockets, one for message in (`Connection_Socket`) and one for messages out (`Out_Socket`).
- It binds `Connection_Socket` to the file system (in the `/tmp` directory) and starts listen for connections.
- It prints its UNIX process number.
- It reads the UNIX process number of the process where to send messages.
- It attempts to connect to the socket of the process where to send messages.
- It accepts the connection from the process that will send messages here.

In `xCloseEnv` the created sockets are closed and removed.

The `xInEnv` and `xOutEnv` functions follow the guidelines for these functions given in the reference section. In `xInEnv` the select function

is used to determine if any messages are ready to be received from the terminal (`stdin`) or from the incoming socket. An available message is then read and the information is converted to an SDL signal, which is sent to the SDL system using the `SDL_Output` function. In `xOutEnv` a test on the NameNode in the signal is used to determine the signal type. Depending on the signal type the appropriate information is written either on the outgoing socket or on the terminal (`stdout`).

Debugging

The first part of the debugging activity is, of course, when the SDL system is simulated and examined through the monitor system. Now we also want to include the environment functions during debugging. The intention of the library *ApplicationDebug* is to use the monitor and the environment functions together.

When the environment functions (`xInEnv`) read information from the keyboard there is, however, a problem in using `xInEnv` together with the monitor. In our system, for instance, a line typed on the keyboard may either be a monitor command or a line typed to the SDL system. As both the monitor and `xInEnv` are polling for lines from `stdin`, the interpretation of a typed line depends on which one first finds the line.

A better way is to eliminate this indeterministic behavior by not polling for typed lines in `xInEnv`. Instead, you may use the monitor command:

```
Output-Via TermInput 'the line'
```

to simulate a line typed on the keyboard. In this way all the other parts of the environment functions can be tested under the monitor. If you enclose the sections in `xInEnv` handling keyboard polling between `#ifndef XMONITOR` and `#endif` this code is removed when the monitor is used; that is if the library *ApplicationDebug* is used (see the code for `xInEnv` in "Appendix D: The Environment Functions" on page 2823).

A C source code debugger is of course also useful when debugging the environment functions. The initialization phase, `xInitEnv`, is probably the most difficult part to get working correctly in our system. All the source code for this function is available, and a C debugger can be used.

While debugging generated code from SDL at the C level, it is always easy to find the currently executing SDL symbol, by using the SDT references (see "Syntax" on page 917 in chapter 18, *SDT References*) in the C code and the *Go To Source* menu choice in the *Edit* menu in the

Organizer. For more details please see "Go To Source" on page 100 in chapter 2, *The Organizer*.

Running the Application

To have an application of the Phone system you now only need to make a new executing program with the library *Application*.

When you run the Phone system, start the program from two (or more) shell tools **(on UNIX)**. Each instance of the program will then print:

```
My Pid: 2311
Connect me to:
```

You should answer these questions in such a way that a ring is formed by the programs. When the initialization is completed for a program it prints:

```
******** Welcome to SDT Phone System ********
phone ->
```

The program is now ready to receive lines printed on the keyboard and messages sent from other programs. A Display signal received from another program is printed as follows:

```
display -> the line received in Display signal
```

Where to Find the Example

All files concerning this example may be found in the directory:

```
<installation directory>/sdt/examples/phone
```

Use these files if you only want to look at the source files and if you are using a Sun workstation you could try the executing versions of the program. Otherwise you should copy the files to one of your own directories. Please be sure not to change the original files.

In the directory you will find the following files:

File name	Purpose
`Phone.sdt`	The system file
`Phone.ssy`	Represents the SDL system

File name	Purpose
PhoneBl.sbk	Represents the SDL block
PhonePr.spr	Represents the SDL process
phone.pr	The generated PR file after GR to PR
phone.c	The generated C file after C code generation
phone.ifc	The generated .ifc file
PhoneEnv.c	Contains the environment functions
Phone.solaris.m	The make file for SunOS 5

Appendix A: Formats for ASCII

The ASCII encoding function, ASCII_ENCODE, encodes the SDL signal parameters and variables as ASCII characters before adding into the buffer. The output into the buffer is illustrated with a number of examples.

Braces { } are used for most data types and show where the data types start and stop. Signal parameters start and stop with braces.

Comma is used to delimit.

For more information about data types see "Using SDL Data Types" on page 42 in chapter 2, *Data Types*.

Array, CArray

`Array` is used to define a fixed number of elements.

`Array` takes two generator parameters, an index sort and a component sort.

Example 446: Using Array ----------

```
newtype A1 Array(b, Integer) endnewtype;

dcl Var_Array A1;

task Var_Array := (. 3 .);
```

Output to the buffer: {3,3,3}

Bag

`Bag` is almost the same as `Powerset`. The only difference is that `Bag` contains the same value several times. `Bag` can be used as an abstraction of other data types.

`Bag` takes one generator parameter, the item sort.

Example 447: Using Bag ----------

```
newtype B1 Bag(Integer) endnewtype;

dcl Var_Bag B1;
```

```
task Var_Bag := (. 7, 4, 7 .);
```

Output to the buffer: {2:7,1:4}

Example 448: Using Bag (old-style SDL operator code generation)

```
newtype B1 Bag(Integer) endnewtype;
dcl Var_Bag B1;
task Var_Bag := Incl(7, Incl(4, Incl(7, Empty)));
```

Output to the buffer: {2:7,1:4}

Bit

`Bit` can only take two values, 0 and 1.

Example 449: Using Bit

```
dcl Var_Bit Bit;
task Var_Bit := 1;
```

Output to the buffer: 1

Bit_String

`Bit_String` is used to represent a sequence of bits.

Example 450: Using Bit_String

```
dcl Var_Bit Bit_String;
task Var_Bit := Mkstring(I20(1101));
```

Output to the buffer: '1101'

Boolean

`Boolean` can only take two values, False and True.

Example 451: Using Boolean

```
dcl Var_Boolean Boolean;
```

```
task Var_Boolean := TRUE;
```

Output to the buffer: T

If `Var_Boolean` is set to FALSE, the output to the buffer will be F.

Character

`Character` is used to represent the ASCII characters.

Example 452: Using Character

```
dcl Var_Character Character;

task Var_Character := 'M'
```

Output to the buffer: M

CharStar, PId, UnionC, Userdef, VoidStar, VoidStarStar

The user has to define encoding/decoding procedures for these types, see "Appendix B: User defined ASCII encoding and decoding" on page 2818. If no encoding/decoding procedure is defined, then there will be no output to buffer.

For threaded integrations, the PId value will be encoded/decoded by coding the memory address as an integer.

CharString, IA5String, NumericString, PrintableString, VisibleString

These string types are used to represent sequences of characters.

Example 453: Using Charstring

```
dcl Var_Charstring Charstring;

task Var_Charstring := 'Hello world'
```

Output to the buffer: 'Hello world'

Choice, Union

`Choice` represents the ASN.1 concept CHOICE and can also be seen as a C *union* with an implicit tag field.

Example 454: Using Choice

```
newtype C Choice
  c1 Character;
  c2 Boolean;
endnewtype;

dcl Var_Choice C;

task Var_Choice := c2:true;
```

Output to the buffer: {1,T}, where 1 is an implicit tag.

Duration, Time

`Time` is used to denote ‘a point in time’ and `Duration` is used to denote ‘a time interval’.

A value of sort `Time` represents a point of time in the real world. The `Time` unit is usually 1 second.

Example 455: Using Time

```
dcl Var_Time Time;

task Var_Time := 1;
```

Output to the buffer: {1,0}. The first field is seconds and the second field is nano-seconds.

Enum

`Enum` contains only the values enumerated in a sort.

Example 456: Using Enum

```
newtype E /*Enum*/
  literals e1, e2, e3;
endnewtype;

dcl Var_Enum E;

task Var_Enum := e2;
```

Output to the buffer: 1

Float

`Float` is equivalent to *float* in C.

Example 457: Using Float

```
dcl Var_Float Float;

task Var_Float := 3.14159;
```

Output to the buffer: 3.1415901e0 (always 7 decimals)

GPowerset, Object_Identifier, String

`GPowerset` is used as an abstraction of other data types. `GPowerset` takes one generator parameter, the item sort.

`Object_Identifier` is a sequence of `Natural` values.

`String` can be used to build lists of items of the same type. `String` has two generator parameters, the component sort and the name of an empty string.

Example 458: Using GPowerset

```
newtype GP Powerset(Integer) endnewtype;

dcl Var_GPowerset GP;

task Var_GPowerset := Incl(7, Incl(4, Empty));
```

Output to the buffer: {3,4}

`Object_Identifier` and `String` are used in the same way as `GPowerset`.

Inherits, Syntype

`Syntype` and `Inherits` create a new type, that has the same properties as an existing type, by inheriting the type or make a syntype of the type.

Example 459: Using Syntype

```
syntype newinteger = Integer endsyntype;

dcl Var_Newinteger newinteger;
```

```
task Var_Newinteger := 2
```

Output to the buffer: 2

Integer, LongInt, ShortInt, UnsignedInt, UnsignedLongInt, UnsignedShortInt, Natural

`Integer` is used to represent mathematical integers.

`Natural` is a syntype of `Integer`.

Example 460: Using Integer

```
dcl Var_Integer Integer;

task Var_Integer := 1
```

Output to the buffer: 1

Null

The sort `Null` only contains one value, Null.

Example 461: Using Null

```
dcl Var_Null Null;

task Var_Null := Null;
```

Output to the buffer: 0

Octet

`Octet` is used to represent eight-bit values.

Example 462: Using Octet

```
dcl Var_Octet Octet;

task Var_Octet := I20(12);
```

Output to the buffer: 0c

Octet_String

`Octet_String` represents a sequence of `Octet` values.

`Octet_String` always contains an equal number of characters, since every octet takes two characters.

Example 463: Using Octet_String

```
dcl Var_OctetString Octet_String;

task Var_OctetString := Mkstring(I20(12));
```

Output to the buffer: ‘0c’

ORef, Own, Ref

`ORef, Own` and `Ref` are used to define pointer types.

Example 464: Using Ref

```
newtype R Ref(r1) endnewtype;

dcl Var_Ref R;

task Var_Ref := (. (. 1, 2, ‘Telelogic’ .) .);
```

Output to the buffer: {{1,2,’Telelogic’}}

Powerset

`Powerset` takes one generator parameter, the item sort, and implements a powerset over that sort. `Powerset` can be used as an abstraction of other data types.

Example 465: Using Powerset

```
newtype P Powerset(p1) endnewtype;

dcl Var_Powerset P;

task Var_Powerset := (. 4, 3 .);
```

Output to the buffer: ‘00110000000000000000000000000000’

The bits are an equal multiple of `sizeof(unsigned long)`.

Example 466: Using Powerset (old-style SDL operator code generation)

```
newtype P Powerset(p1) endnewtype;
```

```
dcl Var_Powerset P;

task Var_Powerset := Incl(4, Incl(3, Empty));
```

Output to the buffer: '00110000000000000000000000000000'

The bits are an equal multiple of `sizeof(unsigned long)`.

Real

`Real` is used to represent the mathematical real values.

Example 467: Using Real

```
dcl Var_Real Real;

task Var_Real := 1.0;
```

Output to the buffer: 1.0000000000000e0 (always 13 decimals)

SignalId

`SignalId` is used to describe the signal ID.

`SignalId` is a sequence with characters.

Example 468: Using SignalId

```
dcl Var_SignalId SignalId;

task Var_SignalId := 'Sig1';
```

Output to the buffer: 'Sig1'

Struct

`Struct` can be used to make an aggregate of data that belong together.

Example 469: Using Struct

```
newtype S struct
  s1 integer;
  s2 integer;
  s3 charstring;
endnewtype;
```

```
dcl Var_Struct S;

task Var_Struct := (. 1, 2, 'Telelogic' .);
```

Output to the buffer: {1,2,'Telelogic'}

Appendix B: User defined ASCII encoding and decoding

The types CharStar, PId, UnionC, Userdef, VoidStar, VoidStarStar do not have a natural transformation to ASCII format. The desired encoding probably differs from application to application. The ASCII encoding procedure and the ASCII decoding procedures do not encode or decode these types, but they can invoke user written procedures for encoding and decoding them.

For threaded integrations, the PId value will be encoded/decoded by coding the memory address as an integer.

If you want to add encoding for these types, then do the following steps:

- Implement a C-function for encoding with input and output parameters compatible with tEncodeFunc, which is declared in file “coderucf.h”. The encode functions in “coderascii.c” can be used as an example.
- Set static variable AsciiUserEncode to your encode function in xInitEnv.

If you want to add decoding for these types, then do the following steps:

- Implement a C-function for decoding with input and output parameters compatible with tDecodeFunc, which is declared in file “coderucf.h”. The decode functions in “coderascii.c” can be used as an example.
- Set static variable AsciiUserDecode to your decode function in xInitEnv.

Example 470 User defined ASCII encoding ––––––––––––––––––––

```
int MyAsciiEncoder( tBuffer Buf,
                    tSDLTypeInfo* TypeNode,
                    void* Value )
{
  /* my error handling code for one or more of
     CharStar, PId, UnionC, Userdef, VoidStar, VoidStarStar */
  /* return 1 if it was succesful,
     return 0 if it failed */
}

In xInitEnv:
```

```
  AsciiUserEncode = MyAsciiEncoder;
-------------------------------------------------------
```

Appendix C: The SDL System

ASN.1 Encoding and Decoding in the SDL Suite

This chapter is a reference manual for the ASN.1 encoding and decoding support in the SDL Suite. The support will help you to create applications and simulators that can both produce and decode protocol data units with bit patterns according to ASN.1 specifications and ASN.1 encoding rules. The SDL Suite supports BER (Basic Encoding Rules) and PER (Packed Encoding Rules).

In order for you to fully take advantage of this reference chapter, you should be familiar with the SDL Suite and the basics of ASN.1.

Note:

This chapter is not intended to describe the ASN.1 syntax or the general theory about ASN.1 encoding and decoding. This information can be found in the standard documents from ITU and from books about ASN.1.

Introduction

Supported Standards

The following standards are supported:

- ASN.1 according to ITU X.680, X.681, X.682 and X.683, 1997 version
- BER (Basic Encoding Rules) according to ITU X.690, 1997 version
- Basic PER (Packed Encoding Rules) according to ITU X.691, 1997 version, both aligned and unaligned variants.

Restrictions are listed in the Known Limitations chapter in the Release Guide.

Overview

The Abstract Syntax Notation One (ASN.1) is a notation language that is used for describing structured information that is intended to be transferred across some type of interface or communication medium. It is especially used for defining communication protocols.

SDL is suitable for specifying the semantic actions of a protocol, something that ASN.1 does not cover.

By using ASN.1 data types in the implementation of your application, you will optimize your development process. The following list displays some of the advantages of ASN.1:

- ASN.1 is a standardized, vendor-, platform- and language independent notation.
- A vast number of telecommunication protocols and services are defined using ASN.1. This means that pre-defined ASN.1 packages and modules are available and can be obtained from standardization organizations, RFCs, etc.
- When ASN.1 data types are transmitted over computer networks, their values must be represented in bit-patterns. Encoding and decoding rules determining the bit-patterns are already defined for ASN.1. The SDL Suite supports BER and PER encoding.

The SDL Suite support for ASN.1 consists of two major parts:

- An ASN.1 to SDL translator, ASN.1 Utilities, which allows you to use the ASN.1 types in your SDL systems.
- ASN.1 coders that will automatically encode your SDL values to bit-patterns and decode from bit-patterns to SDL values.

You can access the ASN.1 coders from SDL diagrams as well as from the C code.

Before you start the encoding and decoding steps, you must perform some preliminary steps. These are presented in chapter 8, *Tutorial: Using ASN.1 Data Types, in the Getting Started*.

Related Documents

Additional information about using ASN.1 and about encoding and decoding can be found in:

- chapter 8, *Tutorial: Using ASN.1 Data Types, in the Getting Started*
- chapter 13, *The ASN.1 Utilities*
- chapter 57, *Building an Application*
- chapter 65, *The Cmicro SDL to C Compiler*

Basic Concept

ASN.1 is suitable for specifying the information in a protocol and SDL is suitable for describing the semantic actions of a protocol. They are often used by standard bodies to specify protocol standards.

One of the main ideas behind ASN.1 is that you should be able to work with information in the protocol in the same way as you work with types and values in your implementation language. It should not be more difficult to create a bit-pattern in a protocol data unit then it is to assign a value to a variable. The encoder and decoder functions will automatically deal with all the details about bit-patterns and bit-layouts.

ASN.1 Utilities

The ASN.1 to SDL translator, *ASN.1 Utilities*, translates ASN.1 types and constants into SDL types and constants. An ASN.1 module generates an SDL package. This allows you to work with translated types and constants in the same way as any SDL type or constant. For instance, you can use them when you declare variables and when you declare signal parameters.

Information about ASN.1 to SDL translation and C representation of SDL data types is available in:

- chapter 13, *The ASN.1 Utilities*
- chapter 2, *Data Types, in the SDL Suite 6.2 Methodology Guidelines*

Encoding and Decoding

Encoding and decoding functionality consists of several parts.

First of all, it is the encoding and decoding algorithms themselves. You encode a variable or signal parameter into a bit-pattern by calling the encoder functions. You decode a bit-pattern into a variable or signal parameter by calling the decoder functions.

Another integral part of the coding functionality is the buffer handling. The decoder function takes the bit-pattern from the buffer and creates values for the application. The encoding function takes the internal value and encodes it into a sequence of bits in the buffer.

Error handling functionality is also present in the coding framework. Several types of errors can occur when encoding and decoding, such as buffer errors, incorrect values, decoding errors. Error handling functions allow to handle all possible erroneous situations.

Coding Access Interfaces

The coding functionality has got several access interfaces that allow you to access it in different ways.

It is possible to access encoding and decoding functions, call buffer functions and check error codes directly from the SDL diagram or from the C code in the environment files. For the C access interface, calls to encoder and decoder functions together with the appropriate buffer access procedures can be generated automatically if a few options in the user interface has been selected.

Basic SDL Interface and Extended SDL Interface

In SDL, you can use the basic interface or the extended interface. The basic interface is easy to use but gives you no possibility to control the buffer management. The extended interface gives you flexibility that the basic interface lacks.

The basic interface contains encode and decode functions which operates at SDL octet strings. The extended interface adds the possibility to access the buffer interface from within SDL and operates at a new type call CoderBuf. Furthermore, the extended interface contains a new type called CustomCoderBuf with which you could implement your own mapping between SDL and the encode and decode functions.

Within an SDL system, it is only possible to use one type of SDL interface. Either the SDL Basic Interface, the SDL Extended Interface with CoderBuf or the SDL Extended Interface with CustomCoderBuf.

C Code Interface

The coder library contains encoding and decoding functions and also several help functions for buffer management, error management and printing information. If you choose to call encoding and decoding from outside the environment files, note that:

- You need a file named `<ASN.1 module>.ifc` with necessary C declarations of types, literals and operators. The SDL to C Compiler

generates this file if you have added the ASN.1 module to your SDL system with a use package clause.

- You need generated C files and static kernel C files. These files will be present if you have generated an SDL system with your ASN.1 module.

General information about using .ifc files and writing C code with SDL is available in:

- chapter 57, *Building an Application*
- chapter 65, *The Cmicro SDL to C Compiler*

Solution

This section describes the structure and design of the encoding and decoding support in the SDL Suite. It is intended to give you an understanding of the solution.

Functionality

The main goal is to help you to develop executable files, applications or simulators, that can:

- produce BER/PER bit patterns
- consume and decode BER/PER bit patterns
- be configured to work with user specific environment (memory management, buffer management and error handling)

ASN.1 coder framework contains the following functional modules:

- Encoding and decoding functionality (see “Encoding and Decoding Functionality” on page 2838)
- Buffer Management System (BMS) (see “Buffer Management System” on page 2850)
- Memory Management System (MMS) (see “Memory Management System” on page 2866)
- Error Management System (EMS) (see “Error Management System” on page 2870)
- Debug print opportunities (see “Printing Opportunities” on page 2885)

All these modules will be described in more details in this chapter.

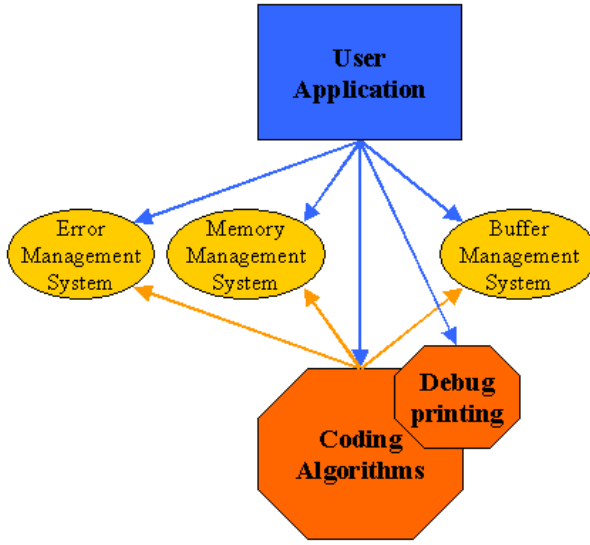

Figure 505: Relationship between functional modules of the encoding/decoding solution

Functionality Access Interfaces

When using the coder functionality, you can choose between different access interfaces. They all share the same implementation.

- **Basic SDL interface**

  SDL operators that put bytes in octet strings and read bytes from octet strings. Buffer access functions are not visible in this SDL interface. For more information see "Encoding/decoding the SDL Basic Interface" on page 2842.

- **Extended SDL interface**

  SDL `encode` and `decode` operators that put bytes in the types CoderBuf and CustomCoderBuf. Parts of the buffer management is

visible in the interface. For more information see "Encoding/decoding the SDL Extended Interface" on page 2844.

- **C code interface**

  This interface is used when calling the coders from C code, for example in the environment files. For more information see "C Encoding and Decoding Interface" on page 2838.

The SDL and C interfaces are not identical. They are adapted to the properties of the languages.

It is preferred to access the coders from SDL when the encoded bit-pattern must be further processed in the SDL system. One interesting example is when the bit pattern is sent in a signal to another process.

It is preferred to access the coders in C-code in the environment files when the SDL-system does not process the bit pattern internally, for example when sending it to a protocol in the environment.

Encoding and Decoding Functionality

Encoding and Decoding Functions

An encoding function encodes an SDL variable or signal parameter into a bit-pattern according to BER or PER. A decoding function decodes from a PER or BER bit-pattern to an SDL variable or signal parameter. You can access the encoding and decoding functions either from the C code (see "C Encoding and Decoding Interface" on page 2838) or from SDL diagrams (see "SDL Encoding and Decoding Interfaces" on page 2842).

C Encoding and Decoding Interface

The most common example of implementing coders in C is in the environment file. The SDL to C Compiler automatically generates an environment file with all needed calls. The coders can be accessed from any function or module implemented in C code.

There is one set of functions for BER and one set of functions for PER. The functions are accessed by using macros `BER_ENCODE` and `BER_DECODE`, respectively `PER_ENCODE` and `PER_DECODE`.

There is also a set of common functions which choose encoding rules dynamically according to the parameter written to the buffer by function `BufSetRule(buffer, rule)`, see "Buffer Management Functions" on page 2853. The functions are accessed by using macros `ASN1_ENCODE` and `ASN1_DECODE`.

Example 471 Dynamic encoding rules configuration ----------

```
   BufInitWriteMode(buf);
   BufSetRule(buf, er_PER | er_Aligned);
/* PER Aligned will be applied */

   ASN1_ENCODE( buf, (tASN1TypeInfo *)&yASN1_MyType1,
                (void *)&((yPDP_Sig1)(*S))->Param1));
   BufSetRule(buf, er_BER | er_Definite);
/* BER Definite will be applied */

   ASN1_ENCODE( buf, (tASN1TypeInfo *)&yASN1_MyType2,
                (void *)&((yPDP_Sig2)(*S))->Param1));
   BufCloseWriteMode(buf);
```

All the encode and decode macros, `ASN1_ENCODE`, `ASN1_DECODE`, `BER_ENCODE`, `BER_DECODE`, `PER_ENCODE` and `PER_DECODE` have three parameters:

- **First parameter**:

  The first parameter is a reference to a buffer of type `tBuffer` (see "Types and definitions" on page 2851). During encoding the resulting bit pattern will be stored in a memory section associated with the buffer. The buffer must be in the write mode when the `encode` function is called, because it writes bytes to the buffer. During decoding a bit pattern will be read from a memory section associated with the buffer. The buffer must be in read mode when the `decode` function is called, because it reads bytes from the buffer. For more information about buffer handling see "Buffer Management System" on page 2850.

- **Second parameter**:

  Pointer to ASN.1 type information (see "ASN.1 Type Information Generated by ASN.1 Utilities" on page 2841). All information that is needed about the type in the ASN.1 specification is represented in this type information. The reference to type information is of type `tASN1TypeInfo*`. The type information structure is a global variable with a name `yASN1_<type name>`. The reference to the type information structure is then `(tASN1TypeInfo*)&yASN1_<type name>`.

- **Third parameter**:

  Memory pointer to variable or signal parameter to encode or decode. The memory pointer is of type `void*` .

The buffer macro returns an error code which is a literal from an enumerated type (see "Error codes" on page 2873). The return value indicates whether the encoding or decoding procedure was successful or not. If this value is `ec_SUCCESS`, then procedure was successful.

Example 472: BER encoding of signal parameter ––––––––––––––––

In ASN1:

```
Message ::= SEQUENCE {
                        id     INTEGER,
                        info   INFOTYPE
                      }
```

In SDL:

```
SIGNAL Sig2(Message);
```

In xOutEnv:

```
BufInitWriteMode(buf);
BER_ENCODE( buf,
           (tASN1TypeInfo *)&yASN1_Message,
            (void *)&((yPDP_Sig2)(*S))->Param1));
BufCloseWriteMode(buf);
```

Example 473: PER encoding of signal parameters

In xOutEnv:

```
BufInitWriteMode(buf);
PER_ENCODE( buf,
            (tASN1TypeInfo *)&yASN1_Message,
            (void *)&((yPDP_Sig2)(*S))->Param1));
BufCloseWriteMode(buf);
```

Example 474: BER decoding of signal parameters

In xInEnv:

```
BufInitReadMode(buf);
BER_DECODE( buf,
           (tASN1TypeInfo *)&yASN1_Message,
            (void *)&((yPDP_Sig2)(S))->Param1));
BufCloseReadMode(buf);
```

Example 475: PER decoding of signal parameters

In xInEnv:

```
BufInitReadMode(buf);
PER_DECODE( buf,
           (tASN1TypeInfo *)&yASN1_Message,
            (void *)&((yPDP_Sig2)(S))->Param1));
BufCloseReadMode(buf);
```

ASN.1 Type Information Generated by ASN.1 Utilities

The encoder and decoder functions need information about the types from the ASN.1 specifications. This information is stored in type information structures, called type information nodes or simply type nodes. Almost all information about the types that you can find in the ASN.1 specifications is stored in the type information nodes.

The internal structure of the type information nodes is important in an implementation of encoding and decoding functions, but not from the application that calls the functions. There, it is only important to find a reference to a node. The internal details of the type nodes are not described in this section.

The type information nodes are represented in C code as a set of global read-only variables. The information in a node cannot be changed during execution. The nodes are linked to each other by using memory references. The type nodes can be declared as `const` variables by defining a macro, which means that in some application they can be moved to program memory or read only memory. For more information, see "Compilation switches" on page 2891.

The name of a node is `yASN1_<type name>`. A reference to a type node is simply a memory pointer to the type node cast to a basic type node declaration.

Example 476: Reference to a type node ––––––––––––––––––––––

If the type name is `Pdu1` in the ASN.1 specification, the reference to the type node is:

```
(tASN1TypeInfo*)&yASN1_Pdu1.
```

––

The nodes reflect the information in ASN.1 specifications and must be generated by ASN.1 Utilities. ASN.1 Utilities parses and analyzes the ASN.1 information and generates C code containing type nodes. One .c-file and one .h file per ASN.1 module is generated and the files are named `<module name>_asn1coder.c` and `<module name>_asn1coder.h`.

SDL Type and Operator Information Generated by the SDL to C Compiler

The encoder and decoder functions also need information generated by the SDL to C compiler, for example declarations of operators and literals for manipulating the translated ASN.1 types. This information is also stored in the type nodes.

ASN.1 utilities generates one SDL package for each ASN.1 module. The SDL to C Compiler generates one `.c` and `.h` file for each package, with type and operator information, together with one `.ifc` file for an external view of the types and operators. For more detailed information about the C code generation see "System Interface Header File" on page 2777 in chapter 57, *Building an Application*.

The ASN.1 type information files includes the `<package>.ifc` files. All relationships are resolved during compile and link time and the information is read-only at execution time.

SDL Encoding and Decoding Interfaces

In the SDL interface, the ASN.1 type information pointer is not seen. It is implicit and derived from the type of the memory pointer.

There are two types of coder interfaces available from within an SDL system: SDL basic interface (see "Encoding/decoding the SDL Basic Interface" on page 2842) and SDL extended interface (see "Encoding/decoding the SDL Extended Interface" on page 2844). In the SDL basic interface, the buffer reference is replaced with an octet_ string and the encoded bit-pattern is put directly in a variable of octet_string type. In the SDL extended interface, the buffer reference is CoderBuf or CustomCoderBuf.

Encoding/decoding the SDL Basic Interface

You can encode and decode directly from the SDL diagram by using the operators `encode` and `decode`.

The syntax of the `encode` function is:

```
result:= encode(encoded_octet_string, ASN1_variable)
```

The two parameters of the `encode` function are defined as:

- `encoded_octet_string` is an `Octet_string` that contains the encoded value of the ASN1_variable if the encoding was successful.

- `ASN1_variable` is the ASN.1 variable to be encoded.

The function returns an integer, `result`. If the value is equal to `ec_SUCCESS` the encoding was successful. For more information about return status see "SDL error interface" on page 2873.

The encoded value in the octet string could then be used in a signal sent to an other part of the system or to the environment.

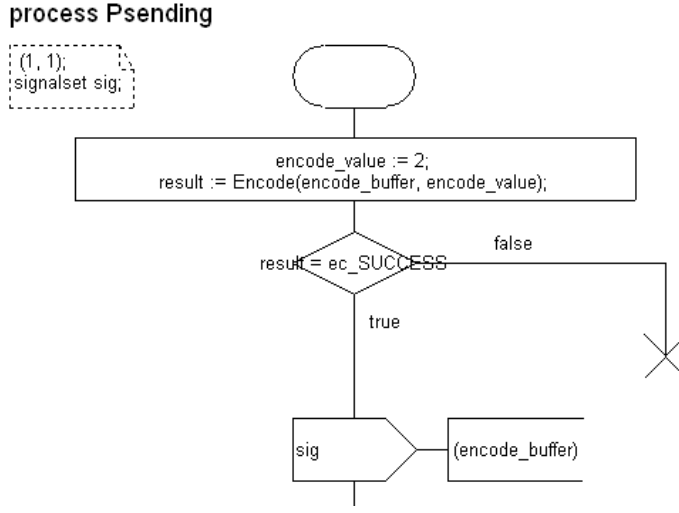

Figure 506 Example of a encode call in an SDL diagram

The syntax of the `decode` function is:

```
result:= decode(octet_string_to_decode,
ASN1_variable)
```

The two parameters of the `decode` function are defined as:

- `octet_string_to_decode` is an `Octet_string` that contains the encoded value to decode.
- `ASN1_variable` is the ASN.1 variable that will contain the result after the decoding was performed.

The function returns an integer, `result`. If the value is equal to `ec_SUCCESS` the encoding was successful. For more information about return status see "SDL error interface" on page 2873.

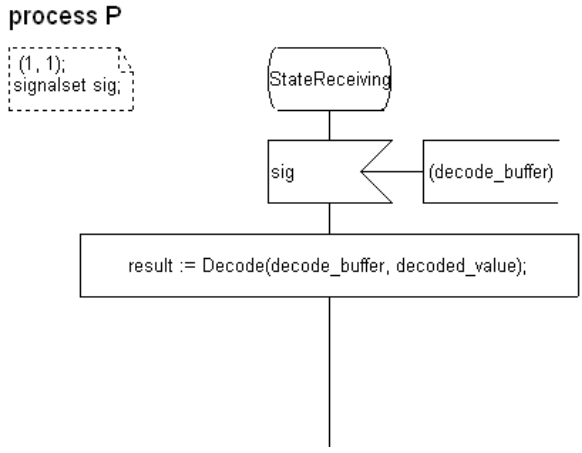

Figure 507 Example of a encode call (SDL Basic Interface)

Encoding/decoding the SDL Extended Interface

As with the Basic SDL Interface you can encode and decode directly from the SDL diagram by using the operators `encode` and `decode`.

The syntax of the `encode` function is:

```
result:= encode(CoderBuf, ASN1_variable)
```

The two parameters of the `encode` function are defined as:

- `CoderBuf` is a type defined in the file `CoderBuf.sdl` . It is a mapping of the buffer management C-interface (see "C interface to buffer management system" on page 2851). For more information about operations at CoderBuf see "SDL CoderBuf interface" on page 2862.
- `ASN1_variable` is the ASN.1 variable to be encoded.

The function returns an integer, `result`. If the value is equal to `ec_SUCCESS` the encoding was successful. For more information about return status see "SDL error interface" on page 2873.

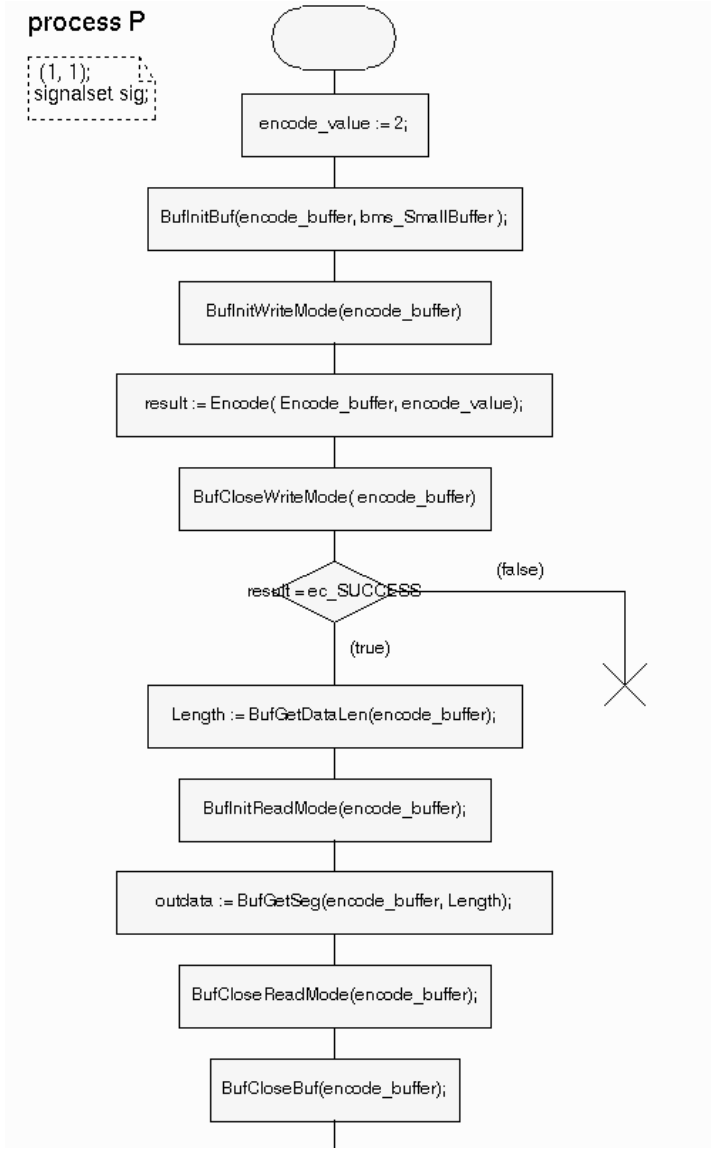

Figure 508: Example of en encode call (SDL Extended interface)

The syntax of the `decode` function is:

```
result:= decode(CoderBuf, ASN1_variable)
```

The two parameters of the `decode` function are defined as:

- `CoderBuf` is a type defined in the file `CoderBuf.sdl`. It is a mapping of the buffer management C-interface (see "C interface to buffer management system" on page 2851). For more information about operations at CoderBuf see "SDL CoderBuf interface" on page 2862.
- `ASN1_variable` is the ASN.1 variable that will contain the result after the decoding was performed.

The function returns an integer, `result`. If the value is equal to `ec_SUCCESS` the encoding was successful. For more information about return status see "SDL error interface" on page 2873.

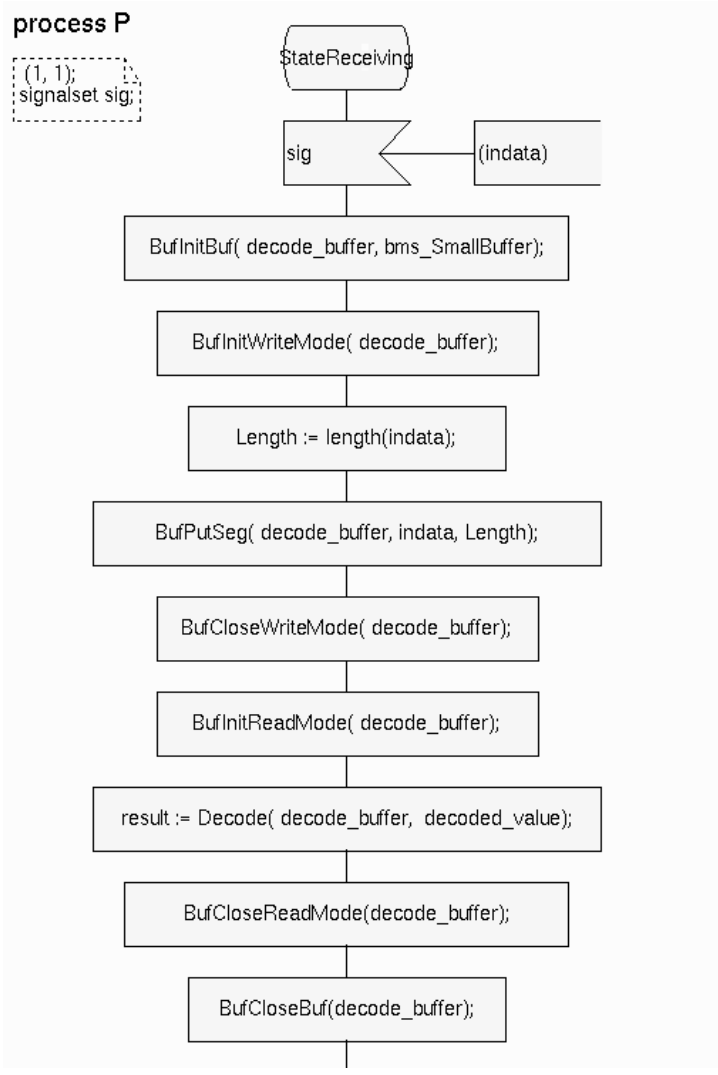

Figure 509: Example of decode call (SDL Extended Interface)

How to Include the Extended SDL Interface in Your System

Add the package in the Organizer. In the directory `<installation_directory>/sdt/include/ADT/` there are two versions of the BufferInterface package. One for C, `CoderBuf.sun`, and one for C++, `CoderBufCPP.sun` . When the package is included in the Organizer, add a use statement of the BufferInterface in your system.

> **Note: Types in the BufferInterface package**
>
> In the BufferInterface package BasicCTypes and CPointer or the corresponding C++ versions of those files are included. This must be considered when using `cpp2sdl` together with your system so that those files are included only once.

The Extended SDL Interface in the Simulator

You can display the value of a CoderBuf and change it when running the Simulator by using the commands examine-variable and assign-variable. If you have written your own buffer you can add information in the provided files to be able to use them in the Simulator, see below.

Examine CoderBuf

Command: ex-va encode_buffer

encode_buffer (CoderBuf) = bms_UserBuffer(NM)3'020102'H

bms_UserBuffer is the buffer type, (NM) shows the current mode of the coderbuffer(NoMode, ReadMode or WriteMode), 3 is the length of the coder buffer value in bytes and '020102'H is the value of the coder buffer in octet string form

Limitations:

Examining the value when the coder buffer is in Write Mode is not possible.

If the user has defined a new buffer type other than Small Buffer and User buffer the buffer type will not be displayed.

Example:

encode_buffer (CoderBuf) = BufferType(NM)3'020102'H

To display the right buffer type the user has to do some modifications in the write function (yWri_CoderBuf) in the file CoderBuf.sdl.

Only the first 100 bytes of a coder buffer value are displayed during simulation.

Assign new values to a coder buffer:

Command: ass-va encode_buffer 2 '0101'H ReadMode(RM)

Value assigned:

encode_buffer (CoderBuf) = bms_UserBuffer(RM)2'0101'H

When you assign value to a coder buffer:

Command: ass-va <length> <value> <Mode>

Length is the length of the value in bytes. Value is the new value (octet string). Mode, the user sets the mode of the coder buffer (Read, Write and No).

In order for the assignment to be successful the user has to give the two first parameters; otherwise the command will not be executed. An error message will be displayed to the user.

If the length of the value passed as parameter is less than the length passed as parameter, extra zeros (0) are added to the octet string to match the length passed by the user. If the length of the value passed as parameter is greater than the length passed as parameter, then the octet string to be assigned will be cut to match the length.

If the user does not choose the buffer mode, the buffer mode will be set to No Mode (default).

Limitations:

If the user has defined a new buffer type other than Small Buffer and User buffer, the user has to do some modifications in the read function (yRead_CoderBuf) in CoderBuf.sdl in order to initiate the new coder buffer to be assigned to the old coder buffer with right coder buffer type.

The maximum size of the coder buffer is assumed to be 128 Mega bytes.

Buffer Management System

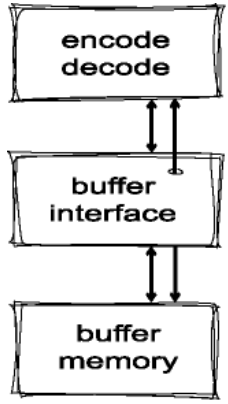

Figure 510: Relationship between coders and buffer management

The buffer interface is a set of functions that operates with data. Buffer management stores data in the buffer memory. Data is presented as `byte`, `bit` or `character segment`. Available basic operations are `get`, `put`, `peek` and `skip`. The buffer interface also opens a possibility for direct access to buffer memory from BMS environment (from encode and decode). According to this there is direct access to the buffer memory which presented as one continuos piece.

The buffer management functions have an open design, where it is possible to choose between different buffer implementations with different characteristics. This choice is available in runtime mode and also within compilation by switches defined in "Buffers configuration" on page 2896. This is possible due to an open and specified buffer interface that all encode and decode functions use and that your SDL specifications and C functions should use as well. The interface is specified as a set of C macros. See "C interface to buffer management system" on page 2851 for more information. The buffer management implements all the macros in the interface.

The buffer management is accessed from an SDL system by using operators in the buffer management Abstract Data Type. The operators are mapped to the open buffer management interface.

The only buffer management implementation at present in the SDL Suite is the small buffer (see "Small Buffer Implementation" on page 2862).

C interface to buffer management system

This chapter describes the open buffer interface. This is the C access interface to the buffer management.

Types and definitions

The buffer access type is `tBuffer`. `tBuffer` is defined as a pointer to a structure `tCoder`.

Example 477: Buffer as a reference ––––––––––––––––––––––––––

```
tBuffer buf = NULL;
BufInitBuf(buf, bms_SmallBuffer);
```

`tCoder` is used as access type only in tiny mode (see Example 487 on page 2896).

BMS introduces several specific types which are described below.

tBMSLength

BMS length type is defined as `unsigned long`.

tBMSUserMemory

This type is structure describing information about memory provided by the user. It contains three fields:

- `MemSize` of type `tBMSLength` - size of the provided memory
- `DataLength` of type `tBMSLength` - size of the data written to the provided user memory
- `MemPtr` of type `void *` - pointer to the provided memory

This type is used as parameter type in the buffer interface functions `BaseBufInitBufWithMemory` and `BaseBufCloseBufToMemory`.

tBMSBufType

This type is an enumeration describing all following possible types of buffers. Two types of buffers are available:

- `bms_SmallBuffer` - predefined buffer type (see "Small Buffer Implementation" on page 2862)
- `bms_UserBuffer` - type denoting user defined buffer (see "User defined Buffer Handling" on page 2864)

This type is used for specifying the type of buffer which will be used.

tERRule

This type is an enumeration describing possible kinds of encoding rules. It contains basic rules (BER, PER, etc.) as well as their different variations:

- `er_BER`
- `er_Definite`
- `er_Indefinite`
- `er_PER`
- `er_Aligned`
- `er_Unaligned`
- `er_NoEndPad` - PER without end padding
- `er_UER` - User defined encoding rules
- `er_NoRule`

The enumeration values are regarded as bit masks for different kinds of encoding rules, for example, PER Aligned can be specified with `er_PER | er_Aligned`; expression `( SpecifiedRule & ( er_PER | er_Aligned ) )` will check if the specified type of encoding rules `SpecifiedRule` is PER Aligned.

tBMSMode

This type is an enumeration describing possible modes for the buffer:

- `bms_ReadMode` - reading mode, writing is allowed for appending. See `BufSetAppendBufFunc( buffer, func )` for more information.
- `bms_WriteMode` - writing mode, reading is not allowed
- `bms_NoMode`

Buffer Management Functions

The buffer management functions put bytes and bits into a buffer which you can use to send over a protocol. The buffer management also provide several interfaces to operate with buffer memory and buffer handling.

The internal implementation of the buffer is not shown in the buffer interface, thus all manipulation of the buffer should be done using the macros. A buffer must be created before use. It must be opened before a read/write session and closed after a session. A buffer can be in either a read mode or a write mode, but not in both modes at the same time.

The open buffer interface macros are described below (parameter `buffer` in all functions is of type `tBuffer`, see "Types and definitions" on page 2851):

- `BufInitBuf( buffer, buffer_type )`

  This function is used to initialize the buffer management. Memory used by the buffer is allocated by `CUCF_ALLOC` function, so memory management used in the buffer handling can be configured by means of MMS configuration opportunities (see "User defined Memory Handling" on page 2868). The second parameter is the type of the buffer (see "tBMSBufType" on page 2851). The function returns error status (see "Error codes" on page 2873).

- `BufCloseBuf( buffer )`

  Closes a buffer and if the buffer has not been initialized by the user memory, releases buffer memory by using `CUCF_FREE`. The function returns error status (see "Error codes" on page 2873).

- `BufInitBufWithMemory( buffer, buffer_type, user_memory)`

  This function initializes the buffer with the user memory provided in the third parameter (see "tBMSUserMemory" on page 2851) without allocating any memory. If user memory contains any encoded data, the buffer can be used further by the decode function. The second parameter is the type of the buffer (see "tBMSBufType" on page 2851). The function returns error status (see "Error codes" on page 2873).

- `BufCloseBufToMemory( buffer, user_memory )`

This function closes the buffer. It does not release any memory, but returns it in the `user_memory` parameter of type "tBMSUserMemory" on page 2851 passed by reference. The function returns error status (see "Error codes" on page 2873).

- `BufGetMemory( buffer, length )`

  Returns pointer to the buffer memory. The second parameter is used for returning. It is pointer to the length of memory.

- `BufAppendMemory( buffer, append_length )`

  Used for the appending of the buffer memory with required `append_length`. Returns pointer to the beginning of the memory (root).

- `BufGetDataCurr( buffer, bit_position )`

  Returns current data pointer in the buffer handling. The second parameter is used for returning. It is a pointer to a char with current bit position in the buffer handling. This function is used by the decoder.

- `BufSetDataCurr( buffer, length, bit_position )`

  Used to increment current data pointer by `length` in the buffer handling and also sets current bit position to `bit_position` there. This function is used by the decoder.

- `BufGetDataEnd ( buffer, bit_position )`

  Returns end data pointer in the buffer handling. The second parameter is used for returning. It is a pointer to a char with the end bit position in the buffer handling. This function is used by the encoder and decoder.

- `BufSetDataEnd ( buffer, length, bit_position )`

  Uses to increment end data pointer by `length` in the buffer handling and also sets end bit position to `bit_position` there. This function is used by encoder.

- `BufCopyBuf( buffer_dst, buffer_src )`

  This function copies the source buffer `buffer_src` to target buffer `buffer_dst`. The function returns error status (see "Error codes" on page 2873).

- `BufInitReadMode( buffer )`

Prepares the buffer for read operations (read mode, see "tBMSMode" on page 2852) and puts the current pointer to the start of the buffer data. The buffer content is not changed or released. The function returns error status (see "Error codes" on page 2873).

- `BufCloseReadMode( buffer )`

  Closes read mode for the buffer. The buffer content is not changed or released. The function returns error status (see "Error codes" on page 2873).

- `BufCloseDeleteReadMode( buffer )`

  Closes read mode for the buffer and logically (without memory releasing) removes read bytes from buffer. Bytes that are not read are still in the buffer. The function returns error status (see "Error codes" on page 2873).

- `BufInitWriteMode( buffer )`

  Prepares the buffer for write operations (write mode, see "tBMSMode" on page 2852) and sets the current pointer to the start of the buffer. Previous information in buffer is logically lost (the bytes are still there but they are considered to be empty). The function returns error status (see "Error codes" on page 2873).

- `BufCloseWriteMode( buffer )`

  Closes write mode for the buffer. The buffer content is not changed or released. The function returns error status (see "Error codes" on page 2873).

- `BufGetBufType( buffer )`

  Returns the type of the buffer, see "tBMSBufType" on page 2851. It can be useful when the system supports more than one buffer interface and the type of the buffer is not obvious and can change dynamically.

- `BufGetDataLen( buffer )`

  Returns the byte length (see "tBMSLength" on page 2851) of all data that is physically present in the buffer.

- `BufGetDataBitLen( buffer )`

  Returns the bit length (see "tBMSLength" on page 2851) of all data that is physically present in the buffer.

- `BufGetReadDataLen( buffer )`

  Returns the byte length (see "tBMSLength" on page 2851) of the information which has been read from the buffer.

- `BufGetReadDataBitLen( buffer )`

  Returns bit length (see "tBMSLength" on page 2851) of the information which has been read from the buffer.

- `BufGetValueLen( buffer )`

  Returns byte length (see "tBMSLength" on page 2851) of the last value encoded to the buffer or decoded from the buffer.

- `BufGetValueBitLen( buffer )`

  Returns bit length (see "tBMSLength" on page 2851) of the last value encoded to the buffer or decoded from the buffer.

- `BufGetMode( buffer )`

  Returns buffer mode, see "tBMSMode" on page 2852.

- `BufInReadMode( buffer )`

  This is a boolean function returning `true` if the buffer is in the read mode (see "tBMSMode" on page 2852).

- `BufInWriteMode( buffer )`

  This is a boolean function returning `true` if the buffer is in the write mode (see "tBMSMode" on page 2852).

- `BufInNoMode( buffer )`

  This is a boolean function returning `true` if the mode of the buffer is not defined.

- `BufSetRule( buffer, rule )`

  This function sets the encoding rules to the buffer. Each setting overrides the previous. They are checked later in the encode and decode functions. The second parameter is combination of encoding rule masks of type `tERRule` (see "tERRule" on page 2852), it is automatically cast to `unsigned long`, which is the type of the second parameter. For example, PER without end padding encoding rule is set with an expression `BufSetRule(er_PER | er_NoEndPad)`. If not a complete set of rules is specified then `BufSetRule` will use default settings, for example `BufSetRule(er_PER)` is used (with-

out bit masks `er_Aligned`, `er_Unaligned` and `er_NoEndPad`), then default PER variant will be applied which is configured by compilation switches, see "Compilation switches" on page 2891. The BufGetRule will return the encoding rules including those that have been applied depending on default settings.

- `BufGetRule( buffer )`

  This function returns value of type `unsigned long` which can be checked by binary "AND" operation with bit masks of type `ERRule` (see "tERRule" on page 2852), for example, `(SpecifiedRule & er_PER)` returns true if specified rule is PER.

Caution! Checking specified encoding rules

```
unsigned long SpecifiedRule = BufGetRule( buffer );
```

`( SpecifiedRule & er_PER & er_Aligned )` is not a correct check for PER Aligned.

`( SpecifiedRule & ( er_PER | er_Aligned ) )` should be used instead.

- `BufGetUserData( buffer )`

  This function returns a reference to the user data defined by `tUser-Data` type (see "User Data" on page 2884).

- `BufSetErrInitFunc( buffer, func )`

  This function sets a reference to the user error handling function. The interface is available only if `CODER_REMOVE_PATH` compile switch is absent (see "Error handling configuration" on page 2898).

- `BufGetErrInitFunc( buffer )`

  This function returns a reference to the user error handling function. `NULL` is returned if the function has not been set. The interface is available only if `CODER_REMOVE_PATH` compile switch is absent (see "Error handling configuration" on page 2898).

- `BufGetErrorPath( buffer )`

  This function returns a reference to the `tErrorPath` structure that contains a path of fields from the root type up to the field where an error has occurred. The C-representation of the `tErrorPath` is:

  ```
  typedef struct
  ```

```
{
  void*          Fields[CODER_PATH_DEEP];
  unsigned long  NumOfFields;
  ...
} tErrorPath;
```

where `CODER_PATH_DEEP` is the maximum number of nested types, see "Error handling configuration" on page 2898. It is used within the user error handling function. The interface is available only if `CODER_REMOVE_PATH` compile switch is absent (see "Error handling configuration" on page 2898). The first element in the `Fields` array is a reference to the root Type Info - `tASN1TypeInfo*`. The next element might be one of the following:

`tASN1Component*` - for the SEQUENCE/SET component

`tASN1Alternative*` - for the CHOICE alternative

`tASN1Object*` - for an open object

`long*` - for the SEQUENCE OF/SET OF item index

- `BufGetMainVal( buffer )`

  This function returns a reference to the encode/decode value and it is used in the user error handling to assign the default contents to the value if an error has occurred. The interface is available only if `CODER_REMOVE_PATH` compile switch is absent(see "Error handling configuration" on page 2898).

- `BufSetErrorCode( buffer, error_code )`

  This function sets an error code (see "Error codes" on page 2873) to the buffer.

- `BufGetErrorCode( buffer )`

  This function returns an error code (see "Error codes" on page 2873).

- `BufGetByte( buffer )`

  Reads one byte from the buffer and returns it in a variable of type `unsigned char` after logically removing it from the buffer. The byte that has been returned will not be read from the buffer once again by another reading procedure. This function returns `unsigned char`.

- `BufPeekByte( buffer )`

Takes one byte from the buffer and returns it in a variable of type `unsigned char` without removing it from the buffer. The byte that has been returned can be peeked from the buffer any number of times. This function returns `unsigned char`.

- `BufPutByte( buffer, byte )`

  Puts one byte from the second parameter of type `unsigned char` to the buffer.

- `BufGetSeg( buffer, length )`

  Reads a segment of length (see "tBMSLength" on page 2851) bytes from a buffer and returns a segment pointer that points at the start of the retrieved segment. Note that this pointer should not be freed, because it is pointing into the memory segment of the buffer. The segment that has been returned will not be read from the buffer once again by another reading procedure. This function returns `unsigned char*`.

- `BufSkipSeg( buffer, length )`

  Skips `length` (see "tBMSLength" on page 2851) bytes from the buffer.

- `BufPeekSeg( buffer, length )`

  Takes `length` (see "tBMSLength" on page 2851) bytes from the buffer and returns a segment pointer from buffer without moving current pointer in a variable of type `unsigned char*`. The segment that has been returned can be peeked from the buffer any number of times. Note that this pointer should not be freed, because it is pointing into the memory segment of the buffer.

- `BufPutSeg( buffer, segment, length )`

  Puts a whole segment of `length` (see "tBMSLength" on page 2851) bytes to the buffer. The second parameter `segment` is of type `unsigned char*` and is a pointer to the segment start.

- `BufGetBit( buffer )`

  Reads one bit from the buffer and returns it in a variable of type `unsigned char` after logically removing it from the buffer. The bit that has been returned will not be read from the buffer once again by another reading procedure. This function returns `unsigned char`, where returned bit is the right-most bit in the `unsigned char` value.

- `BufPutBit( buffer, bit )`

  Puts one bit which is the right-most bit of function parameter of type `unsigned char` to the buffer.

- `BufGetBits( buffer, number )`

  Reads `number` bits from the buffer and returns them in `number` right-most bits in a variable of type `unsigned long` after logically removing them from the buffer. The bits that have been returned will not be read from the buffer once again by another reading procedure. The second parameter `number` is of type `unsigned char`. Bits are returned in a variable of type `unsigned long`, so `number` should be less or equal to `sizeof(unsigned long)*8`.

- `BufPutBits( buffer, bits, number )`

  Puts `number` right-most bits from a variable of type `unsigned long` to the buffer. Bits are passed in a variable of type `unsigned long`, so `number` should be `<= sizeof(unsigned long)*8`.

- `BufAlign( buffer )`

  This procedure skips all the bits from the buffer till the end of the byte.

- `BufSetAppendBufFunc( buffer, func )`

  Sets a reference to an append function. The append function is called when there are not enough bytes left in the buffer for a get operation and more bytes must be put into the buffer. Default is no append function.

Example 478: Sending a buffer ----------

```
unsigned char * data;
unsigned int    datalen;

BufInitReadMode(buf);
datalen = BufGetDataLen(buf);
data = BufGetSeg(buf,datalen);
send_protocol(sa,data,datalen);
BufCloseReadMode(buf);
```

Example 479: Receiving from protocol and putting in a buffer ------

```
unsigned char data[MAXSIZE];
unsigned int datalen;
```

```
BufInitWriteMode(buf);
datalen=1;
while(datalen>0) {
   datalen = receive_protocol(sa,data,MAXSIZE,0);
   if (datalen>0)
      BufPutSeg(buf,data,datalen);
}
BufCloseWriteMode(buf);
```

You can write an append function that will be called when there are not enough bytes left in the buffer for a read operation. An example of when this can occur is during the execution of a decode function. The calling function calculates how many bytes that must be added to the buffer. The append function can choose to add more bytes than this. An append function can be called several times during a decode execution.

The buffer is in write mode when the append function is called and will automatically be set to read mode after the append function is finished. Do not use the `BufInitWriteMode` or `BufInitReadMode` macros in the append function.

If you want to add an append function for a buffer, then do the following steps:

1. Implement a C-procedure for appending data to the buffer. The C-procedure must have parameters compatible with `tBufAppend-Func`.

   ```
   typedef void (*tBufAppendBufFunc)(tBuffer buf,
   unsigned int len);
   ```

2. Use the macro `BufSetAppendBufFunc`, with the buffer and the append procedure as input parameters, immediately after a call to `BufInitBuf`.

Example 480: Buffer Append Procedure ----------

```
void MyAppendBuf( tBuffer buf,
                  unsigned int minbytes );
{
    /* receive at least minbytes from
       protocol or sockets or ... */

    BufPutSeg(buf,seg,len );
}
```

Setting appending function:

```
BufInitBuf(buf);
```

```
BufSetAppendBufFunc(buf,MyAppendBuf);
```

- `BufGetAppendBufFunc( buffer )`

  Returns a reference to an append function. Returns `NULL` if the append function does not set.

Small Buffer Implementation

A small buffer has a memory segment, an array of `unsigned char`. The encoded bit patterns are written to this segment and the bit patterns to decode are read from it.

The buffer pointer is a pointer to a control structure and a data structure. The control structure and the data structure contains information and memory pointers that the small buffer uses.

In the data structure, there is a pointer that points at the beginning of the memory segment, a pointer that points at the end of the memory segment and a pointer that points at current position for a read or write operation.

Memory is allocated inside the small buffer implementation. An initial memory segment is allocated. The size of the initial segment is set by defining the macro `CODER_SMALLBUF_SIZE`, which has the default value equal to 0x1000, see "Buffers configuration" on page 2896. When a memory segment is full and a bigger segment is needed, then a 2 times larger segment is allocated, the contents in the old segment copied and the old segment freed. The macros `CUCF_ALLOC` and `CUCF_FREE` are used for all memory allocation and de-allocation.

SDL Interface to Buffer Management System

SDL CoderBuf interface

In the Extended SDL Interface, encoded data is stored in the C-buffer interface. From SDL, this data is accessed via the SDL type CoderBuf. The interface is not a direct mapping of the C-interface. Some of the functions are not accessible from SDL. For more detailed information about C-interface to the buffer management system see "C interface to buffer management system" on page 2851.

Below is a summary of the contents in the file `CoderBuf.sdl`.

Types

The SDL buffer interface type names are the same as the ones in the C buffer interface (see "Types and definitions" on page 2851). The following type is introduced in the SDL buffer interface

- Type `ptr_tBMSUserMemory` is a pointer to `tBMSUserMemory`.

Operators

- `BufInitBuf : CoderBuf, tBMSBufType [-> int];`
- `BufInitBufWithMemory : CoderBuf, tBMSBufType, ptr_tBMSUserMemory [-> int];`
- `BufCloseBuf : CoderBuf [-> int];`
- `BufCloseBufToMemory : CoderBuf, ptr_tBMSUserMemory [-> int];`
- `BufInitReadMode : CoderBuf [-> int];`
- `BufInitWriteMode : CoderBuf [-> int];`
- `BufCloseReadMode : CoderBuf [-> int];`
- `BufCloseDeleteReadMode : CoderBuf [-> int];`
- `BufCloseWriteMode : CoderBuf [-> int];`
- `BufGetDataLen : CoderBuf -> tBMSLength;`
- `BufGetReadDataLen : CoderBuf -> tBMSLength;`
- `BufGetByte : CoderBuf -> unsigned_char;`
- `BufPeekByte : CoderBuf -> unsigned_char;`
- `BufPutByte : CoderBuf, unsigned_char;`
- `BufSetRule : CoderBuf, tERRule;`
- `BufGetRule : CoderBuf -> tERRule;`
- `BufCopyBuf : CoderBuf, CoderBuf [-> int];`
- `BufPutSeg : CoderBuf, Octet_string, int;`
- `BufGetSeg : CoderBuf, int -> Octet_string;`
- `BufPeekSeg : CoderBuf, int -> Octet_string;`

These operators are mapped to the C buffer interface functions, so the semantics of SDL operators is the same as described for the corresponding C procedures in "Buffer Management Functions" on page 2853.

SDL CustomCoderBuf interface

If you want a solution of your own for accessing the coder library from within SDL, you can use `CustomCoderBuf`. This can be achieved by modifying the file `CustomCoderBuf.sdl` and writing two C-procedures. `CustomCoderBuf` can then be used in the calls of `encode` and `decode` instead of `CoderBuf`.

If only minor changes are of interest, you could copy the `CoderBuf.sdl` file to `CustomCoderBuf.sdl` as a start. Even when the goal is to make a completely new access interface, `CoderBuf.sdl` could be used as an example.

Implementing the procedures `ASN1EncodeCustomBuf` and `ASN1DecodeCustomBuf` in a file of your own, means that the file should then be included in the build process. For further information about parameters and return values of those procedures see the file `cucf_er_sdt.h` in the coder library. When `CustomCoderBuf` is selected in the user interface, the code generator generates code that calls those two procedures.

The procedures `ASN1EncodeCoderBuf`/`ASN1DecodeCoderBuf` and `ASN1EncodeOctet`/`ASN1DecodeOctet` could be seen as SDL Suite versions of a CustomCoderBuf. The first parameter in that implementation is `CoderBuf` and `Octet_string` respectively. When implementing your own `CustomCoderBuf`, you can select whatever type of this first parameter you want. However, it is important that the type defined in `CustomCoderBuf.sdl` file corresponds to the first parameter of the two above procedures.

The choice of using a custom implementation must be selected in the Analyzer dialog. See "Analyze SDL" on page 113 in chapter 2, *The Organizer*.

User defined Buffer Handling

The coder library can be configured to work with user defined buffers. It is possible to write your own specific buffer handling procedures which will be invoked instead of the default buffer handlers.

All coder library buffer implementations are based on the open buffer interface approach which allows you to introduce user types of buffer management in the same style as, for example, predefined small buffer management implementation.

If you want to use your own buffers, then perform the following steps:

1. Define the structure `UserBufFuncs` of type `tBaseBuf` (see "Types and definitions" on page 2851).
2. Set the value `bms_UserBuffer` to the field `BufType`.
3. Implement the buffer access functions and assign references to these functions to the corresponding fields of `UserBufferFuncs`. Buffer access functions should have compatible interfaces with the function pointer types defined for `tBaseBuf` structure in the file `bms.h` (see "Buffer Management System sub-directory" on page 2889) and should support the semantics of buffer access functions described in "Buffer Management Functions" on page 2853.

Note: Buffer implementation example

The small buffer implementation is based on the open buffer interface and can be used as an example of a user defined buffer implementation. Looking into the files `bms_small.h` and `bms_small.c` in the installation (see "Buffer Management System sub-directory" on page 2889) will be helpful before starting the implementation.

4. Compile coder library with `CODER_USE_USERBUF` compile switch, see "Buffers configuration" on page 2896,
5. Compile and link the application with the user buffer handling functions and the defined structures.

Memory Management System

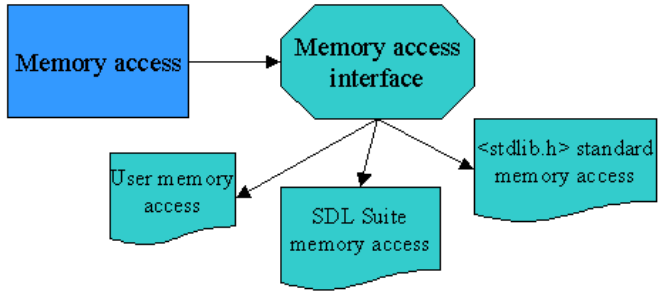

Figure 511: Memory management

The coder solution contains memory management functions. There are only two basic functions used for memory management: alloc and free.

Memory management in the coder library consists of allocation and freeing of memory, and releasing of memory in case of errors.

Coder library contains two levels of memory access functions:

- Pure allocation and freeing of memory - `CUCF_ALLOC(size, type)` and `CUCF_FREE(ptr, size, type)`,
  - where `size` is of type `size_t` and represents the size of memory in bytes to be allocated,
  - `type` is not used (reserved for the future),
  - `ptr` is of type `void*` and is a pointer to the memory to be released.
- Safe memory allocating and releasing - `CUCFAlloc(info, size, type)`, `CUCFFree(info, ptr, size, type)` and `CUCFRelease(info, ptr)`, where `size`, `type` and `ptr` are the same as for the previous memory handling functions. Apart from allocating, `CUCFAlloc` function saves a pointer to the allocated memory block in the internal stack, which is used for memory freeing in case of error. The first parameter `info` in these three memory handling functions is of type `tEMSInfo*` and it is a pointer to the stack where all

allocated memory segments are stored. Safe functions use pure memory management functions for memory operations. `CUCFAlloc` calls `CUCF_ALLOC` for allocating memory for storage cell in the stack and for allocating `size` required bytes, `CUCFFree` frees memory pointed by `ptr` and also the corresponding stack cell.

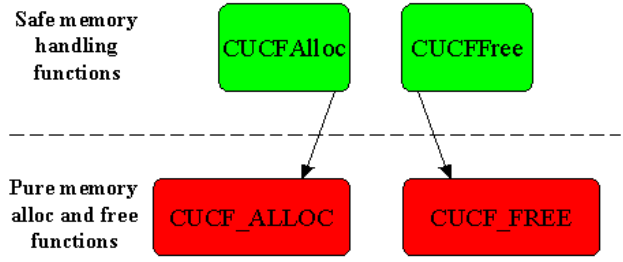

Figure 512: Memory management functions

Safe memory handling functions are used in those places where memory freeing procedure will not be performed in case of error, for example, in the coder library kernel. Pure memory handling functions are called from the safe functions. They are also called directly in those places where memory can still be released even after an error has occurred, for example, buffer memory allocation (memory is released by BufCloseBuf function).

Predefined Memory Handling

There are two types of predefined memory handling functions which can be used to perform allocation and freeing of memory:

- SDL Suite memory handlers `XALLOC` and `XFREE`, see "Functions for Allocation and Deallocation" on page 3117 in chapter 61, *The Master Library*, and
- standard `malloc` and `free` functions from `<stdlib.h>` which are the default memory handlers.

Users can also define their own application specific memory handling functions, see "User defined Memory Handling" on page 2868.

The type of memory handler to be invoked for allocation and freeing of memory is configured when compiling coder library by compile switches, see "Memory management configuration" on page 2897.

User defined Memory Handling

The coder library can be configured to work with user-specific memory handling procedures. It is possible to write your own allocate and free procedures, which will be invoked instead of the default memory handlers.

> **Note: Performance optimization**
>
> Fast memory handling, if applicable, can help optimize the performance of the executable quite a lot. One of the examples of fast memory handling is working with statically allocated memory instead of dynamically allocated in alloc and free procedures.

If you want to use your own memory handler, perform the following steps:

1. Create file `mms_user.h` and insert definitions of macros `USER_ALLOC_FUNC(size, type)` and `USER_FREE_FUNC(ptr, size, type)` to point to the user defined memory handling procedures. These macros will be used for redefining pure memory handling procedures.
2. Compile the coder library with the `CODER_MMS_USER` compile switch, see "Memory management configuration" on page 2897.
3. Add include path for the file `mms_user.h` to the compilation settings.
4. Compile and link the user memory handler function to the application.

Example 481: File mms_user.h ——————————————————

```
#ifndef mms_user_h
#define mms_user_h

#define USER_ALLOC_FUNC(size,type)  UserAlloc(size)
#define USER_FREE_FUNC(ptr,size,type) UserFree(ptr)

extern void* UserAlloc(size_t size);
extern void UserFree(void* ptr);
```

```
#endif
```

There are also two BMS user-specific memory handling procedures that are referenced through macros defined in the `mms_user.h`:

```
#define USER_BMS_ALLOC_FUNC(buffer, size, type)
UserBmsAlloc(buffer, size)
#define USER_BMS_FREE_FUNC(coder, ptr, size, type)
UserBmsFree(buffer, ptr, size)
```

These interfaces are used only in the buffer functions (see "Buffer Management Functions" on page 2853). By default (without this definition) `USER_ALLOC_FUNC` and `USER_FREE_FUNC` are used inside the buffer functions.

The BMS user-specific memory handlers use buffer access types `tCoder*` or `tBuffer` as the first argument. This argument opens the access to the `tUserData` (see "User Data" on page 2884) inside the BMS memory handling:

```
void* UserBmsAlloc(tCoder* Coder, size_t Size)
{
  tUserData* data = BufGetUserData(Coder);
  ... /* user implementation */
}

void UserBmsFree(tCoder* Coder, void* Ptr, size_t
Size)
{
  tUserData* data = BufGetUserData(Coder);
  ... /* user implementation */
}
```

Error Management System

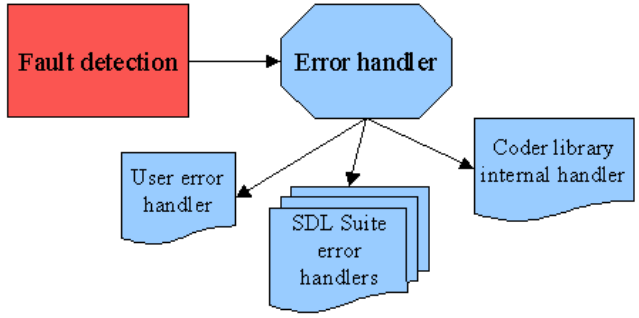

Figure 513: Error management

The coder solution contains error management functions. The error management consists of fault detection, error handling and error output. The error management is optional and can be removed from the application.

The fault detection consists of monitoring code that checks for all kinds of faults when encoding and decoding. When a problem is detected the fault detection part will start the error handler. The monitoring code is controlled by C macros and can be removed by defining macros, see "Error checking configuration" on page 2893. The user defined error handling functionality is described in "User defined Error Handling" on page 2880.

SDL Suite error output functionality has several error output implementations for the different types of kernels. The behavior is different for simulation and for application. It is possible to register a different error output function. See "User defined Error Output" on page 2883.

There are several types of error output functions which can be used to perform error output:

- SDL Suite error output as default
- Coder library error output
- user defined application specific error output functions.

The type of error output to be invoked upon error detection is configured when compiling coder library by compile switches, see "Error output configuration" on page 2897.

Error Management Interface

Encode and decode functions return a status code, which is equal to a success code, or one of the error codes in case of failure. Error codes are visible in both SDL and C functional interfaces. If an error occurs, its code is returned by the encoding or decoding function, and is written into the buffer at the same time.

The behavior of the fault detection can be controlled by compilation switches, that are described in "Error checking configuration" on page 2893. For instance, it is possible to remove all fault detection by defining a corresponding switch.

Detailed error messages

Error messages contain a type name with a path to the field where an error has occurred. The path contains a sequence of SET/CHOICE/SEQUENCE fields and open type objects from the root type up to the field where an error has occurred.

There are two possible representations for the path:

- Path fields are represented by their names. This representation is available only if one of the following compile switches are present, `CODER_TI_NAMES` (see "Error output configuration" on page 2897) or `CODER_VMS_PRINT` (see "Printing configuration" on page 2899). For example:

  ```
  ERROR 21 No more data for read at BOOLEAN, type:
  BOOLEAN, path: yASN1_Type1.field2.comp1
  ```

- Path fields are represented by their indexes - in this case root type is named "undef" and path contains indexes of SEQUENCE/SET components, CHOICE alternatives and open type objects, for example:

  ```
  ERROR 21 No more data for read at BOOLEAN, type:
  undef, path: SEQUENCE.2.1
  ```

By default the second representation with indexes is used.

If an error occurs within the encoding/decoding then you can unambiguously understand the exact place of the error. For example if we have a complex type with the several nested sequences:

```
Type1 ::= SEQUENCE {
  field1 Type2,
  field2 Type2
}
Type2 ::= SEQUENCE {
  comp1 [0] Bool,
  comp2 [1] Int
}
Bool ::= [0] BOOLEAN
Int ::= [1] INTEGER
```

And the error is:

```
ERROR 21 No more data for read at BOOLEAN, type:
BOOLEAN, path: yASN1_Type1.field2.comp1
```

(in the first representation)

```
ERROR 21 No more data for read at BOOLEAN, type:
undef, path: SEQUENCE.2.1
```

(in the second representation)

Then the exact place of the error is known. The error occurred in `Bool` type in the second nested sequence by the path `Type1.field2.comp2`.

The benefits of this feature become significant in a huge ASN.1 specifications with the long nested fields, like UMTS. This is an example of a real error message from the RRC specification (subpart of UMTS):

```
ERROR 22: Wrong TAGGED identifier octet, type:
CPCH_SetInfo_INLINE_3, path: yASN1_DL_DCCH_Message.mes-
sage.radioBearerSetup.modeSpecificPhysChIn-
fo.fdd.cpch_SetInfo.ap_AICH_ScramblingCode
```

Detailed error messages (type and path) is used in the `ec_VAL_` and `ec_DEC_` errors.

The default configuration includes detailed error messages. Detailed messages require extra resources from the speed and from the Type Info size (if names information is enabled). The encoding/decoding speed becomes a bit slower because the feature requires extra manipulations with the stack to store the temporary path. If you do not need to use this feature then you should use `CODER_REMOVE_PATH` compile switch (see "Error handling configuration" on page 2898). Error messages in this case will look like:

```
ERROR 21 No more data for read at BOOLEAN, type:
undef, path: undef
```

SDL error interface

In SDL, error codes are represented by integer values and are defined as Integer synonyms. Names of synonyms are the same as error codes described in "Error codes" on page 2873. The file `codererrors.sdl` contains a complete list of Integer synonyms for coder error codes. This file must be included to the SDL system that is going to check coder error codes after encoding and decoding.

C error interface

In the C error interface, error codes are literals of one big enumerated type, and they can be treated as C integer values. All possible error codes are listed in the file `errors.h` in the 'ems' folder of the library installation (see "Files and File Descriptions" on page 2886). For detailed description of error codes see "Error codes" on page 2873.

Error codes

If the decode or encode succeeded, `ec_SUCCESS` is returned.

In case of failure, an error code is returned that helps to understand the reason of the failure. All possible error codes with short descriptions are listed below.

Memory access errors

ec_MEM_NotEnoughMemory

The application has run out of memory and one of the coder library functions can not allocate memory.

Buffer errors

ec_BUF_DifferentBufferTypes

This is a buffer copying error. The `BufCopyBuf` function belongs to the general buffer interface which supports different buffer types. The error occurs when the source and destination buffers in the copying function are of different buffer types.

ec_BUF_WrongBufferType

The message is reported when the buffer initialize function has been called with the buffer type which has been excluded from the application by compile switches (see "Buffers configuration" on page 2896).

ec_BUF_CloseNotInitialized

The message is reported when `BufCloseBuf` is called on a buffer that has not been initialized.

ec_BUF_WorkWithNotInitialized

One of the two buffer modes, read or write, has to be initialized before accessing the buffer with reading or writing procedures. If a read or write procedure has been applied to a buffer that has not been initialized, the ec_BUF_WorkWithNoneInitialized error is reported.

ec_BUF_NullPtrToUserMemory

BufInitBufWithMemory or BufCloseBufToMemory is called with `NULL` pointer to user memory.

ec_BUF_NotEnoughUserMemory

This error is specific for buffers that are initialized by the user memory, and it denotes that the size of the user memory assigned to the buffer is not enough for storing data.

ec_BUF_OpenOpened

This error is reported when trying to reopen the buffer which has already has been opened for write or read mode, and has not been closed afterwards.

ec_BUF_IllegalClose

This error is reported when BufCloseBuf is called on the buffer for which one of the modes, reading or writing, has not been closed.

ec_BUF_CloseWrongMode

This error is returned when trying to close the buffer for a mode different from the opened one. This situation can happen, for example, when BufCloseWriteMode follows the function BufInitReadMode, or when

BufCloseReadMode is called to the buffer which mode has been initialized by the function BufInitWriteMode.

ec_BUF_OperationWrongMode

This error denotes that you are trying to perform an incorrect operation for the current buffer mode. For example, you are trying to read data from the buffer which has been opened for writing by function BufInitWriteMode.

ec_BUF_NoMoreDataForRead

This error is returned when you are trying to read data from a buffer which is already empty.

ec_BUF_TooBigNumberOfBits

The error is returned when you are trying to put or get more bits from the buffer than it is possible to pass to the bit buffer interface function. The operations BufGetBits and BufPutBits operate with bits stored in the value of type long and can not process more then sizeof(long) number of bits. So when they are called with a number of bits more then sizeof(long), an error message is reported.

ec_BUF_InvalidEncodingRules

This error code is returned when the combination of bit masks passed as the second parameter to the function BufSetRule does not form a valid encoding rule. For example, `BufSetRule( buffer, er_BER | er_Aligned )` will return this error code because `er_Aligned` is an alternative of PER and does not have any sense together with BER.

Value errors

ec_VAL_IllegalRealBase

The real value received for encoding is represented with a base that cannot be handled by the encoder function.

ec_VAL_WrongConstrainedValue

The value passed to the coder function does not satisfy constraints specified for the corresponding type.

ec_VAL_WrongConstrainedLength

The size of the value passed to the coder function does not satisfy the size constraint specified for the corresponding type.

ec_VAL_WrongConstrainedAlphabet

Characters in the string value passed to the coder function do not satisfy the permitted alphabet constraint specified for the corresponding type.

Decoding errors

ec_DEC_NoMoreDataForRead

This error is returned when you are trying to read data from a buffer which is already empty. There is a difference in the formats between `ec_DEC_NoMoreDataForRead` and `ec_DEC_NoMoreDataForRead`. `ec_DEC_NoMoreDataForRead` uses the detailed error message approach (with type and path) but `ec_BUF_NoMoreDataForRead` does not.

ec_DEC_WrongIdentifierOctet

This is a BER specific error, based on BER encoding TLV (Type-Length-Value) structure. The type information from TLV is stored in a so called identifier octet. If the data in the identifier octet for the sequence of bits to be decoded is wrong (for example, ASN.1 type is defined to be INTEGER, but the identifier octet for the value of that type claims that value to be decoded if of type BOOLEAN), an error is returned.

ec_DEC_WrongLength

For some ASN.1 types, the range of the encoded value length is restricted. When length is out of range, the wrong length error is returned.

ec_DEC_TooBigTagNumber

Tag numbers are stored in the variable of type unsigned long, so the value of a tag is restricted. When the tag number occupies more then 32 bits, restriction is violated and this error message is returned.

ec_DEC_WrongConstructedLengthPrefix

When constructed encoding is used, each group of bytes from the encoding is prefixed by the group information. For example, if it is the last group in the constructed encoding or not, and similar. Constructed encoding prefix occupies 8 bits, but not all bit combinations are meaningful. When the combination is wrong, this error is returned.

ec_DEC_WrongUnusedBits

This is a BER specific error. BIT STRING values in BER are encoded into a sequence of bytes, although they cannot contain exactly an integer number of 8 bits. For correct value encoding, the number of unused bits in the last byte is also encoded. When this number is not in the range between 0 and 7, an error is returned.

ec_DEC_TooBigSubIdent

This object identifier decoding error is reported when the sub-identifier is too big and cannot be stored in the variable of type long (4 bytes).

ec_DEC_WrongRealPrefix

The real value encoding contains a prefix denoting the type of real value that has been encoded, plus infinity and minus infinity real values, zero real value, other common real value (mantissa + base + exponent). The real prefix is encoded into 8 bits but not all of them have meaning. If the real encoding contains a bad prefix, this error is reported.

ec_DEC_UnsupportedRealBase

Trying to decode a real value which has been encoded with a base that is not supported in the coding library.

ec_DEC_UnsupportedRealDecimalEncoding

Decimal encoding of real values is not supported. If real value has been encoded according to decimal real encoding algorithm, the decoder will not be able to decode it and it will return this error code.

ec_DEC_RequiredComponentIsAbsent

This error can be reported when decoding SEQUENCE or SET type values and it denotes that not all required components are present in the value encoding.

ec_DEC_ExtRequiredComponentIsAbsent

This is SEQUENCE and SET decoding specific error. It points out that not all required components from extension addition group are present in the value encoding, although the group itself is encoded as present.

ec_DEC_AbsentComponentIsPresent

This error can appear while decoding a value of sequence or set type with the ABSENT constraint applied. When the component constrained to be absent is present in the encoded value, this error message is reported.

ec_DEC_AbsentAlternativeIsPresent

This error can appear while decoding a value of choice type with the ABSENT constraint applied. When the alternative constrained to be absent is present in the encoded value, this error message is reported.

ec_DEC_UnknownComponent

This is SEQUENCE and SET specific decoding error, and it is reported when the encoded field tag is not a known tag from the type fields of SEQUENCE or SET type.

ec_DEC_UnknownAlternative

This is CHOICE specific error, and it is returned when the encoded choice alternative has got a tag which does not belong to the set of possible tags for the decoded choice type.

ec_DEC_NoOpenId

This is open type specific error. It is reported when open type value can not be decoded because open type identifier field is absent for some reason in the encoding.

ec_DEC_UnknownObject

This is open type specific error. It is reported when decoded open type identifier is not equal to any of identifier in the open type restricting table.

ASCII decoding errors

Each ASCII decoding error refer to a particular type and denotes that there are problems or errors when decoding value of that type, for example, ec_ERROR_DECODING_PARSTART is reported when there are errors when decoding start of signal parameter or variable from the buffer.

All possible ASCII decoding errors are listed below.

ec_ERROR_DECODING_INTEGER
ec_ERROR_DECODING_REAL
ec_ERROR_DECODING_BOOLEAN
ec_ERROR_DECODING_TIME
ec_ERROR_DECODING_CHARSTRING
ec_ERROR_DECODING_BIT
ec_ERROR_DECODING_BITSTRING
ec_ERROR_DECODING_OCTET
ec_ERROR_DECODING_OCTETSTRING
ec_ERROR_DECODING_SIGNALID
ec_ERROR_DECODING_STRUCT
ec_ERROR_DECODING_CHOICE
ec_ERROR_DECODING_POWERSET
ec_ERROR_DECODING_BAG
ec_ERROR_DECODING_STRING
ec_ERROR_DECODING_ARRAY
ec_ERROR_DECODING_REF
ec_ERROR_DECODING_USERDEF
ec_ERROR_UNKNOWN_TYPE_NODE
ec_ERROR_DECODING_PARSTART
ec_ERROR_DECODING_PAREND

Internal errors

ec_INT_InternalError

This is coder library internal error. If coder function returns this error, please, contact IBM Rational Customer Support. Internal error will never be reported if `CODER_CHECK_NONE_INNER` compile switch is set up (see "Error checking configuration" on page 2893), in this case all internal error checks are removed from the library code.

ec_INT_UnsupportedType

This is also coder library internal error. It is reported when the type specified for the encode or decode function in the ASN.1 type info structure is not supported by the coder library. Internal error will never be reported if `CODER_CHECK_NONE_INNER` compile switch is set up (see "Error checking configuration" on page 2893), in this case all internal error checks are removed from the library code.

> **Note: Error codes backwards compatibility**
>
> Backwards compatibility is implemented for those error codes which have been removed or renamed in comparison with the previous versions of the coder library error management system. All old error names will be mapped to new ones with the same functionality for the systems using previous version of coder library. An example of error code which is not used in the new coder library any more is `ec_SMLBUF_READ_ERROR`.

Definition of your own error codes

It is possible to specify your own error codes. It might be useful for user encoding rules or user memory management implementation.

If you want to use your own error codes, perform the following steps:

1. Create file `errors_user.h` and insert your own error codes by using the following format:

CUCF_ERROR(ec_<error identifier>, "Error message")

Example 482: File errors_user.h ----------

```
CUCF_ERROR(ec_MY_ERROR_ONE, "My error one")
CUCF_ERROR(ec_ME_ERROR_TWO, "My error two")
```

----

2. Compile the coder library with the `CODER_EC_USER`="errors_user.h".
3. Add include path for the file `errors_user.h` to the compilation settings.

User defined Error Handling

This functionality allows to call a user defined error handling function inside the decoding procedure. If an error occurs this function will be

called. Combined with the `BufGetErrorPath( buffer )` buffer interface (see "Buffer Management Functions" on page 2853), error handling function gives an opportunity to insert a default value to the field for which the decoding failed.

An error handler function must be written by the user according to the following format:

```
typedef void (*tBufErrInitFunc)(tBuffer Buffer);
```

There is an interface in the buffer functionality `BufSetErrInitFunc( buffer, func )` that allows to set user error handling by reference into the buffer and it will be used by the decoder. `BufGetErrInitFunc( buffer )` returns a reference to an error handling function. By default there is no error handler and it returns `NULL`. Below there is an example with the user defined error handling.

These two checks between ErrorPath and TypeInfo help to determine the exact place where an error has occurred:

```
#define EQ_TI(field, ti) \
  ((tASN1TypeInfo*)(field)==(tASN1TypeInfo*)&ti)
#define EQ_CMP(field, ti) \
  (((tASN1Component*)(field))->TypeInfo==(tASN1TypeInfo*)&ti)
```

Error handling:

```
void TinyErrorHandling(tBuffer b)
{
  int res = BufGetErrorCode(b);
  tErrorPath *ep = BufGetErrorPath(b);
  LineB* lineB = (LineB *)BufGetMainVal(b);
  if ( res == ec_VAL_WrongConstrainedValue &&
       ep->NumOfFields == 2 &&
       EQ_TI(ep->Fields[0], yASN1_LineB) &&
       EQ_CMP(ep->Fields[1], yASN1_PointB_INLINE_0))
    {
      lineB.point1.x = 40;
      return;
    }
  if ( res == ec_VAL_WrongConstrainedValue &&
       ep->NumOfFields == 2 &&
       EQ_TI(ep->Fields[0], yASN1_LineB) &&
       EQ_CMP(ep->Fields[1], yASN1_PointB_INLINE_1))
    {
      lineB.point2.y = 25;
      return;
    }
}
```

ASN.1:

```
Tiny DEFINITIONS AUTOMATIC TAGS ::=
BEGIN
  PointA ::= SEQUENCE {
    x         INTEGER (0..42),
    y         INTEGER (0..26)
  }
  PointB ::= SEQUENCE {
    x         INTEGER (0..40), -- lineA.point2.x = 42
    y        INTEGER (0..25)  -- lineB.point1.y = 26
  }
  LineA ::= SEQUENCE {
    point1   PointA,
    point2   PointA
  }
  LineB ::= SEQUENCE {
    point1   PointB,
    point2   PointB
  }
  lineA LineA ::= { point1 { x 11, y 26 }, point2 {
x 42, y 24 } }
  lineB LineB ::= { point1 { x 11, y 25 }, point2 {
x 40, y 24 } }
END
```

The code example with the encoding of `LineA` type and `LineB` as the type for the decoding. The encoded `lineA` value does not satisfy the `LineB` constraint and that is why there are two constraint errors:

```
ERROR 18 Wrong INTEGER constrained value, type:
PointB_INLINE_0, path: yASN1_LineB.point1.x
ERROR 18 Wrong INTEGER constrained value, type:
PointB_INLINE_1, path: yASN1_LineB.point2.y
```

The `TinyErrorHandling` function catches these errors with a corresponding assignment to the correct values.

```
BufInitBuf(b, bms_SmallBuffer);
BufSetErrInitFunc(b, TinyErrorHandling); /* set
TinyErrorHandling as decoding
BufInitWriteMode(b);
res = ASN1_ENCODE(b, (tASN1TypeInfo *)&yASN1_LineA,
lineA);
BufCloseWriteMode(b);
BufInitReadMode(b);
res = ASN1_DECODE(b, (tASN1TypeInfo *)&yASN1_LineB,
dec_lineB); /*
BufCloseReadMode(b);
BufCloseBuf(b);
```

User error handling requires the same resources as for detailed error messages (see "Detailed error messages" on page 2871). The encoding/decoding speed becomes slower because of some extra manipula-

tions with the stack. CODER_REMOVE_PATH compile switch (see "Error handling configuration" on page 2898) should be defined to disable the error handling.

User defined Error Output

It is possible to write your own error output function, which will be invoked when a fault is detected.

If you want to use your own error output, perform the following steps:

1. Implement a C-procedure for error output with the prototype `void USERErrorOutputFunc(FILE* File, tEMSErrorCode Code, va_list MessageArguments)`. `tEMSErrorCode` is an enumerated type containing all possible error codes returned by coder library functions, see "Error codes" on page 2873. You can also find a list of the different error codes in `errors.h` from `/cucf/ems` folder.
2. Compile the coder library with CODER_EO_USER compile switch, see "Error output configuration" on page 2897,
3. Compile and link the user error output function to the application.

The `USERErrorOutputFunc` function takes error message arguments as the third parameter which corresponds to the message string defined in the coder library. The error management system provides a function that allows you to get the coder library message string for the error code: `char* CUCFGetErrorMessage(tEMSErrorCode Code)`.
Example 483 illustrates one possible way of defining a user error output function.

Example 483 Error output

```
void USERErrorOutputFunc( FILE* File,
                          int Code,
                        va_list MessageArguments )
{
  /* user error output with the code and message */
  fprintf(File, "USER ERROR %d ", Code);
  vfprintf(File, ErrorMessageArray[Code],
MessageArguments);
  fputc('\n', File);
}
```

User Data

There is an option to include your own data fields into the buffer type. C-type `tUserData` is defined in the `user_data.h` file and it can be included into the buffer by `CODER_USER_DATA` compile switch (see "User data configuration" on page 2898). By default type `tUserData` is defined as `void*`, but you can redefine it according to your needs.

`tUserData` with your own fields might be useful in the user error handling function (see "User defined Error Handling" on page 2880) to store the data for the later manipulation outside the decoder or in the `USER_BMS_ALLOC_FUNC`/`USER_BMS_FREE_FUNC` (see "User defined Memory Handling" on page 2868). The buffer interface `BufGetUserData( buffer )` (see "Buffer Management Functions" on page 2853) returns a reference to `tUserData` for your further handling. If you want to use your own data fields as `tUserData`, perform the following steps:

1. Create file `user_data.h` and insert declaration of the `tUserData` C-structure.
2. Compile the coder library with the `CODER_USER_DATA` compile switch.
3. Add include path for the file `user_data.h` to the compilation settings.

Example 484: File user_data.h ----------

```
#ifndef user_data_h
#define user_data_h

typedef struct {
  int UserInt1;
  int UserInt2;
  int UserInt3;
} tUserData;

#endif
```

Printing Opportunities

The print functions can be used for test and debug purposes. They will be available at runtime only if the compilation switch CODER_VMS_PRINT is set, see "Printing configuration" on page 2899.

There are two print functions available, ASN1_PRINT_TYPE and ASN1_PRINT. The print functions use the type information in the same way as an encoding function.

The function ASN1_PRINT_TYPE prints the contents of the type information structure for one particular type. There are two input parameters, the first is a file handle and the second is a reference to the type information.

The function ASN1_PRINT prints the value of a variable or signal parameter. This print function has got three input parameters, the first is a file reference, the second is a reference to the type information structure and the third is a reference to the variable or the signal parameter.

Example 485: Print type information

```
FILE * logfile;

logfile = fopen( "asn1print.log", "w" );

ASN1_PRINT_TYPE( logfile,
                 (tASN1TypeInfo *)&yASN1_TestType);

fclose( logfile );
```

Example 486: Print value of signal parameter

```
FILE * logfile;

logfile = fopen( "asn1print.log", "w" );

ASN1_PRINT( logfile, (tASN1TypeInfo *)&yASN1_TestType,
     (void *)&((yPDef_outsig *)(*SignalOut))->Param1);
fclose( logfile );
```

Structure and Configuration

An application with ASN.1 encoding or decoding support contains the following:

- Encoding and decoding functions. One set of functions for BER encoding and decoding and one set of functions for PER encoding and decoding.

> **Note: ASCII coder**
>
> ASCII encoding and decoding, which is based on SDL Suite internal encoding rules is also available. ASCII encoding and decoding is described in "SDL Data Encoding and Decoding, ASCII coder" on page 2790 in chapter 57, *Building an Application*.

- Buffer management functions.
- Error management functions (optional).
- Print functions (optional).
- ASN.1 type information generated by the ASN.1 Utilities.
- SDL type and operator information generated by the SDL C code generators.

Files and File Descriptions

This section describes the static file structure of the coder directories in the installation.

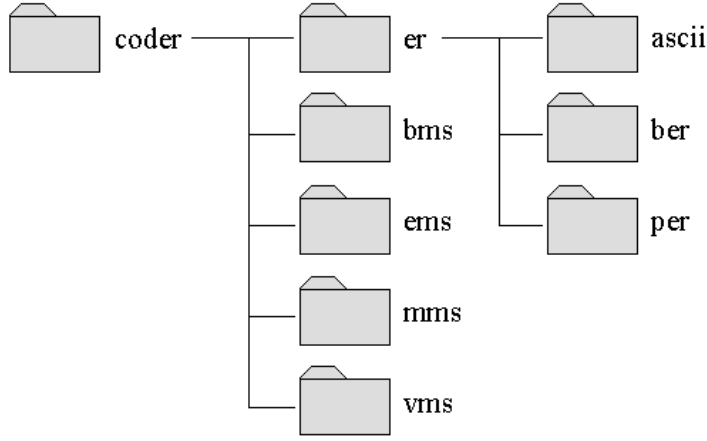

Figure 514: The coder directory

The coder directory contains five sub-directories which correspond to the functional modules in the coder library:

- `coder/er` - this directory contains three sub-directories which correspond to different encoding rules supported by the coder library.
- `coder/bms` - Buffer Management System files.
- `coder/ems` - Error Management System files.
- `coder/mms` - Memory Management System files.
- `coder/vms` - Value Management System files.

There are also several files included to the root coder directory:

- `cucf.h` - main header file of the coder library. It includes all useful header files from the library functional modules.
- `cucf_cfg.h` - standard C library includes, like `<stdio.h>`, `<sdtlib.h>` and others.
- `cucf_er.h` - declarations of main encode and decode coder interface functions.
- `cucf_er.c` - definition of main encode and decode coder interface functions.

- `cucf_er_sdt.h` - declarations of SDL Suite specific encode and decode interface functions which are used for encode and decode within SDL support.
- `cucf_er_sdt.c` - definition of SDL Suite specific encode and decode interface functions which are used for encode and decode within SDL support.
- `cucf_er_ttcn.h` - declarations of TTCN Suite specific encode and decode interface functions which are used for encode and decode within TTCN support.
- `cucf_er_ttcn.c` - definition of TTCN Suite specific encode and decode interface functions which are used for encode and decode within TTCN support.
- `coderascii.h`, `coderber.h`, `coderper.h`, `coderucf.h` - these files are not used inside the library, but provide backwards compatibility solutions for the SDL systems created with the previous versions of SDL coder support.

Encoding rules sub-directory

Sub-directory `coder/er` contains three sub-directories corresponding to different types of encoding rules supported by the coder library:

- `ascii`

  This directory contains files with encoding and decoding function according to internal rules of the SDL Suite. The ASCII coders are described in "SDL Data Encoding and Decoding, ASCII coder" on page 2790 in chapter 57, *Building an Application*.

- `ber`

  This directory contains files with encoding and decoding functions according to BER (Basic Encoding Rules), see "BER sub-directory" on page 2888.

- `per`

  This directory contains files with encoding and decoding functions according to PER (Basic Encoding Rules), see "PER sub-directory" on page 2889.

BER sub-directory

Sub-directory `coder/er/ber` contains the following files:

- `ber.h` - header file with declaration of `BEREncode` and `BERDecode` functions.

- ber_base.h - contains declarations of basic functions needed by the encode and decode functions.
- ber_base.c - contains implementation of basic functions needed by encode and decode functions.
- ber_content.h - contains declarations of functions that encode and decode ASN.1 predefined types.
- ber_content.c - contains implementation of functions that encode and decode ASN.1 predefined types.
- ber_decode.c - definition of main outermost function BERDecode which references functions from ber_base and ber_content modules.
- ber_encode.c - definition of main outermost function BEREncode which references functions from ber_base and ber_content modules.

PER sub-directory

Sub-directory coder/er/per contains the following files:

- per.h - header file with declaration of PEREncode and PERDecode functions.
- per_base.h - contains declarations of basic functions needed by the encode and decode functions.
- per_base.c - contains implementation of basic functions needed by encode and decode functions.
- per_content.h - contains declarations of functions that encode and decode ASN.1 predefined types.
- per_content.c - contains implementation of functions that encode and decode ASN.1 predefined types.
- per_decode.c - definition of main outermost function PERDecode which references functions from per_base and per_content modules.
- per_encode.c - definition of main outermost function PEREncode which references functions from per_base and per_content modules.

Buffer Management System sub-directory

Sub-directory coder/bms contains the following files:

- bms.h - base buffer management declarations, this header contains base buffer control structure definitions. This is the main header file for buffer management.

- `bms.c` - implementation of base buffer functions which are common for all types of buffers.
- `bms_small.h` - small buffer management specific declarations.
- `bms_small.c` - implementation of small buffer management.

Error Management System sub-directory

Sub-directory `coder/ems` contains the following files:

- `ems.h` - error management declarations. This is the main header file for coder error handling.
- `ems.c` - implementation of common error management functions.
- `ems_eo_sdt.h` - SDT specific error management declarations and includes.
- `ems_eo_sdt.c` - implementation of SDT specific error handling functions.
- `errors.h` - declaration of error codes and error information.

Memory Management System sub-directory

Sub-directory `coder/mms` contains the following files:

- `mms.h` - declarations of pure memory handling macros `CUCF_ALLOC` and `CUCF_FREE` and safe memory management functions `CUCFAlloc` and `CUCFFree` (see "Memory Management System" on page 2866). This is the main header file for coder memory handling.
- `mms.c` - implementation of safe memory handling functions.

Value Management System sub-directory

Sub-directory `coder/vms` contains the following files:

- `vms.h` - this is the main header file for value management system, it contains includes of all other useful header files from this folder.
- `vms_type.h` - definitions of types used in ASN.1 type nodes.
- `vms_macro.h` - definitions of macros which are used for declaration and filling ASN.1 type structure nodes. Calls to these macros are generated by ASN.1 coder generator.
- `vms_vr_sdt.h` - definitions of macros which are used for inserting SDL Suite specific information to ASN.1 type structure nodes. Calls to these macros are generated by ASN.1 coder generator only for SDL Suite coder generation.
- `vms_vr_ttcn.h` - definitions of macros which are used for inserting TTCN Suite specific information to ASN.1 type structure nodes.

Calls to these macros are generated by ASN.1 coder generator only for TTCN Suite coder generation.

- `vms_export.h` - type node declarations for predefined ASN.1 types, such as `BOOLEAN`, `INTEGER`, `BIT STRING`, `OCTET_STRING`, `NULL`, `OBJECT IDENTIFIER`, `REAL`, string types.
- `vms_export.c` - type node definitions for predefined ASN.1 types.
- `vms_internal.h` - internal value representation type and macro definitions.
- `vms_base.h` - declarations of internal value representation access procedures.
- `vms_base.c` - implementation of internal value representation access procedures.
- `vms_check.h` - declarations of check procedures.
- `vms_check.c` - implementation of procedures that perform error checking of type nodes and values.
- `vms_print.h` - declarations of print procedures used for test and debug purposes.
- `vms_print.c` - implementation of print procedures used for test and debug purposes.

Compilation switches

You can change the default properties and configure the BER and PER coders by setting the compilation switches. Some of these switches can be set by choosing options in the Targeting Expert, see chapter 59, *The Targeting Expert*.

Available compile switches can be separated onto several groups. Below there are descriptions of compile switches that can be used to configure the behavior of coder functions.

Encoding rules configuration

Removing runtime encoding rules availability

- CODER_REMOVE_ASCII - compile coding library without ascii encoding rules available at runtime
- CODER_REMOVE_BER - compile coding library without BER encoding rules available at runtime

- CODER_REMOVE_PER - compile coding library without PER encoding rules available at runtime
- CODER_USE_UER - add user defined encoding and decoding functions to be available at runtime (file “uer.h“ will be used during library compilation)

By default all the library included ascii, ber and per encoding rules to be present in the compiled object library.

Choosing default encoding rules

This compilation switches influence on which encoding rules will be applied when the coder function is called without specifying which type of encoding rules should be applied

- CODER_ER_DEFAULT_PER - use PER as default encoding rules
- CODER_ER_DEFAULT_BER - use BER as default encoding rules
- CODER_ER_DEFAULT_UER - apply USER encoding rules by default

The default setting is CODER_ER_DEFAULT_BER.

- CODER_BER_DEFINITE - use definite length form encoding for BER by default
- CODER_BER_INDEFINITE - use indefinite length form encoding for BER by default

The default setting is CODER_BER_INDEFINITE.

- CODER_PER_NO_ENDPAD - use PER unaligned without end padding as default encoding rules
- CODER_PER_ALIGNED - use PER aligned as default encoding rules
- CODER_PER_UNALIGNED - use PER unaligned as default encoding rules

The default setting is CODER_PER_UNALIGNED.

- CODER_BER_CONSTRUCTED - use constructed form of BER by default

- CODER_BER_PRIMITIVE - use primitive form of BER by default

The default setting is CODER_BER_PRIMITIVE.

- CODER_BER_CONSTRUCTED_LENGTH=<number> - use <number> as length of constructed sequence of bytes for BER

The default setting is CODER_BER_CONSTRUCTED_LENGTH=1000.

- CODER_BER_CANONICAL_ON - restrict BER decode for SET type by canonical order.
- CODER_BER_CANONICAL_OFF - BER decode for SET type as defined in ITU X.690.

The default setting is CODER_BER_CANONICAL_ON.

Real values encoding

For encoding real values are divided into the following number values: (sign * 2^factor * number * base^exponent). It is the user option to choose which factor and which base should be used when encoding.

- CODER_BER_REAL_FACTOR_0 - use real factor 0 for coding
- CODER_BER_REAL_FACTOR_1 - use real factor 1 for coding
- CODER_BER_REAL_FACTOR_2 - use real factor 2 for coding
- CODER_BER_REAL_FACTOR_3 - use real factor 3 for coding
- CODER_REAL_BASE_2 - use real base 2 for encoding
- CODER_REAL_BASE_8 - use real base 8 for encoding
- CODER_REAL_BASE_16 - use real base 16 for encoding

The default setting is CODER_BER_REAL_FACTOR_0 and CODER_REAL_BASE_2.

Error checking configuration

- CODER_CHECK_NONE - remove all error checks from compiled library
- CODER_CHECK_NONE_VALUE - remove error checks of input values to encoding and decoding function from the compiled library

- CODER_CHECK_NONE_BUFFER - remove error checks in buffer management from the compiled library
- CODER_CHECK_NONE_DECODING - remove error checks in decoding functions from the compiled library
- CODER_CHECK_NONE_INNER - remove internal error checks in encoding and decoding functions from the compiled library

Note: Error checks in decoding functions

All decoding functions start with a check of type nodes and input values. These tests are not removed by defining the CODER_CHECK_NONE_DECODING macro. Checks in the buffer management are not affected by the macro either. You can remove these checks by using other macros in this list.

By default all checks are switched ON.

Encoding configuration

You can use the following switches to remove code for ASN.1 type from the compilation:

- CODER_NOUSE_BOOLEAN
- CODER_NOUSE_INTEGER
- CODER_NOUSE_NULL
- CODER_NOUSE_OBJECT_IDENTIFIER
- CODER_NOUSE_REAL
- CODER_NOUSE_BIT_STRING
- CODER_NOUSE_OCTET_STRING
- CODER_NOUSE_CHARACTER_STRING - NumericString, PrintableString, IA5String, VisibleString, UTCTime, GeneralizedTime
- CODER_NOUSE_ENUMERATED
- CODER_NOUSE_ENUMERTAED_ITEMS - ENUMERATED items if they are 0 1 2 3 etc

- CODER_NOUSE_SEQUENCE
- CODER_NOUSE_SET
- CODER_NOUSE_SET_OF
- CODER_NOUSE_SEQUENCE_OF
- CODER_NOUSE_CHOICE
- CODER_NOUSE_OPEN
- CODER_NOUSE_EXT - extension marker in ASN.1 sequence and set

You can use the following switches to redefine C type for ASN.1 type information field:

- CODER_ENUMERATED_TYPE=<type> - enumerated value. Default is “long”
- CODER_TagNumber_TYPE=<type> - ASN.1 tag class number. Default is “unsigned long”
- CODER_NumOf_TYPE=<type> - number of components. Default is “unsigned long”
- CODER_INTEGER_LBOUND_TYPE=<type> - low bound in integer constraint. Default is “long”
- CODER_INTEGER_UBOUND_TYPE=<type> - upper bound in integer constraint. Default is “long”
- CODER_SIZE_LBOUND_TYPE=<type> - low bound in size constraint. Default is “unsigned long”
- CODER_SIZE_UBOUND_TYPE=<type> - upper bound in size constraint. Default is "unsigned long"

These compile switches can be set automatically. `asn1util` generates `asn1_cfg.h` file for the `-c` option where the above compile switches are included after `#define` directives to minimize coder library code size automatically, see also “Configuration file generation” on page 703 in chapter 13, *The ASN.1 Utilities*. To be able to use this `asn1_cfg.h` automatic configuration you should define the following compile switch:

- CODER_AUTOMATIC_CONFIG - enables automatic configuration generated to the `asn1_cfg.h` file. This switch can be set by choosing the corresponding option in the Targeting Expert.

Buffers configuration

- CODER_BMS_SMALLBUF - uses small buffer implementation. The second argument of BufInitBuf interface - type of the buffer (see "tBMSBufType" on page 2851) will not be in use for this case.
- CODER_REMOVE_SMALLBUF - removes small buffer code from the compiled library

The default is including only small buffers to the library. When all buffers are absent, then only a null buffer will be available (a null buffer is a stub buffer without any functionality).

- CODER_USE_USERBUF - includes the user buffer into the library to be available at runtime
- CODER_BMS_USERBUF - uses the user buffer implementation if it is made available by previous switch
- CODER_BMS_TINY - uses a minimum set of bms interfaces. Interfaces to operate with buffer mode, character segment, bytes, bits also copy buffer interface are not available for this switch. It is allowed to use both buffer access types `tBuffer` and `tCoder` in this mode.

Example 487: Encoding in tiny mode ----------

```
tCoder coder;
tBMSUserMemory UserMemory;

BufInitBuf(&coder, bms_SmallBuffer);
ASN1_ENCODE(&coder,
            (tASN1TypeInfo *)&yASN1_Message,
            encValue);
BufCloseBufToMemory(&coder, &UserMemory);
...
BufInitBufWithMemory(&coder, &UserMemory);
ASN1_DECODE(&coder,
            (tASN1TypeInfo *)&yASN1_Message,
            decValue);
BufCloseBuf(&coder);
CUCF_FREE(UserMemory.MemPtr, UserMemory.MemSize, 0);
```

Example 488: `tBuffer` **access type in tiny mode**

```
tBuffer buf = NULL;
BufInitBuf(buf, bms_SmallBuffer);
```

> **Note:**
> The buffer value for this mode must be initialized by NULL before being used in buffer management. The behavior will otherwise be unpredictable.

Following buffer interfaces are not available in this mode:

```
BufGetMode, BufInNoMode, BufInReadMode, BufInWrite-
Mode

BufCopyBuf

BufInitWriteMode, BufCloseWriteMode

BufInitReadMode, BufCloseReadMode, BufCloseDele-
teReadMode

BufGetByte, BufPeekByte, BufPutByte

BufGetSeg, BufSkipSeg, BufPeekSeg, BufPutSeg

BufPutBit, BufGetBit, BufPutBits, BufGetBits
```

- CODER_SMALLBUF_SIZE=<number> - <number> defines small buffer allocation block

The default setting for the size is CODER_SMALLBUF_SIZE=0x1000.

Memory management configuration

- CODER_MMS_SDT - use SDT alloc/free procedures when working with memory in the coder library functions
- CODER_MMS_USER - apply user defined alloc/free functions when working with memory in the coder library functions (file “mms_user.h“ will be added for library compilation)

By default standard malloc and free functions from <stdlib.h> are used.

Error output configuration

- CODER_EO_SDT - use SDT error output functions (when this switch is turned on, SDT error output switch XECODER can influence error output functionality)

- CODER_EO_USER - apply user defined error output procedures to the library and use them for error output (file “ems_eo_user.h“ will be added for library compilation)
- CODER_EO_DEBUG - use internal library functions for printing error messages
- CODER_EO_NONE - do not output error messages text

The default setting is CODER_EO_SDT.

- CODER_TI_NAMES - enable name information in the Type Info.

Error handling configuration

- CODER_PATH_DEEP=<number> - nesting coefficient. It depends on the ASN.1 specification. The nesting coefficient is the maximum number of nested SEQUENCE, SET, CHOICE, SEQUENCE OF, SET OF or open types. By default `CODER_PATH_DEEP` is defined to 16. If the nesting coefficient in the ASN.1 specification is greater then 16 then you should define the `CODER_PATH_DEEP` compile switch with this value yourself, otherwise “segmentation fault” error will occur. The nesting coefficient for the following example is 4:

```
MySeq ::= SEQUENCE { -- NC=4
  a MyChoice,
  b NULL
}
MySet ::= SET { -- NC=1
  a INTEGER,
  b BOOLEAN
}
MyChoice ::= CHOICE { -- NC=3
  a MySeqOf,
  b MySetOf
}
MySeqOf ::= SEQUENCE OF MySet -- NC=2
MySetOf ::= SET OF BOOLEAN -- NC=1
```

- CODER_REMOVE_PATH - do not use detailed error messages (see “Detailed error messages” on page 2871) and user error handling (see “User defined Error Handling” on page 2880)

User data configuration

- CODER_USER_DATA - include `tUserData` defined in the `user_data.h` into the coder buffer, see “User Data” on page 2884

Value management configuration

- CODER_VMS_SDT - use SDT value interface when accessing external values from the encoding and decoding functions (this switch comes together with SDT switch XUSE_GENERIC_FUNC, which chooses generic value representation out of two available value representations for SDT/C values, by default it is turned off and old (backwards compatible) value representation is used)
- CODER_VMS_TTCN - use TTCN value interface when accessing external values from the encoding and decoding functions
- CODER_VMS_USER - choose user value interface for accessing external values from the encoding and decoding functions (file “vms_vr_user.h“ must be edited to configure user value access, it is included for library compilation)

By default CODER_VMS_SDT is chosen.

Printing configuration

- CODER_VMS_PRINT - enable debug printing opportunities (see “Printing Opportunities” on page 2885)

By default the coder library is compiled without debug printing functionality.

Generating Environment Files with Coding

You can call the encoding and decoding functions from the environment functions if you do not want to manipulate the encoded bit pattern explicitly in your SDL system.

The SDL Suite tools generate templates for the environment files that contains all necessary calls to buffer management functions, encoding functions and decoding functions. You can, of course, adapt this template to your needs or even write all the calls yourself. See chapter 57, *Building an Application* or chapter 65, *The Cmicro SDL to C Compiler*.

The template solution in the environment files has the following properties:

- One global buffer reference created at start-up of system. This buffer reference is used in all calls for all signals and for both encoding and decoding.

- All signals out from the system are encoded into bit-patterns. All parameters of the signals are encoded.
- All signals into the system decodes bit-patterns.

Compiling and Linking

The instructions you must perform in order to compile and link are listed in chapter 8, *Tutorial: Using ASN.1 Data Types, in the Getting Started*.

Chapter

59 *The Targeting Expert*

When doing targeting there is a lot of information to be provided, for instance how to generate the C source code, how to configure the SDL to C compiler, which compiler to be used etc.

The Targeting Expert is a tool managing the complete process of targeting (for the Cadvanced, Cmicro and Cextreme SDL to C compilers only).

The easiest way to get an executable from an SDL specification (just generate C code for a complete SDL system - compile and link the executable) is as well supported as more complex cases. Therefore there are several Pre-defined Integration Settings which are ready-to-use.

Furthermore the Targeting Expert is able to re-use the deployments done in the Deployment Editor (see "The Deployment Editor" on page 1769 in chapter 40, *The Deployment Editor*) and to configure any single option thinkable in the process of doing targeting with SDL Suite. Those options can be the SDL to C compiler's options, the compiler, linker and make tool options, for example.

After all this chapter is a description of the Targeting Expert Interactive Mode and a reference for the Batch Mode.

A list of FAQs (frequently asked questions) can be found at the end of this document.

Introduction

The Targeting Expert assists you in setting up and configuring a complete target application. A sub-set of the Targeting Expert functionality can be used in Batch Mode when it is only desired to re-build the complete system (or just several components).

Starting the Targeting Expert

In graphical Mode

Starting the Targeting Expert in the graphical mode means that the user interface is visible and you can directly interact by selecting function and menu items.

You enter the graphical mode by selecting *Targeting Expert* in the Organizer's *Generate* menu or by using the following command line options:

sdttaex [-h | -v | -pdm `<partition_diagram>.pdm` | -sdt `<systemname>.sdt` | -pr `<systemname>.pr`] [-t `<target>`] [-hostsim | -realsim | -sim | -val | -makeall]

Option	Relevance
-v	The version number is shown and the application exits.
-h	Information about the usage is shown and the application exits.
-pdm `<partition_diagram>.pdm`	The partitioning diagram file to be used.
-sdt `<systemname>.sdt`	The system file to be used.
-pr `<systemname>.pr`	The system's PR file to be used
-t `<target>`	The qualifier of the SDL system's part to build
-makeint `<integration>`	Make the given integration
-makeall	Re-make last configuration

More information about the user interface can be found in "The Main Window" on page 2904.

See "Interactive Mode" on page 2910 to get familiar with the Targeting Expert functionality.

In Batch Mode

The command line mode is also called Batch Mode. Please see the appropriate sections for a more detailed description.

Possible command line options are:

taexbatch [-v | -h | -t `<target>`| -yes | -no]

Option	Relevance
-v	The version number is printed to stdout and the application exits.
-h	Information about the usage is printed to stdout and the application exits.
-t `<target>`	The qualifier of the SDL system's part to build
-yes	All the questions that probably come up will be answered with 'yes'.
-no	All the questions that probably come up will be answered with 'no'.

For more information about the commands allowed in a batch file see "Description of Batch Mode Commands" on page 2962.

Note:

Targeting Expert does not startup properly if there is more than one instance of the Postmaster running (sdt.exe on Windows and sdt on UNIX). Be sure you have at most one SDL Suite running when starting Targeting Expert.

The Graphical User Interface

This section describes the appearance and functionality of the graphical user interface of the Targeting Expert (sdttaex). Some user interface descriptions common to all tools can be found in chapter 1, *User Interface and Basic Operations*.

The Main Window

When you start the Targeting Expert in the interactive mode its main window is displayed.

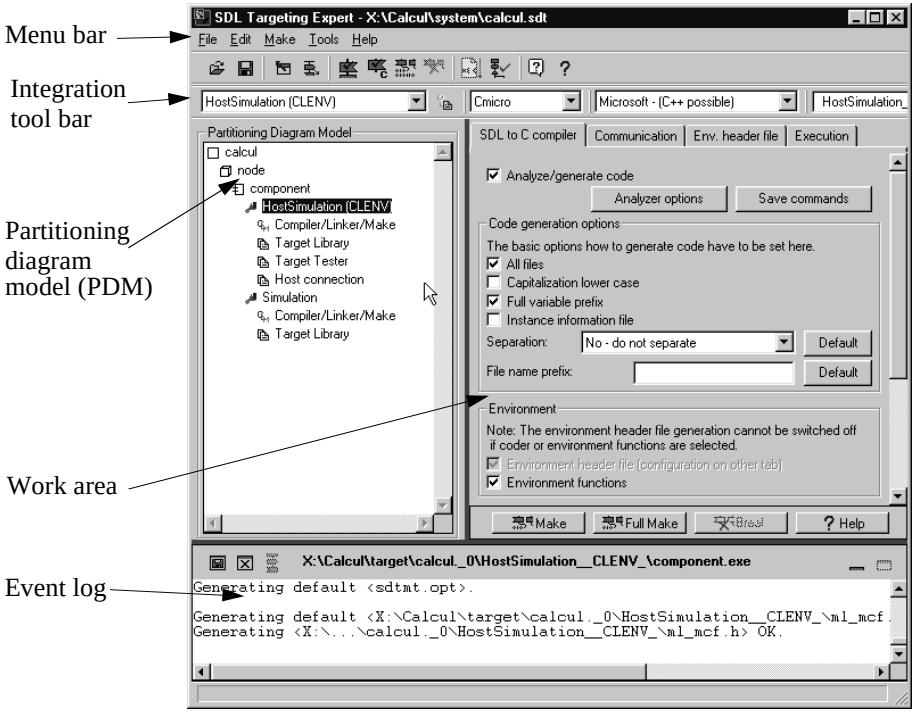

Figure 515: The Targeting Expert main window

The Menu Bar

This section describes the menu bar of the Targeting Expert Main window and all the available menu choices.

The menu bar contains the following menus:

- *File Menu*
- *Edit Menu*
- *Make Menu*
- *Tools Menu*
- *Help Menu*
  (See "Help Menu" on page 15 in chapter 1, *User Interface and Basic Operations*.)

Configurable Menus

Some menu choices may be available through the concept of user-defined menus. For more information, see "Defining Menus in the SDL Suite" on page 18 in chapter 1, *User Interface and Basic Operations*.

The definition file for user-defined menus searched for by the Targeting Expert is called `taex-menus.ini`.

There are several placeholders possible to be used with the `FormattedCommand` clause in `taex-menus.ini`.

placeholder	... will be replaced by ...
%s	system directory
%b	target directory (the one given in the Organizer)
%t	sub target directory (the one calculated depending on the selected component and integration)
%e	executable name (inclusive extension)
%i	intermediate directory

File Menu

The *File* menu contains the following menu choices:

- *Open*
- *Save*

- *Exit*

See "File Menu" on page 8 in chapter 1, *User Interface and Basic Operations*.

Edit Menu

The *Edit* menu gives access to the enlargement of the Targeting Expert configuration files.

- *Add Compiler*
- *Edit Compiler Section*
- *Remove Compiler*
- *Add Communications Link*
- *Remove Communications Link*
- *Edit Makefile*

  A text editor is displayed where you can modify the generated makefile.

- *Edit Configuration Header File*

  A text editor is displayed where you can modify the generated configuration header file.

- *Edit Environment File*

  A text editor is displayed where you can modify the generated environment C file.

Make Menu

The *Make* menu allows to control the make process of the Targeting Expert.

- *Analyze*

  The selected integration will be analyzed.

- *Generate code*

  C code will be generated for the selected integration.

- *Make all*

  All the configured components will be made again.

- *Clean*

All the object files in the object directory will be removed.

Tools Menu

The *Tools* menu gives access to other SDL Suite tools.

- *Show Organizer*

  The Organizer main window is displayed.

- *Load SDL System*

  The partitioned SDL system that is currently worked on in the Targeting Expert can be loaded into the Organizer. Use this entry if the Targeting Expert main window is displayed after the execution in the batch mode has failed.

- *Utilities > DOS to UNIX*

  It is possible to specify a list of ASCII files. All the files in this list will be converted from DOS to UNIX style. See "DOS to UNIX" on page 3010

- *Utilities > UNIX to DOS*

  It is possible to specify a list of ASCII files. All the files in this list will be converted from UNIX to DOS style. See "UNIX to DOS" on page 3010

- *Utilities > Indent*

  The indentation of all the ASCII files in the list of files specified by the user will be corrected. See "Indent" on page 3010

- *Utilities > Preprocess*

  The list of generated C files that is specified by the user will be preprocesses. See "Preprocessor" on page 3011

- *Wizards > TCP/IP communication*

  A wizard dialog pops up and allows you to configure the TCP/IP communication between different components. See "TCP/IP signal sending" on page 2952

- *SDL > Simulator UI*

This menu choice starts a new, empty Simulator UI. Several Simulator UIs may exist at the same time. See *"Graphical User Interface" on page 2199 in chapter 49, The SDL Simulator*.

- *SDL > Explorer UI*

  This menu choice starts a new, empty Explorer UI. Several Explorer UIs may exist at the same time. See *"Graphical User Interface" on page 2349 in chapter 52, The SDL Explorer*.

- *SDL > SDL Target Tester*

  This menu choice starts a new, empty SDL Target Tester UI. See "Graphical User Interface" on page 3656.

- *Customize*

  A dialog pops up and allows to customize the Targeting Expert. See "Customization" on page 2924 for more details.

The Integration Tool Bar

The integration tool bar should be used to (from left to right)

- Select the Pre-defined Integration Settings
- Get help about the selected integration
- Select an SDL to C Compiler
- Select a C Compiler to be used

Furthermore it should also be used to handle pre-defined and user-defined integration settings (see "Handling of Settings" on page 2920), i.e.

- to set a new user settings file name
- to export user settings as pre-defined settings
- to import node or application settings

The Work Area

The work area of the Targeting Expert is used for giving input masks for the different configurations and scalings.

The different input masks are described in

- "Configure how to Make the Component" on page 2948
- "Configure Compiler, Linker and Make" on page 2930
- "Configure and Scale the Target Library" on page 2946

- "Configure the SDL Target Tester (Cmicro only)" on page 2947
- "Configure the Host (Cmicro only)" on page 2948

The Event Log

The Targeting Expert has an event log containing information about found inconsistencies, read/write problems concerning file access, output, etc.

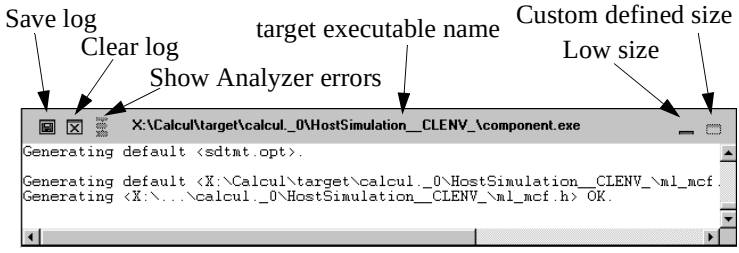

Figure 516: The event log

Analyzer/Compiler Errors

You can access analyzer and compiler errors by double clicking the error message in the event log.

- In case of an analyzer error the SDL Editor is displayed with the erroneous SDL symbol highlighted.
- In case of a compiler error the selected editor is displayed with the erroneous line highlighted.
  Note 1: the selected editor must be able to highlight the desired line. It has to be selected in the Customization of the Targeting Expert.
  Note 2: the compiler's error message syntax must be described in the Compiler Error Descriptions section in file `sdttaex.par` for the compiler used.

Interactive Mode

You can use the Targeting Expert interactive mode to achieve different targets to:

- Build an un-configured or optimized target executable by following the steps described in "Targeting Work Flow" on page 2926.
- Configure the distributed SDL Suite release and handle the already done settings. Please see below.

Although most of the steps in targeting are supported in the Targeting Work Flow you sometimes need access to other functionality, for example:

- Compiler Definition for Compilation to the target library's known compilers.
- Communications Link Definition for Compilation (for the inter-communication with the SDL Target Tester's host application).
- Handling of Settings
- Customization

Compiler Definition for Compilation

> **Note:**
>
> All the modifications that can be done here are only valid for the current system, i.e. all the information will be stored into the system's target directory.

Add

The following is applicable only if using the Cmicro SDL to C compiler:

Select *Add a new Compiler* from the *Edit* menu. The Add compiler dialog is displayed.

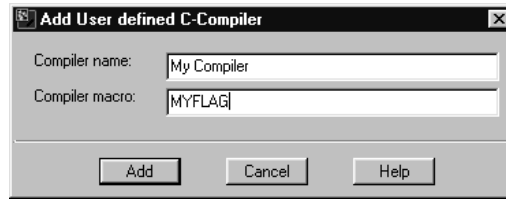

Figure 517: Add compiler dialog

- Compiler Name

  The text you enter here will be used to identify the compiler in the *Compiler Flag* list.

- Compiler Macro

  The macro name you enter here will be used to identify the compiler in the target library. The compiler macro must fit to `[A-Za-z_][A-Za-z0-9_]*`

When you click *Add* the compiler is added to the `c*_conf.def` file. Please see "Configuration Files" on page 2974 for information about the file's syntax and duty.

Edit

For each compiler that is supported by a target library there is a specific section in

- `scttypes.h` (Cadvanced), see "Compiler Definition Section in scttypes.h" on page 3147.
- `ml_typ.h` (Cmicro), see "Adaptation to Compilers" on page 3523 in chapter 66, *The Cmicro Library*
- `extreme_kern.h` (Cextreme), see Compile and Link an Application.

Whenever there is a compiler flag defined, not known by the library, a file called `user_cc.h` (for Cadvanced and Cmicro) or `comphdef.h` (for Cextreme) will be included which has to contain the compiler specific settings.

The dialogs shown below are input masks that request all the needed information to generate such a file. Select *Edit Compiler Section* from the Edit Menu.

Cadvanced

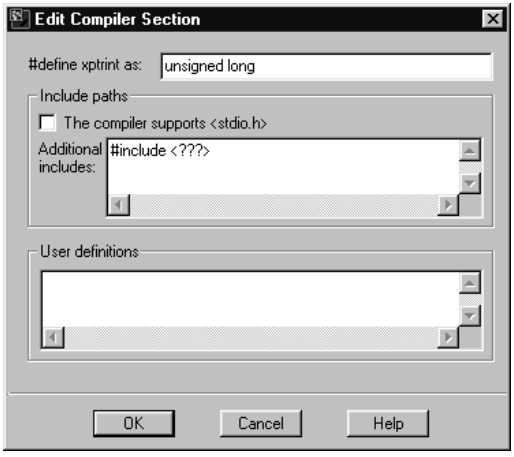

Figure 518: Edit compiler section dialog (Cadvanced)

For Cadvanced the following is requested:

- *#define xptrint*

  Enter the mapping for xptrint values; usually `unsigned long`.

- *Include paths*

  – *The compiler supports <stdio.h>*

  If selected this section will be generated:

  ```
  #ifdef XREADANDWRITEF
    #include <stdio.h>
  #endif
  ```

  Otherwise nothing will be generated here.

  – *Additional includes*

  The contents of the edit box will simply be copied in to the `user_cc.h` file. It should carry something like `#include <file>`.

- *User definitions*

  Enter user definitions for the `user_cc.h` file.

Cmicro

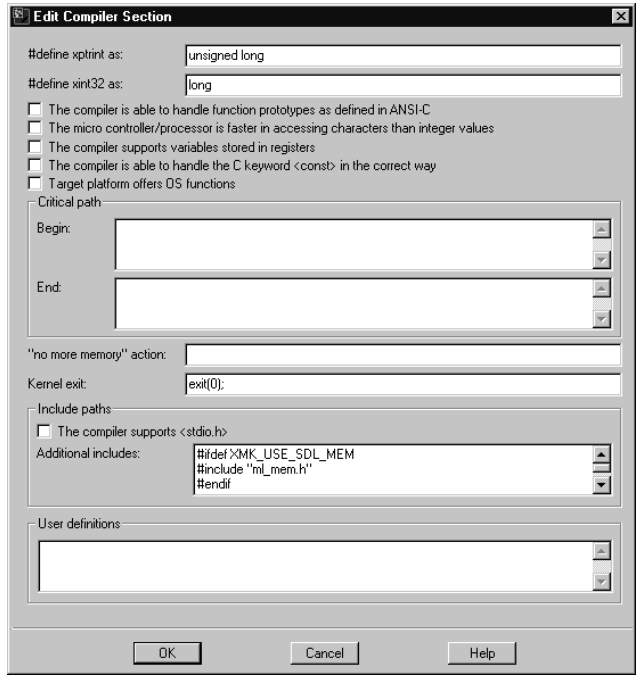

Figure 519: Edit compiler section dialog (Cmicro)

For Cmicro the following is requested:

- *#define xptrint*

  Enter the mapping for `xptrint` values; usually `unsigned long`.

- *#define xint32*

  Enter the mapping for `xint32` values; usually `long`.

- *The compiler is able to handle function prototypes as in ANSI C*

  – If selected this section will be generated:

```
#undef XNOPROTO
#define XPP(x) x
#define PROTO(x) x
```

– If **not** selected this section will be generated:

```
#define XNOPROTO
#define XPP(x)
#define PROTO(x)
```

- *The micro controller/processor is faster in accessing characters than integer values.*

  – If selected this section will be generated:

  ```
  #define xmk_OPT_INT char
  ```

  – If **not** selected this section will be generated:

  ```
  #define xmk_OPT_INT integer
  ```

- *The compiler supports variables stored in registers*

  – If selected this section will be generated:

  ```
  #undef X_REGISTER
  #define X_REGISTER register
  ```

  – If **not** selected this section will be generated:

  ```
  #undef X_REGISTER
  #define X_REGISTER
  ```

- *The compiler is able to handle the C keyword <const> in the correct way*

  – If selected this section will be generated:

  ```
  #undef XCONST
  #define XCONST const
  ```

  – If **not** selected this section will be generated:

  ```
  #undef XCONST
  #define XCONST
  ```

- *Target platform offers OS functions*

  – If selected this section will be generated:

  ```
  #define XMK_USE_OS_ENVIRONMENT
  ```

  – If **not** selected this section will be generated:

  ```
  #undef XMK_USE_OS_ENVIRONMENT
  ```

- *Critical paths*

  Enter the commands which are needed to have critical paths, i.e. how to disable and enable interrupts.

Note:

All the commands you enter will be copied in to `user_cc.h`. If there is more than one line of source code, each line must end with a '\' because the compiler's preprocessor depends on it.

- *"no more memory" action*

  Enter the action (e.g. a function call) to process if no more memory can be allocated.

- *Kernel exit*

  Enter the function call to process if the kernel should be exited. DEfault is `exit();`

- *Include paths*

  – *The compiler supports <stdio.h>*

  If selected this section will be generated:

```
#ifdef XMK_ADD_PRINTF
  #include <stdio.h>
#endif
```

  Otherwise nothing will be generated here.

  – *Additional includes*

  The contents of the edit box will simply be copied into the `user_cc.h` file. It should carry something like `#include <file>`.

- *User definitions*

  Enter user definitions for the `user_cc.h` file.

Remove

The following is applicable only if using the Cmicro SDL to C compiler:

To remove a compiler from the private `c*_conf.def` file, select *Remove an Unused Compiler* from the Edit Menu

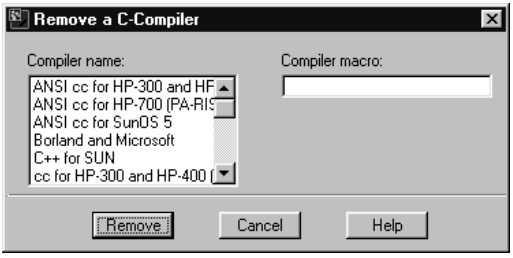

Figure 520: Remove compiler dialog

Note:

The file `user_cc.h` will not be affected by removing a compiler from the `c*_conf.def` file.

Communications Link Definition for Compilation

The following is only applicable if using the Cmicro SDL to C compiler.

Note:

All the modifications that can be done here are only valid for the current system, i.e. all the information will be stored into the system's target directory.

Add

To allow the selection of a new communications link in the Targeting Expert user interface the appropriate macros should be given in the Targeting Expert.

Select *Add a User Defined Communications Link* from the Edit Menu.

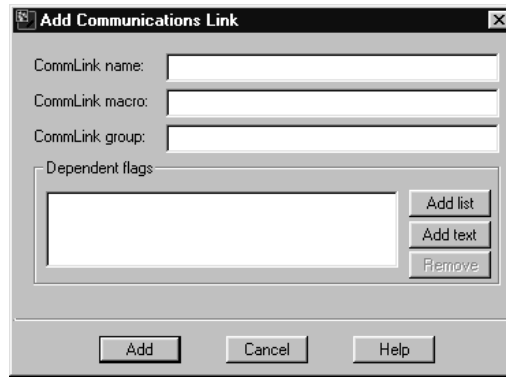

Figure 521: Add a user defined communications link

- *CommLink Name*

  The text will be shown in the Targeting Expert UI to identify it in the dialog described in "Configure the SDL Target Tester (Cmicro only)" on page 2947.

- *CommLink Macro*

  The macro name will be used to identify the communications link in the target library. The communications link macro must fit to `[A-Za-z_][A-Za-z0-9_]*`

- *CommLink Group*

  The text will be used to build a group of the communications link description done here, i.e. the CommLink macro and the dependent flags will be summarized as the group given here.

- *Dependent Flags*

  – *Add List*

    A dialog where you enter a Value List is displayed.

  – *Add Text*

    A dialog where you enter a Text Value Flag is displayed.

  – *Remove*

    The entry you have selected in the list box will be removed.

When you click *Add* the communications link is added to the `c*_conf.def` file. Please see "Configuration Files" on page 2974 for information about the file's syntax and duty.

Note:

The communications link source code has to be set up by the user.

Value List

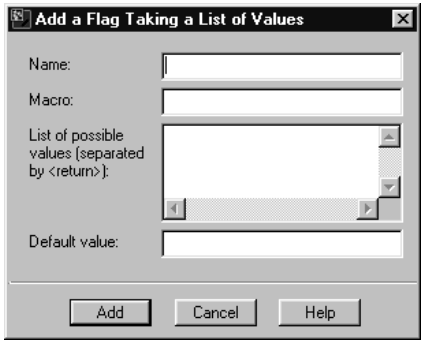

Figure 522: Add a flag taking a list of values

- *Name*

  The name is used for identification purposes in the Targeting Expert user interface.

- *Macro*

  The macro will be used for scaling purposes in the target library. It must fit to `[A-Za-z_][A-Za-z0-9_]*`

- *List of possible values*

  Enter a list of all allowed values the macro can take. Each entry has to be delimited by `<return>`.

- *Default value*

  Enter the default value which must be one of the possible values entered above.

When you click *Add* this value list is added to the communications link you entered in the dialog in Figure 521 on page 2917.

Text Value Flag

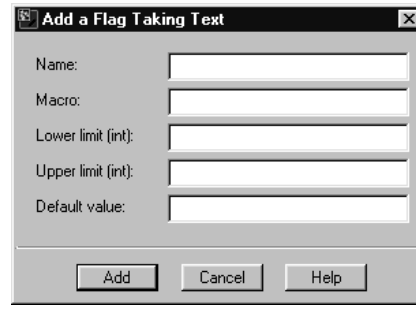

Figure 523: Add a flag taking text

- *Name*

  The name is used for identification purposes in the Targeting Expert user interface.

- *Macro*

  The macro will be used for scaling purposes in the target library. It must fit to `[A-Za-z_][A-Za-z0-9_]*`

- *Lower limit*

  Enter the lower limit if the value given with this macro is an integer value.

- *Upper limit*

  Enter the upper limit if the value given with this macro is an integer value.

- *Default value*

  The default value of the macro in this edit line has to be between the lower and upper limit if it is an integer value. Of course, it is possible to enter an alphanumeric value here, too.

When you click *Add* this value list is added to the communications link you entered in the dialog shown in Figure 521 on page 2917.

Remove

To remove a communications link from the private `c_conf.def` file, select *Remove a communications link* from the Edit Menu.

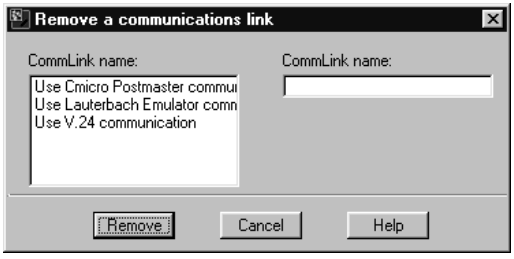

Figure 524: Remove a communications link

Handling of Settings

General

The integration tool bar on the main window offers four buttons to handle the settings, i.e. the way settings are stored and where they are taken from can be influenced.

Figure 525: Integration tool bar in the main window

Note:

The settings addressed in this section are only compiler, linker and make settings. The configuration of the SDL to C compiler library is not touched!

After selecting pre-defined integration settings the Targeting Expert automatically creates a file called `<integration_name>.uis` in the according component directory. (Please see "Target Sub-Directory Structure" on page 2996).

For some reasons it is sometimes useful to modify this way of saving the user done settings. E.g.

- To be able to “play” with settings it can be useful to switch to another file while the default one is not touched. After playing it is easy to switch back to the old settings by selecting the old file again.

- After doing an adaptation for a specific target the manually modified settings can be exported as new pre-defined integration settings. Please see “Export” on page 2922.

- Estimated there are several components inside of a node and each of them should be build the same way, then it is probably useful to do the adaptation of settings once on node level and to import these settings for each component.
  This also means that the compiler, linker and make settings can no longer be modified on component level.

- Estimated there are several components in different nodes that should be build the same way, then it is possible to import the setting from the application.
  This also means that the compiler, linker and make settings can not be modified any longer on component level.

Estimated there is an integration ’A’ and there are modified settings on this integration on application, node and component level. Then there are three different files `A.uis` saved in the correspondent application, node and component directories.
Figure 526 shows where the settings can be done and where they are taken from when the component is selected.

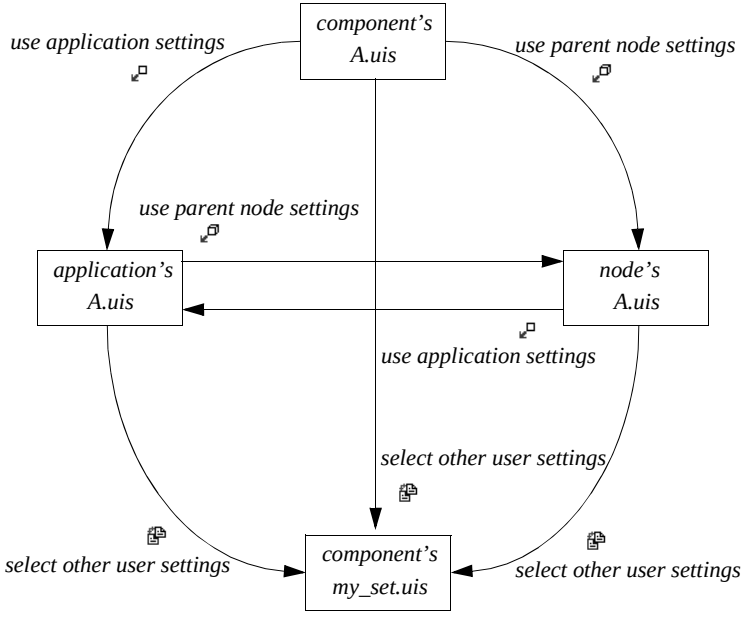

Figure 526: handling the user settings

Export

The settings of the currently selected integration will be exported as new Pre-defined Integration Settings with the name given in the first dialog that pops up.

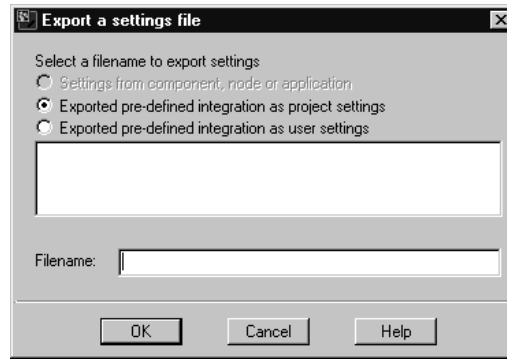

Figure 527

Note:

All the integrations must have unique names, i.e. it is not possible to export settings with an already known name.

- *Export pre-defined integration as project settings*

  In this case the new `.its` file is stored in the same directory as the `<systemname>.sdt` file. This has the advantage that all users working on the system can access the pre-defined integration.

- *Export pre-defined integration as user settings*

  The `.its` file is stored in the `<installationdir>` **in Windows** or respectively the `§HOME/.telelogic` directory **on UNIX**. This has the advantage that other users do not see all the new pre-defined integration settings.

In the second dialog a list of template files which have to be copied into the target directory can be specified. As default, the list of files from the "parent" settings will be given. Modify the list to your needs. Directly after exporting the settings they can be used for further configurations.

Note:

The sections Configuration Settings to Be Set and Configuration Settings to Be Reset are not exported.

Customization

The Targeting Expert interactive mode can be customized. After selecting the *Customize* entry in the Tools Menu the dialog shown in Figure 528 pops up.

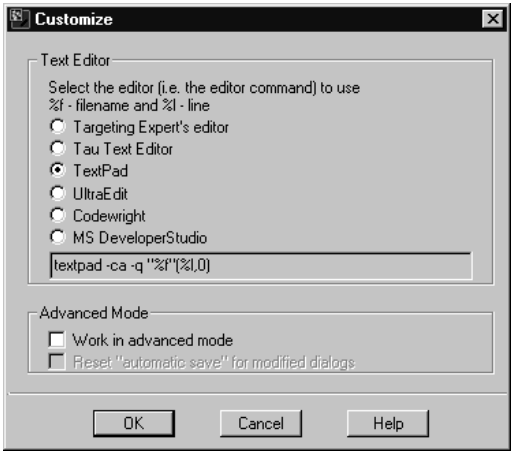

Figure 528: Customize dialog

Text Editor

The text editor which should be opened to edit or view text files can be selected here. The list of supported editors depends on the platform the Targeting Expert is running on (Windows/UNIX). It can be modified or extended in the file `sdttaex.par`. Please see "Parameter File sdttaex.par" on page 3000.

Advanced Mode

The advanced mode allows you to:

- do more configurations than possible in the non-advanced mode. See "More Configurations" on page 2925 for more information.
- switch between different dialogs without using the *Cancel* or *Save* button
- start the code generation automatically when selecting a new integration

- configure all compilers. Even the ones that are not available on the used platform.

More Configurations

- Normally there is no need to modify the compiler flag if using a pre-defined integration, but in the advanced mode the Compiler Flag can be modified.
- The standard pre-defined integrations do not allow you to use all the configuration options in the Configure and Scale the Target Library dialog (disabled). If the advanced mode is switched on, it is possible to switch on and off all the options supported by the SDL to C compiler library.

Caution!

The pre-defined integrations distributed are tested only with the given library configuration. It is not guaranteed that it will work for all kinds of modifications!

Targeting Work Flow

Introduction

You can start the Targeting Expert form the Organizer's *Generate* menu when having a deployment diagram, the SDL system or a block/process of the SDL system selected.

Estimated the SDL system is selected the Targeting Expert converts the system into a default partitioning diagram model (deployment diagram). This is done because the Targeting Expert can only handle partitioning diagram models as an input. The tree window shown in Figure 529 gives an idea how the default partitioning diagram model looks like.

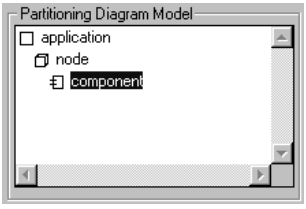

Figure 529: Partitioning diagram in the Targeting Expert

The different entries have got the following meaning:

	application This is the collection of all the deployed SDL systems. It is used as an object to allow configurations of several nodes only, i.e. it is not possible to make an application.
	node A node symbolizes an instance of the platform/computational resource that components execute on, i.e. it is not possible to make a node.
	component A component is interpreted as an executable program.

I.e. an application or node can be configured but not build. Only components can end up in executable programs.

In the start-up phase, directly after the partitioning diagram model has been displayed, the Targeting Expert generates a sub-directory structure into which all the configuration settings, object files and so on will be put. Please see "Target Sub-Directory Structure" on page 2996 for more information.

Now you can use the Targeting Expert to configure each component.

> **Hint:**
>
> If you switch the Targeting Assistant on in the "Help" menu, there are tool tips displayed for each entry on the main window.

Operation Steps

The following operation steps should be done at least once when doing targeting for a component the very first time. When the Targeting Expert is used again later to optimize the target it is of course not necessary to do all the steps once more.

1. Actions to perform:
   - Select the component which should be configured.

> **Note:**
>
> All the settings you define and the actions automatically performed by the Targeting Expert have an influence only on the component selected in the Targeting Expert tree window (see Figure 529 on page 2926).
>
> If the configuration should be re-used (this is sometimes reasonable if several components should be built using exactly the same settings), you can modify the way your settings are handled. Please see "Handling of Settings" on page 2920.

2.

Actions to perform:

- Select the Pre-defined Integration Settings
- Select an SDL to C Compiler (if not already done in the pre-defined integration settings)
- Select a C Compiler (if not already done in the pre-defined integration settings)

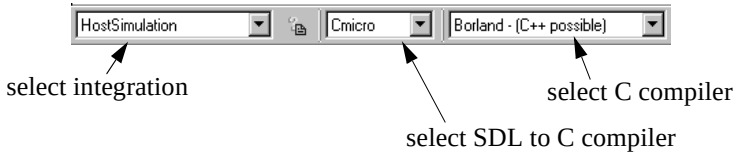

Figure 530: Integration selection in the main window

Select the Pre-defined Integration Settings

With every SDL Suite distribution there are several Pre-defined Integration Settings which you can use to get a target executable in an easy manner.

To get an optimized target executable concerning size and speed these pre-defined integration settings should only be seen as templates.

Please see "Distributed Pre-defined Integration Settings" on page 2979.

The pre-defined integration settings can be selected in the integration tool bar in the main window (see Figure 530). All the pre-defined integration settings are sorted into the groups

- Simulations
- Validations
- Target Tests
- Light Integrations
- Threaded Integrations

Additionally the integration `<user defined>`, which does not belong to an integration type and is not pre-defined, can be selected.

Hint:

If there is no set of pre-defined integration settings that fits your needs (e.g. a not yet supported compiler), it is recommended to select `<user-defined>` and to do the further configurations by hand.

Select an SDL to C Compiler

The SDL to C compiler to be used will automatically be set if you select one of the pre-defined integration settings. It is only necessary to select the SDL to C compiler if the `<user-defined>` settings have been selected. All the available SDL to C compilers will be given in the combo box shown in Figure 530.

Depending on the licenses found the following SDL to C compilers are supported:

- Cadvanced
- Cmicro
- Cextreme

Note:

Directly after the SDL to C compiler is selected (i.e. after pre-defined integration settings are selected) the Targeting Expert checks if there is already an automatic configuration file `sdl_cfg.h` or `extreme_user_cfg.h` (done by the SDL to C compiler) available.

If not, the SDL to C compiler should be invoked to generate an automatic configuration.

For Cadvanced this is only done if the flag `USER_CONFIG` is set in the compiler options (e.g. `-DUSER_CONFIG`).

Select a C Compiler

After a pre-defined integration setting is selected the Targeting Expert tries to automatically set the compiler to be used, i.e.

- if there is only one compiler supported with the selected pre-defined integration settings than that one is set.
- if there are more than one compiler supported the Targeting Expert tries to set the default compiler selected in the Preferences. (Please see chapter 3, *The Preference Manager*)

However, it is possible to set another compiler by selecting it in the combo box shown in Figure 530.

If the *<user defined>* integration has been chosen, a new compiler can be added by selecting the entry “Add new compiler description”.

3. Actions to perform:

- Configure Compiler, Linker and Make
- Configure and Scale the Target Library
- Configure the SDL Target Tester (Cmicro only)
- Configure the Host (Cmicro only)

To select the desired configuration dialog, please select the correspondent entry in the partitioning diagram.

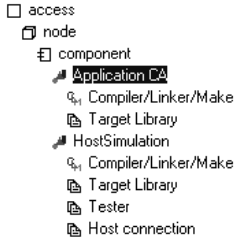

Figure 531: Tree structure in the partitioning diagram

Configure Compiler, Linker and Make

This part of the configuration is divided into four sub-steps which are taken from the selected pre-defined integration settings as far as possible.

Compiler

You enter the needed compiler configuration in a special input mask. The compiler you specify here will be used to compile the generated code and the target library.

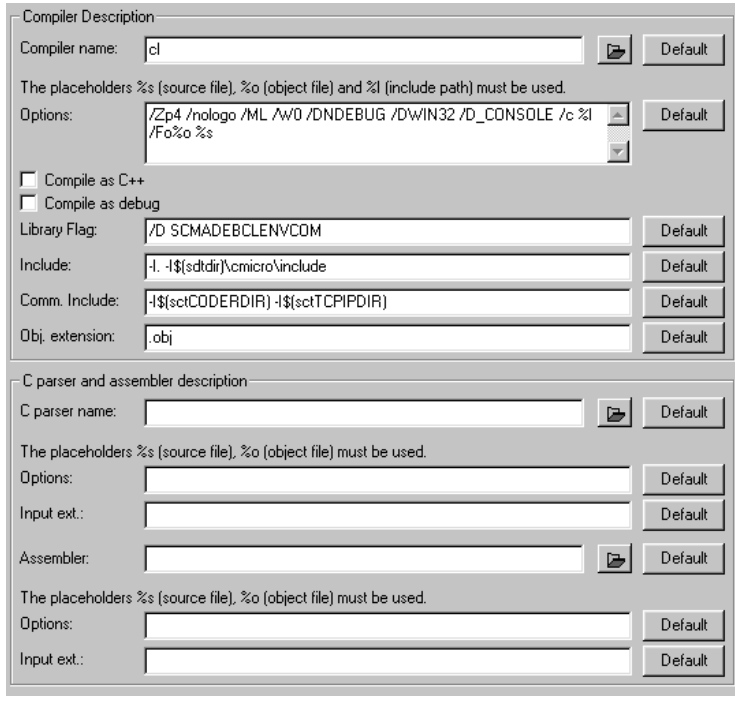

Figure 532: Compiler configuration

Click *Default* if you want to restore the default values.

- *Compiler Name*

  Enter the name of the compiler application.

- *Options*

Enter the options given to the compiler as command line arguments here.

- Enter the placeholder `%s` where the source file name of the file to be compiled has to be inserted (used for the makefile generation).
- Enter the dummy parameter `%o` where the object file's name has to be inserted (used for the makefile generation).
- Enter the dummy parameter `%I` where the include path option has to be placed (see below).

- *Compile as C++*

  The compiler options to compile C files as C++ files will be added/removed from the Options. For a definition of the used compiler options see the "Parameter File sdttaex.par" on page 3000.

- *Compile as debug*

  The compiler options to generate the object files including debug information will be added/removed from the Options. For a definition of the used compiler options see the "Parameter File sdttaex.par" on page 3000.

- *Library Flag*

  The compiler option to define a flag plus the C macro used to select the desired library must be given here. (When using Cmicro this field is empty per default.)

- *Include*

  Enter the compiler option needed to specify include paths and the include paths themselves here. The complete contents of this entry will replace the entry `%I` in the Options (see above).

  The include path can contain the following environment variables (The environment variables will be expanded during the make execution):

Variable	Path it points to
`sdtdir`	`<installationdir>/sdt/sdtdir/<platform>` as long as Library directory is not set

Variable	Path it points to
`scttargetdir`	Absolute path to the current target directory (depends on the selected component)
`sctobjdir`	`$(scttargetdir)` + the relative path selected in Object directory
`sctuseinclude` (Cadvanced only)	`$(sdtdir)/INCLUDE`
`sctincludedir` (Cmicro only)	`$(sdtdir)/cmicro/include`
`sctkerneldir` (Cmicro only)	`$(sdtdir)/cmicro/kernel`
`scttesterdir` (Cmicro only)	`$(sdtdir)/cmicro/tester`

- *Comm Include*

  The compiler option needed to specify include paths and the include paths to the coder library must be given here. (Only used if the ASN.1 and/or SDL coder functions are generated and used)

- *Obj. extension*

  Enter the object extension to be used for the compiler output.

If only the information up to here is specified in this dialog, each C file is compiled in one single step as shown in Figure 533.

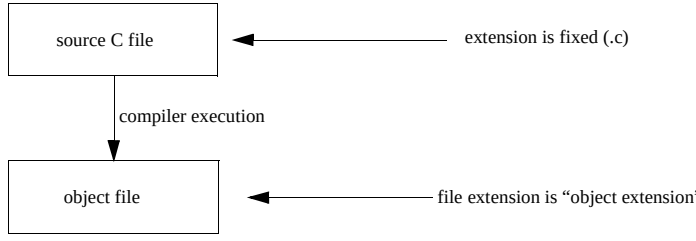

Figure 533:Single step compilation model

For some target compilers, compilation is done in three steps using three different tools. If that is the case, the compilation of each C file is

done like shown in Figure 534. In this case the following entries also need to be given.

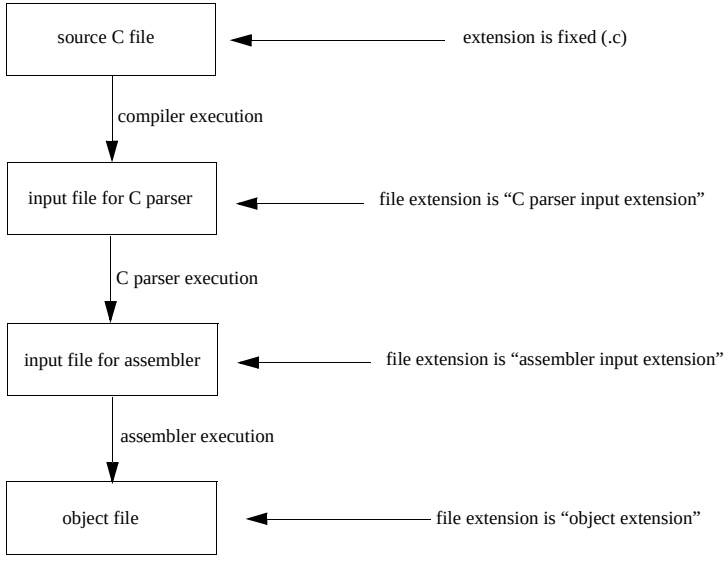

Figure 534:Three step compilation model

- *C parser name*

  The name of the C parser application has to be given here.

- *Options (C parser)*

  Enter the options given to the C parser as command line arguments here.

  – Enter the placeholder `%s` where the input file name of the file to be parsed has to be inserted (used for the makefile generation).
  – Enter the dummy parameter `%o` where the output file’s name has to be inserted (used for the makefile generation).

- *Input extension (C parser)*

  Enter the input file’s extension for the C parser.

- *Assembler*

The third step to process is the execution of the assembler. Enter the name of the assembler application here.

- *Options (Assembler)*

  Enter the options given to the assembler as command line arguments here.

  – Enter the placeholder `%s` where the input file name of the file to be assemble has to be inserted (used for the makefile generation).
  – Enter the dummy parameter `%o` where the output file's name has to be inserted (used for the makefile generation).

- *Input Extension (Assembler)*

  The input file's extension used by the assembler has to be specified in this edit line.

Source Files

All the files (except the coder and the generated files) which will be compiled and linked to the target executable are listed here.

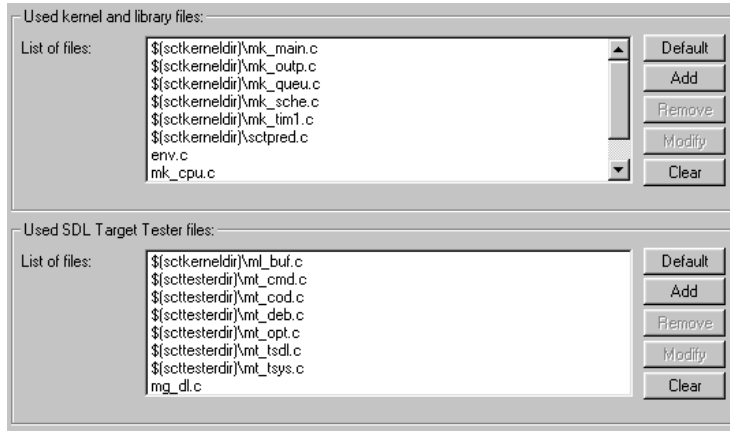

Figure 535: Source files used

- *Used kernel and library files* and
  Used SDL Target Tester files (Cmicro only)

  – *Default*

    Restores the default values.

  – *Add*

    A file selection dialog is opened where you can select the file which should be added to the list of kernel files.

  – *Remove*

    Removes the item you have selected in the list box.

  – *Modify*

    A dialog pops up and the selected entry can be modified.

  – *Clear*

    Deletes all the items in the list box.

Compiler Flag

> **Note:**
> This section is only available if the Advanced Mode is selected and the SDL to C compiler Cmicro is used.

When compiling the generated code and/or the SDL to C compiler's library you need to set a compiler flag to adjust the code.

The list of available compilers shown in Figure 536 belongs to the Cadvanced target library.

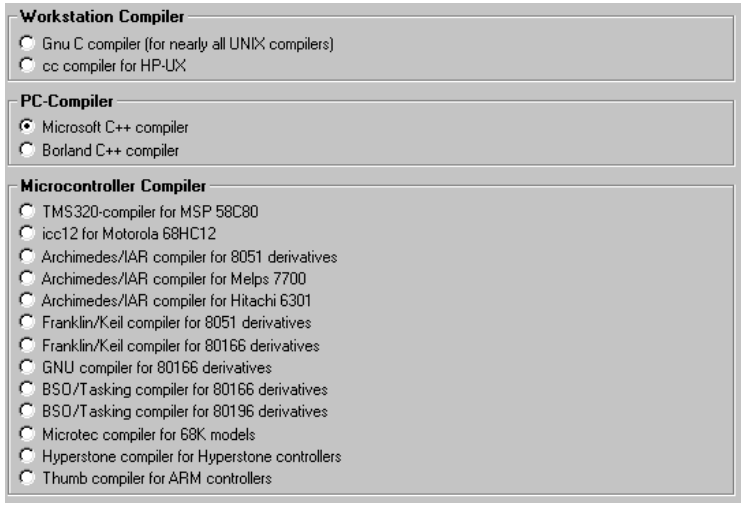

Figure 536: Flag selection

Caution!

You must select the correct compiler flag in order to avoid compilation errors.

For more information concerning the compiler specific adjustment of the libraries see

- `scttypes.h` (Cadvanced), see "Compiler Definition Section in scttypes.h" on page 3147.
- `ml_typ.h` (Cmicro), see "Adaptation to Compilers" on page 3523 in chapter 66, *The Cmicro Library*
- `extreme_kern.h` (Cextreme), see Integration with Compiler and Operating System.

Additional Compiler

If there are other files than the generated ones or the SDL to C compiler's library to be compiled all the requested things in this section have to be entered.

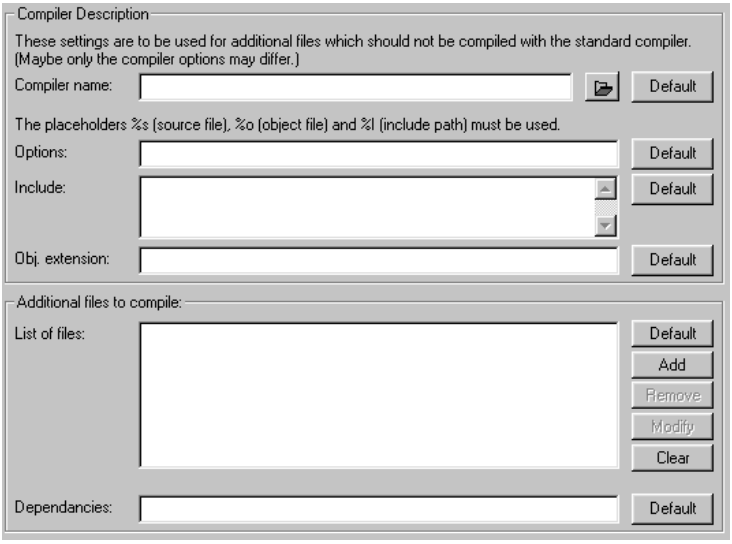

Figure 537: Additional compiler configuration

- *Compiler Name*

  Enter the name of the compiler application.

- *Options*

  Enter the options given to the compiler as command line arguments here.

  – Enter the placeholder `%s` where the source file name of the file to be compiled has to be inserted (used for the makefile generation).
  – Enter the dummy parameter `%o` where the object file's name has to be inserted (used for the makefile generation).
  – Enter the dummy parameter `%I` where the include path option has to be placed (see below).

- *Include*

  Enter the compiler option needed to specify include paths and the include paths themselves here. The complete contents of this entry will replace the entry `%I` in the Options (see above).

- *Obj. extension*

  Enter the object extension to be used for the compiler output.

- *List of files*

  – *Default*

    Restores the default values.

  – *Add*

    A file selection dialog is opened where you can select the file which should be additionally compiled.

  – *Remove*

    Removes the item you have selected in the list box.

  – *Modify*

    A dialog is displayed and the selected entry can be modified

  – *Clear*

    Deletes all the items in the list box.

- *Dependencies*

  List the dependencies for the makefile here. Note that the name of the additional file itself is automatically generated as a dependency.

Linker

To link all the compiled files (generated ones, the ones building the library and additional ones) you must configure a linker.

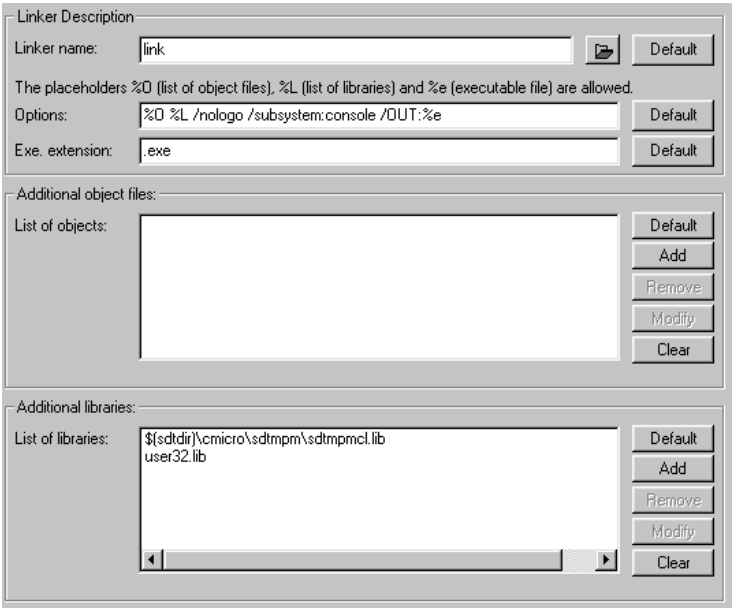

Figure 538: Linker configuration

Click *Default* if you want to restore the default values.

- *Linker name*

  Enter the name of the linker application.

- *Options*

  Enter the options given to the compiler as command line arguments here.

  – Enter the dummy parameter `%O` in the place of the list of all compiled files and the additional object files to link (used for the makefile generation).
  – Enter the dummy parameter `%L` in the place of the list of all the libraries (if there are some) which have to be linked.
  – Enter the dummy parameter `%e` in the place where the executable file's name has to be inserted (used for the makefile generation).

- *Exe. extension*

  Enter the executable extension to be used for the linker output.

- *Additional object files* and *Additional libraries*

  – *Default*

  Restores the default values.

  – *Add*

  A file selection dialog is opened where you can select the file which should be additionally linked to the executable.

  – *Remove*

  Removes the item you have selected in the list box.

  – *Modify*

  A dialog is displayed and the selected item in the list box can be modified.

  – *Clear*

  Deletes all the items in the list box.

Library Manager

> **Note:**
> This section is available only if an SDL and/or ASN.1 coder is selected. Please see "Communication" on page 2952 for details on how to select a coder.

The library manager offers the command that will be used to build a library from all the coder files. The dialog is shown in Figure 539

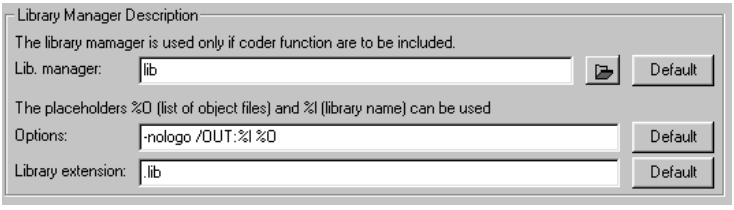

Figure 539: Library Manager Configuration

Note:

If no library manager is given all the coder object files will be linked directly to the target application.

Click *Default* if you want to restore the default values.

- *Lib. Manager*

  Enter the name of the library manager application.

- *Options*

  Enter the options given to the library manager as command line arguments here.

  – Enter the dummy parameter `%O` in the place of the list of all coder object files to link (used for the makefile generation).
  – Enter the dummy parameter `%l` in the place where the library's name has to be inserted (used for the makefile generation).

- *Library extension*

  Enter the library extension here.

Make

You can select the make tool to do all the compile and link actions here.

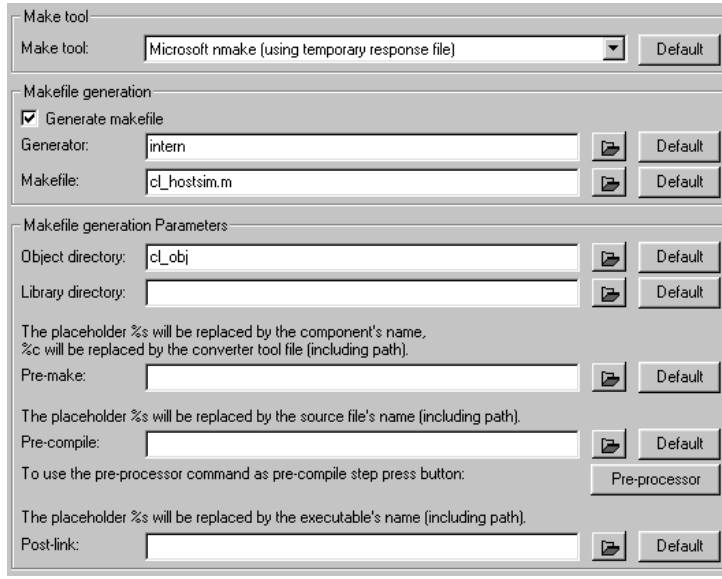

Figure 540: Make tool configuration

Click *Default* if you want to restore the default values.

- *Make tool*

  Select the make tool you wish to use. Currently the following make tools are supported: (see "Make Applications" on page 3003)

  – Microsoft nmake (using temporary response file)
  – Microsoft nmake (ignore exit codes)
  – Microsoft nmake
  – UNIX make
  – Tasking mk166
  – VxWorks gnu tool chain make

Hint:

"Using temporary response file" means that the compiler's and the linker's command line options are passed to the compiler/linker via a temporary file generated by the make tool.

This feature can only be used if the compiler in use supports this facility.

Note:

If the make tool you would like to use is not in the list. Please add a new definition in `sdttaex.par`. For more information view "Make Applications" on page 3003

- *Generate makefile*

  Select this if a makefile should be generated before make is invoked. The name of the generated makefile is the one in *Makefile*.

- *Generator*

  The Targeting Expert is designed to execute external makefile generators whenever the build-in makefile generator (`intern`) is not sufficient.

  Enter the name (and the path) of the external makefile generator here. Please see "External Makefile Generator" on page 3009 for further information about how to build an external makefile generator.

- *Makefile*

  Enter the name of the makefile.

- *Object directory*

  The object directory is the relative path seen from the current target directory, in which the compiler output files (object files) should be written.

Note:

If the directory `<target_directory>/<object_directory>` does not exist it will be automatically created.

- *Library directory*

The library directory is the absolute path to the target library to be used. Under normal circumstances this field can be left empty as the Targeting Expert automatically uses the path in the installation:

`<installationdir>/sdt/sdtdir/<platform_sdtdir>`

Note:

The Cmicro target library will be expected in a sub-directory called `cmicro`.

The Cadvanced library will be expected in a sub-directory called `INCLUDE`.

The Cextreme library will be expected in a sub-directory called `cextreme`.

- *Pre-make*

  The pre-make step will be executed before any other action specified in the makefile is performed.

  – The placeholder `%s` will automatically be replaced by the component's name.

- *Pre-compile*

  The pre-compile of the generated file(s) will be executed before they are compiled.

  Enter the application which performs the pre-compile here.

  – The placeholder `%s` can be used to represent the source files name.

  – The preprocessor button inserts the complete command that is necessary to pre-process the generated C file with the default compiler before the compilation with the target compiler.

Hint:

It is probably useful to use the utility functions delivered in combination with the Targeting Expert. Please see "Utilities" on page 3010

- *Post-link*

The post-link of the linked files will be executed as the last step in the make task.

Enter the application which performs the post-link here. (E.g. a conversion from absolute to Intel-HEX format).

– The placeholder `%s` can be used to represent the linker output file.

Configure and Scale the Target Library

The configuration and the scaling of the used target library is done by setting/resetting compiler macros (`#define` in C). These macros will be called “flags” in the further description.

For more information concerning allowed flags see

- `sct_mcf.h` (Cadvanced), see “Some Configuration Macros” on page 3156.
- `ml_mcf.h` (Cmicro), see “Compilation Flags” on page 3486 in chapter 66, *The Cmicro Library*
- `extreme_user_cfg.h` (Cextreme), see Optimization and Configuration.

The Targeting Expert offers an easy way of setting/resetting these flags. All the allowed flags are divided into different groups, e.g. SDL support and environment.

Figure 541 shows an example for Cmicro.

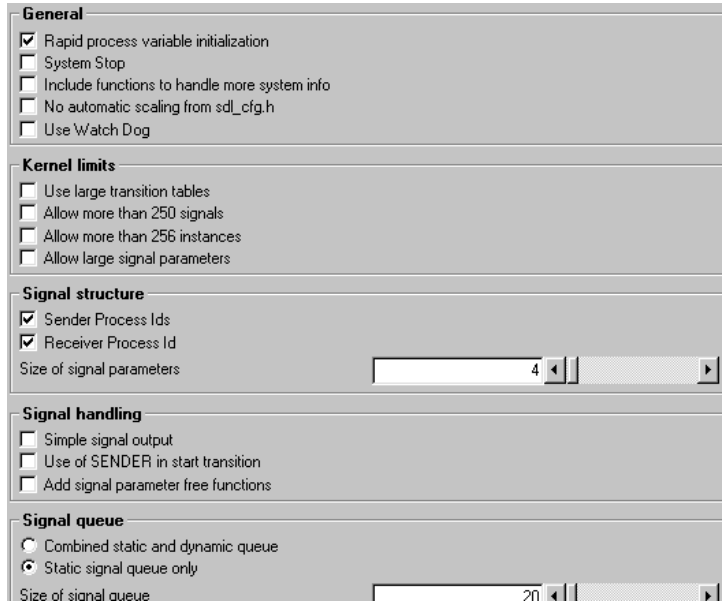

Figure 541: Configuration flag dialog

When all the configurations have been done the Targeting Expert generates

- `ml_mcf.h` (a C header file for Cmicro) which will be included in `ml_typ.h` during the compilation of the corresponding files.
  This is done for all the pre-defined integrations using the SDL to C compiler Cmicro.
- `sct_mcf.h` (a C header file for Cadvanced) which will be included in `scttypes.h` if the flag `USER_CONFIG` is defined.
  The flag `USER_CONFIG` is only defined for the pre-defined integrations Application (applclenv) and Application, debug (debclenv-com) using the SDL to C compiler Cadvanced.
- `extreme_user_cfg.h` (a C header file for Cextreme) which will be included in `extreme_kern.h` during compilation.

Configure the SDL Target Tester (Cmicro only)

The configuration of the SDL Target Tester is very similar to the configuration of the target library.

The settings done for the target will also be generated into the file `ml_mcf.h`. (Please see "Configure and Scale the Target Library" on page 2946.)

Configure the Host (Cmicro only)

The settings for the host will be generated into the file `sdtmt.opt` which will be read by the SDL Target Tester during start-up to get information about the gateway to be used and the target's memory layout. Please see "Communication Setup on the Host System" on page 3615 in chapter 67, *The SDL Target Tester* for more information about how to configure the SDL Target Tester's host application.

4. Actions to perform:
   - Configure how to Make the Component
   - Make the Component

Configure how to Make the Component

The possible options are divided into four pages:

> **Note:**
>
> All the Analyzer options entered in the Organizer will be re-used by the Targeting Expert.
>
> When a warning or error is found during analysis a warning message will popup. By setting the Organizer preference Organizer*ShowLogLevel to Never this dialog will be suppressed.

SDL to C Compiler

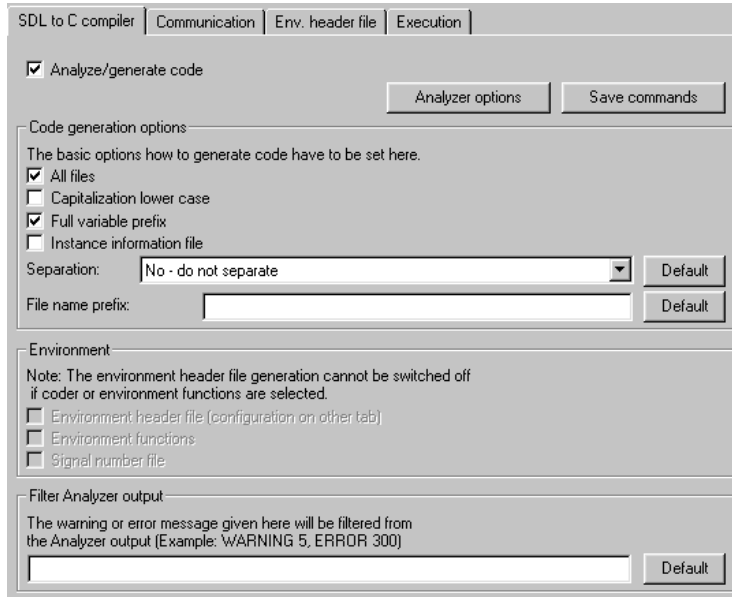

Figure 542

Note:

Because the Advanced Mode is switched off there might be some controls disabled because it does not make sense to modify them for the selected integration.

- *Analyze/generate code*

  Switch the Analyzer and SDL to C compiler execution on/off when starting the make process.

- *Analyzer options*

  The Organizer's Analyzer-Options dialog is displayed and the Analyzer options used for all the integrations can be modified. Please see "Analyze SDL" on page 113 in chapter 2, *The Organizer*.

- *Save commands*

A text file containing all the Analyzer commands configured for the selected integration can be saved. It is possible to start the Analyzer directly using this command file with `sdtsan < commandfile`

- *All files*

  If selected, the SDL to C compiler will generate all files anew. It does not matter whether the file's contents have changed or not. Unselecting it can economize the build process.

- *Capitalization lower case*

  When selected all identifiers are translated to lower case. Otherwise capitalization is used in the declaration of the object

- *Full variable prefix*

  All the variables used in SDL will be generated with a full prefix to C to make them unique if this item is selected. This comes with a disadvantage of long variable names.

- *Instance information file*

  An instance information file will be generated. Please see "SDL Instance Information" on page 2512 in chapter 54, *The SDL Analyzer*.

- *Separation*

  It is possible to select between three alternatives:

  – do not separate
  – use the user defined separation done in Organizer
  – separate each SDL entity into one C file

- *File name prefix*

  All the generated files (except those with fixed names like `sdl_cfg.h`) will be generated with the given file name prefix.

- *Environment header file*

  The environment header file (`.ifc`) which is used in the coder and environment functions will be generated if switched on.

- *Environment functions*

  Environment functions will be generated or not.

Note:

If the generation of environment functions is switched on it may be needed to add the environment source file to Source Files.

Please see

- "Initializing the Environment / Interface to the Environment" on page 3532 in chapter 66, *The Cmicro Library* for Cmicro
- "Building an Application" on page 2767 for Cadvanced

- *Signal number file* (Cadvanced only)

  Generate a signal number file if selected.

- *Conversion style* (Cmicro only)

  Select the rules how to generate the converter file here.

- *Filename* (Cmicro only)

  Give a name to the converter file

- *Amount of comments* (Cextreme only)

  Selects the amount of comments that the code generator will generate.

- *Generate run time tests* (Cextreme only)

  Controls if run time tests should be generated.

- *Generate sdt references* (Cextreme only)

  Adds comments with sdt references used to navigate from code to model.

- *Generate trace code* (Cextreme only)

  Controls if trace code should be generated.

Communication

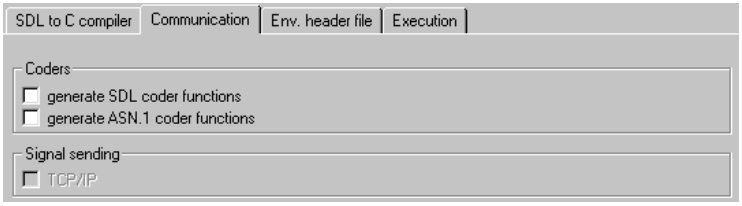

Figure 543: Communication configuration

- *Generate/do not generate SDL coder functions.*
  (Please see "Type description nodes for SDL types" on page 2791 in chapter 57, *Building an Application*.)
- *Generate/do not generate ASN.1 coder functions.*
  (Please see "ASN.1 Type Information Generated by ASN.1 Utilities" on page 2841 in chapter 58, *ASN.1 Encoding and De-coding in the SDL Suite*.)
- *TCP/IP signal sending*

Note:

The TCP/IP communication is supported only for a threaded integration using the SDL to C compiler Cadvanced.

The signal sending to other components can be done via a communications link. If it is switched on, a wizard dialog to set up all the needed information pops up (see Figure 544).

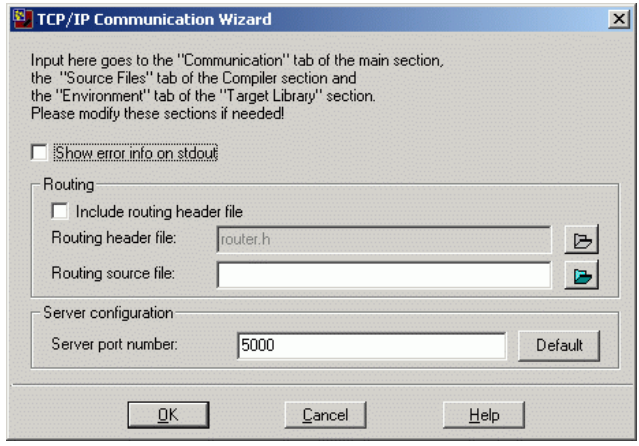

Figure 544: TCP/IP communication wizard

As described in the dialog there are settings done in different sections of the Targeting Expert:

- the manual configuration file `sct_mcf.h`
- the list of source files to compile, i.e. the makefile

Furthermore the generation of

- an Environment header file
- Environment functions and
- SDL coder functions

will be switched on.

Caution!

If the TCP/IP communication is switched **on,** a routing source file has to be provided, so that the signals destination can be calculated correctly! Otherwise all the signals will be sent to the sending application.

Caution!

If the TCP/IP communication is switched **off** the routing source file needs to be removed from the list of source files to compile by hand!

Env. Header File

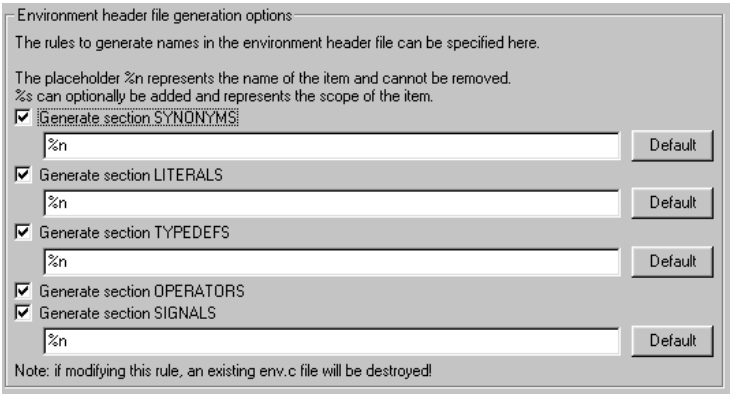

Figure 545: Env. header file configuration

The way the environment header file(`.ifc` file) is generated can be configured here. Please see "System Interface Header File" on page 2777 in chapter 57, *Building an Application* for more information.

Note:

The CHANNELS section cannot be configured for Cmicro because the SDL systems structure (blocks and channels) will be lost after code generation.

Execution

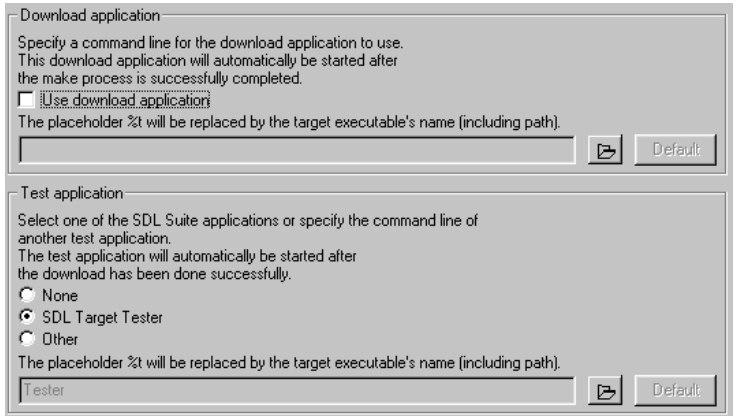

Figure 546: Download and test tool configuration

- *Download Application*

  Enter also the complete command line which will be necessary to invoke the download application. You can use the placeholder `%t` which will automatically be replaced by the name of the target executable's name (including the full path).

Note:

The selected download application will automatically be started if make was successful. The Targeting Expert does not try to invoke a download application if "Use download application" is un-checked.

- *Test Application*

  There are two kinds of test applications:

  – The applications that are part of the SDL Suite, i.e. *"The SDL Simulator" on page 2129*, *"The SDL Explorer" on page 2297* and "The SDL Target Tester" on page 3601.
  – The applications from other vendors, e.g. a debugger or emulator.

  If you select *Other* you have to enter also the complete command line for the desired test tool. You can use the placeholder `%t` which

will automatically be replaced by the target executable (including the full path).

Make the Component

The whole make process consists of several different tasks which will automatically be executed one after another. These tasks are:

- Analyze and Generate Code
- Generate a Makefile
- Compile and link
- Execute (target application or the application in Download Application and/or Test Application)

The execution of the next task will be stopped if the current task returns with an error. The Targeting Expert event log will give information about the process' state.

Analyze and Generate Code

The selected SDL to C compiler will be invoked and code will be generated for the selected component.

There are two possibilities:

- make
  In that case only code for the modified parts of the SDL system will be generated.
- full make
  Code for the complete SDL system is generated. Even if there are no modifications.

Generate a Makefile

The makefile to be used will be generated. Please see "Make" on page 2942 for information on how to give the makefile's name and how to switch the makefile generation on or off.

> **Hint:**
>
> If the build-in makefile generation does not fit your needs it is possible to customize the makefile generation.
>
> Please see "External Makefile Generator" on page 3009 to get information on how to build a makefile generator.

Compile and link

The external make tool will be invoked using the generated makefile. Please see "Make" on page 2942 for information on how to select the make tool.

> **Hint:**
>
> To force a compilation of all the C source files the object files have to be deleted first. Please use the *Clean* entry in the Make Menu.

Execute

The target executable will be executed.

> **Note:**
>
> It is sometimes not possible to invoke the target executable from the Targeting Expert, e.g. if the target executable is built for a micro controller. In this case you can select a download application or any other test tool (e.g. debugger) which will be executed instead. Please see "Download Application" on page 2955 and "Test Application" on page 2955.

> **Hint:**
>
> For running test cases the target executable's output to `stdout` and `stderr` will be re-directed automatically into the Targeting Expert event Log. The target simply should be executed by entering "`%t`" as the test application (Please see "Test Application" on page 2955).

Batch Mode

Using the Targeting Expert in the batch mode means starting `taexbatch` instead of `sdttaex`.

The commands have to be given one after another by hand or in a command file. (Please see an Example of a Batch File.) In this case the Targeting Expert has to be started with `taexbatch < commandfile`

> **Note:**
>
> If the commands are given in a command file the Targeting Expert should be started with one of the options `-yes` or `-no` to answer all upcoming questions automatically. Otherwise the application will probably hang up.

Syntax of Batch Mode Commands

Command Names

You may abbreviate a command name by giving sufficient characters to distinguish it from other command names. A hyphen ('-') is used to separate command names into distinct parts.

Abbreviation of Commands

You may abbreviate any part as long as the command does not become ambiguous.

> **Hint:**
>
> Commands used in command files should not be abbreviated because future implementations may conflict with those abbreviations.

Parameters in Commands

Parameters are separated by one or several spaces. Parameters containing spaces have to be given in quotation marks.

Case Insensitivity in Commands

In command names there is no distinction made between upper and lower case letters.

Some more Detailed Description of Parameter Types

- `<flagname>`

  Allowed flag names depend on the SDL to C compiler in use.

  – For Cadvanced a description of allowed flags can be found in section "Some Configuration Macros" on page 3156.
  – For Cmicro see "Compilation Flags" on page 3486 in chapter 66, *The Cmicro Library* for a more detailed description.
  – For Cextreme see Optimization and Configuration.

  `<flagname>` parameters are case sensitive.

- `<boolvalue>`

  Allowed boolean values can be `true`, `on` and `yes` which all have the same meaning no matter if written lower case or not. The same applies for the values `false`, `off` and `no`.

- `<stringvalue>`

  Any string value is allowed here. There is no check at all if the value can be interpreted correctly. E.g. if "abc" is entered although and integer value is needed it will not be checked but probably cause a compilation error afterwards.

- `<entry>`

  Allowed entries depend on the class used in the command. Please see `<class>`. Parameters of type `<entry>` are case insensitive.

- `<class>`

  Allowed classes and the depending entries are shown in the table below. Parameters of type `<class>` are case insensitive.

  For all allowed combinations of classes and entries the commands Get-Setting and Default-Setting can be used.

  – Compiler

allowed entries	function to set contents

Description of Batch Mode Commands

In this section, the batch mode commands are listed in alphabetical order, along with their parameters and a description.

Add-PR

Parameters:

<pr-filename>

Further PR files can be specified here which should be considered by the SDL to C compiler.

The first PR file has to be given by using Open-PR command.

Add-Setting-String

Parameters:

`<class> <entry> <stringvalue>`

The list `<entry>` will be extended for the item `<stringvalue>`.

Add-UserSection-String

Parameters:

`<stringvalue>`

The `<stringvalue>` will be added in the user section of `ml_mcf.h` (Cmicro), `sct_mcf.h` (Cadvanced) or `extreme_user_cfg.h` (Cextreme).

Analyze

Parameters:

`<none>`

The SDL system will be analyzed.

Append-Setting-String

Parameters:

`<class> <entry> <stringvalue>`

`<stringvalue>` will be appended to the current value of `<class> <entry>`.

Clear-UserSection

Parameters:

`<none>`

The complete user section of `ml_mcf.h` (Cmicro), `sct_mcf.h` (Cadvanced) or `extreme_user_cfg.h` (Cextreme) will be removed.

Default-Setting

Parameters:

`<class> <entry>`

The default value of the given `<entry>` will be restored.

Exit
Parameters:
<none>

The Targeting Expert exits (same as Quit).

Generate-Code
Parameters:
<none>

A code generation for the selected component is done using the SDL to C compiler selected in the associated settings.

Generate-Code-Full
Parameters:
<none>

A full code generation for the selected component is done using the SDL to C compiler selected in the associated settings.

Generate-Makefile
Parameters:
<none>

A makefile will be generated for the selected component. The make-file's name is taken from the associated settings.

Get-Setting
Parameters:
<class> <entry>

The current contents of <entry> will be printed on the screen.

Include
Parameters:
<batch-filename>

All the commands listed in <batch-filename> will be processed.

Help
Parameters:
<none>

A list of all commands with their needed parameters is printed.

Make-All
<none>

For the application or all the nodes and components that are configured (combined or separate configuration) the steps of analysis, code generation, makefile generation and compilation/linkage will be performed.

Make-Clean

Parameters:

`<none>`

All the object files will be removed.

Make-Selected

Parameters:

`<none>`

The make tool will be executed using the associated make tool and the associated makefile of the selected component.

Open-PDM

Parameters:

`<filename>`

The partitioning diagram file `<filename>` will be loaded.

Open-PR

Parameters:

`<filename>`

The PR file `<filename>` will be loaded and internally converted into a partitioning diagram model.

Open-SDT

Parameters:

`<filename>`

The system file `<filename>` will be loaded and internally converted into a partitioning diagram model.

Prepend-Setting-String

Parameters:

`<class> <entry> <stringvalue>`

`<stringvalue>` will be prepended to the current value of `<class> <entry>`.

Qualifier

Parameters:

`<SDL-qualifier>`

The given <SDL-qualifier> will be used for building a part of the SDL system.

Quit

Parameters:

<none>

The Targeting Expert exits (same as Exit).

Replace-Setting-String

Parameters:

<class> <entry> <old-stringvalue> <new-stringvalue>

The string <old-stringvalue> of <entry> will be replaced with <new-stringvalue>.

Save-Settings

Parameters:

<none>

The modified settings of all the available applications, nodes and components will be saved.

Select

Parameters:

[<application-node-component>]

The entry specified by <application-node-component> in the partitioning diagram will be selected. This step has to be executed before you can generate.

One of the commands Open-PDM, Open-PR or Open-SDT has to be executed before.

Set-Compiler

Parameters:

<compilername>

The given <compilername> will be set as the used compiler. The <compilername> must be available in the default settings of the Set-Integration.

The command Set-Integration has to be executed before.

Set-Flag-Bool

Parameters:

<flagname> <boolvalue>

The SDL to C compiler's library flag <flagname> will be set/reset due to the <boolvalue>.

> **Caution!**
>
> There is no check for interdependencies to other flags.

Set-Flag-String

Parameters:

```
<flagname> <stringvalue>
```

The SDL to C compiler's library flag <flagname> will be set to the <value>.

> **Caution!**
>
> There is no check for upper and lower limits. You must be aware to set a value that is in the allowed range!

Set-Integration

Parameters:

```
<integration>
```

The pre-defined integration settings <integration> will be set.

- Simulations
  - Performance Simulation
  - Realtime Simulation
  - Simulation
  - TTCN Link
- Validations
  - Validation
- TargetTest
  - Application DEBUG CA
  - Application DEBUG CE
  - HostSimulation
  - HostSimulation (CL)
  - HostSimulation (CLENV)
- Light Integrations
  - Application CA
  - Application CE
  - Application CM
  - Application TEST

- Threaded Integrations
  - OSE
  - Solaris
  - VxWorks
  - POSIX/Linux
  - Win32

Note:

To set a Realtime Simulation for example, the `<integration>` has to be given in quotation marks, i.e.

```
Set-Integration "Realtime Simulation"
```

Caution!

In batch mode there is no check if the selected integration fits to the component settings!

Please have a look to "Distributed Pre-defined Integration Settings" on page 2979 for more information.

The command Select has to be executed before.

Set-Setting-Bool

Parameters:

`<class> <entry> <boolvalue>`

The boolean `<entry>` will be set to its new value.

Set-Setting-String

Parameters:

`<class> <entry> <stringvalue>`

The non-boolean `<entry>` will get the new content `<stringvalue>`.

Start-Download

Parameters:

`<none>`

The download application selected in Download Application will be invoked.

Start-Testtool

Parameters:

`<none>`

The test application specified in Test Application will be invoked.

system

Parameters:

`<systemcommand>`

Executes the `<systemcommand>` on the underlying OS. The following placeholders can be used in `<systemcommand>` and will be replaced before execution:

placeholder	... will be replaced by...
`%s`	system directory
`%b`	target directory (the one given in the Organizer)
`%t`	sub target directory (the one calculated depending on the selected component and integration)
`%e`	executable name (inclusive extension)
`%i`	intermediate directory

Target

Parameters:

`<target>`

The `<target>` becomes the SDL system's part to build. The generated files will be placed in a subfolder with `<target>` as part of the folder name.

Write-Log

Parameters:

`<filename>`

All the output to `stdout` and `stderr` will also be written into the file `<filename>`.

Example of a Batch File

The following batch file can be used to build a Simulator using the Targeting Expert batch mode.

Example 489: Simple batch file ––––––––––––––––––––––––––––––

```
Open-SDT access.sdt
select access-node-component
```

```
set-integration Simulation
set-Compiler Microsoft
Generate-Code
Generate-Makefile
Make-selected
Exit
```

Note:

The items `application`, `node` and `component` depend on the partitioning diagram model used.

Internal

Partitioning Diagram Model File

The Targeting Expert needs to know how the SDL system which is used for targeting should be partitioned. This is done by using a partitioning diagram model.

> **Note:**
>
> The partitioning diagram model will be generated by the Deployment Editor for deployed systems into a partitioning diagram model file `<partitioning diagram model>.pdm`. It should not be modified by hand! Please see "Generating Partitioning Diagram Data for the Targeting Expert" on page 1787 in chapter 40, *The Deployment Editor* for more information.
>
> If there is no deployment done for a system, the Targeting Expert generates a default partitioning diagram model for its internal use. This partitioning diagram model is not available as a file. For a default partitioning diagram model there is no chance to specify integration models or threads.

Definitions

The complete SDL system is mirrored in the partitioning diagram's *application* which takes several *nodes*.

Each *node* can represent a run-time (physical) object with memory and processing capability and is a collection of several *components*.

Each *component* is a collection of different *objects*, with each *object* representing an SDL qualifier. A *component* will result in one executable or OS task.

File Syntax Example

Estimated there is an SDL system like the one shown in Figure 547,

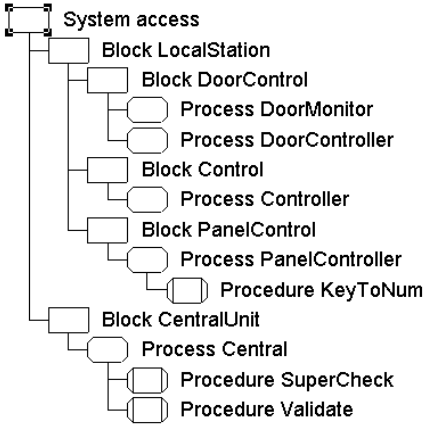

Figure 547: An SDL system

then the simplest possible partitioning diagram model looks like the one shown in Figure 548.

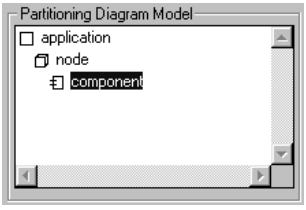

Figure 548: A possible partitioning diagram model

The first few lines of the corresponding partitioning diagram model file is shown in Example 490:

Example 490: Partitioning diagram model file ––––––––––––––––––––

```
TIMESTAMP: 948787119

APPLICATION*0: access
detail+SystemFileName: access.sdt

NODE*1: node

COMPONENT*2: component
```

```
OBJECT*3: object
detail+Qualifier: access
-------------------------------------------------------
```

Explanations

- The `TIMESTAMP` entry is needed for future implementations.
- The `APPLICATION*0: access` gives the name of the used SDL system. The `0` is used as an identifier for internal purposes.
- `detail+SystemFileName` is the name of the used `<system-name>.sdt` file
- `detail+PRFileName` is the name of the used `<systemname>.pr` file. Subsequent entries of `detail+PRFileName` can be used to insert more than one PR file.
- `NODE*1: node` specifies that the following `components` belong to the node. The node is called `node` and the unique id `1` is used for internal purposes.
- `COMPONENT*2: component` specifies that the following `objects` belong to this component. The component is called `component` and the unique id `2` is used for internal purposes.
- `OBJECT+5: object` gives one further object which will be assigned to the current `component`.
- `detail+Qualifier: access` means that all the SDL entities that are sub entities of the qualifier access (in this case the complete system) will be part of the `object`.

More Supported Keywords

Details of COMPONENT

- `detail+Integration: Light|Threaded` specifies in which integration model the component should be build. For backwards compatibility, the keyword `ThreadedLight` is accepted as an alias for `Threaded`.

Details of OBJECT

- `detail+Type: system|block|process` tells which kind of SDL agent the qualifier is all about.

Details of THREAD

- `THREAD: name` is a sub entry of `COMPONENT` and specifies a thread, e.g. for a threaded integration.
- `detail+ThreadPriority: value` specifies the OS priority of the particular thread.
- `detail+StackSize: value` specifies the stack size of the thread. (bytes)
- `detail+QueueSize: value` specifies the maximum number of signals that are allowed in the queue.
- `detail+MaxSignalSize: value` specifies the maximum size of an individual signal in the queue. (bytes)
- `detail+OneThreadPerInstance: true|false` tells if each process instance will become its own thread in a threaded integration if the value is `true`.

Configuration Files

For each SDL to C compiler that will be used there is one configuration file `ca_conf.def` (Cadvanced), `cm_conf.def` (Cmicro) and `ce_conf.def` (Cextreme).

The configuration files for all SDL to C compilers can be found in `<installationdir>/sdt/sdtdir`.

The `c*_conf.def` files are ASCII text files that can be (should be) extended by you to adapt a new compiler or to adapt a new communications link (Cmicro only).

You can find all the known configuration flags in:

- "Some Configuration Macros" on page 3156 (Cadvanced)
- "Compilation Flags" on page 3486 in chapter 66, *The Cmicro Library* (for Cmicro)

Structure of the Configuration File cm_conf.def

Note:

All the descriptions in this section are valid for the SDL to C compiler Cmicro only.

Compiler

All the compilers currently supported by a SDL to C compiler library are listed in the c*_conf.def file like displayed in Example 491.

Example 491: Structure of a compiler entry

```
BEGIN
  IAR_C51
  IAR systems compiler of 8051
  COMPILER
  Microcontroller compiler
END
```

The first and the last line of the example simply marks the start and the end of one entry.

Line 2 is the flag which will be used to include the appropriate compiler section in the used library (see `ml_typ.h` for Cmicro and `scttypes.h` for Cadvanced).

Line 3 is the text which will be shown in the Targeting Experts user interface.

Line 4 must be `COMPILER` in this case.

Line 5 is the compiler group this compiler should be associated with. In the distributed files `c*_conf.def` there are three groups, namely:

- `Micro controller compiler`
- `PC compiler`
- `Workstation compiler`

Communications Link

Note:

This section is valid only if the Cmicro SDL to C Compiler is used.

The example below shows the structure of one entry.

Example 492: Structure of a `cm_conf.def` entries

```
 1 BEGIN
 2   XMK_USE_V24
 3    V24 communication
 4    COMMLINK
 5    V24 interface
 6   AUTOSET
 7     XMK_V24_BAUD
 8     XMK_V24_DEVICE
 9   END
10 END
```

Lines 1 and 10 mark the start and the end of one entry.

Line 2 gives the name of the flag as it appears in the generated file `ml_mcf.h`. According to this example line 3 is the marker which appears in the Targeting Expert graphical user interface.

Line 4 specifies the main group this entry belongs to. It has to be `COMMLINK` in this case.

Line 5 gives the subgroup of the entry. This subgroup can be anything you like. In the delivered version there is only the subgroup `V24 interface`. However, you can define your own communications link `CAN Bus` for example.

The lines 6 and 9 belong together and between these lines all flags are listed which have to be set when the flag on line 2 is set. The amount of flags (lines 7 and 8 in the example) is free. In the same way as `AUTOSET` in line 6 there can also be the entries `RESET` or `DEPEND`.

`RESET` means the following flags will be reset if this flag is defined and `DEPEND` means this flag can only be set if the following flags (lines 7 and 8) are already defined.

Not given in the example above is the section `VALUE`, (like `AUTOSET` finished by an `END`) which assign a value to the flag. This section can include three lines of information. The first gives the default value. And, if the value is numeric, the second line gives the lowest and the third one the highest value. You are asked to have a look into `c*_conf.def`.

Also not given in the example above is the section `VALUE_LIST` (finished by an `END`) which assign a value to the flag with a list of allowed values given. The first value is the default value, the following values

(with no upper limit) are giving the list of allowed values. The default value must be given in the list again.

Pre-defined Integration Settings

Introduction

Pre-defined integration settings must be seen as a set of default values which can be used for targeting purposes.

There are several pre-defined integration settings distributed with each installation.

- Each set of predefined integration settings is stored in an ASCII file with the extension `.its`.
- The amount of pre-defined integration settings that are to be handled by the Targeting Expert can simply be enlarged by copying a new file `<name>.its` or by exporting own settings. (See "Export" on page 2922)
- The integration names have to be unique!
- The Targeting Expert searches for `.its` files in the following directories:

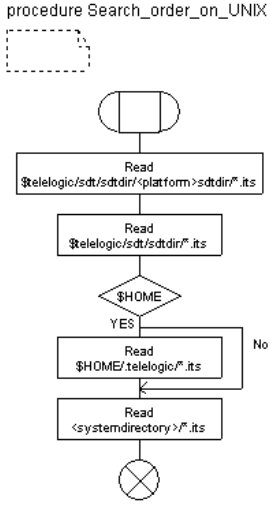

Figure 549: Search order on UNIX

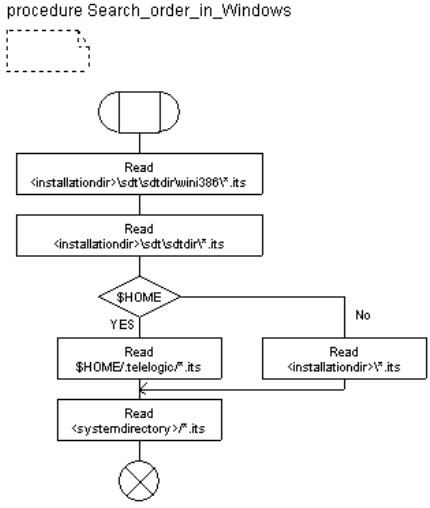

Figure 550: Search order in Windows

Distributed Pre-defined Integration Settings

For Use with Cadvanced SDL to C Compiler

- Simulation (`debcom`)

Supported compiler	On Sun: – Sun GNU gcc – Sun Workshop cc – Sun Workshop CC In Windows: – Microsoft VC++
Used kernel directory	-
Timers	Timers are not implemented, i.e. timers set in the SDL system will expire at once
Environment	Will be handled in the Simulator UI
More info	See chapter 49, *The SDL Simulator*.

- Realtime Simulation (`debclcom`)

Supported compiler	On Sun: – Sun GNU gcc – Sun Workshop cc – Sun Workshop CC On Windows: – Microsoft VC++
Used kernel directory	-
Timers	Timers are implemented in a way that one timer tick is equal to one second, i.e. a timer set to 10 in the SDL system will expire after 10 seconds.
Environment	Will be handled in the Simulator UI
More info	See chapter 49, *The SDL Simulator*.

- Performance Simulation (`perfsim`)

Supported compiler	On Sun: – Sun GNU gcc – Sun Workshop cc – Sun Workshop CC In Windows: – Microsoft VC++
Used kernel directory	-
Timers	Not handled
Environment	Not handled
More info	See chapter 63, *The Performance Library*.

- TTCN Link

Supported compiler	On Sun: – Sun GNU gcc – Sun Workshop cc On Windows: – Microsoft VC++
Used kernel directory	`$(sdtdir)/SCT*TTCNLINK`
More info	See chapter 35, *TTCN Test Suite Generation*.

- Validation

Supported compiler	On Sun: – Sun GNU gcc – Sun Workshop cc On Windows: – Microsoft VC++
Used kernel directory	`$(sdtdir)/SCT*VALIDATOR`
More info	See chapter 52, *The SDL Explorer*.

- Application (`applclenv`)

Supported compiler	On Sun: – Sun GNU gcc – Sun Workshop cc – Sun Workshop CC On Windows: – Microsoft VC++
Used kernel directory	-
Timers	Timers are implemented in a way that one timer tick is equal to one second, i.e. a timer set to 10 in the SDL system will expire after 10 seconds.
Environment	Has to be implemented by the user.
More info	See "Compilation Switches" on page 3119 in chapter 61, *The Master Library*.

- Application, debug (`debclenvcom`)

Supported compiler	On Sun: – Sun GNU gcc – Sun Workshop cc – Sun Workshop CC On Windows: – Microsoft VC++
Used kernel directory	-
Timers	Timers are implemented in a way that one timer tick is equal to one second, i.e. a timer set to 10 in the SDL system will expire after 10 seconds.
Environment	Has to be implemented by the user.
More info	See "Compilation Switches" on page 3119 in chapter 61, *The Master Library*.

- Threaded integrations for the platforms
  - OSE (Softkernel Solaris and Windows)
  - Solaris
  - VxWorks (Softkernel Solaris and Windows)

Note: (VxWorks only)

The environment variable `WIND_BASE` has to be set on your system!

- Win32
- OSE (Softkernel Solaris)

Note: (OSE only)

The environment variable `OSE_ROOT` has to be set on your system!

Supported compiler	OSE: – Sun GNU gcc – Microsoft VC++ Solaris: – Sun GNU gcc – Sun Workshop cc – Sun Workshop CC VxWorks: – gnu tool chain Win32: – Microsoft VC++
Used kernel directory	-
Timers	OS timer
More info	See "Threaded Integration" on page 3303 in chapter 64, *Integration with Operating Systems*.

For Use with the Cmicro SDL to C Compiler

- Application (`applclenv`)

Supported compiler	On Sun: – Sun GNU gcc – Sun Workshop cc – Sun Workshop CC On Windows: – Microsoft VC++
Used kernel directory	-

Timers	Timers are implemented in a way that one timer tick is equal to one second, i.e. a timer set to 10 in the SDL system will expire after 10 seconds.
Environment	Has to be implemented by the user.
Template files	Taken from $(sdtdir)\cmicro\template
More info	The target executable can be executed on a command line.

- Application including Target Tester and communication via sockets

Supported compiler	On Sun: – Sun GNU gcc – Sun Workshop cc – Sun Workshop CC On Windows: – Microsoft VC++
Used kernel directory	-
Timers	Timers are implemented in a way that one timer tick is equal to one second, i.e. a timer set to 10 in the SDL system will expire after 10 seconds.
Environment	Has to be implemented by the user.
Template files	Taken from $(sdtdir)\cmicro\template
More info	The target executable has to be started manually after the Target Tester is started by the Targeting Expert.

- Host Simulation (`debcom`)

Supported compiler	On Sun: – Sun GNU gcc – Sun Workshop CC On Windows: – Microsoft VC++
Used kernel directory	-

Timers	Timers are not implemented, i.e a timer set in the SDL system will never expire.
Environment	Will be handled in the SDL Target Tester UI.
Template files	Taken from $(sdtdir)\cmicro\template
More info	The target is executed as the SDL Target Tester's gateway. After a complete make The SDL Target Testerwill be started and the target can be tested.

- Real-time Host Simulation (`debclcom`)

Supported compiler	On Sun: – Sun GNU gcc – Sun Workshop CC On Windows: – Microsoft VC++
Used kernel directory	-
Timers	Timers are implemented in a way that one timer tick is equal to one second, i.e. a timer set to 10 in the SDL system will expire after 10 seconds.
Environment	Will be handled in the SDL Target Tester UI.
Template files	Taken from $(sdtdir)\cmicro\template
More help	The target is executed as the SDL Target Tester's gateway. After a complete make The SDL Target Tester will be started and the target can be tested.

- Real-time Host Simulation with environment (`debclenvcom`)

Supported compiler	On Sun: – Sun GNU gcc – Sun Workshop CC On Windows: – Microsoft VC++
Used kernel directory	-

Timers	Timers are implemented in a way that one timer tick is equal to one second, i.e. a timer set to 10 in the SDL system will expire after 10 seconds.
Environment	Has to be implemented by the user.
Template files	Taken from $(sdtdir)\cmicro\template
More help	The target is executed as the SDL Target Tester's gateway. After a complete make The SDL Target Tester will be started and the target can be tested.

For Use with the Cextreme SDL to C Compiler

- Application (applclenv)

Supported compiler	On Sun: – Sun GNU gcc – Sun Workshop cc – Sun Workshop CC On Windows: – Microsoft VC++ On Linux: – Linux GNU gcc
Timers	Timers are implemented in a way that one timer tick is equal to one second, i.e. a timer set to 10 in the SDL system will expire after 10 seconds.
Environment	Has to be implemented by the user
More info	See Optimization and Configuration

- Application, debug (debclenvcom)

Supported compiler	On Sun: – Sun GNU gcc – Sun Workshop cc – Sun Workshop CC On Windows: – Microsoft VC++ On Linux: – Linux GNU gcc
Timers	Timers are implemented in a way that one timer tick is equal to one second, i.e. a timer set to 10 in the SDL system will expire after 10 seconds.
Environment	Has to be implemented by the user
More info	Debug options for code generation and compiler settings enabled by default. See Optimization and Configuration

- Threaded integrations for the platforms
  - Posix
  - Win32
  - VxWorks (Windows)

Supported compiler	On Sun: – Sun GNU gcc – Sun Workshop cc – Sun Workshop CC On Windows: – Microsoft VC++ On Linux: – Linux GNU gcc On VxWorks: – GNU tool chain
Timers	Use OS timers
Environment	Has to be implemented by the user

More info	WIND_BASE has to be set for VxWorks. Other options, see Optimization and Configuration. A deployment diagram is needed to specify what the code generator should generate threads for, see The Deployment Editor.

Syntax of the .its Files

There is a more or less complex syntax to be followed in `.its` files which will be described here. In principle each `.its` file is divided into four sections:

- The Description about the Settings
- The Settings which are once more split into
  - the Global Settings (A)
  - the Compiler specific Definitions
- The Configuration Settings to Be Set
- The Configuration Settings to Be Reset

You can find further syntax information in “Comments and empty Lines” on page 2995 and “Other Rules” on page 2996.

Description about the Settings

The Targeting Expert will read in the description and display it in the user interface whenever a set of pre-defined integration settings is selected.

This section starts with `[DESCRIPTION]` and has got the only entry `HelpLink`. The description is a link name to this manual.

The Settings

The section of the `.its` files which contains the settings starts with `[SETTINGS]`. They must be ordered with the Global Settings (A) first, followed by the Compiler specific Definitions.

- Global Settings (A)

The global settings start with the `<keyword1>` equal to `Preferences` and the delimiter ’+’, i.e. an allowed line in this section looks like:

```
Preferences+<keyword2>: parameter
```

Example 493: Pre-defined integration settings (2A)

```
Preference+IntegrationSettings: <name>
```

The meaning of `<keyword2>` can be found in the table below.

Keyword 2	Meaning of the parameter
`IntegrationSettings`	The name of this pre-defined integration setting is entered here.

- Global Settings (B)

The global settings part B start with the `<keyword1>` equal to the name of the pre-defined integration settings (see Global Settings (A)) and the delimiter '+', i.e. an allowed line in this section looks like:

```
<name>+<keyword2>: parameter
```

Example 494: Pre-defined integration settings (2B)

```
Simulation+CompilersUsed:       Microsoft
Simulation+CodeGenerator:       Cadvanced
Simulation+GenerateMakefile:    YES
```

The meaning of `<keyword2>` can be found in the table below.

Keyword 2	Meaning of the parameter
`CompilersUsed`	The name of a compiler which is used to build the target application must be entered here. This line can appear more than once per file to allow the description of more than one compiler.
`CodeGenerator`	The name of the SDL to C compiler this pre-defined integration settings are designed for must be entered to the right of this keyword. Currently the SDL to C compilers – Cadvanced – Cmicro – Cextreme are possible here.

Keyword 2	Meaning of the parameter
GenerateAllFiles	All the files will be re-generated even if the contents have not changed (YES) or not (NO)
GenerateMakefile	The makefile generation should be switched on (YES) but can of course be switched off by specifying NO here.
GenerateLowerCase	The SDL to C compiler should generate all SDL identifiers in lower case (YES) or as defined (NO)
GenerateEnvFunctions	The SDL to C compiler should generate template environment functions (YES) or not (NO)
GenerateEnvHeader	The SDL to C compiler should generate an environment header file (YES) or not (NO)
GeneratePrefix	All variables will be generated with full prefix. Default is (YES) but can of course be switched off by specifying NO here.
GenerateSignalNumber	The SDL to C compiler should generate a signal number file (YES) or not (NO)
GenerateSDLCoder	The SDL to C compiler should generate an SDL coder functions file (NO, ASCII or <user>)
GenerateASNCoder	The SDL to C compiler should generate an ASN.1 coder functions file (NO, BER, PER or <user>)
Separation	The SDL to C compiler shall generate the C files separated according to the given value: NO, USER, FULL
Analyze	The Analyzer/SDL to C compiler should be invoked during the make (YES) or not (NO)
TestTool	The Test application to be used can be entered here, i.e. the entries Simulator, Validator or Tester but also a complete command line.
FileNamePrefix	The SDL to C compiler will generate all files with the given filename prefix.

Keyword 2	Meaning of the parameter
GenerateIfcSynonyms	The SDL to C compiler should generate the SYNONYMS section into the env. header file (YES) or not (NO). (depends on GenerateEnvHeader)
GenerateIfcLiterals	The SDL to C compiler should generate the LITERALS section into the env. header file (YES) or not (NO). (depends on GenerateEnvHeader)
GenerateIfcTypedefs	The SDL to C compiler should generate the TYPEDEFS section into the env. header file (YES) or not (NO). (depends on GenerateEnvHeader)
GenerateIfcOperators	The SDL to C compiler should generate the OPERATORS section into the env. header file (YES) or not (NO). (depends on GenerateEnvHeader)
GenerateIfcSignals	The SDL to C compiler should generate the SIGNALS section into the env. header file (YES) or not (NO). (depends on GenerateEnvHeader)
GenerateIfcChannels	The SDL to C compiler should generate the CHANNELS section into the env. header file (YES) or not (NO). (depends on GenerateEnvHeader)
IfcPrefixSynonyms	The SDL to C compiler will generate SYNONYMS using the specified rule (Default is %n)
IfcPrefixLiterals	The SDL to C compiler will generate SYNONYMS using the specified rule (Default is %n)
IfcPrefixTypes	The SDL to C compiler will generate SYNONYMS using the specified rule (Default is %n)
IfcPrefixSignals	The SDL to C compiler will generate SYNONYMS using the specified rule (Default is %n)
IfcPrefixChannels	The SDL to C compiler will generate SYNONYMS using the specified rule (Default is %n)

Keyword 2	Meaning of the parameter
SuppressText	The Analyzer error or warning message to suppress can be given here.

- Compiler specific Definitions

This segment has got all the definitions for an unlimited amount of compilers. All the keywords start with

```
<name of the setting>+<compiler-name>*
```

followed by one or two further keywords. If it is followed by two keywords both are separated by '~'.

Example 495: Pre-defined integration settings (3) ----------

```
Simulation+Microsoft*Compiler~Tool:    cl
Simulation+Microsoft*Compiler~Options: -nologo %I -ML -c -D_Windows -DSCTDEBCOM
/Fo%o %s
Simulation+Microsoft*Compiler~Include: -I$(sctuseinclude)
Simulation+Microsoft*Compiler~Flag:   IC86
Simulation+Microsoft*Linker~Tool:     link
Simulation+Microsoft*Linker~Options:  -nologo -subsystem:console %O /OUT:%e
Simulation+Microsoft*ObjectExtension:      _smc.obj
Simulation+Microsoft*ExecutableExtension: _smc.exe
Simulation+Microsoft*FileToCompile:   $(sdtdir)\INCLUDE\sctsdl.c
Simulation+Microsoft*FileToCompile:   $(sdtdir)\INCLUDE\sctpred.c
Simulation+Microsoft*FileToCompile:   $(sdtdir)\INCLUDE\sctos.c
Simulation+Microsoft*FileToCompile:   $(sdtdir)\INCLUDE\sctmon.c
Simulation+Microsoft*FileToCompile:   $(sdtdir)\INCLUDE\sctutil.c
Simulation+Microsoft*FileToCompile:   $(sdtdir)\SCTADEBCOM\sctpost.c
Simulation+Microsoft*LibrariesToLink: $(sdtdir)\INCLUDE\msvc50\libpost.lib
Simulation+Microsoft*LibrariesToLink: user32.lib
Simulation+Microsoft*Make~Tool: Microsoft nmake (using temporary response file)
Simulation+Microsoft*MakefileName:        my_makefile.m
Simulation+Microsoft*MakefileGenerator:   -
Simulation+Microsoft*ObjectDirectory:     objects
```

All the keywords and the allowed combinations can be found in the table below.

Keyword 3	Keyword 4	Meaning of the parameter
Compiler	Tool	Name of the compiler application
Compiler	Tool2	Name of the C parser application (optional)
Compiler	Tool3	Name of the assembler application (optional)

Keyword 3	Keyword 4	Meaning of the parameter
Compiler	Options	Compiler command line options (Please see "Compiler" on page 2975)
Compiler	Options2	C parser command line options (optional)
Compiler	Options3	Assembler command line options (optional)
Compiler	LibFlag	The compiler's option to set defines plus the library flag (e.g. SCTDEBCOM)
Compiler	Include	The compiler's option for include paths and the include paths
Compiler	CodInclude	The compiler's option for include paths and the include paths to the coder files
Compiler	Flag	Compiler flag (Please see "Compiler Flag" on page 2936)
Linker	Tool	Name of the linker application
Linker	Options	Linker command line options (Please see "Linker" on page 2939)
ObjectExtension		Extension of the object files
ExecutableExtension		Extension of the target executable
FilesToCompile		Kernel, library and template files to be compiled. This entry can be used more than once.
TesterFilesToCompile		Tester files to be compiled. This entry can be used more than once. (Cmicro only)
FilesToCopy		Template files which should be copied into the target directory. Environment variable $(sdtdir) can be used
ObjectsToLink		Additional object files to be linked. This entry can be used more than once.

Keyword 3	Keyword 4	Meaning of the parameter
LibrariesToLink		Additional libraries to be linked (e.g. the compiler's libraries). This entry can be used more than once.
Make	Tool	The name of the make application. This can be: • Microsoft nmake (using temporary response file) • Microsoft nmake • UNIX make
MakefileName		The name of the makefile to be generated (or respectively to be used) is entered here.
MakefileGenerator		The Targeting Experts supports the use of external makefile generators which is to be entered here. An intern means that the build-in makefile generator is to be used
ObjectDirectory		The relative path (seen from the target directory) for the object directory can be entered here. If not specified Targeting expert will generate the makefile in a way that the object files will be written into the target directory when make is executed.
LibraryDirectory		If this entry is specified the SDL to C compiler's library will be taken from the specified path. If not specified it will be taken from $sdtdir (%SDTDIR%).
Download	Tool	The full command line to invoke the download application.
PreMake		Action to perform before the target application will be made in the makefile.

Keyword 3	Keyword 4	Meaning of the parameter
PreCompile		If the generated code should be modified before it is compiled, an appropriate application (complete command line) should be entered here.
PostLink		If the linked target application needs to be modified (e.g. conversion into HEX format), the appropriate application (complete command line) should be entered here.
AddCompiler	Tool	For the additional files (see FilesToCompile) the name of the compiler application must be entered here.
AddCompiler	Options	The command line options for the compiler in AddCompiler must be specified here.
AddCompiler	Include	The compiler's option for include paths and the include paths for the compiler entered in AddCompiler
AddCompiler	Depend	The dependencies for the additional files (used inside of the generated makefile).
AddObjectExtension		The object extension of the AddCompiler must be entered here.
AddFilesToCompile		Kernel files to be compiled (e.g. communications link). This entry can be used more than once.

Default Configuration Settings

For several pre-defined integrations it is necessary to have some configuration flags defined as default. In this section a simple list of all configuration flags which should be set is given.

This section starts with [CONFIGURATION_DEFAULT].

Please see *"Configuration Files" on page 2974* for more information about configuration flags.

Configuration Settings to Be Set

For several pre-defined integrations it is necessary to have some configuration flags set without giving you the chance to un-select them. In this section a simple list of all configuration flags which have to be set is given.

This section starts with `[CONFIGURATION_SET]`.

Please see *"Configuration Files" on page 2974* for more information about configuration flags.

Configuration Settings to Be Reset

In opposite to the configuration flags which have to be set, it is of course necessary sometimes to prevent the selection of other flags. This can be done in this section by simply listing all the flags that have to be reset.

This section starts with `[CONFIGURATION_RESET]`.

Please see *"Configuration Files" on page 2974* for more information about configuration flags.

SDL to C Compiler Settings to Be Disabled

For some pre-defined integrations it does not make sense to configure all the SDL to C compiler options available. It is possible here to list all the options to be disabled in the user interface.

This section starts with `[SDL_TO_C_COMPILER_DISABLED]`.

SDL to C Compiler Settings to Be Enabled

For some pre-defined integrations some SDL to C compiler options needs to be enabled by default. It is possible here to list all the options to be enabled in the user interface.

This section starts with `[SDL_TO_C_COMPILER_DEFAULT]`.

Comments and empty Lines

- Empty lines are allowed everywhere in the an `.its` file.
- Comments are allowed everywhere in the `.its` file but have to start with an '#' in the first column.

Other Rules

- Only one set is allowed per `.its` file
- The amount of compilers supported for each set is unlimited.
- The characters '[', ']', '+', '*', '~' and ':' are forbidden in compiler names or the name of the pre-defined integration settings itself.

User-defined Integration Settings

All the settings done by the user will be stored in separate files into the target directory, i.e.:

- The complete set of settings will be stored (not the difference to the defaults)
- There is one file for each integration configuration done for an application, node or component
- If several nodes or components have to use the same settings it is possible to manually select one file for them.
  Please see "Handling of Settings" on page 2920.

Target Sub-Directory Structure

The Targeting Expert automatically sets up a sub-directory structure for all the applications, nodes and components. Furthermore there is a sub directory for each kind of integration done.

Example 496: Sub-directory structure ----------

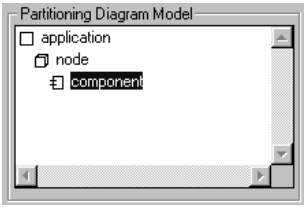

Figure 551: Example of a partitioning diagram

Estimated there is a partitioning diagram which looks like Figure 551, the Targeting Expert generates a sub-directory structure like:

```
<target_dir>
   + application._0
       + node._1
           + component._2
```

Note:

The suffixes `._*` give unique identifiers which make it possible to rename the application, nodes or components and to keep the done settings. In this case the Targeting Expert automatically modifies the names of the subdirectories.

Later, after you have built a Simulator and an Explorer for the `component`, for example, then the sub-directory structure was extended to:

```
<target_dir>
     + application._0
          + node._1
              + component._2
                   + Simulator
                   + Validator
```

Flat Directory Structure

When using an `.sdt` or `.pr` file as input the directory structure will be flatten automatically. I.e it will look like

```
<target_dir>
     + application._0
          + Simulator
          + Validator
```

This is possible because there can only be one node with one component in both cases.

Generated Makefile

Before the selected make tool is invoked the Targeting Expert generates a makefile with all of the necessary settings done. (Please see "Configure Compiler, Linker and Make" on page 2930 for information on how to set up the makefile generation.)

Caution!

The standard header files of the used SDL to C compiler library are **not** used as dependencies in the compilation rules, i.e. after modifying one of these files you have to select the *Clean* entry in the Make Menu.

Comparisons

There are a few differences that need to be mentioned when comparing the way the Targeting Expert handles makefiles with the way the Organizer's Make dialog does.

When using the Targeting Expert...

- ... there is no makefile (`systemname.m`) generated by the SDL to C compiler. Instead it generates a sub-makefile (`component_gen.m`) which is automatically parsed and inserted into the Targeting Expert makefile, i.e. the Targeting Expert still gets all the information from the SDL to C compiler but in a different way.
- ... there is not support of template makefiles by the Targeting Expert. The makefiles generated by the Targeting Expert can be modified directly in the so called "user sections". Please see "User Modifications" on page 2999.
- ... there are no `makeoptions/make.opt` files (taken from the kernel directories) used at all. Instead of this, the Targeting Expert gets all the make information from the Pre-defined Integration Settings and places them into its makefile.
- ... the `comp.opt` files placed in the kernel directories are not used at all! Again all the information is taken from the Pre-defined Integration Settings.
- ... the `sccd` cannot be used for pre-processing purposes as default because the Targeting Expert does not use `sccd.cfg` files from the kernel directories. It is recommended to use the Targeting Expert Preprocessor instead.

Note:

The only exceptions in which the Targeting Expert uses some information from the associated kernel directory are the integrations Validation and TTCN Link. In both cases a library is taken from the kernel directory.

User Modifications

After all it is possible that there are a few adaptations to be done, e.g. if there is an assembler file which needs to be assembled and linked.

Example 497 shows the section of a generated makefile where it is possible to add further object files.

Example 497: Generated makefile (1)

```
######## UserObjectsStart (Do not edit this line!) ##########
userOBJECTFILES1 =

userOBJECTFILES2 =

######## UserObjectsEnd   (Do not edit this line!) ##########
```

The list `userOBJECTFILES1` will be inserted at the front of all the object files to link. Accordingly `userOBJECTFILES2` will be inserted at the end.

The rules and the dependencies for the files in Example 497 must be given in the section shown in Example 498.

Example 498: Generated makefile (2)

```
######## UserRulesStart (Do not edit this line!) ##########

######## UserRulesEnd   (Do not edit this line!) ##########
```

Caution!

Any modification that is done outside of the sections described in Example 497 and Example 498 will be overwritten when the makefile is generated anew.

Parameter File sdttaex.par

General

One of the delivered configuration files used by the Targeting Expert is called `sdttaex.par`. Several different sections give information that is statically used during runtime. Under normal circumstances this file does not need to be modified. However, there might be the need to extend the Targeting Expert functions.

Please see the following sub-sections for more information what can be configured:

- Compiler Error Descriptions
- Preprocessor Commands
- Make Applications
- C++ Options
- Debug Options
- Compiler Dependent Defaults
- Restricted Compilers
- Editor Commands
- Additional Files
- Host Configuration Options (used for Cmicro only)

Search Order for sdttaex.par

The following shown search order applies when the Targeting Expert is started. The distributed version of `sdttaex.par` is always placed in `<installationdir>/bin/<platform>bin`

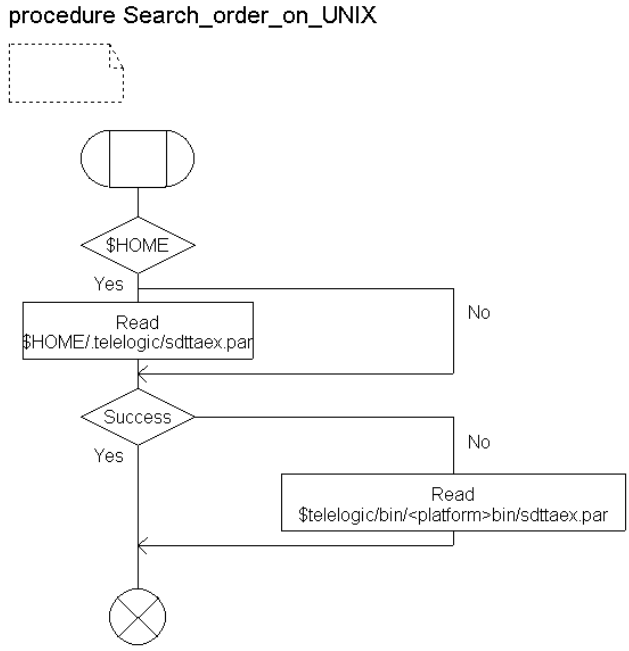

Figure 552: Search order for sdttaex.par on UNIX

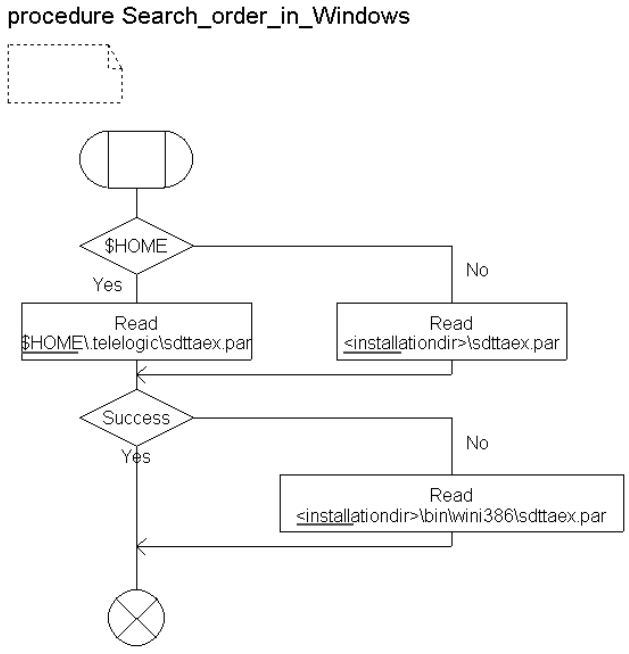

Figure 553: Search order for sdttaex.par in Windows

Compiler Error Descriptions

The section `[COMPILER-ERROR-DESCRIPTION]` of `sdttaex.par` is filled with regular expressions describing the construction of compiler error messages.

Example 499: `[COMPILER-ERROR-DESCRIPTION]`

```
[COMPILER-ERROR-DESCRIPTION]
{cl}       {1} {.*([1234567890]}       {0} {2} {([1234567890]*)}       {1} {1}
{cc166}    {2} {.*[A-Za-z]:}           {0} {1} {[1234567890]*: }       {0} {2}
{gcc}      {1} {.*:[1234567890]}       {0} {2} {:[1234567890]*:}       {1} {1}
{icc8051}  {1} {.*,[1234567890]}       {1} {3} {,[1234567890]* }       {1} {1}
{c51}      {1} {OF .*[CH]: }           {3} {2} {LINE [1234567890]* OF} {5} {3}
{cc}       {1} {.*, l}                 {1} {4} {line [1234567890]*:}   {5} {1}
{CC}       {1} {.*, l}                 {1} {2} {line [1234567890]*:}   {5} {1}
{aCC}      {1} {: .*,}                 {3} {2} {line [1234567890]* #}  {5} {2}
{ccpentium} {1} {.*:[1234567890]}      {0} {2} {:[1234567890]*:}       {1} {1}
{icpp}     {1} {!E .*(}                {3} {1} {(.*)}                  {1} {1}
```

Each line gives the description for one compiler. The eight entries have the meaning shown below (explained on the gcc entry):

1. The name of the compiler executable
2. The amount of lines the compiler error message takes
3. The regular expression to determine the erroneous file
4. The amount of characters thrown away at the beginning of the found file name
5. The amount of characters thrown away at the end of the found file name. (In this example the colon and the numeric character do not belong to the file name but both are needed to find it.)
6. The regular expression to determine the line number
7. The amount of characters thrown away at the beginning of the found line. (In this example the colon at the front of the regular expression does not belong to the line number but is needed to find it).
8. The amount of characters thrown away at the end of the found line. (In this example the colon at the end of the regular expression does not belong to the line number but is needed to find it).

Preprocessor Commands

This section takes the preprocessor commands for all the default compilers that can be set in the preferences. It has got the following contents:

Example 500: `[PREPROCESSOR-COMMANDS]`

```
[PREPROCESSOR-COMMANDS]
{Sun GNU gcc}     {gcc -P -E -C}
{Sun Workshop cc} {cc -C -P}
{Sun Workshop CC} {CC -E}
{Microsoft}       {cl -P -EP -C -nologo}
```

Make Applications

The section `[MAKE_APPLICATIONS]` of `sdttaex.par` is used to specify the command line of the make application, i.e. how it will be invoked.

Example 501: `[MAKE_APPLICATIONS]`

```
[MAKE_APPLICATIONS]
{Microsoft nmake}                                {nmake /f}    {}        {}
{Microsoft nmake (ignore exit codes)}            {nmake /i /f} {}        {}
{Microsoft nmake (using temporary response file)} {nmake /f}   {@<<\n\t} {\n<<}
```

```
{Tasking mk166}                                  {mk166 -f}    {}        {}
{VxWorks make}                                   {make -f}     {}        {}
{UNIX make}                                      {make -f}     {}        {}
```

Each line is the description for one make application. The four entries (given between '{' and '}') have the following meaning.

1. The text to identify it in the make configuration. See "Make tool" on page 2943
2. The name of the make application and the option used to specify the makefile.
3. This is the start sequence for the generation of temporary response files. Empty for most make applications.
4. This is the stop sequence for the generation of temporary response files. Empty for most make applications.

C++ Options

The C++ options specify what has to be added to the compiler's Options and the linker's Options to compile and link the SDL to C compiler's library as C++ code.

Example 502: `[C++-OPTIONS]`

```
[C++OPTIONS]
{Sun GNU gcc} {-xc++}  {-lstdc++}
{Microsoft}   {-TP}    {}
```

Each line consist of the three entries

1. compiler name
2. compiler command line option
3. linker command line option

Debug Options

The debug options specify what has to be added to the compiler's Options and the linker's Options to compile and link the target application including debug information.

Example 503: `[DEBUG_OPTIONS]`

```
[DEBUG-OPTIONS]
{Sun GNU gcc}     {-g}              {-g}
{Sun Workshop cc} {-g}              {-g}
{Sun Workshop CC} {-g}              {-g}
```

```
{Microsoft}        {-D "_DEBUG"}     {/debug}
{icc12}            {-g}              {-g}
```

Each line consist of the three entries

1. compiler name
2. compiler command line option
3. linker command line option

Compiler Dependent Defaults

The compiler dependent defaults ease the implementation of new pre-defined integrations because the values given here do not need to appear again in the .its file(s).

Example 504: `[COMPILER-DEPENDENT-DEFAULTS]`

```
[COMPILER-DEPENDENT-DEFAULTS]
{Borland}   {bcc32} {bcc32} {tlib} {.obj} {.exe} {.lib} {%I -c -w- -DUSING_DLL -
DIC86 -o%o %s} {-e%e %L %O} {%l /C /E /P256 %O} {-I$(sctCODERDIR)} {bcc_obj}
{Borland make (using temporary response file)}
```

The different entries mean the following (listed from left to right):

1. Compiler name
2. Compiler tool name
3. Linker tool name
4. Library manager name
5. Object file extension
6. Executable file extension
7. Library file extension
8. Compiler options
9. Linker options
10. Library Manager Options
11. Coder include path
12. Relative path to intermediate directory
13. make application to use per default

Restricted Compilers

There are a few target compilers which do not support file names which are longer that 8.3 (8 character in front of '.' and a 3 character extension). To ensure that files are generated only which fit to the 8.3 requirement. This section looks as follows:

Example 505: `[8.3-COMPILERS]` ----------

```
[8.3-COMPILERS]
{c51}
{icpp}
{icc12}
```

Editor Commands

The Targeting Expert allows to use other text editor different to the build-in one. The information how to start these editors is given in the section `[EDITOR-COMMANDS]` shown below.

Example 506: `[EDITOR-COMMANDS]` ----------

```
[EDITOR-COMMANDS]
{Windows} {TextPad}            {textpad -ca -g "%f"(%l,0)}
{Windows} {UltraEdit}          {UEdit32 %f/%l/0}
{Windows} {Codewright}         {codewright %f -G%l}
{Windows} {MS DeveloperStudio} {msdev %f}
{UNIX}    {Emacs}              {emacs %f}
{UNIX}    {dtpad}              {/usr/dt/bin/dtpad %f}
{UNIX}    {nedit}              {nedit -line %l %f}
```

There are 2 placeholders used in the command. `%f` will be replaced by the name of the file to open and `%l` gives the line number which should be shown.

Additional Files

The sections shown in Example 507 will used to find out which files belong to external parts of the distributed SDL to C compiler libraries.

Example 507: Additional Files Sections ----------

```
[CMICRO-KERNEL-FILES]
$(sctkerneldir)/mk_main.c
$(sctkerneldir)/mk_sche.c
$(sctkerneldir)/mk_queu.c
$(sctkerneldir)/mk_outp.c
$(sctkerneldir)/mk_tim1.c
$(sctkerneldir)/sctpred.c

[CMICRO-TI-KERNEL-FILES]
$(sctkerneldir)/ti_sche.c
$(sctkerneldir)/ti_queu.c
$(sctkerneldir)/ti_outp.c
$(sctkerneldir)/ti_tim1.c
$(sctkerneldir)/ti_init.c
$(sctkerneldir)/sctpred.c
```

```
[TESTER-FILES]
$(scttesterdir)/mt_tsdl.c
$(scttesterdir)/mt_tsys.c
$(scttesterdir)/mt_cod.c
$(scttesterdir)/mt_cmd.c
$(scttesterdir)/mt_opt.c
$(scttesterdir)/mt_deb.c
$(scttesterdir)/mt_rec.c
$(scttesterdir)/mt_play.c
$(sctkerneldir)/ml_buf.c

[TI-TESTER-FILES]
$(scttesterdir)/mt_tsdl.c
$(scttesterdir)/mt_tsys.c
$(scttesterdir)/mt_cod.c
$(scttesterdir)/mt_cmd.c
$(scttesterdir)/mt_opt.c
$(scttesterdir)/mt_deb.c
$(sctkerneldir)/ml_buf.c

[CODER-FILES]
$(sctCODERDIR)/cucf_er.c
$(sctCODERDIR)/cucf_er_sdt.c
$(sctCODERDIR)/bms/bms.c
$(sctCODERDIR)/bms/bms_small.c
$(sctCODERDIR)/ems/ems.c
$(sctCODERDIR)/ems/ems_eo_sdt.c
$(sctCODERDIR)/er/ascii/ascii.c
$(sctCODERDIR)/er/ber/ber_base.c
$(sctCODERDIR)/er/ber/ber_content.c
$(sctCODERDIR)/er/ber/ber_decode.c
$(sctCODERDIR)/er/ber/ber_encode.c
$(sctCODERDIR)/er/per/per_base.c
$(sctCODERDIR)/er/per/per_content.c
$(sctCODERDIR)/er/per/per_decode.c
$(sctCODERDIR)/er/per/per_encode.c
$(sctCODERDIR)/er/mms/mms.c
$(sctCODERDIR)/vms/vms_base.c
$(sctCODERDIR)/vms/vms_check.c
$(sctCODERDIR)/vms/vms_export.c
$(sctCODERDIR)/vms/vms_print.c

[TCP-IP-FILES]
$(sctTCPIPDIR)/tcpipcomm.c
```

Note:

The [TESTER-FILES] and [TI-TESTER-FILES] only apply for the Cmicro SDL to C compiler.

The [TCP-IP-FILES] only applies for the Cadvanced SDL to C compiler.

If the environment variable SDTTAEXIGNOREDEFAULTFILES is set, the contents of the sections [CMICRO-KERNEL-FILES], [CMICRO-TI-KERNEL-FILES], [TESTER-FILES] and [TI-TESTER-FILES] are ignored by the Targeting Expert (the files listed are not included in the resulting Makefiles). This enables the customer to manage the complete list of files in custom (.its) files.

Host Configuration Options

The host configuration options are the default host configurations for different compilers when using the Target Tester, i.e. these options are only used for Cmicro applications. An example can be found below.

Example 508: [HOST-CONFIGURATION-OPTIONS] **(Borland compiler)**

```
[HOST-CONFIGURATION-OPTIONS]
bcc32 "UNIT-NAME            sec"
bcc32 "UNIT-SCALE           1.0"
bcc32 "LENGTH_CHAR          1"
bcc32 "LENGTH_SHORT         2"
bcc32 "LENGTH_INT           4"
bcc32 "LENGTH_LONG          4"
bcc32 "LENGTH_FLOAT         4"
bcc32 "LENGTH_DOUBLE        8"
bcc32 "LENGTH_POINTER       4"
bcc32 "ALIGN_CHAR           8"
bcc32 "ALIGN_SHORT          8"
bcc32 "ALIGN_INT            8"
bcc32 "ALIGN_LONG           8"
bcc32 "ALIGN_FLOAT          8"
bcc32 "ALIGN_DOUBLE         8"
bcc32 "ALIGN_POINTER        8"
bcc32 "ENDIAN_CHAR          1"
bcc32 "ENDIAN_SHORT         21"
bcc32 "ENDIAN_INT           41"
bcc32 "ENDIAN_LONG          41"
bcc32 "ENDIAN_FLOAT         41"
bcc32 "ENDIAN_DOUBLE        81"
bcc32 "ENDIAN_POINTER       41"
```

External Makefile Generator

General

As it is probably necessary for you to modify the layout of the generated makefile, the source code of the external makefile generator “makegen” is delivered with every distribution. It can be found in `<installationdir>/sdt/sdtdir/util/<platform>`.

Source and Make Files

The source files delivered are:

- `makegen.[ch]`
- `ini_api.h`
- `pdm_api.h`

Furthermore there are makefiles and libraries:

- cc - compiler **on UNIX**
  - `makegencc.m`
  - `makegenlib.a`
- gcc 2.95.2 - compiler **on UNIX**
  - `makegengcc.m`
  - `makegenlib.a`
- Microsoft VC++ 6.0 compiler **in Windows**
  - `makegencl.m`
  - `makegencl.lib`

Utilities

General

Delivered in combination with the Targeting Expert there is an application called `taexutil`. This application can be used directly from the Targeting Expert *Tools* menu or on the command line, e.g. in makefiles.

The following utility functions are supported:

- DOS to UNIX
- UNIX to DOS
- Indent
- Preprocessor

Note:

Each utility will create a backup file called `<inputfile>.bak`

DOS to UNIX

This utility can be used to modify ASCII files. It replaces all the found '`\r\n`' sequences against '`\n`'.

- Command line:
  `taexutil D2U <inputfile> <outputfile>`
  `<inputfile>` and `<outputfile>` can be equal but both must be given.

UNIX to DOS

This utility can be used to modify ASCII files. It replaces all the found '`\n`' characters against '`\r\n`' sequences.

- Command line:
  `taexutil U2D <inputfile> <outputfile>`
  `<inputfile>` and `<outputfile>` can be equal but both must be given.

Indent

The indentation of the given ASCII file will be corrected. This means

- all the preprocessor directives (staring with '#') will be moved into the first column. This is necessary to conform with K&R compilers.

- all the other lines will be indented according to the given blocks in C, i.e. it is controlled by the use of '{' and '}' characters.
- all TAB characters ('\t') will be removed.
- all the SPACE (' ') characters at the end of lines will be removed.

Caution!

The indent offered by here does not offer the same functionality as indent known from UNIX!

- Command line:
  `taexutil INDENT <inputfile> <outputfile>`
  `<inputfile>` and `<outputfile>` can be equal but both must be given.

Preprocessor

Note:

The main intention of the preprocessor given here is **not** to get an easy to read source file. Instead it is to get a preprocessed file that can be compiled by a target compiler (e.g. Keil, Tasking,...) because long macros are not supported by some target compilers.

The preprocessor utility should only be used to preprocess generated C files. The following tasks will be processed:

1. Copy the SDL to C compilers main header file (`ml_typ.h`/`sct-types.h`) beside the output file.
2. Put all the lines of the main header file containing `#include <...>` statements into comments
3. Preprocess the selected generated C file by using the default compiler (see chapter 3, *The Preference Manager*).
4. Remove all the empty lines in the preprocessed file.
5. Run Indent on the preprocessed file.
6. Remove all the comments surrounding `#include < ...>` in the preprocessed file.
7. Remove the private copy of the main header file.

Note:

All the files given with `#include "..."` will be included during the preprocessing.

- Command line:
  `taexutil PREPRO <inputfile> <outputfile> "<cmd>" <compiler_flag>`
  - `<inputfile>` and `<outputfile>` can be equal but both must be given.
  - `<cmd>` is the command line needed to invoke the preprocessor of the default compiler
  - `<compiler_flag>` is the define to select the target compiler. (Please see "Compiler Flag" on page 2936)

FAQs

- **How can I set the target directory in the Targeting Expert?**

  It is not possible to set the target directory in the Targeting Expert. The one given in the Organizer will be used instead. To make it possible to have different integrations in one target directory the Targeting Expert creates a Target Sub-Directory Structure.

- **Where can I add my own macro definitions?**

  There is a manual configuration file written for each integration. It is called `sct_mcf.h` for Cadvanced, `ml_mcf.h` for Cmicro and `extreme_user_cfg.h` for Cextreme.

  This header file is included in the SDL to C compiler's library during compilation and contains a section where you can insert your own macro definitions. The section begins with

  ```
  /* BEGIN User Code */
  ```

  and ends with the line

  ```
  /*   END User Code */
  ```

  All the text given between both lines will be saved if the manual configuration file is re-generated.

> **Caution!**
>
> The manual configuration file `sct_mcf.h` for Cadvanced is included only if the flag `USER_CONFIG` is set. This can be done in most cases by defining `-DUSER_CONFIG` in the compiler options.

- **How can I modify the value of `$sdtdir` in the generated makefile?**

  Per default the value of `$sdtdir` is set to `<installationdir>/sdt/sdtdir/<platformsdtdir>`. In some cases it is probably necessary to get the library files from another directory. In this case you can modify the *Library Directory* in the Make dialog. The sub-directory structure must be the same as given under `<installationdir>/sdt/sdtdir/<platformsdtdir>`.

- **How can I modify the configuration flags that are disabled in the Targeting Expert user interface?**

The Targeting Expert can be customized in a way so that the configuration flags listed under Configuration Settings to Be Set or Configuration Settings to Be Reset are not disabled. To achieve that open the Customize dialog via the menu choice *Tools* > *Customize* and select the Advanced Mode. (Please see "Customization" on page 2924 for more details)

- **How can I create my own pre-defined integration?**

  You can create your own pre-defined integrations by

  – selecting one of the distributed pre-defined integrations (the one that fits most to your needs
  – configure it as you like (maybe it is necessary to switch into the Advanced Mode to have access to all the dialogs)
  – export the settings like it is described in "Export" on page 2922#

  After you have done so the pre-defined integration will be available.

- **I have exported an pre-defined integration but my colleagues are not able to access it in my home directory/in my PC installation. What to do?**

  When exporting settings to pre-defined integration settings it is possible to

  – export as project settings - or
  – export as user settings

  You have probably exported as user settings, i.e. the *.its* file is not accessible for other users. You can move the `<integration>.its` file in the same directory where the `<systemname>.sdt` file of your project is saved. So it will be visible for all users working on this system.

Chapter

SDL C Compiler Driver (SCCD)

The SDL C Compiler Driver (SCCD) is a utility intended to simplify C level debugging of code generated by the SDL Suite and hand-written code. It can be invoked from the makefiles used by the SDL Suite or stand-alone from the OS command line.

Introduction

The SDL C Compiler Driver (SCCD) is intended to simplify C level debugging by generating an intermediate C file placed in a user defined directory. This C file has all its macros expanded and is optionally "beautified" (pretty-printed). For ease of use SCCD is used as a C compiler driver called from the SDL Suite generated or handwritten makefiles. SCCD may also be used as a command line option when compiling C code.

The simplest way to introduce this facility for use in the standard SDL Suite environment is to modify the `makeoptions` or `make.opt` file associated with the predefined run-time library to be used. To enable this feature in a modified the SDL Suite run-time library, the directory and file structure must be similar to the pre-defined one.

The `makeoptions` or `make.opt` file is found in the `$sdtdir/SCT[Kernel name]` directory. The only modification **required** is to change the line

```
sctCC = cc      /* or some other compiler executable name */
```

to

```
sctCC = sccd cc     /* or some other compiler executable name */
```

SCCD must of course be visible in your path.

To customize the behavior of SCCD, modify the configuration file `sccd_<your_compiler_type>.cfg` variables described in the following sections.

Syntax for Invoking

The following syntax can be used to invoke SCCD:

To execute SCCD:

```
sccd <C compiler command line>
```

The C compiler command line should be the normal command line used to compile a C file: it should include the name of your C compiler, possible compiler options, and finally the name of the C file.

To print the values of the variables in the configuration file `sccd.cfg`:

```
sccd
```

To print the variables with extra help information:

```
sccd -h
```

Return Codes

0: Success.

1: After printing “help”.

2: No `.c` file.

3: Could not open `InFile.c`.

4: Could not open `InFile.i` for write.

5: `sccdMOVE` or `sccdOUTFILEREDIR` needs to be defined.

6: Could not open `InFile.i` for read.

7: Could not open/create `TmpDir/InFile.c`.

Actions Performed by SCCD

1. Execute an optional first-user defined command (`sccdUSER_CMD1`).
2. Create a sub-directory for temporary files and the pre-processed `.c` files.
3. Execute an optional second user-defined command (`sccdUSER_CMD2`).
4. Run a C pre-processor pass to expand all macros.
5. Execute an optional third user-defined command (`sccdUSER_CMD3`).
6. Pretty print the file.
7. Optional clean-up of the sub-directory.
8. Optionally copy `.hs` files to the sub-directory.
9. Execute an optional fourth user-defined command (`sccdUSER_CMD4`). You should use this command if you wish to invoke the "indent" utility from SCCD (see "C Beautifier" on page 3021 for more information).
10. Optionally compile, i.e. run the original command line.
11. Optional clean-up of the sub-directory, but leave the pre-processed `.c` file(s) for debugging purposes.

Configuration File

The behavior of SCCD is defined using a number of variables, each starting with "sccd". The variables are defined in a configuration file, `sccd_<your_compiler_type>.cfg`. Select the configuration file that corresponds to your C compiler and copy this file as `sccd.cfg`. If run from the SDL Suite, SCCD uses `$sctdir/sccd.cfg` as the configuration file; otherwise SCCD searches for `sccd.cfg` in the current directory, `$SCCD`, and **(on UNIX)** `$HOME`.

> **Note:**
>
> If `sccd.cfg` is not found, hard-coded defaults suitable for the Gnu C compiler (gcc) are used.

Below are the variables that control the behavior of SCCD. Note that all characters in variable values are significant, including white spaces.

`sccdNAME = "Default"`

Compiler name as defined in `scttypes.h`.

`sccdINFILESUFFIX = ".c"`

The expected file name suffix of the In-file(s), Default ".c".

`sccdCPP = ""`

The name of the C pre-processor. If this is left empty, CPP is used. Default "".

`sccdCPPFLAGS = ""`

Enable CPP and do not remove comments. This is C compiler dependent. Default for gcc is "-P -E -C", and for cc "-C -P".

`sccdMACROPREFIX = "-D"`

CPP command line define MACRO prefix. Default "-D".

`sccdINCLUDE1 = "-I"`

CPP command line include-path prefix. Default "-I".

`sccdINCLUDE2 = ""`

Alternative CPP command line include-path prefix. Default "".

`sccdOUTFILEREDIR = "-o "`

Character sequence to control CPP output file name. If empty, use `sccdFMOVE` instead.

`sccdFMOVE = ""`

OS forced file move or copy command. Used instead of `sccdOUTFILEREDIR`. Default: "".

`sccdDELETE = "rm -f"`

OS forced delete file command. Default: "rm -f".

`sccdCOPY = "cp"`

OS normal copy command. Default: "cp".

`sccdCOMPILE = "ON"`

Controls whether the final compilation pass should be run or not. Values are: "OFF" and default is "ON".

`sccdDEBUG = "OFF"`

Enable execution. Values are: “ON” and default is “OFF”.

`sccdPURGE = "ON"`

Purge temporary files. Values are: “OFF” and default is “ON”.

`sccdUSE_HS = "OFF"`

When set “ON”, the `.hs` files are not included until the compilation pass. Values are: “ON” and default is “OFF”.

`sccdSILENT = "OFF"`

Enable trace printout. Values are: “ON” and default is “OFF”.

`sccdTMPDIR = "sccdtmp"`

Temporary directory for the pre-processing. Default is `sccdtmp`. Setting `sccdTMPDIR` to “” or “.” in the configuration file suppresses temporary directory creation.

```
sccdUSER_CMD1 = ""
sccdUSER_CMD2 = ""
sccdUSER_CMD3 = ""
sccdUSER_CMD4 = ""
```

User-defined commands (see “Actions Performed by SCCD” on page 3018). The following pseudo variables can be used in all but the first one (`sccdUSER_CMD1`):

- `%f` expands to In-file name without extension.
- `%p` expands to In-file path.
- `%d` expands to the value of `sccdTMPDIR`.

Example: `echo \"Pre-processed C-file = %p/%d/%f.c\"`

To include ‘#’ in `sccdUSER_CMDx` and `sccdTMPDIR`, enter **`\#`**
To include ‘"’ in `sccdUSER_CMDx` and `sccdTMPDIR`, enter **`\"`**
To include ‘\’ in `sccdUSER_CMDx` and `sccdTMPDIR`, enter **`\\`**

C Beautifier

If you need a C beautifier to further format the C code from the SDL Suite, do as follows.

Try the `indent` utility (courtesy of Joseph Arcaneaux), see "Additional required tools and utilities" on page 3 in chapter 1, *Platforms and Products* for information how to obtain it.

The indent executable must be placed in your path.

In order to easily invoke indent from SCCD, insert the following statement in `sccdUSER_CMD4` in the appropriate `sccd.cfg` file(s), assuming no other changes have been made to the `sccd.cfg` file(s):

For UNIX compiler environments:

```
sccdUSER_CMD4 = "indent -kr -l70 -i2 %p/%d/%f.c"
```

For "DOS"-like compiler environments:

```
sccdUSER_CMD4 = "indent -kr -l70 -i2 %p\\%d\\%f.c"
```

This setup gives a `.c` source file formatted according to rules very like the ones used in the Kernighan & Richie "C" book. It will also try to force lines to be shorter than 70 characters and will use 2 positions indentation in if/while/... statements.

A slightly more elaborate example:

```
sccdUSER_CMD4 = "indent -kr -l70 -br -nce -nlp -ci3
-i2 %p/%d/%f.c"
```

Chapter 60 SDL C Compiler Driver (SCCD)

Chapter

61 *The Master Library*

This chapter covers the following topics:

- **The structure of the source code of the SDL Suite Master Library**
- **The runtime model used for the programs generated by the SDL to C compiler. The chapter also describes the data structures for representing the various SDL objects.**
- **The memory requirements for applications**
- **How to make a customized Master Library**
- **The compilation switches which affect the properties of the Master Library**

Note that the Master Library is only used together with the Cadvanced/Cbasic SDL to C Compiler. It cannot be used together with the Cmicro SDL to C Compiler.

Introduction

This chapter describes the source code of the runtime library for applications generated by the Cadvanced/Cbasic SDL to C Compiler. Applications generated by the Cmicro SDL to C Compiler are **not** covered.

The chapter covers basically two topics:

1. The sections "File Structure" on page 3025, "The Symbol Table" on page 3028, and "The SDL Model" on page 3070 describe the runtime model for programs generated by the SDL Cadvanced/Cbasic SDL to C Compiler.

   Mainly it is the data structure used to represent various SDL objects that is discussed, both from the static point of view (the type definitions), and from the dynamic point of view (what information it represents and how it is initialized, changed, and used).

   The full runtime model that is used during simulations (with the monitor) is described. From this model, an optimization is made to obtain an application (not using the monitor). The optimization is discussed under "Compilation Switches" on page 3119.

2. In the sections "Compilation Switches" on page 3119, "Creating a New Library" on page 3139, and "Adaptation to Compilers" on page 3147, different aspects on how to make new versions of the runtime library are discussed.

   The compilation switches treated in the section "Compilation Switches" on page 3119 are used to determine the properties of the runtime library and the generated C code, while section "Creating a New Library" on page 3139 shows how to make new versions of the runtime library using for example new combinations of compilation switches.

   In the section "Adaptation to Compilers" on page 3147, porting issues are discussed.

File Structure

The runtime library is structured into a number of files. These are:

- `scttypes.h`
- `sctlocal.h`
- `sctpred.h`
- `sctsdl.c`
- `sctpred.c`
- `sctutil.c`
- `sctmon.c`
- `sctpost.c`
- `sctos.c`
- `post.h, sdt.h, itex.h, dll.h`

On UNIX:

- `post.o (use post64.o for solaris 64-bit)`

In Windows:

- `libpost.lib` (the statically linked library)
- `post.lib` (for dynamically linking)
- `post.dll` (the dynamically linked library)

On UNIX, all files can be found in the directory `$telelogic/sdt/sdt-dir/<machine dependent dir>/INCLUDE` where <*machine dependent dir*> is for example `sunos5sdtdir` on SunOS 5.

In Windows, all files can be found in the directory `<installation directory>\sdt\sdtdir\wini386\include`.

Description of Files

scttypes.h

This file contains type definitions and extern declarations of variables and functions. The file is included by `sctsdl.c, sctpred.c, sctutil.c, sctmon.c, sctpost.c, sctos.c`, and by each generated C file.

sctlocal.h

This file contains type definitions and extern declarations of variables and functions that are used only in the kernel. This file is not included in generated code.

sctpred.h

This file contains type definitions and extern declarations handling the predefined data types in SDL (except PId, which is in `scttypes.h`). This file is included in generated code via `scttypes.h`.

sctsdt.c

In this file the implementation of the SDL operations can be found, together with the functions used for scheduling. In more detail, this file contains groups of functions for:

- Handling and reporting SDL dynamic errors
- SDL operations, such as Output, Create, Stop, Nextstate, Set, Reset, together with help functions for these activities
- Initialization and the main loop (the scheduler).

sctpred.c

The functions implementing the operations defined in the SDL predefined data types can be fund in this file. Operators for PId is implemented in `sctsdl.c`.

sctutil.c

This file contains basic read and write functions together with functions to handle reading and writing of values of abstract data types, including the predefined data types. It also contains the functions for MSC trace.

sctmon.c

The `sctmon.c` file contains the functions that implement the monitor interface, that is, interpreting and executing monitor commands.

sctpost.c

This file contains all the basic functions that are used to connect a simulator with the other parts of the SDL Suite.

sctos.c

In this file, some functions that represent the dependencies of hardware, operating system and compiler are placed.

The basic functions necessary for an application are a function to read the clock and a function to allocate memory.

To move a generated C program plus the runtime library to a new platform (including a new compiler), the major changes are to be made in this file, together with writing a new section in `scttypes.h` to describe the properties of the new compiler.

post.h and sdt.h

These files are included in `sctpost.c` if the communication mechanism with other the SDL Suite applications should be part of the actual object code version of the library. The file `post.h` contains the function interface, while `sdt.h` contains message definitions.

Caution!

Windows only: When linking with the PostMaster's dynamically linked libraries (`post.lib` and `post.dll`), the environment variable `USING_DLL` must be defined before including `post.h`. Example:

```
#define USING_DLL
#include "post.h"
#undef USING_DLL
```

post.o (post64.o for solaris 64-bit, post.lib in Windows)

This file contains the implementation of functions needed to send messages, via the Postmaster, to other tools in the SDL Suite.

The Symbol Table

The symbol table is used for storing information mainly about the static properties of the SDL system, such as the block structure, connections of channels and the valid input signal set for processes. Some dynamic properties are also placed in the symbol table; for example the list of all active process instances of a process instance set. This is part of the node representing the process instance set.

The nodes in the symbol table are structs with components initialized in the declaration. During the initialization of the application, in the `yInit` function in generated code, a tree is built up from these nodes.

Symbol Table Tree Structure

The symbol table is created in two steps:

1. First, symbol table nodes are declared as structs with components initialized in the declaration (in generated code).
2. Then, the `yInit` function (in generated code) updates some components in the nodes and builds a tree from the nodes. This operation is not needed in an application!

The following names can be used to refer to some of the nodes that are always present. These names are defined in `scttypes.h`.

```
xSymbolTableRoot
xEnvId
xSrtN_SDL_Bit
xSrtN_SDL_Bit_String
xSrtN_SDL_Boolean
xSrtN_SDL_Character
xSrtN_SDL_Charstring
xSrtN_SDL_Duration
xSrtN_SDL_IA5String
xSrtN_SDL_Integer
xSrtN_SDL_Natural
xSrtN_SDL_Null
xSrtN_SDL_NumericString
xSrtN_SDL_Object_Identifier
xSrtN_SDL_Octet
xSrtN_SDL_Octet_String
xSrtN_SDL_PId
xSrtN_SDL_PrintableString
xSrtN_SDL_Real
xSrtN_SDL_Time
xSrtN_SDL_VisibleString
```

xSymbolTableRoot is the root node in the symbol table tree. Below this node the system node is inserted. After the system node, there is a node representing the environment of the system (xEnvId). Then there is one node for each package referenced from the SDL system. This is true also for the package predefined containing the predefined data types. The nodes for the predefined data types, that are sons to the node for the package predefined, can be directly referenced by the names xSrtN_SDL_xxx, according to the list above.

Nodes in the symbol table are placed in the tree exactly according its place of declaration in SDL. A node that represent an item declared in a block is placed as a child to that block node, and so on. The hierarchy in the symbol table tree will directly reflect the block structure and declarations within the blocks and processes.

A small example can be found in Figure 560 on page 3107. The following node types will be present in the tree:

Node Type	Description
xSystemEC	Represent the system or the system instance.
xSystemTypeEC	Represents a system type.
xPackageEC	Represents a package.
xBlockEC	Represent blocks and block instances.
xBlockTypeEC	Represents a block type.
xBlockSubstEC	Represents a block substructure and can be found as a child of a block node.
xProcessEC	Represent processes and process instances. The environment process node is placed after the system node and is used to represent the environment of the system.
xProcessTypeEC	Represents a process type.
xServiceEC	Represents a service or service instance.
xServiceTypeEC	Represents a service type.
xProcedureEC	Represents a procedure.

Node Type	Description
xOperatorEC	Represents an operator diagram, i.e. an ADT operator with an implementation in SDL.
xCompoundStmtEC	Represents a compound statement containing variable declarations.
xSignalEC xTimerEC	Represents a signal or timer type.
xRPCSignalEC	Represents the implicit signals (pCALL, pREPLY) used to implement RPCs.
xSignalParEC	There will be one signal parameter node, as a child to a signal, timer, and RPC signal node, for each signal or timer parameter.
xStartUpSignalEC	Represents a start-up signal, that is, the signal sent to a newly created process containing the actual FPAR parameters. An xStartUpSignalEC node is always placed directly after the node for its process.
xSortEC xSyntypeEC	Represents a newtype or a syntype.
Struct Component Node (xVariableEC)	A sort node representing a struct has one struct component node as child for each struct component in the sort definition.
xLiteralEC	A sort node similar to an enum type has one literal node as child for each literal in literal list.
xStateEC	Represents a state and can be found as a child to process and procedure nodes.
xVariableEC xFormalParEC	Represents a variable (DCL) or a formal parameter (FPAR) and can be found as children of process and procedure nodes.
xChannelEC xSignalRouteEC xGate	Represents a channel, a signal route, or a gate.
xRemoteVarEC	Represents a remote variable definition.
xRemotePrdEC	Represents a remote procedure definition.

Node Type	Description
xSyntVariableEC	Represents implicit variables or components introduced by the Cadvanced/Cbasic SDL to C Compiler. Used only by the Explorer.
xSynonymEC	Represent synonyms. Used only by the Explorer.

The nodes (the struct variables) will in generated code be given names according to the following table:

```
ySysR_SystemName
        (system, system type, system instance)
yPacR_PackageName
yBloR_BlockName
        (block, block type, block instance)
yBSuR_SubstructureName
yPrsR_ProcessName
        (process, process type, process instance)
yPrdR_ProcedureName  (procedure, operator)
ySigR_SignalName
        (signal, timer, startup signal, RPC signal)
yChaR_ChannelName    (channel, signal route, gate)
yStaR_StateName
ySrtR_NewtypeName    (newtype, syntype)
yLitR_LiteralName
yVarR_VariableName
       (variable, formal parameter, signal
        parameter, struct component, synt.variable)
yReVR_RemoteVariable
yRePR_RemoteProcedure
```

In most cases it is of interest to refer to a symbol table node via a pointer. By taking the address of a variable according to the table above, i.e.

```
& yPrsR_Process1
```

such a reference is obtained. For backward compatibility, macros according to the following example is also generated for several of the entity classes:

```
#define yPrsN_ProcessName  (&yPrsR_ProcessName)
```

Types Representing the Symbol Table Nodes

The following type definitions, from the file `scttypes.h`, are used in connection with the symbol table:

```
typedef enum {
  xRemoteVarEC,
  xRemotePrdEC,
  xSignalrouteEC,
  xStateEC,
  xTimerEC,
  xFormalParEC,
  xLiteralEC,
  xVariableEC,
  xBlocksubstEC,
  xPackageEC,
  xProcedureEC,
  xOperatorEC,
  xProcessEC,
  xProcessTypeEC,
  xGateEC,
  xSignalEC,
  xSignalParEC,
  xStartUpSignalEC,
  xRPCSignalEC,
  xSortEC,
  xSyntypeEC,
  xSystemEC,
  xSystemTypeEC,
  xBlockEC,
  xBlockTypeEC,
  xChannelEC,
  xServiceEC,
  xServiceTypeEC,
  xCompoundStmtEC,
  xSyntVariableEC
  xMonitorCommandEC
}   xEntityClassType;

typedef enum {
  xPredef, xUserdef, xEnum,
  xStruct, xArray, xGArray, xCArray,
  xOwn, xORef, xRef, xString,
  xPowerSet, xGPowerSet, xBag, xInherits, xSyntype,
  xUnion, xUnionC, xChoice
}   xTypeOfSort;

typedef char  *xNameType;
```

```
typedef struct xIdStruct {
   xEntityClassType  EC;
#ifdef XSYMBTLINK
   xIdNode           First;
   xIdNode           Suc;

}  xRemoteVarIdRec;
```

There are also pointer types defined for each of the `xECIdStruct` according to the following example:

```
typedef XCONST struct xIdStruct  *xIdNode;
```

The type definitions above define the contents in the symbol table nodes. Each `xECIdStruct`, where EC should be replaced by an appropriate string, have the first five components in common. These components are used to build the symbol table tree. To access these components, a pointer to a symbol table node can be type cast to any of the `xIdECNode` types. The type `xIdNode` is used as such general type, for example when traversing the tree.

The five components present in all `xIdNode` are:

- **`EC`** of type `xEntityClassType`. This component is used to determine what sort of SDL object the node represents. `xEntityClassType` is an enum type containing elements for all entity classes in SDL.
- **`First`**, **`Suc`**, and **`Parent`** of type `xIdNode`. These components are used to build the symbol table tree. `First` refers to the first child of the current node. `Suc` refers to the next brother, while `Parent` refers to the father node. Only `Parent` is needed in an application.
- **`Name`** of type `xNameType`, which is defined as `char *`. This component is used to represent the name of the current SDL object as a character string. Not needed in an application.

Next there are components depending on what entity class that is to be represented. Below we discuss the non-common elements in the other `xECIdStruct`.

Package

- **`ModuleName`** of type `xNameType`. If the package is generated from ASN.1, this component holds the name of the ASN.1 module as a `char *`.

System, System Type

- **Content** of type xIdNode *. This component contains a list of all channels at the system level.
- **VirtPrdList** of type xPrdIdNode *. This is a list of all virtual procedures in this system instance.
- **Super** of type xSystemIdNode. This is a reference to the inherited system type. In a system this component in null. In a system instance it is a reference to the instantiated system type.
- **Trace_Default** of type int. This component contains the current trace value defined for the system.
- **GRTrace** of type int. This component contains the current GR (graphical) trace value defined for the system.
- **MSCETrace** of type int. This component contains the current MSCE (Message Sequence Chart Editor) trace value defined for the system.

Channel, Signal route, Gate

For channels, signal routes, and gates there are always two consecutive xChannelIdNodes in the symbol table, representing the two possible directions for a channel, signal route, or gate. The components are:

- **SignalSet** of type xIdNode *. This component represents the signal set of the channel in the current direction (a unidirectional channel has an empty signal set in the opposite direction).

  SignalSet is an array with components referring to the xSignalIdNodes that represent the signals which are members of the signal set. The last component in the array is always a NULL pointer (the value (xSignalIdNode)0).

- **ToId** of type xIdNode *. This is an array of xIdNodes, where each array component is a pointer to a symbol table node representing an SDL object, which this Channel/Signal route/Gate is connected to (connected to in the sense: to the SDL objects that signals are sent forward to).

  The SDL objects that may be referenced in ToId are channels, signal routes, gates, processes, and services. The last component in the

array is always a NULL pointer (the value (xIdNode)0). See also "Channels and Signal Routes" on page 3106.

- **Reverse** of type xChannelIdNode. This is a reference to the symbol table node that represents the other direction of the same channel, signal route, or gate.

Block, Block Type, Block Instance

- **Super** of type xBlockIdNode. In a block, this component is NULL. In a block type this component is a reference to the block that this block inherits from (NULL if no inheritance). In a block instance, this is a reference to the block type that is instantiated.
- **Contents** of type xIdNode *. In a block instance, these components contains list of:
  - The process instantiations in the block
  - The signal routes in the block
  - The outgoing gates from the block
  - The processes in the block
  - The gates defined in process instantiations in the block.
- **VirtPrdList** of type xPrdIdNode *. This is a list of all virtual procedures in this block instance.
- **ViewList** of type xViewListRec *. This is a list of all revealed variables in the block or block instance.
- **NumberOfInst** of type int. This is the number of block instances in a block instance set. The component is thus only relevant for a block instance.
- **Trace_Default** of type int. This component contains the current value of the trace defined for the block.
- **GRTrace** of type int. This component contains the current value of the GR trace defined for the block.
- **MSCETrace** of type int. This component contains the current MSCE (Message Sequence Chart Editor) trace value defined for the block.
- **GlobalInstanceId** of type int. This component is used to store a unique id needed when performing MSCE trace.

Process, Process Type, Process Instance

- **StateList** of type `xStateIdNode *`. This is a list of references to the `xStateIdNodes` for this process or process type. Using the state value of an executing process, this list can be used to find the corresponding `xStateIdNode`.

- **SignalSet** of type `xIdNode *`. This represents the valid input signal set of the process or process type.

  `SignalSet` is an array with components that refer to `xSignalIdNodes` that represent the signals and timers which are part of the signal set. The last component in the array is always a `NULL` pointer (the value `(xSignalIdNode)0`).
