Chapter

1 User Interface and Basic Operations

This chapter describes the general graphical concepts that are used throughout the user interfaces of the SDL Suite and TTCN Suite tools. It also describes some common menu choices. This information will not be repeated in other chapters of the User's Manual.

You should have a basic understanding of the SDL Suite and TTCN Suite concepts and tool family before you read this chapter. Such information can be found in:

- ***chapter 2, Introduction to the SDL Suite, in the SDL Suite 6.2 Getting Started***
- **chapter 3, *Introduction to the TTCN Suite (on UNIX), in the TTCN Suite 6.2 Getting Started***
- **chapter 2, *Introduction to the TTCN Suite (in Windows), in the TTCN Suite 6.2 Getting Started***

Graphical Environments and Style Guides

The SDL Suite and the TTCN Suite tools family is designed to be available on workstations running UNIX and on PCs running Windows. Since the majority of the tools are graphical, it is assumed that the computer you are to run the tools on has the required graphical support.

IBM Rational supports the following graphical environments:

- On UNIX workstations, the X Windows system, managed by the Motif window manager. The versions currently supported are X11 R6 and Motif 2.1.
- On PCs, the Microsoft Windows system. SDL Suite and TTCN Suite supports Windows 2000 and Windows XP.

Throughout the manuals, it is assumed that you are familiar with the graphical environment that is currently used. Otherwise, we recommend you to read the literature that describes that graphical environment. See for instance "References" on page 38.

The SDL Suite for Windows is fully compatible with the SDL Suite on UNIX workstations, with respect to functionality and storage formats. However, since they are implemented on different graphical environments, there may be slight differences in the appearance of each tool. Also, we have tried to adopt the respective style guide for each environment as long as feasible, but have been forced to compromise in order to provide a uniform user interface between the UNIX workstation and PC environments.

Constraints

The constraints that are imposed on SDL Suite and TTCN Suite by the graphical environment are identified in "Microsoft Windows System Factors" on page 46, "X Window System Factors (UNIX only)" on page 47 and "OSF/Motif Factors (UNIX only)" on page 49 in chapter 4, *System Setup, in the Installation Guide*.

Application Windows

All SDL Suite and TTCN Suite tools have a main window with a common general appearance. The tools may also have sub windows that depend on the main window. Apart from these, there are also dialog windows, see “Dialog Windows” on page 28.

In the TTCN Suite **in Windows**, the windows will be displayed in the working area of the TTCN Suite desktop.

Main Windows

A general main window of an SDL Suite and TTCN Suite tool in Windows and on UNIX, as well as the TTCN Suite desktop in Windows, is depicted and explained below:

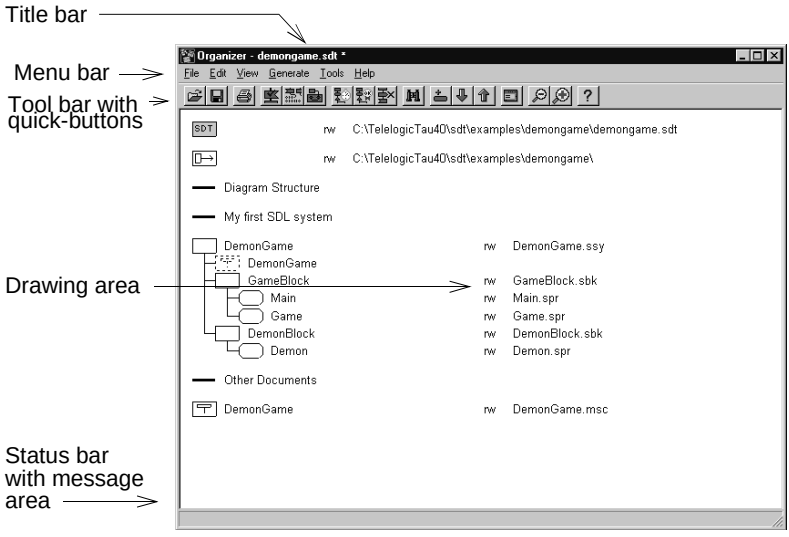

Figure 1: A main window **(in Windows)**

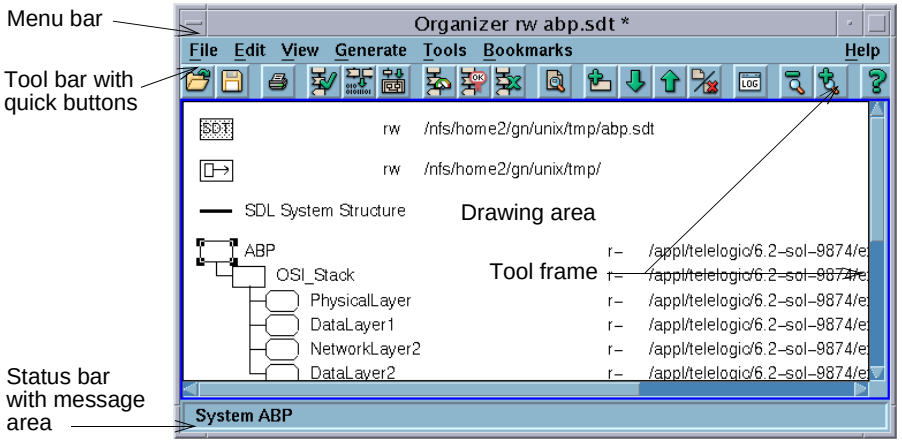

Figure 2: A main window **(on UNIX)**

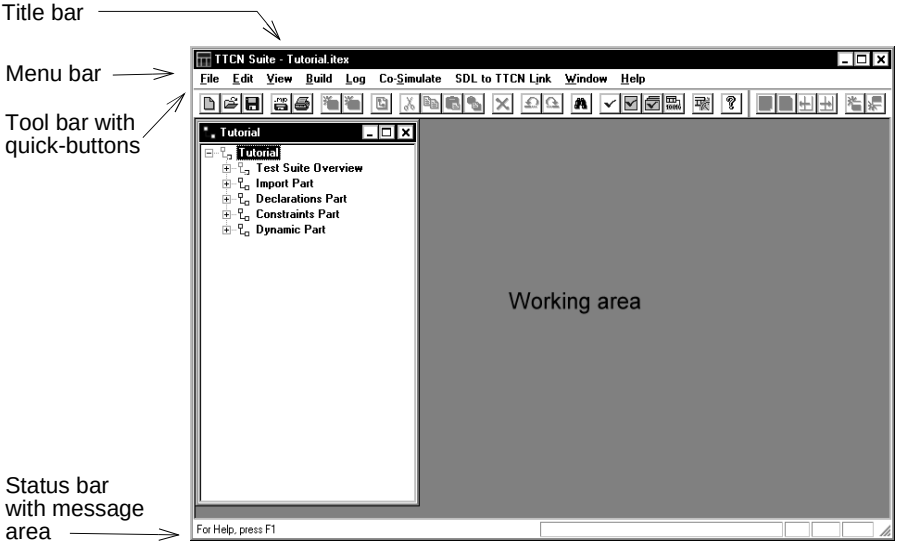

Figure 3: The TTCN Suite desktop **(in Windows)**

Title Bar

The title bar may identify the tool family, the tool and the opened document. In some tools, an asterisk signifies that the document is not saved since the last change.

Menu Bar

The menu bar contains pull-down menus. The menu choices operate either on the whole document or file that is opened in the tool, or on any selected object(s). More information on menus and menu choices can be found in "General Menus" on page 8 and "General Menu Choices" on page 8.

You can "preview" the functionality of a menu choice by pointing to it. In the SDL Suite **on UNIX** you also have to press the mouse button. An explanation will appear in the status bar.

If a menu or menu choice is dimmed, it is not appropriate or meaningful in the current situation, or the associated tool license is temporarily lost.

If a menu or menu choice is hidden, you do not have a license for the associated tool, or the tool has a long/short menu concept which allows hiding of menu choices.

Tool Bar

Most operations that the quick-buttons in the tool bar provide, have an exactly corresponding menu choice, but some quick-buttons have a slightly different functionality compared to their corresponding menu choice. See also "General Quick-Buttons" on page 24.

You can "preview" the functionality of a quick button by pointing to it. In the TTCN Suite **on UNIX** you also have to press the mouse button. An explanation will appear in the status bar, and as a tool tip just below the button (not available in the TTCN Suite **on UNIX**).

In the TTCN Suite **in Windows**, the tool bars are dockable on all sides of the desktop.

Drawing Area

The information a tool handles is displayed and may possibly be edited in the drawing area. The drawing area may also give access to popup menus. See also "The Drawing Area" on page 25.

Working Area (only in the TTCN Suite in Windows)

The working area of the desktop will display the TTCN Suite windows that you open. For example, when you open a TTCN document, the Browser window will be displayed in the working area.

Tool Frame (only in the SDL Suite on UNIX)

A tool frame, with a unique color for each tool, surrounds the drawing areas in the SDL Suite. This makes it easier for you to identify a tool, without the need to see the whole drawing area or the title bar.

Status Bar

The status bar displays information about menu choices and quick-buttons, the progress or result of an invoked operation, and the name of a selected object or additional information about an object.

Sub Windows

A sub window of an SDL Suite and TTCN Suite tool is a window that depends on the main window of the tool. A sub window is opened either automatically when the main window is opened or as a result of user interaction with the main window. All sub windows are automatically closed when the main window exits. However, to close a sub window does not affect the main window.

The TTCN Suite Logs

Some TTCN Suite tools, for example the Analyzer, produce logs.

On UNIX, the relevant tool dialog allows the log device to be set to *Screen*, *File* or *None*. If set to *Screen*, the log will be displayed in its own log window. If set to *File*, a directory dialog will be displayed where you can specify a file to save the log in.

In Windows, the Log Manager will display the logs, and tabs are used for viewing different logs. The contents of the window can be copied and saved. For more information, see "Viewing Log Information" on page 1279 in chapter 30, *Editing TTCN Documents (in Windows)*.

Zooming a Window

You can change the scale of the drawing area of an SDL Suite window by selecting *Set Scale* in the *View* menu or by using quick buttons for zooming in and out. The scale is normally between 20% and 800%.

General Menus

The following menus are generally available in a menu bar:

- The *File* menu contains menu choices related to files, documents and the whole drawing area, as well as the tool/window itself. Examples: *New*, *Open*, *Save*, *Print* and *Exit*.
- The *Edit* menu contains menu choices concerning editing of the current document. It may also contain menu choices for changing objects. Examples: *Undo*, *Cut*, *Copy*, *Paste*, *Add* and *Edit.*
- The *View* menu contains menu choices that changes the appearance of the window and the information in the drawing area. Examples: *Expand*, *Collapse, Window Options* and *Set Scale*.
- The *Tools* menu contains menu choices for starting tools and utilities, and opening or raising other windows. Examples: *Search, Show Organizer* and *Show <window name>*.
- The *Help* menu contains menu choices for supporting you with help and other useful information.

General Menu Choices

Some common menu choices are described below and the descriptions will not be repeated elsewhere.

File Menu

The most common menu choices in the *File* menu are only described in this section. If a tool provides additional menu choices in the *File* menu, they will be described in the corresponding chapter. If a common menu choice has a different functionality, it will also be described in its corresponding chapter but minor differences will be mentioned below.

New

When you select this menu choice, a new document, diagram or file will be created and displayed. In some tools, it will be given a default file name which you later may change, and in some tools you have to specify the name and the type of document/diagram in a dialog before it will be displayed.

- For information on adding new pages to SDL diagrams, see "Add" on page 2035 in chapter 43, *Using the SDL Editor*.
- In the Text Editor, you have to select in a dialog whether to create a new file, copy an existing file, or to copy a template file. The directory for template files is defined by the preference TE*TextTemplateDirectory. For more information, see "Text Editor Preferences" on page 266 in chapter 3, *The Preference Manager*.
- When you create a new link file in the Link Manager, the current endpoint and link information will be deleted. You will be warned if a link file is already opened.

Open

When you select this menu choice, a file selection dialog will be issued, in which you select what file to open. For more information, see "File Selection Dialog" on page 30.

A default file filter, which depends on the tool, will be used. It corresponds to the default file name extensions applied when a document or diagram is saved (see "Save" on page 11). The tools and the filters are listed in the table below.

- When you open a new SDL simulator, a currently running simulator will be stopped after user confirmation. The Watch window will be updated and the text area will be cleared from previously executed commands.
- When you open a new link file in the Link Manager, a currently opened and modified file has to be saved first.

Tool	Default File Filter
SDL Target Tester	`*.sym`
SDL Coverage Viewer	`*.cov`
HMSC Editor	`*.mrm`
Index Viewer	`*.xrf`
The TTCN Suite **in Windows**	`*.itex`
Link Manager	`*.sli`
MSC Editor	`*.m??`
OM Editor	`*.som`
Organizer Log	`*.log`
SDL Editor	`*.s??`
SDL Simulator	`*_sm*.exe` **(in Windows)** `*.sct` **(on UNIX)**
SDL Explorer	`*_vl*.exe` **(in Windows)** `*.val` **(on UNIX)**
State Chart Editor	`*.ssc`
Text Editor	`*.txt`

Note:

No specific file name extension on diagrams are imposed. If other file name extensions than the ones suggested have been used when saving diagrams, a different filter than the given must be applied.

Note: The MSC Editor and instance oriented MSC/PR

The MSC Editor supports reading MSC/GR (default file name extension is `.msc`) and MSC/PR (default file name extension is `.mpr`). However, the MSC Editor cannot read MSC/PR expressed in instance-oriented form. Only the event-oriented form can be read by the tool. See the Z.120 recommendation for more information on these two alternative formats.

Note: Opening *.cif files in SDL editor

If a *.cif file is opened in an SDL editor, then the information from the SDL/CIF file is presented in a new, dirty and unsaved diagram buffer.

Save

When you select this menu choice, the current information in the document/diagram/window will be saved in a file.

When you save a document/diagram for the first time, a file selection dialog is opened. A default file name and file name extension is suggested. You have to specify where the file is to be saved and you may also change the file name and extension. If you try to overwrite an existing file, you will be warned.

Note:

If you keep the file name extensions for different documents/diagrams listed below, it will be easier to locate the files. It is also impossible to add an existing file to the Organizer unless it has the default extension.

Document/Diagram Type or Storage Format	Default File or Extension
Command definitions (SDL Simulator UI)	`.cmds`
Coverage	`.cov`
HMSC	`.mrm`
Link file	`.sli`
MSC	`.msc`
Object Model	`.som`
Organizer Log	`.log`
SDL System	`.ssy`
SDL Block	`.sbk`
SDL Substructure	`.ssu`
SDL Service	`.ssv`

Document/Diagram Type or Storage Format	Default File or Extension
SDL Process	.spr
SDL Procedure	.spd
SDL System Type	.sst
SDL Block Type	.sbt
SDL Service Type	.svt
SDL Process Type	.spt
SDL Macro Definition	.smc
SDL Operator	.sop
SDL Package	.sun
SDL Overview	.sov
State Chart	.ssc
State Overview	.ins
Text	.txt
TTCN test suite **(in Windows)**	.itex .mp .imp
Variable definitions (SDL Simulator UI)	.vars

Save Document

The *Save Document* menu choice only exists in the TTCN Browser and Table Editor **on UNIX**. When you select it, the TTCN document will be saved. See also "Save" on page 11.

Save As

Select this menu choice to save the current document/diagram in a new file. A default file name and file name extension will be suggested, see "Save" on page 11. If you change the file name and extension and try to overwrite an existing file, you will be warned.

If the document/diagram was already connected in the Organizer, it will be reconnected to the newly created file. This does not happen in the following cases:

- *Save As Text*. By specifying *.txt as the file name extension for graphical diagrams, the diagram text will be saved in the specified file.
- *Save As CIF*. By specifying *.cif as the file name extension for SDL diagrams, the diagram will be saved in SDL/CIF format, a standardized textual format that includes layout information. When this extension is used in the SDL editor and the Save As dialog is closed, you will be asked to select diagram pages to include in the generated file. As default, all pages are selected. A *.cif file can be opened in the SDL editor. When doing so, the information from the *.cif file is presented as a new, dirty and unsaved diagram buffer.

Note:

If you keep the file name extensions for different documents/diagrams listed above, it will be easier to locate the files. It is also impossible to add an existing file to the Organizer unless it has the default extension. In the TTCN Suite **in Windows**, you can only open test suites that have the extension `.itex`, `.mp` or `.imp`.

- In the TTCN Suite **on UNIX**, there are three alternatives for compression when you save as TTCN-GR: *None*, *Gzip* and *Compress*. *None* gives maximum compatibility. *Gzip* is preferred over *Compress*, both for portability and performance.

Save a Copy As

This menu choice is available in the SDL Suite editors. It saves a copy of the current document/diagram in a new file.

Note:

The window will hold the **original** file, **not the newly saved copy**. The document/diagram remains connected to the old file and the Organizer's structure is left unaffected by the operation.

The name of the new file is to be specified in a file selection dialog and a default file name and extension will be suggested; see "Save" on page 11. If you try to overwrite an existing file, you will be warned.

Save All

This menu choice is available in the SDL Suite editors. It saves all modified documents/diagrams that are opened. Except for that, it works as described in "Save" on page 11.

Print

The different *Print* dialogs and how to print is described in chapter 5, *Printing Documents and Diagrams*.

Close

When you select this menu choice, the current document/diagram (or in some cases the window) will be closed. In most documents, you will not have to confirm the closing.

- In the TTCN Suite, when you close the last open Browser on a document, you will be asked for confirmation if it has not been saved.
- When you close the Link Manager window, the Link Manager will still be active in the background but the user interface will not be available.
- In the SDL and TTCN Integrated Simulator Editor **on UNIX**, the window is closed, but current document is not closed until the associated setup is closed.
- In the SimUI's Command window, the commands currently displayed will be saved and shown again when the window is opened again. This is also valid for the variables in the Watch window.

Close Diagram

This menu choice is available in the SDL Suite editors. When you select it, the current diagram will be closed. If changes in the diagram have not been saved, a dialog will be issued where you can select to save or not before closing.

If the closed diagram was the last open diagram, the editor will exit. If there are more editor windows open, the window will be closed. If there is only one editor window, but more diagrams open, another diagram will be displayed in the window.

Revert Diagram

This menu choice is available in the SDL Suite editors. When you select it, the current diagram will be re-loaded from the file system. This operation is useful if the file has changed in any way in the file system.

Exit

When you select this menu choice, the current tool will exit. If a document/diagram has been changed since last save, a dialog will be issued where you may select to save it, not save it or – where applicable – save all opened documents/diagrams or quit without saving anything.

- In the SDL Simulator, you will be asked to save unsaved changes to the SimUI's definition files. See "Definition Files" on page 2221 in chapter 49, *The SDL Simulator*.

Tools Menu

A *Tools* menu is available in most tools. It contains various menu choices, but the following is included in almost all *Tools* menus:

Show Organizer

This menu choice raises the parent Organizer main window, that is from where the tool was started.

Help Menu

A *Help* menu is available in most main and sub windows of the tools. However, the menu choices in this menu are not the same in each tool or on each platform, but they work in the same way: When you select a menu choice in the *Help* menu, a help viewer will be opened with the corresponding help topic.

The following *Help* menu choices, that may need an explanation, are described below:

- *About <Tool>*
- *Help Desk*
- *Index*
- *Latest News*
- *License Information*
- *License Info*

- *New Features*
- *On Field*
- *On Shortcuts*
- *On Window*
- *Search*
- *IBM Home Page*

About <Tool>

Opens the *About* message box for the tool that the menu choice was invoked from, which gives information on the current tool version, copyright, etc.

Help Desk

Opens the online help to guide the user how to contact IBM Rational Software Support, http://www.ibm.com/software/awdtools/sdlsuite/support or http://www.ibm.com/software/awdtools/ttcnsuite/support, see also "How to Contact Customer Support" on page *iv in the Release Guide*. This menu choice is only available in the Organizer.

Index

Opens the help viewer with an index of all entries in the documentation. This menu choice is only available in the Organizer.

Latest News

Opens the help viewer with a "readme" file, containing late information about the release.

License Information

Opens a dialog with license information for all tools. For more information on this dialog, see "License Information" on page 166 in chapter 2, *The Organizer*. This menu choice is available in the Organizer.

License Info

On UNIX, this menu choice opens a dialog with additional license information on the TTCN Suite tools. For more information, see "License Info" on page 1122 in chapter 24, *The TTCN Browser (on UNIX)*. **In Win-**

dows, the dialog lists the IBM Rational licenses currently in use as well as the number of licenses available for each tool.

New Features

Opens the help viewer with information about new and changed functionality.

On Field

This menu choice is available in the TTCN Table Editor **on UNIX**. It displays the TTCN BNF syntax applicable for the relevant field.

On Shortcuts

Opens the help viewer with information about various user interface shortcuts that can be used within the Organizer tool.

On Window

Opens a text describing the TTCN Suite tool that the menu choice was invoked from. This menu choice is only available in the TTCN Suite **on UNIX**.

Search

Starts a textual search across all help files. This menu choice is available in the Organizer and all the SDL Suite tools.

IBM Home Page

Opens the web browser with IBM's home page on the World Wide Web (`http://www.ibm.com/software/rational`). This menu choice is only available in the Organizer.

Defining Menus in the SDL Suite

The graphical the SDL Suite tools allow you to define additional menus and menu items that execute external commands or send PostMaster messages. Separate user-defined menus can be defined and added to each graphical tool. However, the pre-defined menus in each tool can **not** be removed or changed.

User-defined menus are described by menu definition files that are read by the tools when they start up.

It is sometimes more useful to add user-defined menus to the tools after they have been started; this can be accomplished if you use the IBM Rational Public Interface. For more information see "Menu Manipulation Services" on page 525 in chapter 11, *The Public Interface*.

> **Note:**
>
> The fact that a set of menus have been defined in a menu definition file, does not prevent using the public interface services to add additional menus, or even to modify the menus that were defined by the menu definition file.

Tools and Menu Definition File Names

Menu definition files must have fixed names that indicate which tool the menus are intended for.

The following tools allow addition of user-defined menus, and also offer the possibility of letting the menu commands access the internal state information of the tool. This is accomplished if you use *format codes* that are documented separately for each tool in the Public Interface.

Tool	Menu definition file name
Organizer	`org-menus.ini`
MSC Editor	`msce-menus.ini`
SDL Editor	`sdle-menus.ini`
OM/SC/HMSC Editor	`ome-menus.ini`
Text Editor	`te-menus.ini`

The following tools allow addition of user-defined menus, but do not offer the possibility of accessing the internal state of the tool.

Tool	Menu definition file name
Preference Manager	`pref-menus.ini`
Type Viewer	`typ-menus.ini`
Coverage Viewer	`cover-menus.ini`
Index Viewer	`xref-menus.ini`
Tree Viewer	`tree-menus.ini`
Simulator/Explorer UI [a]	`simui-menus.ini`

a. **In Windows**, the Simulator/Explorer UI's can **not** read menu-definition files.

Menu Definition File Location

On start-up, each tool that supports menu-definition files will search for a menu definition file with the given pre-defined name in up to three locations:

1. First, the directory from where the SDL Suite was started is searched. If a file with the expected name is found, the tool will attempt to read it and install the menus described therein.
2. Second, the directory named in the `HOME` environment variable will be searched. If a file with the expected name is found, it will be used.
3. Last, the directory where the SDL Suite is installed will be searched (**on UNIX**, `$telelogic/`, and **in Windows** the top installation directory, by default `C:\IBM\Rational\SDL_TTCN_Suite6.3`).

If no file is found, no user-defined menus will be added on start-up.

Format of Menu Definition Files

A menu definition file is a line-oriented text file separated into sections by lines containing special section markers. Each section contains lines formatted in the same way, containing an option/value pair. Each section describes either a menu or a menu item.

The first line of a menu definition file is a format tag that identifies the file as menu definition file:

```
SDT-DYNAMICMENUS-6.3
```

Each section is started by adding a line with a section name between brackets "[ ]". Valid sections in a menu definition file are:

```
[MENU]
[MENUITEM]
[MENUEND]
```

[MENU] Section

The menu section starts a new menu. Subsequent `[MENUITEM]` sections will add a menu item to this menu until a `[MENUEND]` section is encountered. A `[MENU]` section should be the first line after the initial tag or follow directly after a `[MENUEND]` section.

After the `[MENU]` section tag follows the option below, using the syntax:

`Name=`*`NameOfMenu`*

Option	Explanation/Value
`Name`	A string that contains the name of the menu. The name is presented in the tool's menu bar. The ampersand '&' character may be placed just in front of a letter to indicate that this letter will be underlined in the menu name and thus function as a keyboard shortcut for menu traversal. Make sure that the letter is not used as a shortcut in any other menu in the menu bar, or it may not be possible to open the menu with the keyboard.

[MENUITEM] Section

A `[MENUITEM]` section must occur between a `[MENU]` and a `[MENUEND]` section.

Following the `[MENUITEM]` section tag is a number of options and their values, using the syntax:

```
Option=Value
```

This section adds a menu choice to the specified menu. The menu choice could either perform an OS command or issue a PostMaster notification when selected. The OS command to perform or the message to broadcast could be sensitive on a selected symbol.

The exact interpretation of two of these options (`ProprietaryKey` and `AttributeKey`, described below) will depend on which tool the menu will be installed in. In particular, the `ProprietaryKey` option will only have significance in the Organizer and the graphical editors. The `AttributeKey` option will only have significance in the graphical editors. If not used these options should be set to 0.

For tools supporting access to internal state information, format codes can be used in the command string or as message parameter, providing additional context-sensitive information.

For more information on options and format codes, see *"Add Item to Menu" on page 584 in chapter 11, The Public Interface*.

Option	Explanation/Value
`ItemName`	A string that contains the menu item text that appears in the menu item. Ampersand syntax is supported, as for menu names. Make sure that different letters are selected for each menu item in the menu; otherwise keyboard activation of the menu item may not work.
`Separator`	A boolean value (0 or 1) that indicates whether a separator (a thin line) should precede the menu item in the menu.
`StatusbarText`	A string that should be displayed in the tool's status bar while the menu item is selected to hint you about the function of the menu choice.

Option	Explanation/Value
`ProprietaryKey`	An integer whose interpretation depends on the tool; the Organizer interprets this parameter as `lastAction`, and the graphical editors interpret it as `ProprietaryKey`. For more information, see "lastAction" on page 589 and "ProprietaryKey" on page 594 in chapter 11, *The Public Interface*. For the Organizer, you can use either an integer or a symbolic string as the value. If not used, simply set to 0.
`AttributeKey`	An integer whose interpretation depends on the tool; the graphical editors interpret this parameter as `AttributeKey`. For more information, see "AttributeKey" on page 594 in chapter 11, *The Public Interface*. If not used, simply set to 0.
`Scope`	An enumerated value that indicates when the menu item should be dimmed. For the valid values, see "scope" on page 585 in chapter 11, *The Public Interface*. You can use either an integer or a symbolic string as the value. If not used, simply set to 0.
`ConfirmText`	A text string that contains a dialog box text. If not empty, this will issue a two button dialog with *OK* and *Cancel* buttons and an editable text field containing the command to be performed. You can alter the command text before pressing *OK*.
`ActionInterpretation`	An integer value indicating the desired action when a menu item is activated: `PM_MESSAGE` (0) - send PostMaster message `OS_COMMAND` (1) - execute OS command
`BlockCommand`	Only significant if `Action` is set to 1: A boolean value (0 or 1) indicating whether the Organizer should wait for the execution of the command to complete (1), or allow you to perform other operations while the command executes (0).

Option	Explanation/Value
FormattedCommand	Only significant if Action is set to 1: The OS command to perform. Some tools evaluate specific context sensitive format codes.
MessageNumber	Only significant if Action is set to 0: Indicates the number of the PostMaster message to send.
FormattedMessage	Only significant if Action is set to 0: The parameters to the PostMaster message. Some tools evaluate specific context sensitive format codes.

[MENUEND] Section

The [MENUEND] section indicates that a menu definition has come to an end and that no more [MENUITEM] sections should appear until a new [MENU] section is encountered. This section has no options.

Example of a Menu Definition File

An example of a typical menu-definition file could be:

```
SDT-DYNAMICMENUS-3.6
[MENU]
Name=&RCS
[MENUITEM]
ItemName=Check &Out
Separator=0
StatusbarText=Check out the selected object
ProprietaryKey=1
AttributeKey=0
Scope=SELECTED_OBJECT_NOT_IN_EDITOR
ConfirmText=
ActionInterpretation=OS_COMMAND
BlockCommand=1
FormattedCommand=co %f
[MENUEND]
```

General Quick-Buttons

If you hear a beep when you click a quick-button, then the operation is currently not available.

The following quick-buttons can be considered as standard buttons that are available in many tools:

Back
The same as *Back* in the *Diagrams* menu.

Forward
The same as *Forward* in the *Diagrams* menu.

Open
The same as *Open* in the *File* menu.

Save
The same as *Save* in the *File* menu.

Print
The same as *Print* in the *File* menu.

Search
The same as *Search* in the *Tools* menu.

Search Again
The same as *Search Again* in the *Tools* menu.

Show Organizer
Raises the parent Organizer window, from where the tool was started. In a sub window to a tool, this button raises the main window of the tool.

Decrease Scale
Decrease the scale of the drawing area by 20%.

Increase Scale
Increase the scale of the drawing area by 20%.

Help
The same as *On <Tool>* in the *Help* menu.

The Drawing Area

Popup Menus

You invoke a popup menu with the right mouse button. A menu choice in a popup menu generally have the same name and work in the same way as a corresponding menu choice in the menu bar.

There are two types of popup menus: context sensitive popup menus and the background popup menu.

Context Sensitive Popup Menus

Objects visible in the drawing area may have associated popup menus, whose contents may vary with the type of the object.

In the SDL Suite, a context sensitive popup menu can be displayed in two slightly different ways:

- By a right-click directly on a visible object.

  The current selection also changes with this operation, i.e. the object pointed at becomes selected and replaces any previous selection.

- By a right-click on the background, outside any object, when there exists a current selection.

  In this case, the popup menu applies to the selected object(s) and the selection does not change.

In the TTCN Suite, the popup menu **always** applies to the object the mouse pointer is placed on, but the current selection **does not change**. If you right-click on the background of the drawing area, outside of any visible object, the background popup menu is displayed, regardless of any current selection.

The Background Popup Menu

In the SDL Suite, the background popup menu is displayed if you right-click on the drawing area background, and there is no current selection in the drawing area. This popup menu contains some of the most important and/or commonly performed menu choices from the menu bar. The popup menu choices operate on the whole file, document or drawing area, in the same way as the corresponding menu choices from the menu bar do.

In the TTCN Suite, the background popup menu is always displayed if you right-click on the drawing area background, regardless of any selected objects.

List and Tree Structures

Many tools can present a hierarchical structure in two ways; as a list structure and as a tree structure. The example below is from the Organizer.

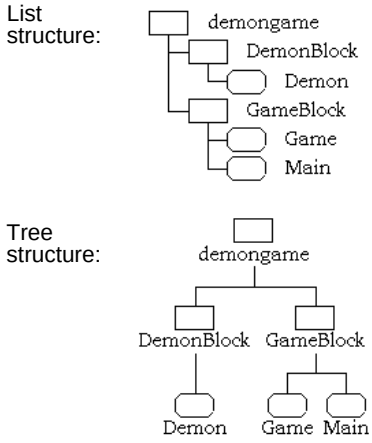

Figure 4: List and tree structures

It is possible to switch between the two structures if you select an *Option* menu choice on the *View* menu. It is also possible to collapse and expand nodes in a hierarchical structure with the *Expand* and *Collapse* commands in the *View* menu. A collapsed node is indicated by a small triangle below the node:

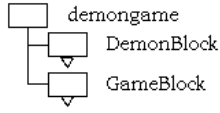

Figure 5: Collapsed nodes in list structure

Selections and Input Focus in the TTCN Suite (on UNIX)

In the TTCN Suite **on UNIX** there is a difference between *selection* and *input focus*. Selection is a marked item or text string. You select items with the left mouse button. The input focus is set when you point to an item and click with the middle mouse button. The input focus is indicated by a rectangular border surrounding the relevant item.

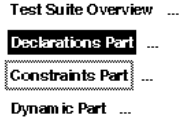

Figure 6: Selection and input focus in the TTCN Suite **on UNIX**

Dialog Windows

There are two types of dialogs, *modeless* and *modal*. A modeless dialog does not prevent you from using other parts of the application while the dialog is visible. A modal dialog does prevent this, that is, the dialog must be dealt with before any work can continue.

Modeless Dialogs

A modeless dialog can be considered as an extension to the main window. It contains an *Apply* button which executes the functionality of the dialog but does not close it. The button is often renamed to indicate the functionality, for example *Search*. The *Close* button closes the dialog but does not apply any functionality.

Note:

There is no button with the functionality of an *OK* button, i.e. execute the functionality **and** close down the dialog.

Modal Dialogs

A modal dialog is used for operations that must be confirmed or that affect the view or the information used in the tool. A typical example is an *Open* dialog. The *OK* button in a modal dialog both executes the functionality and closes the dialog. The *Cancel* button closes the dialog but the settings you may have changed in the dialog are ignored.

File Name Completion

Wherever you are supposed to input a file or directory name as text in a text field in a dialog, you can take advantage of file name completion. To do this, you type the beginning of an absolute file name or a directory and then press `<Space>`. This will add characters at the end of the text field. If there are several matches, the initial characters of the matching names will be added. Then you have to press `<Space>` again to get the alternatives one by one. And after the final alternative, you will get a space character.

File name completion is not provided in the TTCN Suite.

Example 1: File name completion

Suppose you have the files `/home/lat/hello.txt` and `/home/lat/henderson.txt`.

1. Type **`/home/l`**, and then press `<Space>`.
   The result will be `/home/lat/`.
2. Then type an additional **`h`**, and then press `<Space>` again.
   The result will be `/home/lat/he`.
3. Press `<Space>` again.
   The result will be `/home/lat/hello.txt`.
4. Press `<Space>` again.
   The result will be `/home/lat/henderson.txt`.
5. Press `<Space>` again.
   The result will be `/home/lat/he` (with a space character at the end).

Folder Button

When the name of a file or directory is to be specified in a dialog, a combination of a text field and a *folder button* is often used. You can type the name directly in the text field, or press the folder button to open a file or directory selection dialog (see the following subsections).

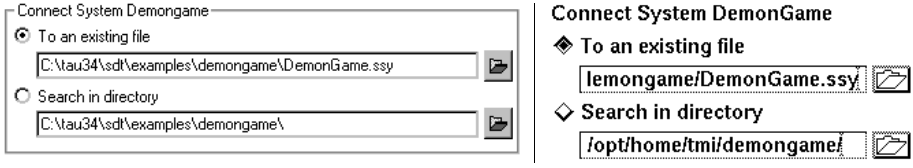

Figure 7: Folder buttons for selecting files and directories (Windows and UNIX)

File Selection Dialog

When you are going to save or open (or something similar) a file, a file selection dialog will be issued. The dialog will also be opened if you click on the folder button associated with a file name field in a dialog.

In Windows, the file selection dialog looks and behaves exactly like the normal file selection dialog used in Microsoft Windows.

In the SDL Suite **on UNIX**, the file selection dialog behaves like described below. The the TTCN Suite version **on UNIX** is described in "The TTCN Suite File and Directory Dialog (on UNIX)" on page 31.

- The text in the *Filter* field determines which files are shown in the *Files* list. The field is initially set to match the file type that the invoking tool or dialog operates on but you may change it.
- If you click the *Filter* button, the file matching pattern in the *Filter* text field is applied to the current directory in the *Directories* list and the *Files* list is updated. This is the same as pressing `<Return>` or clicking the default button when no file name is present in the *File* text field.
- If you click the *Current* button, the directory will be changed to the source or target directory, depending on which kind of operation you have initiated. For more information, see "Set Directories" on page 71 in chapter 2, *The Organizer*. The *Files* list will be updated accordingly.
- The *Directories* list shows the absolute path to the currently chosen directory, as well as the names of any subdirectories in that directory. The directories in the path are shown within brackets, slightly indented for each directory level. The last directory in the list is the name of the currently chosen directory. To change to another directory, double-click on any directory in the list. Both the *Directories* list and the *Files* list are then updated to show the contents of the new directory.
- The *Files* list shows the files in the currently chosen directory that match the pattern in the *Filter* text field. You can select the file to operate on from this list, in which case the *File* text field is updated to contain the name of the file. To double-click on a file name is the same as selecting it and then pressing the default button.

- The *File* text field contains the name of the file selected in the *Files* list. This field may initially contain a default file name, suggested by the invoking tool or dialog. You can enter any file name in this field, including a relative or absolute path. You may also specify paths to home directories with the "tilde" syntax (`~/` or `~user/`).

  When `<Return>` or the default button is pressed, it is the file in this text field that is operated on. If the field is empty and no file is selected in the *Files* list, this is the same as pressing the *Filter* button.

Directory Selection Dialog

A directory selection dialog is opened when you select menu choices dealing with directories. The dialog will also be opened if you click on the folder button associated with a directory name field in a dialog.

In Windows, the directory selection dialog looks and behaves exactly like the normal directory selection dialog used in Microsoft Windows.

In the SDL Suite **on UNIX**, the directory selection dialog behaves like described below. The TTCN Suite version **on UNIX** is described in "The TTCN Suite File and Directory Dialog (on UNIX)" on page 31.

- The *Directories* list works in the same way as in the file selection dialog. It is the last directory in the indented list of directories that is chosen when the *OK* button is pressed, unless the text field is specified. This means that it is not enough to select a directory in the list; it has to be double-clicked to become the chosen directory.
- The *Text Field* may be used to enter any directory name, including a relative or absolute path. When `<Return>` or the *OK* button is pressed, it is the directory in this text field that is chosen, if it is specified.
- The *Current* button works in the same way as in the file selection dialog. For more information, see "File Selection Dialog" on page 30.

The TTCN Suite File and Directory Dialog (on UNIX)

Many TTCN Suite dialogs **on UNIX** require the specification of directory paths and file names. A special dialog is used for this purpose.

The example used in the description of the dialog below is taken from a *Log file* dialog, but the principle is the same for all file/directory oriented dialogs.

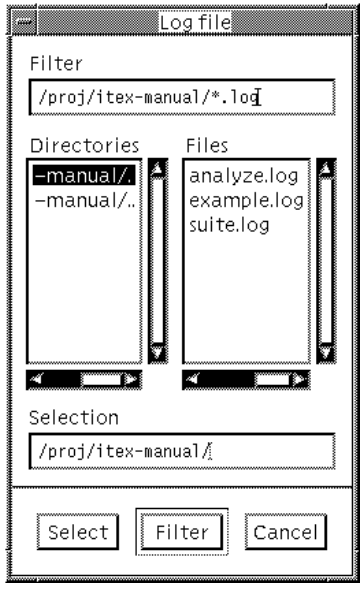

Figure 8: The TTCN Suite file and directory dialog **(on UNIX)**

- The *Filter* field enables you to specify a name pattern which will cause only those file names which match the pattern to be displayed in the *Files* list. Note that the name pattern must be preceded by the complete directory path. This path is set by the TTCN Suite to the currently selected directory (by selecting a directory path in the directories list), but you may edit it directly.
- The *Directories* list shows the directories in the current directory. This list will contain at least two entries, the current directory (a path ending in `/.`) and the parent directory (a path ending in `/..`). To change to another directory in the dialog, select the required directory path and double-click (see also the *Filter* command).
- The *Files* list shows the files that are in the selected directory which match the name pattern. If no files match the pattern or the directory is empty, this is indicated by “[ ]”.

- The *Selection* field displays the currently selected file. This input field also enables you to directly type in a file name.
- The *Filter* button updates the *Files* list depending on the filter pattern (including the file path). Select a directory in the *Directories* list, then choose the *Filter* button to open the directory and display the files in that directory (if any) in the *Files* list.
- The *Select* button terminates the dialog with the selection indicated in the *Selection* input field (in other dialogs this button may have another name, e.g. *Open*, *Export*, etc. but the effect is the same). If there is already a file name chosen before invoking this dialog (i.e. from import dialog when selecting a database name) and no name is specified in the *Selection* input field in this dialog, only the directory path will be modified.

Filename Error Dialogs (UNIX only)

For compatibility reasons, file names on UNIX platforms must not contain colon characters. For an overview on file compatibility issues, see "Windows and UNIX File Compatibility" on page 215 in chapter 2, *The Organizer*.

In the SDL Suite, this restriction is checked whenever the you change a file or directory specification that is stored in the system file (see "System File" on page 189 in chapter 2, *The Organizer* for more information). If they are not followed, an error dialog is shown and you are returned to the dialog where the file was specified.

If you use the TTCN Suite, this restriction affects you only when you choose a name for the system file in the Organizer.

The Busy Dialog

In some special circumstances, a message dialog may be opened, stating that a tool is "busy." This is **not** an indication of a system error. The dialog is opened when a tool is busy performing an operation that you have not finished. A typical example is when you select *Show Organizer* from another tool, and you have not closed a modal dialog in the Organizer, for example the *Print* dialog.

The remedy for a situation like this is to close the message dialog and finish the operation that caused the busy message.

The Timeout Warning

When a tool is started on a heavily loaded computer system, it may fail to start and respond within a certain time limit. When this happens, a timeout warning dialog is opened.

The time limit is specified, in seconds, by the environment variable `STARTTIMEOUT`. The default time limit is 60 seconds. If timeout problems occur, this variable should be adjusted to a higher value to match the typical response times for the computer system where the tool is running. For the changed time limit to take effect, the tools must be restarted.

Keyboard Operations

It is possible to reach and invoke all commands, menu choices and selections by using the keyboard. This section describes the general keyboard operations available.

Menu Traversal

The name of each menu in the menu bar contains an underlined character, as in the menu name *File*. To display, or pull down, the menu, press `<Meta>` **(on UNIX)** or `<Alt>` **(in Windows)** and the corresponding key, for example `<Meta+F>` or `<Alt+F>`.

One character in each menu choice is also underlined. To invoke a menu choice when the menu is displayed, simply press the corresponding key.

The arrow keys can also be used to move between the menu choices and the adjacent pull-down menus.

To invoke a selected menu choice, press `<Return>` or `<Space>`. To cancel the menu traversal and bring down the menu, press `<Esc>`.

Keyboard Accelerators

You can invoke most common menu choices by using an accelerator. An accelerator is a key combination of the form `Ctrl+X`. An accelerator is always case insensitive.

An accelerator always invokes the same kind of command in all SDL Suite tools where it is available. The standard accelerators are:

Accelerator	Functionality or menu command
`Ctrl+F`	Find, *Search* (in the *Tools* menu)
`Ctrl+H`	Help (*On <tool>* in the *Help* menu)
`Ctrl+N`	*New* (in the *File* menu)
`Ctrl+O`	*Open* (in the *File* menu)
`Ctrl+P`	*Print* (in the *File* menu)
`Ctrl+Q`	Quit, *Exit* (in the *File* menu)
`Ctrl+S`	*Save* (in the *File* menu)

Accelerator	Functionality or menu command
`Ctrl+X`	*Cut* (in the *Edit* menu)
`Ctrl+C`	*Copy* (in the *Edit* menu)
`Ctrl+V`	*Paste* (in the *Edit* menu)
`Ctrl+Z`	*Undo* (in the *Edit* menu)
`Ctrl+D`	Scroll one page down
`Ctrl+U`	Scroll one page up

Key Bindings

By using some special keys, you may perform an operation without holding down any modifier key at the same time.

Note:

All keys are not present on all keyboards.

Key	Operation
Arrow keys	Moves the selection in tree structures, list structures and ordinary lists to the closest object in the indicated direction.
`Return (Enter)`	• In a drawing area: the same action as a double-click on the selected object. • In a dialog: the same action as pressing the default button.
`Delete (Remove)`	For texts, clears the character **after** the insertion point. (May be changed with a preference.)
`Backspace`	For texts, clears the character **before** the insertion point.
`F1 / Help`	Opens the help viewer with help on the current window.
`F2`	Raises the popup menu.
`Page Up (PgUp, Prev)`	Moves the visible part of the drawing area a screen upwards.

Key	Operation
`Page Down (PgDn, Next)`	Moves the visible part of the drawing area a screen downwards.
`Home`	Moves the visible part of the drawing area to show the top of the drawing area.
`End`	Moves the visible part of the drawing area to show the bottom of the drawing area.
`Open`	As the menu choice *Open*.
`Find`	As the menu choice *Search*.
`Again`	As the menu choice *Search Again*.
`Undo`	As the menu choice *Undo*.
`Copy`	As the menu choice *Copy*.
`Paste`	As the menu choice *Paste*.
`Cut`	As the menu choice *Cut*.

Key Bindings in the TTCN Suite

More information on keyboard accelerators and key bindings in the TTCN Suite can be found in:

- "Shortcuts" on page 1296 in chapter 30, *Editing TTCN Documents (in Windows)*
- "Key and Button Bindings" on page 1163 in chapter 24, *The TTCN Browser (on UNIX)*
- "Key and Button Bindings" on page 1187 in chapter 25, *The TTCN Table Editor (on UNIX)*
- "Customizing the TTCN Suite (on UNIX)" on page 1243 in chapter 29, *Customizing the TTCN Suite (on UNIX)*

Chapter

2 *The Organizer*

The Organizer is the main tool in SDL Suite and TTCN Suite. When you invoke any SDL Suite or TTCN Suite tool, the Organizer is started and displayed on the screen.

This chapter contains a reference manual for the Organizer; the functionality it provides, its menus, windows and symbols.

Overview

Terminology

The following basic terminology is used throughout this chapter:

- *Document*

  A *document* is a file containing information that can be edited in a particular editor available through SDL Suite and TTCN Suite. Examples of documents in the Organizer are SDL diagrams, MSC diagrams, TTCN documents, and text documents.

- *Generic Document*

  Files containing document types that the Organizer does not normally handle can be included in the Organizer by using a *generic document* symbol and connecting that symbol to the file. The Organizer uses the file extension and the preference variable Organizer*GenericCommand to determine a command to perform when the user tries to edit a generic document.

- *Tau Workspace / Tau Project*

  (Windows only) Files of types .ttw or .ttp that contains a Workspace or a Project handled by the IBM Rational Tau tool. When editing such a document the Organizer will launch the IBM Rational Tau tool.

- *Rhapsody Project*

  (Windows only) Files of types .rpy that contains a Project handled by the IBM Rational Rhapsody tool. When editing such a document the Organizer will launch the IBM Rational Rhapsody tool.

- *Diagram*

  A *diagram* is a graphical document that only can be edited in a graphical editor. Diagrams are either SDL diagrams, MSC diagrams, HMSC diagrams, Object Model (OM) diagrams, or State Chart (SC) diagrams.

- *TTCN Document*

A *TTCN Document* signifies a document of type Test Suite, Modular Test Suite, TTCN Module, or TTCN Package.

- *SDL System*

  An *SDL system* in SDL Suite signifies the topmost SDL diagram with all its sub diagrams, and all used SDL packages with their sub diagrams. In the normal case, the topmost diagram is an SDL system diagram, but the Organizer allows all types of SDL diagrams to be the topmost diagram, as long as the standard hierarchical rules of SDL diagrams are respected.

- *TTCN System*

  A *TTCN system* in TTCN Suite signifies the topmost TTCN document with all its sub TTCN documents.

- *System*

  Not to confuse with an SDL or TTCN system, a *system* in the Organizer refers to a set of documents that, according to your view, are related and thus managed by the Organizer. You decide which documents make up a system and how they are related and grouped together in the Organizer.

  A system can contain documents for analysis, design and testing of one or more SDL and/or TTCN systems. The documents can be textual requirements, analysis and design diagrams, test specifications, source code in different forms, and other types of related documentation.

  In the normal case, one system in the SDL Suite contains one SDL system. But for special purposes it is possible to have more than one SDL system in the system context. Such a purpose could be when working with communicating simulators on UNIX where the source diagrams of each system are required to show and trace the graphical source symbols.

- *Root Document*

  The topmost document in a document structure, or a stand-alone document, or a top-level document in a module. For an SDL system, the topmost diagram in the system, usually an SDL system diagram.

  SDL package diagrams and macro diagrams are special in the sense that they are used by an SDL system diagram. Therefore, they are also placed at the root level and are considered root diagrams.

- *Association*

  An *association* is a link between two documents. Any document can be associated with any other document; a typical example is to associate an MSC diagram with a related SDL diagram. In the document structure, an association symbol is included to the associated document. This symbol is handled like a document, even though it simply represents a document residing somewhere else.

- *Chapter*

  The drawing area of the Organizer is divided into several chapters. You may freely add, remove, and rename chapters, as well as rearrange the order of the chapters. Each chapter has an associated chapter level. It is possible to set the start chapter number.

- *Module*

  A concept specific to the Organizer, used for freely grouping root documents together into a document structure. The user can use modules as a kind of scope unit. Modules have no corresponding concept in SDL, MSC or TTCN terminology. Note, however, that a TTCN Module is not the same concept as a module in the Organizer.

- *Logical Diagram Name*

  The Organizer can identify diagrams in the system by their logical diagram names. The logical diagram name may contain the entire qualified name of the diagram in a specific format. The connection between logical diagram names and physical file names is explicit and under user control.

- *System File*

  A file containing information about the structure and state information of a system as seen by one user. Organizer user settings and viewing options are also stored in this file. The system file is described further in "System File" on page 189.

- *Control Unit File*

  A file that contains a *control unit*, i.e. structure information for a part of a system, common to all users that work with the system. The purpose is to provide workgroup support and a means to put a system under revision control. The user has full control of what parts of a system should be managed as control units. The control unit file is described further in "Control Unit File" on page 200.

- *Link File*

  A file that contains the endpoint and link information, which is managed by the Link Manager. The link file is described further in "The Link File" on page 485.

- *Source Directory*
- *Target Directory*

  The source directory specifies where new documents that you have created, are saved by default, and where to read from when opening and converting documents. **On UNIX,** the source directory is also the directory normally shown when you click *Current* in a standard file selection dialog or a standard directory selection dialog. For more information, see "File Selection Dialog" on page 30 and "Directory Selection Dialog" on page 31 in chapter 1, *User Interface and Basic Operations*.

  The target directory specifies where to put generated files.

  These directories are set in the Organizer, see "Set Directories" on page 71. They are also saved in the system file.

- *Footer File*
- *Header File*

  Footer and header files are used to define how footers and headers should look like when pages are printed. The footer and header file symbols makes it easy to edit the appearance of the footer or header using a text editor. The footer and header file format is described in "Footer and Header Files" on page 344 in chapter 5, *Printing Documents and Diagrams*.

Organizer User Interface

The Organizer consists of two windows: a main window and a log window. For a general description of the user interface, see chapter 1, *User Interface and Basic Operations*.

The main window of the Organizer is also the main window of the tool environment. It manages the current system structure and is responsible for invocation and termination of other tools.

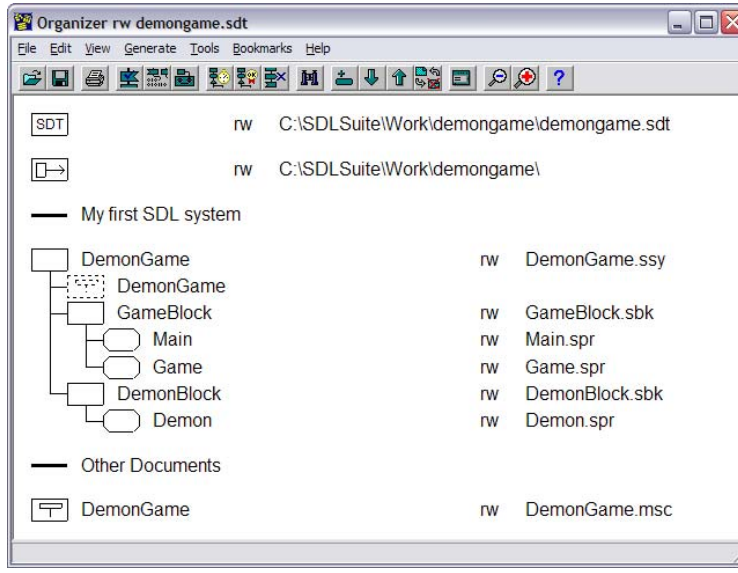

Figure 9: The Organizer main window

The main window exists in one instance only. If more than one Organizer is required, another instance of the SDL Suite or the TTCN Suite must be started. For special purposes, the Organizer can handle more than one TTCN or SDL system simultaneously.

The log window is a text window used for displaying output during analysis and code generation and for displaying general logs. The window is described in "Organizer Log Window" on page 183.

Drawing Area

In the Organizer's drawing area, the files in the system and their structure are presented graphically using icons.

Presentation Modes

The Organizer can present the system information in two different ways graphically:

- As an *indented list*, i.e. a compact, line-oriented list of icons using indentation to suggest the structure (see Figure 10).
- As a *vertical tree*, which is depth- or level-oriented and requires a larger amount of space (see Figure 11).

The user can change the amount of information and the way it is presented in the drawing area with the menu choice *View Options* in the *View* menu. See "View Options" on page 106 for more information.

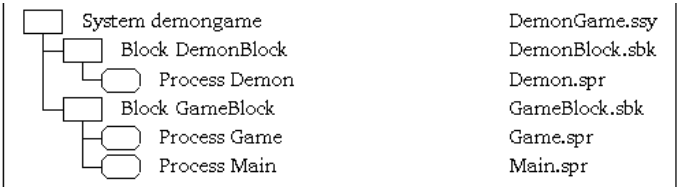

Figure 10: Indented list mode

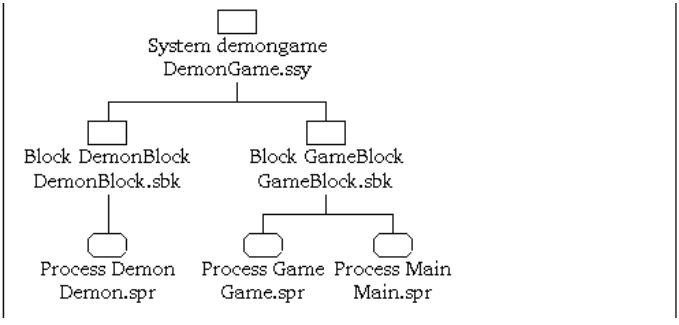

Figure 11: Vertical tree mode

Chapters

The *chapter* concept can be used to define a collection of documents. There are no restrictions on what kind of documents that may be placed in a certain chapter, or on the order of documents in a chapter; this is for the user to decide. Chapters can further be used to structure a print-out of the system included in the Organizer view. More information about this can be found in "Advanced Print Facilities" on page 357 in chapter 5, *Printing Documents and Diagrams*.

A chapter has a name, and possibly a number. A chapter is shown as a thick horizontal line in the drawing area, together with its number and name. A chapter symbol can be placed inside a Module, as well as inside an SDL diagram structure and a TTCN Module structure.

In addition to the line icon, it is possible to have the Organizer show the text "Chapter" ahead of the number and name; see "Icon Names and Types" on page 56.

Chapter Levels

A chapter has an associated chapter level, ranging from 0 to 4, which is reflected in the numbering of the chapter:

- Level 0: a chapter without a number (only a name)
- Level 1: a chapter with a single number: 1, 2, 3, etc.
- Level 2: a chapter with two numbers: 1.1, 1.2, 1.3, etc.
- Level 3: a chapter with three numbers: 1.1.1, 1.1.2, 1.1.3, etc.
- Level 4: a chapter with four numbers: 1.1.1.1, 1.1.1.2, 1.1.1.3, etc.

Numbered chapters are auto-numbered by the Organizer. The initial number for the first chapter in the drawing area can be specified. The initial level of a chapter is specified when the chapter is created, but can later be changed.

Chapter Introduction Text

A chapter can be associated with a text, which can be regarded as an introduction text to the chapter. When the chapter is included in a print-out, this text will be inserted on a separate page corresponding to the position of the chapter symbol.

The text is saved in a text file, which the chapter symbol is connected to.

Default Chapters

There is a default set of unnumbered chapters, known as the *basic Organizer view*, intended for different kinds of documents. This view appears when creating a new system file and contains the following chapters:

- *Chapter Analysis Model*
- *Chapter Used Files*
- *Chapter SDL System Structure*
- *Chapter TTCN Test Specification*
- *Chapter Other Documents*.

The intended use of these default chapters is described below. The default set of chapters can be changed by editing the preference Organizer*Areas.

Chapter Analysis Model

The *Analysis Model* chapter is intended for documents used in a system's analysis, such as Object Model and State Chart diagrams, text requirement documents, MSC, HMSC and SDL requirement diagrams, etc.

Chapter Used Files

The *Used Files* chapter is intended for documents that are not generated but are used, included, or imported by other documents in other chapters. Such documents may be C/C++ header files, etc.

Chapter SDL System Structure

The *SDL System Structure* chapter is intended for the SDL diagram structure that normally is the primary information managed by the Organizer. The diagram structure contains a strictly hierarchical view of one or more root diagrams and their substructures. Most often only one diagram structure is used (a system) with one or more package or macro structures present as separate roots in the system. A characteristic of these diagrams is that they are directly involved in the analysis/code generation process. Multiple system roots are allowed, mainly to support the possibility of running communicating simulators with graphical trace.

Chapter TTCN Test Specification

The *TTCN Test Specification* chapter is intended for TTCN documents used for test specifications.

Chapter Other Documents

The *Other Documents* chapter is intended for documents that do not fit into any of the other chapters. It may contain SDL, MSC, and HMSC diagrams, text documents, etc. that are not directly part of an SDL system and that are not related to the other document structures in the Organizer.

Structure Icons

A few special icons in the Organizer are used for showing how document icons are structured, and for specifying where they are stored in the file system by default.

In addition to the icon, it is possible to have the Organizer show the type of the structure icon textually; see "Icon Names and Types" on page 56.

Different operations are applicable to different types of icons. Double-clicking an icon is described in "Double Clicks" on page 57, and associated popup menus are described in "Pop-Up Menus" on page 170.

System File
The name of the system file. This system file could be managed as a control unit (CM group) to allow revision control of the system file in a multiuser environment.

Link File
The name of the link file.

Control Unit File
This icon designates a control unit whose contents have not yet been resolved.

Source Directory
The name of the source directory.

Target Directory
The name of the target directory.

Header File
The name of the header definition file. Note that it is possible to connect a text file to this symbol, i.e. the symbol can act as a plain text symbol.

Footer File
The name of the footer definition file. Note that it is possible to connect a text file to this symbol, i.e. the symbol can act as a plain text symbol.

Chapter
A chapter in the drawing area. A chapter can have a number and a name and may be connected to a text file.

Module
Another way to define a collection of documents, within a chapter. A module has a name but no associated file name.

More
Indicates that a number of documents are hidden in the document structure (see “Hide” on page 106). The text associated with the icon indicates the number of hidden (additional) documents, e.g. “5 More”.

Bookmark
Quick access to a place in an SDL Suite diagram or document via an SDT reference or to a place on the Web via a URL.

Document Icons

To visualize the different types of documents that are present in the user’s system, a large number of graphical icons are used. A unique icon is provided for every document type that is commonly used in a system. In particular, each SDL diagram type (except packages, systems, macro definitions and operators) already have a given icon (the reference symbol specified in the Z.100 recommendation).

In addition to the icon, it is possible to have the Organizer show the type of the document textually; see “Icon Names and Types” on page 56.

Different operations are applicable to different types of icons. Double clicking an icon is described in “Double Clicks” on page 57, and associated popup menus are described in “Pop-Up Menus” on page 170.

Icon Types

The list below shows the icons that may be part of a system display in the Organizer:

Other icons

The icon for an association or a dependency is a dashed version of the icon of the referenced document. The example to the left shows an association referencing an MSC icon.

Generic Document

Tau Workspace / Tau Project

Rhapsody Project

Index icon, representing a generated cross reference file that can be viewed in the Index Viewer.

Page (used for SDL, HMSC, State Chart, and OM diagrams)

Diagram and Document Icon States

The diagram and document icons can have different background colors indicating the state of the information entity associated with the icon. If the icon state is anything else than normal, additional information about the corresponding file is provided in the Status Bar when the icon is selected.

Normal
The normal state of the icon. Information is not modified.
All diagram and document icon types can be normal. This is also the background color used by all non-diagram/document icons.

Invalid
The connected file does not exist or is not a diagram file of the correct type. This state is only possible when connected to a file.
All diagram and document icons can be invalid.
For more information on invalid icons, see "Open" on page 60 and "The Drives Section" on page 192.

Mismatch
The SDL diagram is not referenced in the diagram file where this diagram is referenced in the Organizer, i.e. there is a SDL diagram structure mismatch between the system file and the diagram files.
This state is only possible when connected to a file. Mismatched diagrams that are unconnected are removed from the diagram structure in the Organizer.
SDL diagram icons that are not root diagrams can be mismatched.
The reason for a mismatch is that the reference symbol in the parent diagram states a diagram name different than the kernel heading in the mismatched SDL diagram.
For more information on mismatches, see "Open" on page 60 and "No Save" on page 64.

Dirty
The associated information entity is modified, but not yet saved. This state is only possible when connected to a file.
All diagram and document icons can be dirty.

Ordering

The order of root documents in a chapter is not fixed and can be changed by the user; see "Move Down" on page 182 and "Move Up" on page 182. Moving documents in the Organizer is also used for two other purposes:

- Grouping root documents in a module. Trying to move a root document "over" a non-collapsed module, will result in that the root document becomes a child symbol to the module. A document is also moved out of a module by moving the document up (or down) one or several times.
- Grouping TTCN documents to form a TTCN system. Trying to move a root TTCN document with no children over another (non-collapsed) root TTCN document (possibly with children), will result in that the moved TTCN document will become a child symbol

below the other root TTCN document. A non-root TTCN document is moved out of a TTCN system by moving the TTCN document up (or down) one or several times.

However, the order in which "child" icon types to a "parent" icon appear is fixed according to the following:

1. Page icons
2. Association icons
3. Dependency icons
4. SDL Instance icons
5. SDL Dashed icons
6. Child diagram and document icons

The ordering of page icons is specified in the appropriate editor for the diagram/document type (see "SDL Page Order" on page 1850 in chapter 43, *Using the SDL Editor*, or "Diagrams and Pages" on page 1622 in chapter 39, *Using Diagram Editors*). The ordering of association icons, dependency icons, SDL instance icons and SDL dashed icons is fixed and cannot be changed by the user. The ordering of child diagram and document icons can also be changed.

Icon Names and Types

The names of chapters, modules and documents in the Organizer are always shown to the right of the icon.

It is possible to show the *type* of each icon, i.e. a text of the form "System file", "Chapter", "Module", "Object Model", "Block", etc., directly to the right of the icon (ahead of the name). For SDL diagrams, it is also possible to show the virtuality of the diagram. Both these options are available from the menu choice *View Options* in the *View* menu. See "View Options" on page 106 for more information.

If the document is not opened in an editor, the icon text is presented in a normal, plain type face. If the document is opened in an editor, the text is presented in **bold face**.

Double Clicks

To double click on an icon invokes a default action on the information type that the icon represents.

The menu choices and operations corresponding to the double clicks are:

Type of icon	Menu choice / operation
Diagram and document icons	*Edit* on the selected diagram/document itself
Page icons	*Edit* on the selected page in the associated diagram/document
Association and Dependency icons	*Edit* on the diagram the link points to
SDL Instance icons and SDL Dashed icons	*SDL > Type Viewer* The corresponding symbol becomes selected in the Type Viewer. A double-click on the symbol in the type viewer shows and selects the symbol in the parent SDL diagram.
Source Directory and Target Directory icons	*Set Directories*
System File icon	*Configuration > Group File*
Link File icon	*Link > Link Manager*
Header File and Footer File icons	*Edit* on the connected text file
Chapter icon	*Edit* on the chapter, i.e. brings up the *Edit Chapter* dialog for that symbol
Module icon	*Edit* on the module, i.e. brings up the *Edit* dialog for that symbol
More icon	*Show Sub Symbols*
Bookmark icon	*Edit* on the bookmark, i.e. navigate to the place specified by the associated SDT reference or URL.

Menu Bar

This section describes the menu bar of the Organizer Main window and all the available menu choices.

The menu bar contains the following menus:

- *File Menu*
- *Edit Menu*
- *View Menu*
- *Generate Menu*
- *Tools Menu*
- *Bookmarks Menu*
- *Help Menu*.

Available Menu Choices

The following concepts affect the menu choices that are available in the menu bar.

Long and Short Menus

The user can choose between long and short menus with the menu choice *View Options* in the *View* menu. Menu choices only available in long menu mode are presented with the menu choice name within parenthesis in the textual enumeration of menu choices for a menu in the following sections.

License Dependent Menu Choices

The following menu choices are only available if the corresponding tool is available according to the license configuration:

License	Affected menu choices
Code Generator	*Make*
Simulator	*SDL > Simulator UI*
Explorer	*SDL > Explorer UI*

Configurable Menus

In the SDL Suite, some menu choices may be available through the concept of user-defined menus. For more information, see "Defining Menus in the SDL Suite" on page 18 in chapter 1, *User Interface and Basic Operations*.

File Menu

The *File* menu contains the following menu choices. (Menu choices within parenthesis are not available in short menu mode.)

- *New*
- *Open*
- *Save*
- *Save As*
- *Pack Archive*
- *Unpack Archive*
- *Print > All*
- *Print > Selected*
- *Print > Selected and Colored*
- (*Set Directories*)
- *PC Drives*
- (*Compare System*)
- (*Merge System*)
- (*Import SDL*)
- *Recently used system files*
- *Exit*

New

This menu choice displays a dialog, with the following possibilities:

- Start with a new and empty system, containing the basic Organizer view (see "Chapters" on page 47).
- Start with a standard template system, saved as an archive file (*.tgz) in the SDL Suite installation. The archive files for the standard template systems are and should be saved in directory <install dir>/sdt/include/template/.
- Start with any template system, saved as an archive file (*.tgz) anywhere in the file system.

If you want to start with a template system, you will have to specify the directory to unpack the archive file in, in "Unpack Archive" on page 69 that follows.

If a system file already is open in the Organizer, the behavior is determined by the status of the existing system. If modified information exists, the user first gets the possibility to save it; see "The Save Before Dialog" on page 65.

The new system is then created in memory. *Source Directory* and *Target Directory* are left unchanged, i.e. set to the values they had before the *New* operation.

> **Note:**
>
> The actual value of a directory in the *Set Directories* dialog may change if the directory is set to *System file directory*. Since there is no system file associated with a new system, the SDL Suite and TTCN Suite start-up directory is used until the file is saved.

You have to save the system to create a system file on disk.

The old contents of the drawing area is replaced with the basic Organizer view. If any of the documents in the old system managed by the Organizer were opened in an editor, these editor windows are closed.

Open

This menu choice is usually used to open an existing system file. It can also be used to open a single diagram or document file, as well as to open and resolve a *.scu file.

Opening a System File

If a system file is already open in the Organizer, the behavior is determined by the status of the existing system. If the information is not modified, the *Open* dialog is issued (see below). If modified information exists, the user first gets the possibility to save it; see "The Save Before Dialog" on page 65.

The *Open* dialog is a standard file selection dialog, with the file filter set to `*.sdt`. The *Open* button in the dialog opens the specified system file. The old contents of the drawing area is replaced with the new system. If a system window state file is found, see "System Window State File" on page 199, the window position and size is restored to the position and

state it had when the system file was saved. If any of the documents managed by the Organizer were opened in an editor, the editor windows are closed.

If the system file does not specify the *Source Directory* and/or the *Target Directory* explicitly, these directories are set to the directory where the system file was found.

The following information consistency checks are performed when opening a system:

- That the opened file is a valid system file. The case when an SDT-2 diagram file is opened is discussed above. If a system file created with an earlier version of SDT-3 is opened, you will be warned that the file will be saved in the current format
- All file bindings in the system file are verified. For each file, a check is made to see that the file exists and that the file is of the correct type. The file access permissions are also determined. If something is not correct, it is reported in the Organizer Log.

  If a document is marked Invalid, the user must later correct the file binding. The user could either reconnect the document to a valid file, or perform a disconnection in which case the document disappears.
- The SDL diagram structures in the system file and in the SDL diagram files are also compared, in terms of existing SDL reference symbols. If connected SDL diagrams in the system file are not present in the corresponding SDL diagram files, the diagram icons are marked Mismatch and the status is logged in the Organizer Log window. Unconnected SDL diagrams are removed from the system file and the Organizer's diagram structure. New reference symbols found in the SDL diagram files are added as unconnected diagrams in the system file and the Organizer's diagram structure.

  If an SDL diagram is marked mismatched, the user must later correct the diagram structures. The user could either perform a disconnection in which case the diagram disappears, or change the appropriate diagram in an editor to include the mismatched reference symbol.
- File protection of the system file and the working directory. If either of them is write protected, a warning message appears.

Opening a Diagram or Document File

If you are only interested in examining the contents of a single diagram or document file, you can specify the filename of that diagram or document in the open dialog. (It might be helpful to change the filter in the open dialog first, to be able to view the existing files of the type that you are interested in.)

If you specify the filename of a single diagram or document in the open dialog, then a new system file will be created, only containing the specified diagram or document. The diagram or document will also be loaded and shown in an appropriate editor. Note that no sub(structure) diagram files will be visible in the Organizer view.

*Opening a *.scu File*

Software control unit files *.scu are used to allow several people to work in parallel on the same SDL diagram structure. When you update your *.scu files, for instance by using the Configuration > Update menu choice, the SDL diagram structure might change, if someone else has changed the structure and checked in an updated *.scu file.

You can have a top *.scu file associated with the system file symbol in the Organizer drawing area. This *.scu file will take control of the diagram and document structure in the Organizer, leaving the *.sdt file with only control over the user settings (print, view...) and a little system state information (when was the SDL system analyzed without errors last?)

Opening an *.scu file is the same as creating a new system by attaching a *.scu file to the system file symbol in the Organizer and using Configuration > Update to update the diagram and document structure according to the contents of the *.scu file.

Opening an Archive File

Opening an archive file (*.tgz) invokes the unpack archive file operation. Read more about this in "Unpack Archive" on page 69.

Save

This menu choice saves all modified documents and control unit files known to the Organizer, the link file, and finally the system file used by the Organizer. You can still perform a save even if the Organizer contains a completely new system, or if the system has not been changed

since the last save operation. The menu choice has the text *Save (not needed)* in this situation.

Whenever the system file is saved, the system window state file is saved as well. See "System Window State File" on page 199.

If the system file is modified and needs saving, an asterisk '*' is appended to the name of the system file in the Organizer's title bar.

When the first document that is modified is encountered in the Organizer's view of files, the *Save* dialog below appears. If not *Save All*, *Quit All* or *Cancel* is selected, the dialog will remain on the screen and all modified documents will be handled by the dialog subsequently.

Whether the document is connected to a file or not will affect the layout and behavior of the *Save* dialog. For any unsaved and unconnected documents found, the user must provide a filename to connect to.

If the system has been saved before, the system file is saved (without a dialog) after all diagrams and documents have been saved. If the system never has been saved, the Organizer presents a dialog and proposes a name for the system file; the prefix is the name of the first document in the structure, the extension is `.sdt`.

The fields and buttons in the *Save* dialog are:

- *Save in file*

  If the document is connected, the name of the connected file is shown. If the system file is to be saved for the first time, a proposed name for the system file is shown. The filename can be edited by the user.

  If the document is not connected, the Organizer proposes a filename based on the document name and a file extension corresponding to the document type, making the file name unique in the file system (see "Save" on page 11 in chapter 1, *User Interface and Basic Operations* for more information). The filename can be edited by the user.

  The Organizer will not accept a file name that would overwrite another document or a diagram file that is loaded in an editor.

  The user is prompted to confirm the file name if it is already used by a document included in the document structure.

If the file exists in the file system when the *Save* button is pressed, the user is warned in a message box that the existing file will be overwritten.

If a valid filename is provided, *Save* or *Save All* below also connects the diagram to the supplied file.

- *Save*

  Saves the document file. Then the next file which needs to be saved is shown.

- *No Save*

  Ignores the file without saving it. Then the next file which needs to be saved is shown. If, during the save process, the user saves some SDL diagram files but not others, there is a risk of SDL diagram structure mismatches between the system file and the diagram files. Therefore, a warning dialog with the following alternatives is opened:

  – Clicking *OK* **does not** save the file and continues with the next file.

  – Clicking *Cancel* returns to the original Save dialog, making it possible to save the file.

- *Save All*

  Saves all files (diagram and document files, control unit files, the link file, and the system file) without a confirmation by the user, with the exception of unconnected files, which causes the dialog to appear again.

- *Quit All*

  Quits all files (document files, control unit files, the link file, and the system file) without saving. If, during the save process, the user saves some SDL diagram files but not others, there is a risk of SDL diagram structure mismatches between the system file and the dia-

gram files. Therefore, a warning dialog with the following alternatives is opened:

– Clicking *OK* as a response to an *Exit* operation, completes the exit process without saving any more documents / files.

– Clicking *Cancel* aborts the save process (possibly the exit process) completely.

Save As

This menu choice works as the Save menu choice with the following differences:

- *Save As* is always selectable.
- There is always a Save dialog for the system file.
- The *Save As* menu choice is used to save the system file under a new name. If the system file is saved under the old system file name, the user has to confirm this in a dialog.

The *Save Before* Dialog

Some operations in the Organizer need to save information before the actual operation can be performed. The saving is only performed if modified information exists in the system. In these cases a *Save Before* dialog is opened, which is very similar to a normal *Save* dialog. The dialog title is *Save before* <*command*> and some buttons may behave differently (see Figure 12 on page 71). If not *Save All*, *Quit All* or *Cancel* is selected, the dialog will remain on the screen and all modified files will be handled by the dialog subsequently.

The *Save Before* dialog is opened for the following menu choices:

- *File* menu: *New*, *Open* and *Exit*

  The save process handles modified documents in all chapters. In the case of *Exit*, unsaved diagrams in editors that are not yet in the document structure of the Organizer are also handled.

  If an SDL diagram is modified, has a diagram substructure and some of these SDL diagrams are either opened in an editor or connected to a file, special care must be taken. If the user chooses not to save such an SDL diagram, inconsistencies between the system file and the diagram files may result. The user is warned in a dialog

and may choose to continue, i.e. not to save, or to return to the Save Before dialog. (See "No Save" on page 64 and "Quit All" on page 64.)

- *File* menu: *Compare System* and *Import SDL*

  The save process handles modified documents in all chapters. However, if any modified documents are opened in an editor, only the system file may be saved, not any of the documents.

- *Generate* menu: *Analyze*, *Make* and *SDL Overview*

  The save process handles modified SDL diagrams in all chapters. The buttons *No Save* and *Quit All* are dimmed.

- *Generate* menu: *Convert to PR/MP*

  The save process handles modified SDL diagrams in all chapters. The buttons *No Save* and *Quit All* are dimmed. If the user clicks *Cancel*, the Convert to PR/MP dialog is opened with the GR source diagram toggle dimmed.

Auto Saving

When selecting any of the *Generate* commands *Analyze*, *Make*, *Convert to PR/MP* or *SDL Overview*, the *Save Before* dialog does not appear if the preference AutoSaveBefore is set. However, unconnected and modified documents still require user interaction. If such documents exist, the dialog appears.

Pack Archive

Pack files related to the system loaded in the Organizer into an archive file (*.tgz).

The archive file has the extension *.tgz and is packed using tar and gzip. This means that the archive file can also be unpacked without using the SDL Suite, from the command line, using g(un)zip and tar.

Note:

Packing and unpacking archive files will only work if the SDL Suite can access the external tar and gzip programs, see "Additional required tools and utilities" on page 3 in chapter 1, *Platforms and Products*. The external tools can be pointed out with the preferences "TarCommand" on page 246 in chapter 3, *The Preference Manager* and "GzipCommand" on page 246 in chapter 3, *The Preference Manager*.

The first Pack Archive Dialog

To use the pack operation, have the files you want to create an archive file for in the Organizer and invoke the operation. The first pack archive dialog will appear, where you can do the following things:

- **Pack all diagrams into archive**. This text field is used to specify where the archive file should be saved, and under what name. As default, the archive file is saved in the target directory, with a name based on the SDL system diagram name, and with a *.tgz extension.
- **Diagram files are relative to**. This text field is used to specify a source directory for files put into the archive. As default, the source directory specified in the Organizer is used. Note that files outside this directory, that should be included in the archive file, are put in a separate directory named *external*.
- **Include top directory in archive**. To avoid mixing files from an archive with other files when unpacking, it is possible to create a top directory for all files in the archive when packing. As default, a top directory is created, with the same name as the SDL system diagram that is packed.
- **Save system file for archive in**. With this option, it is possible to create a new system file for the archive, only referencing files that really are packed with file references updated for the archive. Use this option (instead of packing the original system file) to get a portable archive file. As default, an archive system file is created, in the archive top directory, with a name based on the SDL system diagram that is packed.

The second Pack Archive Dialog

When pressing the Next button in the first pack archive dialog, the second pack archive dialog appears, where file types to include can be decided. The following file types are included as default:

- Archive System File
- SDL Package Diagrams
- Other SDL Diagrams
- MSCs
- UML Diagrams
- Chapter Files
- Other Text Files
- Index Files
- Header and Footer Files

The following file types are not included as default:

- Original System File
- Generic Files
- Tau Workspace / Project
- Rhapsody Project
- Simulator Script Files
- *.scu files

The second pack archive dialog also makes it possible to include files from the source or target directories with specific extensions. These extensions should be specified in the **Also include files with the following extensions** text field (a comma separated list of extension names). As default, *.lst files from the source or target directory are included in this way, with the text field text set to *lst*.

The third Pack Archive Dialog

Pressing the Next button in the second pack archive dialog displays the third pack archive dialog, where all files that will be included in the archive are listed. A file in the list is usually presented in the following way:

```
<file system file name> (-> <archive file name> )
```

In the dialog, it is possible to include or exclude individual files.

- To include a file, press the *Add* button and specify the file in the file selection dialog that appears.
- To exclude a file, select it in the list, and press the *Remove* button.

When you are satisfied with the list of files that will be packed, press the *Pack* button to start the pack operation. Information from the pack operation can be found in the Organizer Log.

Unpack Archive

This operation unpacks files in an archive file (*.tgz), and places them in a directory in the file system.

An archive file is created and unpacked with the external tools *tar* and *gzip*, that both must be available for the operation to work. The external tools can be pointed out with the preferences "TarCommand" on page 246 in chapter 3, *The Preference Manager* and "GzipCommand" on page 246 in chapter 3, *The Preference Manager*.

An archive file can be unpacked in one of the following ways:

- By invoking the unpack archive operation in SDL Suite:
  - Select the Organizer > File > Unpack Archive menu choice.
  - Specify a *.tgz file in the Organizer > File > Open dialog.
  - Start SDL Suite with a *.tgz file as a parameter.
- From the command line, using gzip and tar directly. (For more information about this alternative, see the documentation for these tools.

The Unpack Archive Dialog

Whenever SDL Suite is used to unpack, and the unpack directory has not been specified, the Unpack Archive dialog appears. The dialog has three things that should be considered:

- **Unpack archive file**. In this text field, the archive file to unpack should be specified.
- **In directory**. In this text field, the directory to unpack the files in should be specified.
- **Open unpacked system file in Organizer**. If this option is on, the Organizer will after the unpack operation search for a system file (*.sdt) among the unpacked files, and if there is a system file, it will be opened in the Organizer.

Print > All

Similar to *Print > Selected*. The difference is that for *Print All*, the selection is not considered, all diagrams and documents are always printed, if the set of diagrams and documents to print is not further refined in the print dialog.

Print > Selected

Prints all or some of the diagrams in the Organizer. See chapter 5, *Printing Documents and Diagrams*, for more information about the dialog and some examples of how to print. The Organizer selection decides the set of diagrams and documents to print, if the set is not further refined in the print dialog.

Print > Selected and Colored

Similar to *Print > Selected*. The difference is that for *Print Selected and Colored*, only pages (when pages are shown in the Organizer drawing area) or diagrams (when pages are not shown in the Organizer drawing area) with at least one colored symbol are printed. A symbol is colored when the symbol has a border color other than black or a fill color other than white.

Print > Selection File

A file selection dialog appears, where a print selection file should be specified (*.sel). The print selection file is read, and the Organizer print dialog is displayed, updated to reflect the state that the print dialog had when the print selection file was saved from the print dialog. The print selection file is capable of remembering:

- Selected diagrams/documents/pages.
- Print options (scale, paper format...)
- Index Viewer filter options (filter types, uses and diagrams)
- State Matrix Viewer filter options (in Text Editor) (filter processes)

Note that print selection files can also be used by having a print selection symbol in the Organizer. In that case, you can use the print selection file and invoke the print dialog by double-clicking on the print selection symbol.

Set Directories

This menu choice sets the source and target directories. For more information on these directories, see "Source Directory" on page 44 and "Target Directory" on page 44.

This menu choice is only available if the system file can be changed.

If the source directory is changed while a *Save* dialog is active in an editor, the directory where the editor saves the diagram is undefined. An ongoing analysis is not affected by changing the target directory.

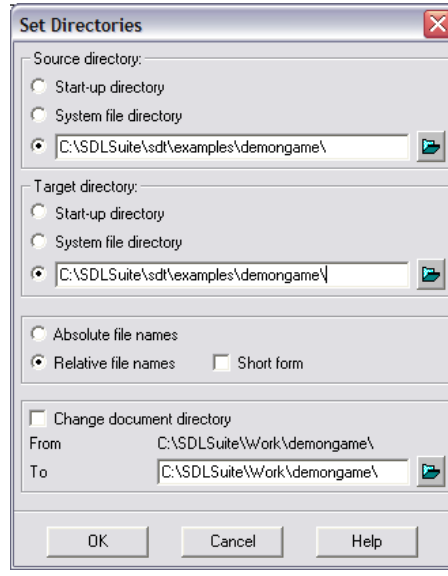

Figure 12: The Set Directories dialog

- *Source Directory*
- *Target Directory*

  Source and target directory settings are saved in the system file. Both these directories can be specified in three ways:

  – SDL Suite start-up directory: Source or target directory is set to the directory where the tool was started from (**in Windows** the directory of the executable file or the specified start directory for a shortcut icon). This setting means that relative file bindings in

the system will be evaluated starting from the start-up directory the next time the system file is loaded into the Organizer.

– *System file directory:* This is the default value for both source and target directory. Source or target directory is set to the directory where the system file resides. For a new system that has not been saved yet, the start-up directory is used until the system is saved. This setting means that relative file bindings in the system will be evaluated starting from the system file directory the next time the system file is loaded into the Organizer. This setting also makes it possible to move a system file and all related diagram and document files to a new directory without having to update the system file, provided that the positions of all diagram and document files relative to the system file are preserved.

– A specific directory. The directory specified in the text field will be used. Note that the target directory can here be specified using a relative file name. If this is done, the source directory is used as a base to dynamically calculate an absolute target directory. This is useful when you want to have a target directory as a sub directory to the source directory and you want to be able to move all your system files in or between file systems without great effort.

- *Absolute file names*

  If this option is set, the Organizer shows and stores document files with full (absolute) path.

- *Relative file names*

  If this option is set (the default), the Organizer stores document files with paths relative to the source directory. There are two variants regarding showing document files in the Organizer drawing area:

  – *Short form* on (the default). The file connection is shown exactly as it is stored in the system file.

  – *Short form* off. The directory part of a file connection is shown in *italics* for a file connection that exactly matches the *Source Directory* path. All other file connections are shown as absolute file names, even if they are not necessarily stored with absolute file paths in the system file.

- *Change document directory*

  This operation is used to change the directory part of one or more file connections in one operation. A symbol that has a file connection including the directory that should be changed has to be selected before invoking the dialog. This operation will be dimmed if there is no selection or if the selected file has no file connection.

  In the *To* text field, the directory which the selected directory should be changed into should be specified. When pressing OK with *Change document directory* on, all file connections matching the *From* directory will be changed to the *To* directory.

PC Drives

This menu choice displays the *drive table* of the currently opened system, i.e. the mapping between drive names in Windows and the beginning of corresponding directory paths on UNIX. For more information, see "Windows and UNIX File Compatibility" on page 215.

This menu choice is only available if the system file can be changed.

The following dialog is opened:

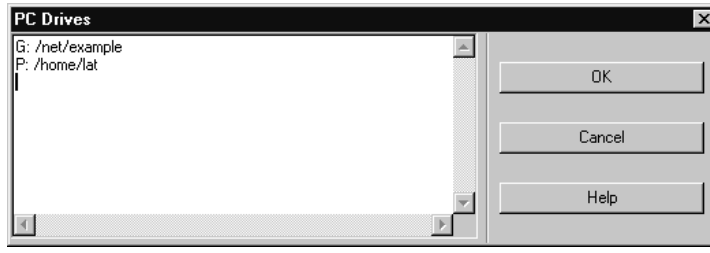

Figure 13: The PC Drives dialog

The text area displays the drive table currently used in the system. The table can be edited directly in the text area. When the system file later is saved, the table is stored in the The Drives Section.

When clicking *OK*, a basic syntax check is performed on the entered drive table. Each line should consist of two items only:

- A Windows path, either a drive letter followed by a colon, e.g. `H:`, or a full path (e.g. `C:\TEMP`). UNC paths can be used (e.g.

`\\<host>\file`). If you include a trailing backslash (optional) you must also include a trailing slash in the corresponding UNIX path.

- A UNIX directory path starting with a slash '/'. If you include a trailing slash (optional) you must also include a trailing backslash in the corresponding Windows path.

Paths containing spaces must be put within double quotes. Note that within double quotes, each backslash must be entered as two backslashes, i.e. a UNC path `\\host\dir name` (containing spaces) must be entered as `"\\\\host\\dir name"`.

If any errors are found, the user is notified and the dialog is not closed. If the table was changed and found to be syntactically correct, the system file is marked as modified.

> **Note:**
> Changes made in the *PC Drives* dialog only take effect when the system file is reloaded.

Compare System

Works as *Merge System*, except that there is no possibility to merge the differences found during the compare operation.

Merge System

This menu choice compares the contents of the Organizer Main window with the contents of a system file (`.sdt` file). The compare operation is performed on a diagram/document level.

This menu choice is only available if the system file can be changed.

The two systems are compared and possible differences are reported to the user, with the option to merge them, by specifying which documents to add and which to remove in the Organizer system.

The information is processed according to the following scheme:

1. The user is asked to exit any editors, if any is found running. This means that modified documents must be saved before the comparison can be started.
2. If the system file is modified, the user is prompted to save it in a The Save Before Dialog.

3. A standard file selection dialog is issued, where the system file to compare the Organizer system with may be selected. Choosing a system file in this dialog starts the compare operation.

4. If there are differences between the options set in the Organizer and the options saved in the system file to compare with, these are reported first, as a text in a separate dialog. The text might look like this:

```
Comparing system in Organizer
with /home/develop/lat/target/DemonGame.sdt.

Options saved in system file differs:

SemanticControl differs: False True
Kernel differs: SCTVALIDATOR SCTADEBCOM
```

   If you want to remove these differences, you have to do it manually by changing different settings in the Organizer. For instance, to remove the SemanticControl difference by updating the Organizer settings, bring up the Analyzer dialog and select *Semantic analysis*. (*SemanticControl* is the word used in the system file, *Semantic analysis* are the words used in the graphical user interface for the same thing.)

5. The *Compare System* dialog is issued, where the diagram and document differences are reported (if the Organizer system and the contents of a system file are found identical, this is reported in a message box and the operation is terminated).

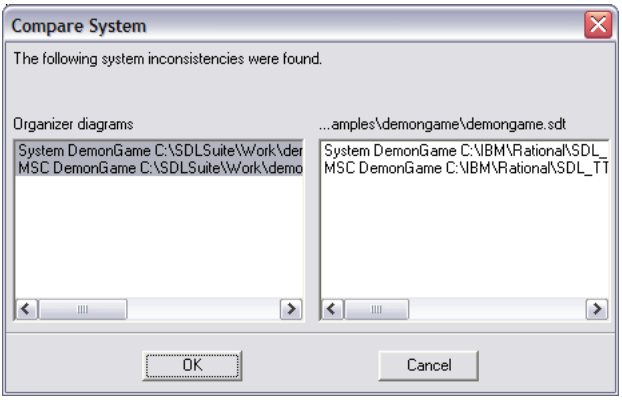

Figure 14: The Compare System dialog

6. The user decides if and how to merge the two views, by selecting or deselecting the items to include or exclude from the resulting system. *OK* updates the system in accordance with the settings.

The *Merge System* Dialog

- The lists are sorted according to the order of appearance of the items in the Organizer Main window and the order of appearance in the system file.
- Each item in a list identifies a chapter, module or document that was found in only one of the two systems (i.e. in the Organizer or in the system file) or were found in both systems, but differ from each other (see "How Systems Are Compared" on page 78 for more information about how structures and documents are compared).

A document is listed with its type, name and the file it is stored on. A module is listed with its type and name. A chapter is listed with its name.

  – A chapter, module or document that was found in one system but missing in the other, is present in one list only and is identified in the other list with a non-selectable '-' (hyphen).

  – Documents that were found in both systems and that are considered *equal* are not listed. See "equal" on page 78 for more information.

  – Documents that were found in both systems and that are considered *almost equal* are presented in both lists. See "almost equal" on page 79 for more information.

- Association and dependency links are not included in the lists, but are preserved as far as possible. See "Associations and Dependencies" on page 79 for more details.
- The items in the two lists that are selected will be included in the resulting (merged) Organizer view.

The items in the *Organizer diagrams* list are the icons that were found in the Organizer's chapters.

By default, all items that originate from the Organizer are selected, meaning that they will be included in the merged view.

Figure 15: A diagram originating from two sources

The MSC DemonGame has been found both in the current Organizer view (where the diagram is connected to a file) and in the system file (where it is connected to another file). The dialog suggests by default to include the diagram originating from the Organizer (the left list) and to exclude the diagram originating from the system file. The user may however change the selection to merge the systems in a different way.

The <*system file*> list indicates the directory and name of the selected system file. The items in this list are the items that were found in the system file.

By default, given two documents that are considered *almost equal*, the dialog will select the document originating from the Organizer, not the document originating from the system file. See example in Figure 15, above.

How Systems Are Compared

Some rules that govern how systems are compared:

- **Relative file names**:

  Relative file names are managed as if they were relative to the *Source Directory* as currently specified in the Organizer.

- Handling of **SDL diagrams** (including packages, excluding macro diagrams):

  SDL diagrams in a tree structure are examined starting from the top and down. When two diagrams are found to differ, their diagram subtree is not examined further, the subtrees being considered as a part of the diagrams that differed.

  This means that if the user chooses to include a diagram that has a subtree, the complete subtree will also be included. Similarly, if the user chooses to exclude a diagram that has a subtree, the complete subtree will be excluded.

  The level of indentation used when listing SDL diagrams in the dialog indicates the structural level at which a diagram is found.

- Handling of **Object Model diagrams**, **State Chart Diagrams, HMSC diagrams, MSC diagrams**, **SDL macro diagrams**, and **SDL overview diagrams**:

  Since these diagrams cannot be part of a subtree, adding or removing any of these does not affect the remaining parts of the structure.

- **Rules for equality of diagrams:**

  Two diagrams/documents with the same type and name can be *equal* or *almost equal*.

  – **equal**

They are considered *equal* if the file names are equal (equal diagrams/documents are not listed in the dialog).

– **almost equal**

They are *almost equal* if the file names are not equal. Two documents that are almost equal are presented on one line in the dialog. For root documents it is possible to select both diagrams on one line in the dialog. For non-root documents it is only possible to select one of the diagrams.

Note:

Compare System and *Merge System* do only compare the structural system information saved in the system file. Compare System and Merge System do **not** compare the document contents, such as page names.

Associations and Dependencies

The Compare System function preserves, as far as possible, the association and dependency links that exist between documents:

1. When an association link is found in a system file, the file names of the two documents are saved.
2. If a document with an association link is selected by the user to be included in the Organizer, a new link is generated if a document with the previously saved file name can be found in the Organizer structure. If such a document cannot be found, the association link is removed from the included document.

Import SDL

Imports an SDL diagram or a number of SDL diagrams in SDT-2 or SDT-3 format, and extracts the diagram structure with the possibility to save it in a system file. The command may, on demand, convert the imported diagrams into SDT-3 format without the need to involve the user for each diagram to convert. It is not possible to import an SDT-3 system file.

This menu choice is only available if the system file can be changed.

To avoid potential name conflicts when saving an imported diagram structure, the menu choice will not perform any action, and causes a message box to be displayed, in the case any files are opened in an editor.

Basically, the involved diagrams and their corresponding files are bound and presented in the Organizer. A number of information entities can be extracted from the diagrams.

If a system file already is open in the Organizer, the behavior is determined by the status of the existing system structure. The user is first asked to exit any editors, if any is found running. This means that modified documents must be saved before the import is started. If a modified system file exists, the user first gets the possibility to save it; see "The Save Before Dialog" on page 65.

The following dialog is then opened:

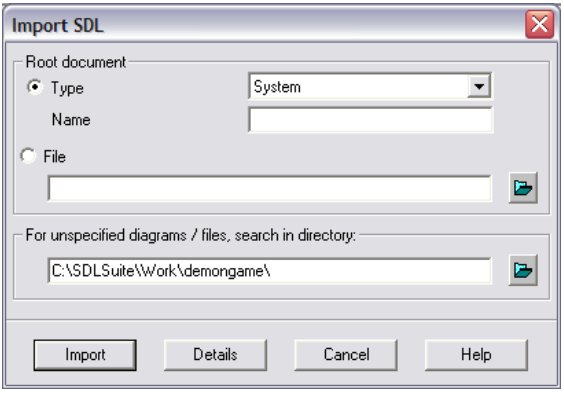

Figure 16: The Import SDL dialog

The root diagram to import and convert can either be named logically with type and name, or physically with a file name. The specified diagram will become a new root diagram, placed last in the Organizer.

- *Type*

  The type of the diagram is selected with this option menu. Used when naming a diagram logically.

- *Name*

  The name of the diagram. Used when naming a diagram logically.

- *File*

  The name of a diagram file. Used when naming a diagram physically.

- *For unspecified diagrams/files, search in directory*

  Specifies that search for diagram files should be done in the specified directory.

- *Import*

  Starts the import operation. Both a root diagram and a search method must be specified in order to start the conversion. If this is not done, an error message is shown. The Organizer log window informs about the progress and result of the conversion.

- *Details*

  Issues this dialog:

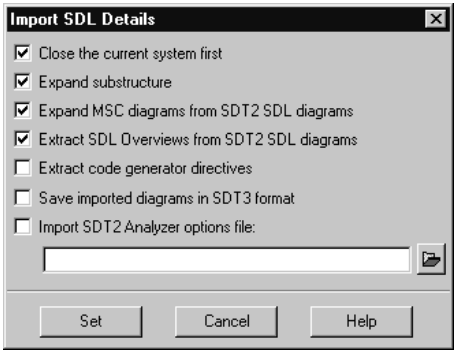

Figure 17: The Import SDL Details dialog

– *Close the current system first*

  If this option is set (the default), the current system in the Organizer will be closed and the SDL diagrams will be imported in a new system. If this option is not set, the SDL diagrams will be imported and added to the current system.

– *Expand Substructure*

  If this option is set (the default), the conversion will be done recursively in the diagram substructure from the specified root diagram. If not set, files corresponding to referenced diagrams are not imported.

– *Extract MSC Diagrams from SDT2 SDL diagrams*

  If this option is set (the default), references to MSC diagrams found in SDL diagrams saved in SDT-2 format will be extracted and placed after the SDL diagram structure, together with a file binding. An association link to the MSC diagram is also inserted in the SDL diagram structure where the MSC diagram was extracted.

– *Extract SDL Overviews from SDT2 SDL diagrams*

  If this option is set (the default), existing overview diagrams stored in SDL diagrams saved in SDT-2 format will be extracted and stored in a separate file. The overview diagram is placed after the SDL diagram structure. An association link to the overview diagram is inserted in the SDL diagram structure where the overview diagram was extracted.

– *Extract code generator directives*

  If this option is set, the diagrams will be searched for a number of directives to be included in the system file. The option is not set as default. The directives #SEPARATE and #WITH are handled

  #SEPARATE: a separator is set in the system structure on each diagram containing the directive (see "Separator symbols" on page 109).

  #WITH: a warning is issued in the Organizer log and a template makefile is generated with the object files found.

  For more information on directives, see "Directives to the Cadvanced/Cbasic SDL to C Compiler" on page 2720 in chapter 56, *The Cadvanced/Cbasic SDL to C Compiler*.

– *Save imported diagrams in SDT 3.X format*

  If this option is set, parts of the diagrams which are obsolete in SDT-3 are removed from the diagram files to convert them to SDT-3 format. The parts removed are the ones controlled by the options *Extract SDL Overviews from SDT2 SDL diagrams* and *Extract MSC Diagrams from SDT2 SDL diagrams*, described above. If these options are not set, some information may be lost when importing SDT-2 diagrams. In this case, the user will be warned in a dialog when pressing the *Import* button:

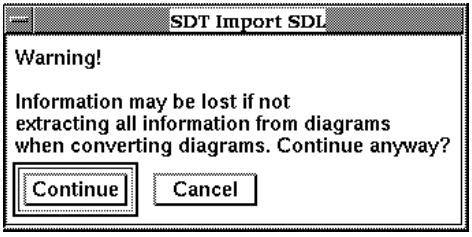

Figure 18: Import diagrams warning

– *Import SDT-2 Analyzer options file*

  If this option is set and a file is specified, the Analyze and Make options found in an SDT-2 Analyzer file (typically `<system>.san`) will be used.

Recently used system files

Just above the *Exit* menu choice, there can be up to four menu choices representing recently opened system files. To open one of them again, select the appropriate menu choice. The information about recently used system files is saved in a file called `.sdtfiles`, in your home directory (see "Environment Variables" on page 45 in chapter 4, *System Setup, in the Installation Guide*).

Exit

This menu choice exits the Organizer.

The exit operation consists of four phases:

1. Handling of modified files managed in the Organizer structure.

   If modified information exists in the current system structure, the user gets the possibility to save it; see "The Save Before Dialog" on page 65. The dialog is opened for the first file (document/system file) that is modified in the Organizer's view of files. The user can then choose how to continue. If the user does not select *Save All*, *Quit All* or *Cancel*, the dialog will remain on the screen and all modified files will be handled by the dialog subsequently.

   The link file and the system file are saved last, if necessary. If the Exit process at a later stage is cancelled, all documents in the editors

are still available, since they are not closed until all modified documents are handled.

2. Confirmation of Exit.

   If no analyze, make, simulation or validation jobs are active, the Organizer exits without user confirmation. If there are such active jobs, or a simulator/explorer UI is executing, the user has the possibility to force an exit of these jobs:

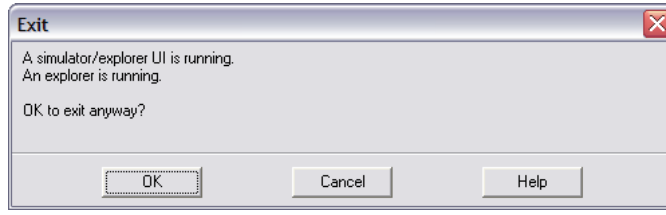

Figure 19: Exit confirmation with active jobs

3. Removing of documents in editors.
4. Shutdown of tools.

   All SDL Suite and TTCN Suite tools are terminated, possibly issuing a *Save before exit* dialog. Finally, the Organizer itself is terminated.

Edit Menu

A general mechanism to edit the document structure(s) in the Organizer does not exist. Some of the menu choices in the *Edit* menu are used for basic operations on root documents and file connections. However, most changes to the document structure are a result of operations made in the diagram editors; see "Reference Symbols" on page 1893 in chapter 43, *Using the SDL Editor*.

The *Edit* menu features the following menu choices (menu choices within parenthesis are not available in short menu mode):

- *Edit*
- *Add New*
- *Add Existing*
- *Remove*

- (*Connect*)
- (*Disconnect*)
- (*Configuration > Group File*)
- (*Configuration > Update*)
- (*Configuration > Full Update*)
- (*Color > Set Default Colors*)
- (*Color > Set Black and White*)
- (*Associate*)
- (*Paste As*)
- (*Go To Source*)
- (*Update Headings*)
- (*Update Visibility*)
- (*Properties*)

Edit

This menu choice edits the selected symbol or document. A document is edited by starting the corresponding editor. A document which is opened in an editor has its name shown in **bold face** in the Organizer.

The menu choice is dimmed if the selected icon is invalid, or if an instance or dashed SDL diagram icon is selected.

The operation performed depends on the type of symbol or document selected, according to the following:

Type of symbol or document	**Operation performed**
System file	The *CM Group* dialog is opened (see "Configuration > Group File" on page 97).
Link file	The Link Manager is opened.
Directory symbol	The *Set Directories* dialog is opened (see "Set Directories" on page 71).

Type of symbol or document	Operation performed
Chapter	The *Edit Chapter* dialog is opened. This dialog contains three choices: • *Edit chapter symbol:* the *Edit* dialog is opened (see below) to allow editing the symbol type, the chapter name, or the connected text file. • *Edit chapter options:* the *Chapter Options* dialog is opened (see "Chapter Options" on page 110). • *Edit first page after chapter:* the first connected SDL diagram or page after the chapter symbol is edited (see below).
Module	The *Edit* dialog is opened (see below) to allow editing the module name.
Connected document or header/footer file	The document/file is opened in an editor. For a diagram, the first page in the diagram is shown, or if the user has specified a page to open first in the editor (see "The Open This Page First Option" on page 2036 in chapter 43, *Using the SDL Editor*), this page is shown instead.
Association or dependency link	The corresponding referenced document is edited as if it was the selected document.
Page symbol	The page is opened in an editor.
Unconnected document or header/footer file	The Edit dialog is opened (see below).

The *Edit* dialog looks like this:

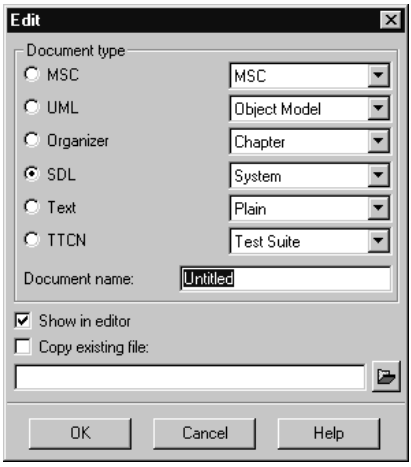

Figure 20: The Edit dialog

- The *Document type* and *Document name* fields can be used to change the type and name of a root document. If a non-root document is selected, these fields are dimmed. If the type is changed, the new document icon will replace the old one. However, the type of a module that contains documents cannot be changed.

  The wanted document type is specified by selecting the correct radio button and selecting the document type in the option menu. It is also possible to select a document in an option menu without selecting the associated radio button first; the radio button will be auto-selected in this case.

- The *Document name* text field contains the current name of the document, chapter or module. The name must conform to the naming rules for the document type; otherwise an error dialog is issued. The name of a module must conform to the naming rules for SDL diagrams, but the name of a chapter may contain any printable characters except quotation marks.

- The *Show in editor* option opens the document in an editor. This option is by default on for document types that can be shown in an editor. Deselecting this option automatically deselects the *Copy existing file* option.

- The *Copy existing file* option copies the specified file and uses it as a starting point/template for the document. If no file is specified, or the file does not exist, no file is copied. Selecting this option automatically selects the *Show in editor* option.

Add New

This menu choice adds a new document to the system. Normally, the added document is placed as a root document below the current selection. If there is no selection, the document is placed as the first root document in the Organizer. Adding a diagram also involves an update of a control unit if there is one that is associated with the diagram substructure affected by the *Add New* command.

There are two exceptions to this:

- If the selection is a module, the new document is instead added at the top level in the module. If the selection is a document in a module, the new document is added in the module at the top level after the selection. To move diagram and documents in and out of modules when they are already in the Organizer, the Move Down and Move Up quick buttons should be used.
- If the selection is a root TTCN document and the user adds a TTCN document, the added document will be placed as a child document below the selected document. If the selection is a child TTCN document, the added document will be placed below the selected document in the same TTCN system. This menu choice is therefore, together with the Move Down and Move Up quick buttons, used to build TTCN systems.

This menu choice is only available if the system file can be changed.

To add SDL diagrams other than root SDL diagrams, the SDL Editor is used (see "Adding a Diagram Reference Symbol" on page 1911 in chapter 43, *Using the SDL Editor*).

The same dialog is opened as for *Edit* on an unconnected document (see Figure 20 on page 88). By default, the *Show in editor* button is on.

If there is a selection, *Document type* and *Document name* in the dialog will be set to the selected symbol's type and name. If there is no selection, the dialog will show the settings from the previous invocation. If

it is the first time this dialog is used, the default type *Module* and the default name “Untitled” will be used.

Multiple root diagrams with the same name are allowed.

If an SDL diagram was selected and an MSC diagram is added, an association link to the MSC diagram is automatically added to the SDL diagram.

Add Existing

This menu choice adds an existing document file to the system. (It is also possible to add several documents by specifying a directory) The existing document is added at the same place as described for the *Add New* menu choice. Adding a diagram also involves an update of a control unit if there is one that is associated with the diagram substructure affected by the *Add Existing* command.

This menu choice is only available if the system file can be changed.

A dialog will be opened, that allows you to specify the file to add, either via a text field or via a standard file selection dialog.

There are also three options in the dialog:

- One to specify if the substructure of the added SDL diagram should be expanded.
- One to specify if the added diagram or document should be shown in an editor.
- One to specify if files existing in sub directories to the specified directory (or the directory where the specified file resides) should be added.

If the standard file selection dialog is used, the file filter is set to reflect the currently selected document type. If a module is selected, the file filter is the same as in the previous invocation. If no document is selected, the file filter is set to `.s??`.

The document type and logical name of the existing document is determined in different ways for different document types. The type and name is determined by:

- Reading the specified file for SDL, MSC, HMSC, OM, SC, and TTCN documents.

- Looking at the file name and extension for text files and generic documents.

> **Note:**
> It is not possible to add a document that does not have a default file extension. For information about default file extensions, see "Save" on page 11 in chapter 1, *User Interface and Basic Operations*.

If an SDL diagram was selected and an MSC or Overview diagram is added, an association link to the MSC or Overview diagram is automatically added to the SDL diagram.

The existing document is by default opened in an editor. This behavior can be changed by the preference Organizer*ShowAddExisting.

Remove

This menu choice removes a selected root document and its document substructure, if any, from the system structure. Modules, chapters and top-level documents in modules can also be removed.

This menu choice is only available if the system file can be changed.

Removing a root document may also involve the update of one control unit file if there is any containing the diagram substructure that has been removed. The menu choice is dimmed if no such document, module or chapter is selected, or if the document is modified.

Removing a chapter symbol does not remove the documents in that chapter; only the chapter symbol itself is removed.

The following dialog is opened:

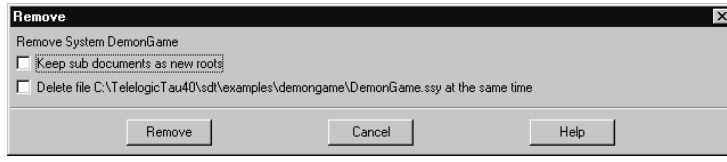

Figure 21: The Remove dialog

- *Keep sub documents as new roots*

If the selected document contains a substructure, this option moves all documents in the substructure to become new root documents (but with their substructures kept intact). It also keeps all bindings to diagrams loaded in an editor. The new root documents are placed directly after the selected root document. If the selected document is a top-level document in a module, the new root documents are placed as top-level documents in the module.

If this option is not set, the document substructure is removed together with the selected document, but documents being edited are still kept as buffers in editors. This is the default setting, except when a module is selected.

The option is dimmed if the document contains no substructure, if no substructure document is connected, or if a chapter symbol is selected.

- *Delete file <file> at the same time*

  This option also deletes the connected file from the file system. It is dimmed if the document is not connected or is opened in an editor, or if a chapter or module is selected.

Connect

This menu choice connects a selected document to a file. It is possible to reconnect an already connected document. The menu choice is hazed if a directory, page, instance diagram, dashed diagram, chapter, or module symbol is selected. The menu choice is also hazed if the loaded system file (*.sdt) or any associated configuration group file (*.scu) file is read-only.

The following dialog appears:

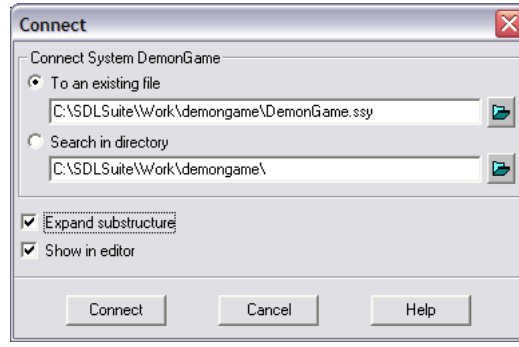

Figure 22: The Connect dialog

- *To an existing file*

  This option connects the document to an existing file. If the document already is connected, the name of the connected file is shown. If the document is unconnected, the field is filled in with the directory component of the file used the last time a document was connected. The filter in the associated file selection dialog corresponds to the file extension for the document type.

  It is possible to use an environment variable to specify the first part of the file path. This can be useful if you want the system to "update its file references" when the environment variable value has changed. For instance, there is an environment variable called "`telelogic`" that points out the top installation directory for SDL Suite when SDL Suite is run. You can use this environment variable to point out one of the SDL diagram files in the installation:

  $telelogic/sdt/examples/demongame/Main.spr

  (Please consider using relative file names first, because that is often a better solution. See "Set Directories" on page 71.)

  When the connection is to be made, the selected file is inspected. For instance, for an SDL diagram, if the file is not an SDL Suite object file, an error message box is issued:

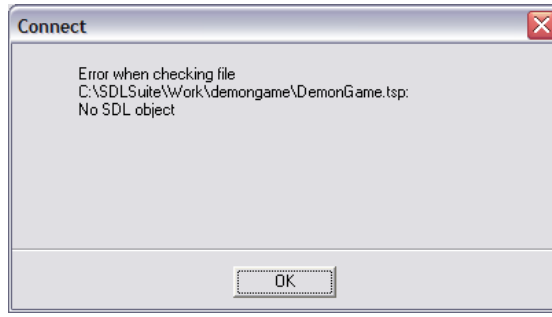

Figure 23: The Connect error message

If the file contains a document of the correct type but with an incorrect name, the symbol in the Organizer is renamed.

If the file contains a document which has an incorrect type or name, the user is warned in a dialog:

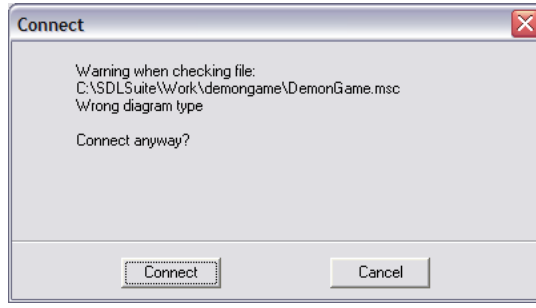

Figure 24: The Connect warning dialog

If the document already is connected and only the directory part of the existing file connection is changed, the following dialog is opened:

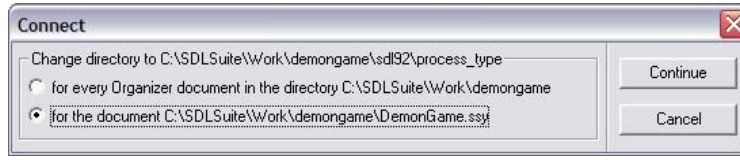

Figure 25: The Connect change directory dialog

- *Search in directory*

  This option searches the specified directory for a document file of a type and name matching the selected document. If such a file is found, the document is connected to the file. If no such file is found, an information box is opened. Pressing *OK* in the dialog returns to the Connect dialog.

  The directory field is filled in with the Source Directory the first time the dialog is used. After that, the directory from the previous usage of the dialog is remembered.

- *Expand substructure*

  This option is only available for SDL diagram symbols. This option recursively expands and connects SDL diagrams to files until no more reference symbols are found. If an SDL diagram has a USE clause, i.e. it references a package diagram, this option also tries to expand the package and put it as a root diagram in the system. The diagram substructure of the package is expanded. Package references are expanded recursively.

  After the expansion is completed, the Organizer display is updated.

- *Show in editor*

  This option opens the document in an editor after the connection has been established.

Error Notification

If an error occurs, the user is informed in a message box and control is returned to the Connect dialog.

Reconnect Connected SDL Diagram

When performing a reconnect to an already connected SDL diagram, the current SDL child diagram references are matched against those found in the connected file. If mismatches are found, icons are marked as such but the structure is kept intact, if possible.

Connect Open Documents

When connecting an unconnected document that is opened and unsaved in an editor, the file name binding is not conveyed to the editor, i.e., the editor binding is lost.

Disconnect

This menu choice disconnects the connected file from the selected diagram. The menu choice is hazed if the selected symbol has no file connection. The menu choice is also hazed if the loaded system file (*.sdt) or any associated configuration group file (*.scu) file is read-only.

The following dialog is opened:

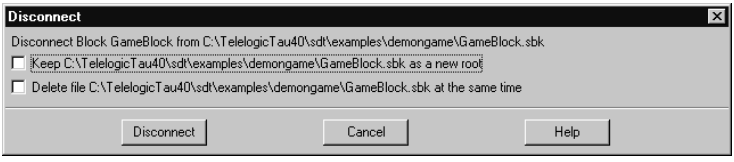

Figure 26: The Disconnect Diagram dialog

- *Keep <file> as a new root*

  This option keeps the connected document in the Organizer structure by making it a new root document. The disconnected document remains in the same place in the Organizer structure.

- *Delete file <file> at the same time*

  This option also deletes the connected file from the file system.

If the document is currently loaded in an editor and is modified, the document reference in the Organizer gets the same status as if a new document is edited, i.e. new and unconnected. The editor binding is then lost.

Configuration > Group File

This command operates on the currently selected diagram, and is used to create or remove a *Configuration Management Group* for the diagram structure. The menu choice is hazed if the loaded system file (*.sdt) or any associated configuration group file (*.scu) file is read-only. When invoked, a dialog appears:

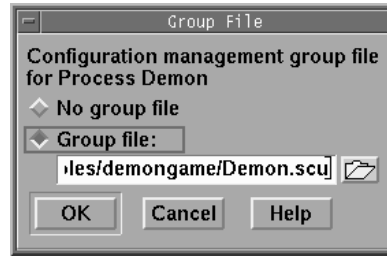

Figure 27: The Group File dialog

- *No group file*

  No group file should be associated with this document; any existing group file for this document group will be removed.

- *Group file*

  Associates a group file with this document, i.e. a *Control Unit* file (*.scu) will be created to hold the structural information about the document and its document substructure. In the text field, the name of the Control Unit file is specified. See "Control Unit File" on page 200 for more information.

  A check is made that the name of the control unit file given by the user is unique within the system. If not, a warning dialogue is issued, making it possible to cancel the operation and to provide a new file name.

  The group file will be shown in the Organizer view like this:

Figure 28: A group file in the Organizer view

The name of the group file is presented directly below the document name, in *italics*. The asterisk '*' indicates that the control unit file is dirty and needs saving. After saving, the asterisk will be removed.

The name of the control unit file is presented directly below the document's file name.

Configuration > Update

A faster version of *Configuration > Full Update*. The *.scu files are only read if they have changed since the last save.

Configuration > Full Update

Updates configuration groups recursively below the selection in the Organizer. Use this menu choice to update the Organizer contents if you have a system with configuration groups loaded in the Organizer and the configuration groups have changed outside the control of the Organizer, for instance by a software configuration management system operation.

Color > Set Default Colors

Invoking this menu choice will make sure that all SDL diagram symbols are colored according to preference values (such as Editor*StateSymbolColor) instead of individual colors set with SDLE > Edit > Symbol Border Color and SDLE > Edit > Symbol Fill Color. Note that this menu choice only operates on the diagrams selected in the Organizer.

Color > Set Black and White

Same as Organizer > Edit > Color > Set Default Colors, but instead of preference values, black and white is used for all symbols.

Associate

This menu choice associates or disassociates a selected document with another document. An association symbol indicates that two document symbols are connected. (A related symbol is the dependency symbol, see "Dependencies" on page 138.)

The menu choice is hazed if the loaded system file (*.sdt) or any associated configuration group file (*.scu) file is read-only.

If an association icon is selected, this menu choice operates on the associated document, not the icon itself. Any document may be associated with any other document, and a document may have more than one associated document.

The following dialog is opened:

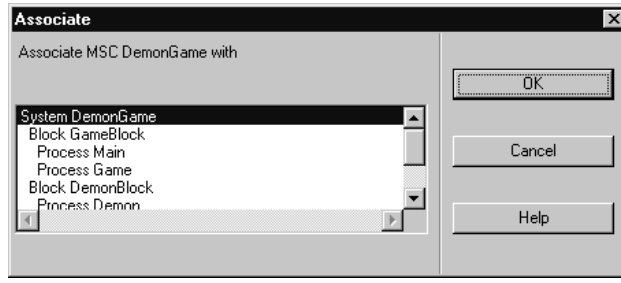

Figure 29: The Associate dialog

- *Associate <document> with*

  The multiple selection list displays the type and name of all documents in the Organizer structure. When the dialog is opened, all documents that the current document is associated with are selected, i.e. the list shows all its associated documents.

  By selecting a new document in the list, an association link to the current document will be created in the selected document's structure. By deselecting a document in the list, the corresponding association link will be removed from the selected document's structure.

Paste As

This menu choice is used to paste copied objects as new diagrams in the Organizer. This menu choice is only available if the system file can be changed. A root diagram is created and opened in an editor. The following transformations are possible via *Paste As* in the Organizer:

- An Object Model class symbol can be pasted as an SDL system diagram.
- An Object Model object symbol can be pasted as an SDL system diagram.
- A text fragment can be pasted as an MSC diagram.

For more information about the Paste As dialog, see "The Paste As Command" on page 448 in chapter 9, *Implinks and Endpoints*.

Go To Source

This menu choice is used to open an editor with a document according to an SDT reference. The SDT reference is specified in a dialog, see Figure 30. If the SDT reference includes information about an object in the document, that object will be selected. SDT references can be obtained by using the menu choice *Show GR Reference* in an editor.

For information about SDT references, see chapter 18, *SDT References*.

The following dialog is opened:

Figure 30: The Go To Source dialog

- *SDT Reference*

  The textual SDT reference is specified in the input field.

- *Go To*

  Shows the symbol in an editor.

An error message appears if the format of the SDT reference is incorrect or if the requested SDT reference cannot be found.

Update Headings

This menu choice checks the headings of SDL, HMSC, OM, and SC diagrams for correctness with respect to what is defined in the Organizer structure.

It operates on the selected diagram and its substructure. If no diagram is selected, all SDL, HMSC, Object Model, and State Chart diagrams in the Organizer are checked. For SDL diagrams, the kernel headings are checked.

Before the headings are checked, a check is made to see if any file is connected to more than one diagram. Such files are reported in the Organizer log, and a warning box is issued to the user. These files may be modified for each appearance and will cause all but the last update to be incorrect.

The heading check is made silently until the first incorrect heading is found. The diagram checked is then shown in the dialog below. If an incorrect qualifier is found, the user is prompted in the dialog whether to update the header or not. The user also has the possibility to silently update all incorrect headings. That is, they are loaded in an editor and are then corrected without confirmation by the user.

After the operation, all updated headings are in an unsaved mode in the editor.

This operation should be done regularly in order to avoid peculiar and hard-to-find analysis error caused by incorrect diagram headings.

In SDL diagrams, qualifiers can be placed in other symbols than the heading in the system, such as qualifying data types in a text symbol. Such qualifiers are not found by the *Update Headings* menu choice.

The following dialog is opened:

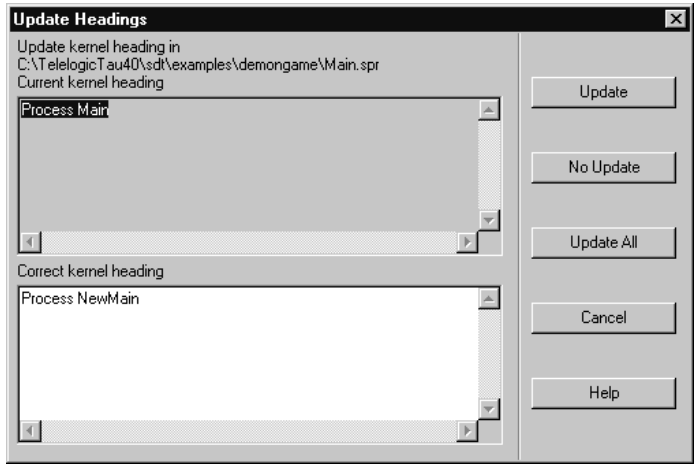

Figure 31: The Update Headings dialog

- *Current kernel heading*

  A read-only text field that shows the contents of the heading as defined in the SDL, HMSC, Object Model, or State Chart diagram, i.e. what is displayed in the editor. (*The Kernel Heading* in SDL diagrams.)

- Correct kernel heading

  A text field with the correct heading according to the structural location of the diagram. This field may be edited by the user.

- *Update*

  Updates the heading in the editor according to the text in the *Correct kernel heading* text field. Continues to search for the next incorrect heading and keeps the dialog open. When the updating is completed, a message appears in the status bar.

- *No Update*

  Does not update the diagram's heading. Continues to search for the next incorrect heading and keeps the dialog open.

- *Update All*

  Updates all headings without a confirmation by the user and closes the dialog. When the updating is completed, a confirmation message is shown in the status bar.

Update Visibility

Update SDL symbol visibility according to include expressions and external synonym values.

The SDL symbol visibility can also be set manually, see "Symbol Visibility > Hide" on page 2014 in chapter 43, *Using the SDL Editor* and "Symbol Visibility > Show" on page 2014 in chapter 43, *Using the SDL Editor*.

For more information about include expressions, see "Include Expression" on page 2014 in chapter 43, *Using the SDL Editor*.

External synonyms are saved in a plain text file with the extension *.syn in the Organizer. To specify that the boolean external synonym variable DEBUG should have the value of true, and the boolean external syn-

onym variable VERSIONTWO should have the value of false, the *.syn file should have the following contents:

```
DEBUG 1
VERSIONTWO 0
```

By using these variable names as include expressions on selected symbols, and by having a reference to the *.syn file in the Organizer, it is possible to hide or show groups of symbols by setting up the correct values in the external synonym file and applying this command. Note that the symbol visibility can not be updated in read-only diagrams.

Properties

Edit bookmark properties for a selected bookmark symbol. *Location* should be set to a valid SDT reference or URL. *Name* is any name that makes it easy to remember the place the bookmark represents. You can get valid SDT references from SDL Suite editors, by selecting a symbol and using <editor>>*Tools*>*Show GR Reference*. The easiest way to create a new bookmark with a valid SDT reference is to use <editor>>*Tools*>*Create Bookmark*.

This menu choice is only available if the system file can be changed.

View Menu

The *View* menu includes the following menu choices (menu choices within parenthesis are not available in short menu mode):

- *Expand*
- *Expand Substructure*
- *Collapse*
- (*Show Sub Symbols*)
- (*Hide*)
- *View Options*
- *Chapter Options*
- (*Set Scale*)
- (*Show High-Level View*)
- (*Show Detailed View*)

Expand

This menu choice expands the symbol structure tree one level down for the selected document. If any symbols one level down are hidden, they

are still hidden after this operation. (Use the menu choice *Show Sub Symbols* to show hidden symbols.)

The menu choice is dimmed if:

- No document is selected
- The selected icon is a leaf (no child icons)
- The selected diagram is not connected
- The selected icon is marked invalid
- The selected icon is already expanded

Expand Substructure

This menu choice expands the symbol structure tree the whole way down for the selected document. This also expands sub symbols that are hidden, but those sub symbols are still hidden after this operation. (Use the menu choice *Show Sub Symbols* to show hidden symbols.)

The menu choice is dimmed if:

- The selected icon is a leaf (no child icons)
- The selected diagram is not connected
- The selected icon is marked invalid
- The selected icon is already expanded

If no document is selected, all icons will be expanded.

Collapse

This menu choice collapses the selected document, i.e. the sub symbols are not shown after this operation. A collapsed document has a small triangle drawn below the icon to indicate that it is collapsed.

The menu choice is dimmed if:

- The selected icon is a leaf (no children icons)
- The selected document is not connected
- The selected icon is marked invalid
- The selected icon is already collapsed

If no document is selected, all icons will be collapsed. A collapsed document does not affect a corresponding document file opened in an editor, i.e. it does not have to be closed or saved.

Show Sub Symbols

This menu choice is used to specify which sub symbols of the selected document that should be shown or hidden. The sub symbols can be documents, instance diagrams, pages, or associations. If a More symbol is selected, the operation applies to the parent document, which becomes selected instead.

Only the sub symbols one level down from the selected document is affected, not the complete symbol substructure. The menu choice is dimmed if there is no selection or the selected symbol has no sub symbols.

Note:

This menu choice does not expand or collapse the document.

The following dialog is opened:

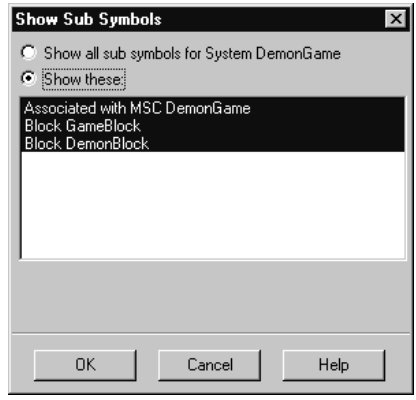

Figure 32: The Show Sub Symbols dialog

- *Show all sub symbols for <document>*

  This option shows all sub symbols for the selected document. It is a shortcut for selecting all sub symbols in the list below.

- *Show these*

  This option shows the sub symbols that are selected in the list, and hides the sub symbols that are unselected. Already shown sub sym-

bols are pre-selected when the dialog is opened. The list is a multiple selection list that toggles the state of the selected item.

Hide

This menu choice hides the selected non-root document and its substructure. The document and its substructure is replaced by a More symbol, which is always placed last of the symbols on that level. If such a symbol already existed in the parent document, the document is hidden under the same More symbol. The symbol's count of hidden documents is updated.

The menu choice is dimmed if there is no selection, or the selected document is a root document.

By double-clicking on the More symbol, the *Show Sub Symbols* dialog is opened.

View Options

This menu choice sets options for controlling the appearance of the Organizer window, as well as options for which icon attributes to show.

The options are set in a modeless dialog, i.e. the Organizer can continue working without waiting for the dialog to be closed. The options are saved in the system file.

The following dialog is opened:

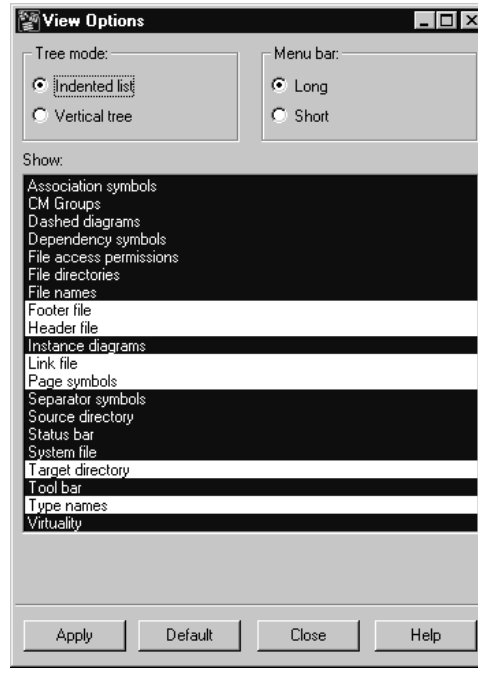

Figure 33: The View Options dialog

The figure above shows the default settings. The settings made in the dialog are preserved as default values the next time the dialog is invoked.

Tree mode

The *Tree mode* section contains options for the two different tree presentation modes available in the chapters (see "Presentation Modes" on page 46).

- *Indented list*
- *Vertical tree*

Menu bar

The *Menu bar* section contains options for which menu choices that are available (see "Long and Short Menus" on page 58).

- *Long*

- *Short*

Show

The *Show* section contains options for which window parts, documents and file attributes to show. The options are available as items in a multiple selection list, which can be selected or deselected. Options already turned on are pre-selected when the dialog is opened.

- *Association symbols*

  Show/hide association symbols (links to associated documents).

- *CM Groups*

  This option governs whether CM Groups should be displayed or not. By default, CM Groups are visible. However, note that they are not shown in vertical tree mode (see "Presentation Modes" on page 46).

- *Dashed diagrams*

  Show/hide dashed diagrams.

- *Dependency symbols*

  Show/hide dependency symbols (links to documents which a document is depending on).

- *File access permissions*

  Add/remove the file access permissions for connected files. An access permission can have one of the following values:

  `rw` Readable and writable
  `r-` Only readable
  `-w` Only writable
  `--` Neither readable nor writable

  In list mode, the permissions are added in front of the file names, if they are shown. In tree mode, the permissions are added on a separate line under each node in the document structure tree, just above the file names if they are shown.

- *File directories*

  Complements the *File names* option below. Add/remove the directory path of the connected files, in the same location as *File names*. If the *File names* option is set, the directory path is added in front of

the file name. The path added is determined by the *Source Directory* option; see "Set Directories" on page 71.

- *File names*

  In list mode: Add/remove a column of connected file names to the documents.

  In tree mode: Add/remove a line of text with the connected filename under each node in the document structure tree. The texts do not overlap; document symbols are separated to make space for the full text.

  If a document is not connected to a file, `[unconnected]` is shown.

- *Footer file*

  Show/hide the Footer File icon.

- *Header file*

  Show/hide the Header File icon.

- *Instance diagrams*

  Show/hide instance diagrams.

- *Link file*

  This option sets the visibility of the Link File icon. The link file icon is hidden by default.

- *Page symbols*

  Show/hide page symbols below SDL, HMSC, OM, and SC diagrams.

- *Separator symbols*

  Show/hide separators between diagrams. Separator symbols show how the generated code will be separated into different files. The lines between diagrams are broken by two vertical or horizontal bars where the separations occur.

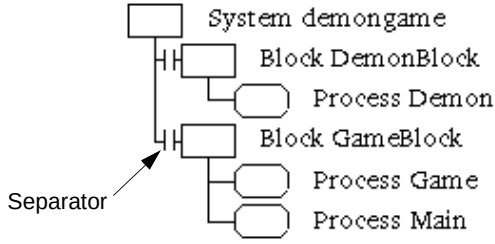

Figure 34: Separators between SDL diagrams

- *Source directory*

  Show/hide the Source Directory.

- *Status bar*

  Show/hide the status bar of the Organizer Main window.

- *System file*

  This option sets the visibility of the System File icon. The system file icon is visible by default.

- *Target directory*

  Show/hide the Target Directory.

- *Tool bar*

  Show/hide the tool bar of the Organizer Main window.

- *Type names*

  Show/hide the type of all icons and documents in textual form, e.g. Object Model, Module, Block, System file, Chapter, etc. The text is placed to the left of the name of the icon.

- *Virtuality*

  Show/hide the virtuality of SDL type diagrams in textual form.

Chapter Options

This menu choice is used to set chapter properties.

The following dialog appears:

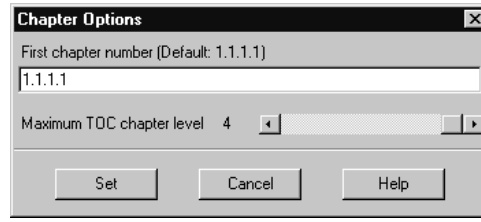

Figure 35: The Chapter Options dialog

The first chapter number is defined in the text field. This number defines the chapter number to use for the first chapter symbol of type Chapter 1, Chapter 1.1, Chapter 1.1.1 or Chapter 1.1.1.1 in the Organizer View area. For example, if the first chapter number is specified as “3.2”, then an initial chapter symbol of type Chapter 1 will get chapter number 3. If the initial chapter symbol instead is of type Chapter 1.1.1.1, it will get a chapter number of 3.2.1.1.

The *maximum TOC chapter level* decides which chapter symbols that will be visible in the table of contents when a print is done from the Organizer. A maximum TOC chapter level of zero will only show chapter symbols of type Chapter, while a chapter level of 4 will show all chapter symbol types in the table of contents.

Set Scale

Sets the scale (20%–800%) used in the Organizer window. The setting is saved in the system file.

Show High-Level View

Sets the current view of all diagrams in the SDL Editor to the high-level view, showing only symbols which are marked as “important”.

Show Detailed View

Sets the current view of all diagrams in the SDL Editor to the detailed view, showing all symbols.

Generate Menu

The *Generate* menu contains the following menu choices (menu choices within parenthesis are not available in short menu mode):

- *Analyze*
- (*Make*)
- *Stop Analyze/Make (UNIX only)*
- *Targeting Expert*
- *SDL Overview*
- *State Overview*
- (*CPP2SDL Options*)
- (*Convert to PR/MP*)
- (*Convert to GR*)
- (*Convert GR to CIF*)
- (*Convert CIF to GR*)
- (*Convert State Chart to SDL*)
- (*Edit Separation*)
- (*Dependencies*)
- (*Merge ASN.1*)

Analyze

This menu choice analyzes the selected SDL or TTCN system. If there is no SDL or TTCN system selected, the Organizer operates on the first SDL system found in the Organizer. The menu choice is dimmed if:

- A job using the Analyzer is already running.
- No SDL diagram is present in the Organizer and no TTCN system is selected.
- The selected SDL diagram or TTCN document is not connected.
- The selected icon is marked invalid.

The Analyze SDL variant of this menu choice is described below, followed by the Analyze TTCN variant.

Analyze SDL

This menu choice starts the Analyzer for one or several related SDL diagrams. If modified information exists in the current system structure, the user should first save it. See "The Save Before Dialog" on page 65 for more information.

Any SDL diagram can be selected for analysis, but in practice at least the parent block diagram will be the source of the analysis. If no SDL diagram is selected, the first SDL diagram found in the Organizer view will be used. The diagram will be analyzed in its context and together with its substructure.

Options for the Analyzer are specified in the modal dialog below. The settings are saved in the system file and persist until the next time the dialog is invoked for the same system.

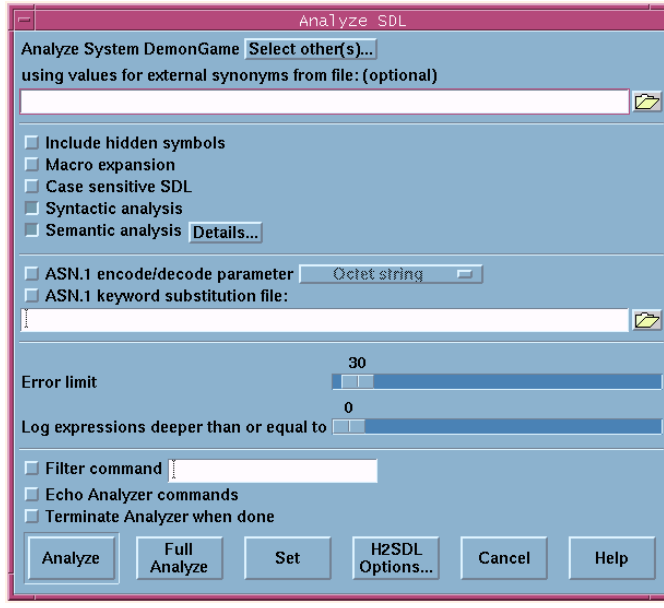

Figure 36: The Analyze dialog

The *Analyze SDL* Settings

Note: Normal versus full analyze (make)

In the *Analyze* and the *Make* dialog, the user can choose between the normal *Analyze*/*Make* and the *Full Analyze*/*Make* buttons. The last used button (normal or full) will be the default when any of these two dialogs is used the next time. The last used button will also determine if normal or full analyze/make will be used when invoking operations via the quick buttons *Analyze*, *Make*, *Simulate* and *Explore*. It is possible to toggle between normal or full analyze/make by pressing `<Ctrl+T>`.

- *Select other(s)*

  When the Analyze dialog is opened, the selection in the Organizer decides the SDL diagrams that will be analyzed. The part that will be considered for analysis is the diagram itself, all diagrams below the diagram and all parent diagrams. A used package is considered to be a parent diagram. All diagrams below a used package will be analyzed.

  This button opens a sub dialog, with the possibility to analyze SDL diagrams other than the one selected in the Organizer. For instance, it is possible to analyze two out of many blocks from the same level in one SDL system. In the sub dialog, just select the diagrams that you want analyzed. Note that you only have to select the top diagram you want analyzed, all sub diagrams will be included in the analysis. The initial label in the Analyze dialog (*Analyze <diagram type> <diagram name>*) will change to reflect the new selections you have made.

- *Using values for external synonyms from file*

  Instead of having a text symbol connected to an external synonym file (*.syn), the external synonym file can be specified here. If there is at least one synonym file in the Organizer view, the one closest to the SDL system will be used as the default value. See "Supplying Values of External Synonyms" on page 2240 in chapter 50, *Simulating a System* for more information.

- *Include hidden symbols*

Decides if hidden SDL symbols should be included in SDL/PR or not. Read more about hidden SDL symbols in *Symbol Visibility > Hide* and *Symbol Visibility > Show*.

If hidden symbols are excluded, then lines to and from hidden symbols will also be excluded. One exception to this is that flow lines going to a symbol that will be excluded, are reconnected to the first following symbol that will be included, if there is one and only one such symbol.

To use include expressions is another way to decide if SDL/GR symbols should be included in SDL/PR or not. Read more about include expressions in *Include Expression*.

- *Macro expansion*

  Run the Macro Expander before the analysis. (See "The Macro Expander" on page 2502 for more information.)

- *Case sensitive SDL*

  Use case sensitive SDL names. If this option is selected, keywords must be all upper or lower case.

- *Syntactic analysis*

  Perform a syntax check.

- *Semantic analysis*

  Perform a semantic check. This option automatically sets the option *Syntactic analysis*.

  Pressing the Details button displays the Semantic Analysis - Details dialog. These options are only used if a semantic analysis is done. They are also not used if a system or package was not the target for the analysis. For more information on these options, see "Perform-

ing Semantic Check" on page 2620 in chapter 55, *Analyzing a System*.

- *Check output semantics*
- *Check unused definitions*
- *Check optional parameters*
- *Check trailing parameters*
- *Check references*
- *Check missing else answers*
- *Check missing answer values*
- *Check parameter mismatch*
- *External types should call GenericFree*
- *Allow implicit type conversion*
- *Include optional fields in make operator*
- *Generate a cross reference file*

  Generate a cross reference file when performing the analysis. In the text field, a file name is proposed with the diagram to be analyzed as prefix and `.xrf` as extension. The file is by default generated in the Target Directory.

- *Generate a complexity measurement file*

  Generate a complexity measurement file when performing the analysis. In the text field, a file name is proposed with the diagram to be analyzed as prefix and `.csv` as extension. The file is by default generated in the Target Directory. See chapter 48, *Complexity Measurements* for more information.

- *Generate an instance information file*

  Generate an instance information file when performing the analysis. In the text field, a file name is proposed with the diagram to be analyzed as prefix and `.ins` as extension. The file is by default generated in the Target Directory.

- *ASN.1 encode/decode parameter*

  This option decides if the ASN.1 encode/decode buffer can be accessed from SDL. If the option is on, it is also possible to specify how the ASN.1 encode/decode buffer should be represented in SDL. For more information, see "SDL Encoding and Decoding Interfaces" on page 2842 in chapter 58, *ASN.1 Encoding and De-coding in the SDL Suite*.

- *ASN.1 keyword substitution file*

  Change keywords in files output by asn1util according to file. If no file is specified, the keywords in the file `asn1util_kwd.txt` in the SDL Suite installation are used. For more information, see "Keywords substitution" on page 705 in chapter 13, *The ASN.1 Utilities*.

- *Error limit*

  The error limit before aborting the analysis (0–1000). A limit of 0 (zero) means that there is no error limit.

- *Log expressions deeper than*

  The performance of the Analyzer depends to a large extent on the depth of the SDL expressions to be resolved. This option is used to emit warnings when the depth of an expression exceeds a certain value (0–100). A limit of 0 (zero) means that no warnings will be issued.

- *Filter command*

  If used, this option allows preprocessing of files before the different analyzer phases. An executable (script), possibly with parameters, should be specified in the text field. The executable will be called before the analyzer processes any file in any phase. The executable will be called with two parameters:

  – The first parameter is the file that is going to be processed.

  – The second parameter identifies the analyzer phase that is going to be executed. Three different phases are distinguished: *import* (before conversion to PR), *macro* (before macro expansion) and *parse* (before syntax analysis).

- *Echo Analyzer commands*

  Print (echo) all Analyzer commands in the Organizer Log as they are executed.

- *Terminate Analyzer when done*

  Terminate the Analyzer process after analysis is done. By default, the Analyzer process is left running in the background after completed analysis.

The options above are forwarded to the Analyzer when the analysis process starts.

The *Analyze SDL* Buttons

- *Analyze*

  Starts the Analyzer in the background and closes the dialog. Status information from the ongoing analysis is shown in the Organizer Log window. Among those diagrams that are considered for analysis according to the top of the dialog (Select other(s)), only the following diagrams are really analyzed:

  – Diagrams that had errors the last time the system was analyzed.

  – Changed diagrams.

  – Diagrams that any diagram mentioned above are depending on.

- *Full Analyze*

  Has the same effect as the *Analyze* button, except that it forces all diagrams that are considered for analysis to be analyzed.

- *Set*

  Saves the Analyzer option settings and closes the dialog, but does not perform an analysis.

Analyze TTCN

This menu choice is used to analyze a TTCN system and/or to generate a Flat View for a TTCN system.

Options for the Analyze process are specified in the modal dialog below. A selectable *Generate Flat View* phase is executed in the analyze process. The settings are saved in the system file and persist until the next time this dialog is invoked for the same TTCN system.

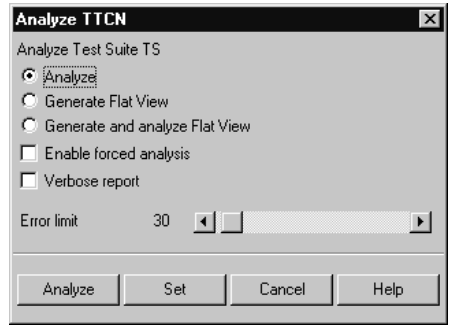

Figure 37: The Analyze TTCN dialog

The *Analyze TTCN* Settings

- *Analyze*

  Selecting this radio button means that the complete TTCN document will be considered for analysis. This radio button is set as default when the dialog is invoked.

- *Generate Flat View*

  Selecting this radio button means that a Flat View will be generated for the selected TTCN system. For a detailed description of this operation, see "Generating a Flat View" on page 1201 in chapter 26, *Analyzing TTCN Documents (on UNIX)*.

- *Generate and analyze Flat View*

  Selecting this radio button means that a Flat View will be generated for the selected TTCN system and it will be considered for analysis.

- *Enable forced analysis*

  This option is described in "Enable Forced Analysis" on page 1193 in chapter 26, *Analyzing TTCN Documents (on UNIX)*.

- *Verbose report*

  This option is described in "Verbosity" on page 1193 in chapter 26, *Analyzing TTCN Documents (on UNIX)*.

- *Error limit*

The error limit before aborting the analysis (0–1000). A limit of 0 (zero) means that there is no error limit.

The *Analyze TTCN* Buttons

- *Analyze*

  Starts the Analyzer and closes the dialog. Status information from the ongoing analysis is shown in the TTCN Suite log. For more information, see "The TTCN Suite Logs" on page 6 in chapter 1, *User Interface and Basic Operations*.

- *Set*

  Saves the Analyzer option settings and closes the dialog, but does not perform an analysis.

For more information about this dialog, see "The TTCN Analyzer" on page 1190 in chapter 26, *Analyzing TTCN Documents (on UNIX)*.

See also chapter 31, *Analyzing TTCN Documents (in Windows)*.

Make

This menu choice makes the selected SDL or TTCN system, or the selected SDL block or process diagram (see "Partitioning" on page 2641 in chapter 56, *The Cadvanced/Cbasic SDL to C Compiler*). If a Build Script containing commands to the SDL to C Compiler is selected, that file will be used as input to the SDL to C Compiler, without opening the *Make* dialog (see "Build Scripts" on page 2642 in chapter 56, *The Cadvanced/Cbasic SDL to C Compiler*.

If no document or file of the above mentioned type is selected, the Organizer operates on the first SDL system found in the Organizer. The menu choice is dimmed if:

- A job using the Analyzer is already running
- There is no SDL system diagram in the chapters and no TTCN system is selected
- The selected diagram is not connected
- The selected icon is marked invalid

If modified information exists in the current system structure, the user should first save it; see "The Save Before Dialog" on page 65.

The *SDL Make* variant of this menu choice is described below, followed by the *TTCN Make* variant.

SDL Make

Options for the Make process are specified in the modal dialog below. An analysis phase is executed as part of the Make process. The existing Analyzer options as set in the *Analyze* dialog are used.

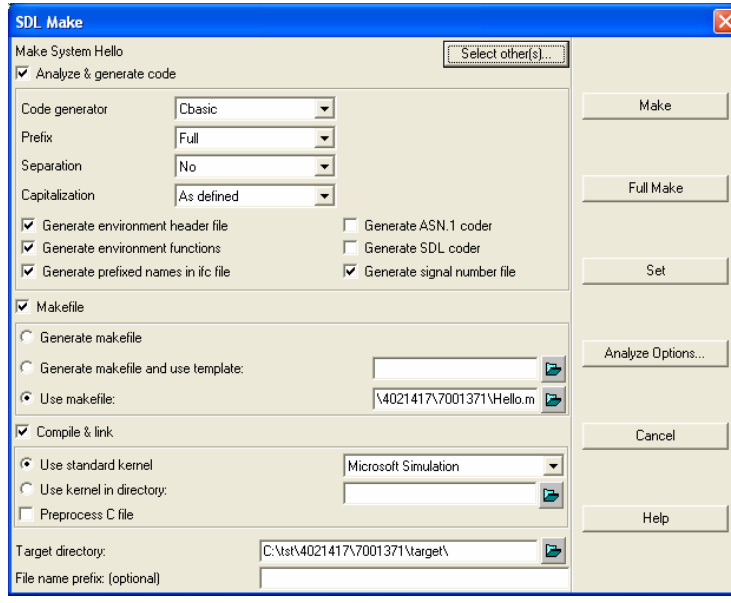

Figure 38: The Make dialog

Code Generation Options

- *Select other(s)*

  When the Make dialog is opened, the selection in the Organizer decides the diagrams that will be used when code is created. This is used to select a partition to build. For a description on partitioning see "Partitioning" on page 2641 in chapter 56, *The Cadvanced/Cbasic SDL to C Compiler*. This button opens a sub dialog, with the possibility to generate code for diagrams other than those selected in the Organizer. For instance, it is possible to generate code for two out

of many blocks on the same level in one SDL system. In the sub dialog, select the diagrams that you want to include in the code generation process. Note that you only have to select top diagrams, sub diagrams will be automatically included. The initial label in the Make dialog (*Make <diagram type> <diagram name>*) will change to reflect the new selections you have made.

- *Analyze & generate code*

  This option generates code, and performs an analysis if necessary. If not set, the settings below do not affect the Make process.

- *Code generator*

  The code generator is selected with this option menu. The following code generators are supported to date:

  – *Cbasic* (see chapter 56, *The Cadvanced/Cbasic SDL to C Compiler*)
  – *Cadvanced* (see chapter 56, *The Cadvanced/Cbasic SDL to C Compiler* and chapter 61, *The Master Library*)
  – *X*[1] **(UNIX only)**

- *Prefix*

  The type of prefix for variables is selected with this option menu: *Full* (default), *Entity Class*, *No* or *Special*. For more information, see "Prefixes" on page 2736.

- *Separation*

  The type of modularity is selected with this option menu: *No* (default), *Full* or *User Defined*. For more information, see "Selecting File Structure for Generated Code – Directive #SEPARATE" on page 2721.

- *Capitalization*

  The type of capitalization is selected with this option menu: *Lower Case* or *As Defined* (default). For more information, see "Case Sensitivity" on page 2738.

- *Generate environment header file*

1. X is reserved for future extensions in the SDL Suite applied to code generation.

If this option is set, a header file is generated containing the definitions of the SDL system's interface to the environment. For more information, see "System Interface Header File" on page 2777.

- *Generate environment functions*

  If this option is set, environment functions are generated. For more information, see "The Environment Functions" on page 2774.

- *Generate prefixed names in ifc file*

  If this option is set, the names generated in the ifc file will avoid name clashes by being prefixed with `sig_%s_%n`, `lit_%s_%n` etc. For more information, see "Avoiding name clashes" on page 2779.

- *Generate signal number file*

  If this option is set, a file with signal numbers will be generated. For more information, see "Generation of Support Files" on page 2645.

- *Generate ASN.1 coder*

  If this option is set, encoders and decoders from ASN.1 modules will be generated. This option is only available through a special license.

- *Generate SDL coder*

  If this option is set, encoders and decoders from SDL will be generated, see "Type description nodes for SDL types" on page 2791. This option is only available through a special license.

Makefile Options

- *Makefile*

  This option controls makefile creation/usage. If not set, a makefile will not be created/used.

- *Generate makefile*

  Generate a makefile (default). Choose the file by adding a `.m` extension to the separation name of the selected unit and the file is created in the directory specified as target directory. See "Target Directory" on page 71 for more information.

- *Generate makefile and use template*

Generates a makefile and appends the specified, user defined, template at the end of the makefile. Two “hooks” are provided in the generated part of the makefile: USERTARGET and USERLIBRARIES. This enables the user to define his own targets as well as adding properties in the make file. The recommended file name extension for a template file is `.tpm`.

In the template file, USERTARGET is used to add additional object files to the link script in the generated make file, by defining this name as a list of object files.

In the template file, USERLIBRARIES is used to add library modules, for example `-lm` or `-lsocket`, to the link script in the generated make file, by defining this name as a list of libraries.

The template file can also contain the compilation scripts for the object files specified as USERTARGET.

Example 2: Contents of a UNIX Make Template File ––––––––––––––

```
USERTARGET = sctenv$(sctOEXTENSION)
USERLIBRARIES = -lm -lsocket

# Dependencies and actions
sctenv$(sctOEXTENSION): sctenv.c
        $(sctCC) $(sctCPPFLAGS) $(sctCCFLAGS) \
        $(TARGETDIRECTORY) sctenv.c \
        $(sctIFDEF) -o sctenv$(sctOEXTENSION)
```

––

- *Use makefile*

  Specifies an existing makefile to use.

Compile & Link Options

- *Compile & link*

  This option controls if compilation and linking should take place. If set, compilation or linking will be done according to the settings below.

- *Standard kernel*

  Use one of the available standard kernels. The kernel is selected from this option menu. The available kernels depend on the license configuration.

Each kernel is available in versions for different compilers. You should use a kernel corresponding to a compiler you have access to on your system.

On UNIX, the following kernels are available. There are versions for standard ANSI C compilers (e.g. cc) and for the GNU C compiler (gcc).

- *Simulation*
- *gcc-Simulation*
- *RealTimeSimulation*
- *gcc-RealTimeSimulation*
- *PerformanceSimulation*
- *gcc-PerformanceSimulation*
- *Application*
- *gcc-Application*
- *ApplicationDebug*
- *gcc-ApplicationDebug*
- *Validation*
- *gcc-Validation*
- *TTCN-Link*
- *gcc-TTCN-Link*

In Windows, the following kernels are available. There are versions for the Microsoft Visual C++ compiler (cl).

- *Microsoft Simulation*
- *Microsoft RealTimeSimulation*
- *Microsoft PerformanceSimulation*
- *Microsoft Application*
- *Microsoft ApplicationDebug*

Information about the kernels can be found in "Compilation Switches" on page 3119 in chapter 61, *The Master Library* and "Libraries" on page 2770 in chapter 57, *Building an Application*[1]. A list of the available kernels can also be found in the file `sdtsct.knl` (see "File sdtsct.knl" on page 3141 in chapter 61, *The Master Library*).

- *Use kernel in directory*

  Specifies a non-standard kernel to use. The user should specify the directory where the actual kernel is stored.

1. The TTCN-Link kernel is described in the TTCN Suite manuals.

- *Preprocess C file*

  This option informs the SDL to C Compilers if the SDL C Compiler Driver (SCCD) should be invoked. See chapter 60, *SDL C Compiler Driver (SCCD)* for more information.

Miscellaneous Options

- *Target directory*

  This option is by default set to Target Directory. This option determines where the generated files will be put in the file system.

- *File name prefix*

  The names of the generated files will be prefixed by the text put in this field.

Dialog Buttons

> **Note:**
>
> For information about how *Make/Full Make* relates to *Analyze/Full Analyze* and quick buttons, see "Normal versus full analyze (make)" on page 114.

- *Make*

  Starts the code generation in the background and closes the dialog. Status from the ongoing Make process is shown in the Organizer Log window. First the time stamps of the SDL files, e.g *.sbk, *.spr, *.spd, etc, are compared with all their dependent generated c-file counterparts. Only those diagrams that have a newer timestamp are converted from SDL GR to PR, analyzed, and code is generated. After any needed code is generated the make function corresponding to the specified compiler is called to compile and/or link the system. Situations where a make will prove useful are when the following circumstances exist:

  – Diagrams had errors the last time the system was analyzed.

  – Diagrams were changed.

  – Diagrams for which the target files have been removed.

  – Diagrams that any diagram mentioned above are depending on.

- *Full Make*

  Has the same effect as the *Make* button, except that it forces the entire system to be regenerated, even if only certain parts needs to be regenerated. After any needed code is generated the make function corresponding to the specified compiler is called to compile and/or link the system.

- *Set*

  Saves the Make option settings and closes the dialog, but does not perform a make.

- *Analyze Options*

  Opens the *Analyze* dialog to set the analyze options. The *Set* button returns to the *Make* dialog.

TTCN Make

This menu choice is used to make (generate code, compile and link) a TTCN system.

For more information about this operation, see chapter 27, *The TTCN to C Compiler (on UNIX)* or chapter 32, *The TTCN to C Compiler (in Windows)*.

Stop Analyze/Make (UNIX only)

This menu choice stops an ongoing analyze/make operation. The Analyzer tool is also stopped. (The Analyzer tool normally remains resident in memory for the rest of the SDL Suite session once the first analyze/make is performed, and this menu choice is then renamed to *Stop Analyzer*. Using this menu choice is one way to free memory if needed.) Several commands, such as *Analyze*, *Make*, *Convert to PR/MP* and *Convert to GR*, are not available when the Analyzer is processing data. Stopping the Analyzer enables these commands again.

A message with the essence “Analyzer could not be stopped” may be issued as a response to this command; in this case, repeat the menu choice until the message “Analyze/make stopped” is issued in the message area.

Targeting Expert

This menu choice starts the Targeting Expert tool. See chapter 59, *The Targeting Expert* for more information.

SDL Overview

This menu choice generates an SDL overview diagram for the selected SDL diagram as the top diagram. The menu choice is dimmed if:

- No SDL diagram is present in the Organizer.
- The selected SDL diagram is not connected.
- The selected icon is marked invalid.
- The system file is read-only.

If modified information exists in the current system structure, the user should first save it; see "The Save Before Dialog" on page 65.

Any SDL diagram can be selected for generation. If no SDL diagram is selected, the first SDL diagram found in the Organizer view will be used.

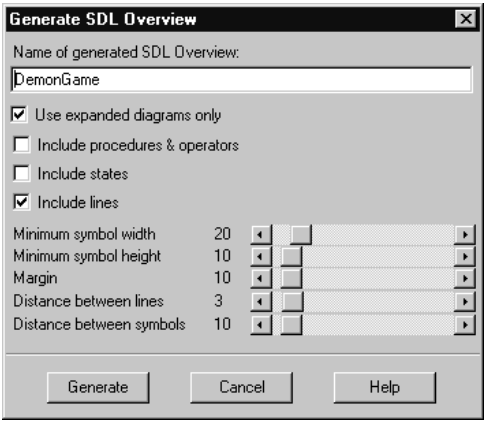

Figure 39: The Generate SDL Overview dialog

- *Name of Generated SDL Overview*

  Specifies the name of the generated Overview diagram. The Organizer proposes a name based on the SDL diagram which the Overview should be generated from.

- *Use Expanded Diagrams Only*

  Controls whether the resulting SDL Overview should comprise all diagrams that are included in the SDL diagram substructure, or only include the diagrams which are expanded (i.e. visible in the Organizer).

- *Include Procedures & Operators*

  Governs if SDL procedure and operator diagrams should be included in the SDL Overview.

- *Include States*

  Controls whether state symbols should be added to the SDL Overview or not.

- *Include Lines*

  Governs whether lines (such as channels and signal routes) should be added to the SDL Overview or not.

- *Minimum Symbol Width*
- *Minimum Symbol Height*

  These slide bars control the minimum size the tool will apply on symbols. (Symbols will be shrunk, if possible, to make the SDL Overview smaller.)

- *Margin*

  This slide bar specifies the distance (in any direction) between symbols at one SDL level and the enclosing frame (the boundaries of the enclosing SDL symbol).

- *Distance between Lines*
- *Distance between Symbols*

  These slide bars define what distance will be inserted between lines that otherwise will overlap each other in the generated SDL Overview diagram.

- *Generate*

  Causes the generation of the overview diagram to start. The user is informed about the progress of the generation in the Organizer Log window. The generated SDL Overview is added as a root document directly after the SDL structure for which the Overview diagram is

generated. An SDL Editor opens and presents the Overview diagram.

State Overview

This menu choice is used to generate a state overview information file from an SDL system or a group of state charts. The state overview can be viewed either as state matrices in the Text Editor or as state charts in the State Chart Editor.

Before selecting this menu choice, make sure that the information source (an SDL system or one or more state charts) is selected directly or indirectly. For instance, you can select a group of state charts by selecting the chapter symbol that contains the state charts.

When you select this menu choice, a dialog is displayed where you can:

- Decide if the information source should be SDL or state charts.
- Change SDL system, if several SDL systems were selected in the Organizer. Use the first *change* button for this.
- Pick out individual state charts, among the state charts that were selected in the Organizer. Use the second *change* button for this.
- Decide name and directory for the generated state overview information file.
- Decide if an Organizer symbol should be created.
- Decide if the Text Editor should show the state overview information as state matrices.
- Decide if the State Chart Editor should show the state overview information as state charts.

CPP2SDL Options

This menu choice is available if a C or C++ Import Specification is selected. For more information, see "The CPP2SDL Tool" on page 761 in chapter 14, *The CPP2SDL Tool*.

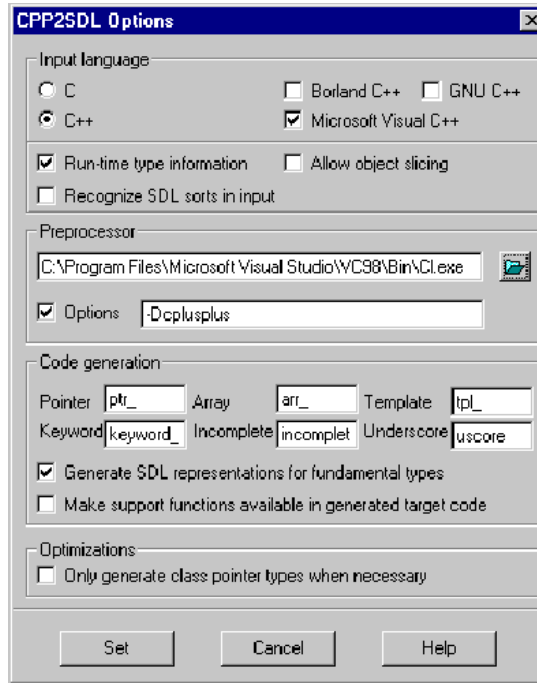

Figure 40

Convert to PR/MP

This menu choice converts the selected diagram/document to textual form. SDL/GR is converted to SDL/PR and TTCN-GR is converted to TTCN-MP. If no diagram/document is selected, the Organizer operates on the first SDL system found in the Organizer. The menu choice is dimmed if a job using the Analyzer is already running.

The *Convert to PR (SDL)* variant of the menu choice is described below, followed by the *Convert to MP (TTCN)* variant.

Convert to PR (SDL)

The SDL variant of the *Convert to PR/MP* menu choice generates a formatted (pretty printed) SDL/PR file. Input is either an SDL/PR file or an SDL/GR diagram structure.

If modified information exists in the current system structure, the user should first save it; see "The Save Before Dialog" on page 65.

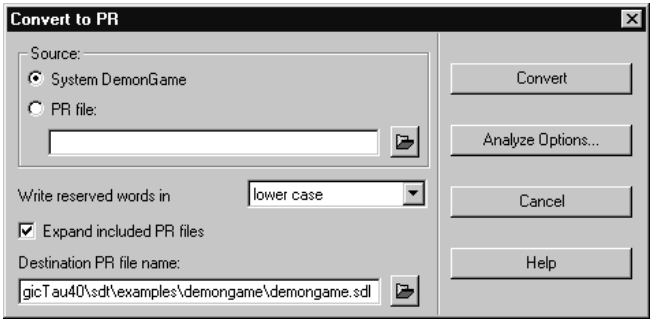

Figure 41: The Convert to PR dialog

- *Source:*
  <type> <name>

  Converts an SDL/GR diagram structure to PR. The top of the diagram structure appears in the name of the button.

  If an SDL diagram is selected, that diagram will be converted. Otherwise, the first SDL diagram structure found in the Organizer will be converted. If no SDL diagrams are found, this option is dimmed, in which case the name of the button is "<No SDL/GR diagram selected>". This will also be the case if the SDL diagram is not connected, or if its icon is marked invalid.

  If the SDL diagram to be converted has an expanded diagram substructure visible in the Organizer, this substructure is also converted. All PR code is put in the destination PR file.

- *PR file*

  Generates a pretty printed PR file from an existing PR file, which is specified in the input field. By default, this file is read from the Source Directory.

- *Write reserved words in*

  Specifies whether reserved words in SDL are to be written in lower case or upper case.

- *Expand included PR files*

  Expands SDL/PR include files found in `/*#INCLUDE...*/` comments.

- *Destination PR file name*

  Specifies the pretty printed PR file to generate. The default name uses the selected diagram name as prefix and `.sdl` as extension. By default, this file is stored in the Target Directory.

  If no file name is provided, the user is warned and no conversion is performed.

  An Overwrite confirmation dialog is issued if the user changes the suggested file name and specifies a file that already exists.

- *Convert*

  Generates the pretty printed PR file and closes the dialog. Status from the ongoing conversion process is shown in the Organizer Log window.

- *Analyze Options*

  Opens the *Analyze* dialog to set the analyze options. The *Set* button returns to the *Convert to PR/MP* dialog.

Convert to MP (TTCN)

This TTCN variant of the *Convert to PR/MP* menu choice converts a TTCN-GR document to a TTCN-MP text file.

For more information about *Convert to MP*, see "Exporting a TTCN Document to TTCN-MP" on page 1152 in chapter 24, *The TTCN Browser (on UNIX)* or "Converting to TTCN-MP" on page 1293 in chapter 30, *Editing TTCN Documents (in Windows)*

Convert to GR

This menu choice converts a textual file to one or more graphical diagrams. A TTCN-MP file is converted to TTCN-GR diagrams, and an SDL/PR file is converted to SDL/GR diagrams. The menu choice is dimmed if a job using the Analyzer is already running.

The *Convert to GR (SDL)* variant is described below, followed by the *Convert to GR (TTCN)* variant.

Convert to GR (SDL)

The *Convert to GR* dialog is in SDL mode when the radio button *Convert* SDL/PR to SDL/GR is on (see Figure 42).

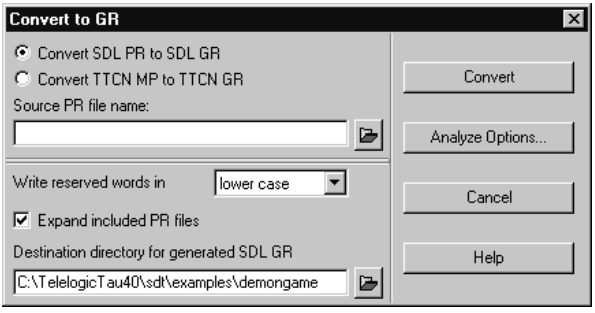

Figure 42: The Convert to GR dialog in SDL mode

- *Source PR file name*

  Specifies the PR file to convert.

- *Write reserved words in*

  Specifies whether reserved words in SDL are to be written in lower case or upper case.

- *Expand included PR files*

  Expands SDL/PR include files found in `/*#INCLUDE...*/` comments.

- *Destination directory for generated SDL/GR*

  Specifies the directory where to put the generated SDL diagrams. By default, the Source Directory will be used (see "Set Directories" on page 71).

- *Convert*

  Generates the SDL/GR diagrams. The SDL/GR files are named in the same way as when saving unconnected documents in the Orga-

nizer, i.e. files are named so that no files are overwritten. Status from the ongoing conversion process is shown in the Organizer Log window.

- *Analyze Options*

  Opens the *Analyze* dialog to set the analyze options. The *Set* button returns to the *Convert to GR* dialog.

The *Convert to GR* command can be used to import SDL systems created using Object Geode. However, Object Geode allowed some extended SDL syntax that is not accepted by the SDL Suite Analyzer.

Note:

In Object Geode, strings can be surrounded by double quotes. This is not accepted by the SDL Suite, only single quotes are allowed. E.g. the statement

```
Writeln("Take your card")
```

must be changed to

```
Writeln('Take your card')
```

In Object Geode it is allowed to have an Operator call with an empty string. E.g. the statement

```
j := tstOperator()
```

must be changed to

```
j := tstOperator
```

to be accepted by the SDL Suite.

In Object Geode you can split the system into many CIF files, where a special #REF directive is used in a comment for the reference symbol. This construct can cause a loop forever during import. A possible workaround is to change the following constructs:

```
PROCESS P1 REFERENCED
COMMENT '#REF <some_path>\<some_file>.cif.pr';
```

into:

```
PROCESS P1 REFERENCED;
```

Convert to GR (TTCN)

The *Convert to GR* dialog is in TTCN mode when the radio button *Convert TTCN-MP to TTCN-GR* is on (see Figure 42).

For more information about the Convert to GR dialog in TTCN mode, see "Importing a TTCN-MP Document" on page 1157 in chapter 24, *The TTCN Browser (on UNIX)* or "Converting to TTCN-MP" on page 1293 in chapter 30, *Editing TTCN Documents (in Windows)*.

Convert GR to CIF

This menu choice converts SDL/GR diagrams to the Common Interchange Format (CIF).

On UNIX, the *Convert GR to CIF* dialog is opened. For more information, see "Convert GR to CIF Dialog (UNIX only)" on page 904 in chapter 16, *CIF Converter Tools*.

In Windows, the SDT2CIF converter tool is started. For more information, see "Graphical User Interface (Windows only)" on page 906 in chapter 16, *CIF Converter Tools*.

Convert GR to Tau/Developer CIF

This menu choice generates a CIF file for an SDL system that should be imported into IBM Rational Tau. The command is a shortcut for the *Convert GR to CIF* command where it is only needed to specify the system file and the resulting CIF file. The functionality is the same as running *Convert GR to CIF* with the following options:

- "Generate one CIF file" on
- "Include graphical SDT references" off
- "Include CIF comments" on
- The input file must be a system file (*.sdt)
- The output file will be the same as the input with extension .cif if not explicitly specified

Convert CIF to GR

This menu choice converts diagrams in Common Interchange Format (CIF) to SDL/GR diagrams.

On UNIX, the *Convert CIF to GR* dialog is opened. For more information, see "Convert CIF to GR Dialog (UNIX only)" on page 889 in chapter 16, *CIF Converter Tools*.

In Windows, the CIF2SDT converter tool is started. For more information, see "Graphical User Interface (Windows only)" on page 890 in chapter 16, *CIF Converter Tools*.

Convert State Chart to SDL

This menu choice transforms the selected State Chart to an SDL process diagram. For more information, see "Converting State Charts to SDL" on page 1702 in chapter 39, *Using Diagram Editors*.

Edit Separation

This menu choice inserts or edits a separation on the selected SDL diagram. It is dimmed if the selected diagram type is not one of system, system type, block, block type, process, process type, procedure, and package. This menu choice is only available if the system file can be changed.

Diagram separation symbols are used during code generation and controls both the splitting of the target into separate modules and the naming of these modules. For more information, see "Selecting File Structure for Generated Code – Directive #SEPARATE" on page 2721 in chapter 56, *The Cadvanced/Cbasic SDL to C Compiler*. Separations can be shown in the diagram structure of the Organizer; see "Separator symbols" on page 109. Information about separations are stored in the system file.

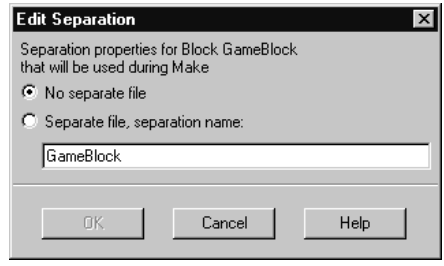

Figure 43: The Edit Separation dialog

- *No separate file*

  No separation is to be used on this diagram; any existing separation is cleared. This option is disabled on system and package diagrams.

- *Separate file*

  Inserts a separation on this diagram, i.e. the diagram and its substructure is generated separately. In the text field, the name of the separation is specified, i.e. the prefix of the files generated for this separation.

Dependencies

This menu choice introduces or removes dependencies between a selected document and other documents. A dependency symbol below a document indicates that the document is depending on another document. For instance, if an SDL system is depending on an ASN.1 document, then the SDL system must be re-analyzed each time the ASN.1 document is updated. A related symbol is the association symbol, see "Associate" on page 98.

This menu choice is only available if the system file can be changed.

> **Note:**
>
> Dependency links between SDL systems and C header files or ASN.1 documents are **not** required, but serve mainly as comments. The SDL Analyzer will re-analyze the SDL system automatically for such dependencies.

If a dependency icon is selected, this menu choice operates on the document the dependency icon is referring to, not the icon itself. Any document may depend on any other document, and a document may have be depending on more than one document.

The following dialog is opened:

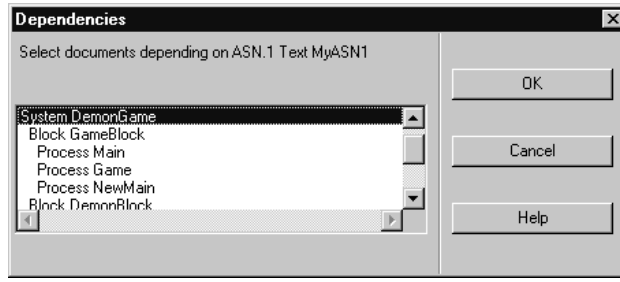

Figure 44: The Dependencies dialog

- *Select documents depending on <document>*

  The multiple selection list displays the type and name of all documents in the Organizer structure. When the dialog is opened, all documents that the current document is depending on are selected, i.e. the list shows all dependencies for the document.

  By selecting a new document in the list, a dependency for the current document will be created. By deselecting a document in the list, the corresponding dependency link will be removed from the selected document's structure.

Merge ASN.1

This menu choice controls whether the ASN.1 files in an Organizer module should be merged (joined) into a single SDL package or not. For more information, see "Using the ASN.1 Utilities" on page 701 in chapter 13, *The ASN.1 Utilities*.

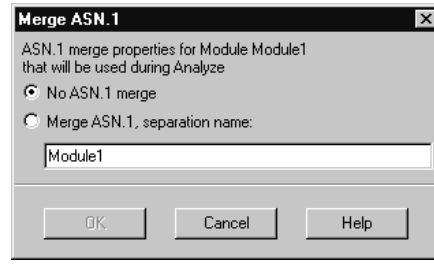

Figure 45: The Merge ASN.1 dialog

- *No ASN.1 merge*

  The ASN.1 files in this Organizer module should not be merged; a separate SDL package is generated for each of the ASN.1 files.

- *Merge ASN.1, separate name*

  The ASN.1 files in this Organizer module should be merged; one SDL package will be generated, containing all ASN.1 modules from the ASN.1 files. The name of the SDL package will be the same as the name of the Organizer module, and the separate name will be used for the code generation in a similar way as for ordinary ASN.1 files.

Tools Menu

The *Tools* menu contains the following menu choices:

- *Organizer Log*
- *Link > Create Endpoint*
- *Link > Traverse*
- *Link > Link Manager*
- *Link > Clear Endpoint*
- *Search*
- *Spelling > Comments*
- *Spelling > All Text*
- *Change Bars*
- *Compare > SDL Diagrams*
- *Compare > MSC Diagrams*
- *Compare > HMSC Diagrams*
- *Merge > SDL Diagrams*
- *Merge > MSC Diagrams*
- *Merge > HMSC Diagrams*
- *Split*
- *Join*
- *Compare State Machines*
- *Simulator Test > New Simulator*
- *Simulator Test > Existing Simulator*
- *Editors > Deployment Editor*
- *Editors > HMSC Editor*
- *Editors > MSC Editor*
- *Editors > OM Editor*
- *Editors > SDL Editor*
- *Editors > State Chart Editor*
- *Editors > Text Editor*
- *Editors > TTCN Browser*
- *SDL > Type Viewer*
- *SDL > Coverage Viewer*
- *SDL > Index Viewer*
- *SDL > Simulator UI*
- *SDL > Explorer UI*
- *SDL > Target Tester UI*
- *TTCN > Find Table*
- *TTCN > Access*
- *TTCN > Simulator UI*
- *Preference Manager*

Organizer Log

This menu choice raises the Organizer Log window. The Organizer Log window can be raised automatically when the user performs an analysis or other forms of generation. There is only one Organizer Log window.

The Organizer Log window is described in "Organizer Log Window" on page 183.

Link > Create Endpoint

This menu choice creates an endpoint for the selected document. A document with an endpoint is recognized by a small triangle in the upper left corner of the document symbol. See "Link > Create Endpoint" on page 444 in chapter 9, *Implinks and Endpoints*.

This menu choice is only available if the system file can be changed.

Link > Traverse

This menu choice traverses a link for the selected document. A document with at least one link is recognized by a small black triangle in the upper left corner of the document symbol. See "Link > Traverse" on page 444 in chapter 9, *Implinks and Endpoints*.

Link > Link Manager

This menu choice opens the Link Manager's main window. For more information about the Link Manager, see "The Link Manager" on page 462 in chapter 9, *Implinks and Endpoints*.

Link > Clear Endpoint

This menu choice removes an existing endpoint for the selected document. See "Link > Clear Endpoint" on page 447 in chapter 9, *Implinks and Endpoints*.

This menu choice is only available if the system file can be changed.

Search

This menu choice searches for text in SDL, MSC, HMSC, Object Model, and State Chart diagrams. Textual documents (C Header, Text ASN.1, and Text Plain) are also searched if the Text Editor is used. (The Text Editor is used if the preference variable SDT*TextEditor is set to

"SDT.") It is not possible to search in TTCN, Word, Tau/Rhapsody or Generic documents with this menu choice. To search in TTCN documents, use *TTCN > Find Table*.

The document scope of the search depends on the selection:

- If a module is selected, all searchable documents in that module will be searched.
- If a chapter is selected, all searchable documents in that chapter will be searched.
- If a root document is selected, all searchable documents in that document's substructure will be searched.
- If there is no selection, all searchable documents in the Organizer will be searched.

The menu choice is dimmed if the selected document is not a root document, not connected, or marked invalid.

The search will only take place in diagrams that are connected and do not have an invalid status. The search will start in the selected diagram and continue in top-down order for the rest of the diagrams (the order is left-right in a tree view).

The search function will go through the list of diagrams and stop each time the search criteria, as set in the dialog below, matches. If a search/replace string or any option is changed when the search is stopped (a match is found or the user pressed *Abort*), these values become the basis when the search is continued.

The search process will open an editor window, if necessary, and select the matched search text.

The searching is based on ASCII character matching. All text fragments in symbols are searched, with a few restrictions (see below).

When all diagrams have been searched, a beep is issued and the message *Search completed* appears.

Dialog Fields and Options

The *Search* dialog contains the following fields and options.

- *Search for*

The text to search for. To the left of the text field, there is an option menu containing old search strings. To search again for a string that has already been searched for, select the search text in the option menu.

- *Replace with*

  The text which is to replace the text searched for. Does not have to be specified.

- *Search in*

  Two option menus where it is possible to restrict the search to a selected diagram or symbol type. For instance, you can find all SDL input symbols by not specifying any search text, and specifying "SDL" as a diagram type and "Input" as a symbol type.

- *Consider case*

  If this option is set, search is case sensitive.

- *Wildcard search*

  Specifies whether a wildcard matching will be used. In wildcard search the asterisk ('*') matches a sequence of zero or more characters of any kind, e.g. whether the search text *dist*ution* will find the text *distribution* or not.

- *Search substructure*

  If this option is set, not only the selected diagram but also its diagram substructure will be searched.

- *Whole word search*

  If this option is set, the search will only find whole words. An whole word is delimited by non alphanumeric characters.

Note:

Only the textual elements that are visible in an MSC will be searched. See "Diagram Options" on page 1676.

Dialog Buttons

When the dialog is first opened, all buttons except *Replace&Search* and *Replace All* are enabled. When *Search*, *Replace&Search* or *Replace All*

is pressed all fields and buttons are disabled except the *Close* button. (The *Close* button changes name during the search to *Abort*.) If a search string is found in an editor, it is selected and all buttons and fields are enabled.

When the first search or replace operation has been applied and control returns to the *Search* dialog, it is possible to perform a new search on the same diagram(s).

- *Search*

  Searches for the search string. An editor is opened when the search string is found. If no text is supplied in the *Search for* field, a warning message appears. Confirming the message box will return control to the *Search* dialog.

- *Replace&Search*

  Replaces the current match with the replace string and searches for the next match. An editor is opened when the search string is found.

- *Replace All*

  Replaces all occurrences of the search string with the replace string. No editors are opened. However, diagrams with replaced text are loaded in the editor and gets a “dirty” state in the Organizer.

  Text in reference symbols and in kernel headings are not replaced.

- *Close/Abort*

  The *Close* button closes the *Search* dialog. The *Close* button is temporarily renamed to *Abort* during search in diagrams. If *Abort* is pressed, the current search is stopped as soon as possible (when a new file is to be searched). After an *Abort*, the dialog remains on screen, ready for new input.

Search Restrictions

All data in the editors that affects the diagram structure maintained by the Organizer (primarily reference symbols and kernel headings in the SDL Editor) is regarded as **read only** during the search operation. That is, they are not affected by the search.

Externally editing (i.e. through means other than using replace) of a diagram during a search operation completely resets the search, i.e. the next search starts from the first diagram.

The search may fail if dialogs are opened in the editor during the search. In this case the editor blocks the continuation of the search process. To continue the search process, the editor dialog must be closed.

The Organizer's data is locked during the search process. This is normally not noticed since the *Search* dialog is modal, but the SDL Editor needs to access that data to perform operations affecting the diagram structure. The Organizer will deny the editor's requests to modify the data structure. The duration of the search process is the period of time during which the *Search* dialog is visible in the Organizer.

Fast Search

Fast search is invoked by pressing Ctrl+F on the keyboard.

Fast search behaves like normal search, except that:

- No dialog is used.
- The replace functionality can not be used.
- Consider case is always off.
- Wildcard search is always off.
- Search substructure is always on.

When Fast search is invoked, the message area displays the text that will be searched for. Initially, the text is *Search for:*. When you type on the keyboard with the mouse pointer over the drawing area, the characters will turn up in the message area. When you have typed the text pattern to search for, press enter or return to start the search operation.

The same search operation as for normal Search is used. If the search operation finds a match, you can search for another match by pressing enter or return once more in the Organizer window.

To finish the Fast search operation, click in the drawing area or select another operation.

The next time Fast search is invoked with Ctrl+F, the search text that was used the last time is proposed as a search text once more. To use it, press enter or return. To use another search text, press Ctrl+F once more or the delete key several times, to erase the search text.

Spelling > Comments

Check the spelling of comments in selected diagrams. Comments can be either comment symbols or /* C-style comments */

> **Note:**
> This command only works if the spelling checker *ispell* has been installed on your computer, and the preference SDT*ISpellCommand correctly identifies the *ispell* executable. *ispell* can be found on the internet and uses the same kind of license as the *emacs* text editor.

For spelling errors, the Spelling dialog appears, with the following possibilities:

- *Word replacement text field*. Initially, the word from the diagram is presented here. One way to correct the spelling mistake is to correct the spelling in this text field and press the *change* button.
- *List of suggestions*. For most words, the spelling checker will present possible corrections here. Click on a word in this list to update the *word replacement text field*. Double-click on a word to update the diagram.
- *Add button*. Add the word currently in the *word replacement text field* to your personal dictionary.
- *Change button*. Update the diagram with the word from the *word replacement text field* and find the next spelling error.
- *Ignore button*. Ignore the current spelling error and find the next spelling error.
- *Ignore All button*. Ignore all occurrences of the current spelling error during this session and find the next spelling error. For more “permanent ignorance”, use the *Add button*.

Spelling > All Text

Works in the same way as *Spelling > Comments*, but all text is checked instead of just comment texts.

Change Bars

This menu choice is used to control the usage of change bars in SDL diagrams. A dialog with two options is opened:

- *Reset change bars for selected SDL diagrams*

  This option is used to reset change bars in SDL diagrams that fall under the selection in the Organizer. Note that removing a change bar makes the diagram dirty, i.e. change bars cannot be removed from diagram files where you do not have write access. If this option is on, a second dialog will be opened telling you about the diagrams that the operation will be applied upon.

- *Create change bars when SDL changes occur*

  This option is used to decide if change bars should be created when an SDL diagram is edited. This option is saved in the system file and is valid for all SDL diagrams in the system. The preference *ChangeBars* is used as default for new SDL systems. See "ChangeBars" on page 249 in chapter 3, *The Preference Manager*.

Compare > SDL Diagrams

This menu choice compares the contents of SDL diagram file pairs. A diagram file pair is constructed by matching an SDL diagram file loaded into the Organizer with an SDL diagram file with the same name, but in a different directory.

> **Note:**
>
> There is a similar operation in the SDL Editor for comparing one SDL diagram pair at a time. See "Compare Diagrams" on page 2027 in chapter 43, *Using the SDL Editor*.

The menu choice is dimmed if there are no SDL diagrams in the Organizer.

In the same way as for the *Search* menu choice, the compare operation is limited by the selection in the Organizer. Only SDL diagrams within the scope of the selection will be considered for the compare operation.

When the Compare SDL Diagrams menu choice is invoked, the compare SDL diagrams setup dialog appears.

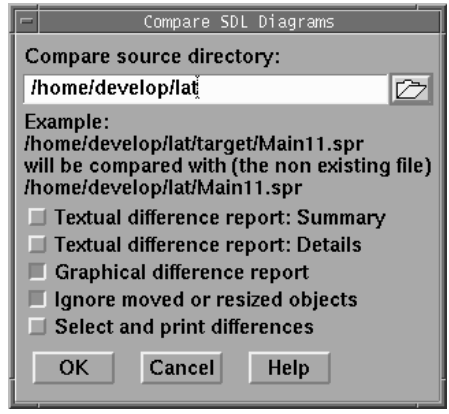

Figure 46: The Compare SDL Diagrams Setup dialog

In the compare SDL diagrams setup dialog, the following input parameters to the compare operation can be specified:

- *Compare source directory*

  The directory specified here is used instead of the normal source directory to find SDL diagrams to compare the SDL diagrams in the Organizer with.

  – For SDL diagrams in the Organizer that are relative to the normal source directory, the relative part of the file path is kept, but the part of the file path that matches the normal source directory is replaced with a part of a path constructed from the diff source directory instead.

    For example, if the source directory is `/home/lat` (`E:\home\lat` **in Windows**) and the diff source directory is `/opt/home/gn` (`E:\opt\home\gn`), then the Organizer file `/home/lat/demo/x.ssy` (`E:\home\lat\demo\x.ssy`) will be compared with `/opt/home/gn/demo/x.ssy` (`E:\opt\home\gn\demo\x.ssy`), if that file exists.

  – For SDL diagrams in the Organizer that are not relative to the normal source directory, the directory part of the file path is replaced with diff source directory.

For example, if the source directory is `/home/lat` (`E:\home\lat` **in Windows**) and the diff source directory is `/opt/home/gn` (`E:\opt\home\gn`), then the Organizer file `/usr/local/lat/y.ssy` (`E:\usr\local\lat\y.ssy`) will be compared with `/opt/home/gn/y.ssy` (`E:\opt\home\gn\y.ssy`), if that file exists.

- *Textual difference report: Summary*

  When this option is chosen, a summary of found differences is printed for each diagram pair that is compared. If more than one diagram pair is compared, a summary for all compared diagram pairs is also printed. The textual difference report is printed in the Organizer Log window.

- *Textual difference report: Details*

  When this option is chosen, detailed information about every found difference is printed as a textual report in the Organizer Log window.

- *Graphical difference report*

  When this option is chosen, differences are shown in the SDL Editor, one difference group at a time.

- *Ignore moved or resized objects*

  When this option is chosen, the compare operation tries to ignore reporting differences only caused by moved or resized symbols by using symbol ids. This option should only be used when comparing two versions of the same original diagram file: moved symbols cannot be accurately detected by using symbol ids when comparing two versions of a diagram that are both built from scratch.

- *Select and print differences*

  When this option is chosen, pages from the compared diagram versions are printed, but only those pages that contain differences.

When the OK button in the dialog is pressed, the Organizer checks if a matching diagram can be found for all SDL diagrams in the operation. If that is not the case, a dialog appears to inform about this fact.

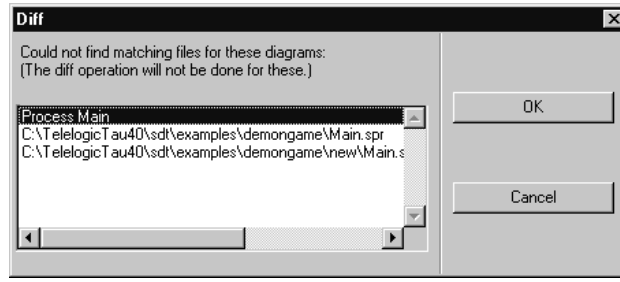

Figure 47: The Compare SDL Diagram missing files dialog

Finally, the real compare operation starts in the SDL Editor. Read more about this in "Compare Diagrams" on page 2027 in chapter 43, *Using the SDL Editor*.

Compare > MSC Diagrams

This menu choice compares the contents of MSC diagram file pairs in the same way as "Compare > SDL Diagrams" on page 148 does. Read more about this in "Compare Diagrams" on page 1690 in chapter 39, *Using Diagram Editors*.

Compare > HMSC Diagrams

This menu choice compares the contents of HMSC diagram file pairs in the same way as "Compare > SDL Diagrams" on page 148 does. Read more about this in "Compare Diagrams" on page 1690 in chapter 39, *Using Diagram Editors*.

Merge > SDL Diagrams

This menu choice compares the contents of SDL diagram file pairs in the same way as "Compare > SDL Diagrams" on page 148 does. The main difference is that this menu choice gives the possibility to merge differences: For each diagram pair, a new merge result diagram is created. Read more about how the actual merge is performed in "Merge Diagrams" on page 2028 in chapter 43, *Using the SDL Editor*.

Merge > MSC Diagrams

This menu choice compares the contents of MSC diagram file pairs in the same way as "Compare > MSC Diagrams" on page 151 does. The

main difference is that this menu choice gives the possibility to merge differences: For each diagram pair, a new merge result diagram is created. Read more about how the actual merge is performed in "Merge Diagrams" on page 1690 in chapter 39, *Using Diagram Editors*.

Merge > HMSC Diagrams

This menu choice compares the contents of SDL diagram file pairs in the same way as "Compare > HMSC Diagrams" on page 151 does. The main difference is that this menu choice gives the possibility to merge differences: For each diagram pair, a new merge result diagram is created. Read more about how the actual merge is performed in "Merge Diagrams" on page 1690 in chapter 39, *Using Diagram Editors*.

Split

This menu choice is used to split one SDL diagram into two SDL diagrams. This menu choice can be applied several times to split one SDL diagram into several parts. This menu choice is, together with the menu choice *Join*, useful in situations where several people have to work simultaneously on one SDL diagram. The SDL diagram file is partitioned into several SDL diagram files and each person is given one part to work on.

To split an SDL diagram consisting of several pages, select the diagram symbol in the Organizer and select the *Split* menu choice. (It is also possible to select a page symbol associated with the diagram that should be split.)

A dialog appears with a list of all pages but the first one in the diagram, see Figure 48. Select a page to define how the SDL diagram should be split. All pages before the selected page will end up in the first SDL diagram part. The selected page and all pages after the selected page will end up in the second SDL diagram part.

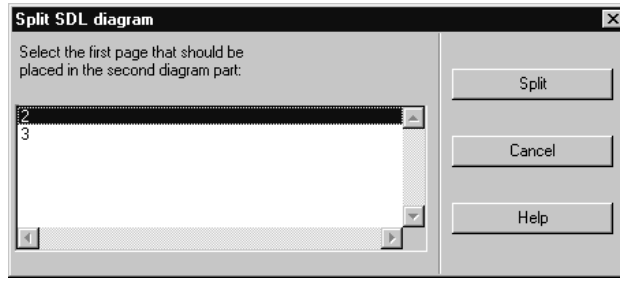

Figure 48: The first Split dialog

The Split button in the first Split dialog closes the dialog and brings up the second Split dialog, as shown in Figure 49. The second Split dialog is used to specify the files that the two resulting SDL diagram parts should be saved in.

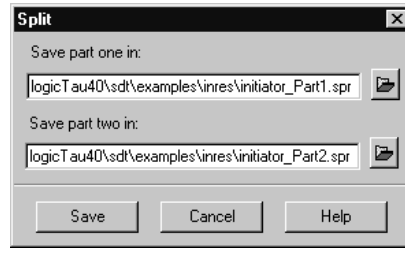

Figure 49: The second Split dialog

When the second Split dialog is closed with the *Save* button, the split operation is performed: The SDL Editor is loaded with the SDL diagram that should be split. Two new smaller SDL diagrams are created in the SDL Editor and saved under the file names specified in the second Split dialog.

The visible result of the Split operation is that the SDL Editor contains at least the diagram that was split and the resulting SDL diagram parts. Note that no additional symbols are created in the Organizer. The SDL diagram parts are accessed by opening the SDL diagram part files in the SDL Editor with the *Open* menu choice. It is of course possible to manually add symbols for the SDL diagram parts in the Organizer with for instance the *Add Existing* menu choice.

Join

This menu choice is used to join two SDL diagrams of the same type into one SDL diagram. This menu choice is, together with the *Split* menu choice, useful when several people have to work on the same SDL diagram at the same time.

Note that it is not necessary to do a Split before doing a Join. One way to work in parallel on the same diagram is to let one designer work on the existing SDL diagram, while another designer creates new pages destined for the same SDL diagram, in a new SDL diagram with the same type as the existing SDL diagram. A join operation when the parallel work is finished puts the new SDL pages in the correct SDL diagram.

The resulting SDL diagram is produced by copying the complete first diagram part and merging/joining pages from the second diagram part by copy and paste. This means that information that is common for all pages in an SDL diagram is taken from the first diagram part. This includes:

- The diagram name and any other information in the header.
- The information in the extended heading symbol.
- The information in the use text symbol.

Another consequence of this way of working is that duplicate page names and reference symbol names emerging from the second diagram part are changed by the join operation to make them unique. Auto-numbered pages from the second diagram part will also have their names changed.

When the *Join* menu choice is invoked, the Join dialog appears, see Figure 50.

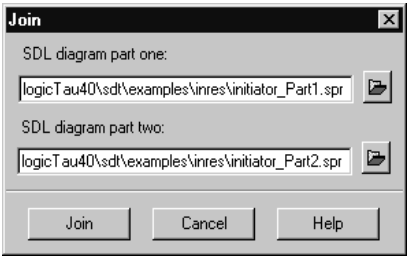

Figure 50: The Join dialog

In the dialog, specify the names of the two SDL diagram files that should be merged. Pressing the *Join* button will close the dialog and start the Join operation.

The result of the Join operation is that three diagrams will be loaded in the SDL Editor; the two SDL diagram parts that act as input to the Join operation and a new and unsaved SDL diagram that contains all the pages from both the input diagrams. The first thing that you will normally do after a Join operation is to save the new SDL diagram in a file. After that, it might be appropriate to check the new SDL diagram in the context of the SDL system with the Analyzer.

Compare State Machines

This menu choice is used to compare state machines with other state machines. This menu choice makes it possible to keep state machines expressed as a group of state charts consistent with state machines expressed as processes in an SDL system.

Before selecting this menu choice, make sure that the information sources (SDL systems and/or state charts) are selected directly or indirectly. For instance, to compare the only SDL system in the Organizer with all state charts in the Organizer, make sure that there is no selection in the Organizer by clicking in the background. The Organizer will interpret this as “everything is selected”.

When you select this menu choice, a dialog is displayed where you can:

- Specify the two groups of state machines that should be compared. A group of state machines is either the state machines in an SDL system or a group of state charts. It is only possible to choose among the state machines that were selected in the Organizer. Use the *Select* buttons to select individual SDL systems or state charts.
- Specify the two state overview information files that will be generated and compared.
- Specify if SDL procedure calls and/or state chart call actions should be compared.
- Specify if SDL outsignals and/or state chart send events should be compared.

When the dialog is closed, two state overview information files are generated. A state overview describes a state machine in a normalized form:

- For an SDL system, diagram type inheritance and diagram type instantiation have been removed.
- For a state chart, state hierarchies (states in states) have been removed. The same rules as when converting a state chart to SDL are used, for more information, see "Converting State Charts to SDL" on page 1702 in chapter 39, *Using Diagram Editors*.

The compare operation compares the two generated state overview information files in the following way:

- State machines are matched by their names. For instance, SDL process A is matching state chart A.
- States are matched by their names.
- Transitions are matched by a combination of from-state name, in-signal name and to-state name

> **Note:**
>
> The compare operation does not compare all the details for a transition. For instance, the conditional expression in an SDL decision symbol is not compared with the guard condition in a state chart transition.

If the compare operation finds anything that does not match, this is reported in the Organizer Log. You use the Organizer Log quick button *Show Error* to navigate to the SDL diagram or state chart with an entity that did not match anything in the other group of state machines.

Simulator Test > New Simulator

This menu choice is used to execute test cases in the simulator for an SDL system. Test cases can be described either as MSCs or as simulator UI input scripts (*.cui). A description of how to express MSCs in this context can be found in *Using MSCs as test cases*.

When this menu choice is invoked, a dialog appears with a list of all MSCs and input scripts. In the dialog, it is possible to select test cases that should be executed. The selection in the Organizer decides:

- primarily the SDL system to be used,
- but also the default test case selection in the dialog.

When the dialog is closed, an SDL simulator is generated and each selected test case is run. When all test cases have been executed, the Organizer Log will contain a one-line summary for each test case, with information about if the test case passed or failed. For test case failures, the MSC editor will pop up, showing the symbol in the MSC that failed (this happens only if the test case was expressed as an MSC). To be able to examine test case failures in detail, run each test case that fails separately, because then the MSC editor will show the place of the MSC test case failure and the textual output from the simulator will contain information about the test case failure.

Using MSCs as test cases

MSC test cases are MSCs written in a special way. MSC test cases are high-level test cases that are auto-converted to low-level simulator UI input script test cases before they are executed.

When MSCs are used as test cases, you can:

- send in a signal to the system and check that the expected signal is received as a response from the system.
- check that a process instance is in a certain state.
- check that a process instance variable has a certain value.
- check if a process instance exists.
- ...

Figure 51 illustrates MSC test case building blocks that are described in the text below.

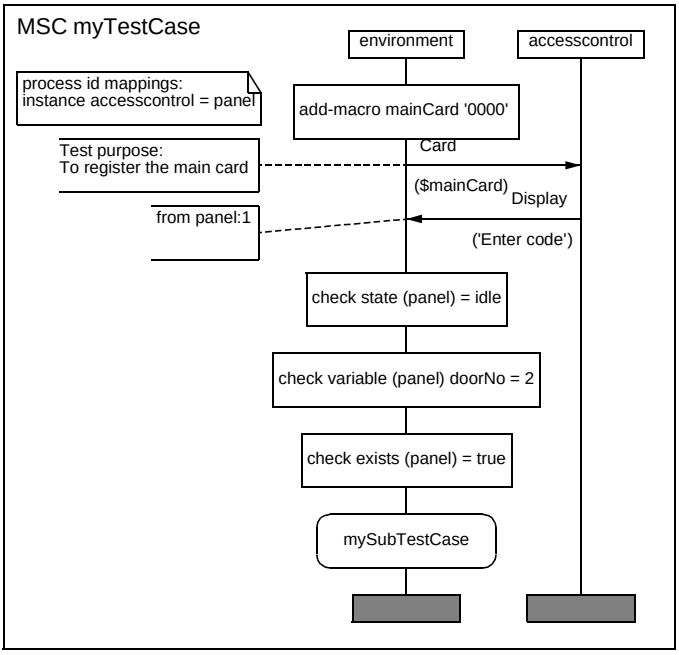

Figure 51 MSC test case building blocks

MSC instance symbols are used in the following way in MSC test cases:

- Use an MSC instance symbol called *environment* or *env_1* or something similar as an instance to send and receive signals to and from the SDL system.

  By using an .itt file other instances than environments can be mapped to act as an environment during testing. See "Mapping Instances to Different Environments" on page 2230 in chapter 49, *The SDL Simulator*.

- Use one or several MSC instance symbols to represent the SDL system. If you use one instance, give it the same name as the SDL system (for instance *accesscontrol*). If you use several instances, give each the name of an SDL process instance that you want to send and receive signals to and from (for instance *panel* or *panel:1*).

To send a signal into the system, draw an MSC signal from the environment instance to one of the instances representing the SDL system. Specify the signal name and any parameters that you know about.

To check that a signal is sent out from the system, draw an MSC signal from an instance representing the SDL system to the environment instance. Also here, you should specify the signal name and any parameters. The check is done by matching a text string created from the MSC with the actual textual output from the simulator. You can use the * character (matching any characters) if you for instance do not want to specify all parameters in the MSC.

MSC test scripts can check for unexpected signals sent to the environment. If unexpected (unchecked) signals are detected **before** the **currently** checked signal the test case will fail and a message will be displayed:

```
Unexpected signal(s) to environment arrived before
currently checked signal:
* OUTPUT of DSignal to env:1
* OUTPUT of ASignal to env:1
```

If unexpected (unchecked) signals are detected **after** the **last** checked signal in the script the test case will fail and a message will be displayed:

```
Unexpected signal(s) to environment arrived after
last checked signal:
* OUTPUT of CSignal to env:1
```

Make sure that the script will run sufficiently long after the last checked signal, for the unexpected signals to arrive at the environment and be detected. This can for example be achieved with a finite number of “next-state” commands at the end of the test script. The statistics displayed after the test script has executed have been updated to show unexpected signals as follows:

```
Command statistics:
        checked: 2
        failed: 0
        updated: 0
        unexpected: 2
```

There are several overlapping ways of specifying the process instance a signal should be sent to or from. Two of them involves a mapping table in an MSC text symbol. The text should look something like this (one line with a ‘=’ for each mapping rule):

```
process id mappings:
instance accesscontrol = panel
signal display = panel
```

- First of all, the SDL Suite finds out if there is a comment symbol connected to the signal. If there is, and the text is something like *to panel* or *from panel*, the SDL Suite uses panel as the process instance name (with *:1* added because no *:* with a number was specified).
- Second, the SDL Suite finds out if there is a signal mapping rule matching the current signal name. If there is, the process instance name in that rule is taken.
- Third, the SDL Suite finds out if there is an instance mapping rule matching the instance name of the instance representing the SDL system that is attached to the current signal. If there is, the process instance name in that rule is taken.
- If no process instance name has been found yet, then the MSC instance name of the instance representing the SDL system is taken as the SDL process instance name. If a qualifier exists in the instance kind text this will be added to the name.

It is possible to include any simulator command in an MSC test script by attaching an MSC action symbol to the environment instance, and typing the simulator commands in it. One line for each command.

This can for instance be used to declare macros representing parameter values. If you have done `add-macro myMacroName 5` in an action symbol, you can type `$myMacroName` instead of `5` as the value of a parameter. Macros can be defined in a separate MSC and used in normal MSC test cases. Just make sure that the macro MSC is executed before the normal MSC test cases when you do a simulator test.

There are three textual shortcuts that can be used in an action symbol:

- To check that an SDL process instance is in a certain state:

```
check state (panel) = IDLE
```

- To check the value of a variable in an SDL process instance:

```
check variable (panel) DoorNo = 1
```

- To check if an SDL process instance exists or not:

```
check exists (panel) = false
```

The MSC reference symbol can be attached to the environment instance. Type in a name of a sub MSC test script that should be executed. This is a way to avoid repeating the same information in many places. It can for instance be used in the beginning of a test script to perform common initialization of the system.

Simulator Test > Existing Simulator

Same as "Simulator Test > New Simulator" on page 156, except that an already created simulator is used. Before the normal simulator test dialog (used to specify test cases to execute), a file selection dialog appears, where a simulator executable can be specified.

Editors > Deployment Editor

Adds a Deployment diagram symbol to the Organizer view, and starts the Deployment Editor. The symbol is added at the same place as when using the *Add New* command.

Editors > HMSC Editor

Adds a HMSC diagram symbol to the Organizer view, and starts the HMSC Editor. The symbol is added at the same place as when using the *Add New* command.

Editors > MSC Editor

Adds an MSC diagram symbol to the Organizer view, and starts the MSC Editor. The symbol is added at the same place as when using the *Add New* command.

Editors > OM Editor

Adds an Object Model diagram symbol to the Organizer view, and starts the OM Editor. The symbol is added at the same place as when using the *Add New* command.

Editors > SDL Editor

Adds an SDL System diagram symbol to the Organizer view, and starts the SDL Editor. The symbol is added at the same place as when using the *Add New* command.

Editors > State Chart Editor

Adds a State Chart diagram symbol to the Organizer view, and starts the State Chart Editor. The symbol is added at the same place as when using the *Add New* command.

Editors > Text Editor

Adds a Plain Text document symbol to the Organizer view, and starts the Text Editor. The symbol is added at the same place as when using the *Add New* command.

Editors > TTCN Browser

Adds a TTCN module symbol to the Organizer view, and starts the TTCN Browser. The symbol is added at the same place as when using the *Add New* command.

SDL > Type Viewer

This menu choice starts the Type Viewer. It is dimmed if there is no SDL diagram in the Organizer, or if the preference SDT*StartInformationServer is set to false. Only one instance of the Type Viewer exists. If the Type Viewer has already been started, its window is raised.

If a Referenced Diagram Type icon, an Instance Diagram icon or a Dashed diagram icon is selected in the Organizer, the Type Viewer selects the corresponding symbol when this menu choice is used.

The Type Viewer is described in chapter 45, *The SDL Type Viewer*.

SDL > Coverage Viewer

This menu choice starts a Coverage Viewer. A new instance of the Coverage Viewer is started each time this command is selected.

The Coverage Viewer is described in chapter 47, *The SDL Coverage Viewer*.

SDL > Index Viewer

This menu choice starts an Index Viewer. A new instance of the Index Viewer is started each time this command is selected.

The Index Viewer is described in chapter 46, *The SDL Index Viewer*.

SDL > Simulator UI

This menu choice starts a new, empty Simulator UI. Several Simulator UI's may exist at the same time.

The Simulator UI is described in "Graphical User Interface" on page 2199 in chapter 49, *The SDL Simulator*.

SDL > Explorer UI

This menu choice starts a new, empty Explorer UI. Several Explorer UI's may exist at the same time.

The Explorer UI is described in "Graphical User Interface" on page 2349 in chapter 52, *The SDL Explorer*.

SDL > Target Tester UI

This menu choice starts a new, empty SDL Target Tester UI. The SDL Target Tester UI is described in "Graphical User Interface" on page 3656 in chapter 67, *The SDL Target Tester*.

TTCN > Find Table

This menu choice invokes the find table operation on a selected TTCN system. **In Windows**, this functionality is not available and the menu choice is dimmed.

For more information about the find table operation **on UNIX**, see "TTCN Suite Preprocessor" on page 1205 in chapter 26, *Analyzing TTCN Documents (on UNIX)*. For more information about finding tables **in Windows**, see "Finding and Sorting Tables" on page 1282 in chapter 30, *Editing TTCN Documents (in Windows)*.

TTCN > Access

This menu choice starts a TTCN Access application for a selected TTCN document/system.

For more information, see chapter 21, *TTCN Access*.

TTCN > Simulator UI

This menu choice starts a TTCN simulator UI.

For more information about this, see chapter 28, *The SDL and TTCN Integrated Simulator (U)* or chapter 33, *The SDL and TTCN Integrated Simulator (W)*.

Preference Manager

This menu choice starts the Preference Manager. Only one instance of the Preference Manager exists. If the Preference Manager has already been started, its window is raised.

The Preference Manager is described in chapter 3, *The Preference Manager*.

Bookmarks Menu

The *Bookmarks* menu contains the following menu choices:

- *Add Bookmark*
- *Edit Bookmarks*
- *More Bookmarks*

Add Bookmark

This menu choice opens a dialog where a new bookmark can be created. The information needed is the *location* (a URL or a SDTREF), and a *name* for the bookmark. If desired, a *systemfile* can be specified that will be loaded together with the SDTREF.

Edit Bookmarks

Edit Bookmarks will open a dialog with a list with all bookmarks. After selecting a bookmark the buttons will have the following effect:

- *OK* - all changes made willbe saved and the dialog will close.
- *Open* - the selected bookmark will be opened
- *Edit* - provides a dialog with the information form the selected bookmark, where the information can be edited.
- *Remove* - removes the selected bookmark from the list.
- *Cancel* - all alteration made will be disregarded and the dialog will be closed.

More Bookmarks

This choice will appear if more than 25 bookmarks are present. The dialog appearing is the same as in the *Edit Bookmark* menu choice. Selecting the desired bookmark and clicking on the *Open* button will open the bookmark.

Help Menu

For more information about *Help* menus, see "Help Menu" on page 15 in chapter 1, *User Interface and Basic Operations*. Two of the Organizer *Help* menu choices are described in more detail below.

About All

This menu choice starts an operation that presents version information about the individual tools in your SDL Suite configuration. The information is presented in the Organizer Log window. The produced information might look like this:

```
About All. Version information:
Help Tool              Version 6.3.0
Link Manager           Version 6.3.0
MSC Editor             Version 6.3.0
OM InfoServer          Version 6.3.0
OM/SC/HMSC/DP Editor   Version 6.3.0
Organizer              Version 6.3.0
Preference Manager     Version 6.3.0
SDL Coverage Viewer    Version 6.3.0
SDL Editor             Version 6.3.0
SDL Index Viewer       Version 6.3.0
SDL Type Viewer        Version 6.3.0
SDT Welcome Window     Version 6.3.0
Text Editor            Version 6.3.0

About All. Additional version and kernel
information:
Information Server version 6.3.0
SDT Analyzer
SDT Analyzer 6.3.0
SDT CPP2SDL 6.3.0
ASN.1 Analyzer 6.3.0
SDL Targeting Expert: Version 6.3.0

Simulation kernel:
  2 lrwxrwxrwx 1 nnn  sdl  66 May 5 16:05 sctworld.o
RealTimeSimulation kernel:
  2 lrwxrwxrwx 1 nnn  sdl  68 May 5 16:05 sctworld.o
...
```

License Information

Opens a dialog with license information for all SDL Suite and TTCN Suite tools.

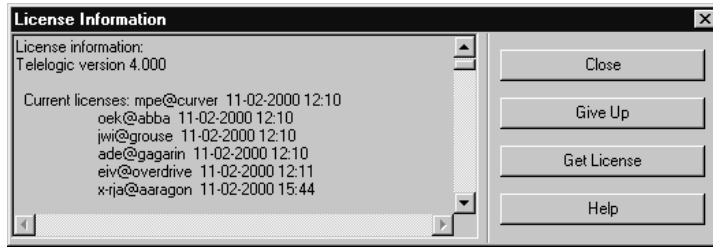

Figure 52: The License Information dialog

The dialog contains the following:

- The names of the tools that are included in SDL Suite and TTCN Suite and that are separately licensed.

  Each name consists of the prefix SDT or ITEX, followed by a hyphen and an abbreviated name for the tool. See the table below for a reference to these abbreviations.

Abbreviation	**Tool(s)**
Telelogic	Organizer
SDT-Base	SDL Editor, SDL Analyzer and SDL Viewers.
SDT-OME	Object Model Editor and State Chart Editor
SDT-MSCE	Message Sequence Chart Editor and High-Level Message Sequence Chart Editor
SDT-Cbasic	Cbasic SDL to C Compiler
SDT-Cadvanced	Cadvanced SDL to C Compiler
SDT-Cmicro	Cmicro SDL to C Compiler
SDT-Cmicro-Bodybuilder	Cmicro BodyBuilder
SDT-Cmicro-Tester	SDL Target Tester UI
SDT-X[a] **(UNIX only)**	<Configuration dependent>

Abbreviation	Tool(s)
SDT-Explorer	Explorer Library
SDT-Simulator	Simulator Library
SDT-Application	Application Library
SDT-Performance	Performance Simulation Library
SDT-TTCN-Link	Interactive link to TTCN Suite
ITEX-Base	TTCN Browser, TTCN Table Editor and TTCN Analyzer
ITEX-Access	TTCN Suite Access API Library
ITEX-Simulator	TTCN Suite Simulator
ITEX-C-Code-Generator	TTCN Suite C Code Generator
SDT-Author	Package licenses, see "Description of packages" on page 59 in chapter 5, *Licensing Management*
SDT-ModelBuilder	
SDT-CodeBuilderCMicro	
SDT-CodeBuilderCAdvanced	

a. The SDT-X is a generic name that allows to introduce new code generators that are under development. In "normal" installations, it has no meaning.

- **On UNIX**, beneath each tool, the following information is displayed:
  - Current licenses, along with the name of the host computer, the user identity and the time the license was checked out
  - Remaining available licenses
  - Total available licenses
  - If a license has expired, the information would be replaced by:

```
SDT-<ToolName>
  Expired: <Date>
```

- A *Give Up License* button which allows you to release the interactive licenses in your current SDL Suite session.

This will disable licensed tools without closing them, making the licenses available to other users. You can reclaim these licenses at a later time, if there are corresponding licenses available, by using the *Get License* button, allowing you to continue working in the licensed applications.

- A *Get License* button which allows you to reclaim licenses released by either the use of the *Give Up License* button or the automatic release of licenses.

  Licenses will be automatically released if the idle time limit, set in the preference LicenseTimeout, is exceeded. For more information, see "LicenseTimeout" on page 244 in chapter 3, *The Preference Manager*.

  The reclamation of licenses is limited in the sense that it will only attempt to reclaim lost licenses once, implying that you will have to save your work in and restart the tools for which licenses could not be obtained.

- A *Configure License* button which allows you to configure package licenses. See "Set up and change a Package license" on page 60 in chapter 5, *Licensing Management*.

Shortcuts

There are several ways to invoke an operation in the Organizer. An operation is usually available in the menu bar and in at least one pop-up menu. Menus can be operated via the keyboard (keyboard navigation). Several operations are also available in the tool bar or via keyboard accelerators. For instance, the Print operation can be invoked by:

- Choosing the menu choice in the *File* menu in the menu bar with the mouse.
- Choosing the menu choice in the *File* menu in the menu bar with keyboard navigation. (`<Alt+F> P`)
- Using the keyboard accelerator `<Ctrl+P>`.
- Pressing the *Print* quick button.
- Choosing the menu choice in the *File* sub menu of the background pop-up menu. (The *Print* menu choice is also available in several other pop-up menus.)

The sections below are “Pop-Up Menus” on page 170, “Keyboard Accelerators” on page 178 and “Quick Buttons” on page 180.

Pop-Up Menus

This section describes pop-up menus for different types of icons. The operations available depend on the type of file that icon represents.

The following tables lists the menu choices in the pop-up menus and a reference to the corresponding menu choice in the menu bar.

On SDL Diagrams (but not SDL Overview Diagrams)

Print Selected	“Print > Selected” on page 70
Set Directories	“Set Directories” on page 71
Edit > Edit	“Edit” on page 86
Edit > Remove	“Remove” on page 91
Edit > Connect	“Connect” on page 92
Edit > Disconnect	“Disconnect” on page 96

Edit > CM Group	“Configuration > Group File” on page 97
Edit > CM Update	“Configuration > Update” on page 98
Edit > Associate	“Associate” on page 98
Edit > Update Headings	“Update Headings” on page 100
View > Expand	“Expand” on page 103
View > Expand Substructure	“Expand Substructure” on page 104
View > Collapse	“Collapse” on page 104
View > Show Sub Symbols	“Show Sub Symbols” on page 105
View > Hide	“Hide” on page 106
Generate > Analyze	“Analyze” on page 112
Generate > Make	“Make” on page 120
Generate > Stop Analyze/Make	“Stop Analyze/Make (UNIX only)” on page 127
Generate > Generate SDL Overview	“SDL Overview” on page 128
Generate > Convert to PR	“Convert to PR/MP” on page 131
Generate > Convert to GR	“Convert to GR” on page 133
Generate > Edit Separation	“Edit Separation” on page 137
Generate > Dependencies	“Dependencies” on page 138
Search	“Search” on page 142
Change Bars	“Change Bars” on page 147
Compare SDL Diagrams	“Compare > SDL Diagrams” on page 148
Merge SDL Diagrams	“Merge > SDL Diagrams” on page 151
Create Endpoint	“Link > Create Endpoint” on page 142
Traverse Link	“Link > Traverse” on page 142

Clear Endpoint	"Link > Clear Endpoint" on page 142
Type Viewer	**(On SDL type diagrams only)** "SDL > Type Viewer" on page 162. Opens the Type Viewer with the type diagram selected.

On MSC and SDL Overview Diagrams

Print Selected	"Print > Selected" on page 70
Set Directories	"Set Directories" on page 71
Edit > Edit	"Edit" on page 86
Edit > Remove	"Remove" on page 91
Edit > Connect	"Connect" on page 92
Edit > Disconnect	"Disconnect" on page 96
Edit > CM Group	"Configuration > Group File" on page 97
Edit > CM Update	"Configuration > Update" on page 98
Edit > Associate	"Associate" on page 98
Hide	"Hide" on page 106
Dependencies	"Dependencies" on page 138
Search	"Search" on page 142
Change Bars	"Change Bars" on page 147
Create Endpoint	"Link > Create Endpoint" on page 142
Traverse Link	"Link > Traverse" on page 142
Clear Endpoint	"Link > Clear Endpoint" on page 142

On Instance and Dashed Diagrams

Edit	"Edit" on page 86.
Type Viewer	"SDL > Type Viewer" on page 162. Opens the Type Viewer with the diagram selected.

Hide	"Hide" on page 106

On Pages

Print Selected	"Print > Selected" on page 70
Edit	"Edit" on page 86.
Hide	"Hide" on page 106

On Associations

Associations have the same pop-up menu as the associated document. All menu choices operate on the associated document, except *Hide* and *Remove* that operate on the association symbol itself.

Keyboard Accelerators

Apart from the general keyboard accelerators, as described in "Keyboard Accelerators" on page 35, the following accelerators can be used in the Organizer:

Accelerator	Reference to corresponding command or quick button
`Ctrl+A`	"Add New" on page 89
`Ctrl+B`	"Connect" on page 92
`Ctrl+E`	"Edit" on page 86
`Ctrl+I`	"Import SDL" on page 80
`Ctrl+K`	"Stop Analyze/Make (UNIX only)" on page 127
`Ctrl+M`	"Make" on page 120
`Ctrl+R`	"Disconnect" on page 96
`Ctrl+T`	Toggles between *Analyze*/*Make* (default) and *Full Analyze*/*Full Make*. A text is presented in the message area to confirm that `<Ctrl+T>` has been pressed: Either "Organizer will now use full analyze/make" or "Organizer will now use normal analyze/make". For more information, see "Normal versus full analyze (make)" on page 114.
`Ctrl+0 (zero)`	"Set Directories" on page 71
`Ctrl+1`	"Organizer Log" on page 142
`Ctrl+2`	"Add Existing" on page 90
`Ctrl+3`	"Associate" on page 98
`Ctrl+4`	"Analyze" on page 112
`Ctrl+5`	"SDL Overview" on page 128
`Ctrl+6`	"SDL > Type Viewer" on page 162
`Ctrl+7`	"SDL > Coverage Viewer" on page 162
`Ctrl+8`	"SDL > Index Viewer" on page 162

Accelerator	Reference to corresponding command or quick button
`Ctrl+9`	“Preference Manager” on page 164
`Del`	“Remove” on page 91. For documents that can not be removed (non-root SDL diagrams), see “Disconnect” on page 96.
`arrow up`	Select the symbol one step up (move the selection)
`Shift+arrow down`	“Move Up” on page 182.
`Ctrl+Shift+ arrow up`	Place the selected symbol first in the Organizer structure.
`arrow down`	Select the symbol one step down (move the selection)
`Shift+arrow down`	“Move Down” on page 182
`Ctrl+Shift+ arrow down`	Place the selected symbol last in the Organizer structure.

Quick Buttons

The following quick buttons are special to the Organizer's Main window. The general quick buttons are described in "General Quick-Buttons" on page 24. Each quick button in the Organizer has a preference parameter that specifies if the button is shown or hidden; see "Organizer Preferences" on page 246. As default, all quick buttons except *New* and *Add Existing* are shown.

New
Creates a new system; see "New" on page 59.

Save
Performs a silent *Save All* of all diagrams including the system file. Does not bring up the *Save* dialog, except if diagrams are modified and unconnected, or no system file exists. Corresponds to the *Save All* button in the Save dialog; see "Save" on page 62.

Print
Brings up the *Print* dialog, see chapter 5, *Printing Documents and Diagrams*.

Analyze
Analyzes the part of the system defined by the selected diagram or the whole system. Brings up a *Save Before* dialog if any diagram is modified and not saved. Does not bring up the *Analyze* dialog. Corresponds to the *Analyze* button in the Analyze dialog. The current Analyze options are used. The same restrictions and checks apply as described in "Analyze" on page 112.

Make
Makes the part of the system defined by the selected diagram or the whole system, i.e. generates code, compiles and links it. Does not bring up the *Make* dialog. Corresponds to the *Make* button in the Make dialog. The current Analyze and Make options are used. The same restrictions and checks apply as described in "Make" on page 120.

Generate SDL Overview
Generates an SDL overview diagram for the selected diagram or the whole system. Does not bring up the *SDL Overview* dialog. Corresponds to the *Generate* button in the *Generate SDL Overview* dialog. The current *Generate SDL Overview* options are used. The same restrictions and checks apply as described in "SDL Overview" on page 128.

Simulate
Generates a simulator for the part of the system defined by the selected diagram or the whole system, and starts a Simulator UI (see "Simulator/Explorer UI Started from Quick Buttons" on page 182). Does not bring up the *Make* dialog if the simulator needs to be regenerated. If a simulation kernel has not been selected in this dialog, the default simulation kernel is used. The default simulation kernel is determined by the preference Organizer*DefaultSimulator. The default value is "SCTADEBCOM" which is the same as using the standard kernel *Simulation* in the Make dialog. The same restrictions and checks apply as described in "Make" on page 120.

Explore
Generates an SDL Explorer for the part of the system defined by the selected diagram or the whole system, and starts an Explorer UI (see "Simulator/Explorer UI Started from Quick Buttons" on page 182). Does not bring up the *Make* dialog if the explorer needs to be regenerated. If a validation kernel has not been selected in this dialog, the default validation kernel is used. The default validation kernel is determined by the preference Organizer*DefaultExplorer. The default value is "SCTAVALIDATOR" which is the same as using the standard kernel *Validation* in the Make dialog. The same restrictions and checks apply as described in "Make" on page 120.

Generate Cross References
Generates a cross reference file for the current system and presents the information in the Index Viewer. An index symbol is added in the Organizer view. Does not bring up the *Analyze* dialog. Corresponds to setting the *Generate a cross reference file* option in this dialog. The same restrictions and checks apply as described in "Analyze" on page 112 and "Semantic analysis" on page 115.

Add New
Adds a new document as root; see "Add New" on page 89.

Add Existing
Adds an existing document as root; see "Add Existing" on page 90.

Move Down
Moves the selected symbol one step down in the Organizer structure. For more information about moving symbols, see "Ordering" on page 55.
Moves down the selected page. For more information about moving pages, see "Move down" on page 2035 in chapter 43, *Using the SDL Editor* and "Move down" on page 1680 in chapter 39, *Using Diagram Editors*.

Move Up
Moves the selected symbol one step up in the Organizer structure. For more information about moving symbols, see "Ordering" on page 55.
Moves up the selected page. For more information about moving pages, see "Move up" on page 2034 in chapter 43, *Using the SDL Editor* and "Move up" on page 1680 in chapter 39, *Using Diagram Editors*.

Toggle Pages
Shows or hides page symbols below diagram symbols in the Organizer structure.

Organizer Log
Opens the Organizer Log window; see "Organizer Log" on page 142.

Simulator/Explorer UI Started from Quick Buttons

When the Simulate quick button is used and if the generated simulator already was loaded in a Simulator UI, the same Simulator UI will be re-used for the newly generated simulator. If no Simulator UI is active, a new Simulator UI will be started. However, if there already are other started Simulator UI's, the user has the choice of selecting one of these to load the generated simulator in.

The following dialog is opened:

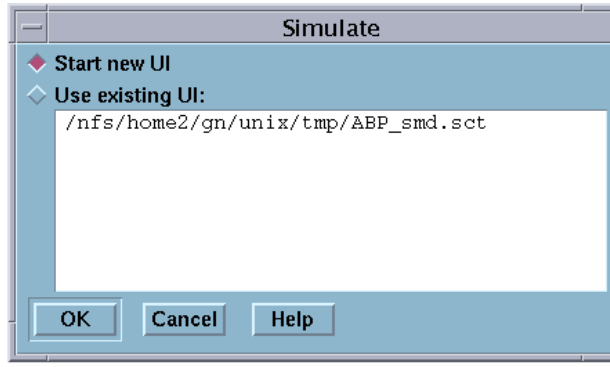

Figure 53: The Simulator/Explorer dialog

- *Start new UI*

  Starts a new Simulator UI and loads the simulator.

- *Use existing UI*

  From the list box, one of the active Simulator UI's can be selected to load the simulator in. If a simulator already was running in the selected Simulator UI, that simulator will be terminated.

The same applies also for an SDL Explorer and the Explorer UI.

Organizer Log Window

The Organizer log window is a sub window to the main window. It works as a console for the SDL Suite and TTCN Suite tools. The window can be visible (raised or iconified) or not visible on the screen. All log information is output to this window independently of whether the window is visible or not.

The window is used in the following situations:

- To log information from the Analyze and Make process.
- To log the activities when an SDL system is imported.
- When files are checked during the *Open* command. Inconsistent files are reported.
- To show status information from the Generate tools.

- Other tools, such as TTCN Suite and tools started with dynamic menus, may also use the window to output textual information.

The window is opened or raised when the menu choice *Organizer Log* is selected from the *Tools* menu, or when something is written to the log. The preference ShowLogLevel controls which output to the window should cause a raise of the window (see chapter 3, *The Preference Manager*).

There is only one Organizer Log window. The Organizer main window is not locked for user input when the Organizer Log window is visible.

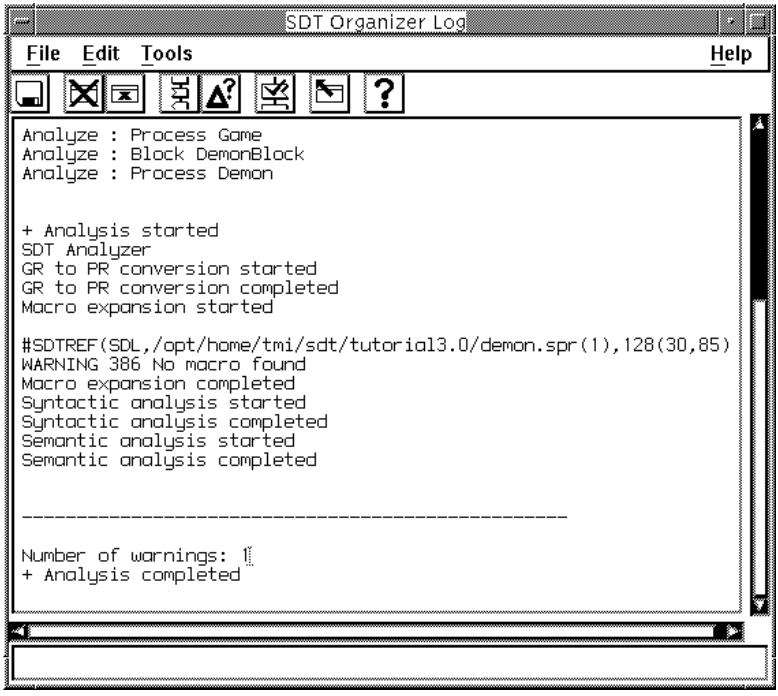

Figure 54: The Organizer Log window

Quick Buttons

The following quick buttons are special to the Organizer Log window. The general quick buttons are described in "General Quick-Buttons" on page 24. Each quick button in the Organizer Log window has a preference parameter that specifies if the button is shown or hidden; see "Organizer Preferences" on page 246 in chapter 3, *The Preference Manager*. All quick buttons in the Organizer Log are shown by default.

Close
Exactly the same as *Close* in the *File* menu.

Clear Log
Exactly the same as *Clear Log* in the *Edit* menu; see "Clear Log" on page 186.

Navigate Down
Move to the next error visible in the Organizer Log. See "Log Options" on page 186 for details.

Navigate Up
Move to the previous error visible in the Organizer Log. See "Log Options" on page 186 for details.

Show Error
Exactly the same as *Show Error* in the *View* menu; see "Show Error" on page 187.

Help on Error
Exactly the same as *Help on Error* in the *View* menu; see "Help on Error" on page 187.

Analyze
Exactly the same as the *Analyze* quick button in the Organizer Main window; see "Analyze" on page 180.

Show Organizer
Exactly the same as *Show Organizer* in the *Tools* menu; see "Show Organizer" on page 187.

File Menu

See "File Menu" on page 8 in chapter 1, *User Interface and Basic Operations*.

Edit Menu

The following menu choices are available in the Organizer log window *Edit* menu:

Copy

This menu choice copies the selected text to the clipboard buffer.

Select All

This menu choice selects all text in the Organizer Log window.

Clear Log

This menu choice clears all text in the Organizer Log window.

Log Options

This menu choice lets you decide how error, warning and information messages from the Analyzer should be handled in the Organizer Log:

- The Filter text field can be used to specify warning messages that should not be shown.
- By pressing the Ignore WARNINGs button and enter a previuosly saved Organizer Log file, all warnings issued by the Analyzer that already exist in the Log file are ignored.
- The navigation level decides if the navigate up and down quick buttons should navigate through:
  - Error messages
  - Error and warning messages
  - All messages

The default value for the Filter text field is taken from the preference Organizer*LogFilter. The default value for the navigation level is taken from the preference Organzier*LogNavigationLevel.

The Ignore WARNINGs button can be used when you repeatedly analyze the same system and only are concerned with warnings issued by new changes in the system. In the Log file any line starting with "#SDTREF" together with the next line will be used to match a warning issued by the Analyzer. The initial number on the second line is always replaced by a wildcard character '*', which means that any number of

characters will match. Additional wildcards can be added manually to tailor the exact behavior of what warnings to be ignored. To make the Log file independent of a specific source directory path, the initial path can be exchanged by a wildcard character.

Example 3 ----------

```
#SDTREF(SDL,*Main1.spr(1),179(80,75),1,1)
1: WARNING 295 Consider adding else answer
```

Tools Menu

The following menu choices are available in the *Tools* menu of the Organizer log window:

Show Organizer

This menu choice raises the Organizer's Main window.

Show Error

This menu choice opens an editor and shows an object/text that corresponds to a selected error/warning. If no text in the log is selected, the menu choice operates on the first error/warning in the log, which becomes selected. If this menu choice is invoked several times without changing the selection manually, the selection is updated automatically to point to the next error/warning before opening the editor and selecting the corresponding object/text.

Help on Error

This menu choice activates the Help tool on the selected error/warning or the next found error/warning. The selection is not updated automatically when selecting this command repeated times (as opposed to *Show Error*, above).

Search

This menu choice opens a dialog that allows you to search for a text in the Organizer log; see "Search" on page 142.

Repeated Search

Repeated search can be invoked without opening the Search dialog by pressing Ctrl+F on the keyboard. This will use the settings of the Search dialog for a new search.

System File

The Organizer maintains a system file that contains a description of all files that are included in the system, together with all settings the user has made to this particular system. The default file name extension for a system file is `.sdt`.

In addition, a system window state file contains information about window positions and sizes, and it uses the extension `.sdt.state`.

Contents of the System File

The contents of the system file summarizes the information that the Organizer manages:

- Source Directory and Target Directory.
- Link file reference (used by the Link Manager) and information about endpoints in the Organizer view.
- All document names are listed, both with logical names and file names. The fact that document names are present means that the Organizer will have a robust recovery when files are manipulated outside the Organizer.
- Associations and dependencies are stored as indexes to other documents for a document.
- The names of all chapters and modules are listed.
- The names of all Control Unit files.

The system file may contain a mapping of directory paths on Windows and UNIX to allow the system to be accessed on both platforms. See "Windows and UNIX File Compatibility" on page 215 for more information.

A number of options are also stored in the system file, but only if they differ from the values in the preference file or if the preference Organizer*AllPreferences is on. The options are:

- Window options as set in the *View Options* and *Set Scale* dialogs
- Analyze options as set in the *Analyze* dialog
- Make options as set in the *Make* dialog
- Print options as set in the *Print > Selected* dialog

In addition, information about collapsed, hidden and selected documents are saved to enable the Organizer to open with the same appearance as when the system file was saved. However, simply changing which documents are collapsed, hidden and selected will not mark the system file as “dirty” in the Organizer.

Format of the System File

The system file is a line-oriented, human-readable text file. The system file is divided into sections. Each section contains lines formatted in the same way. Any lines before the first section are ignored, but saved for the next system file save. This means that it is possible to have user defined comments in the beginning of the file.

Caution!

The sections that describe the diagram and document structure should not be modified by the user unless absolutely necessary. Modifying these sections in a way that errors or inconsistencies are introduced may corrupt the system file.

The file has the following format:

```
<file> ::= <comments> SDT-SYSTEM-6.3(<drives> | $)
           (<dir> | $) (<links> | $)
           (<diagram> | $) (<view> | $) (<analys> | $)
           (<cpp2sdl> | $) (<make> | $) (print | $)

<comments> ::= <comment>*
<comment> ::= Any line of ASCII characters not
beginning with "SDT-SYSTEM-".

<drives> ::= [DRIVES] <drive>*
<drive> ::= <Windows dir> <UNIX dir>

<dir> ::= [SOURCE-TARGET-DIRECTORY] <option>*
<links> ::= [LINKS] <option>*

<diagram> ::= [DIAGRAMS] <dia>*
<dia> ::= <indent> <type> <name>
          (<path> | <fileName> | %unconnected%)
          <viewState> <timeStamp> <separateName>
          <associations> <dependencies>

<view> ::= [VIEWOPTIONS] <option>*
<analys> ::= [ANALYSEROPTIONS] <option>*
<cpp2sdl> ::= [CPP2SDLOPTIONS] <option>*
<make> ::= [MAKEOPTIONS] <option>*
```

<print> ::= [PRINTOPTIONS] <option>*

<Windows dir> ::= <string>
An Windows path. This is either a drive letter and a colon (e.g. C:) or a full path (e.g. C:\SDL). UNC paths can be used (e.g. \\MYHOST\SDL). If you include a trailing backslash you must also include a trailing slash in the corresponding <UNIX dir>.

<UNIX dir> ::= <string>
A UNIX directory path corresponding to the <Windows dir>. If you include a trailing slash you must also include a trailing backslash in the corresponding <Windows dir>.

<indent> ::= <int>
The indentation level. 0 is root, -1 is used for chapters.

<type> ::= <int>
Type of document, module or chapter. If the diagram has some kind of virtuality, the value is factored with a number with the base 100. The value corresponds to the kind of virtuality. These numbers correspond to an enumerated value found in the file sdt.h. If the diagram is an instance, a value of 1000 will be added to the type.

<name> ::= <string>
Logical name of diagram or document.

<path> ::= <string>
File path including a directory.

<fileName> ::= <string>
File name.

<viewState> ::= <integer>
Viewing state, consisting of four weighted booleans for separation, expanded, shown and selected states:
Separation + 2*NotExpanded + 4*NotShown + 8*Selected.

<timeStamp> ::= <integer>
Last time the file was modified, and that the Organizer was aware of. When the Organizer reads the system file, only files with modification dates later than the time stamp are checked for correctness.

<separateName> ::= <string>
Name of separation. Only applicable for units that are separately analyzed.

<associations> ::= <string>
A string of space separated values referencing associated documents, e.g. “1 4 5”. The values index documents in the DIAGRAMS section.

<dependencies> ::= <string>

A string of space separated values referencing documents that this document is depending on, e.g. “1 4 5”. The values index documents in the DIAGRAMS section.

```
<option> ::= (<option-name> = <option-value>)
<option-name> ::= <string>
```

Any option found in the named dialogs.

```
<option-value> ::= <string>
```

Any valid value bound to an option.

If a section is missing entirely from the system file, a warning will be logged, except for the `cpp2sdl` section which is optional and only useful in batch. If no recognizable sections could be found, the file is not a valid system file.

When loading system files, warnings will be registered in the Organizer Log window if any non-recognized option is encountered, but not if an option never was initialized.

The Drives Section

The purpose of the `DRIVES` section in the system file is to achieve file compatibility between UNIX and Windows systems. It specifies the *drive table*; a mapping between Windows and UNIX directory paths. See “Windows and UNIX File Compatibility” on page 215 for more information.

The path format of the current platform is used for directory paths stored in the system file: UNIX path names on UNIX systems (i.e. starting with a slash ‘/’ and directories separated by slashes), and Windows path names on Windows systems (i.e. starting with a drive letter “x:” and directories separated by backslashes ‘\’, or using the UNC format “\\<host>\file”).

Diagrams with file specifications in an incorrect format are marked as Invalid in the Organizer.

When reading the system file on Windows systems, file specifications in UNIX format are converted to Windows format using the mapping in the `DRIVES` section, if possible, including converting slashes to backslashes. When the system file is saved, the file specifications are saved in Windows format, i.e. they are not converted back to UNIX format.

On UNIX systems, file specifications in Windows format are converted to UNIX format using the mapping in the `DRIVES` section, if possible,

including converting backslashes to slashes. When the system file is saved, the file specifications are saved in UNIX format, i.e. they are not converted back to Windows format.

Example 4 ----------

The `DRIVES` section of the system file looks like this:

```
[DRIVES]
C:\TEMP /tmp
\\MYHOST\STORAGE /home/user
```

The file specification `/tmp/a.ssy` in the system file is converted to `C:\TEMP\a.ssy`.

The file specification `/home/user/mydir/a.ssy` is converted to `\\MYHOST\STORAGE\mydir\a.ssy`.

The file specification `/usr/local/dir/a.ssy` is converted to `\usr\local\dir\a.ssy`. Since no drive or host name could be matched, the file will not be found and the diagram will be marked as Invalid in the Organizer.

Options in the System File

A number of sections contain options for the Organizer, representing values that can be set in the Organizer dialogs. If an option in the file is not recognized by the Organizer, it will be ignored, and if an option is not included in the file, a default preference value will be used. A few of the options have no corresponding preference parameters.

The following tables list the Organizer options that are saved in the system file. The user should not normally need to know or change these options in the system file. However, when running the SDL Suite in batch mode **on UNIX**, it may be useful to change some options by editing a system file to be submitted as input to `sdtbatch`. See "Batch Facilities" on page 208 for more information.

The options must appear in the correct section of the system file, but the ordering of options within a section is not important. The options are stored in the system file according to the format:

```
NameOfOption=Value
```

The option names and option values are case insensitive.

Possible and allowed values are not specified; the user should run the Preference Manager in order to obtain a reference to the permitted values.

SOURCE-TARGET-DIRECTORY Section

System Window State File

When the system file is saved, a second file is saved as well; the system window state file. This file contains information about window positions and sizes. If an editor window is not open when the system file is saved, the last known position and size of that window is saved instead. While the system file uses the `.sdt` extension, the system window state file uses the `.sdt.state` extension.

If the Organizer finds a system window state file when opening a system file, the positions and sizes of the Organizer and editor windows are restored to the positions they had when the system file was saved. Note that the editor windows are not restored until they are opened from the Organizer.

Control Unit File

In addition to the System file (see "System File" on page 189), the Organizer also manages *Control Unit* files, `.scu` files. These control units are introduced to facilitate the workgroup (multiuser) support when working with an SDL system managed by the SDL Suite, and merging the individual results to a common system file.

General

The multiuser support is based on, from a revision control point of view, letting the user split the system file into several files. Information that is updated often should be split and stored in control unit files.

When and where to split the SDL structure is an active action taken by the user.

The multiuser mode is effective when control unit files are used. The use of the control unit files is optional, whereas the system file is mandatory. The Organizer thus always requires a system file and can manage multiple control unit files. By not taking advantage of control units simply means using the Organizer and system files as was done before, i.e. in previous versions (3.0X/3.1X/3.2).

Definitions

A definition for a *system file* (`.sdt` file) from a revision control point of view: a file that contains structure and state information for a document system as seen by one user. This file is normally not considered as an essential part of the system and is not suitable for revision control as it is private to one user.

- The diagram structure information is common to all developers of the system in a multiuser environment.
- The state information is specific for one user.

A similar definition for a *control unit* file (`.scu` file): a file that contains structure information for a subset of a document system and which is common to all users that work with the document system. Control unit files are part of the document system and are suitable for revision control.

The control unit files can be inserted and made visible in the Organizer's file structure view. The control unit files contain information that is specific to the Organizer file structure for diagrams, modules and chapters.

Splitting the System File

The users control what parts of the file structure managed by the Organizer need a separate control unit file. When several users work on a system, the management of the system file may be difficult to synchronize. This problem is solved if every user or group have control over their own part of the system file.

The Organizer structure information is hence split into several files – control unit files. The decision of where and how many control unit files are needed is left to the users; the idea being to partition the diagram system according to the user's work responsibilities and assign control unit files to these partitions. An example can be a large SDL diagram system where there are several blocks on the system level developed in parallel by different developers. Each block could then be associated with a control unit file. Now, the blocks can be updated independently and the changes are shaping the local control unit files. There is no need to manually merge changes into the system file when the work is done – the management of control unit files performed by the Organizer also includes the merge.

The user decides how control unit files and the system file cooperate to produce the Organizer view of the document system. Two scenarios are possible here. In one scenario the user decides that the system file is valid and the diagram structure is read from it. This is done when the user opens the system file and loads the document system into the Organizer. In the other scenario the control unit files are used to load the Organizer view and automatically update it accordingly to a specific revision for the document system – the system file is used only to fill in document state information (if any is available). This is done with a menu command when control unit files are used to explicitly update the document system or some part of it.

An Example

To illustrate the use and contents of control unit files and facilitate the understanding, let us discuss the topic with a simple example as input.

Example 5 ----------

Say we have the following system managed by the Organizer:

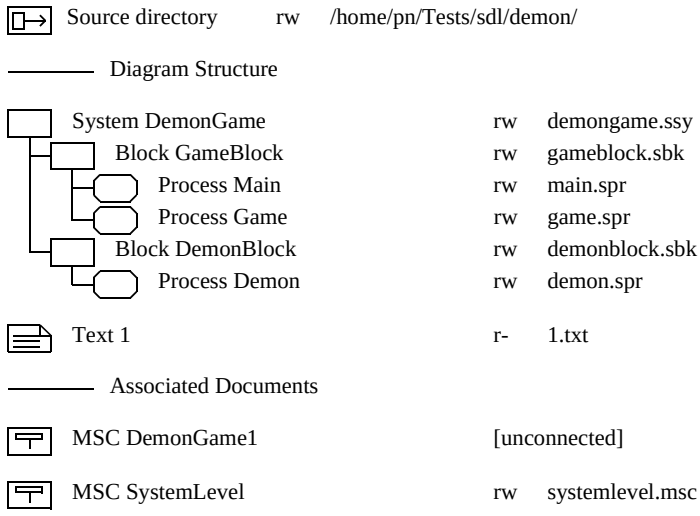

Figure 55: A simple system, managed by the Organizer

Let us say that we create control units (using the *Configuration > Group File* command) for the following items:

- One control unit that holds the entire system file together
- One control unit for the whole diagram structure
- One control unit for the system DemonGame
- One control unit for the block GameBlock.

We would now have a system that looks like this:

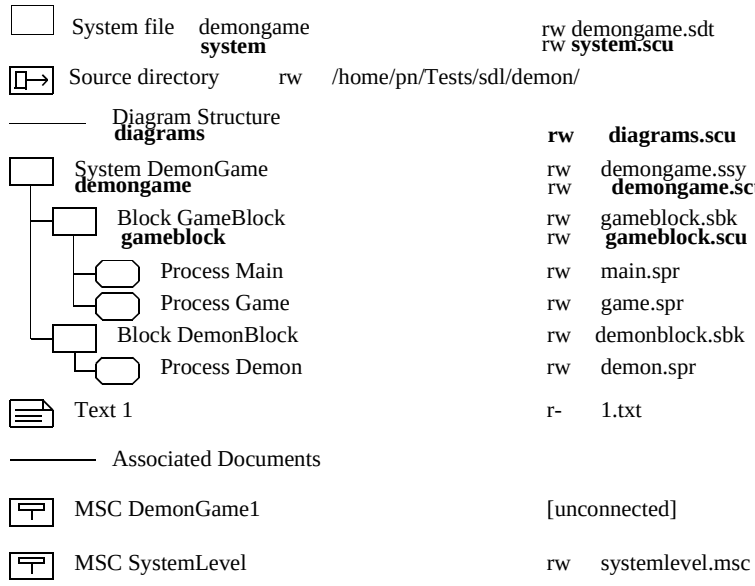

Figure 56: The same system, now with control units

The control units are depicted in bold face.

The [DIAGRAMS] section of the `demongame.sdt` file will contain:

```
[DIAGRAMS]
-2 102 system system.scu 0 0 - ""
-1 102 diagrams diagrams.scu 0 0 - ""
-1 23 "Diagram Structure" %unconnected% 0
0 102 demongame demongame.scu 0 0 - ""
0 1 DemonGame demongame.ssy 0 0 demongame ""
1 102 gameblock gameblock.scu 0 0 - ""
1 2 GameBlock gameblock.sbk 0 0 gameblock ""
2 5 Main main.spr 0 0 main ""
2 5 Game game.spr 0 0 game ""
1 2 DemonBlock demonblock.sbk 0 0 demonblock ""
2 5 Demon demon.spr 0 0 demon ""
0 33 1 1.txt 0 0 - ""
-1 23 "Associated Documents" %unconnected% 0
0 16 DemonGame1 %unconnected% 0 0 - ""
0 16 SystemLevel systemlevel.msc 0 0 - ""
```

The files `system.scu, diagrams.scu, demongame.scu` and `gameblock.scu` will contain the following information:

```
system.scu:
-1 102 diagrams diagrams.scu 0 0 - ""
-1 23 "Associated Documents" %unconnected% 0
0 16 DemonGame1 %unconnected% 0 0 - ""
0 16 SystemLevel systemlevel.msc 0 0 - ""

diagrams.scu:
-1 23 "Diagram Structure" %unconnected% 0
0 102 demongame demongame.scu 0 0 - ""
0 33 1 1.txt 0 0 - ""

demongame.scu:
0 1 DemonGame demongame.ssy 0 0 demongame ""
1 102 gameblock gameblock.scu 0 0 - ""
1 2 DemonBlock demonblock.sbk 0 0 demonblock ""
2 5 Demon demon.spr 0 0 demon ""

gameblock.scu:
0 2 GameBlock gameblock.sbk 0 0 gameblock ""
1 5 Main main.spr 0 0 main ""
1 5 Game game.spr 0 0 game ""
```

Format and Structure of the Control Unit File

Format

The format of the control unit file complies with the syntax of the [DIAGRAMS] section in the system file (see "Format of the System File" on page 190). There are however some exceptions:

The first line of the scu file indicates the source directory to use for relative files mentioned in the scu file. This information is saved in the same way as the same information is saved in the system file. By having this information in the scu file, it is possible to re-use/reference the same scu file from different system files with different source directories.

`<viewState>`
: This field is only used for the separation value - the value is therefore either 0 or 1.

`<timeStamp>`
: This field is not used - the value is always 0.

`<associations> ::= " <qualifiernameList> "`

A list of quoted qualifier names, each name denoting a document. See Example 6, below.

```
<dependencies> ::= " <qualifiernameList> "
```

A list of quoted qualifier names, each name denoting a document.

```
<qualifiernameList> ::= $ | (<qualifierName>
                          (, ($ | \NL) <qualifierName>)*)

<qualifierName> ::= ' <qualifierTuple>
                    (/<qualifierTuple>)* '

<qualifierTuple> ::= <integer> <string>
```

<string> is the name of the system file, chapter, module or diagram.

Example 6 ——————————————————————————

```
" '23 Diagrams Area/1 DemonGame/2 DemonBlock', \
'23 Diagrams Area/1 DemonGame/2 GameBlock' "
```

————————————————————————————————

Structure

Associations between Control Units and Document Structures

A control unit file is associated with a document structure in the Organizer. The control unit file holds information about the top node of the structure and information about lower level documents under the top node and/or other lower level control unit files.

Levels (Indents)

Document nodes in a control unit file have a relative level (i.e. `<indent>`) starting from 0. (Exceptions: a chapter node and an control unit file node associated with a chapter have always level -1). This gives the flexibility that the control unit file can be associated with a node on different levels in the system structure of documents. To get the actual level for a document node from an control unit, the control unit file node level should be added to the document's relative node level.

Example 7: For the control unit level 1 from Example 5 on page 202

```
0 2 GameBlock gameblock.sbk 0 0 gameblock ""
1 5 Main main.spr 0 0 main ""
1 5 Game game.spr 0 0 game ""
```

————————————————————————————————

Hierarchy

The control unit files are hierarchical. The top control unit file is for the whole system of documents in the Organizer. We give this control unit file level (-2). If this file has an information line in the system file this means that the top of the whole system structure is found in that file. Other structure information about diagrams mentioned in the system file is then only a mirror of the structure information found in the control unit hierarchy.

Example 8:

```
-2 102 system system.scu 0 0 - ""
```

Modularity

The user can choose to use a control unit file only for a specific chapter, module or diagram structure (without a top level control unit system file). This means that not all information in the system file is a mirror for structure information from control unit files. Some of the information can be actual structure information that is not controlled by control unit files. When the Organizer expands structure information from control unit files it tries to match that information against the contents in the system file. This matching is necessary because only the system file holds state information about documents. The structure information from control unit files takes precedence over structure information found in the system file. If there is an inconsistency between the control unit file structure information and the system file, the control unit information takes precedence and the SDL Suite contents are treated as an error situation. Say, for instance, that according to a control unit file there are three blocks in an SDL system but there are four blocks in the system file. The extra block is probably old information.

Example 9: A control unit file for a chapter

```
-1 102 diagrams diagrams.scu 0 0 - ""
```

Order of Appearance

A control unit information line in the system file is followed by a mirror information line of the top node that the control unit file is associated with. If the Organizer cannot open the control unit hierarchy the mirror information will function as a back-up document structure information.

Example 10 ----------

```
-1 102 diagrams diagrams.scu 0 0 - ""
-1 23 "Diagram Structure" %unconnected% 0
```

Batch Facilities

SDL Suite supports operations in batch mode, such as *printing* the documentation, *analyzing* an SDL structure and *generating code*. These operations are managed by the Organizer in a batch, windowless mode.

Batch Syntax

The syntax for a batch command is:

```
sdtbatch <systemfile> <options>
```

Where `<systemfile>` and `<options>` are described in "Batch Options" on page 212.

When the `sdtbatch` command is issued, the Organizer interprets the command line arguments, performs the requested operation and then terminates. Error logging is performed by the Organizer.

Information concerning the batch job is directed the standard output device.

> **Note:**
>
> When executing a Batch command, external service management via the PostMaster interface is disabled.

Print Multiple Files

Syntax:

```
sdtbatch -p[rint] systemfile \
         [-s[elect] documentfile] \
         [-o[ption] optionfile]
```

Prints the contents in the system file. Corresponds to clicking the *Print* quick button.

Print One File

Syntax:

```
sdtbatch -p[rint] \
         -s[elect] documentfile \
         [-o[ption] optionfile]
```

Prints one file.

Compare Two Diagram Files

> **Note:**
>
> This sdtbatch command produces a textual difference report. To get a graphical difference report, consider using the -grdiff option with the sdt startup command. Read more about this in chapter 2, *Introduction to the SDL Suite*.

Syntax:

```
sdtbatch -d[iff] [ -b ] [ -n ] \
          documentfile1 documentfile2
```

Compares two SDL, HMSC or MSC diagram files. By default, a summary of how many differences that were found is printed. When using the `-b` option (verbose), information about every differing object is presented, including an SDT reference to the object in question. The use of the `-n` option corresponds to setting the option Ignore moved or resized objects to off. Normally this means that moved and resized symbols will not be detected as being different.

Analyze

Syntax:

```
sdtbatch -a[nalyse] systemfile \
        [-s[elect] diagramfile] \
        [-o[ption] optionfile]
```

Analyzes the contents in the system file. Corresponds to the *Analyze* quick button.

Make

Syntax:

```
sdtbatch -m[ake] systemfile \
         [-s[elect] diagramfile] \
         [-o[ption] optionfile]
```

Makes a target as specified by the system file. Corresponds to the *Make* quick button.

Extract Text

Syntax:

```
sdtbatch -extract [ -comment ] \
```

```
[ -keyword <keyword> ] <diagram file>
```

Extracts text from the diagram file. As default, all text in the diagram is shown. By using the *-comment* option, only text in comment symbols and /* C-style comments */ in other symbols is shown. The *-keyword* option limits the shown text to text from symbols containing the <keyword>. The <keyword> itself is not shown. For instance, if you have a comment symbol with the following text:

```
diagramversion 1.44
```

Then...

```
sdtbatch -extract -comment \
         -keyword diagramversion a.ssy
```

...will produce the following output:

```
1.44
```

Show License Information

Syntax:

```
sdtbatch -licenseinfo
```

Show information about license holders and number of available licenses, as textual output in the console window where the command was entered.

Show Version Information

Syntax:

```
sdtbatch -v[ersion]
```

Reports the current program version number for the installed tools.

List Files

Syntax:

```
sdtbatch -files systemfile
```

Lists all files referenced from the system file, as textual output in the console window where the command was entered.

Pack Files

Syntax:

```
sdtbatch -pack systemfile [ archivefile ]
```

Create an archive file (*.tgz) for a system, using default pack settings. If the archive file name is not given, then an archive file will be created in target directory, with a default name.

Unpack Files

Syntax:

```
sdtbatch archivefile [ directory ]
sdt archivefile [ directory ]
```

Extracts an archive file into the current or supplied directory. If executed in normal mode it will open the systemfile.

Change Case

Syntax:

```
sdtbatch -changecase cross-reference-file
```

Change the case for all words found in all referenced files in the cross reference file to the case used in the declaration.

The command will also change the case for all keywords. These should be located in a special keyword file found in the same directory, with the same name as the name of the given cross reference file but with the extension `.key`.

The command does only work with the standard SDL text editor.

To generate a more extensive cross reference file and a file containing keywords, run the `sdtbatch -analyze` command with the options

```
SDLKeywordFile=True

SetPredefinedXRef=True
```

added to the option file. The analyzer will then generate more information in the cross reference file, case-sensitive `.xrf`, and furthermore a keyword file, case-sensitive.key, in the target directory of the system.

Configuration Update

Syntax:

```
sdtbatch -r[ecursive] systemfile \
         [-s[elect] diagramfile] [-u[pdate]]
```

Does a recursive update of the structure in the Organizer according to the Control Unit files in the system file. Corresponds to the *Configuration > Update* menu choice having the diagram file selected. Without the -s option the action is as if the systemfile has been selected.

Checking diagrams for duplicated object IDs

Syntax:

```
sdtbatch -checkdiagrams systemfile
sdtbatch -checkandfixdiagrams systemfile
```

Normally each object in an SDL diagram have a unique ID within the diagram. This ID can be shown for example when using the SDL editor command Show GR Reference. For some existing SDL diagrams, especially diagrams that have been created using the Merge or Add Differences functions, the same ID has been used by more than one object. This will result in unpredictable behaviour when using GR References, e.g. when transforming the system to case-sensitive SDL or when an analysis error should be shown, the wrong symbol might appear. Also if the two objects having the same ID are on the same SDL Page, the lines can be connected to symbols in a way that is different from the way you expect by looking at the geometrical layout of the lines. This can give strange errors when generating SDL/PR, giving strange analysis errors. This problem has been fixed in versions 4.2.7, 4.3.3, and 4.4, therefore diagrams that are saved with these or later versions will not have this problem.

To test the diagrams for duplicated IDs you can run the batch command `-checkdiagrams`. The command will produce a report on duplicates for all the SDL diagrams.

Whenever there are problems with duplicates you can run `-checkandfixdiagrams`. This will fix all duplicates and save the diagrams such that all diagrams are free from duplicated IDs.

Batch Options

- `<systemfile>`

  `<systemfile>` is an Organizer *System File*. A valid system file should be supplied.

- `-select <file>`

`<file>`, which should be included in the document structure, (associated documents are also included if the `-print` option specified) becomes the selected object upon which the command is applied. This option corresponds to a manual selection of the document in the Organizer drawing area.

A full file path for the file must be supplied.

- `-o[ption] <optionfile>`

  `<optionfile>` is a file with the same syntax as a *System File*, containing options which supersede the options found in the system file. An optional section CPP2SDLOPTIONS can manually be entered into the option file to supersede the SDL systems cpp2sdl import specification files. An arbitrary number of options may be supplied, but options in the file must be preceded with an option section field as found in the system file.

Example 11: CPP2SDL section in a batch ".sdt" -file ----------

```
[CPP2SDLOPTIONS]
InputLanguageC=False
InputLanguageCpp=True
InputLanguageMicrosoft=False
InputLanguageGNU=False
RTTI=False
RecognizeSDLsorts=False
ObjectSlicing=False
Preprocessor=""
UsePreprocessorOptions=False
PreprocessorOptions=""
PtrPrefix=ptr_
KeywordPrefix=keyword_
ArrPrefix=arr_
IncompletePrefix=incomplete_
TplPrefix=tpl_
UscoreSuffix=uscore
NoAbsolutePath=True
GenerateCPPTypes=False
OptimizeClassPointers=False
```

An optional section PRINTSETUPOPTIONS can manually be entered into the option file to identify the print setup options to be used during batch printing.

Example 12: PRINTSETUP section in an options file used for batch printing

```
[PRINTSETUPOPTIONS]
TOCAfterText=True
OnlyChaptersInTOC=False
OrganizerScale=FitPage
LinkScale=100
OMScale=100
HMSCScale=100
SCScale=100
DPScale=100
SDLInteractionScale=FitPage
SDLFlowchartScale=FitPage
SDLOverviewScale=100
MSCScale=FitWidth
CoverageScale=100
IndexScale=100
TypeScale=100
MSCInstanceRuler=True
OrgViewPageRef=True
```

Note:

Note that if the options contains a filename in quotes all backslashes must be escaped with one more backslash. Example of correct file-name uses:

`PrinterFile=d:\tmp\printfile.ps`

or

`PrinterFile="d:\\tmp\\printfile.ps"`

- `-u[pdate]`

  If this option is supplied, the system file will be saved after the batch operation has finished.

Windows and UNIX File Compatibility

Systems can be created with SDL Suite and TTCN Suite on both the UNIX and Windows platforms. To allow systems to be accessed on both platforms, SDL Suite and TTCN Suite provides a file compatibility concept.

The *drive table* contains a mapping between Windows and UNIX directory paths. This mapping is included in the system file to allow file specifications in the system file to be translated to the correct format on both platforms. See "The Drives Section" on page 192 for more information.

The menu choice *PC Drives* is available in the Organizer's *File* menu, and allows editing the drive table that is stored in the system file. See "PC Drives" on page 73 for more information.

The drive table takes care of translating absolute paths between the two different file name formats (UNIX and Windows). On a UNIX system, some restrictions apply to file names to be compatible with Windows. These restrictions are checked whenever the user changes a file specification that is stored in the system file; if they are not followed, an error dialog is shown and the user is returned to the dialog where the file was specified. See "Filename Error Dialogs (UNIX only)" on page 33 for more information.

File specifications are always stored in the correct format according to the current platform.

In general, diagrams with file specifications that are of incorrect format or that cannot be translated to the correct format, are marked as Invalid in the Organizer.

Chapter

3 *The Preference Manager*

The Preference Manager is used for setting up the default behavior of the SDL Suite tools, and the common tools.

This chapter is a reference to the Preference Manager; the functionality it provides, its menus, windows and symbols and a description of the preference parameters.

For a guide to how to use the Preference Manager to customize the behavior, see chapter 4, *Managing Preferences*.

Preferences Manager User Interface

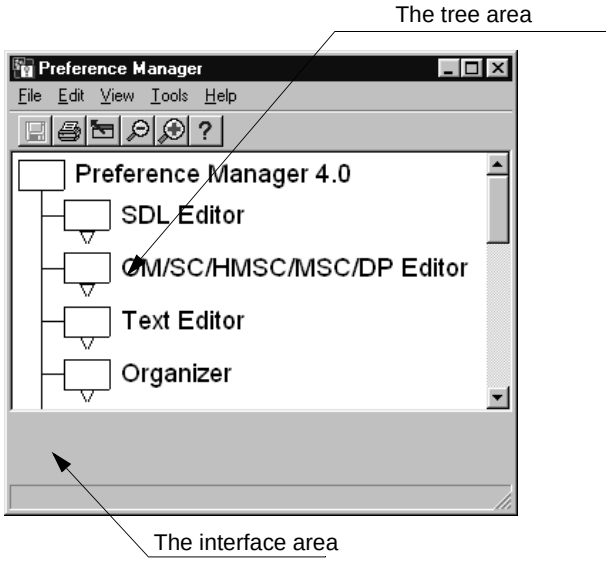

Figure 57: The Preference Manager window

The items that build up the Preferences Manager window are:

- The *Tree Area*
- The *The Interface Area*
- The *Menu Bar*

Tree Area

The *tree area* displays the tools that obey to the preference mechanism in the tools and their respective preference parameters. The notation uses a graphical approach featuring a tree with icons symbolizing the various items that are managed by the tool.

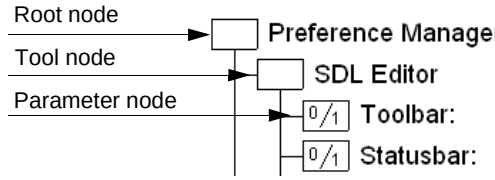

Figure 58: Node in the tree area

Node Syntax

Each node in the tree represents either a:

- *root node*

  The root node is identified by the name Preference Manager, followed by a version number.

- *tool node*

  A tool node is identified by the name of a tool.

> **Note:**
> The Preference Manager only supports the SDL Suite tools, and the common tools. See chapter 29, *Customizing the TTCN Suite (on UNIX)*, for information about how to customize the TTCN Suite **on UNIX**.

- *parameter node*

  Each parameter node in the tree is identified with an icon showing:

  – the *name* of the parameter

  – the *current value* for the parameter

  – the *saved value* and the *default value* within one or two parentheses: `(( ))`

  – the *Preference Source* within brackets, `[]`, i.e. whether it is a *company* or *project* or *user-defined* setting

  – a *descriptive text* providing additional information about the preference parameter.

Example 13: A Line in the Preferences Window ––––––––––––––––––

Given the following line in the Preferences window, with all *View Options* turned “on”:

Figure 59: A line in the Preferences window

The information on the line in Figure 59 should be interpreted as:

Item	Interpretation
	The *icon* informing that the preference parameter is a boolean parameter (0/1, false/true or off/on parameter.
`Editor*SymbolMenu`	The *name* of the preference parameter, consisting of • the name of the tool it affects, `Editor` • the name of the parameter, `SymbolMenu` Separated with an asterisk
`off`	The *current value* for the parameter.
`(off)`	The *saved value* for the parameter.
`((on))`	The *default value* for the parameter.
`[User]`	The parameter’s *source*, in this case the parameter is defined by the user.
`Show the symbol menu`	The parameter’s *description*, i.e. what tool property the parameter affects.

––

The tree is a visualization of the merged preference parameters, supplied from different sources (see “Search Order When Reading Preference Parameters” on page 238), as the tools will perceive them. Furthermore, each node in the tree can be collapsed or expanded (see “Collapse” on page 229) in order to reduce or extend the amount of information that is visible, thus facilitating the work with the tool. It is

also possible to filter the information that is displayed with respect to various view options (see "View Options" on page 230).

Dirty Notification

When a preference parameter is modified but not saved, this is indicated by the icon appearance changing from a light color to a gray pattern. The parent *tool node* and the *root node* are also marked as dirty when any parameter is changed.

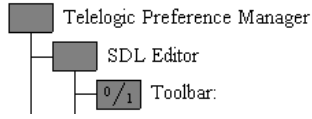

Figure 60: Nodes marked as dirty

The Interface Area

The interface section located under the tree view is where values are edited in an *Edit Area*. The type of *Edit Area* varies with the type of value selected.

There are different types of preference parameters:

- *Textual Preference*
- *Option Menu Preference*
- *Option Menu Textual Preference*
- *Font Preference (Windows only)*
- *Boolean Preference*
- *Ranged Integer Preference*
- *File Preference*
- *Directory Preference*
- *Color Menu Preference*

Icon	Edit Area
T	.bld Textual Preference – The preference parameter is edited as a text string.

Icon	Edit Area
{x,y}	 Option Menu Preference – The preference parameter may be selected from a number of predefined values in the option menu.[a]
E	**On UNIX:**  **In Windows:**  Option Menu Textual Preference – The preference parameter may be selected from a number of predefined values in the option menu.[a] An alternative is to type in the value into the text field, which grants access to not predefined values.

Icon	Edit Area
F	 Font Preference **(Windows only)** – The font must be selected by clicking the folder button, which opens a Microsoft Windows Font dialog. It is not possible to edit the text field to the left of the folder button. – In the dialog, all fonts in the system are listed. It is also possible to select font style and size, but these values have no effect; only the specified font name is used. – Any font name can be entered by editing the *Font* text field in the font dialog. This possibility is useful when setting a font for printing that is not available in the system, but exists on the printer. – The three font names “Times”, “Helvetica” and “Courier” are recognized. These are translated into the TrueType fonts Times New Roman, Arial and Courier New, respectively. – When using other fonts than the three mentioned above for printing, the preference Print*Destination-Format should be set to *MSWPrint* to get the best result for symbols that are adjusted to the text size.
0/1	 Boolean Preference – The value is changed by clicking the corresponding radio button.
[a..b]	 Ranged Integer Preference – The preference parameter may be assigned any integer value within the range supported by the slide bar.

Icon	Edit Area
	 File Preference – The preference parameter may be assigned any file name, entered as a text string into the text field or selected in a dialog issued by the folder button. Directory Preference – The preference parameter may be assigned any directory name, entered as a text string into the text field or selected in a dialog issued by the folder button.
	 Color Menu Preference – The preference parameter may be selected from a number of predefined values in the option menu.

a. When the mouse pointer is moved over a value in the option menu, a short description of the value is printed in the status bar. Values whose description starts with “(UNIX only)” or “(Windows only)” should only be selected on a UNIX system or a Windows system, respectively.

Selecting a parameter and editing its value with the provided UI device changes its value. The parameter’s icon is set as dirty (see “Dirty Notification” on page 221).

Menu Bar

The menu bar contains the following menus:

- *File Menu*
- *Edit Menu*
- *View Menu*
- *Tools Menu*
- *Help Menu*

File Menu

The *File* menu contains the following menu choices:

- *Save*
- *Revert*
- *Print*
  (see "The Print Dialogs in the SDL Suite and in the Organizer" on page 316 in chapter 5, *Printing Documents and Diagrams*)
- *Info*
- *Exit*
  (see "Exit" on page 15 in chapter 1, *User Interface and Basic Operations*)

Save

This menu choice saves the parameters that have been modified in the *User's Preference File*, **on UNIX** in `$HOME/.sdtpref`, and **in Windows** in `%HOME%\sdt.ini`

But, before saving the preference settings, the user will be warned if there are modified preferences that are defined as company or project preferences:

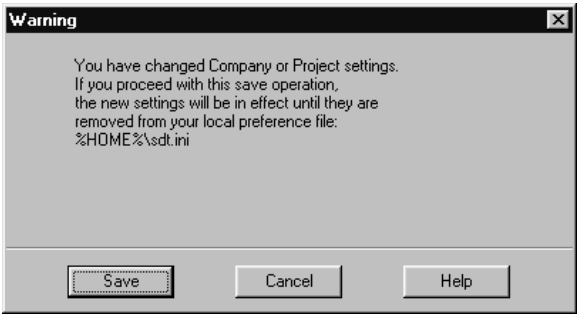

Figure 61: Attempting to save a modified project or organization parameter

- Clicking *Save* saves **all** modified preference parameters on the *User's Preference File*, which may implicate a violation of the rules set up in the project!

Caution!

Consider the implications before you click *Save*.

When the save has been performed the user will be warned that changes will not be in effect before the tools have been restarted.

Revert

The menu choice reverts all preference parameters to the currently *saved values*, as they were defined when starting the Preference Manager. The *Revert* command requires to be confirmed, in case any preference parameters are modified and have not been saved:

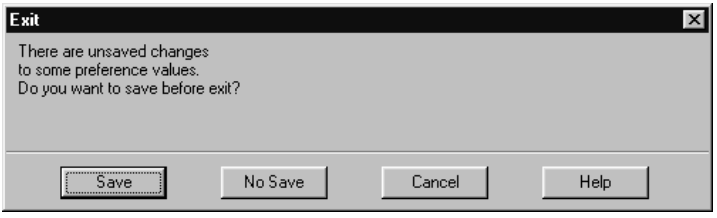

Figure 62: The Confirm to Revert dialog

Info

This menu choice issues a message with information about the preference source for the preference parameters.

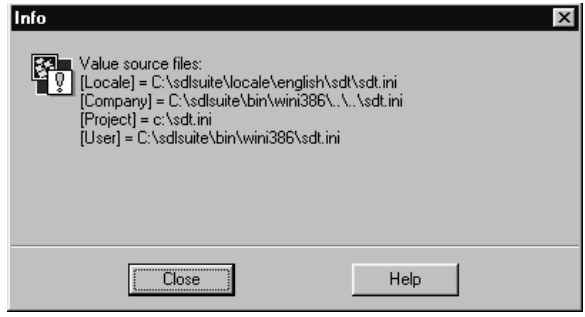

Figure 63: Information about preference sources

The message shows four items:

- `[Locale] - <file specifier>`
  The location of the locale preference file
- `[Company] - <file specifier>`
  The location of the company / organization preference file
- `[Project] - <file specifier>`
  The location of the project preference file
- `[User] - <file specifier>`
  The location of the user's preference file.

See "Preference Files" on page 235 for more information on preference files and search order.

Edit Menu

The *Edit* menu contains the following menu choices:

- *Set Saved Value*
- *Set Default Value*
- *Unsave*

Set Saved Value

This command restores the selected parameter to its currently *saved* value. The menu choice is also available from the pop-up menu.

Set Default Value

This command restores the selected parameter to its *default* value (i.e. factory setting). The menu choice is also available from the pop-up menu.

Unsave

This command allows to remove a preference parameter from the *User's Preference File* when saving the file, i.e. *Unsave* it. The command is available on user-defined parameters only; user-defined parameters are shown with their *Value Sources* set to [User].

A dialog is displayed following invocation of the command:

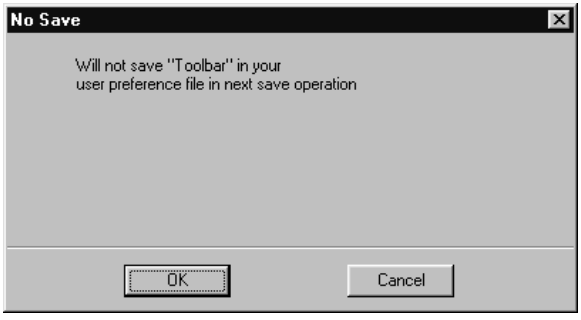

Figure 64: The Unsave dialog

- Clicking *OK*, the parameter's source changes to [User (No Save)]. The preference parameter will be removed from the user's prefer-

ence **after the next** *Save* command, changing its source to [Project] or [Company].

View Menu

The *View* menu contains the following menu choices:

- *Expand*
- *Expand All*
- *Collapse*
- *Collapse All*
- *View Options*
- *Set Scale*

Expand

This menu choice is available only if the currently selected object is a *tool node*. The command expands the subtree starting from the selected tool, making all parameters for that tool visible.

The operation is also available from the pop-up menu and with a double-click.

Expand All

This command expands the entire tree, thus making all parameter nodes visible.

The operation is also available from the pop-up menu.

Collapse

This menu choice is available only if the currently selected object is a *tool node*. The command collapses the parameter nodes belonging to the current tool, leaving only the tool node visible in the subtree.

The operation is also available from the pop-up menu and with a double-click.

Collapse All

This menu choice collapses all *tool node*s and hides the *parameter node*s. Only the *root node* and the *tool node*s are left visible.

The operation is also available from the pop-up menu

View Options

This menu choice issues a modeless dialog, the View Options dialog:

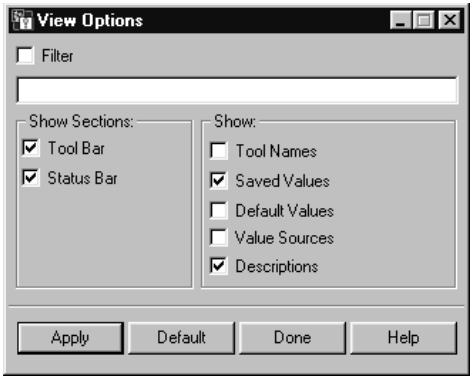

Figure 65: The View Options dialog

The dialog contains the following toggle buttons:

- A *Tool Bar* button
- A *Status Bar* button
- A *Filter Field and Filter Button*
- A *Tool Names* button
- A *Saved Values* button
- A *Default Values* button
- A *Value Sources* button
- A *Descriptions* button

Tool Bar

This button controls the presence of the quick buttons.

The tool bar is visible by default.

Status Bar

This option determines whether the *Status Bar* should be visible or not.

The status bar is by default visible.

Filter Field and Filter Button

If the *Filter Button* is on, the *Tree Area* will only show the preference parameters which name contain the text string that is entered in the *Filter Field*.

> **Note:**
>
> The name of a preference parameter consists of a combination of a tool name and of the parameter itself (see "Syntax of Preference Files" on page 237).
>
> The filter option compares the text strings without respect to upper or lower case characters.

By default, no filtering is applied.

Tool Names

This option controls whether the prefix in preference parameters (consisting of the tool name and of an asterisk) should be displayed or not (see "Syntax of Preference Files" on page 237).

Tool names are not displayed by default.

Saved Values

This option determines whether the *saved values* should be made visible or not. The saved values are the values that are currently stored on the preference files.

Saved values are displayed within one level of parentheses *(saved value)*. See Example 13 on page 220.

Saved values are displayed by default.

Default Values

This option determines whether the *default values* (i.e. factory settings) should be made visible or not.

Default values are displayed within two levels of parentheses *((default value))*. See Example 13 on page 220.

Default values are not displayed by default.

Value Sources

This option determines whether the *Preference Source* for the parameters should be displayed or not. A preference parameter may be retrieved from any of the following sources:

- The *company settings*
- The *project settings*
- The *user's own settings*

Source values are displayed within brackets [] and are not visible by default.

Descriptions

This option determines whether an informative text should be displayed or not. The text is purely informational and provides an additional description of the function of the preference parameter. See Example 13 on page 220.

Parameter descriptions are not displayed by default.

Set Scale

This menu choice opens a dialog where you may set the scale used in the preferences window. The scale may be set between 20% and 800%. 100% is the default.

Tools Menu

The *Tools* menu contains one menu choice:

- *Show Organizer*
  (see "Show Organizer" on page 15 in chapter 1, *User Interface and Basic Operations*)

Popup Menu

The contents of the popup menu depends on which node you click on.

On the Root Node

Collapse All	See “Collapse All” on page 229.
Expand All	See “Expand All” on page 229.

On a Tool Node

Collapse	See “Collapse” on page 229.
Expand	See “Expand” on page 229.

On a Value Node

Set Saved Value	See “Set Saved Value” on page 228.
Set Default Value	See “Set Default Value” on page 228.
Help	Request on-line help for the preference parameter in question.

Keyboard Accelerators

Apart from the general keyboard accelerators, as described in "Keyboard Accelerators" on page 35 in chapter 1, *User Interface and Basic Operations*, the following accelerators can be used in the References window:

Accelerator	Operation
`Arrow Up`	Move selection up among the expanded nodes
`Arrow Down`	Move selection down among the expanded nodes
`Page Up`	Scroll up
`Page Down`	Scroll down
`Home`	Scroll left
`End`	Scroll right
`Ctrl+Home`	Display first line
`Ctrl+End`	Display last line
`Space or Return`	Expand or collapse a node. Traverse through option menu. Toggle parameters on/off.
`F2`	Raise the pop-up menu.

Preference Files

All of the preference parameters along with their values (exception made for the default settings which are programmed into the tools) are stored on dedicated files, the *preference files*. The preference files may be edited with any text editor since the information is stored in textual form.

The Preference Manager manages these files and provides a graphical user support for customizing tools in an easy way.

> **Note:**
>
> The TTCN Suite cannot be customized by preferences. Instead, see chapter 29, *Customizing the TTCN Suite (on UNIX)*.

Preference Source

The following files build up the preference environment:

- The *Locale Preference File*
- The *User's Preference File*
- The *Project Preference File*
- The *Company Preference File*

The following items constitute the various sources for preference parameters. The source identifier may be made visible with the *Value Sources* options in the *View Options* dialog.

Source Identifier	Source Description
`[User]`	The *User's Preference File*
`[User (No Save)]`	The *User's Preference File*, will be removed from the user's preference file next time the parameters are saved
`[Project]`	The *Project Preference File*
`[Company]`	The *Company Preference File*
`[Locale]`	The *Locale Preference File*
`[Default]`	The default *Factory Settings*.

User's Preference File

This file stores the preferences parameters that a user has modified. The file is created / updated as a result of the *Save* command.

The user's preference file is identified **on UNIX** by:

```
$HOME/.sdtpref
```

and **in Windows** by:

```
%HOME%\sdt.ini
```

Note: $HOME and %HOME%

On UNIX, `$HOME` is assumed always to be defined in the computer environment.

In Windows, if `%HOME%` is not set, the user's preferences will be stored in the directory from which SDL Suite and TTCN Suite is started.

Project Preference File

This file stores the preference values that are to be applied to a specific instance of a project where the SDL Suite is used.

The project preference file is identified **on UNIX** by:

```
$SDTPREF/.sdtpref
```

and **in Windows** by:

```
%SDTPREF%\sdt.ini
```

Note: $SDTPREF and %SDTPREF%

`If $SDTPREF` **(on UNIX)** or `%SDTPREF%` **(in Windows)** is not set, the project preference file feature will be disabled. In a multi-user environment, it is strongly recommended to use a directory resident on a network drive for the project preferences. All project members should have read access to this directory.

Company Preference File

This file stores the preference values that are common for an entire company or organization and therefore should be applied to all projects and users of SDL Suite and TTCN Suite.

The company preference file is identified **on UNIX** by:

```
$telelogic/.sdtpref
```

and **in Windows** by:

```
<Installation directory>\sdt.ini
```

> **Note:**
>
> **On UNIX**, `$telelogic` is assumed always to be set in the environment.
>
> **In Windows**, to function properly (in the sense of being unique) in a multi-user environment, the company preference file should be stored on a directory on a network drive, e.g. if SDL Suite is installed on a network. Also, all users should have read access to the company preference file.

Locale Preference File

This file stores the preference values that are locale dependent and should therefore be applied to all projects and users of the SDL Suite tool.

Factory Settings

These are the settings that are defined by default in the SDL Suite and TTCN Suite tools. The factory settings will be used whenever a preference parameter could not be found in the *Preference Files*.

Syntax of Preference Files

A line in the preference file contains two items:

1. The first item specifies a tool and a parameter, separated by an asterisk.
2. The second item specifies the current value that is to be assigned to that parameter when starting up the tool.

The syntax is:

```
tool*parameter: value
```

Example 14: A Line in Preferences File ––––––––––––––––––––––

An example line in a preferences file could look like this:

```
Print*Scale:100
```
Meaning that the scale when printing is 100%.

The order of appearance of the parameters in a file is of no significance.

Search Order When Reading Preference Parameters

This section discusses how the tools read the preference parameters.

When a tool starts, it will automatically (i.e. no user-interaction is required) retrieve the preference values **in an incremental way**, following the order of search described below and illustrated in Figure 66 and Figure 67:

1. First, fallback values (default factory settings) are loaded, followed by the locale settings.
2. Then, if the environment variable `SDTPREF` is set:
   - If `$SDTPREF/.sdtpref` **(on UNIX)**, or `%SDTPREF%\sdt.ini` **(in Windows)** exists, that file is read **incrementally**[1] as the project preference file.
   - Otherwise, the tools will look for organization preferences in the installation directory, in the file designated by `$telelogic/.sdtpref` **(on UNIX)** or `<`*`Installation directory`*`>\sdt.ini` **(in Windows)**.
3. Finally, if the `HOME` environment variable is set, and `$HOME/.sdtpref` **(on UNIX)** or `%HOME%\sdt.ini` **(in Windows)** exists, that file is read **incrementally** as the user's preference file.
   - Otherwise, if `HOME` is not set, the preference file in the directory from which SDL Suite was started is read **incrementally** as the user's preference file.

The method above allows to configure a tool environment by defining some preferences as company-wide or project-wide, while allowing users to customize other preferences.

---

1. Incrementally in the sense that only parameters that are stored in the project preference file will override previous settings.

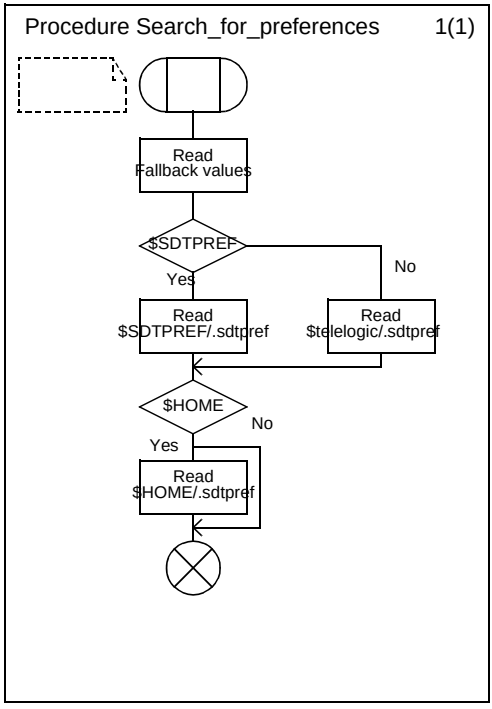

Figure 66:How the tool searches for preference parameters **(on UNIX)**

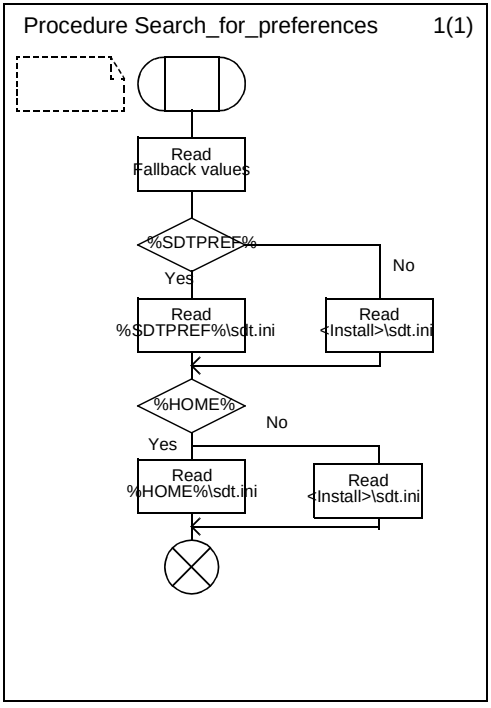

Figure 67: How the tool searches for preference parameters **(in Windows)**

Save of Preference Values

When a preference parameter is saved, it is always stored as a user-defined preference parameter in the user's preference file, i.e. `$HOME/.sdtpref` **(on UNIX)**, or `%HOME%\sdt.ini` **(in Windows)**, if `HOME` is set. If `HOME` is not set, the preference parameters are stored in a preference file in the directory from which SDL Suite was started.

The above implies that modifying a parameter that was originally defined as a project or organization parameter, the parameter will from now on be considered as a user-defined parameter. The user is however notified about this (see Figure 61 on page 226).

Preference Parameters

The following sections are a reference to the preference parameters in the tools with their default values and a description of what the parameter affects.

> **Note:**
>
> All preference parameters for the tools that are available on UNIX and in Windows are listed and described. This is to ensure compatible interchange of preferences between UNIX and Windows platforms, even if the preference parameter has no impact on one of the platforms. When this is the case, it is clearly noted.

For clarity reasons, the prefix that identifies the tool that the parameter applies to is specified once only, at the beginning of each tool section.

Preference parameters are grouped tool-wise. Within each tool section, parameters are listed in alphabetic order.

Where the parameter is specified with a numeric default value, the sort is specified within parentheses "()". Parameters whose value is specified as a text and which do not have any default value are identified as "". Possible values are not specified; the user should run the Preference Manager in order to obtain a reference to the permitted values.

The following preference groups exist:

The TTCN Suite tools cannot be customized by preferences. Instead, see chapter 29, *Customizing the TTCN Suite (on UNIX)*.

Common Preferences

These preferences apply to tools that are available in all SDL Suite and TTCN Suite tools.

Generic Preferences

Prefix: SDT*

Generic preferences may be used by tools that have not defined any specialization for these preferences.

Preference Parameter	Default	Affects
AllowSpaceInFileNames	off	Whether SDL Suite or TTCN Suite allows the user to add files with names containing spaces. The default setting of not allowing file names with spaces is set to ensure maximum compatibility with other tools that may be connected to SDL Suite and TTCN Suite. Unless you are using SDL Suite and TTCN Suite stand-alone, you should carefully consider if your environment can correctly support spaces in file names before enabling this feature.
CaseSensitive	off	Whether the SDL language should be case sensitive or not. It will effect the syntax check in the SDL Editor and the work of the Analyzer. The default setting is as SDL96, i.e. the language is not case sensitive. Also used as the default value for the Analyzer option *Case sensitive SDL* in the Organizer.

Preference Parameter	Default	Affects
CMIntegration	No integration	Specifies if SDL Suite and TTCN Suite are used together with an external configuration management tool. When set to *ClearCase*, the name of the view is shown in the Organizer window title.
Drives	""	The default contents of the The Drives Section in the system file for a newly created system.
EmacsCommand	"emacs"	The command used to start the Emacs text editor. **UNIX only**, see **Note: on page 241**.
FileNameCompletion	on	Whether file name completion is invoked by a completion character.
FileNameCompletionChar	""	The character that invokes file name completion.
FunctionFrequencyLogFile	""	File to save tool usage statistics on; see FunctionFrequencyLogging. In addition, tool usage statistics is also saved to a file `sdtfreq.log` in the installation directory.
FunctionFrequencyLogging	on	Whether to collect statistics on the usage of menu commands, quick buttons and accelerators. The tools that support collecting statistics are: • the Organizer • the SDL Editor • the OM Editor
ISpellCommand	"type %1 | ispell -w "_" -f %2 -a"	Template for the command used to communicate with ispell spelling checker.

Preference Parameter	Default	Affects
LicenseTimeout	0	The time interval (in hours) an interactive SDL Suite and TTCN Suite user is allowed to remain idle before licenses are automatically released. Setting this value to 0 disables the automatic release of licenses.
PrintFontFamily	“Times”	The font face to use when printing text.
RelativeSDTREF	off	If file names in SDT references should be expressed as relative to source directory or not.
Scale	100 (%)	The scale to use when displaying on screen.
ScreenFontFamily	“Helvetica”	The font face to use when displaying text on screen.
SearchUnderscoreAware	on	Decides if the search operation should find “a_ b” when searching for “ab” in SDL diagrams and MSCs.
Sound	on	The emission of an alert sound (beep) when performing an illegal operation.
StartInformationServer	on	If an Information Server should be allowed to start or not.
TextEditor	Telelogic	The text editor to use when editing text documents.
UseLowerCaseInFileNames	off	If turned on, saved diagram names are converted to lower case to provide UNIX/DOS file name compatibility. Activating this preference can lead to problems when accessing existing files with names containing non-lowercase letters.

Preference Parameter	Default	Affects
WordCommand	“Winword.exe”	The command used to start Microsoft Word. **Windows only**, see Note: on page 241.
TextWindowFontFamily	Courier New	The font used in text windows. **Windows only**, see Note: on page 241.
TextWindowFontHeigth	10	The size of the font used in text windows. **Windows only**, see Note: on page 241.
UserInterfaceFontFamily	MS Sans Serif	The font used in the user interface. **Windows only**, see Note: on page 241.
UserInterfaceFontHeight	9	The size of the font used in the user interface. **Windows only**, see Note: on page 241.
SimulatorExplorerFont-Family	Arial	The font used in the SDL Simulator and SDL Explorer user interface. **Windows only**, see Note: on page 241
SimulatorExplorer-FontHeight	11	The size of the font used in the SDL Simulator and SDL Explorer user interface. **Windows only**, see Note: on page 241.
TabSize	2	Number of spaces inserted when the TAB key is pressed in a text area. **Windows only**.

Organizer Preferences

Organizer Pack Preferences

Prefix: Organizer*Pack. For more information about the pack operation, see "Pack Archive" on page 66 in chapter 2, *The Organizer*.

Preference Parameter	Default	Affects
TarCommand	tar	The command used by the pack archive operation to access the tar utility. See "Additional required tools and utilities" on page 3 in chapter 1, *Platforms and Products*.
GzipCommand	gzip	The command used by the pack archive operation to access the gzip utility. See "Additional required tools and utilities" on page 3 in chapter 1, *Platforms and Products*.
ArchiveSdt	on	Decides if a system file adapted for the archive contents should be included.
OriginalSdt	off	Decides if the original system file should be included.
Packages	on	Decides if SDL package diagrams should be included.
OtherSDL	on	Decides if other SDL diagrams (system, block, process...) should be included.
MSC	on	Decides if MSC diagrams (MSC, HMSC) should be included.
UML	on	Decides if UML diagrams (object model, state chart, deployment) should be included.

Preference Parameter	Default	Affects
Chapter	on	Decides if chapters should be included.
Generic	off	Decides if files attached to the Organizer generic symbol should be included.
Tau	off	Decides if files attached to the Organizer Tau documents symbol should be included.
Rhapsody	off	Decides if files attached to the Organizer Rhapsody documents symbol should be included.
SimScript	off	Decides if simulator scripts (*.cui and *.com files attached to a plain text symbol) should be included.
OtherText	on	Decides if other text documents (not simulator scripts) should be included.
Scu	off	Decides if configuration unit files (*.scu) should be included.
Index	on	Decides if index files (*.xrf) should be included.
Header	on	Decides if header and footer files should be included.
Extensions	lst	Files in source or target directory with the extensions specified here (space separated) are included.

Other Organizer Preferences

Prefix: Organizer*

Preference Parameter	Default	Affects
AbsolutePath	off	If file names should be specified with an absolute directory path or not. See "Set Directories" on page 71 in chapter 2, *The Organizer*.
AllowImplicitTypeConv	off	The default value for the Analyzer option *Allow implicit type conversion*.
AllPreferences	off	If all preferences or if only the "diff" between current Organizer options and Organizer start-up options should be written as options in the system file. See "Options in the System File" on page 193 in chapter 2, *The Organizer*.
Areas	"Analysis Model,Used Files,SDL System Structure,TTCN Test Specification,Other Documents"	The names of the chapters in the Organizer's drawing area, separated by commas. The default is known as the *basic Organizer view*.
ASN1KeywordFileName	""	The default value for the Analyzer option *ASN.1 keyword substitution file*.
ASN1Suffix	".asn"	File name extension used to recognize ASN.1 files.
AutoCMUpdate	off	If this preference is on, then a configuration update operation will be done each time a system file is loaded in the Organizer. The system file will be updated with *.scu file information.

Preference Parameter	Default	Affects
AutoSaveBefore	off	If modified diagrams should be saved on file without user confirmation when selecting any of the commands *Analyze*, *Make*, *SDL Overview* and *Convert to PR/MP*.
BuildScript	".bld"	File name extension used for build script files.
Capitalisation	AsDefined	The default value for the code generation option *Capitalization*.
ChangeBars	off	If change bars should be created when SDL diagrams are edited.
ClearLog	on	Clear text in Organizer Log before running the Analyzer.
CoderBufferInSDL	"None"	The default value for the encoding used for ASN.1 Buffer in SDL (see *ASN.1 encode/decode parameter*).
CompileAndLink	on	The default value for the code generation option *Compile & link*.
DefaultCompiler	**On UNIX:** gcc **On Windows:** Microsoft	The default compiler to be used.
DefaultSimulator	"SCTADEBCOM"	The default value for the compile and link option *Standard kernel* when generating a simulator.
DefaultExplorer	"SCTAVALIDATOR"	The default value for the link option *Standard kernel* when generating an SDL Explorer.

Preference Parameter	Default	Affects
EchoAnalyzerCommands	off	The default value for the Analyzer option *Echo Analyzer commands*.
ErrorLimit	30	The default value of the Analyze parameter *Error limit*.
ExpandPR	off	The value of the Convert to PR option *Expand included PR files*.
ExpressionLimit	0	The value of the Analyze parameter *Log expressions deeper than*.
FileNamePrefix	“”	The default value for the code generation option *File name prefix*.
FilterCommand	“”	*Filter command* to invoke before Analyzer stages.
GenerateASN1Coder	off	The default value for the code generation option *Generate ASN.1 coder*.
GenerateCode	on	The default value for the code generation option *Analyze & generate code*.
GenerateEnvFunctions	off	The default value for the code generation option *Generate environment functions*.
GenerateEnvHeader	off	The default value for the code generation option *Generate environment header file*.
GeneratePrefixedNames	off	The default value for the code generator option *Generate prefixed names in ifc file*. Note: This preference is not recognized by Targeting Expert.

Preference Parameter	Default	Affects
GenerateSDLCoder	off	The default value for the code generation option *Generate SDL coder*.
GenerateSignalNumbers	off	The default value for the code generation option *Generate signal number file*.
GenericCommand	**On UNIX:** ".txt "ls %f"" **In Windows:** ".txt "notepad %f""	A list of file extensions and the corresponding command to be performed when editing a generic document. See "Generic Document" on page 40 in chapter 2, *The Organizer*. If used on Windows with full path some extra escape characters must be inserted. As an example to use Microsoft Word as an application for documents with the .doc extension the preference must be set to " .doc "\"C:\\Program Files\\Microsoft Office\\Office10\\WinWord.exe\" %f" " Note that when specifying paths the path delimiter must be entered twice, also if the path contains spaces the path must be enclosed by the \" characters. You can use a list of different file extensions and applications. An example is " .txt "notepad %f" .fm "c:\\frame\\frame.exe %f" .doc "\"c:*path with space*\\ww.exe\" %f" ".
HeaderFileSuffix	".h"	File name extension used to recognize C/C++ header files.

Preference Parameter	Default	Affects
IncludeSdtRef	on	Include SDT References when generating code from SDL.
IDLSuffix	**UNIX only:** .idl	File suffix used for IDL files.
IgnoreHidden	on	Ignore hidden symbols during analyze.
IncludeOptionalFields	off	The default value for the Analyze option *Include optional fields in make operator*.
Kernel	“SCTADEBCOM”	The default value for the compile and link option *Standard kernel*.
LicenseInfo	on	If this preference is on, when failing to get a license during start-up, then information about license holders and number of available licenses is presented in the command line window.
LogFilter		What Analyzer messages are shown in the log window.
LogNavigationLevel	Error	The navigation between messages in the log window.
MacroExpansion	off	The default value for the Analyze option *Macro expansion*.
MakefileMode	Generate	The default value for which option to select from the compile and link options • *Generate makefile* • *Generate makefile and use template* • *Use makefile*

Preference Parameter	Default	Affects
MissingAnswerValues-Control	on	The default value for the Analyze option *Check missing answer values*
MissingElseControl	on	The default value for the Analyze option *Check missing else answers*
ParameterMismatchControl	on	The default value for the Analyze option *Check parameter mismatch*
ExternalTypeFreeControl	on	The default value for the Analyze option *External types should call GenericFree*
MoveWindow	off	The size and position of the Organizer window when a system file is opened. That is, if the size and position will be the same as when that system file was last saved.
OptionalParamControl	on	The default value for the Analyze option *Check optional parameters*.
OutputControl	on	The default value for the Analyze option *Check output semantics*.
PathLineLength	0	How many characters that a file or directory may be, before being split into several lines in the Organizer window. 0 = no limit.
PrefixType	Full	The default value for the code generation option *Prefix*.
QBAddExisting	Hide	The presence of the *Add Existing* quick button.

Preference Parameter	Default	Affects
QBAddNew	Space & Show	The presence of the *Add New* quick button.
QBAnalyze	Space & Show	The presence of the *Analyze* quick button.
QBGenerateSim	Space & Show	The presence of the *Simulate* quick button.
QBGenerateVal	Show	The presence of the *Explore* quick button.
QBGenerateView	Show	The presence of the *Generate SDL Overview* quick button.
QBHelp	Space & Show	The presence of the *Help* quick button.
QBLog	Space & Show	The presence of the *Organizer Log* quick button.
QBLogAnalyze	Space & Show	The presence of the Organizer Log *Analyze* quick button.
QBLogClear	Show	The presence of the Organizer Log *Clear Log* quick button.
QBLogClose	Space & Show	The presence of the Organizer Log *Close* quick button.
QBLogErrorHelp	Show	The presence of the Organizer Log *Help on Error* quick button.
QBLogHelp	Space & Show	The presence of the Organizer Log *Help* quick button.
QBLogMoveDown	Space & Show	The presence of the Organizer Move Down quick button.
QBLogMoveUp	Show	The presence of the Organizer Move Up quick button.
QBLogSave	Show	The presence of the Organizer Log *Save* quick button.

Preference Parameter	Default	Affects
QBLogShowError	Space & Show	The presence of the Organizer Log *Show Error* quick button.
QBLogShowOrganizer	Space & Show	The presence of the Organizer Log *Show Organizer* quick button.
QBMake	Show	The presence of the *Make* quick button.
QBMoveDown	Show	The presence of the *Move Down* quick button.
QBMoveUp	Show	The presence of the *Move Up* quick button.
QBNew	Hide	The presence of the *New* quick button.
QBOpen	Show	The presence of the *Open* quick button.
QBPrint	Space & Show	The presence of the *Print* quick button.
QBSave	Show	The presence of the *Save* quick button.
QBSearch	Space & Show	The presence of the *Search* quick button.
QBTogglePages	Show	The presence of the Show Pages quick button.
QBXref	Show	The presence of the *Generate Cross References* quick button.
QBZoomIn	Show	The presence of the *Increase Scale* quick button.
QBZoomOut	Space & Show	The presence of the *Decrease Scale* quick button.
ReferenceControl	on	The default value for Analyze option *Check references*.

Preference Parameter	Default	Affects
SDLPRFileSuffix	.pr	File suffix used for SDL PR files.
SemanticControl	on	The default value for Analyze option *Semantic analysis*.
Separation	No	The default value for the code generation option *Separation*.
ShowAddExisting	on	If an existing document should be opened in an editor when added.
ShowDashed	on	The default value for the view option *Dashed diagrams*.
ShowDependencies	on	The default value for the view option *Dependency symbols*.
ShowDirectories	off	The default value for the view option *File directories*.
ShowFileName	on	The default value for the view option *File names*.
ShowFooter	off	The default value for the view option *Footer file*.
ShowGroups	on	The default value for the view option *CM Groups*.
ShowHeader	off	The default value for the view option *Header file*.
ShowInstances	on	The default value for the view option *Instance diagrams*.
ShowLinkFile	off	The default value for the view option *Link file*.
ShowLinks	on	The default value for the view option *Association symbols*.

Preference Parameter	Default	Affects
ShowLogLevel	Warning	Under which circumstances the Organizer Log Window should be raised automatically. This preference is also used by Targeting Expert to avoid the popup message when an Analyzer warning or error is found, see "Configure how to Make the Component" on page 2948 in chapter 59, *The Targeting Expert*.
ShowLongMenus	on	The default value for the view options *Long* / *Short*.
ShowPages	off	The default value for the view option *Page symbols*.
ShowPermissions	on	The default value for the view option *File access permissions*.
ShowSeparators	on	The default value for the view option *Separator symbols*.
ShowSource	on	The default value for the view option *Source directory*.
ShowSystemFile	on	The default value for the view option *System file*.
ShowTarget	off	The default value for the view option *Target directory*.
ShowTypeName	off	The default value for the view option *Type names*.
ShowVirtuality	on	The default value for the view option *Virtuality*.
SourceDirectory	""	The default *Source directory* when creating a new system.

Preference Parameter	Default	Affects
StandardKernel	on	The default value for the compile and link option *Standard kernel*.
Statusbar	on	The default value for the view option *Status bar*.
SuppressLevel	5	The number of issued identical Organizer messages before they are suppressed in the Organizer Log window.
SyntaxControl	on	The default value for Analyze option *Syntactic analysis*.
TargetDirectory	""	The default *Target directory* when creating a new system.
TargetLanguage	Cbasic	The default value for the code generation option *Code generator*.
TerminateAnalyzer	off	The default value for the analysis option *Terminate Analyzer when done*.
Toolbar	on	The default value for the view option *Tool bar*.
TrailingParamControl	on	The default value for the Analyze option *Check trailing parameters*.
TreeRepresentation	List	The default value for the view options *Indented list* / *Vertical tree*.
UpperCase	off	The default value of the Convert to PR option *Write reserved words in* (off means lower case).

Preference Parameter	Default	Affects
UsageControl	on	The default value for Analyze option *Check unused definitions*.
UserKernel	""	The default value for the compile and link option *Use kernel in directory*.
UserMakefile	""	The default value for the compile and link option *Use makefile*.
UserTemplate	""	The default value for the compile and link option *Generate makefile and use template*.
WelcomeWindow	on	If a Welcome window should be displayed at start-up of the Organizer.
WordSuffix	".doc"	File name extension used to recognize Microsoft Word files. **Windows only**, see **Note: on page 241**.
XCodeGenerator	"X"	The name of the code generator that appears last in the option menu *Code generator* in the Analyze and generate code options. **UNIX only**, see **Note: on page 241**.
XRef	on	The default value for Analyze option *Generate a cross reference file*.

Help Viewer Preferences

Prefix: Help*

Preference Parameter	Default	Affects
HelpDirectory	""	What help root directory to use for on-line help files. Useful if the on-line help files is available on a network server. See "Configuring the Help Environment" on page 298 in chapter 4, *Managing Preferences* for more information.
HelpViewer	Firefox	The choice of help viewer. "Default Web Browser" (Firefox, Netscape or Internet Explorer) is the default choice **on Windows**.
FirefoxCommand	"firefox"	What command the tools use when starting the help viewer when the preference parameter *HelpViewer* is specified as Firefox.
NetscapeCommand	"netscape"	What command the tools use when starting the help viewer when the preference parameter *HelpViewer* is specified as Netscape.
InternetExplorerCommand	"iexplorer"	What command the tools use when starting the help viewer when the preference parameter *HelpViewer* is specified as Internet Explorer. This is useful on the UNIX platform when the Internet Explorer is not available via your PATH variable.

Preference Manager Preferences

Prefix: Preference*

Preference Parameter	Default	Affects
Statusbar	on	The presence of a status bar in the window.

Preference Parameter	Default	Affects
Toolbar	on	The presence of a tool bar in the window.

Print Preferences

Prefix: Print*

Preference Parameter	Default	Affects
BackwardReferences	on	Print backward paper page references in diagrams.
BlackAndWhite	off	The color used when printing symbols and lines.
DateType	ISO	The date format in printouts.
DestinationFormat	PSFile	The default *Format* option in the Print dialog.
FooterFile	off	The default value for the option *Footer file* in the Print dialog.
ForwardReferences	on	Print forward paper page references in diagrams.
Frame*PaperFormat	USLetter	The default value for the paper format used when printing to FrameMaker, Interleaf or EPS.
Frame*UserDefined-Width	210	The default value for the paper width when the Frame*PaperFormat preference is set to UserDefined.
Frame*UserDefined-Height	297	The default value for the paper height when the Frame*PaperFormat preference is set to UserDefined.
Frame*MarginUpper	25	The default value for the upper margin when printing to FrameMaker, Interleaf or EPS.
Frame*MarginLower	35	The default value for the lower margin when printing to FrameMaker, Interleaf or EPS
Frame*MarginLeft	25	The default value for the left margin when printing to FrameMaker, Interleaf or EPS

Preference Parameter	Default	Affects
Frame*MarginRight	27	The default value for the right margin when printing to FrameMaker, Interleaf or EPS
FrameMakerCommand	“maker”	The default *Execute* command in the Print dialog when *Format* is specified as *Import into FrameMaker*. **UNIX only**, see **Note: on page 241**.
HeaderFile	““	The default value for the option *Header file* in the Print dialog.
HeaderTextHeight	12 (pt)	The size of the font face used in headers and footers.
Landscape	off	The default value for the option *Orientation* in the Print dialog (off means landscape).
MarginLeft	10 (mm)	The default value for the parameter *Left margin* in the Print Margins dialog.
MarginLower	25 (mm)	The default value for the parameter *Lower margin* in the Print Margins dialog.
MaxPageReferences	20	Max number of page references at one place.
MarginRight	10 (mm)	The default value for the parameter *Right margin* in the Print Margins dialog.
MarginUpper	42 (mm)	The default value for the parameter *Upper margin* in the Print Margins dialog.
MaxTextLineLength	80	How long a line in a text file can be before it is divided/wrapped, resulting in several lines in the printout. A value of zero means no wrapping. Lines are usually divided at word boundaries.

Preference Parameter	Default	Affects
MinimumLineWidth	3 (1/10 pt)	The minimum thickness applied on lines in the printout.
OnlyChaptersInTOC	off	If only chapter symbols, or chapter symbols and diagrams and documents will be visible in the table of contents.
OrganizerView	on	The default value for the option *Organizer View* in the Organizer *Print* dialog.
PageMarkers	off	The default value for the option *Page markers* in the *Print* dialog.
PaperFormat	A4	The default value for the option *Paper format* in the *Print* dialog. The preference variable Print*PaperFormat will be set to USLetter by default during installation if the current local time is within GMT - 05:00 and GMT - 09:00. (English version only) This is done by setting the preference variable Print*PaperFormat within the file sdt.ini (Windows) or .sdtpref (UNIX) located in .../locale/english/sdt. To change this to default value A4, remove the file or use the Preference manager.
Poster	off	Print header (footer) for each logical page instead of for each physical page.
PrintChapter	on	Print text associated with chapter symbols.
PrintCollapsed	on	If collapsed texts from text, comment and text extension symbols are printed in full on a separate page or not.

Preference Parameter	Default	Affects
PrinterCommand	"lpr -h -r" (**In Windows**, the lpr command is available in the distribution.)	The default *Execute* command in the Print dialog when *Format* is specified as *One PostScript File*.
RemoveTempFiles	on	If temporary files should be removed after printing is done.
Scale	100 (%)	The default value for the parameter *Scale* in the Print dialog.
TableOfContents	off	The default value for the option *Table of Contents* in the Organizer *Print* dialog.
TextHeight	10 (mm)	The font size used when printing expanded text symbols.
ToCShowPages	off	The presence of page numbers in generated table of contents.
UserDefinedHeight	297 (mm)	The default value for the parameter *User paper height* in the Print Margins dialog.
UserDefinedWidth	210 (mm)	The default value for the parameter *User paper width* in the Print Margins dialog.
Word*ImageFormat	Normal.dot	The value for the *Image format (Windows Only)* used when printing to Word. When using Normal.dot, the image size will be calculated from the available print area in a new created Word document.
Word*UserDefined-Height	247 (mm)	The default value for the image height parameter in the Size dialog using the *User Defined size* option.
Word*UserDefined-Width	160 (mm)	The default value for the image height parameter in the Size dialog using the *User Defined size* option.

Text Editor Preferences

Prefix: TE*

Preference Parameter	Default	Affects
AlwaysNewWindow	off	If a new window should be opened or not when opening a text document.
PrintFontFamily	“Courier”	The font face used when printing text.
ShowLinks	on	If endpoints and links should be shown.
StateMatrixShowSelected	on	Decides if processes specified with StateMatrixFilter should be hidden or shown.
StateMatrixSortSignals	on	If signals in state matrices should be sorted.
StateMatrixSortStates	on	If states in state matrices should be sorted.
StateMatrixCalls	off	If a state matrix with procedure call transition information should be shown or not.
StateMatrixFilter	““	Which processes that state matrices will be generated for.
StateMatrixNextstates	on	If a state matrix with nextstate transition information should be shown or not.
StateMatrixOutputs	off	If a state matrix with output transition information should be shown or not.
StateMatrixPageNumbers	on	If a state matrix with page numbers as transition information should be shown or not.
Statusbar	on	The presence of a status bar in the window.
Toolbar	on	The presence of a tool bar in the window.
TextTemplateDirectory	““	Directory for common text file templates.

The SDL Suite Specific Preferences

These preferences are only available for the SDL Suite tools.

SDL Editor Preferences

Prefix: Editor*

The Beige color used has the RGB values: (255, 249, 242)

Preference Parameter	Default	Affects
AdditionalHeadingOnlyOn-FirstPage	off	If the Additional Heading symbol should be shown only on the first page.
AlwaysNewWindow	off	If a new window should be opened or not when opening an SDL diagram. See "Always new Window" on page 2018 in chapter 43, *Using the SDL Editor*.
BlockSubstructureSymbol*Use	on	If the symbol should be available in the symbol menu.
BlockSubstructureSymbol*Color	Black	The color of the symbol.
BlockSubstructureSymbol*Fill-Color	Beige	The fill color of the symbol.
BlockSymbol*Use	on	If the symbol should be available in the symbol menu.
BlockSymbol*Color	Black	The color of the symbol.
BlockSymbol*FillColor	Beige	The fill color of the symbol.
BlockTypeSymbol*Use	on	If the symbol should be available in the symbol menu.
BlockTypeSymbol*Color	Black	The color of the symbol.
BlockTypeSymbol*FillColor		The fill color of the symbol.
ChannelSubstructureSymbol*Use	on	If the symbol should be available in the symbol menu.

Preference Parameter	Default	Affects
ChannelSubstructureSymbol*Color	Black	The color of the symbol.
ChannelSubstructureSymbol*FillColor	Beige	The fill color of the symbol.
ClassSymbol*Use	on	If the symbol should be available in the symbol menu.
ClassSymbol*Color	Black	The color of the symbol.
ClassSymbol*FillColor	Beige	The fill color of the symbol.
CommentLeftSymbol*Use	off	If the symbol should be available in the symbol menu.
CommentLeftSymbol*Color	Black	The color of the symbol.
CommentLeftSymbol*FillColor	Beige	The fill color of the symbol.
CommentSymbol*Use	on	If the symbol should be available in the symbol menu.
CommentSymbol*Color	Black	The color of the symbol.
CommentSymbol*FillColor	Beige	The fill color of the symbol.
CompletionMaxPages	10	The maximum number of initial diagram pages searched by the word completion operation.
ConnectorSymbol*Use	on	If the symbol should be available in the symbol menu.
ConnectorSymbol*Color	Black	The color of the symbol.
ConnectorSymbol*FillColor	Beige	The fill color of the symbol.
ContinuousSignalSymbol*Use	on	If the symbol should be available in the symbol menu.
ContinuousSignalSymbol*Color	Black	The color of the symbol.
ContinuousSignalSymbol*FillColor	White	The fill color of the symbol.
CreateRequestSymbol*Use	on	If the symbol should be available in the symbol menu.

Preference Parameter	Default	Affects
CreateRequestSymbol*Color	Black	The color of the symbol.
CreateRequestSymbol*FillColor	Beige	The fill color of the symbol.
DecisionSymbol*Use	on	If the symbol should be available in the symbol menu.
DecisionSymbol*Color	Black	The color of the symbol.
DecisionSymbol*FillColor	Beige	The fill color of the symbol.
FontText*ScreenFontFamily	“Helvetica”	The font face to use when displaying text on screen.
FontText*PrintFontFamily	“Helvetica”	The font face used when printing text.
FontText*TextSymbolFontFamily	“Helvetica“	The font face to use when displaying text in text symbols on screen **and** in print.
FontText*TextHeight	9 (pt)	The height of text in symbols (except kernel heading symbols and page name symbols) on flow diagrams, and text symbols and signal list symbols on interaction diagrams.
FontText*NameTextHeight	12 (pt)	The height of text in kernel heading symbols, page name symbols and text objects on interaction diagrams (exception from text symbols and signal list symbols). See “Default Font Sizes” on page 1969 in chapter 43, *Using the SDL Editor*.
FontText*TaskSymbolLeftAligned	off	If the text in the task, procedure call, macro call, create request and save symbol should be left aligned.
FontText*MinimumTextUpdateDelay	0 (milliseconds)	The minimum time delay to update text in symbols.

Preference Parameter	Default	Affects
FontText*BlinkingTextCursor	on	If the text cursor (vertical bar) should blink in the drawing area.
GateSymbol*Use	on	If the symbol should be available in the symbol menu.
GateSymbol*Color	Black	The color of the symbol.
GlobalSymbolColor*Color	Black	The color of all symbols
GlobalSymbolColor*UseGlobal-Color	off	If the color for all symbols should be used.
GlobalSymbolColor*FillColor	White	The fill color of all symbols.
GlobalSymbolColor*UseGlobal-FillColor	off	If the fill color for all symbols should be used.
GrammarHelp	off	If the Grammar Help window is to be opened automatically at start-up.
InputLeftSymbol*Use	off	If the symbol should be displayed left-oriented or not.
InputLeftSymbol*Color	Black	The color of the symbol.
InputLeftSymbol*FillColor	Beige	The fill color of the symbol.
InputSymbol*Use	on	If the symbol should be available in the symbol menu.
InputSymbol*Color	Black	The color of the symbol.
InputSymbol*FillColor	Beige	The fill color of the symbol.
InteractionPage*GridHeight	5 (mm)	The vertical grid on interaction pages.
InteractionPage*GridWidth	5 (mm)	The horizontal grid on interaction pages.
InteractionPage*MarginLeft	15 (mm)	The distance between the The Frame and the left boundary of the drawing area.

Preference Parameter	Default	Affects
InteractionPage*MarginLower	15 (mm)	The distance between the The Frame and the lower boundary of the drawing area.
InteractionPage*MarginRight	15 (mm)	The distance between the The Frame and the right boundary of the drawing area.
InteractionPage*MarginUpper	15 (mm)	The distance between the The Frame and the upper boundary of the drawing area.
InteractionPage*SymbolHeight	20 (mm)	The default height of symbols on interaction diagrams.
InteractionPage*SymbolWidth	30 (mm)	The default width of symbols on interaction diagrams.
MacroCallSymbol*Use	on	If the symbol should be available in the symbol menu.
MacroCallSymbol*Color	Black	The color of the symbol.
MacroCallSymbol*FillColor	Beige	The fill color of the symbol.
MacroInletSymbol*Use	on	If the symbol should be available in the symbol menu.
MacroInletSymbol*Color	Black	The color of the symbol.
MacroInletSymbol*FillColor	Beige	The fill color of the symbol.
MacroOutletSymbol*Use	on	If the symbol should be available in the symbol menu.
MacroOutletSymbol*Color	Black	The color of the symbol.
MacroOutletSymbol*FillColor	Beige	The fill color of the symbol.
OperatorSymbol*Use	on	If the Operator reference symbol should be available or not in the symbol menu. (The symbol is an SDL Suite specific extension to Z.100.)
OperatorSymbol*Color	Black	The color of the symbol.

Preference Parameter	Default	Affects
OperatorSymbol*FillColor	Beige	The fill color of the symbol.
OutputLeftSymbol*Use	off	If the symbol should be displayed left-oriented or not.
OutputLeftSymbol*Color	Black	The color of the symbol.
OutputLeftSymbol*FillColor	Beige	The fill color of the symbol.
OutputSymbol*Use	on	If the symbol should be available in the symbol menu.
OutputSymbol*Color	Black	The color of the symbol.
OutputSymbol*FillColor	Beige	The fill color of the symbol.
Page*AutoNumber	on	If added SDL pages should be autonumbered (1, 2,... N). See "The Autonumbered Option" on page 2036 in chapter 43, *Using the SDL Editor*.
Page*Height	230 (mm)	The height of a new page.
Page*Width	190 (mm)	The width of a new page.
Page*EnumerationCharacter	_	When two pages are given the same name X, their default names will be X_1 and X_2. The character used for enumeration can be any of '_', '.', '#', '@', '$' or '|'.
PrintZ100Symbols	off	Printing SDL symbols with an appearance that complies to Z.100.
PriorityInputLeftSymbol*Use	off	If the symbol should be displayed left-oriented or not.
PriorityInputLeftSymbol*Color	Black	The color of the symbol.
PriorityInputLeftSymbol*FillColor	Beige	The fill color of the symbol.

Preference Parameter	Default	Affects
PriorityInputSymbol*Use	on	If the symbol should be available in the symbol menu.
PriorityInputSymbol*Color	Black	The color of the symbol.
PriorityInputSymbol*FillColor	Beige	The fill color of the symbol.
ProcedureCallSymbol*Use	on	If the symbol should be available in the symbol menu.
ProcedureCallSymbol*Color	Black	The color of the symbol.
ProcedureCallSymbol*FillColor	Beige	The fill color of the symbol.
ProcedureReturnSymbol*Use	on	If the symbol should be available in the symbol menu.
ProcedureReturnSymbol*Color	Black	The color of the symbol.
ProcedureReturnSymbol*FillCol-or	Beige	The fill color of the symbol.
ProcedureStartSymbol*Use	on	If the symbol should be available in the symbol menu.
ProcedureStartSymbol*Color	Black	The color of the symbol.
ProcedureStartSymbol*FillColor	Beige	The fill color of the symbol.
ProcedureSymbol*Use	on	If the symbol should be available in the symbol menu.
ProcedureSymbol*Color	Black	The color of the symbol.
ProcedureSymbol*FillColor	Beige	The fill color of the symbol.
ProcessPage*GridHeight	5 (mm)	The vertical grid on flow dia-grams.
ProcessPage*GridWidth	5 (mm)	The horizontal grid on flow dia-grams.
ProcessPage*MarginLeft	0 (mm)	The distance between the The Frame and the left boundary of the drawing area.

Preference Parameter	Default	Affects
ProcessPage*MarginLower	0 (mm)	The distance between the The Frame and the lower boundary of the drawing area.
ProcessPage*MarginRight	0 (mm)	The distance between the The Frame and the right boundary of the drawing area.
ProcessPage*MarginUpper	0 (mm)	The distance between the The Frame and the upper boundary of the drawing area.
ProcessPage*SymbolHeight	10 (mm)	The default height for symbols on flow pages. (The width / height relationship is fixed to 2:1.)
ProcessSymbol*Use	on	If the symbol should be available in the symbol menu.
ProcessSymbol*Color	Black	The color of the symbol.
ProcessSymbol*FillColor	Beige	The fill color of the symbol.
ProcessTypeSymbol*Use	on	If the symbol should be available in the symbol menu.
ProcessTypeSymbol*Color	Black	The color of the symbol.
ProcessTypeSymbol*FillColor	Beige	The fill color of the symbol.
SaveSymbol*Use	on	If the symbol should be available in the symbol menu.
SaveSymbol*Color	Black	The color of the symbol.
SaveSymbol*FillColor	Beige	The fill color of the symbol.
SDLTraceColor	yellow	The temporary background color to use for visited SDL symbols during SDL trace.
Scale	100 (%)	The scale when displaying a diagram on screen.

Preference Parameter	Default	Affects
ScreenZ100Symbols	off	Displaying SDL symbols on screen with an appearance that complies to Z.100.
ServiceSymbol*Use	on	If the symbol should be available in the symbol menu.
ServiceSymbol*Color	Black	The color of the symbol.
ServiceSymbol*FillColor	Beige	The fill color of the symbol.
ServiceTypeSymbol*Use	on	If the symbol should be available in the symbol menu.
ServiceTypeSymbol*Color	Black	The color of the symbol.
ServiceTypeSymbol*FillColor	Beige	The fill color of the symbol.
ShowGrid	off	If grid points should be shown on screen.
ShowLinks	on	If endpoints and links should be shown.
ShowPageBreaks	on	If printer page breaks should be visible or not on the screen.
ShowSignalDeclaration	on	If the signal declaration should be shown in the message area for a selected signal name.
SignalDictionary*Use	off	If a Signal Dictionary window should be opened automatically upon start of the SDL Editor.
SignalDictionary*All	off	If the Signal Dictionary option All should be enabled by default.
SignalDictionary*Down	on	If the Signal Dictionary option Down should be enabled by default.
SignalDictionary*External	off	If the Signal Dictionary option External should be enabled by default.

Preference Parameter	Default	Affects
SignalDictionary*MSC	off	If the Signal Dictionary option MSC should be enabled by default.
SignalDictionary*This	off	If the Signal Dictionary option This should be enabled by default.
SignalDictionary*Up	on	If the Signal Dictionary option Up should be enabled by default.
StartSymbol*Use	on	If the symbol should be available in the symbol menu.
StartSymbol*Color	Black	The color of the symbol.
StartSymbol*FillColor	Beige	The fill color of the symbol.
StateSymbol*Use	on	If the symbol should be available in the symbol menu.
StateSymbol*Color	Black	The color of the symbol.
StateSymbol*FillColor	Beige	The fill color of the symbol.
Statusbar	on	The presence of a status bar in the SDL Editor window.
StopSymbol*Use	on	If the symbol should be available in the symbol menu.
StopSymbol*Color	Black	The color of the symbol.
StopSymbol*FillColor	White	The fill color of the symbol.
SymbolMenu	on	The presence of a symbol menu in the SDL Editor window.
SyntaxCheck	on	Enables or disables the syntactic checking performed by the SDL Editor at editing time.
SystemTypeSymbol*Use	on	If the symbol should be available in the symbol menu.
SystemTypeSymbol*Color	Black	The color of the symbol.

Preference Parameter	Default	Affects
SystemTypeSymbol*FillColor	Beige	The fill color of the symbol.
TabEqualsCompletion	on	If the tab key invokes word completion or produces a tab character.
TaskSymbol*Use	on	If the symbol should be available in the symbol menu.
TaskSymbol*Color	Black	The color of the symbol.
TaskSymbol*FillColor	Beige	The fill color of the symbol.
TemplateFile	“sdt.tpl”	The name of the file containing the grammar templates used by the Grammar Help window.
TextExtensionLeftSymbol*Use	off	If the flipped text extension symbol should be available in the symbol menu.
TextExtensionLeftSymbol*Color	Black	The color of the flipped text extension symbol.
TextExtensionLeftSymbol*FillColor	Beige	The fill color of the flipped text extension symbol.
TextExtensionSymbol*Use	on	If the symbol should be available in the symbol menu.
TextExtensionSymbol*Color	Black	The color of the symbol.
TextExtensionSymbol*FillColor	Beige	The fill color of the symbol.
TextReferenceSymbol*Use	on	If the symbol should be available in the symbol menu.
TextReferenceSymbol*Color	Black	The color of the symbol.
TextReferenceSymbol*FillColor	Beige	The fill color of the symbol.
TextSymbol*Use	on	If the symbol should be available in the symbol menu.
TextSymbol*Color	Black	The color of the symbol.
TextSymbol*FillColor	Beige	The fill color of the symbol.

Preference Parameter	Default	Affects
TextWindow	on	The presence of a text window in the SDL Editor window.
TextualSyntaxCheck	on	Textual syntax check in symbols.
TidyUp*MaxCommentLine-Length	22	Maximum number of characters per line in comment symbols after tidy up
TidyUp*TransNewPage	on	Start each transition on a new page
TidyUp*ExtraSpace	on	Insert extra space after a symbol attached to a large comment or text extension, to avoid overlapping any comment or text extension attached to the next symbol.
TidyUp*FormatInputOutput	on	Format text in input and output symbols using newline characters and text extension symbols, to try to avoid text outside the symbol.
TidyUp*MakeCommentSymbols	on	Replace textual comments with comment symbols.
TidyUp*CommentsLeft	on	Place comment symbols to the left of the symbols that they are attached to.
TidyUp*SmartAutoLabels	on	Generate automatic names for all labels. The names are generated from the closest available state-name. If the preference is off the names for the already existing labels will be preserved and new generated labels will have names LblNNN.
TidyUp*NoStateExtension	on	Avoid attaching text extension symbols to state symbols.

Preference Parameter	Default	Affects
TidyUp*NoDecisionExtension	on	Avoid attaching text extension symbols to decision symbols.
TidyUp*SortStates	off	Sort states and transitions in alphabetical order.
Toolbar	on	The presence of a tool bar in the SDL Editor window.
TransitionOptionSymbol*Use	on	If the symbol should be available in the symbol menu.
TransitionOptionSymbol*Color	Black	The color of the symbol.
TransitionOptionSymbol*FillColor	Beige	The fill color of the symbol.

OM/SC/HMSC/MSC/DP Editor Preferences

Prefix: OME*

Preference Parameter	Default	Affects
AlwaysEndpointClass	on	If an endpoint should be automatically added on new class symbols.
AlwaysEndpointObject	off	If an endpoint should be automatically added on a new object symbol.
AlwaysNewWindow	off	If a new window should be opened or not when opening a diagram. See "Always new Window" on page 1677 in chapter 39, *Using Diagram Editors*.
AutoNumberPages	on	If added pages should be autonumbered (1, 2,... N). See "Autonumbered" on page 1681 in chapter 39, *Using Diagram Editors*.
BlinkingTextCursor	on	If the text cursor (vertical bar) should blink in the drawing area.
DPComponentSymbolColor	Black	The color of the symbol.
DPNodeSymbolColor	Black	The color of the symbol.
DPObjectSymbolColor	Black	The color of the symbol.
DPThreadSymbolColor	Black	The color of the symbol.
HMSCConditionSymbolColor	Black	The color of the symbol.
HMSCConnectionSymbolColor	Black	The color of the symbol.
HMSCReferenceSymbolColor	Black	The color of the symbol.
HMSCStartSymbolColor	Black	The color of the symbol.
HMSCStopSymbolColor	Black	The color of the symbol.
MinimumTextUpdateDelay	0 (milliseconds)	The minimum time delay to update text in symbols.

Preference Parameter	Default	Affects
MSCHorizontalSpacing	25 (mm)	The horizontal spacing unit between instances. See "Spacing" on page 1677 in chapter 39, *Using Diagram Editors*.
MSCInstanceRuler	on	The presence of an Instance Ruler in the MSC Editor window.
MSCPrintInstanceRuler	on	If an Instance Ruler should be included on the printed pages.
MSCVerticalSpacing	3 (mm)	The vertical spacing unit between instances. See "Spacing" on page 1677 in chapter 39, *Using Diagram Editors*.
NameTextHeight	12 (pt)	The height of text in names of symbols.
OMClassSymbolColor	Black	The color of the symbol.
OMObjectSymbolColor	Black	The color of the symbol.
PageHeight	230 (mm)	The height of a new page.
PageWidth	190 (mm)	The width of a new page.
PrintFontFamily	"Helvetica"	The font face used when printing text.
Scale	100 (%)	The scale when displaying a diagram on screen.
ScreenFontFamily	"Helvetica"	The font face to use when displaying text on screen.
SCStartSymbolColor	Black	The color of the symbol.
SCStateSymbolColor	Black	The color of the symbol.
SCStopSymbolColor	Black	The color of the symbol.
ShowGrid	off	If grid points should be shown on screen.
ShowInstanceComposition	on	If the Instance decomposition should be displayed.

Preference Parameter	Default	Affects
ShowInstanceKind	on	If the Instance kind should be displayed.
ShowInstanceName	on	If the Instance name should be displayed.
ShowLinks	on	If endpoints and links should be shown.
ShowMessageName	on	If the Message name should be displayed.
ShowMessageParameters	on	If the Message parameters should be displayed.
ShowPageBreaks	on	If printer page breaks should be visible or not on the screen.
Statusbar	on	The presence of a status bar in the editor window.
SymbolMenu	on	The presence of a symbol menu in the editor window.
TextHeight	9 (pt)	The height of text in symbols (except heading symbols and page name symbols) and line attributes, except for names of symbols.
TextSymbolColor	Black	The color of the symbol.
TextWindow	on	The presence of a text window in the editor window.
Toolbar	on	The presence of a tool bar in the editor window.

Index Viewer Preferences

Prefix: Index*

Preference Parameter	Default	Affects
FilterTypes	""	Which SDL entities to be hidden by default in the *Filter Types* dialog. The entities should be entered as a number of text strings, separated by spaces.
FilterDiagrams	""	Which SDL entities that will be visible.
FilterUses	""	Which kind of entity use that will be visible.
IndexAppearance	Detailed	The layout of SDL entity information. The alternatives are Compact, VerticalCompact, HorizontalDetailed and Detailed.
NameFirst	on	If entities will be sorted by name or by type and name.
ShowSelectedDiagrams	on	If diagrams specified with *FilterDiagrams* should be shown or hidden.
ShowSelectedTypes	on	If types specified with *FilterTypes* should be shown or hidden.
ShowSelectedUses	on	If uses specified with *FilterUses* should be shown or hidden.
Statusbar	on	The presence of a status bar in the window.
Toolbar	on	The presence of a tool bar in the window.

Type Viewer Preferences

Prefix: Type*

Preference Parameter	Default	Affects
ShowInstanceSymbols	on	The default value for the *Instance symbols* option defined in the *List Options*.
ShowNameText	on	The default value for the *Name* option defined in the *Symbol Options*.

Preference Parameter	Default	Affects
ShowQualifierText	off	The default value for the *Qualifier* option defined in the *Symbol Options*.
ShowTypeText	on	The default value for the *Type* option defined in the *Symbol Options*.
Statusbar	on	The presence of a status bar in the window.
Toolbar	on	The presence of a tool bar in the window.

Coverage Viewer Preferences

Prefix: Cover*

Preference Parameter	Default	Affects
AboveThreshold	on	Which option to select by default between *Show symbols executed >= threshold* and *Show symbols executed <= threshold* (on means >=).
FillSymbols	on	Whether to fill symbols or not when displaying a coverage tree.
LogThickness	off	Which option to select by default between *Normal line thickness* and *Logarithmic line thickness* (off means normal).
MaxLineThickness	60 (1/10 mm)	The default value for the parameter *Max line thickness*.
ShowTransitions	on	Which option to select by default between *Transition Coverage* and *Symbol Coverage* (on means transition).
ShowVisibilityLine	on	Which option to select by default between *Show visibility line* and *Hide Visibility line* (on means show).
Statusbar	on	The presence of a status bar in the window.
Toolbar	on	The presence of a tool bar in the window.

Preference Parameter	Default	Affects
VisibilityThreshold	0	The default value for the parameter *Threshold*.

SDL Overview Generator Preferences

Prefix: Overview*

Preference Parameter	Default	Affects
DistanceBetweenLines	3 (mm)	The default value for the option *Distance between Lines*.
DistanceBetweenSymbols	10 (mm)	The default value for the option *Distance between Symbols*.
ExpandedDiagramsOnly	on	The default value for the option *Use Expanded Diagrams Only*.
IncludeLines	on	The default value for the option *Include Lines*.
IncludeProcedures	off	The default value for the option *Include Procedures & Operators*.
IncludeStates	off	The default value for the option *Include States*.
Margin	10 (mm)	The default value for the parameter *Margin*.
MinimumSymbolHeight	10	The default value for the option *Minimum Symbol Height*.
MinimumSymbolLength	20	The default value for the option *Minimum Symbol Width*.
NameTextHeight	10 (pt)	The size of textual elements in Overview diagrams. See "Default Font Sizes" on page 1969 in chapter 43, *Using the SDL Editor*.
PrintFontFamily	"Helvetica"	The font face used when printing text.

Preference Parameter	Default	Affects
ScreenFontFamily	“Helvetica”	The font face to use when displaying text on screen.
ShowLineNames	on	The default value for the SDL Editor option *Show line names*.
ShowSignallists	off	The default value for the SDL Editor option *Show signal lists*.
TextHeight	8 (pt)	The size of textual elements in Overview diagrams. See “Default Font Sizes” on page 1969 in chapter 43, *Using the SDL Editor*.

Simulator GUI Preferences

Prefix: SGUI*

Preference Parameter	Default	Affects
ButtonFileName	“def.btns”	What file containing *Button definitions* to load by default.
CommandFileName	“def.cmds”	What file containing *Command definitions* to load by default.
FailOnUnexpectedSignal	off	Makes the line “unexpected” appear in the “command statistics” when running Simulator test scripts. If this preference is set and an unexpected signal is detected before the current signal is checked, then it will be reported.
WatchFileName	“def.vars”	What file containing *Variable definitions* to load by default.
MaxOutputToRetries	50	Maximum number of retries of next-transition and output-to, when output-to fails during simulator script execution.
TextBufferLimit	10000	Maximum number of characters in the simulator UI text log. A value of 0 means “no limit”.

SDL Explorer GUI Preferences

Prefix: VGUI*

Preference Parameter	Default	Affects
ButtonFileName	“val_def.btns”	What file containing *Button definitions* to load by default.
CommandFileName	“val_def.cmds”	What file containing *Command definitions* to load by default.
WatchFileName	“val_def.vars”	What file containing *Variable definitions* to load by default.

Chapter

4

Managing Preferences

This chapter describes the principles for the management of preference parameters in a SDL Suite and TTCN Suite environment. It also describes how to use the Preference Manager to customize the installation.

For a reference to the Preference Manager and the preference parameters, see chapter 3, *The Preference Manager*.

Introduction

Different users are likely to use SDL Suite and TTCN Suite in different ways. Even the same user may use the tools differently in different work areas. The *Preference Manager* allows you to customize the default behavior of the SDL Suite and TTCN Suite tools in order to minimize the number of operations that you have to perform manually after having started a tool.

The Preference Manager allows you to set up the default behavior for the following tools:

- Organizer
- SDL Editor
- Diagram editors
- Text Editor
- Index Viewer
- Type Viewer
- Coverage Viewer
- Overview Generator and Editor
- Simulator Graphical User Interface
- SDL Explorer Graphical User Interface
- Help viewer
- Preference Manager
- Print
- generic SDL Suite and TTCN Suite tool preferences.

Note:

The Preference Manager only handles the SDL Suite-specific tools, and the common tools. The behavior of the TTCN Suite-specific tools cannot be changed by these preferences. For more information, see chapter 29, *Customizing the TTCN Suite (on UNIX)*.

Preferences may be customized for an individual user or may apply to an entire project or even organization that uses the SDL Suite and TTCN Suite tools.

How Preferences Are Managed

Depending on your needs and how you configure your environment, the SDL Suite and TTCN Suite tools handle preference parameters either as:

- *Organization (company) preferences*

  These are parameters that should affect all work that is done with the tools within an organization; for example you might want to prohibit the use of some specific SDL symbols, to set up printout headers and footers with your company's logotype, etc.

- *Project preferences*

  These are parameters that should affect the properties that are specific for a particular project; for instance what *make* and *build* options should be used by the Analyzer and Code Generators within the scope of a project. *Project preferences* can also be regarded as a specialization of the *organization preferences*, specific for a project.

- *User-defined preferences*

  User-defined preferences are parameters that would typically affect the behavior of the tools to have them fulfil the individual user's needs; such as what additional windows to open or not open at start-up of the tool.

- *Default (factory) settings*

  These settings are "burnt-in" into the tools and will be used whenever no other preferences are available.

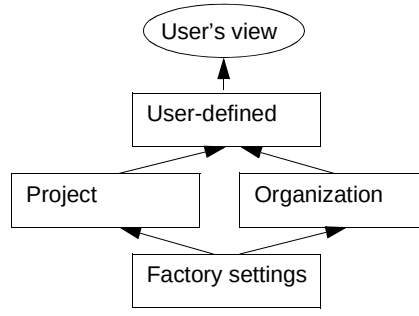

Figure 68: The user's view of the preference parameters

Preferences and Dialog Options

The tools allow you to customize a number of options that define the **default** behavior of a tool, using the Preference Manager (the TTCN Suite specific preferences can be customized as described in chapter 29, *Customizing the TTCN Suite (on UNIX)*). Some of these preferences may be overridden during the current tool session, by assigning a new value to the option. The option's latest value will then be memorized and reused, where possible.

Example 15: Print preferences and options. ––––––––––––––––––––

1. Assume that you have assigned the Print preference parameter *PrinterCommand* the value `lpr` (i.e. send to printer queue).
2. You print from the SDL Editor, change the option *Execute* to `ghostview` (i.e. a PostScript previewer) and click *Print*. Next time you print from the SDL Editor, the Execute option is memorized and reads `ghostview` (until you terminate the SDL Editor session).
3. But, when you print from another tool (the MSC Editor for instance), the *Execute* option is preset to the preferred value, i.e. `lpr`.

––

Preferences and the SDL Suite Diagram Options

The SDL Suite uses your preferred values when you create a new diagram and assign it:

- A width (set with the command *Drawing Size*)
- A height (set with the command *Drawing Size*)
- A viewing scale (set with the command *Set Scale*)

Each individual SDL diagram also stores information about:

- Whether to align symbols and lines to the grid or not
- Whether to check syntax or not when the diagram is edited
- Whether to fix endpoints at frame or not
- Whether to show the Additional Heading symbol only on the first page

  These diagram parameters are set with the SDL Editor command *Diagram Options*.

Each individual MSC also stores information about:

- Whether to show the *instance name* or not
- Whether to show the *instance kind* or not
- Whether to show the *instance composition* or not
- Whether to show the *message name* or not
- Whether to show *message parameters* or not

  These diagram parameters are set with the MSC Editor command *Diagram Options*.

Each individual OM, SC and HMSC diagram also stores information about:

- Whether to align symbols and lines to the grid or not

When you save a diagram, the current diagram parameter values are saved on the diagram file and will be reused next time you open it, **overriding the preference parameters**.

Preferences and System File Options

The tools use your preferred values when creating new system files (the `.sdt` files that are managed by the Organizer).

When you save a system file, the parameters that are related to the system are also stored on the system file, **overriding the preference parameters**:

- The parameters managed by the *Set Directories* dialog
- The parameters managed by the *View Options* dialog
- The parameters managed by the *Set Scale* dialog
- The parameters managed by the *Analyze* dialog
- The parameters managed by the *Make* dialog

See "Options in the System File" on page 193 in chapter 2, *The Organizer* for a reference to the contents of a system file and what parameters are stored on it.

Starting the Preference Manager

> **Note:**
>
> Each individual user should make sure the HOME environment variable is defined in order to take advantage of the Preference Manager. The HOME variable normally denotes the user's home directory.

To start the Preference Manager:

- Select *Preference Manager* from the Organizer's *Tools* menu.

  The Preference Manager will be opened.

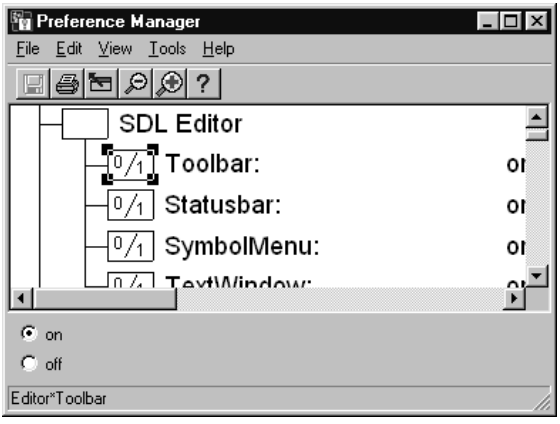

Figure 69: The Preference Manager window

Only one instance of the Preference Manager can be started at a time.

Adjusting a Preference Parameter

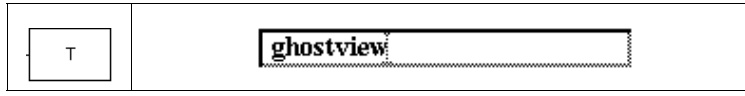
To modify a preference parameter:

1. First, locate the symbol representing the tool it governs (you may have to scroll the tree area up or down to make the symbol visible and to expand it with the *Expand* menu choice from *View Menu*).
2. Once the parameter is located, select it. (The information within parentheses is the current value, the item within brackets shows the source, i.e. user-defined / project / organization).
3. The area at the bottom of the window is updated according to the type of parameter you have selected. The sections below describe how to adjust the preference parameter.

Note:

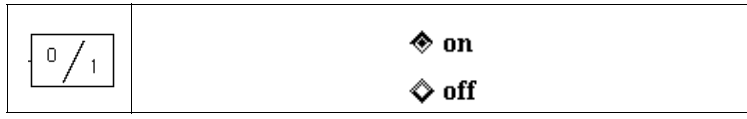
You have the possibility to revert any parameter to its saved value or default value, using the *Set Saved Value* / *Set Default Value* command.

Adjusting a Textual Parameter



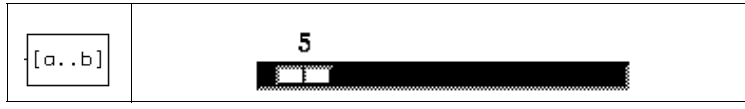
To edit a textual value, simply place the cursor on the text field and enter the text of your choice. No control of what is entered takes place.

Adjusting a Boolean Parameter



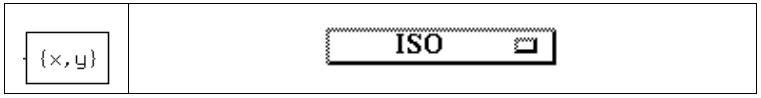
Click *on* to turn an option on.

Adjusting a Ranged Integer



Drag the slider for a coarse adjustment or click the slider bar for a fine adjustment.

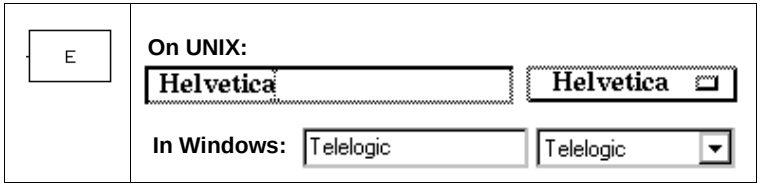
Adjusting an Option Menu



Clicking on the button brings up a pop-up menu where all permissible values are listed. Select the value of your choice.

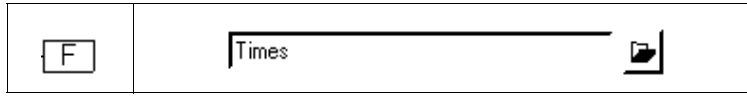
– When you move the mouse pointer over a value in the option menu, a short description of the value is printed in the status bar. Values whose description starts with “(UNIX only)” or “(Windows only)” should only be selected on a UNIX system or a Windows system, respectively.

Adjusting an Option Menu Textual Preference



You may select the preference parameter from a number of predefined values, available on an option menu (see above). As an alternative, you may type in the value into the text field, which grants access to not predefined values.

Adjusting a Font Preference (Windows only)

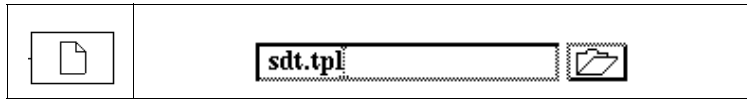


You must select the font by clicking the *folder button*, which opens a Microsoft Windows Font dialog. It is not possible to edit the text field to the left of the folder button.

In the font dialog, all TrueType fonts in the system are listed. It is also possible to select font style and size, but these values have no effect. Only the specified font name is used.

- Any font name can be entered by editing the *Font* text field in the font dialog. This possibility is useful when setting a font for printing that is not available in the system, but it does exist on the printer.
- The SDL Suite will also recognize the three font names “Times”, “Helvetica” and “Courier”. These are translated into the TrueType fonts Times New Roman, Arial, and Courier New, respectively.
- When using other fonts than the three mentioned above for printing, the preference Print*DestinationFormat should be set to *MSWPrint* to get the best result for symbols that are adjusted to the text size.

Adjusting a File Preference



You may assign the preference parameter any file name, entered as a text string into the text field.

- You can also click the folder button, which issues a file selection dialog in which you can select a file.

Customizing the On-Line Help

In SDL Suite and TTCN Suite, you can request on-line help by selecting a menu choice in a *Help* menu, a pop-up menu or by clicking a *Help* button in a dialog. For more information about *Help* menu choices, see "Help Menu" on page 15 in chapter 1, *User Interface and Basic Operations*.

To be able to view the on-line help, you need to have one of the following HTML-viewers installed:

- Firefox
- Netscape Navigator
- Microsoft Internet Explorer

Also, you have to make sure that the on-line help files (in HTML-format) have been installed.

In the on-line help, you can also find information about how to use it.

Configuring the Help Environment

1. In the Preference Manager window, locate the icon symbolizing the help preferences.
2. Double-click the icon. This will expand it and list the available help preferences.
3. Select and, if required, adjust the preference *HelpViewer* to an adequate value, either *Firefox*, *Netscape* or *Internet Explorer*. Use the option menu that appears at the bottom of the window to select the value.
4. Select and, if required, adjust the preference parameter *FirefoxCommand*, *NetscapeCommand* or *InternetExplorerCommand* to a command that starts HelpViewer in your computer environment. Type the command in the text field that appears at the bottom of the window.

Note:

The command must be available via your PATH variable.

To limit local disk space usage in a multi-user environment, you may optionally put the on-line help files on a network server (unless you already have a network installation of SDL Suite and TTCN Suite, which is usually the case on UNIX). To do this, you move all files in the `help` directory and its subdirectories (available in the local installation directory, by default `C:\IBM\Rational\SDL_TTCN_Suite6.3`) to the network server area. This step may already have been performed on your computer system, so check where the on-line help files are stored.

Then check and adjust the preference parameter *HelpDirectory* to the help directory on the network server.

5. Select and, if required adjust the preference parameter *HelpDirectory* to the help directory (by default `C:\IBM\Rational\SDL_TTCN_Suite6.3\help` **in Windows** and `$telelogic/help/` **on UNIX**).
6. Save the preference settings and exit the Preference Manager. The on-line help is now configured in accordance to your computer environment.

Timeout Issues

When you request on-line help from SDL Suite or TTCN Suite, the Postmaster supervises the communication. On a heavily loaded computer system, the help viewer may fail to respond within the time limit specified by the environment variable `STARTTIMEOUT`. When this occurs **on UNIX**, a message is appended to the console window. The environment variable should be adjusted to a higher value to match the typical response times for the computer system where the help viewer is running.

Customizing User-Defined Preferences

Saving Parameters as User-Defined

To preserve the modifications for the future tool sessions, you must save the preference settings. The preferences are saved on a preference file denoted by `$HOME/.sdtpref` **(on UNIX)**, or `%HOME%\sdt.ini` **(in Windows)**.

Note:

In Windows: If the environment variable `HOME` is not set, the preferences are stored on a preference file in the directory from which the tool was started.

Whenever you require to save a company or project preference (and thus customize it as your personal preference), you need to confirm the operation by clicking *Save* in the following dialog:

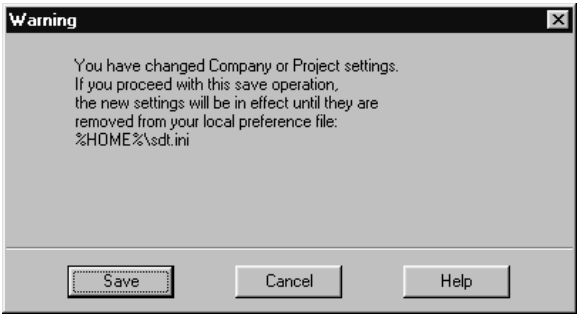


Figure 70: Confirming to modify a project or organization parameter

The reason for this is that a parameter which is defined at the company or project level should not be possible to modify inadvertently by any individual user of the tools.

Reverting User-Defined Parameters

The tools allows you to remove a preference parameter from your personal settings, in which case you will revert to the project or company preferences (or the default settings, if no project or company preferences are defined).

To revert a user-defined preference parameter, you must remove it from your preference file. The tools can do this for you:

1. Locate the preference parameter and select it.
2. From the *Edit* menu, select *Unsave*. A dialog appears, prompting you to confirm the operation.

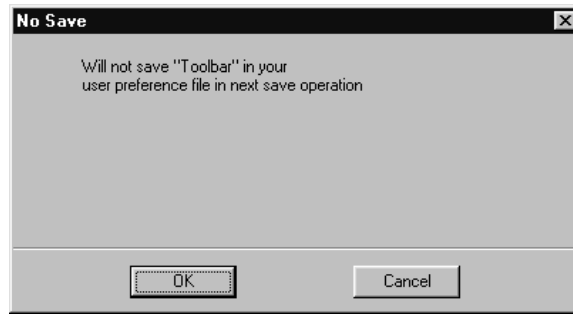

Figure 71: The Unsave dialog

– Click on the *OK* button to confirm the operation.

3. The parameter will be removed from your personal preferences next time you *Save* the preference settings.

Customizing Company Preferences

The installation may contain a file with all Preference parameters, along with their default values. The file is identified as `$telelogic/.sdtpref` **(on UNIX)**, or `sdt.ini` **(in Windows)**, and resides in the installation directory of the tools.

This file is also referred to as the *company / organization preference file*. **In Windows**, to be meaningful in a multi-user environment, the company preference file should be stored on a network drive (and, of course, all users should have read access to this file).

To customize the company's preferences, do as follows:

1. **UNIX only:** Login on a privileged account (for instance as system manager or the user who is the owner of the installation).

2. **On UNIX:** Change the default directory to `$telelogic`. Start the SDL Suite.
   In Windows: Start SDL Suite from the installation directory, i.e. **not** from a shortcut icon that defines another start directory.

3. Start the Preference Manager from the Organizer.

4. Modify the preference parameters of your choice (described in "Adjusting a Preference Parameter" on page 295). For a description of the meaning of the preference parameters, see "Preference Parameters" on page 241 in chapter 3, *The Preference Manager*.

5. Save the parameter setup. This concludes the procedure. From now on, all users (**in Windows**, those that are running from the network installation) will have the company setup as default (unless they have a different setup in their `$HOME/.sdtpref` **(on UNIX)**, or `%HOME%\sdt.ini` **(in Windows)**)

The TTCN Suite specific preferences and their default values **on UNIX** are described in "How Resources Are Read" on page 1244 in chapter 29, *Customizing the TTCN Suite (on UNIX)*.

Customizing Project Preferences

It is possible to customize the default preferences by defining a so called *project preference file*. The values defined here will supersede the company preferences.

To create a preference file that will be used by a specific project, perform the following steps:

1. **UNIX only:** Login on a privileged account (for instance as project manager or a user who has write access to a project directory).

2. **On UNIX:** Copy the company preference file to a suitable directory (where the project preference file will be stored). Change the default directory to that directory, and start the SDL Suite.
   In Windows: Copy the company preference file to a suitable directory on a network drive, where the project preference file will be stored (using a directory on a local HDD for this purpose makes no sense). Start the SDL Suite using a shortcut icon that designates this directory as the start directory.

3. Start the Preference Manager from the Organizer.

4. Modify the preference parameters of your choice (described above in "Adjusting a Preference Parameter" on page 295. For a description of the meaning of the preference parameters, see "Preference Parameters" on page 241 in chapter 3, *The Preference Manager*.

5. Save the parameter setup.

6. **On UNIX:** In a suitable file that all project members should source, insert the following statement:
   `setenv SDTPREF <directory>`

   In Windows 2000 and Windows XP, using the System properties in the Control Panel, set a `SDTPREF` environment variable to `<directory>`

   In all cases, `<directory>` denotes the project directory. Failing to do this will cause the tools to ignore the project preferences and to use company preferences instead.

7. This concludes the procedure. From now on, all project members will have the project setup as default (unless they have a different setup in their `$HOME/.sdtpref` **(on UNIX)**, or `%HOME%\sdt.ini` **(in Windows)**).

Locating the Preference Sources

To obtain information about the preference sources that are currently used (i.e. the directories and files that contain the company, project and user-defined preferences):

- Select *Info* from the *File* menu. A message box is issued:

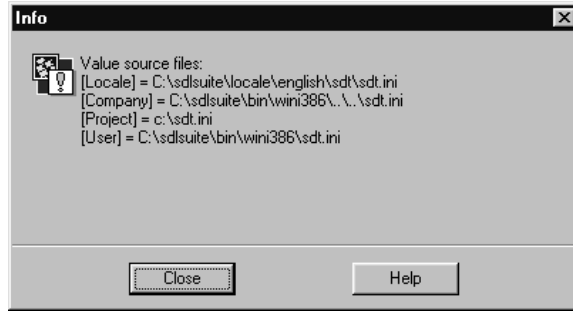

Figure 72: The message with information about preference sources

Chapter 4 Managing Preferences

Chapter

5

Printing Documents and Diagrams

This chapter describes the different *Print* dialogs in SDL Suite and TTCN Suite. It also describes the differences in printing between the Organizer, the SDL Suite and the TTCN Suite.

In the beginning of the chapter you can also find some introductory examples of how to print.

General

You can print from virtually all SDL Suite and TTCN Suite tools that provide a graphical user interface. It is possible to print the information that is managed by an individual tool, such as a graphical editor or a viewer, or to print all (or parts of) information that is related to a document structure, from the Organizer.

Print Dialogs

You specify the print options in *Print* and *Print Setup* dialog. These dialogs have different appearances, depending on where they are invoked from – the Organizer, the TTCN Suite or an SDL Suite tool. The TTCN Suite **in Windows** also provides a print preview.

Output Formats

The following output formats are provided:

- *PostScript Output* (including *Encapsulated PostScript*)
- *FrameMaker Output*
- *Interleaf Output*
- *Web Files (HTML+PNG)*
- *MSWPrint Output (Windows only)*
- *Microsoft Word Output (Windows only)*

When you print a TTCN document, only PostScript output is available. However, in the TTCN Suite **in Windows**, it is also possible to export a document to HTML, see "Converting to HTML" on page 1295 in chapter 30, *Editing TTCN Documents (in Windows)*.

Print Preferences

It is also possible to set the default print options. For more information, see "Print Preferences" on page 262 in chapter 3, *The Preference Manager*.

Printing Documents – Some Examples

This section is a brief guide to how to print some types of documents. The remaining sections of this chapter contains more detailed reference information about the print function and the *Print* dialogs.

You can print documents either from the Organizer or from within an individual tool.

Printing from the Organizer

This is an example of how to print a table of contents, one or more SDL interaction diagrams and type views from the Organizer. It is assumed that you have SDL interaction diagrams included in the Organizer and that a Type Viewer is running. The example describes how to print specific diagrams, but what is explained here may of course apply to other types of diagrams.

To print from the Organizer:

- Select *Print* | *Print All* from the *File* menu.
  - Alternatively, click the quick-button for *Print*.

  The *Print* dialog will be issued, where you may change the print settings.

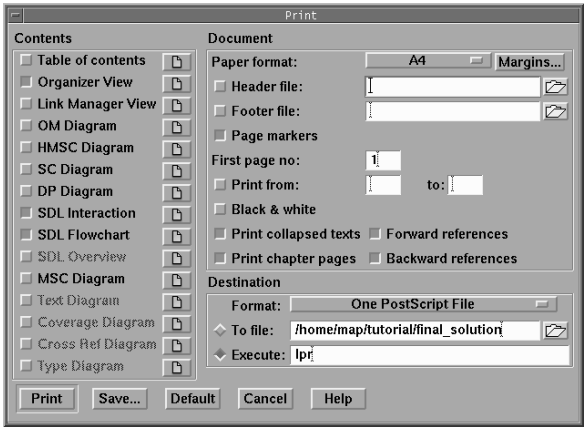

Figure 73: The Organizer Print dialog

You will start by changing the options in the *Contents* area:

1. Turn the *Table of contents* toggle button on.
2. Turn the *SDL Interaction* toggle button on.

3. Click the setup button to the right of the *SDL Interaction* toggle button.

   The *Print Setup* dialog will be issued where you may specify other options:

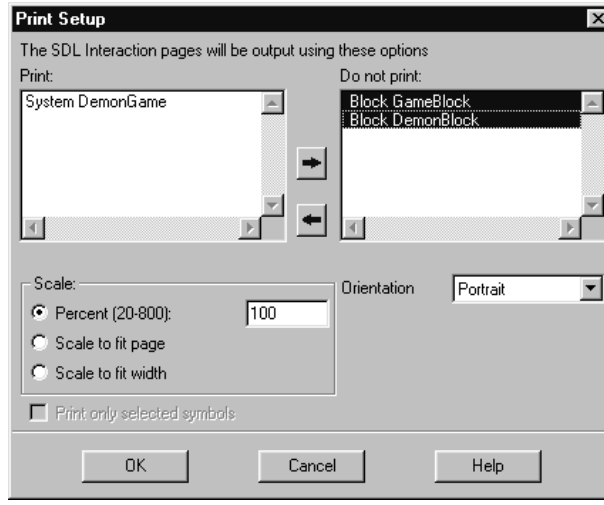

Figure 74: The Print Setup dialog

– You select what to print by using the arrow buttons to move diagrams between the *Print* and *Do not print* lists. Multiple selection is possible.

– You may change the *Scale* of the printout.

– You may change the *Orientation* of the printout.

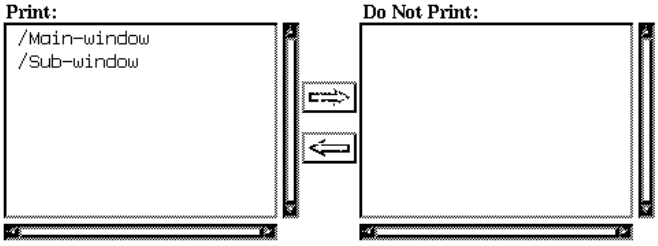
4. Click *OK*.

   The dialog will be closed.

5. Turn the *Type Diagram* toggle button on, and click the setup button to the right of the toggle button.

   The *Print Setup* dialog will be issued and you may set additional options.

   – In the *Print* and *Do not print* lists, you may specify if any of the Type Viewer main window or Tree window (identified as *Subwindow* in the list) is to be excluded.



– You may also change the other settings in the dialog.

6. Click *OK*.

   The *Print Setup* dialog will be closed.

You may also want to specify the options in the *Document* area and the *Destination* area of the *Print* dialog:

1. Select the *Paper format* that you want to use. For Word printing **(Windows only)** select the *Image format*.

2. Click the *Margins* button, to open the *Paper Format Setup* dialog.

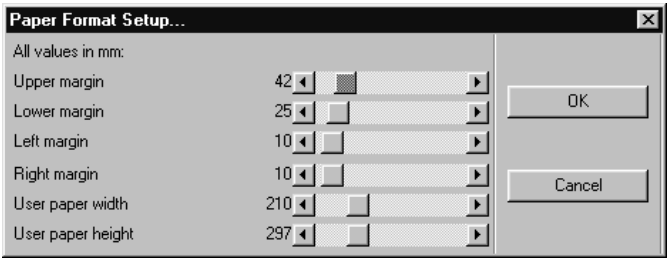


Figure 75: Setting the margins

In the dialog, you may change the paper margins, and in addition you may define your own paper size.

For Word printing **(Windows only)** there is a *Size* button instead. A click on this button allow you to define the size of the generated images imported into Word.

3. You may also want to change other settings in the *Document* area.

4. Select the output format in the *Format* option menu. You may choose between:

   – *One PostScript File*, suitable if you are going to print the documents on a PostScript printer.

   – *One EPS File* (Encapsulated PostScript), suitable if you are going to include graphics in a document. Select *One EPS File Per Page* if multiple pages are to be printed.

   – *One FrameMaker MIF File*, suitable if you want a file that can be imported into FrameMaker. Select *One MIF File Per Page* if multiple pages are to be printed.

   – *Import into FrameMaker (UNIX only)*, suitable if you want to import the file directly into a currently opened FrameMaker document.

   – *One Interleaf IAF File*, suitable if you want a file that can be imported into Interleaf. Select *One Interleaf IAF File Per Page* if multiple pages are to be printed.

   – *MSW Print* **(Windows only)**, which will make the print function use the printer you have set up with the Microsoft Windows Print Manager.

   – *One Word DOC File* **(Windows only)**, suitable if you want a file that can be used in Microsoft Word 2003 or Word 2000.

   – *Word Files (DOC + EMF)* **(Windows only)**, suitable if you want to edit the document file in Microsoft Word and be able to regenerate the pages.

   – *Web Files (HTML+PNG)*, suitable if you want to publish the document on the Web. HTML (text) and PNG (picture) files are produced that can be viewed in a web browser.

5. Select the destination of the printout – a file or a printer.

   – If you want to save the printout on a file, you should make sure that the *To file/Map file* radio button is on. The button is labelled *Map file* if multiple pages are to be printed (when you have selected a *One file Per Page* option in the format menu). The map file will contain a translation table that shows the correspondence between the input diagrams and the generated files.

– If you want to send the printout to a printer, you should ensure that the *Execute* radio button is on. You also have to type a printer command in the field, for example `lpr`. (It is possible to enter any post-processing command, such as a PostScript pre-viewer like `ghostview`.)

6. Click the *Print* button to generate the printout.

For more information on how to use advanced printing features, see "Advanced Print Facilities" on page 357.

Printing from the SDL Suite

In these examples you will learn how to print from the MSC Editor and the Type Viewer. As most settings in those print dialogs are similar to the ones in the Organizer dialog, described above, the explanations below will be quite brief.

Printing from the MSC Editor

1. Open a diagram in the MSC Editor.
2. Select *Print* from the *File* menu.

   The MSC Editor *Print* dialog will be issued.
3. Optionally, change the settings in the dialog.
4. Click the *Setup* button.

   The *Print Setup* dialog will be issued, where you may specify some additional options:

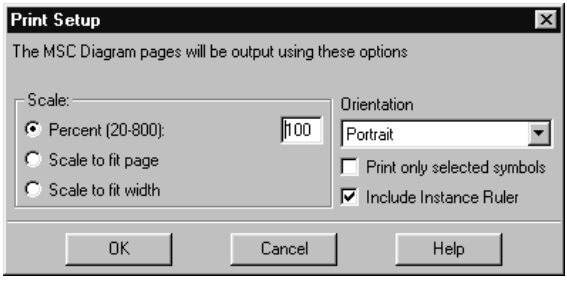

Figure 76: The MSC Editor Print Setup dialog

5. Turn the *Print only selected symbols* toggle button on, if you have selected parts of the MSC diagram that you want to print. Deselected symbols will not be printed.
6. Turn the *Include Instance Ruler* toggle button on, if you want to add an instance ruler into each printed page of an MSC. This means that the instance heads will be visible on each page – useful if you have a vertically extended MSC diagram that will cover more than one page.
7. Click the *OK* button in the *Print Setup* dialog.
8. Click the *Print* button in the *Print* dialog.

   The printout will be generated.

Printing from the Type Viewer

1. Make sure the Type Viewer is running.
2. Locate either the main window (the window labelled *Type Viewer*) or the Tree window.
3. You may also want to change the contents of the window by using commands in the *View* menu.
4. Select *Print* from the *File* menu in either the main window or the Tree window of the Type Viewer.

   If you select *Print* in the main window, the printout will be a type list. If you select *Print* in the Tree window, the printout will be an inheritance tree.

   The *Print* dialog will be issued.
5. Adjust, if required, the options in the *Print* dialog and the *Print Setup* dialog.
6. Click the *Print* button.

   The printout will be generated, based on the contents of the window that the *Print* command was selected in.

Default Scope of Print

In this section you will find information on what will be printed by default if you do not change any settings. It may also be possible to select what documents – of parts of documents – to print. See "Print Setup Dialogs" on page 337 for more information on how to include more in the printout or how to restrict it.

> **Note:**
> Link endpoints are never shown in a printed document.

Printing from the Organizer

The default printout in the Organizer depends on selections and which tools are running:

SDL, OM, SC, MSC and HMSC Diagrams; Text Documents; Cross Reference Files

If choosing Print | Print All or Print | Print Selected and no item is selected in the Organizer, **all documents** that are managed by the Organizer (i.e. are visible in the Organizer view) will by default be included in the printout. If choosing Print | Print Selected and an item is selected in the Organizer, only the document(s) included in that item, and their sub-structure (if any), will by default be included in the printout.

Coverage Files

Coverage files cannot be included in the structure that is managed by the Organizer. The graphical presentation of a coverage file is computed as you request it by running the Coverage Viewer.

Therefore, the graphical presentation of coverage information will be included in the printout if the Coverage Viewer is **running**. The resulting printout will reflect the current contents of the windows, that is, the *Main Window* and the *Coverage Details Window* of the Coverage Viewer.

SDL Types and Type Instances

These entities cannot be included in the structure that is managed by the Organizer. Furthermore, this information is computed automatically by the Type Viewer. Therefore, the Type Viewer must be running in order

to include the information in the resulting printout. The contents of the *Main Window* and *Tree Window* of the Type Viewer may be included.

TTCN Documents

If a TTCN document is selected in the Organizer, it is possible to print it, and the default scope of print is the selected document. A TTCN document cannot be included in a global printout, i.e. from the main *Print* dialog in the Organizer.

Printing from the SDL Suite

When you are going to print from an SDL Suite tool, the printout will be the information that is currently visible in the active tool window.

The *Setup* button issues the *Print Setup* dialog which is used for specifying the scope of print. For example, if you print from the SDL Editor, the default scope of print is the active SDL Editor window, i.e. the SDL page currently being edited. In the *Print Setup* dialog, the scope of print may include any of the pages contained in the SDL diagram, or be restricted to the SDL symbols currently selected in the active window.

OM, SC, HMSC, SDL, MSC and Text Editor

The default scope of print is the active Editor window, i.e. the diagram page or the MSC currently being edited.

SDL Overview Viewer

The default scope of print is the active SDL Editor window, i.e. the SDL Overview diagram currently being viewed.

Type Viewer, Index Viewer and Coverage Viewer

In a Viewer, the scope of print is the contents of the window from where you invoked print.

Preference Manager and Link Manager

The scope of print is the current contents of the window.

Printing from the TTCN Suite

The default scope of print is the entire, currently active, TTCN document. The printout will contain one table per page.

The *Print* Dialogs in the SDL Suite and in the Organizer

To print, you select any of the submenus in the *Print* menu from the *File* menu. This will open a *Print* dialog. Since the print functions in the tools are not identical, the print dialogs look somewhat different depending on where they are invoked from. As you can see in Figure 77 and Figure 78, the differences are that the Organizer print dialog includes the *Contents* area, whereas the SDL Suite tool print dialogs include a *Setup* button.

The main differences between printing from the Organizer and an SDL Suite tool are:

- In an SDL Suite tool, it is only possible to print the information or document that is opened in the tool. In the Organizer, you can select to print all or any of the documents that are managed by the Organizer.
- It is possible to print only selected symbols (when applicable) from an SDL Suite Editor, which is not possible from the Organizer.
- When you print from a viewer, the printout will be the contents of the active window. If you print from the Organizer, it is possible to include or exclude a window from the printout, independently of which window is currently active.
- In the Organizer it is also possible to print a table of contents and the contents of the Organizer window.

Note:

Endpoints are not displayed in printed documents/diagrams, regardless of the value of the *Show Link Endpoints* option.

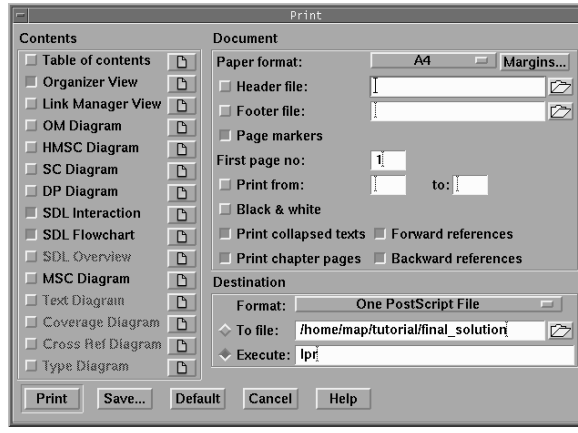

Figure 77: The Organizer Print dialog

Figure 78: An SDL Suite tool print dialog

Both dialogs contain the following areas and buttons:

- *Document Area*
- *Destination Area*
- *Print* button
- *Default* button
- *Cancel* button

The Organizer print dialog also contains the *Contents* area with setup buttons, and a *Save* button. A *Setup* button is also included in each the SDL Suite tool print dialog. The setup buttons in the *Contents* area of the Organizer print dialog are equivalent to the *Setup* button in an SDL Suite tool print dialog. The *Save* button is used to save print dialog settings in print selection files, for later use in the print dialog.

All dialog areas and buttons will be described in this chapter.

Contents Area in the Organizer Dialog

The *Contents* area is only available in the Organizer *Print* dialog. In the area, it is possible to control what information to print, through a number of toggle buttons and *Setup* buttons. Each of the toggles identify a group of documents that may be printed:

- Table of contents
- Organizer view
- Link Manager view
- OM diagram
- HMSC diagram
- SC diagram
- SDL interaction
- SDL flowchart
- SDL overview
- MSC diagram
- Text document
- Coverage diagram
- Cross reference diagram
- Type diagram

Note:

It is not possible to include TTCN documents in a global printout from the Organizer. See "The Print TTCN Dialog in the Organizer" on page 331 for information on how to print TTCN documents from the Organizer.

Some toggle buttons may be turned on by default. This is determined by which document types that are present in the default scope of print.

Table of Contents

This option determines whether a table of contents should be generated or not. The table of contents consists of a textual list with information about what source diagrams and generated diagrams that are included in the printout, with references to physical page numbers. There is also a possibility to only include Organizer chapters in the table of contents, i.e. all other printed entities are suppressed in the table of contents.

The table of contents is either printed on the first pages that constitute the resulting printout, or after an initial text document acting as a title page.

Organizer View

This option determines whether a printout of the *Organizer main window* should be included or not in the generated output. Only the visible parts (i.e. expanded nodes) are included.

The resulting printout will match the Organizer's *View Options*, i.e. file names, directories, etc. will be shown if they are in the Organizer Main window.

Link Manager View

This option determines whether a printout of the *Link Manager Window* should be included or not in the generated output. Only the visible parts (i.e. expanded nodes) are included.

OM/HMSC/SC/MSC/Text Diagram, SDL Interaction, SDL Flowchart, SDL Overview

These options determines whether the documents and diagrams that are visible in the Organizer should be included or not in the printout. The SDL *Interaction diagrams are: system, system type, block, block type, substructure, package diagrams.* The SDL *Flow diagrams are: process, process type, service, service type, procedure, operator, macro diagrams.*

Note:

Endpoint markers will not be included in printed diagrams.

Coverage Diagram

This option determines whether *Transition Coverage* and *Symbol Coverage* trees should be included or not in the generated output.

Cross Ref Diagram

This option determines whether *Definitions and Uses* should be included or not in the generated output.

The resulting output will show the graphical appearance as when displayed in the *Index Viewer*, with the exception that only SDL entities defined or used in SDL diagrams printed together with the index will be visible in the index.

Type Diagram

This option determines whether an SDL-92 Type list and SDL Type Inheritance and Redefinition list should be included in the generated output or not.

The resulting output will show the SDL-92 type lists for the SDL system currently in view in the Organizer. The lists will be produced by using the options defined in the *List Options*, *Tree Options* and *Symbol Options* of the Type Viewer.

Setup Buttons in the *Contents* Area

Furthermore, each group of documents that may be printed is supplied with setup buttons. When you click a setup button, a *Print Setup* dialog will be issued, see "Print Setup Dialogs" on page 337. In the dialog, it is possible to set additional options that affect the printout of the current group of documents.

Document Area

The *Document* area contains a number of settings that make it possible to specify the size of the paper to use, the print range and additional information to be printed on each individual page.

The *Document* options are:

- *Paper format*
- *Image format (Windows Only)*
- *Margins*
- *Header file*
- *Footer file*
- *Page markers*
- *First page no*
- *Print from/to*
- *Black & white*
- *Print collapsed texts*
- *Print chapter pages*
- *Forward references*
- *Backward references*

Note:

When using a printing format other than One Postscript File or MSWPrint the only enabled options in the Document area are Black & white (not for Frame or Interleaf printing) and Print collapsed texts. For these formats the paper layout is determined by the special Print preferences starting with *Frame*PaperFormat*. However when using Word format the margins and layout are determined by the defaults given by the created Word document.

Paper format

The *Paper format* option menu specifies what paper format the print function will use. The paper formats are:

- *A4*, the European standard size(210 * 297 mm)
- *A3*, the European standard double size (297 * 420 mm)
- *US Letter*, the American standard (8.5” * 11”)
- *US Legal* (8.5” * 14”)
- *User Defined*, which makes it possible to customize a size with the *Margins* button. The size may also have been set in the *Preferences Manager*.

Margins

The *Margins* button provides access to the *Paper Format Setup* dialog where the print margins may be specified.

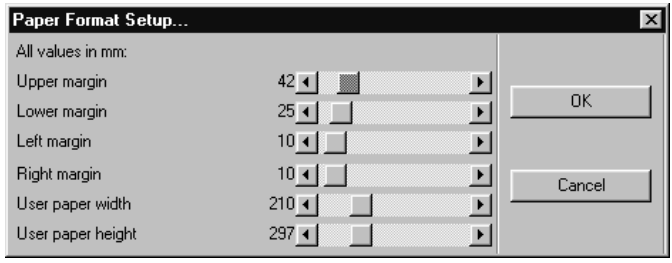

Figure 79: The Paper Format Setup dialog

The print margins govern how much space is reserved around the area used when printing. Values are expressed in millimeters.

- There are four slide bars for the adjustment of the margins:
  - *Upper margin*
  - *Lower margin*
  - *Left margin*
  - *Right margin*

  Margins are calculated with respect to the closest border and remain unaffected when rescaling, changing the paper size or the orientation of the printout.
- The dialog also contains two slide bars used for controlling what paper format to use when the *Paper format* option *User Defined* is set:
  - *User paper width*
  - *User paper height*
- The *OK* button applies the values as currently defined and closes the dialog.
- The *Cancel* button closes the dialog without changing any values.

Image format (Windows Only)

For Word printing the *Image format* option menu specifies what image format the print function will use. The image formats are:

- *Normal.dot*

  The image size will be adjusted to fit in the size calculated from a newly created Word document.

- *User Defined size*

  Makes it possible to customize an image size with the *Size* button. The size may also have been set in the *Preferences Manager*.

Header file
Footer file

This feature controls whether or not a header/footer should be printed on each page. The page header/footer is defined in a text file of its own, which you need to supply. For information about the contents and syntax of this file, see "Footer and Header Files" on page 344.

- The header/footer file options are turned on/off with toggle buttons.
- When you click the folder button, a *Select File* dialog will be issued. In this dialog you may select the header/footer file.
- It is also possible to type the name and directory of the file directly into the text field.

> **Note:**
>
> Header or footer files are only supported in *PostScript Output* (not EPS) or *MSWPrint Output (Windows only)*.

Page markers

An SDL/OM page or an MSC diagram may require multiple physical pages when printed. If you want to print an SDL/MSC/OM document and the document is physically spread over more than one physical page, the *Page markers* toggle button facilitates the reassembling of the paper sheets into the original page.

- If the toggle button is on, adjacent page markers will be inserted on the edge of each physical page. An adjacent page marker looks like a small arrowhead which refers to the adjacent page. If there are lines crossing a physical page border, line identifiers (like X1, X2... or Y1, Y2...) will be attached to the line, making it easy to find the continuation of the line on the other page.

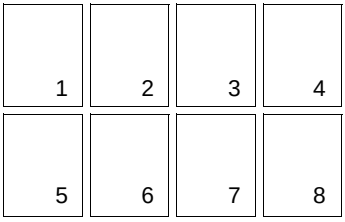

Figure 80: The page numbering

Physical page numbering follows a "first right, then down" fashion.

Note:

The physical page breaks are indicated with dashed lines in the diagram editors. A page number is inserted at the lower right corner of each page in the editor.

Page markers and all other options where page numbers are used are only supported in *PostScript Output* (not EPS) or *MSWPrint Output (Windows only)*.

It is possible to print an individual page number on each printed page. This is done by using a header file. Read more about header files in "Footer and Header Files" on page 344.

First page no

When you order multiple print jobs, you may want to restart the page numbering on each printout with a number different from 1, which is the default value.

If you want to change the number of the first page, you should type the number in the *First page no:* field.

Print from/to

It is possible to exclude a number of pages form a printout. To specify the print range, you type the page numbers in the *Print from* and *Print to* fields. Make sure that the toggle button is on, your settings will have no effect otherwise.

When the toggle button is off, all physical pages that constitute the printout will be generated.

Note:

The print range must be in accordance with the page numbering; i.e. the offset specified in the *First page no* should be added.

The physical page breaks are indicated with dashed lines in the diagram editors. These page breaks are valid only if the printing scale is not changed.

Black & white

If this option is selected, all symbols and lines will be printed with a black border on a white background. If this option is not selected, symbols and lines will be printed with the color they have on screen. As default, this option is off.

For FrameMaker or Interleaf printing this option is always on and disabled as the printing will always be in black and white.

Print collapsed texts

Text symbols, comment symbols and text extension symbols can be collapsed. When they are collapsed, it is not possible to see the complete text these symbols contain in the diagram. Instead, it is possible to print the complete text as a separate text page after the diagram. This option decides if such a text page should be printed or not. As default, this option is on.

Print chapter pages

(Organizer only.) Decides if text connected to chapter symbols in the Organizer should be printed or not. As default, this option is on.

Forward references

(Organizer only.) Decides if forward paper page references should be printed or not. Paper page references makes the printout easier to read. You can get paper page references for the following relations:

- SDL reference symbol -> SDL diagram
- (H)MSC reference symbol -> (H)MSC diagram
- SDL join/out-connector -> SDL label/in-connector
- SDL procedure call -> SDL procedure diagram
- SDL nextstate symbol -> SDL state symbol

Note:

The three last relations will only be printed if there exists an index/cross reference file in the Organizer view with up-to-date information about the SDL system. You can get an index for a correct SDL system by pressing the *Generate Index* Organizer quick button before bringing up the print dialog

As default, forward paper page references are printed.

There is a preference, Print*MaxPageReferences, that decides the maximum number of page references in one place. The default value is 20. A value of 0 is the same as “no limit”.

Backward references

Similar to forward references, but produces paper page references that allows the reader of the printout to follow the flow backwards instead.

Destination Area

The *Destination* area contains print options that affect the output format and the destination of the resulting output. It is for example possible to send a printout to a printer or to look at the results in a pre-viewer.

The options are:

- *Format*
- *To file / Map file*
- *Execute*

Format

This feature controls what output format will be generated when printing. You select the output format in an option menu. The output formats supported are:

- *One PostScript File*

  This option produces one self contained PostScript document.

- *One EPS File*[1]

1. EPS stands for Encapsulated PostScript

If only one page is to be printed, this option is valid and will result in an EPS File containing one physical page. If the *Print setup* caused more than one physical page to be printed, only the first page will be printed. The layout of the page for EPS printing is determined by the preferences in *Frame*PaperFormat*.

- *One EPS File Per Page*

  This format implies that the output will be in the form of multiple EPS files, placed in a specified directory. Along with the EPS files, a *map file* containing the translation scheme is produced. See "To file / Map file" on page 329.

- *One FrameMaker MIF File*[1]

  This format signifies the generation of one FrameMaker MIF file. The file will contain a number of contiguous, cropped anchored frames. The layout of the page for MIF printing is determined by the preferences in *Frame*PaperFormat*.

- *One FrameMaker MIF File Per Page*

  This option produces one FrameMaker MIF file per page. A *map file* is also produced, showing the translation table. See "To file / Map file" on page 329, below.

- *Import into FrameMaker* **(UNIX only)**

  If an instance of FrameMaker is found up and running, this option generates a FrameMaker MIF temporary file that will be imported into an anchored frame, placed below the current insertion point in the active FrameMaker document. If no instance of FrameMaker is found, then an attempt is made to start one with the command `maker` and create a new FrameMaker document, showing the contents of the file.

1. MIF stands for Maker Interchange Format.

Note:

To have this print option function properly, the SDL Suite and FrameMaker must run on the same computer.

Temporary files are stored on the directory designated by the environment variable `TMPDIR`. You have to set up the variable as a complete path specification such as **`setenv TMPDIR /tmp`**
To specify `TMPDIR` such as **`setenv TMPDIR .`** is not sufficient.

See also "Importing into FrameMaker (UNIX only)" on page 353 for how this option functions when multiple instances of FrameMaker are running on your computer.

- *One Interleaf IAF File*[1]

  This format produces one Interleaf ASCII Format file. The layout of the page for IAF printing is determined by the preferences in *Frame*PaperFormat*.

- *One Interleaf IAF File Per Page*

  This option produces one Interleaf ASCII Format file per page. A *map file* is also produced, showing the translation table. See "To file / Map file" on page 329.

- *MSW Print*

  (Windows only)

  The Print function uses the printer that has been set up with the Microsoft Windows Print Manager. If a printer that does not support PostScript is used, this option makes sure the printer driver available in Microsoft Windows is used.

- *One Word DOC File*

  (Windows only)

  This option produces one Word Document format file for use with Microsoft Word 2003 or Word 2000. The generated image sizes can be set by the *Image format* option. When choosing *Normal.dot* the layout of the page for Word printing is determined by the margins and paper format as defined when a new document in Word is created. When choosing *User Defined* the sizes can be set to any desired size, however when they are inserted into the Word document

1. IAF stands for Interleaf ASCII Format.

if necessary they are scaled to fit inside the margins of the document.

- *Word Files (DOC + EMF)*

  (Windows only)

  This option produces one Word Document format file that is a hub for a set of Enhanced Metafiles. When you select this option you also have to specify the main Word Document file in the *To file* text field. The produced Enhanced Metafiles are auto-named and placed in the same directory as the main Word Document file. The generated image sizes can be set as for *One Word DOC File.*

- *Web Files (HTML+PNG)*

  This option produces HTML (text) and PNG (picture) files that can be viewed in a web browser. The PNG file format is similar to the GIF file format and is supported by Netscape Navigator 4.0 and Microsoft Internet Explorer 4.0 or later. When you select this option, you also have to specify the main HTML file in the *To file* text field. All other produced files are auto-named and placed in the same directory as the main HTML file.

To file / Map file

If this radio button is turned on, the output will be a file. The name of this radio button depends on the format specified in the *Format* option menu. If the format selected will generate one output file – i.e. the format name ends with *Per Page* – the name will be *Map file*. Otherwise it will be *To file.*

A map file contains a translation scheme of all files generated (containing information about SDL diagram / page and the corresponding printout file). The naming algorithm of the generated files will ensure a fixed mapping between a diagram and the generated files between two subsequent Print jobs. However, if the input to the Print function is changed (its size!), this is not necessarily true.

See "Map File" on page 350 if you want detailed information on the syntax of a map file.

- When you click the folder button, a *Select File* dialog will be issued. In this dialog you may select the name of the file and where it is to be saved.

- It is also possible to type the name of the file directly into the text field. The directory where the file will be saved is the most currently selected.

Execute

If this radio button is on, the output file will be used as input to an OS command. An example of this is to load a printer with a PostScript file. It may also be used to send the resulting PostScript code to a PostScript previewer. For instance, if type a previewer command in the field – `ghostview` for example – you may preview the PostScript file.

The command `lpr` (or any other related) will send the printout to a printer.

The default command is specified in the *Preference Manager*. In the **Windows** version, the command `lpr` is available, which functions much like the corresponding UNIX print spool command.

Setup

When you click the *Setup* button (only available in an SDL Suite tool *Print* dialog), a *Print Setup* dialog will be issued. In the dialog, it is possible to set additional options. The additional options differ between the the SDL Suite tools. See "Print Setup Dialogs" on page 337 for more information.

The *Print TTCN* Dialog in the Organizer

To print one or more TTCN documents from the Organizer, you select one of the TTCN document in the Organizer and then you select *Print* from the Organizer *File* menu. This will issue the Organizer *Print TTCN* dialog.

When you print a TTCN document, the main difference between printing from the Organizer and printing from the TTCN Suite is:

- If you have more than one TTCN document included in the Organizer, you may select which of the documents to print. In the TTCN Suite, it is only possible to print a document that is displayed in the active Browser.

See also "The Print Dialogs in the TTCN Suite" on page 333.

The Organizer *Print TTCN* dialog contains options for the print range and first page number and whether the document is to be printed to a file or a printer. More options are available in the *Print TTCN Setup* dialog.

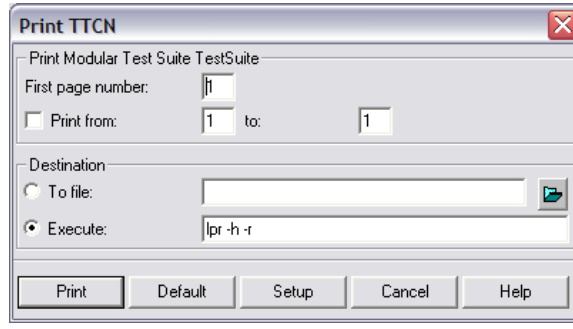

Figure 81 The Organizer Print TTCN dialog

First page number

The number that you type in this field, will be the page number inserted on the first page.

Print from/to

It is possible to exclude a number of pages form a printout. To specify the print range, you type the page numbers in the *Print from* and *Print to* fields. Make sure that the toggle button is on, your settings will have no effect otherwise.

When the toggle button is off, all physical pages that constitute the printout will be generated.

Destination Area

The options in the *Destination* area affects the destination of the printout.

To file

If this radio button is on, the printout will be a PostScript file. You also have to specify the name of the file and where it is to be saved.

- When you click the folder button, a *Select File* dialog will be issued. In this dialog you may select the name of the file and where it is to be saved.
- It is also possible to type the name of the file directly into the text field. The directory where the file will be saved is the most currently selected.

Execute

If this radio button is on, the output file will be used as input to an OS command. An example of this is to load a printer with a PostScript file. It may also be to send the resulting PostScript code to a PostScript previewer. For instance, if type a previewer command in the field – `ghostview` for example – you may preview the PostScript file.

The command `lpr` (or any other related) will send the printout to a printer.

Setup

When you click the *Setup* button, a *Print Setup* dialog will be issued. In the dialog, it is possible to set additional options, such as which of the existing TTCN documents to print. See "Print Setup Dialogs" on page 337 for more information.

The Print Dialogs in the TTCN Suite

To print from the TTCN Suite:

- Select *Print* from the *File* menu. (**On UNIX**, this menu choice is included in the Browser.)

  – **In Windows**, if the test suite overview has not been generated previously, you will have to confirm the generation before the test suite can be printed.

  In the *Print* dialog that will be opened, you may specify the page range and if the file is to be printed to a file or a printer. The output will be in TTCN-GR format – the graphical format of TTCN – according to ISO/IEC 9646-3, and it will include document indices and automatic page numbers.

When you print a TTCN document, the main difference between printing from the Organizer and printing from the TTCN Suite is:

- If you have more than one TTCN document included in the Organizer, you may select which of the documents to print. In the TTCN Suite, it is only possible to print a document that is currently displayed in the active Browser.

See also "The Print TTCN Dialog in the Organizer" on page 331.

Printing in the TTCN Suite in Windows

In Windows, the print dialogs are Windows standard. Besides the actual *Print* dialog there are also *Print Setup* and *Print Preview* dialogs.

To open a *Print Setup* dialog:

- Select *Print Setup* from the *File* menu.

  In the dialog, it is possible to specify what printer, paper size and paper orientation to use.

To open a print preview dialog:

- Select *Print Preview* from the *File* menu.

  In the dialog, the TTCN document is displayed as it will be printed and it is possible to zoom and browse the document.

Printing in the TTCN Suite on UNIX

On UNIX, you can select which Browser parts and items, for example a single table or sets of tables, to include in the printout. The selections may be arbitrary – they will be printed as a coherent document anyway. It is also possible to change the page numbering of the printout.

The settings in the print dialog will be described below:

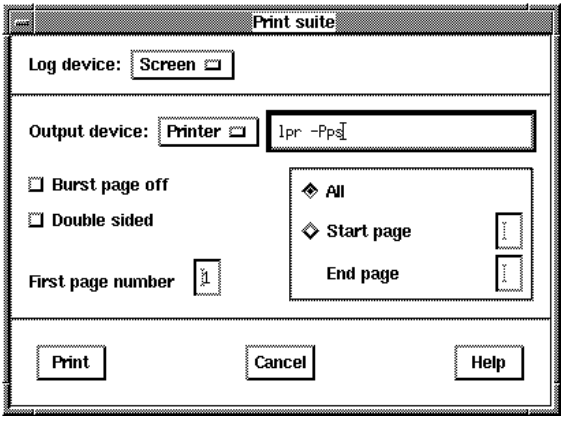

Figure 82: The TTCN Suite Print dialog **on UNIX**

- *Log device*

  Controls the log device for the print function. The default value is *Screen*, but the log can be directed to a named file (*File*) or turned off altogether (*None*).

  For more information, see "The TTCN Suite Logs" on page 6 in chapter 1, *User Interface and Basic Operations*.

- *Output device*

  If you specify the output device to be a printer, you also have to fill in a print command. If you want to print to a file, you will have to specify the destination. See also "Printing PostScript Files" on page 335.

- *Burst page off*

  If this option is set, the burst page will not be printed. The burst page is a generated, unnumbered cover page for the TTCN document, containing the print date and time.

- *Double sided*

  If this option is set, the TTCN document will be printed in a page format suitable for a double-sided copying, otherwise it will be printed in a single-sided format. The appearance of both formats is controlled by resources and can therefore be changed (see the file `<Itex.sample>` in the TTCN Suite directory).

- *First page number*

  You may change the page number of the first page. However, to ensure consistency between the page numbering of the printed TTCN document and the page numbers that appear in the TTCN document overview, make sure that:

  – The Overview Part is generated before you print.

  – The same first page number is used both in the document overview and the printout.

- Printing page ranges

  – *All* causes all pages of the document to be printed.

  – *Start page* and *End page* restricts the printout.

Example 16 ----------

If a TTCN document contains ten pages numbered 1 to 10, then *Start page* = 3 and *End page* = 3 will cause only page 3 to be printed.

Printing PostScript Files

The editable field of the *Print* dialog not only allows to change the name of the printer or to apply flags to the print command. It is also possible to insert the name of a filter for the produced PostScript code. In the public domain there exist a package of programs called `pstools` that make various magic operations with a PostScript file. The following example will print four TTCN Suite pages on each A4 page (the syntax of `pstops` is somewhat hard to read though):

Example 17 ----------

```
pstops '4:0@0.5(0.8cm,14cm)+1@0.5(10.5cm,14cm)\
+2@0.5(0.8cm,0cm)+3@0.5(10.5cm,0cm)' | lpr
```

Other filters are able to print double sided intended to bind into a book, print odd pages first etc.

By using a PostScript viewer as Ghostview instead of the normal print command, the printout of the TTCN document can be viewed on screen rather than being printed:

Example 18 ----------

```
ghostview -
```

The text in this field is controlled by the resource `Itex.print.commandPrefix`. This is by default `lpr -P` or `lp -s` depending on platform but can be altered (note that the content of the environment variable PRINTER/LPDEST is concatenated to this string). See chapter 29, *Customizing the TTCN Suite (on UNIX)* which contains a description on how to modify resources in the TTCN Suite.

Print Setup Dialogs

A *Print Setup* dialog will be issued when you click the *Setup* button in an SDL Suite tool *Print* dialog, or when you click any of the setup buttons in the *Contents* area of the Organizer *Print* dialog. When you click the *Setup* button in the Organizer *Print TTCN* dialog, the *Print TTCN Setup* dialog will be issued. The settings in a setup dialog will affect the current group of documents.

The setup dialogs look somewhat different depending on the tool they are invoked from. There are four types of print setup dialogs:

- *Print Setup* dialog for Table of contents in the Organizer, see Figure 83.
- *Print Setup* dialog in the SDL, OM, SC and HMSC Editors and, when applicable, in the Organizer, see Figure 84.
- *Print Setup* dialog in the MSC Editor, see Figure 85.
- *Print Setup* dialog in tools not mentioned above and, when applicable, in the Organizer, see Figure 86.
- *Print TTCN Setup* dialog in the Organizer, see Figure 87.

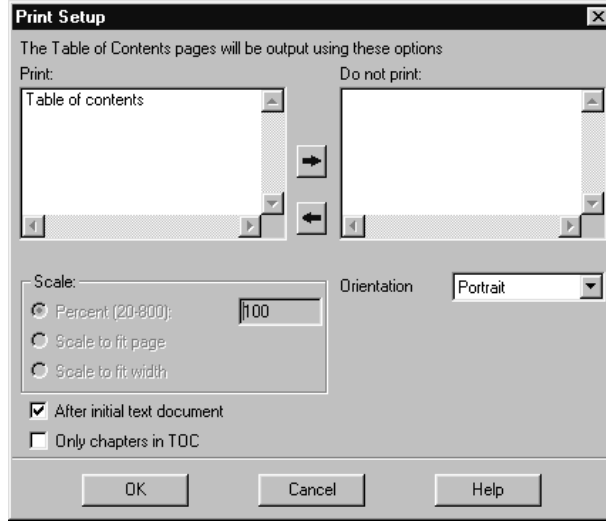

Figure 83: The Table of contents Print Setup dialog

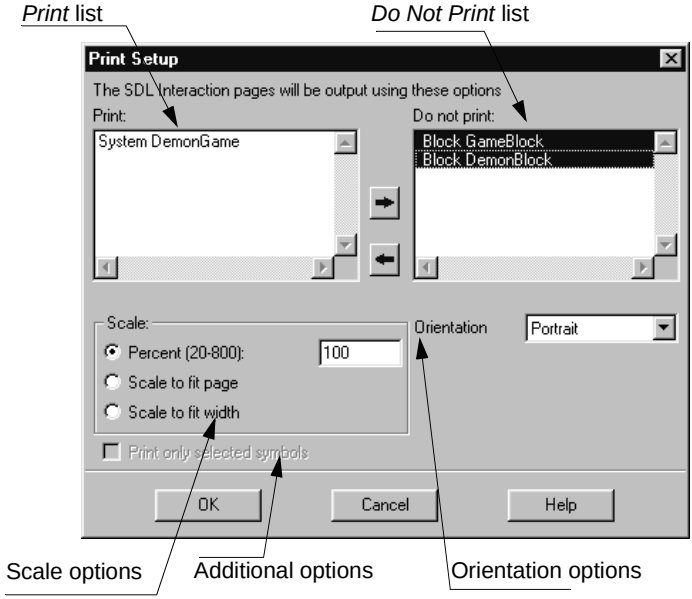

Figure 84: The Organizer Print Setup dialog

The Print Setup dialog looks the same in the Organizer and the SDL, OM, SC and HMSC Editors.

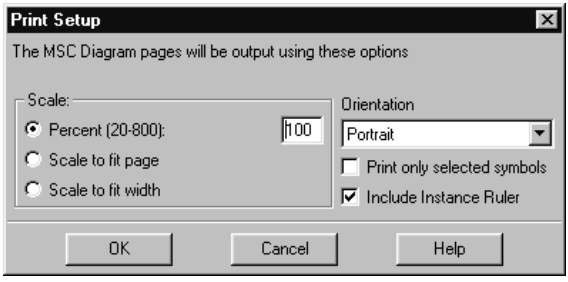

Figure 85: The MSC Editor Print Setup dialog

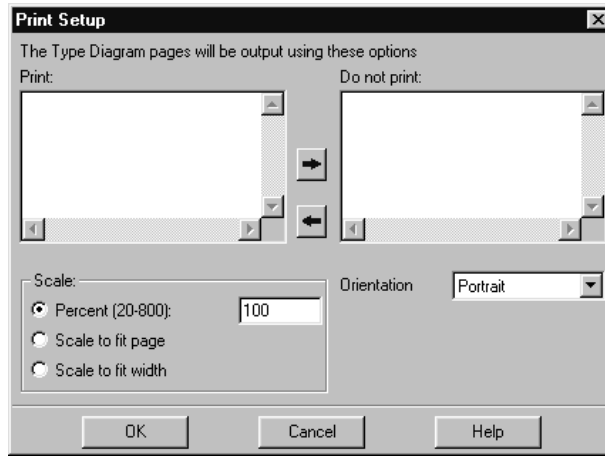

Figure 86: A viewer Print Setup dialog

The Print Setup dialog looks the same in the Link Manager, Type Viewer, the Index Viewer, the Coverage Viewer and the Text Editor.

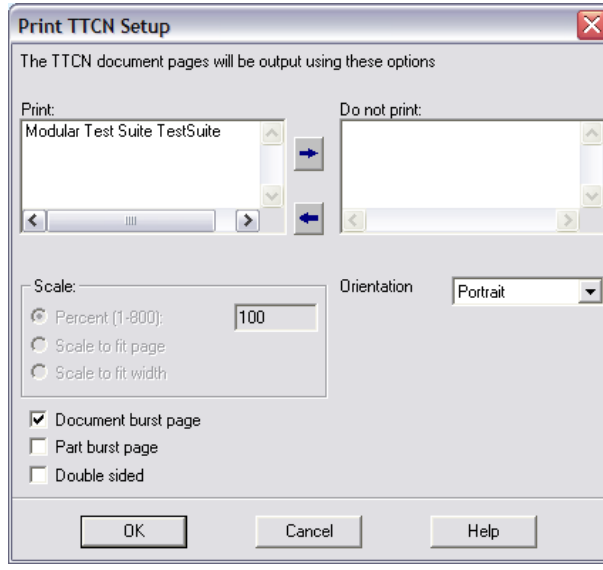

Figure 87 The Organizer Print TTCN Setup dialog

The setup dialogs contain the following:

- All dialogs contain the *Scale* area, the *Orientation* option menu, and the *OK*, *Cancel* and *Help* buttons.
- When applicable, the SDL, HMSC, OM and SC Editor and the Organizer *Print Setup* dialogs, as well as the Organizer *Print TTCN Setup* dialog, also contain the *Print / Do not print* lists.

  The lists are only included in the *Print Setup* dialog of an editor if the diagram that is to be printed consists of more than one page.

  In the Organizer, the *Print Setup* dialog will not contain the lists if you clicked the *Link Manager View* setup button.
- The *Print only selected symbols* toggle button is included in the SDL, HMSC, OM and SC Editor *Print Setup* dialogs.
- The MSC *Print Setup* dialog contains the *Include Instance Ruler* toggle button. This button is also included when MSC setup is invoked from the Organizer *Print* dialog.
- The Organizer View *Print Setup* dialog contains the *Paper page references* toggle button.
- The Table of contents *Print Setup* dialog contains the toggle buttons *After initial text document* and *Only chapters in TOC*.
- The *Print TTCN Setup* dialog contains the toggle buttons *Document burst page*, *Part burst page* and *Double sided*.

All areas and options mentioned will be explained below.

Print / Do not print

- The *Print* list shows the documents/pages that will be printed.

  If the *Print Setup* dialog is invoked from the Organizer, the list contains the documents included in the Organizer scope of print. When the dialog is invoked from the SDL, OM, SC or HMSC Editor, the list contains the current page.

  In the *Print TTCN Setup* dialog, this list shows the TTCN document that was selected in the Organizer (or all TTCN documents within a TTCN Module). Any other TTCN documents are listed in the *Do Not Print* list.

- The *Do not print* list shows the documents/pages that will not be printed.

  When invoked from the SDL, OM, SC or HMSC Editor, the list contains the pages that are included in a diagram, except the current page.

To specify what is to be printed and not:

1. Select one or several items in one of the lists, if you want to move them to the other. Multiple selection is possible.

2. Use the arrow buttons to move selected items from one list to the other.

> **Note:**
>
> **On UNIX**, you may transfer **all** diagrams/pages between the two lists by pressing `<Shift>` while clicking an arrow button.

Scale

It is possible to set the scale in almost all *Print Setup* dialogs. You can select *Percent*, *Scale to fit page* or *Scale to fit width*.

> **Note:**
>
> It is not possible to set the scale in the Text Editor *Print Setup* dialog or in the Organizer *Print TTCN Setup* dialog.

Percent

With the *Percent* radio button on, the printout of the current document category will be scaled according to the value defined in the *Percent* text field. The default value is 100% but you may of course change this.

Scale to fit page

With the *Scale to fit page* radio button on, the printout will be rescaled – if needed – to fit the physical paper size.

Scale to fit width

With the *Scale to fit width* button on, the documents will be rescaled in order to fit the physical paper width. The result becomes a column of pages constituting each document.

Orientation

In the *Orientation* options menu you may choose between the following orientations of the printout:

- *Portrait*
- *Landscape*

By changing the options, you can rotate the printout in order to optimize paper use.

> **Note:**
>
> The Orientation option is only enabled for the output formats One PostScript File or MSWPrint. Other formats use the portrait orientation but the layout can be adjusted by the preferences Print*Frame*XXX.

Additional Options

Below the *Orientation* option, there are a number of additional options, depending on which *Print Setup* dialog you have opened.

Print only selected symbols

If this toggle button is on, only objects that are selected in a window will be printed. This option is not available when you print from the Organizer. In an SDL Suite tool, it is disabled if no object is selected or if more than one window contain a selection.

Include Instance Ruler

This toggle button is only available in the MSC *Print Setup* dialog. It specifies whether an instance ruler (see "Instance Ruler" on page 1724 in chapter 39, *Using Diagram Editors*) should appear on each printed page or not. The instance ruler is, when printed, given an appearance similar to the one shown in the MSC Editor window.

Paper page references

This toggle button is only available in the Organizer View *Print Setup* dialog. It specifies whether paper page references to all printed diagrams and documents should be included in the Organizer view listing.

After initial text document

This toggle button is only available in the table of contents *Print Setup* dialog. It specifies whether the table of contents should be printed after a plain text document placed first among the diagrams and documents that are to be printed. The initial text document then acts as a title page before the table of contents.

Only chapters in TOC

This toggle button is only available in the table of contents *Print Setup* dialog. It specifies whether only the chapters in the Organizer view should be included in the table of contents, or if all diagrams and documents also should be included.

Document burst page

This toggle button is only available in the Organizer *Print TTCN Setup* dialog. If the toggle is on, a document burst page will be printed. The burst page is an unnumbered cover page for the TTCN document, where the name of the test suite and the print date are printed.

Part burst page

This toggle button is only available in the Organizer *Print TTCN Setup* dialog. If the toggle is on, part burst pages will be printed. The part burst pages are unnumbered cover pages, that separate the different parts of a TTCN document. The name of the part, the test suite and the print date, are printed on each part burst page.

Double sided

This toggle button is only available in the Organizer *Print TTCN Setup* dialog. If the toggle is on, the TTCN document will be printed with a page format suitable for a double-sided copying. The appearance is controlled by resources and can therefore be changed (see the file `Itex.sample` in the TTCN Suite installation directory).

Footer and Header Files

You may specify if a header and/or footer is to be inserted on each printed page. The first thing you have to do is to define the header and footer in separate text files. The format is ASCII based and line oriented. A number of variables are available, providing additional information of the kind of diagram printed.

Text is written on a white background, which becomes visible if the text appears on top of any graphical object.

Printing Order

The priority order for writing headers and footers is as the inverse order in which the items appear in the file. That is any text, variable or graphical symbol, overwrites an already written item. (The last row in the file has the highest priority).

Syntax

The syntax used in the header and footer files is given below in a BNF notation:

```
File            ::= ( <LINE> | <EXTENSION-LINES> |
<EPSF> ) *
<LINE>          ::= <X> <Y> ( <TEXT> | <VARIABLE> )
+ \n
<X>             ::= integer, x - position in
millimeter
<Y>             ::= integer, y - position in
millimeter
<TEXT>          ::= any ASCII text - no newlines
allowed
<VARIABLE> ::= any variable as described  in
"Variables" on page 345,
<EXTENSION-LINES> ::= any of the extensions as
defined in "Extensions" on page 347.
<EPSF>          ::= EPSF <X> <Y> <FILE>
<FILE>          ::= user provided filename
containing EPS code
```

Note:

The positions are relative the **upper left corner** of the physical paper in the header and the **lower left corner** in the footer.

Variables

The following variables are supported in header and footer files:

Variable	Explanation
<date>	As set by the Print preference *date*.
<diagramname>	The name of the diagram. Ignored if the printed diagram was not one of: • SDL diagram • SDL Overview diagram • MSC.
<diagramtype>	The type of the diagram. Ignored if the printed diagram was not one of: • SDL diagram • SDL Overview diagram • MSC.
<pagename>	The logical name of current page. Ignored if the printed diagram was not one of: • SDL diagram • SDL Overview diagram.
<file>	The current file being printed. Ignored if no corresponding file exists. It could be a *New* (unsaved) file being printed or it could be a *Type View* which has no corresponding file.
<page>	The current page number.
<directory>	The directory where the current file is located. Ignored if no corresponding file exists. It could be a *New* (unsaved) file being printed or it could be a *Type View* which has no corresponding file.
<chaptername>	The current chapter name, defined by a chapter symbol in the Organizer View.
<chapternumber>	The current chapter number, defined by a chapter symbol in the Organizer View.
<totalpages>	The total number of printed pages, excluding the title page and the table of contents.

Obsolete Variables

(i.e. variables used in SDT 2.3)

Variable	Explanation
`<area>`	Prints *Work Area* or *Original Area* in plain text depending on if the diagram was found in the source directory or not. The variable is available for backwards compatibility only.

Example 19 ----------

For example, you may have a process called Myproc that you are going to print out. First you write a footer file with the following contents:

```
10 20 Telelogic AB
10 15 <date>
150 15 <diagramtype> <diagramname> <pagename>
180 20 Page <page>
```

If the date is March 1, 1999, the 15th printed page would look something like this:

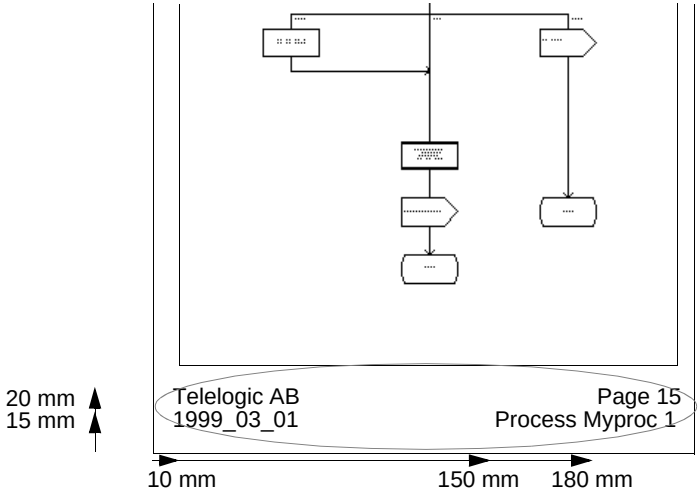

Figure 88: The resulting footer

Extensions

Below are listed the extensions that enhance the appearance of the header and footer.

Frames

The keyword `FRAME` makes a frame appear at any position on the paper. The function is intended for framing the header and/or footer.

Format

The exact format is:

```
FRAME x1 y1 x2 y2 [type]
```

where the start and stop positions are given in millimeters. The optional type argument may be either `3D` or `plain` (default).

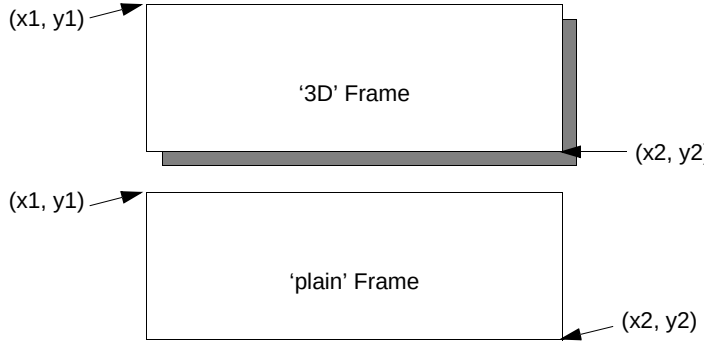

Figure 89: 3D frame and plain frame

Separators

A separator is a horizontal line which is intended to separate the header and/or footer from the data area of a printed page.

Format

The SEPARATOR statement has the general format:

```
SEPARATOR x1 y1 length [type]
```

where the start position and length of the separator are given in millimeters. The optional type argument may be either:

- Filled
- Double
- Single (default)

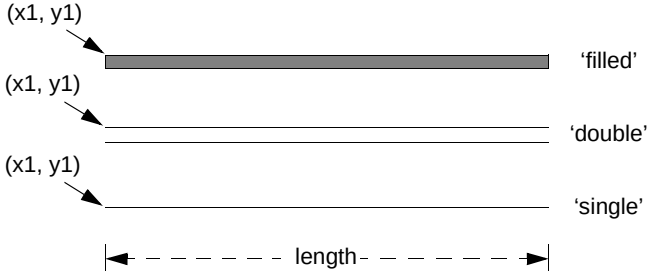

Figure 90: Filled, double and single separators

Boxes

Use the BOX keyword to make a filled rectangle appear anywhere on the paper. It can be used for highlighting sections of the header and/or footer.

Format

The format is:

```
BOX x1 y1 x2 y2 [grayscale]
```

where the start and stop positions are given in millimeters. The optional grayscale argument is a number in the range 0 to 100 (default is 50).

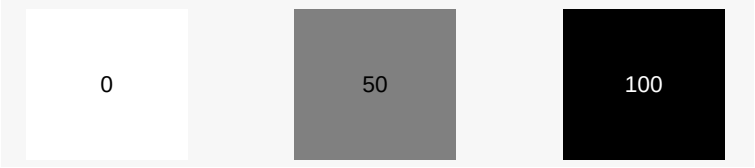

Figure 91: Boxes

Grayscale=0 = white, grayscale=50 = medium gray and grayscale=100 = black.

Defining Multiple Footers and Headers

It is possible to have a separate footer or header for the first printed page. There are three keywords that can be typed on a separate line in a footer or header definition file to achieve this:

- IFFIRST

Definitions after this keyword will only be used for the first printed page.

- IFNOTFIRST

Definitions after this keyword will be used for all pages after the first page, but not for the first page.

- ENDIF

Definitions after this keyword will be used for all pages.

Map File

When multiple output files are generated for one input diagram, a map file is also generated. It shows the translation table between input diagrams and resulting files. The name of this file should be specified in the *Map file* field.

Syntax

The map file is an ASCII text file containing lines of the format:

```
<filename> "[<diagram type>]" "[<diagram name>]"
"[<page name>]"
```

where `<filename>` is an absolute path to a generated file. The file name is composed of:

- the first four letters of the diagram name (fewer if the diagram name is shorter than four letters)
- the first two letters of the page name
- an extension.

If this naming scheme generates two files with the same name, a number (1-99) is added to the second file name, preceding the extension.

Example 20: Contents of a UNIX Map File

```
...
/usr/ope/doc/ContDe.eps "Block" "Controller"
"Declarations"
...
/usr/ope/doc/ContDe1.eps "Block" "Container"
"Declarations"
...
```

Example 21: Contents of a Windows Map File

```
...
C:\tlog\doc\ContDe.EPS "Block" "Controller"
"Declarations"
...
C:\tlog\doc\ContDe1.EPS "Block" "Container"
"Declarations"
...
```

Should either of the descriptive `<diagram type>`, `<diagram name>` or `<page name>` fields be inapplicable to an item, the corresponding field in the map file will be empty (i.e. “”).

More Information on Output Formats

PostScript Output

PostScript output may be generated as one standard PostScript file or one or more Encapsulated PostScript (EPS) files. When multiple EPS files are generated, a translation table will also be produced in a *Map File*, linking the name of a generated file to the contents.

Standard PostScript

A normal print operation generate one PostScript document. All data is represented uniformly, using the same paper format, header, footer etc. Only the scale and orientation might vary between pages.

Encapsulated PostScript (EPS)

The EPS output makes use of the scale and orientation settings for each document category. Since EPS files are not clipped, the internal scale has little importance when the file is imported into an external documentation or desktop publishing system.

Header, footer and adjacent page markers are not included in the output. Paper layout are determined from the Print preferences *Frame*Paper-Format*.

Scaling in EPS Files

The scaling options are handled as follows:

- *Scale to fit page*

  Each logical page is output as one EPS file with an internal scale adjusted to fit the entire logical page into the bounding box given by the current paper format and margins. When the EPS files are scaled into external documentation software, this will correspond to the “Fit Into Page” option for PostScript files.

- *Percent*

  As *Scale to fit page*, but with a user defined internal scale.

- *Scale to fit width*

As *Scale to fit page*, but with the internal scale adjusted to fit the width of the logical page into the space given by the paper width and the left and right margins.

Handling of Expanded Text in PostScript

Expanded texts are the text contained in such symbols that are minimized[1] in a graphical page, see "Text / Additional Heading / Package Reference Symbols" on page 1891 in chapter 43, *Using the SDL Editor*.

Standard PostScript

Expanded text is output as plain text using the font specified by the `SDT*PrintFontFamily` and `SDT*PrintTextHeight` preferences.

Encapsulated PostScript

Expanded text in EPS output is stored on separate files. One text file is generated for each logical page containing expanded text, regardless of the number of expanded texts in that logical page.

- When generating multiple EPS files, the text file for a logical page called `<x>.eps` will be `<x>.exp`.
- When printing to one EPS file, the text file for `<x>` will be `<x>.exp`.

PostScript Standard Conformance

The generated PostScript code conforms to either of these standards:

- PostScript Language Document Structuring Conventions - Version 3.0
- Encapsulated PostScript File Format - Version 3.0.

FrameMaker Output

FrameMaker output may be generated either as:

- One MIF[2] file containing *cropped anchored frames*
- One or more MIF files containing one logical page each

1. Meaning resized to a minimal size.
2. MIF stands for Maker Interchange Format.

The generated pages are the same in both cases. A translation table is also generated in the latter case.

- One temporary MIF file that can be imported directly into FrameMaker. See "Importing into FrameMaker (UNIX only)" on page 353.

Depending on the scale setting (see "Scaling in EPS Files" on page 351), each logical page will be represented as one or more *cropped anchored frames* in the output.

Header, footer and adjacent page markers are not included in the output. Paper layout are determined from the Print preferences *Frame*Paper-Format*.

Handling of Expanded Text in MIF

Expanded text (see "Handling of Expanded Text in PostScript" on page 352 for an explanation) is inserted as plain text after the anchored frames generated for the corresponding logical page. In order to preserve the appearance of the users original text, hard returns are inserted where new lines are found.

MIF Conformance

The generated MIF files conform to FrameMaker Interchange Format version 4.00, which can be read into FrameMaker version 4.x, 5.x and 6.x without problems.

Importing into FrameMaker (UNIX only)

The X Window root window has an atom (property) that governs how FrameMaker communicates with SDL Suite and TTCN Suite. The name is arbitrary, but must defined both in SDL Suite and TTCN Suite as well as in FrameMaker. In the example below, the name `_Frame_Import` will be used.

To have FrameMaker behave in accordance, you should specify what resource to be used by SDL Suite and TTCN Suite when starting FrameMaker. The resource values should be entered in the SDT resource file (in which case all users are affected) or in a suitable user X resource file. The resource is called `sdtfmimp*rpcProp`.

Example 22: X Resource file sample

```
...
sdtfmimp*rpcProp: _Frame_Import
...
```

There are multiple ways to set up FrameMaker. The resource `Maker.rpcProp` may be used for this.

Interleaf Output

Interleaf output may be produced as:

- one IAF[1] file containing *anchored frames*, or
- one or more IAF files containing one logical page each.

The generated pages are the same in both cases. A translation table is also generated in the latter case.

Depending on the scale setting (see "Scaling in EPS Files" on page 351), each logical page will be represented as one or more *anchored frames* in the output.

Header, footer and adjacent page markers are not included in the output. Paper layout are determined from the Print preferences *Frame*Paper-Format*.

Handling of Expanded Text in IAF

Expanded text (see "Handling of Expanded Text in PostScript" on page 352) is inserted as plain text after the frames generated for the corresponding logical page. In order to preserve the appearance of the users original text, hard returns are inserted where new lines are found.

IAF Conformance

The generated IAF files conform to Interleaf ASCII Format version 8.0 (used in Interleaf 5).

MSWPrint Output (Windows only)

The MSWPrint output can be used on Windows to print on any Windows printer, thus this is suitable if the printer does not support Post-

1. IAF stands for Interleaf ASCII Format.

script. As the complete print output using this option will be divided into several print jobs the printing should be done only on one side of the paper, otherwise the page numbering will not be as expected.

Handling of Expanded Text in MSWPrint

Expanded text (see "Handling of Expanded Text in PostScript" on page 352) is handled the same as for standard PostScript.

Microsoft Word Output (Windows only)

Word output can be used to print as a Microsoft Word document. A complete Word document is created and the generated pages are created as enhanced metafiles.

Header, footer and adjacent page markers are not included in the output. Paper layout are determined from the defaults when creating a new Word document. The image sizes can be set by the *Image format* option.

Handling of Expanded Text in Word output

Expanded text (see "Handling of Expanded Text in PostScript" on page 352) is inserted as plain text after the frames generated for the corresponding logical page. In order to preserve the appearance of the user's original text, hard returns are inserted where new lines are found.

Adding Printer Fonts (UNIX only)

By default only three printer fonts are available in printouts: Times, Courier and Helvetica. It is possible to add other printer fonts. The requirement is that there exist AFM (Adobe Font Metrics) files for the desired fonts. An AFM file contains the character metrics necessary for correct layout of text in printouts.

1. Locate AFM files for the regular, bold, italic and bold italic versions of the font. Many AFM files are available from Adobe Systems Inc. through on-line services (e.g. via ftp from `ftp.adobe.com`).
2. Store the files in the directory `$telelogic/fontinfo`.
3. Name the files according to the scheme in the table below. Note that you have to specify *`<basename>`* by using lower case characters (e.g. `palatino-I.afm`). Otherwise, you are free to choose any `<basename>` that does not conflict with other fonts or font files.

File contents	File name
regular font	`<basename>.afm`
bold font	`<basename>-B.afm`
italic font	`<basename>-I.afm`
bold italic font	`<basename>-BI.afm`

4. You may then choose the font as `<basename>` in the Preference Manager (case is not important in this context):

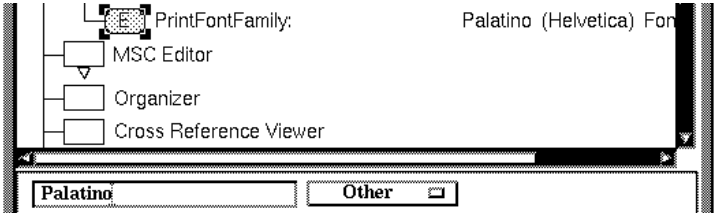

Figure 92: Specifying print font as Other.

Palatino is selected in the current example.

The generated files will use the true name of the font, extracted from the FontName and FamilyName attributes in the AFM files.

Advanced Print Facilities

This section is divided into three parts.

- The first part lists all advanced print facilities.
  See "List of Advanced Print Facilities" on page 357.
- The second part describes how to use the advanced print facilities to produce a nice printout, starting with an SDL system that is not already prepared for printing with advanced print facilities.
  See "Introducing Advanced Print Facilities" on page 368.
- The third part is about using the advanced print facilities when an SDL system is prepared for printing with advanced print facilities.
  See "Using Advanced Print Facilities" on page 382.

List of Advanced Print Facilities

The following print facilities will be described in this section:

- Headers
- Chapters
- Title Page
- State Matrices
- Index
- Fonts
- Text Indentation

Headers

You can create a textual header definition file that defines the appearance of a header that is found at the top of each printed page. All the possibilities for creating a header is described in "Footer and Header Files" on page 344, here you will only find the most important ones.

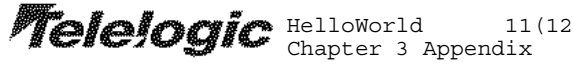

Figure 93: A header example

Creating a Header Definition File

The Organizer preference ShowHeader defines if the header symbol should be visible as default in the Organizer view. If the header symbol is not visible, you can make the symbol visible by selecting *Header File* in the *View > View Options* dialog.

Figure 94: The header symbol in the Organizer view

You can double-click on the header symbol to open a Text Editor to be able to define the header and create a header definition file. When you have defined the header (read more about some of the possibilities for that below), save the file and you are done with this step.

Defining Text in Headers

In the header definition file, insert a line like this:

```
60 20 This printout was produced by X
```

This means that 60 millimeters from the left border and 20 millimeters from the top border, the text “This printout was produced by X” will be placed.

Using Header Variables

In a header definition file, insert a line like this:

```
100 10 <page>(<totalpages>)
```

This means that 100 millimeters from the left border and 10 millimeters from the top border, a text such as “3(9)” will be placed, informing the reader of the printout that this is page three of nine.

Using Pictures in Headers

You can introduce pictures in the headers. The pictures must be in Encapsulated PostScript file format (EPSF), and they are referenced from the header definition file. If you have a picture of for instance your company logo in a file `/home/lat/logo.eps`, then you can get it into your header with the following line:

```
EPSF 10 35 /home/lat/logo.eps
```

This line means that the picture defined in the referenced file will be placed 10 millimeters from the left border, and 35 millimeters from the top border.

Separate First-page Header

You can have one header for the first page, and another header for all other pages. To achieve this, you can divide your header definition file in three parts by using three different keywords, or rather keylines:

```
IFFIRST
(Part 1. Place everything that is unique for the
first page header here.)
ENDIF

IFNOTFIRST
(Part 2. Place everything that is unique for the
other header here.)
ENDIF

(Part 3. Place everything that is common to both the
first page header and the other header here.)
```

Chapters

You can divide the diagrams and documents in your Organizer view into different chapters by using the chapter symbol. You add a chapter symbol to the Organizer view with *Edit > Add New*. In the dialog that follows, select one of the *Chapter* alternatives under the *Organizer* document type group, and specify the chapter name under *New document name*. (If you do not want to create a chapter introduction text (see below), make sure that the *Show in editor* toggle button is off before closing the dialog.)

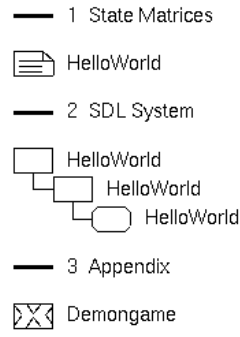

Figure 95: Chapters in the Organizer view

Chapters can be auto-numbered and can be moved with the up and down quick buttons. You can select a chapter symbol to restrict the scope for diagrams and documents that are going to be printed.

Creating a Chapter Introduction Text

It is possible to associate a text with a chapter symbol. The text will be printed at the position of the chapter symbol, and the text can be regarded as a chapter introduction text.

To create a chapter introduction text, you should invoke the Text Editor. This can be done in two ways:

- If you have not closed the *Add New* dialog, then you can bring up the Text Editor by making sure the *Show in editor* toggle button is on, before closing the dialog.
- If you have closed the *Add New* dialog, then you can double-click on the chapter symbol. In the dialog that follows, select *Edit chapter symbol*. In the second dialog that follows, make sure that the *Show in editor* toggle button is on and close the dialog to bring up the Text Editor.

In the Text Editor, type in the chapter introduction text and save the file.

Starting a New Chapter in the Middle of an SDL Diagram

For a large SDL diagram with many pages, it is convenient to divide the different pages of the diagram into different sub chapters.

To make this possible, you have to make the page symbols visible in the Organizer, if they are not visible already. This is done in the *View Options* dialog by turning on *Page Symbols*.

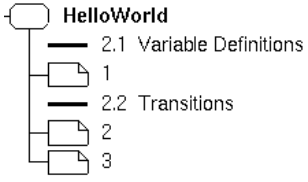

Figure 96: Chapters between SDL pages

When page symbols are visible, you can move chapter symbols into the correct place within the SDL system by using the up and down quick-

buttons. You can also create new chapter symbols directly at the correct place, by selecting the SDL symbol that the chapter symbol should be placed after, before invoking *Add New*.

Note that MSCs can be placed in the middle of an SDL system or diagram, in the same way as chapters. This is useful if you want to print an MSC close to the corresponding SDL.

Defining the Start Chapter Number

Normally, the start chapter number is 1 (or 1.1 if the first chapter symbol has the type *Chapter 1.1*.) You can change this number in the *View > Chapter Options* dialog.

Deciding Maximum Chapter Level in the Table of Contents

As default, all chapters are visible in the table of contents. If you have a lot of chapters, you can limit the number of chapters in the table of contents by using the *View > Chapter Options* dialog. A maximum chapter level of 2 will only include chapter symbols of type *Chapter*, *Chapter 1* and *Chapter 1.1* in the table of contents.

Printing a Table of Contents with Only Chapters

To print a table of contents, you have to turn on the *Table of contents* toggle button in the *Contents* section in the *Print* dialog.

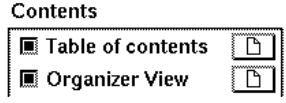

Figure 97: The Table of Contents entry in the Print dialog

As default, the table of contents includes chapters, diagrams and documents. To restrict the table of contents to just chapters, there are two ways:

- If you want to do a temporary restriction just for one printout, then there is a toggle for doing so in a sub dialog to the *Print* dialog: To get to the sub dialog from the *Print* dialog, press the setup button with a picture close to the Table of contents entry in the Contents section. In the sub dialog, turn on the toggle *Only chapters in TOC*.

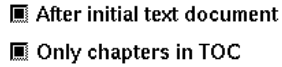

Figure 98: Part of the Print Setup dialog for Table of contents

- If you want the restriction to be more permanent, go to the *Preference Manager*. In that tool, double-click on the *Print* symbol to expand its contents, and set the value of the preference OnlyChaptersInTOC to on. Save the preferences and restart.

Title Page

A plain text document can become a title page by placing it first among the diagrams and documents that are printed. There is nothing special about a title page, except that it can be placed before the table of contents.

Figure 99: A title text document in the Organizer view

Getting the Title Page before the Table of Contents

To print a table of contents, you have to turn on the *Table of contents* toggle button in the *Contents* section in the *Print* dialog.

Normally, you do not have to do anything to get the title page before the table of contents, because the print operation will as default treat an initial text document as a title page. There is however a way to turn this on and off. This is done in the Print Setup dialog for the *Table of contents* entry in the *Contents* section in the *Print* dialog. You can get to this dialog from the *Print* dialog by pressing the setup button with a picture close to the *Table of contents* entry.

State Matrices

State Matrices are described in detail in chapter 6, *The Text Editor*. Here are only the most important things discussed, enabling you to get a nice printout of state matrices for processes in your SDL system.

Creating State Matrices

When you have a correct SDL system, you can create state matrices with the *Generate* > *State Overview* menu choice. A state information file (`*.ins`) will be created in your target directory, a plain text symbol connected to the file will be added in the Organizer view, and a Text Editor will pop up, acting as a State Matrix Viewer.

```
Process HelloWorld: nextstates
States
a Start state
b waiting
c stop
          |  STATES
SIGNALS   |  a    b    c
          |-------------
-         |  b
Hello     |       c
```

Figure 100: A state matrix

Filter State Matrices

The Text Editor has two menu choices that you can use to get the state matrices that you want.

- *View* > *State Matrix* > *Filter Processes*. This menu choice allows you to hide state matrices for SDL processes that you are not interested in.
- *View* > *State Matrix* > *Transition Information*. This menu choice decides the information that should be presented for transitions in your state matrices. As default, you will get two state matrices for each SDL process: One with paper page references to the corresponding SDL transition and one with nextstate information. You can with this menu choice also have state matrices with output/signal sending information and procedure call information.

The options in the two dialogs above can also be set in a more permanent way, using preferences. To do this, use these Text Editor preferences:

- StateMatrixFilter
- StateMatrixCalls
- StateMatrixNextstates
- StateMatrixOutputs
- StateMatrixPageNumbers

Printing State Matrices with Paper Page References

When you view state matrices on-line, you will not see any paper page references in a page number state matrix. All page numbers are undefined and replaced by a "*". The page numbers are only visible in your printout, and only if you print the SDL processes together with the state matrices from the Organizer.

Index

The index is described in detail in chapter 46, *The SDL Index Viewer*. Here are only the most important things discussed, enabling you to get a nice printout of an index of all SDL entities defined and used in your SDL system.

Creating an Index

When you have a correct SDL system, you can press the *Generate Index* quick button in the Organizer. This will pop up an index viewer with an index of all SDL entities defined and used in your SDL system.

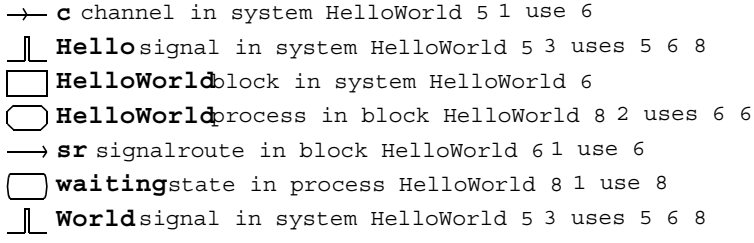

Figure 101: An SDL entity index example

Filter Index Information

The generated index may be too long to be printed in its entirety. You can make the index smaller by filtering out information that you consider unimportant.

You can filter out SDL entities defined in specific SDL diagrams. This is done with the *View > Filter Diagrams* dialog. A common use of this possibility is to filter out SDL entities defined in package Predefined.

You can filter out SDL entity types. This is done in the *View > Filter Types* dialog. For instance, if you want an index of just the signals in your SDL system, then you can use this possibility to filter out all other SDL entity types.

To make your filter more permanent than just for the current Index Viewer session, you should define your filter settings in the Preference Manager before starting the Index Viewer. These two preferences are appropriate:

- FilterDiagrams
- FilterTypes

Deciding Index Appearance

Each SDL entity in the index can be presented in four different ways. You can change the index appearance for the current Index Viewer session with the *View > Index Appearance* dialog. To make your changes more permanent, use the Preference Manager and the following preference:

- IndexAppearance

As default, the index appearance is set to *Detailed*. This setting is appropriate for on-line viewing. For a printout, it might produce unnecessary large indexes. To get a smaller index in a printout, use the *Compact* index appearance.

Printing an Index with Paper Page References

It is possible to get paper page references for both definitions and uses of SDL entities in a printout of an index. To achieve this, leave the Index Viewer window on screen while doing a printout from the Organizer that includes your SDL system and the index view.

Fonts

There are two kinds of fonts:

- Proportional fonts such as Times. These fonts have the advantage of not needing much space.
- Non-proportional fonts such as Courier. These fonts have the advantage of being useful for creating tables where it is important that the same character position on different lines are aligned.

Below, you will learn how to set up SDL Suite and TTCN Suite to use appropriate fonts for different uses.

Using a Non-Proportional Font in the Text Editor

State matrices are viewed and printed from the Text Editor. State matrices should be presented using a non-proportional font. To get a non-proportional font in printouts of state matrices, set the preference SDT*PrintFontFamily to Courier.

Using a Non-Proportional Font for SDL Text Symbols

Sometimes, it is convenient to make aligned tables in SDL text symbols. This requires a non-proportional font. On the other hand, you do not want a non-proportional font for all other symbols in a process diagram, because you want to squeeze as much text as possible into a flow symbol without going outside the symbol border.

You can have a separate, non-proportional font for SDL text symbols. This is achieved by setting Editor*FontText*TextSymbolFontFamily to Courier. This preference is valid both on-line and in print. All the other symbols use the fonts set by Editor*FontText*ScreenFontFamily and Editor*FontText*PrintFontFamily.

Title Fonts: Size and Boldness

The table of contents has a title named “Contents” that is always presented in bold.

Font size and boldness for chapter names in text page titles are determined by the chapter level:

- Chapter level 1 (for instance 1) uses 14 pt bold.
- Chapter level 2 (for instance 1.1) uses 12 pt bold.

- Chapter level 3 (for instance 1.1.1) uses 11 pt bold.
- Chapter level 4 (for instance 1.1.1.1) uses 11 pt, not bold.

A normal text, and a chapter without a chapter number (chapter level 0), uses the same font appearance for the title as the font used for the following text.

To get header titles in a larger font (14 pt) and with a bold text, use a header definition file with a *Title* keyword. (<#Title>, <#Title 2> or something similar.)

Text Indentation

There are three text indentation levels, and each text indentation level has a corresponding preference:

- Print*TextIndentation1. Used by text pages for presenting chapter numbers. Default: 44 mm from the left paper edge.
- Print*TextIndentation2. Used by text pages for presenting chapter names and normal text. Also used by the table of contents for presenting chapter numbers. Default: 67 mm from the left paper edge.
- Print*TextIndentation3. Used by the table of contents for presenting chapter names. Default: 90 mm from the left paper edge.

Introducing Advanced Print Facilities

In this sub section we will take a more detailed and practical look at how an ordinary SDL system can be turned into an SDL system with enhanced print facilities.

> **Note:**
>
> As default in this section, we are talking about menu choices and dialogs in the Organizer.

Initial Setup

Before starting doing print enhancements for the specific SDL system, we should set up some preferences affecting how the final printout will look like.

1. Bring up the Preference Manager with the menu choice *Tools* > *Preference Manager*.
   - To get a non-proportional font in printouts of state matrices, set the preference SDT*PrintFontFamily to Courier.
   - To get a non-proportional font in text symbols in SDL diagrams, set the preference (SDL) Editor*FontText*TextSymbolFontFamily to Courier.
2. Save the preferences and exit the Preference Manager.

The Example SDL System

We will use an SDL system called HelloWorld as an example. When we start, we have a correct SDL system that is not adapted in any way for producing a nice printout. If we just do a plain printout of HelloWorld, we will get the following:

> **Note:**
>
> The figures below are not exact copies of a printout, they have been modified slightly to fit in this manual.

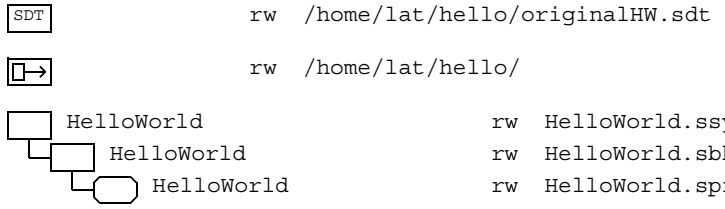

Figure 102: HelloWorld, Organizer view

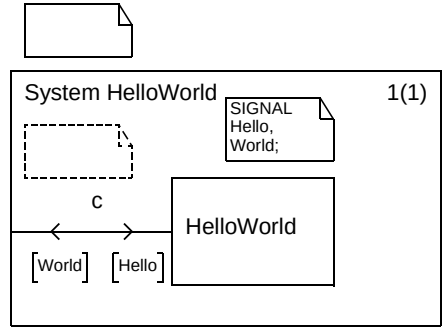

Figure 103: HelloWorld, system diagram

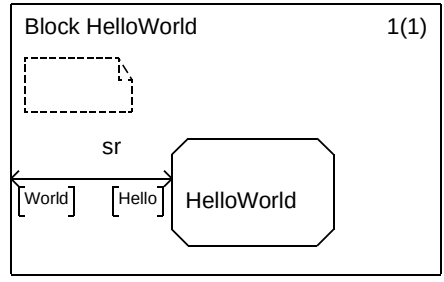

Figure 104: HelloWorld, block diagram

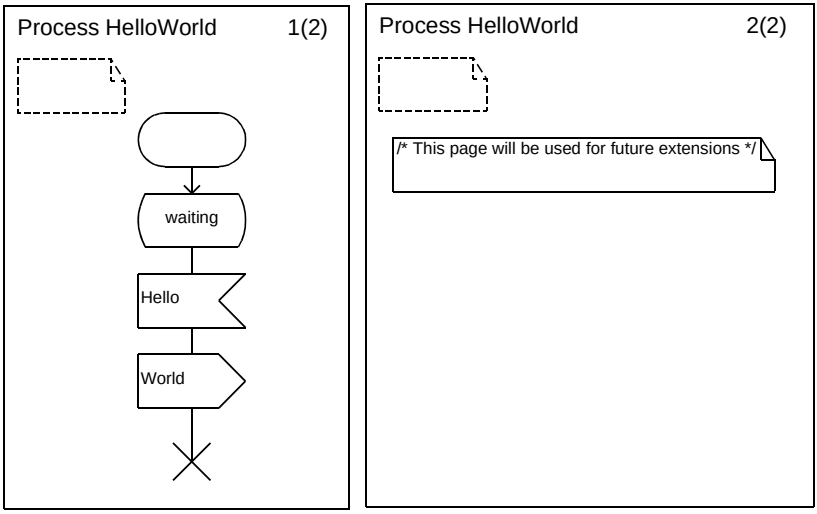

Figure 105: HelloWorld, process diagram

To get a better printout, we will add the following:

- A Header on Each Printed Page
- A Title Page
- Chapters and Sub Chapters
- State Matrices for the SDL Process
- An Index of SDL Entities

When we have done that, we will perform a print operation to actually get our enhanced printout.

A Header on Each Printed Page

The header should have the following properties:

- A separate header appearance for the first page.
- The company logo should be visible on every page.
- The header should include information about page number, total pages, chapter number and chapter name.

Fortunately, someone at our company has provided a company logo in Encapsulated PostScript format (`*.eps`), and a template header definition file. The template looks like this:

```
IFFIRST
18 28 Name of designer
ENDIF

IFNOTFIRST
183 20 <page>(<totalpages>)
90 24 Chapter <chapternumber> <chaptername>
ENDIF

EPSF 10 25 /home/lat/hello/tlog.eps
90 20 Name of SDL system
```

Action

1. The header symbol is not visible in the Organizer view. To make it visible, bring up the *View Options* dialog and select the *Header file* item and press *Apply* and *Close*.

2. To create a new and unique header for the SDL system, double-click on the header symbol in the Organizer view.

3. In the Edit dialog that follows, we should specify the template file under *Copy existing file*. In our case, someone has put the template file in `/home/lat/hello/headerTemplate.txt`.

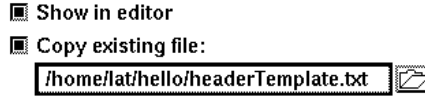

Figure 106: Specifying the template header file in the Add New dialog

4. When we close the Edit dialog, the text editor pops up with a copy of the template header file.

5. To get a unique header for our SDL system, we change the following things:

```
Name of designer -> Lars Tufvesson
Name of SDL system -> HelloWorld
```

6. When that is done, we save our specialized header file in the same directory as our SDL diagrams.

A Title Page

A title page is a plain text document that is placed first among all printed pages and documents.

Action

1. We should add a new plain text document to our SDL system. To make sure it is placed first, select the header symbol before invoking *Add New*.
2. In the Add New dialog, set the document type to *Plain Text* and set the document name to *TitlePage*.
3. When you close the dialog, the Text Editor pops up. Type in an appropriate title page text (like the one below) and save the text file in the same directory as the SDL diagrams.

```
******************
*System HelloWorld*
******************

A revolutionary SDL system software package
```

Chapters and Sub Chapters

We would like to divide our diagrams and documents in three chapters:

- The first chapter contains state matrices for the SDL process(es).
- The second chapter contains the SDL system.
- The third chapter is an appendix that contains the index of SDL entities.

The second chapter will be further divided into two sub chapters. Each chapter and sub chapter should have a chapter introduction text.

Action

1. We would like to place the first chapter directly after the title page text symbol. Select the title page text symbol and bring up the *Add New* dialog.
2. Set the document type to *Organizer > Chapter 1*, and the document name to *State Matrices*.
3. When you close the dialog, the Text Editor will pop up. Type in an appropriate chapter introduction text (like the one below) and save the text file.

```
This chapter contains two state matrices for the
SDL process: One with page numbers to the SDL
process and one with nextstate information.
```

We will produce the state matrices for this chapter in the next sub section. For now, we leave this chapter empty.

4. We introduce a second chapter for the SDL system. Select the *State Matrices* chapter symbol and bring up the *Add New* dialog. Set the document type to *Organizer > Chapter 1*, and the document name to *SDL system*. When you close the dialog, the Text Editor will pop up. Type in an appropriate chapter introduction text (like the one below) and save the text file.

   ```
   In this chapter, you will find the actual SDL
   system.
   ```

5. The SDL system chapter should have two sub chapters for the SDL process. To be able to begin a chapter between two pages in one SDL diagram, we must make page symbols visible in the Organizer. This is done in the *View Options* dialog by selecting *Page symbols* and pressing *Apply* and *Close*.

6. The first sub chapter should begin where the process diagram begins. Select the process diagram symbol and bring up the *Add New* dialog. Set the diagram type to *Organizer > Chapter 1.1*, and the document name to *First process page*. When you close the dialog, the Text Editor will pop up. Type in an appropriate chapter introduction text (like the one below) and save the text file.

   ```
   In this sub chapter, the first process page will be
   defined.
   ```

7. The second sub chapter should be placed between the two pages of the SDL process. Select the first process page symbol and bring up the *Add New* dialog. Set the diagram type to *Organizer > Chapter 1.1*, and the document name to *Second process page*. When you close the dialog, the Text Editor will pop up. Type in an appropriate chapter introduction text (like the one below) and save the text file.

   ```
   In this sub chapter, the second process page will be
   defined.
   ```

8. Finally, we should have an appendix chapter for the index of SDL entities. This chapter should be placed last in the Organizer view.

Select the last symbol in the Organizer and bring up the *Add New* dialog. Set the diagram type to *Organizer > Chapter 1*, and the document name to *Appendix*. When you close the dialog, the Text Editor pops up. Type in an appropriate chapter introduction text (like the one below) and save the text file.

```
The appendix contains an index of all SDL entities.
```

State Matrices for the SDL Process

The Organizer can with the help of the Analyzer generate a state overview information file (`*.ins`). The file is placed in the target directory. The Text Editor can display this file as state matrices.

Action

1. First, we should set the target directory to an appropriate directory where we can allow SDL Suite and TTCN Suite to create files. Bring up the *Set Directories* dialog and type in an appropriate target directory. When that is done, close the dialog.

2. Select the SDL system diagram and invoke the state overview information file generation with *Generate > State Overview*. The Analyzer will check your SDL system and produce some files in the target directory. One of these files is the `*.ins` file.

3. When the Analyzer is ready, the Text Editor will pop up, showing you the state matrices created from the information in the state overview file (`*.ins`). When you have examined the state matrices, exit the Text Editor.

4. The plain text symbol connected to the `*.ins` file should be placed in the first chapter instead of in the same chapter as the SDL system. To move the plain text symbol for the `*.ins` file to the correct location, select the symbol and use the up quick button as many times as required to get the symbol into the first chapter.

An Index of SDL Entities

We would like an index of SDL entities defined in our SDL system last in the printout. The Organizer can with the help of the Analyzer produce a cross reference file. The Index Viewer can present the information in the cross reference file as an index. To keep the size of the index small,

we filter out some SDL entities and we present the index in an as compact way as possible.

Action

1. Make sure that the target directory is set to an appropriate directory where the Analyzer can create some files.
2. Select the SDL system diagram symbol and press the *Generate Index* quick button. The Analyzer will check your SDL system and generate some files in the target directory. One of the files is named `*.xrf` and contains the cross reference information. The Index Viewer pops up when the Analyzer is ready, and presents the cross reference information as an index.
3. If you examine the index, you will notice that there are a lot of SDL entities defined in *package Predefined*. Let us assume that we are not interested in these SDL entities. To get rid of them, we bring up the *Filter Diagrams* dialog and select *package Predefined*. When the dialog is closed, our Index will be much smaller.
4. To get an even smaller index, bring up the *Index Options* dialog and set the index appearance to *Compact*.
5. Now, the index is ready for printing. Since there is no symbol in the Organizer view for the cross reference file, we have to leave the Index Viewer window open until we have completed the print operation.

Performing the Print Operation

Now, everything is in place to do the actual print operation.

Action

1. Make sure you have no selection in the Organizer. This can be done by clicking somewhere outside a symbol or text line. This is done to tell the Organizer that we want to print everything, and not just what we have selected.
2. Bring up the *Print* dialog.

3. Make sure that the following entries in the Contents area are selected:

   – Table of contents
   – Organizer View
   – SDL Interaction
   – Text Diagram
   – Index View

   No other entries in the Contents area should be selected.

4. Bring up the *Table of contents* setup dialog with the picture button close to the *Table of contents* entry. In the setup dialog, make sure that both *After initial text document* and *Only chapters in TOC* are both selected. Close the setup dialog.

5. Make sure that the header file check button is on.

6. Make sure that the settings in the Destination area are appropriate.

7. Click the *Print* button. We will get a printout, looking approximately as the figures below.

HelloWorld

Using Advanced Print Facilities

In the previous section, we took an ordinary SDL system and made enhancements to get a nice printout. In this section, we will look at how we can make the enhancements as permanent as possible. We would like to be able to load a system file, invoke the print operation and get a nice printout without changing any print settings.

Let us take a new look at all the changes we have made, to see how we can make a future print operation as painless as possible.

A Permanent Title Page

Every time the print dialog is invoked, the *Table of contents* setup option *After initial text document* will be turned on. This means that the title page will show up as a title page in future print operations also. No extra actions necessary here.

Permanent Chapters and Sub Chapters

The chapter symbols should stay where they were initially placed. Due to implementation reasons, chapter symbols placed between SDL page symbols might be a little more volatile than they should be. The position of a chapter symbol is determined by remembering the name of the next SDL page symbol. If you rename that SDL page symbol, the chapter looses its hook and may end up in the wrong position.

The chapter options that you can set in the *Chapter Options* dialog are reset every time SDL Suite and TTCN Suite are restarted. This means that if you want the start chapter number to permanently be anything other than 1.1.1.1, or you want to hide sub chapters in the table of contents, then you have to check the *Chapter Options* settings before each print operation.

Permanent State Matrices

State matrix options are not saved together with the state overview file (`*.ins`), but they are saved in the system file (*.sdt) and in print selection files (*.sel).

The state overview file (`*.ins`) is generated in the target directory. You may regard the target directory as a temporary directory where files can be erased after an SDL Suite or TTCN Suite session has ended. It might be cumbersome to regenerate a state overview file each time you want

to do a printout. In this situation, it might be a good idea to move the state overview file to the source directory, where your SDL diagram files resides. The file move is best done outside of SDL Suite, but in the Organizer view you have to reconnect the plain text symbol to the (moved) state overview file in the source directory.

A Permanent Index

Index options are not saved together with the cross reference file (*.xrf), but they are saved in the system file (*.sdt) and in print selection files (*.sel).

The cross reference file (`*.xrf`) is generated in the target directory. You may regard the target directory as a temporary directory where files can be erased after an SDL Suite or TTCN Suite session has ended. It might be cumbersome to regenerate a cross reference file each time you want to do a printout. In this situation, it might be a good idea to move the cross reference file to the source directory, where your SDL diagram files resides. The file move is best done outside of SDL Suite.

To get paper page references in the index, the index has to be printed from the Organizer together with the SDL system.

Performing a Permanent Print Operation

Every time the print dialog is invoked, the *Table of contents* setup option *Only chapters in TOC* will be set to off. This means that if you want only chapters in the table of contents, you have to turn this option on every time you want to print.

In a similar manner, every time SDL Suite and TTCN Suite is started, the *Table of contents* toggle button in the main print dialog is set to off. This means that every time you want to do a print, you have to check the *Table of contents* toggle button and turn it on, if it is off.

Print Selection Files and Print Selection Symbols

Most print, index and cross reference options are saved in the system file (*.sdt). This is often enough for most of your print needs. However, in some situations you might want to save more than one set of print settings: You want to easily switch...

- Header and footer information
- The set of documents/diagrams/pages that should be printed.

This can be done by saving a couple of print selection files with different print settings, and reference these files with print selection symbols in the Organizer.

1. To save print settings in a print selection file, bring up the Organizer print dialog, as you would for performing a normal print operation.
2. Adjust the settings in the dialog to what you want printed, both by changing what diagrams to print and by changing how the print will be performed (paper format etc.).
3. When all settings are correct, use the *Save* button to save the print selection file. In the dialog that appears, you can both decide the print selection file name to use, and if a print selection symbol should be created in the Organizer or not.

A print selection can be reused in several ways:

- Double-click the print selection symbol.
- Select the print selection symbol and invoke File > Print > Selected.
- Invoke File > Print > Selection File, and specify the print selection file in the dialog that appears.

In all these cases, the Organizer print dialog will appear, with settings according to the reused print selection file.

Chapter

6 *The Text Editor*

The Text Editor is the graphical tool that is used to create, edit, display and print text file documents.

The Text Editor can also be used as a state matrix viewer. One or several state-signal matrices can be presented for each process in an SDL system. The state matrices for an SDL system are presented as one read-only text file. As in any other SDL viewer tool, it is possible to navigate from an entity in a state matrix to the corresponding entity in the SDL system.

This chapter contains a reference manual to the Text Editor; the functionality it provides, its menus and windows.

Text Files

The Text Editor works with ASCII text files. The text editor can be used to view, edit and print text files. In addition to providing typical text editor functions, the Text Editor provides special support for embedding link endpoints into the text. For more information on links and endpoints, see chapter 9, *Implinks and Endpoints*.

> **Note:**
>
> The Text Editor is only available if the Organizer is started with the preference SDT*TextEditor set to “SDT”.

Endpoint Support

In the Text Editor, endpoints are user-defined, non-overlapping, contiguous ranges of characters, possibly spanning several lines of text, that are made visible to other tools, allowing you to define links between fragments in your text and endpoints in other documents.

Endpoints are displayed in the text editor by underlining the range of characters that are part of the endpoint.

Note that when you define an endpoint, you do not impose any particular restrictions on the text in the endpoint, meaning that you can still edit the text in the endpoint using the normal text editing functions to modify the endpoint’s contents. The text editor dynamically notifies other tools the changes you make to your endpoints as you make your changes, to make sure that the view of the endpoints in your file is always current.

Considerations when Using Text Endpoints

The requirement that endpoints must be non-overlapping means that you cannot create an endpoint inside another endpoint. Also, while an endpoint is allowed to span several lines, it is generally best to restrict endpoints to small, well-defined fragments of text on a single line, used as external reference points to the information in your files.

Also note that while the Text Editor visualizes endpoints by simply underlining the text in the endpoints, the endpoints are stored in your actual text files using special keywords before and after the characters in the endpoint. This means that it is not advisable to view or edit text documents with endpoints in a text editor that is not aware of the special significance of these keywords. If you do so, you should be careful so

as to not destroy information about the endpoints in the file, as this could cause links attached to these endpoints to break.

Another consequence of how the Text Editor stores the endpoint information is that if you are editing text documents that are intended as input to other tools (such as a C or C++ compiler) you should take care to place endpoints only within commented regions of text. This makes sure that the extra text inserted when storing the endpoints does not conflict with the allowed grammar of the type of file you are editing.

Examples

In the examples below you will find typical placements of text endpoints. These endpoints could then be the basis for creation of links into requirements, analysis, design, and specification documents, to name only a few possibilities.

Example 23 ----------

Improperly commented C header with endpoints:

```
/* Primary protocol packet */
struct Packet { ... };
```

Properly commented C header with endpoints:

```
/* Primary protocol packet */
struct Packet { ... };
```

Example 24 ----------

Improperly commented C++ header with endpoints:

```
class Base {

virtual char *name() const = 0;
        virtual int size() const = 0;
                          ...
}
```

Properly commented C++ header with endpoints:

```
// class Base
class Base {

virtual char *name() const = 0;  // get name
        virtual int size() const = 0;    // get size
                          ...
}
```

State Overview Files and State Matrices

The Organizer can produce a state overview file, see "State Overview" on page 130 in chapter 2, *The Organizer*. The Text Editor recognizes a state overview file by the extension `.ins`. If such a file is opened in the Text Editor, the Text Editor extracts information from the file and presents the information as a read-only text file containing state matrices. State overview files cannot be edited or saved in the Text Editor.

A state matrix is a textual table with the states in a process or procedure along one dimension and the signals in the same process or procedure along the other dimension. In the table, you will find the transitions for the process or procedure.

A state matrix may look like this: ("-" means no signal)

```
Process Main: nextstates

States
a Start state
b Game_Off
c Game_On
           |  STATES
SIGNALS    |  a    b    c
           |-------------
-          |  b
Newgame    |       c
Endgame    |            b
```

The Text Editor keeps track of how entities in the state matrix is related to the SDL system. This makes it possible to navigate back to the SDL system. To do so, place the text cursor close to an entity in a state matrix and bring up the pop-up menu for that entity and invoke one of the available menu choices.

A state overview file can be saved as a normal text file. This might be useful if you want to edit a state matrix. But by doing so, you will lose all the extra information associated with the state matrices that is not visible when viewing a state overview file in the text editor. You will no longer be able to:

- Navigate back to SDL.
- Get paper page references to SDL pages for transitions in the state matrix (read more about how this is done in "Advanced Print Facilities" on page 357 in chapter 5, *Printing Documents and Diagrams*).
- Decide the kind of information that should be presented for a transition in the state matrix.

Text Editor User Interface

The Text Editor window is depicted below. For a general description of the user interface, see chapter 1, *User Interface and Basic Operations*.

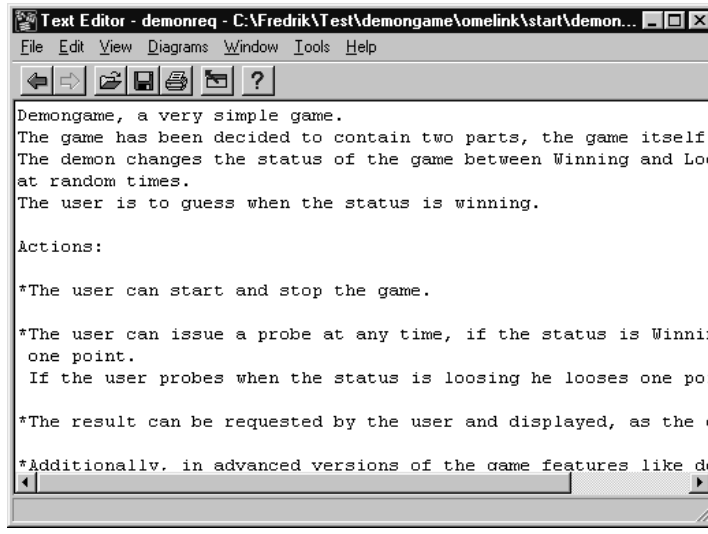

Figure 121: The Text Editor window

Text Area

Text in the Text Editor is displayed and printed using the non-proportional font face *Courier*, which is suitable for displaying ASCII texts such as source code.

While the screen font is fixed, you can change the font face used use for printing by editing the SDT preference SDT*PrintFontFamily.

Text Editing Functions

The following text editing functions are provided in the text window:

Text Selection

To select text you can either:

- Drag the pointer over the text.
- Place the cursor in the beginning or end of the text to be selected and then `<Shift>`-click where you want the selection to end.

Word Selection

Double-click a single word, delimited by spaces, to select it.

Line Selection

Triple-click a line of text to select it.

Text Editing

When you edit text, you can:

- Position the cursor by clicking or by using the arrow keys.
- Insert characters after the current position of the text pointer.
- Delete one character backward by pressing `<backspace>`.
- Delete one character forward by pressing `<delete>`.
- Replace selected text by typing.
- Delete selected text by pressing `<backspace>` or `<delete>`.

Undoing Text Modifications

The *Undo* command reverts the previous editing command. Several undo operations can be performed in sequence to undo sequences of editing commands.

Undo can negate the effects of all commands that alter the text in the Text Editor; however, the effect of user operations on endpoints and links cannot be undone by the undo command.

Depending on the nature of the last performed operation, the effects of the last text editing operation is undone, on a per editing operation. For undo purposes, the text editor recognizes the following operations:

- Typing a character
- Inserting a character or a fragment of text
- Deleting a character or a fragment of text

While having to undo each typed character individually may be somewhat inconvenient, a keyboard accelerator (`<Ctrl+Z>`, see "Keyboard Accelerators" on page 406) can speed up the process.

Note that since the text editor supports unlimited undo, it is not possible to use the undo operation to undo the last undo operation. Instead there is a keyboard accelerator (`<Ctrl+Y>`, see "Keyboard Accelerators" on page 406) which can be used repeatedly to undo the effects of a sequence of undo operations.

Editing Text Containing Endpoints

It is possible to edit text using normal operations even after endpoints have been embedded in your text. To unambiguously determine the effects of editing operations on endpoints, the Text Editor uses the character just before the position of your insertion cursor or your selection (the initial character) to determine if your editing affects an endpoint:

- If the initial character belongs to an endpoint (e.g. the insertion cursor is positioned just after an endpoint), inserted text will become part of the endpoint.
- If the initial character belongs to non-endpoint text (e.g. the insertion cursor is positioned just before an endpoint), the inserted text will not be included in an endpoint.

Note:

When deleting or overwriting text, you should be careful not to delete or overwrite all characters in an endpoint since this will remove the endpoint and the associated links.

Dealing with Consecutive Endpoints

When working with consecutive endpoints (i.e. two endpoints follow each other without any intervening non-endpoint text), it is impossible to insert extra characters between these endpoints using the normal text editing operations, since any text inserted between the two endpoints will be considered a part of the first endpoint.

If this particular case arises, you should use *Clear Endpoint* (see "Link > Clear Endpoint" on page 447 in chapter 9, *Implinks and Endpoints*) to remove some characters from one of the endpoints so that some non-endpoint characters become available between your endpoints.

Also note that while the text editor has no difficulty in dealing with consecutive endpoints, visual limitations will make it difficult to distinguish between the two endpoints. You should therefore avoid using consecutive endpoints if possible.

Menu Bar

The menu bar provides commands available in menus and menu choices for editing diagrams and pages of diagrams. Most the functionality that the Text Editor offers is contained within the commands from the menu bar. The Text Editor's menu bar provides the following menus:

- *File Menu*
- *Edit Menu*
- *View Menu*
- *Diagrams Menu*
- *Window Menu*
- *Tools Menu*
- *Help Menu*
  (see "Help Menu" on page 15 in chapter 1, *User Interface and Basic Operations*)

File Menu

The *File* menu contains the following menu choices:

- *New*
- *Open*
- *Save*
- *Save As*
- *Save a Copy As*
- *Save All*
- *Close Diagram*
- *Revert Diagram*
- *Print*
- *Exit*

The menu choices are described in "File Menu" on page 8 in chapter 1, *User Interface and Basic Operations*, except *Print* which is described in "The Print Dialogs in the SDL Suite and in the Organizer" on page 316 in chapter 5, *Printing Documents and Diagrams*.

Edit Menu

The *Edit* menu provides the following choices, which may or may not be dimmed depending upon whether or not some text is selected:

- *Undo*
- *Cut*
- *Copy*
- *Paste*
- *Paste As*
- *Clear*
- *Select All*

Undo

This command restores the last text editing operation. The following operations can be undone:

- *Typing, insertions and deletions.*
- *Cut*, *Paste*, *Paste As* and *Clear*

> **Note:**
>
> Undo does not restore endpoints or links, even though typing, insertions and deletions can destroy both endpoints and links

For more information on the operation of the *Undo* command, see "Undoing Text Modifications" on page 391.

Cut

Cut removes the selected portion of text from the text window and saves it in the clipboard buffer just as if a *Copy* has been made. *Cut* is only available if a portion of text has been selected. *Cut* is not available for state overview files (`*.ins`), because they are not editable.

Also see "Deleting an Object" on page 461.

Copy

Copy makes a copy of the selected portion of text in the clipboard buffer. The content of the text window is not affected. *Copy* is only valid if a portion of text has been selected.

When copying text to the clipboard buffer it becomes possible to paste into three different contexts:

- As simple text (without endpoint and link information) into applications that normally support cut/copy of text, such as terminal windows and other text editors.
- As text with endpoint and link information when pasting into one of the Text Editor windows, which means that endpoints and links are preserved.
- As a Paste As operation in all the Editors (including the Text Editor itself), provided that the copied text contained no endpoints or exactly matched an endpoint. See "Pasting a Text Fragment" on page 460 for more information.

Paste

Paste inserts the content of the clipboard buffer into the text window. The text in the clipboard buffer will be appended immediately following the cursor position, or replacing the selected text. *Paste* is only available if a portion of text has been cut or copied into clipboard buffer. *Paste* is not available for state overview files.

Also see "Pasting an Object" on page 461.

Paste As

Pastes the currently copied object (from the OM or Text Editor) as a text in the text window. The object is transformed and a link is optionally created between the copied object and the pasted text.

The Paste As dialog is opened. See "The Paste As Command" on page 448 for more information. *Paste As* is not available for state overview files (`*.ins`), because these files are not editable.

Clear

Clear removes the selected portion of text from the text window. The content of the clipboard buffer is not affected. *Clear* is only available if a portion of text has been selected. *Clear* is not available for state overview files (`*.ins`), because these files are not editable.

Also see "Deleting an Object" on page 461.

Select All

Select All selects all of the text contained in the text window.

View Menu

The *View* menu provides rescaling functions and access to various options that affect the behavior of the Text Editor. The following menu choices are available:

- *Window Options*
- *Editor Options*
- *State Matrix > Filter Processes*
- *State Matrix > Matrix Options*

Window Options

This menu choice issues a dialog where the presence of the tool and status bars can be set:

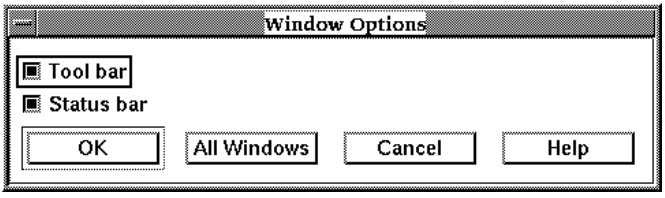

Figure 122: The Window Options dialog

- Clicking *OK* applies the options as defined in the dialog to the current window only.
- Clicking *All Windows* applies the options as defined in the dialog to all windows opened by the Text Editor.

Editor Options

This menu choice issues a dialog where the behavior of the Text Editor can be customized.

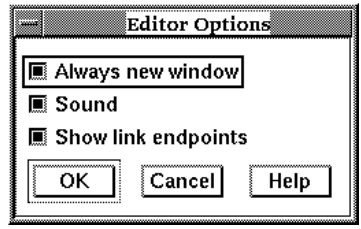

Figure 123: The Editor Options dialog

The options are controlled by toggle buttons. They are:

- *Always new Window*

  This option indicates whether or not a new window should be opened whenever the *New* or *Open* command or any command from the *File* menu is operated.

  The default behavior is not to open a new window.

- *Sound*

  This option indicates whether or not improper actions in the Text Editor, such as attempting to overlap symbols, should be brought to the user's attention by producing an alert sound.

  The default value for this option is on.

- *Show Link Endpoints*

  This option indicates whether link endpoints should be displayed by underlining the endpoint text.

Note:

Regardless of the setting of this option, link endpoints are never shown when printed.

The default value for this option is controlled by the TE*ShowLinks preference.

State Matrix > Filter Processes

This menu choice is only available for state overview files (`*.ins`).

This menu choice brings up a dialog that decides the group of processes that should be visible as state matrices. As default, all processes in the SDL system are visible. The dialog allows you to show selected processes, hide selected processes or show all processes.

State Matrix > Matrix Options

This menu choice is only available for state overview files (`*.ins`).

This menu choice brings up a dialog with options for state matrices. The available options are listed below.

Sort states

The states in the state matrices will be sorted in alphabetical order.

Sort signals

The signals in the state matrices will be sorted in alphabetical order.

Show page reference matrix

The page references refer to the printed page where the transition in question starts, i.e. where the SDL input symbol is placed. '-' means no signal.

Page references are normally not visible, they are replaced with '*'. The only chance you have to see page references instead of '*' is to print the SDL process together with the state overview file (`*.ins`) from the Organizer.

```
Page reference matrix for process Demon:

States
a Start state
b Generate

          |  STATES
SIGNALS   |  a    b
          |--------
-         |  *
T         |       *
```

Show nextstate matrix

For each transition, the possible nextstates are listed. ‘-’ means no signal.

```
Nextstate matrix for process Demon:

States
a Start state
b Generate

          |  STATES
SIGNALS   |  a    b
          |--------
-         |  b
T         |       b
```

Show signal sending matrix

For each transition, signals that might be sent from SDL output symbols during the transition are listed. ‘-’ means no signal or no output.

```
Signal sending matrix for Process Demon:

States
a Start state
b Generate

          |  STATES
SIGNALS   |  a    b
          |--------
-         |  -
T         |       1

1 = Bump
```

Show procedure call matrix

For each transition, procedures that might be called during the transition are listed. ‘-’ means no signal or no procedure call.

```
Process Demon: procedure calls

States
a Start state
b Generate

          |  STATES
SIGNALS   |  a    b
          |--------
-         |  -
T         |       -
```

Diagrams Menu

The *Diagrams* menu records all diagrams and pages that are opened by the Text Editor. The available menu choices are:

- *Back*
- *Forward*
- *<Diagram Name>*
- *List All*

Back

Select this menu choice to browse back to the document that was previously displayed in the window.

Forward

Select this menu choice to browse forward to the document that was displayed in the window before you selected *Back*.

<Diagram Name>

The last edited page always goes to the top of the list, and subsequently moves the other diagrams and pages down a position. A maximum of 9 open pages can be shown. A tenth one will be put at the top of the list, but any subsequent opening of a diagram or page will only show the last 9 that have been opened. Another option – *List All* (at the bottom of the list) – is available to list all the open diagrams in the Text Editor.

Each item in the menu provides information about the diagram name, possibly followed by the file it is stored on (the file information is missing if the diagram has never been saved). A diagram that is preceded by an asterisk (‘*’) denotes that it has been modified during the Text Editor session.

List All

This menu choice becomes available when a maximum of 9 open pages has been surpassed. When *List All* is selected, it provides a dialog containing all diagrams and pages that are currently open in the Text Editor:

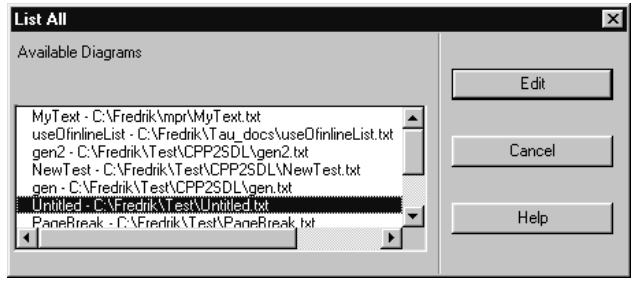

Figure 124: The List All dialog

Window Menu

The *Window* menu contains the following menu choices:

- *Close Window*
- *Entity Dictionary*

Close Window

This option closes the open window, **but**, not necessarily the diagram. If more than one editor window is opened, only the current window is closed and not the diagram. If the last open editor window is closed, the Text Editor will act as if *Exit* has been chosen, possibly in conjunction with a save of information (see "Close Diagram" on page 14 in chapter 1, *User Interface and Basic Operations*).

Entity Dictionary

Opens the Entity Dictionary window. See "The Entity Dictionary" on page 434 for more information.

When working with the Entity Dictionary in the Text Editor, note that the *Link > Create* command will not automatically create an endpoint on the current selection as is the case in the graphical Editors.

Tools Menu

The *Tools* menu contains the following menu choices:

- *Show Organizer*
- *Link > Create*
- *Link > Create Endpoint*
- *Link > Traverse*
- *Link > Link Manager*
- *Link > Clear*
- *Link > Clear Endpoint*

  (The *Link* commands are described in "Link Commands in the Tools Menus" on page 442 in chapter 9, *Implinks and Endpoints*.)

- *Go To Line*
- *Search*
- *Go To Source*
- *Show Transition*
- *Show Nextstate*
- *Show Output*
- *Show Call*
- *Show State*
- *Show Signal*

Go To Line

This menu choice moves the cursor to a line specified by the user. When selected, a dialog will appear querying the user where to move.

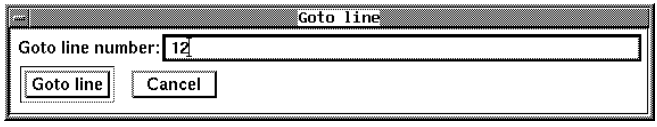

Figure 125: The Go To Line dialog

- *Goto line number*

  In this text field the user can specify a line number.

- *Goto line*

  Moves the cursor to the specified line and closes the dialog. This button will be dimmed if the *Goto line number* text field does not

contain a valid line number. If you have entered a line number that is larger than the number of lines in the document, the cursor is moved to the end of the document.

Search

This menu choice opens a dialog where you may search through the document for a text string and replace it with some other piece of text.

Figure 126: The Search dialog

Dialog Fields and Options

The *Search* dialog contains the following fields and options. Values from the previous invocation is used for settings when the dialog is used again.

- *Search for*

  The text to search for.

- *Replace with*

  Optionally, you can specify a text to replace the text searched for.

- *Search in*

  A read-only field showing the current status of the search. This field will display the text “Current document” until the search has ended, when it will show the text “End of document”.

- *Consider case*

  If this option is set, search is case sensitive.

- *Wildcard search*

  If this option is set, wildcard matching will be used when searching. In wildcard search, the asterisk character (’*’) matches a sequence

of zero or more characters of any kind. The backslash character ('\') escapes the character following it, which is useful if you want to search for asterisks.

- *Whole word search*

  If this option is set, search will only find whole words.

Dialog Buttons

When the dialog is first opened, all buttons except *Close* are disabled. Buttons will be enabled when appropriate, for instance the *Search/Restart Search* button will be enabled when a string is entered in the *Search for* text field.

When the dialog opens, searches always start at the top of the document.

- *Search/Restart Search*

  This button changed its name depending on the current search status. When it displays *Search*, it finds the next match in the text. When it displays *Restart Search* it will restart the search from the top of the document when pressed.

- *Replace & Search*

  Replaces the current match with the replace string and searches for the next match.

- *Replace All*

  Replaces all subsequent occurrences of the search string with the replace string.

Go To Source

This command takes the currently selected text fragment and attempts to interpret it as an SDT Reference and display it in the appropriate editor. The selection must include the selected reference exactly. This command corresponds to *Go To Source* in the Organizer.

The syntax of the graphical references used in the Text Editor is described in chapter 18, *SDT References*.

Show Transition

This operation is only available for state overview files (`*.ins`), and only when the text cursor is placed close to a transition in a state matrix.

An SDL Editor window is popped up with the SDL input symbol corresponding to the start of the transition currently in focus in the Text Editor.

Show Nextstate

This operation is only available for state overview files (`*.ins`), and only when the text cursor is placed close to a transition in a state matrix.

Show Nextstate is a sub menu. The menu choices in the sub menu have the names of the states found in all nextstate symbols that ends the transition currently in focus in the Text Editor. When a nextstate name is selected, an SDL Editor window pops up, showing the nextstate symbol.

Show Output

This operation is only available for state overview files (`*.ins`), and only when the text cursor is placed close to a transition in a state matrix.

Show Output is a sub menu. The menu choices in the sub menu have the names of all signals that might be sent from an SDL output symbol during the transition currently in focus in the Text Editor. When a signal is selected, an SDL Editor window pops up, showing the output symbol with the signal sending.

Show Call

This operation is only available for state overview files (`*.ins`), and only when the text cursor is placed close to a transition in a state matrix.

Show Call is a sub menu. The menu choices in the sub menu have the names of all procedures that might be called during the transition currently in focus in the Text Editor. When a procedure call is selected, an SDL Editor window pops up, showing the procedure call symbol.

Show State

This operation is only available for state overview files (`*.ins`), and only when the text cursor is placed close to a state or transition in a state matrix.

Show State is a sub menu. The menu choices in the sub menu represents all the places where SDL state symbols can be found for the state currently in focus in the Text Editor. If a transition is currently in focus in the Text Editor, the *Show State* operation operates on the start state for the transition. When a menu choice is selected, an SDL Editor window pops up, showing the corresponding state symbol.

Show Signal

This operation is only available for state overview files (`*.ins`), and only when the text cursor is placed close to a signal or transition in a state matrix.

When this operation is invoked, an SDL Editor window is popped up with the signal declaration corresponding to the signal in focus in the Text Editor. If a transition is in focus in the Text Editor, the operation operates on the signal that triggers the transition.

Pop-Up Menu

Open the pop-up menu by right-clicking or pressing `<F2>`. The pop-up menu remains opened until you click the mouse or press `<Esc>`.

Pop-Up Menu in Text Documents

In text documents, the pop-up menu contains some of the menu choices in the *Edit* and *Tools* menus.

In state overview files (`*.ins`), the pop-up menu contains the state overview menu choices in the *Tools* menu. The menu choices are different depending on if a state, signal or transition is closest to the cursor position.

Keyboard Accelerators

In addition to the standard keyboard accelerators, described in "Keyboard Accelerators" on page 35 in chapter 1, *User Interface and Basic Operations*, the Text Editor includes the following:

Accelerator	Command / functionality
`Ctrl+L`	Redraw window.

Accelerator	Command / functionality
`Ctrl+Y`	Redo (i.e. undo last undo)
`Ctrl+1`	Show Organizer
`<Delete>`	Clear

Chapter 6 The Text Editor

Chapter

7

Emacs Integration

(UNIX Only)

On UNIX, Emacs can be used as an external text editor. By configuring SDL Suite and TTCN Suite to use Emacs for handling text documents, the Organizer can interact with Emacs in the same way as with the other Editors.

Handling of SOMT implementation links is supported.

This chapter contains a user manual to Emacs in SDL Suite and TTCN Suite; the functionality it adds and the new commands.

Overview

Introduction

The implementation works with GNU Emacs version 19.31 or later, and only **on UNIX** systems. It does **not** work with any Emacs for Windows.

It is assumed that you are familiar with Emacs terminology and how to use Emacs. Some experience with installing Emacs Lisp packages is also required when setting up the integrated environment.

Text Document Handling

By setting preferences to use Emacs as text editor in SDL Suite and TTCN Suite, text editing support in Emacs is offered both from the Organizer and editors. Text document handling is implemented in the Lisp package “sdtemacs”.

In the Organizer, text documents are identified by the document type “Text Plain” when you add new or existing documents. A new Emacs instance will always be started, even though there may exist one already (started from outside SDL Suite and TTCN Suite).

Link Handling

The Lisp package “sdtlinks” defines the minor mode *SDTlinks* which supports SOMT implementation links in text documents. This gives the possibility to handle link endpoints and follow the links defined for these endpoints. The support for link handling is optional.

When the *SDTlinks* mode is active, endpoints are displayed with a typeface differing from the plain text. Type faces for endpoints with and without links are configurable, see “Type Faces for Endpoints” on page 413.

To be able to represent endpoints in text files, the file contents differ from what is seen in the Emacs buffer containing a file with endpoints. The file format for endpoints look like this:

```
<SDT_LINK_ENDPOINT_BEGIN anchor >text<SDT_LINK_ENDPOINT_END>
```

where `anchor` is an integer uniquely identifying the endpoint and `text` is the endpoint text. If the *SDTlinks* mode is inactive, this raw file contents is displayed in the Emacs buffer.

Caution!

When the SDTlinks mode is *inactive*:

Do not alter any text representing endpoints (described in "Link Handling" on page 410).

Do not duplicate text containing endpoints since this will yield unpredictable results as each endpoint is uniquely identified in a file.

As a general principle, Undo is not available for the link handling commands.w

Installation

Text Document Handling

To be able to use Emacs as an external editor in SDL Suite and TTCN Suite:

1. Put the file `sdtemacs.el` in a Lisp directory known to Emacs (`load-path`). By default, the file is installed in `$telelogic/include/lisp`.
2. Byte-compile `sdtemacs.el` for increased execution speed.
3. Put the line:
   `(require 'sdtemacs)`
   in your `~/.emacs` file or in the file `default.el` in the `../lisp` directory of the Emacs distribution.

Make sure that the environment variable `$telelogicbin` is correctly set.

Link Handling

To be able to use link handling functions in Emacs:

1. Put the file `sdtlinks.el` in a Lisp directory known to Emacs (`load-path`). By default, the file is installed in `$telelogic/include/lisp`.
2. Byte-compile `sdtlinks.el` for increased execution speed.

3. Put the line:
   ```
   (require 'sdtlinks)
   ```
   in your `~/.emacs` file or in the file `default.el` in the `../lisp` directory of the Emacs distribution.

Sdtlinks requires sdtemacs, that is, you must install sdtemacs in order to use sdtlinks.

Installation Example

An example of using both packages:

```
(setq load-path (cons (substitute-in-file-name
"$telelogic/include/lisp") load-path))
(require 'sdtemacs)
(require 'sdtlinks)
```

Preferences

In the Preference Manager, the following parameters should be set:

Parameter	Value
SDT*TextEditor	Emacs
SDT*EmacsCommand	The command that starts GNU Emacs from a UNIX shell (the default is “emacs”).

Customizing

Type Faces for Endpoints

The type face for endpoints without associated links is called `sdtlinks-endpoint-face`. The default appearance is underlined, blue text.

The type face for endpoints with associated links is called `sdtlinks-endpoint-with-links-face`. The default appearance is underlined, bold, blue text.

These type faces can be redefined.

Example 25 ----------

An example to make endpoints without associated links appear as bold, red text:

```
...
(make-face 'sdtlinks-endpoint-face)
(make-face-bold 'sdtlinks-endpoint-face nil t)
(set-face-foreground 'sdtlinks-endpoint-face "red")
...
(require 'sdtlinks)
```

Maximum Number of Endpoints in a Document

Due to the nature of the execution environment for Emacs, only a finite number of endpoints are manageable in a document. By default, this limit is set to 1000 endpoints, which should be sufficient for most situations. If, however, a larger number is required, this can be achieved by setting the variable `sdtemacs-max-no-of-endpoints`.

Example 26 ----------

An example to allow 1500 endpoints:

```
...
(setq sdtemacs-max-no-of-endpoints 1500)
...
(require 'sdtlinks)
```

Emacs Commands

This section lists and describes the Emacs commands and key bindings associated with the integration with SDL Suite and TTCN Suite. Both new commands and the affected ordinary (existing) commands are described.

Text Document Handling

New Commands

Connect

`M-x sdtemacs-connect` connects to SDL Suite and TTCN Suite. Automatic connection can be performed when starting Emacs by providing the UNIX command switch `post` (`emacs -post`). This is done when SDL Suite and TTCN Suite starts Emacs.

Disconnect

`M-x sdtemacs-disconnect` disconnects from SDL Suite and TTCN Suite. All buffers taking part in the interaction will be unloaded after asking about saving modified buffers. Exiting Emacs will disconnect from SDL Suite and TTCN Suite.

Show Organizer

`M-x sdtemacs-show-organizer` opens or raises the Organizer Main window.

Show SDT Reference

`M-x sdtemacs-show-reference` shows an SDT reference in an appropriate editor. This requires that the reference text is selected or that the point is placed inside it.

Affected Ordinary Commands

Exit Emacs (C-x C-c)

Disconnects from SDL Suite and TTCN Suite before exiting.

New File (C-x b <new buffer>, C-x C-f <new file>)

The new buffer is notified to SDL Suite and TTCN Suite and takes part in the interaction with SDL Suite and TTCN Suite.

Open File (C-x C-f <filename>)

The loaded buffer is notified to SDL Suite and TTCN Suite and takes part in the interaction with SDL Suite and TTCN Suite.

Save (C-x C-s) and Save As (C-x C-w <filename>)

The buffer is notified as saved to SDL Suite and TTCN Suite.

Close File (C-x k)

The buffer is notified as unloaded to SDL Suite and TTCN Suite.

First Modification of Buffer Text

The buffer is notified as modified to SDL Suite and TTCN Suite.

Link Handling

The minor mode *SDTlinks*, which implements the link handling commands, requires that Emacs is connected to SDL Suite and TTCN Suite, and will try to connect when switched on if this is not the case. All buffers loaded when connected will automatically have this mode active.

New Commands

SDT Links Mode

`M-x sdtlinks-mode` toggles the minor mode SDTlinks. This is useful if performing editing operations that cannot be done without unintentionally deleting endpoints, e.g. moving (*Cut* and *Paste*) a region of text containing endpoints.

Caution!

When SDTlinks is *inactive*:

Do not alter any text representing endpoints (described in "Link Handling" on page 410).

Do not duplicate text containing endpoints since this will yield unpredictable results as each endpoint is uniquely identified in a file.

Create Endpoint

`M-x sdtlinks-create-endpoint (C-c C-c)` creates a new endpoint that will be marked with a special type face in the text (see "Type Faces for Endpoints" on page 413) and notified to SDL Suite and TTCN Suite. This command requires that the region of text to convert to an endpoint is selected, i.e. both mark and point must be set. Endpoints are not allowed to overlap and must consist of at least one character.

Delete Endpoint

`M-x sdtlinks-delete-endpoint (C-c C-d)` deletes an endpoint. The endpoint text will be converted to plain text and the deletion will be notified to SDL Suite and TTCN Suite. All links associated with the endpoint will be cleared. This command requires that point is placed inside the endpoint text.

Follow Link

`M-x sdtlinks-follow-link (C-c C-f)` follows one of the links associated with the selected endpoint. This results in displaying the endpoint on the other end of the link in an appropriate editor. If only one link is associated with the endpoint, this link is followed. Otherwise, a choice between the associated links is offered in a popup menu:

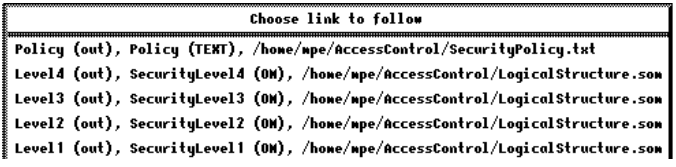

Figure 127 Choose link to follow

Each menu item, representing a link, is of the format:

```
<Link name>(<Direction>), <Other endpoint>(<Type>), <File>
```

where:

```
<Link name>      = The name of the link
<Direction>      = The direction of the link: 'in' or 'out'
<Other endpoint>= The name of the other endpoint of the link
<Type>           = The type of the other endpoint of the link
<File>           = The name of the file (including the path)
                   in which the other endpoint resides
```

This command requires that point is placed inside the text of an endpoint marked as having associated links, see "Type Faces for Endpoints" on page 413.

Show Endpoint in Link Manager

`M-x sdtlinks-show-endpoint-in-link-manager (C-c C-s)` opens the Link Manager and shows the selected endpoint. This requires that point is placed inside the endpoint text.

Affected Ordinary Commands

Modification of Endpoint Text

The endpoint is notified as modified to SDL Suite and TTCN Suite. When point is placed directly after the endpoint text, added characters will become part of the endpoint text.

Cut/Clear (C-w, C-k, M-k and many more)

For all endpoints within the region, *Delete Endpoint* (see "Delete Endpoint" on page 416) is executed.

Copy Region (M-w)

Endpoints in the copy of the region is represented as plain text.

Insert File (C-x i <filename>)

For all endpoints in the inserted file, *Create Endpoint* (see "Create Endpoint" on page 416) is executed. Associated links are not handled.

If point is within an endpoint and the file to insert have endpoints, the operation will fail since overlapping endpoints are not allowed.

Undo (C-x u, C-_)

No undo information is recorded for the link handling commands. Consequently, these commands cannot be undone.

Command Summary

Command	Description
`M-x sdtemacs-connect`	“Connect” on page 414
`M-x sdtemacs-disconnect`	“Disconnect” on page 414
`M-x sdtemacs-show-organizer`	“Show Organizer” on page 414
`M-x sdtemacs-show-reference`	“Show SDT Reference” on page 414
`M-x sdtlinks-mode`	“SDT Links Mode” on page 415
`M-x sdtlinks-create-endpoint (C-c C-c)`	“Create Endpoint” on page 416
`M-x sdtlinks-delete-endpoint (C-c C-d)`	“Delete Endpoint” on page 416
`M-x sdtlinks-follow-link (C-c C-f)`	“Follow Link” on page 416
`M-x sdtlinks-show-endpoint-in-link-manager (C-c C-s)`	“Show Endpoint in Link Manager” on page 417

Chapter

8 *MS Word Integration*

(Windows only)

In Windows, Microsoft Word is integrated with SDL Suite and TTCN Suite and MS Word documents are handled by the Organizer.

Handling of SOMT implementation links is supported.

This chapter contains a user manual to MS Word in SDL Suite and TTCN Suite; the functionality it adds and the new menu.

Overview

Introduction

The implementation works with MS Word 2000 (MS Office 2000) and MS Word 2003 (MS Office 2003) **in Windows**. It is assumed that you are familiar with MS Word terminology and how to use MS Word. Some experience with MS Word templates and macros is also required when setting up the integrated environment.

MS Word Document Handling

Support for MS Word document editing is available in the Organizer. When connecting MS Word to the Organizer, the process `SdtWord` will be started in the background.

In the Organizer, MS Word documents are identified by the document type “Text Word” when adding new or existing documents.

In the Organizer, MS Word document are represented with the icon shown to the left. Unlike other document types, when a MS Word documents becomes modified, its icon is not marked as “dirty”.

A new MS Word documents is always named “Document<x>”, where <x> is an integer, regardless of what name it was given in the Organizer.

Link Handling

SOMT implementation links in MS Word documents are supported. This gives the possibility to handle link endpoints and follow the links defined for these endpoints.

An MS Word endpoint icon in the Organizer looks the same as a document icon.

In MS Word, endpoints are marked with special character formats. The appearance for endpoints without associated links is underlined, blue text. The appearance for endpoints with associated links is double underlined, bold, blue text.

Endpoints in MS Word documents are represented with bookmarks whose names are of the format “SDT_<x>”, where <x> is an integer uniquely identifying the endpoint.

Undo is not available for the link handling commands.

Installation

MS Word

To be able to use MS Word with SDL Suite and TTCN Suite, do as follows:

For MS Word 7.0

1. Put the template file `sdt95.dot` (available in `<Installation Directory>\bin\wini386\sdt95.dot`) into the folder `\MSOffice\Winword\Startup`. This means that the template becomes global and the SDL Suite and TTCN Suite commands will be available in MS Word all the time.

2. Some macros are template dependent, which requires them to be defined for the template on which the document is based. The macros to be copied from `sdt95.dot` to your document templates are:

   ```
   AutoClose
   AutoNew
   AutoOpen
   ```

   Consult the MS Word documentation on how to copy the macros to your templates.

   The macros are (re)definitions of possibly existing MS Word macros. If you already have them defined in your document templates, you must add the code to your own macros.

For MS Word 8.0

There is an automatic installation program available in `<Installation Directory>\bin\wini386\sdtwordinstall.exe`. You can also make a manual installation:

1. Put the template file `sdt97.dot` (available in `<Installation Directory>\bin\wini386\sdt97.dot`) into a temporary folder.

2. Change the file protection from read-only to read/write.

3. Open this `sdt97.dot` in MS Word and copy the modules:

   ```
   SDTAutomacros
   SDTMisc
   ```

   to the template `normal.dot`. Make sure there are no conflicts with other automacros in `normal.dot`.

4. Delete the copied modules from `sdt97.dot`.

5. Close MS Word and move the `sdt97.dot` copy into the folder `\Microsoft Office\Office\Startup`.

6. Add a reference (in the MS Word VB-editor) from `normal.dot` to `sdt97.dot`.

The Startup Folder

You should check that MS Word points at your start-up folder by choosing *Tools* > *Options*. In the dialog that appears, select *File Locations* and check where the file type *Startup* is pointing. It should point at the directory where you placed `sdt95.dot` or `sdt97.dot`.

> **Note:**
>
> Do not use `sdt95.dot` or `sdt97.dot` as a document template. It only contains MS Word macros and should be used solely as a global template.

Preferences

In the Preference Manager, the following parameter should be set:

Parameter	Value
SDT*WordCommand	The command that starts MS Word (the default is “Winword.exe”).

Make sure that the path points to its directory.

MS Word Menu Commands

This section lists and describes the MS Word menu commands associated with the integration with SDL Suite and TTCN Suite. Both new commands and the affected ordinary (existing) commands are described.

New Menu Commands

The new commands are accessible from a menu in MS Word called *SDT*. It contains the following menu choices:

- *Connect to SDT*
- *Disconnect from SDT*
- *Show Organizer*
- *Show Reference*
- *Create Endpoint*
- *Delete Endpoint*
- *Follow Link*
- *Show Endpoint in Link Manager*
- *Update Endpoints*

Connect to SDT

Connects to SDL Suite and TTCN Suite. This is done automatically when starting MS Word.

Disconnect from SDT

Disconnects from SDL Suite and TTCN Suite. This is done automatically when exiting MS Word.

Show Organizer

Opens or raises the Organizer.

Show Reference

Shows the selected SDT reference in an appropriate editor. This requires that the user has selected the reference text or placed the cursor inside it.

Create Endpoint

Creates a new endpoint that will be marked with a special character format in the text (see "Link Handling" on page 420) and notified to SDL Suite and TTCN Suite. This command requires that the user has selected the region of text to convert to an endpoint. Endpoints are not allowed to overlap and must consist of at least one character.

Delete Endpoint

Deletes an endpoint. The endpoint text will be converted to plain text and the deletion will be notified to SDL Suite and TTCN Suite. All links associated with the endpoint will be cleared. This command requires that the user has selected or placed the cursor inside the endpoint text.

Follow Link

Follows one of the links associated with an endpoint. This results in displaying the endpoint on the other end of the link in an appropriate editor. If only one link is associated with the endpoint, this link is followed. Otherwise the user is offered to choose between the associated links in a dialog.

This command requires that the user has selected or placed the cursor inside the text of an endpoint marked as having associated links.

Show Endpoint in Link Manager

Opens the Link Manager and shows the selected endpoint. This requires that the user has selected or placed the cursor inside the endpoint text.

Update Endpoints

When applying styles and character formats to text containing endpoints, the endpoint character format may be changed and thus it becomes impossible to tell where the endpoints are located. By using this command all endpoints in the active document will have the endpoint character format applied to them.

Furthermore, when deleting text containing endpoint using the keyboard (<Delete>) instead of menu choices, or pasting text with endpoints from other documents, this is not notified to SDL Suite and TTCN Suite. By executing this command, a synchronization with the Link Manager takes place in order for it to have a consistent view of the endpoints in the active document.

Affected File Commands

Exit

Disconnects from SDL Suite and TTCN Suite before exiting.

New

The new buffer is notified to SDL Suite and TTCN Suite and takes part in the interaction.

Open

The loaded buffer is notified to SDL Suite and TTCN Suite and takes part in the interaction.

Save and *Save As*

The buffer is notified as saved to SDL Suite and TTCN Suite.

Close

The buffer is notified as unloaded to SDL Suite and TTCN Suite.

Affected Editing Commands

Modification of Endpoint Text

The endpoint is notified as modified to SDL Suite and TTCN Suite.

> **Note:**
> In MS Word, inserted text take the same character format as the character that precedes it. Added characters in front of the endpoint text will not take the character format of the endpoint text until the endpoint is updated (see "Update Endpoints" on page 424).
> MS Word 7.0 only: When the cursor is placed directly after the endpoint text, added characters will **not** become part of the endpoint text, even though the character format will indicate so.

Clear

All endpoints within the selection will be deleted. See "Delete Endpoint" on page 424.

Cut

All endpoints within the selection will be deleted. See "Delete Endpoint" on page 424. Endpoints in the copy of the selection is represented by plain text.

Copy

Endpoints in the copy of the selection is represented by plain text.

Paste

Endpoints (bookmarks) not already defined in the document, in which the Paste operation is done, will be created. However, the text region is still plain text and the endpoints have to be updated in order to apply the endpoint character format to the new endpoints.

Undo

No undo information is recorded for the link handling commands. Consequently, these commands cannot be undone.

Chapter

9 *Implinks and Endpoints*

Implementation links and endpoints are important concepts in the SOMT method (described in the SOMT Methodology Guidelines starting in chapter 69 in the User's Manual). This chapter describes the tool support for implinks and endpoints. The following topics are covered:

- **Link concepts**
- **How endpoints and links are visualized**
- **How to create links**
- **The Entity Dictionary window**
- **Link commands in menus**
- **The Paste As command**
- **The Link Manager tool**

Link Concepts and Overview

The SDL Suite supports creating and maintaining links between different objects in a system. Such links are used to show relations between objects in different documents. Objects that may be linked are:

- Text fragments in text documents
- Graphical objects and symbols in OM, SC, HMSC, SDL and MSC diagrams (but **not** text fragments in such diagrams)
- Documents in the Organizer structure.

Implinks

The link concept in the SDL Suite is designed to support the SOMT method, further described in the SOMT Methodology Guidelines starting in chapter 69 in the User's Manual. In SOMT, an important relation is that one object can be seen as an implementation of another object. For this reason, links between objects are often referred to as implementation links, or *implinks*. For instance, a textual object in the requirement analysis may be implemented as an object class in the system analysis, and later as a process type in the design model.

Implinks are the result of a design decision taken during the development of a system. Using implinks enables traceability between the different models and phases, so that the usage of a particular object or concept can be followed from requirements all the way down to code. Another important aspect of implinks is that they facilitate consistency checks between the different models.

Links and Endpoints

A link has two *endpoints*, one at each of the objects that are linked together. Endpoints can be created for objects without creating a link, i.e. endpoints are entities separate from links. When a link is created, endpoints are created automatically, if they do not already exist. It is possible to have any number of links connected to an endpoint. Endpoints and links can be created from the Organizer and the editors.

Links are bidirectional, i.e. they can be traversed (followed) in both directions. Even so, a link has a "default" direction, defined when the link is created, to indicate the intended direction. This means that an endpoint is either a logical "from" endpoint, or a logical "to" endpoint.

A link has a name and optionally a comment. The name indicates the type of link, e.g. “implementation link”, and the comment is used to describe the link.

Link File

Information about endpoints and links is stored in a central *link file* (extension `.sli`), which is referred to from the Organizer’s system file. This approach makes it easy to get an overview of existing endpoints and links, and to make consistency checks. The link file is saved whenever the system is saved. The link file, and its defined links, are managed by a dedicated tool, the Link Manager (see “Tool Support and Operations” on page 432).

Information about endpoints are also stored in the individual documents. However, link information is only stored in the link file.

Local Link File

To make it easier to use the endpoint and link features in a multiuser environment, the concept of a *local link file* is provided. This is a personal link file for one user, storing all changes made to endpoint and link information compared to the global file, the *master link file*. A controlled merge operation is provided to update the master link file with the local link file information. These operations are available as services in the SDL Suite and TTCN Suite Public Interface (see *“Link File Services” on page 552 in chapter 11, The Public Interface*).

Visualization of Endpoints and Links

By default, endpoints are marked in a special way in the editors and in the Organizer. The markers are slightly different depending on whether or not any links are connected to the endpoint.

Endpoints in Graphical Editors

In the SDL Editor and the SDL Suite diagram editors, the endpoint marker is a small triangle in the upper left corner of the object's enclosing rectangle. The triangle is filled if the endpoint has any links connected to it.

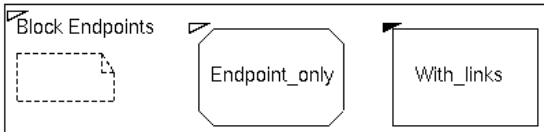

Figure 128: Endpoints with and without links

For lines in the SDL, OM. SC and HMSC diagrams, the marker appears on the name or signal list associated with the line. In SDL diagrams, it is also possible to create endpoints on other text elements associated with the line.

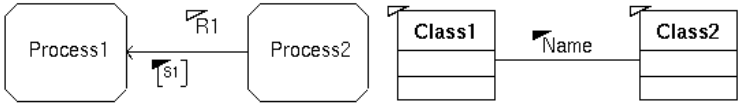

Figure 129: Endpoints on lines and text attributes

For lines in MSC diagrams (messages, timers, create requests), the marker normally appears at the "start" end of the line.

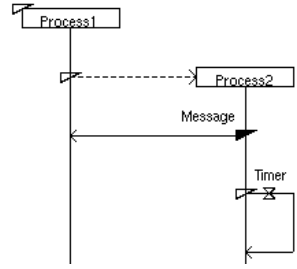

Figure 130: Endpoints on MSC lines

You can hide the endpoint markers by changing the option *Show Link Endpoints* in the *Editor Options* in the *View* menu, or by setting the editor preference ShowLinks to off.

Note:

Endpoint markers are never shown when printing a diagram.

Endpoints in Text Editors

In the Text Editor, endpoints are shown as underlined text, regardless if they have links connected to them or not. The endpoint text can be shown as normal text by changing the option *Show Link Endpoints* in the *Editor Options* in the *View* menu, or by setting the Text Editor preference ShowLinks to off.

In the Emacs editor **(on UNIX)**, endpoints without links are by default shown as blue, underlined text, whereas endpoints with links are shown as bold, blue, underlined text. The default font faces can be changed; see "Type Faces for Endpoints" on page 413 in chapter 7, *Emacs Integration*.

In MS Word **(in Windows)**, endpoints without links are shown as blue, underlined text, whereas endpoints with links are shown as bold, blue, double underlined text.

Endpoint text is always shown as normal text when printing a text document.

Endpoints in the Organizer

In the Organizer, the endpoint marker appears in the same way as in the graphical editors, i.e. a triangle in the upper left corner of the document icon.

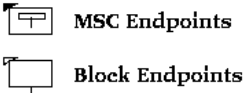

Figure 131: Endpoints in the Organizer.

The endpoint markers are always shown in the Organizer, and they are also shown when printing the Organizer window.

Tool Support and Operations

Operations on endpoints and links are supported in the Organizer, the diagram editors, the Text Editor and the Link Manager.

In the editors, the possible operations are identical and can be found in the *Link* submenu of the *Tools* menu (see "Link Commands in the Tools Menus" on page 442). The operations include:

- Creating and deleting an endpoint
- Creating and deleting a link
- Traversing a link (bringing the other endpoint into view)
- Opening the Link Manager

In the Organizer, the available operations in the *Tools* menu are limited to creating and deleting an endpoint, and opening the Link Manager.

In the editors, it is also possible to open the Entity Dictionary from the *Window* menu. The Entity Dictionary lists all endpoints in the system, together with the documents making up the Organizer structure. It is mainly intended for re-use of entity names, but also supports creating links. See "The Entity Dictionary" on page 434.

The Link Manager shows all endpoints and links in the system. It supports the following main operations:

- File operations on the link file
- Creating and deleting links
- Editing a link's direction, name and comment
- Performing consistency checks on endpoints and links

It is not possible to create and delete endpoints in the Link Manager. For more information about the Link Manager, see "The Link Manager" on page 462.

Creating Links

There are basically three different ways to create links:

1. Manually, by linking together two endpoints.

   This operation requires two already existing endpoints. The endpoints may have been created manually, or as an effect of creating a link earlier.

   This operation is only available through the use of the Link Manager. See "Create Link" on page 468.

2. Manually, by linking together an endpoint and a selected object.

   This operation requires an already existing endpoint (selected in the Entity Dictionary), and a selected object in an editor. The endpoint may have been created manually, or as an effect of creating a link earlier. The selected object does not have to be an endpoint.

   This operation is available from the editors and the Entity Dictionary. See "Link > Create" on page 442.

3. Automatically, by copying and pasting an object (*Paste As*).

   This operation does not require any existing endpoints. An object is first selected and copied in an editor. The object is then pasted in an editor or in the Organizer by using the *Paste As* menu choice. This transforms the object, if necessary, and automatically creates a link between the copied and pasted object.

   This operation is available from the SDL, MSC, OM and Text Editors and the Organizer and supports the SOMT method. See "The Paste As Command" on page 448. It is **not** available in the SC/HMSC Editor.

The Entity Dictionary

The Entity Dictionary Concept

The purpose of the Entity Dictionary is to provide easy access to names of entities being used in the system, and a possibility to reuse these names in all parts of the system. The entities that the Entity Dictionary manage are all the link endpoints defined in the system, as well as all diagrams, documents and modules found in the Organizer structure.

The Entity Dictionary is accessible from the SDL Suite editors. The names in the Entity Dictionary are available for reuse in all texts and graphical objects found in the graphical diagrams. However, the Text Editor does not support reuse of texts in text documents.

The Entity Dictionary is also used for creating links between objects and existing endpoints when using the editors.

Relations to Editor Windows

The Entity Dictionary is implemented as a modeless dialog window. There is not a single Entity Dictionary window, but one window for each type of diagram (SDL, MSC, OM, SC, HMSC and text). All Entity Dictionary windows contain exactly the same information, and all the windows are updated when a change is made. The reason for having an Entity Dictionary window for each editor type is that operations in the window apply to the object currently selected in the respective editor.

Since there might be several editor windows showing different diagrams/documents, there is a need to define the *current window*. This is the editor window that will be associated with the Entity Dictionary, and all operations will act on the current window. The current window is the editor window where the user last performed a menu command or a mouse click detected by the editor.

The editor associated with an Entity Dictionary window is known as the *parent editor*. The editor type is reflected in the window title of the Entity Dictionary window, thus making it possible to distinguish the different Entity Dictionary windows, and to determine the parent editor that the Entity Dictionary operations will affect.

Entity Dictionary Window

The Entity Dictionary Window can be opened from all of the editors through the use of the menu choice *Entity Dictionary* in the *Window* menu.

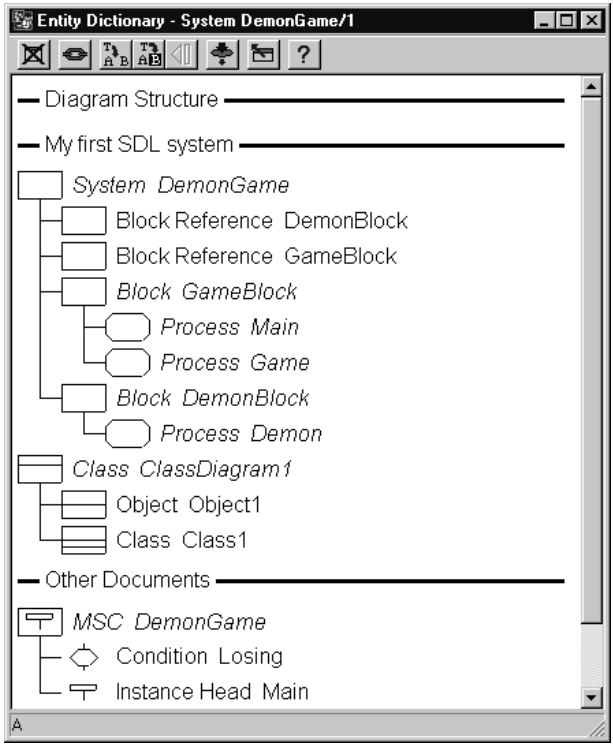

Figure 132: The Entity Dictionary window

Contents and Structure

The window lists all the defined link endpoints, following the structure of diagrams and files in the Organizer. By default, every item in the Organizer is repeated, and the indentation of items is also repeated. All Organizer items and link endpoints listed in the window are known as *entities* in the Entity Dictionary.

Below each Organizer item, the link endpoints defined in that item are listed with indentation:

- Below each SDL diagram, the symbols marked as link endpoints are listed.
- Below each MSC diagram, the instances, messages and other symbols marked as link endpoints are listed.
- Below each OM diagram, the names of all the classes, instances and other symbols marked as link endpoints are listed.
- Below each text document, the text fragments marked as link endpoints are listed.

For an Organizer item that contains both sub-documents and link endpoints, the endpoints are listed first, followed by the sub-documents.

It is possible to hide the Organizer items to display only the link endpoints; see "The Filter Dialog" on page 440 for more information.

The information in the Entity Dictionary is updated whenever a link endpoint is created, changed or cleared in any of the editors or the Link Manager, or when the Organizer structure is modified.

Entity Icons

Each entity has an associated icon that identifies the type of the entity, i.e. the type of the endpoint object. Entities that already have an established icon in the Organizer or the Index Viewer use the same icon in the Entity Dictionary, with a few exceptions. The icons specific to the Entity Dictionary are:

Diagram Heading

Diagram Extended Heading

OM Class

OM Object

OM Association

OM Aggregation

OM Generalization

SC Transition

MSC Message

MSC Create

MSC Timer Set

(H)MSC Reference

HMSC Start

HMSC Stop

HMSC Connection

Text symbols and text fragments

Textual Notation

The type and name of an entity is shown to the right of the icon. For entities containing a name, such as diagram symbols, this name is listed. For other symbols and text fragments, the first 25 characters are shown.

The cases when a diagram reference symbol, a diagram heading, or an Organizer document is an endpoint will result in duplication of information in the Entity Dictionary. To distinguish between such endpoints and the structure of Organizer documents, the following textual notations are used:

- Link endpoints are listed using a plain font face.
- Documents and other Organizer items that are not endpoints are listed using an *italic font.*
- Endpoints that are diagram reference symbols contain the word “Reference” after the diagram type.
- Endpoints that are diagram headings has the word “Heading”, “Additional Heading” or “Extended Heading” as the entity type.

Figure 132 on page 435 shows examples of these textual notations.

Operations in the Entity Dictionary

The Entity Dictionary window does not contain a menu bar. Operations are available as quick buttons or as popup menus.

Quick Buttons

The following quick buttons are special to Entity Dictionary window.

Close
Close the Entity Dictionary window.

Create Link
Create a link between the endpoint selected in the Entity Dictionary and the object selected in the parent editor. The quick button is dimmed if not two such selections are present. If the parent editor is a Text Editor, the selected text must be an already existing endpoint.
The *Create Link* dialog is opened; see Figure 135 on page 443.

Insert
Insert the text in the selected symbol in the Entity Dictionary at the insertion point in the object selected in the parent editor. The quick button is dimmed if not two such selections are present. If text is selected in the parent editor's text window, this text is instead replaced.
This button is not available in the Text Editor's Entity Dictionary.

Replace
Replace the text content of the object selected in the parent editor with the text in the selected symbol in the Entity Dictionary. The quick button is dimmed if not two such selections are present.
This button is not available in the Text Editor's Entity Dictionary.

Undo
Undo the most recent text operation in the Entity Dictionary (Insert, Replace, Undo). The quick button is dimmed if the selection in the parent editor has changed to another object.
This button is not available in the Text Editor's Entity Dictionary.

Filter
Filter the information listed in the Entity Dictionary. See "The Filter Dialog" on page 440 for more information.

Show Editor
Raise the parent editor window.

Popup Menus

The following tables lists the available operations in the popup menus of the Entity Dictionary window.

On the Window Background

Appears when no symbol is selected and the menu is invoked in an area not containing any symbols.

Expand All	Expands all collapsed symbols.
Collapse All	Collapses all symbols; only root symbols will be shown. Collapsed symbols are indicated with a small triangle directly below the symbol.
Show Editor	Raises the parent editor's window.

On a Document Symbol

Appears if an Organizer document symbol is selected, or the menu is invoked where a document symbol is selectable.

Expand	Expands a collapsed symbol one level down.
Expand Substructure	Expands the entire substructure of the symbol.
Collapse	Collapses the substructure of the symbol.

On an Endpoint Symbol

Appears if an endpoint symbol is selected, or the menu is invoked where an endpoint symbol is selectable.

Show Definition	Brings up an editor window, or the Organizer window, where the endpoint is selected.

Double-Clicks

If there is a selection in the parent editor and a symbol in the Entity Dictionary is double-clicked, the text of the symbol is inserted in the parent editor. A double-click thus corresponds to using the *Insert* quick button; see "Insert" on page 438. This functionality is not available in the Text Editor's Entity Dictionary.

The Filter Dialog

The Filter dialog is opened when the *Filter* quick button is pressed in the Entity Dictionary window. The Filter dialog controls what is to be shown in the Entity Dictionary window.

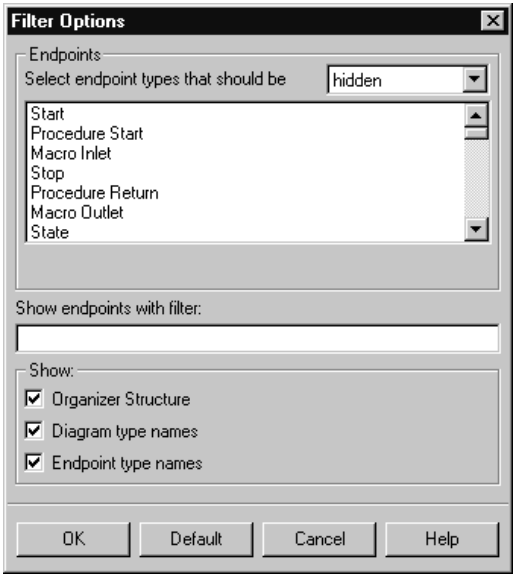

Figure 133: The Filter dialog

- *Select endpoint types that should be*

  This option menu controls whether the selected endpoint types should be *hidden* or *shown*. The possible endpoint types are shown in a multiple selection list, in which any number of items can be selected. If the option menu is set to *shown*, only the selected endpoint types are listed in the Entity Dictionary. If the option menu is set to *hidden*, the selected endpoint types are hidden, and the ones not being selected are thereby shown.

- *Show endpoints with filter*

  This text field is a pattern for matching endpoint names. Only endpoints whose names match the pattern are shown in the Entity Dictionary. The string has the same syntax as a normal UNIX file pattern, and may contain the elements '*' (zero or more characters), '?' (exactly one character), and '[...]' (any character within the brackets).

  An empty text field matches any name, i.e. it is equal to a single '*'.

- *Organizer Structure*

  This option controls whether the documents making up the Organizer structure are shown. If not set, only endpoints are listed in the Entity Dictionary.

- *Diagram type name*

  This option controls whether the diagram type names in the Organizer structure are shown. If not set, only the names of the diagrams are shown in the Entity Dictionary.

- *Endpoint type names*

  This option controls whether the endpoint type names are shown. If not set, only the names of the endpoints are shown in the Entity Dictionary.

- *Default*

  Resets the Filter dialog to its default settings, but does not close the dialog. The default settings are:

  – The endpoint type list contains no selection.
  – The endpoint type option menu is set to *hidden*.
  – The endpoint name filter is empty.
  – The three Show options are set.

Link Commands in the *Tools* Menus

This section describes the link-related commands that are available in the *Link* submenu in the *Tools* menu of the Organizer and all SDL Suite editors.

> **Note:**
>
> None of these commands are possible to *Undo*.
>
> The Organizer only supports a subset of the link commands.

The *Link* submenu contains the following menu choices:

- *Link > Create*
- *Link > Create Endpoint*
- *Link > Traverse*
- *Link > Link Manager*
- *Link > Clear*
- *Link > Clear Endpoint*

Link > Create

This menu command creates a link between the object selected in the editor and the object selected in the Entity Dictionary. If two such objects are selected, the Create Link dialog is opened (see Figure 135 on page 443). The editor object does not need to have a link endpoint defined to be able to create a link, i.e. only one of the objects need to be present in the Entity Dictionary. It is possible to create a link to itself.

> **Note:**
>
> In the Text Editor, the selected text must already be a link endpoint. It is not possible to create links to text that is not an endpoint.

If no object is selected in the editor, or no endpoint is selected in the Text Editor, the menu command is dimmed.

If no object is selected in the Entity Dictionary, or the Entity Dictionary has not been opened, a warning dialog is issued (see Figure 134) and the Entity Dictionary window is opened or raised. When the dialog is closed and the instructions given in it are followed, the Create Link dialog is opened.

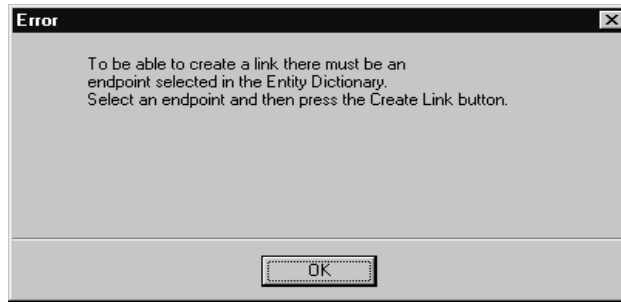

Figure 134: The Create Link warning

The Create Link dialog looks like this:

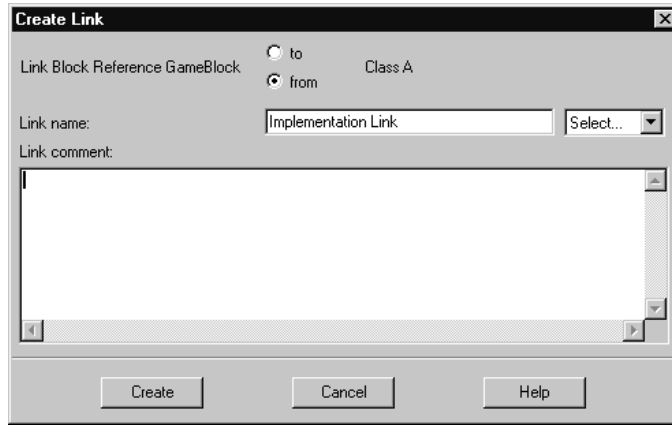

Figure 135: The Create Link dialog

- *Link <editor object> to/from <entity dictionary object>*

  The two selected objects are listed at either side of the *to/from* radio buttons. The radio buttons control which of the objects that is to be the logical to and from object. *Link to* is the default.

- *Link name*

  The name of the link. A name can be entered or edited in the text field, or be selected from the associated option menu. The five latest

used link names when creating links will be available in the option menu, and the name in the text field is preset to the latest used link name. A link name **must** be specified.

- *Link comment*

  An optional comment text, to be provided by the user. The text box is initially empty.

- *Create*

  Creates a link between the two objects. The link will be visible in the Link Manager and the endpoint objects are marked as being an endpoint with at least one link, i.e. if the editor object was not already an endpoint, it will be created.

If the Entity Dictionary window was opened because of the Create Link command, it will stay up until the user explicitly closes it.

Link > Create Endpoint

This menu command defines the currently selected object as a link endpoint. The endpoint is immediately added to the Entity Dictionary and the Link Manager. The object is marked as a link endpoint in the invoking tool – an editor or the Organizer. (See "Visualization of Endpoints and Links" on page 430.)

This command is dimmed if not exactly one object that can be defined as a link endpoint is selected, or if the object already is an endpoint.

This command is also available in the popup menus of all editors and the Organizer.

Link > Traverse

This menu command traverses an existing link from the currently selected object. This is done by opening the tool where the other link endpoint is defined (an editor or the Organizer) and selecting the other endpoint object.

This command is dimmed if more than one object is selected, or if the selected object has no links defined.

This command is also available in the popup menus of all editors and the Organizer, as *Traverse Link*.

If there is only one link defined from the object, that link is traversed, as described above. If more than one link exists, a dialog showing all links is opened and one of the links has to be selected.

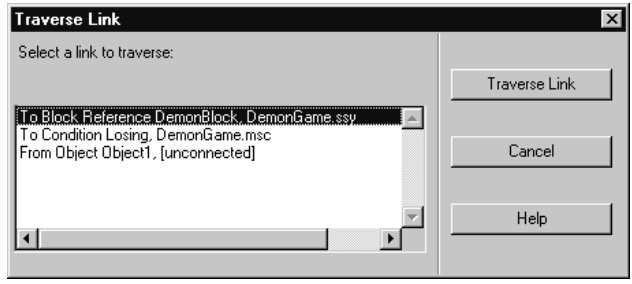

Figure 136: The Traverse Link dialog

The dialog presents a list of all links to and from the object in the following form:

`From` | `To` <*type and name of linked object*>, <*file name*>

The type and name of the linked object follow the same notation as in the Entity Dictionary; see "Textual Notation" on page 437. The file name of the document where the linked object is found contains a path if the file is not in the Organizer's Source Directory.

- To traverse a link, select the link and click the *Traverse Link* button, or double-click the link.

Link > Link Manager

This menu command opens or raises the Link Manager window. If exactly one object is selected and this object is a link endpoint, this endpoint will be selected and made visible in the Link Manager. This command is never dimmed.

For more information about the Link Manager, see "The Link Manager" on page 462.

Link > Clear

This menu command removes one or more links to or from the currently selected object. However, the link endpoints are preserved. This command is dimmed if more than one object is selected, or if the selected object has no links defined.

Caution!

Removing a link cannot be undone.

A dialog showing all links is opened and one or more of the links has to be selected.

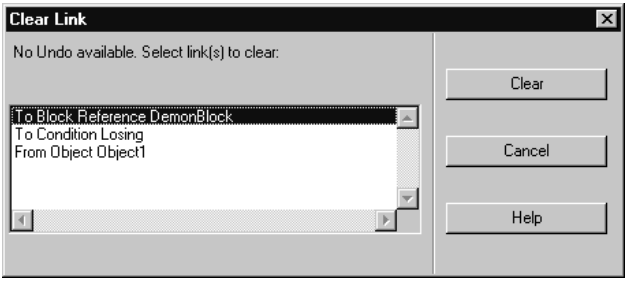

Figure 137: The Clear Link dialog

The links to and from the object are listed in the following form:

`From | To` <*type and name of linked object*>

The list of links is a multiple selection list, in which one or more links can be selected. When a selection is made in the list, the *Clear* button becomes active.

To remove links, select the links in the list and click the *Clear* button. A link is removed from both endpoint objects, but the link endpoints themselves are **not** removed. If either of the endpoint objects had only this link defined, and no others, the mark of the object changes to indicate that the object is only an endpoint with no links defined. For information on how to remove an endpoint, see "Link > Clear Endpoint" on page 447 (below).

Link > Clear Endpoint

This menu command removes the link endpoint from the currently selected object, and subsequently all links connected to the endpoint.

This command is dimmed if more than one object is selected, or if the selected object is not an endpoint.

If the selected object has no links connected to the endpoint, the endpoint is removed without further user interaction. The endpoint is removed from the Entity Dictionary and the Link Manager. The object is no longer marked as a link endpoint in the invoking tool (an editor or the Organizer).

Note:

In the Text Editor, this command can also be used to reduce the extent of an already existing endpoint. If the selection only indicates a partial range of the endpoint, at the start or end of the endpoint, a dialog will appear allowing you to choose whether to remove the entire endpoint, or just remove the selected part of the endpoint from the selection.

If a partial range in the middle of the endpoint text is selected, the only possibilities are to remove the entire endpoint or cancel the operation.

If the selected object has one or more links connected to the endpoint, a warning dialog is opened, since the operation of removing a link cannot be undone:

The *Paste As* Command

The command *Paste As* is available in the *Edit* menu of the Organizer and in the SDL Suite editors (except for SC or HMSC diagrams).

The Paste As command is used to paste a copied object as another object, and at the same time create an implementation link between the copied and pasted objects. It is also possible to paste a cut object, but in this case no link can be created.

It is possible to paste the object into an editor different from the one the object was copied from. This requires a transformation of the object according to the user's choice.

Paste As supports the SOMT method, which governs the possible transformations for a particular object. See the SOMT Methodology Guidelines starting in chapter 69 in the User's Manual for information and advice on when to use a particular transformation.

> **Note:**
>
> The normal *Paste* command in the *Edit* menu is very different from *Paste As*. A normal paste can only be performed in the same editor as the object was copied from, and the pasted object is as far as possible an identical copy of the object.

The Paste As Process

The process of using Paste As consists of the following steps:

1. Copy (or cut) an object to the clipboard.

   A **single** object is selected and copied to the clipboard by using the *Copy* command in the *Edit* menu of the editor. The Paste As command supports the following objects being copied:

   – A class symbol in an OM Editor.
   – An object symbol in an OM Editor.
   – A text fragment in a Text Editor that either contains no endpoints or exactly matches an endpoint.

   It is thus not possible to use Paste As with copied SDL or MSC symbols, or with Text symbols copied in an OM Editor.

2. Paste the object using *Paste As*.

   In the desired editor or the Organizer, the *Paste As* command is selected from the *Edit* menu. The menu choice is dimmed if:

   – More than one object was copied.

   – An object different from the list above was copied.

   – The copied object cannot be pasted into the tool, i.e. there is no transformation defined for this particular object–tool combination. The possible transformations are listed in "Transformation Scheme" on page 452.

   After selecting the menu choice, the Paste As dialog is opened. See "The Paste As Dialog" on page 450.

3. Select the type of object to paste the copied object as.

   In the Paste As dialog, the possible resulting object types are listed in an option menu. The object types listed reflects the transformations possible for this particular copy–paste situation. If the desired object type is not present in the list, the user may have to change which object is being copied, the editor where the paste is made, or (for the SDL Editor) the type of SDL diagram being pasted into.

4. Select the type of link to create, if any.

   In the Paste As dialog, it is possible to change the default of creating an "Implementation Link" between the copied and pasted objects. See "The Link Info Dialog" on page 451. If the object was cut instead of copied, no link can be created.

5. Place the pasted object.

   If the pasted object is a graphical symbol, a "floating" symbol must be placed with the mouse in the usual way, and the paste can be cancelled by pressing `<Esc>`. If the pasted object is a textual description or an Organizer document, the object is placed at the text cursor or the current selection.

6. Edit the pasted object, if needed.

   The results of the object transformation may not be complete or accurate. The user may need to change the pasted object to achieve the desired result.

The *Paste As* Dialog

The Paste As dialog is opened when *Paste As* is selected from the *Edit* menu.

Figure 138: The Paste As dialog

- *Paste <copied object> as*

  The option menu contains all possible types of objects that can be created in the current situation; in some cases, only a single alternative is available. A default object type is pre-selected. The possible object types and the default are presented in "Transformation Scheme" on page 452.

- *Create link from copied object to pasted object*

  This option controls whether a link is to be created between the copied and pasted objects. This is by default set, and the link will always be made from the copied object to the pasted object. If the object was cut instead of copied, this option is dimmed.

- *Link name: <link name>*

  States the name of the link to create, and is only valid if the *Create link* option is set. By default the link name is "Implementation Link", but this can be changed in the Link Info dialog; see below.

- *Paste As*

  Closes the dialog, creates an object of the selected type, pastes it in the invoking tool (the Organizer or an editor), and optionally creates a link. In graphical editors, pressing `<Esc>` cancels the paste.

- *Link Info*

  Brings up the *Link Info* dialog (see below), where the attributes of the link can be changed before it is created. This button is dimmed if the *Create link* option is dimmed or not set.

The *Link Info* Dialog

The *Link Info* dialog is opened when the *Link Info* button is pressed in the *Paste As* dialog.

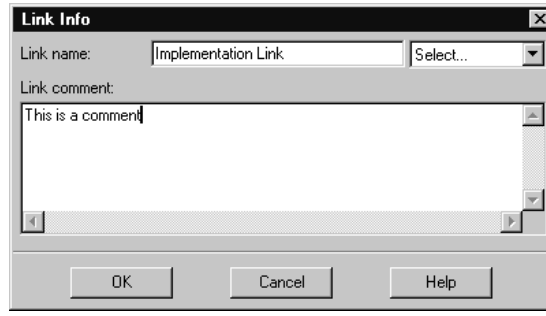

Figure 139: The Link Info dialog

- *Link name*

  An editable text field specifying the name (type) of the link to create. The name is preset to “Implementation Link”. The five latest used link names when creating links is available in the *Select* option menu. Selecting a name from this menu inserts the name into the text field.

  The link name text field must not be empty.

- *Link comment*

  An optional comment text to be provided by the user. The text in the comment field is initially empty. The comment associated with a link can only be viewed and changed later on by using the Link Manager.

Transformation Scheme

The table below presents all the possible object type combinations for the copied and pasted object in the Paste As operation. The preselected choice shown when the Paste As dialog is opened is shown in **bold face.**

Copied object	Paste As in OM Editor	Paste As in SDL Editor	Paste As in MSC Editor	Paste As in Text Editor	Paste As in Organizer
Class (in OM Editor)	**Class** Object	System Type Block Type Block **Process Type** Process Service Type Service Text symbol with NEWTYPE Text symbol with SDL interface	—	**C++ class** C struct IDL Module IDL interface ASN.1 sequence	**System**
Object (in OM Editor)	**Class** Object	Block instance **Process instance** Service instance	—	—	**System**
Text fragment (in Text Editor)	**Class** Object	—	**Instance** Message	**Text fragment**	**MSC**

Note:

Not all object types are possible to Paste As in all situations. Especially in the SDL Editor, the available object types depend on which diagram type the Paste As is performed in.

Transformation Details

The details of the specific object transformations are described in the following subsections. Please refer to the above table to see which tools that support a particular object transformation.

Some general transformation details are:

- The name of a copied symbol can be empty. When pasted as an SDL diagram, the name “EmptyName” will be used.
- In SDL diagrams, if the name used for a pasted symbol will be in conflict with an already existing name, the pasted name will be the original name suffixed by “_<number>”. For example, if “Name” already exists for a reference symbol in an SDL diagram, the pasted symbol will have the name “Name_1”. The number is incremented until the name is unique.
- The size of the pasted SDL, MSC and OM symbols are the same as when a symbol is manually picked from the editor’s symbol menu.
- The exact layout of generated diagrams may not be depicted correctly in the following illustrations. Only the upper left part of a diagram is shown.

Pasting an OM Class

An OM class may be represented and defined by several class symbols in the OM diagrams. This is the case if more than one class symbol with exactly the same class name is found within the OM scope (the diagram itself or the diagrams in the same Organizer module).

When an OM class is pasted, **all class symbols defining the class in the scope are considered**. It is the combined set of attributes and operations in the class symbols that will be used in the transformation to the pasted object.

In the following descriptions of object transformations, we use the two class symbols shown in Figure 140 (within the same scope) as a generic example. Regardless of which class symbol is copied, both class symbols are considered in the transformations.

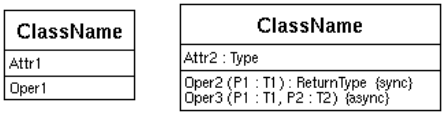

Figure 140: Two class symbols in the same scope

Note:

Even if there are more than one class symbol in the scope, only the copied symbol will be linked with the pasted object (if a link is created). Links are not created for the other symbols in the scope.

Paste As object, with description	Resulting objects and diagrams
Class symbol The pasted class is simply a copy of the merged class.	Object symbol The pasted object contains the merged attributes of the class. The object is named ‘a’ followed by the class name.	System Type diagram **Block Type diagram** **Block diagram** In these cases, only a reference symbol is created, not any contents of the diagram.	
Paste As object, with description	Resulting objects and diagrams
Process Type diagram **Service Type diagram** A reference symbol is created, as well as the referenced diagram with some contents. The keyword “{async}” after an operation means that it will be transformed using a signal interface. A gate named ‘G’ followed by the class name, and a signal list named “SL” followed by the class name, is added. The keyword “{sync}” after an operation means that it will be transformed using an RPC interface. The procedure diagram is created with an additional heading symbol containing FPAR and RETURNS statements for parameters and return type. If no keyword is given, signal interface is the default for operations without return value, and RPC interface is the default for operations with return value. **NOTE:** Text symbols containing the declarations of the signal list and the remote procedures must be created by a separate Paste As operation, usually in a diagram at a higher level. See “Text symbol with SDL interface” on page 456 (below).	
Paste As object, with description	Resulting objects and diagrams
Process diagram **Service diagram** The same transformation as for process type and service type, but the signal interface is added as a SIGNALSET statement in the additional heading symbol. **NOTE:** Text symbols containing the declarations of the signal list and the remote procedures must be created by a separate Paste As operation, usually in a diagram at a higher level. See "Text symbol with SDL interface" on page 456 (below).	Text symbol with SDL interface A text symbol is added, containing declarations for the signal list and/or remote procedures, as described for process type and service type above.	
Paste As object, with description	Resulting objects and diagrams
Text symbol with NEWTYPE A text symbol is added, containing a NEWTYPE definition. Operator diagrams are added for all operations, with additional heading symbols containing FPAR and RETURNS statements for parameters and return type. If an operation does not have parameters, a parameter is inserted with the class name as type. The class name is also used as return type if an operation does not specify any.	System diagram In the Organizer, the system diagram is added in the same way as for the *Add New* operation, i.e. the diagram is added as a new root diagram at the current selection. The diagram is also opened in the SDL Editor.	C++ class definition The link to the class definition is inserted inside a C++ comment.	`// class ClassName` `class ClassName {` `public:` `  void Oper1();` `  ReturnType Oper2(T1 P1);` `  void Oper3(T1 P1, T2 P2);` `private:` `  Attr1;` `  Type Attr2;` `};`

Paste As object, with description	Resulting objects and diagrams
C struct definition The link to the struct definition is inserted inside a C comment.	`/* struct ClassName */` `typedef struct {` `  Attr1;` `  Type Attr2;` `} ClassName;` `void Oper1(ClassName *);` `ReturnType Oper2(ClassName *,` `  T1 P1);` `void Oper3(ClassName *,` `  T1 P1, T2 P2);`
IDL module Only the class name is used. The link to the module is inserted inside an IDL comment.	`// module ClassName` `module ClassName {` `};`
IDL interface Operations marked with keyword "{async}" will get the string `oneway void` inserted before the name of the operation. The link to the interface is inserted inside an IDL comment.	`// interface ClassName` `interface ClassName {` `  attribute Attr1;` `  attribute Type Attr2;` `  oneway void Oper1();` `  ReturnType Oper2(T1 P1);` `  oneway void Oper3(T1 P1,` `  T2 P2);` `};`
ASN.1 sequence The link to the sequence is inserted inside an ASN.1 comment.	`// ClassName SEQUENCE` `ClassName ::= SEQUENCE {` `  Attr1,` `  Attr2 Type` `}`

Pasting an OM Object

In a similar way as when pasting an OM class, all object symbols of exactly the same class in the scope are considered. It is the combined set of attributes in the object symbols that will be used in the transformation to the pasted object.

In addition, the class that the object is an instance of is also considered, if it exists. That is, it is the combined set of attributes and operations in the class symbols and the objects symbols that will be used in the transformation.

In the following descriptions of object transformations, we use the object symbol shown in Figure 141 as a generic example. In addition, the object is assumed to be located in the same scope as the two class symbols shown in Figure 140 on page 454.

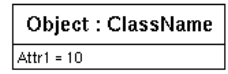

Figure 141: An Object symbol

Paste As object, with description	Resulting objects and diagrams
Class symbol The pasted class uses the class name, attributes and operations from the copied object and the object's class symbols.	Object symbol The pasted object uses the name and attributes from the copied object and the object's class symbols, but without attribute values.	Block instance diagram **Process instance diagram** **Service instance diagram** The pasted diagram becomes an instance diagram (indicated in the Organizer).	System diagram Works in the same way as when pasting an OM class. The name of the diagram will be "Object : ClassName".	See "System diagram" on page 457.

Pasting a Text Fragment

In the following descriptions of object transformations, we use the text fragment “Text Fragment” as a generic example.

> **Note:**
>
> The copied text fragment must either contain no endpoints, or exactly match an existing endpoint in the text. If the text fragment contains both endpoint text and non-endpoint text, it cannot be used for Paste As.

Paste As object, with description	Resulting objects and diagrams
Class symbol Syntax check is performed on the class name.	Object symbol Syntax check is performed on the object name.	Text fragment The pasted text is simply a copy of the copied text.	Text Fragment
MSC instance **MSC message out** **MSC message in** The two message types place the endpoint at different ends of the message line.	MSC diagram In the Organizer, the MSC diagram is added in the same way as for the *Add New* operation, i.e. the diagram is added as a new root diagram at the current selection. The diagram is also opened in the MSC Editor.	 
Other *Edit* Commands

Some of the commands in the *Edit* menu in the editors are affected when operating on objects that have endpoints with connected links.

Pasting an Object

If objects with endpoints are cut or copied, the endpoints and any existing links to the objects are saved in the clipboard.

When pasting (by using the ordinary *Paste* command) an object with an endpoint, but without connected links, the endpoint is pasted together with the object without further user interaction.

When pasting objects that also have links connected to their endpoints, the following dialog appears:

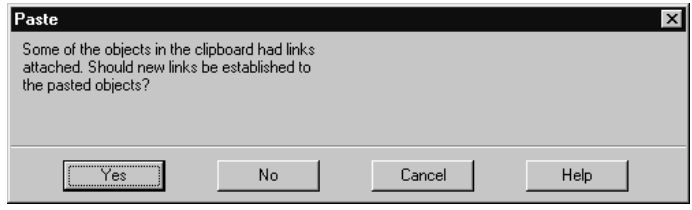

Figure 142: The Paste dialog

- The *Yes* button pastes the objects and keeps the links. An object having connected links will be pasted with new links created between the pasted object and the objects the original object was linked to.
- The *No* button pastes the objects without endpoints and links. No pasted objects will have any endpoints or connected links.

Deleting an Object

If you delete an object that has links, the link information will be destroyed and cannot be restored. Therefore, when you want to cut or clear objects with links, a warning dialog will be issued where it is possible to cancel the operation.

The Link Manager

The Link Manager manages endpoints and links in a system. The Link Manager handles the link file, containing information about the endpoints and links in a system. The syntax of the link file is described in "The Link File" on page 485.

For an overview of link concepts, see "Link Concepts and Overview" on page 428. In addition, the following concepts are used in the Link Manager:

- *Entity*

  A collection of endpoints with the same type and name in the same scope is called an *entity*. The scope is defined as the file the endpoint resides in. If the file is in an Organizer module, the scope is the module.

- *Cardinality*

  The number of links associated with an endpoint, i.e. the total number of links going to and from the endpoint.

Link Manager Window

The Link Manager's window is shown in Figure 143. The window title contains the name of the loaded link file, and is appended by an asterisk '*' if the link file is modified.

In the window, the endpoints in the system are presented graphically using icons. The links between the endpoints are represented as lines between them, with an arrow stating the direction of the link. The Link Manager can present different *views* of the endpoint/link information; these are described in "Presentation Views and Link Trees" on page 464.

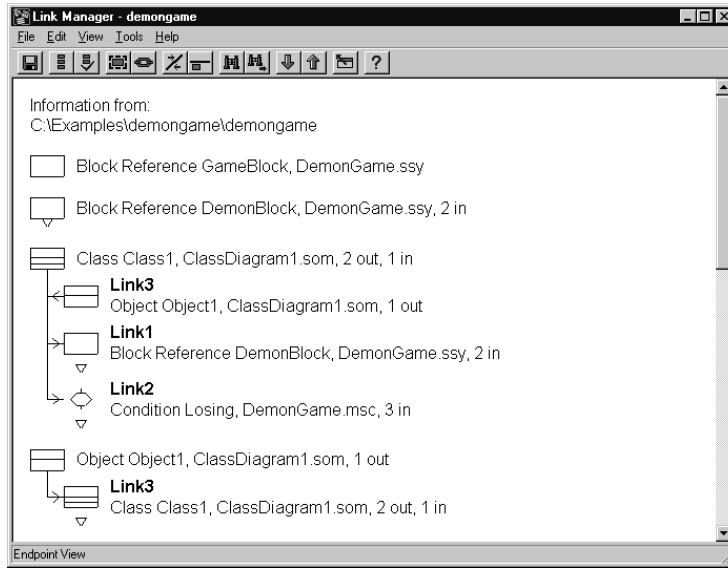

Figure 143: The Link Manager window

At the top of the drawing area, the name of the current link file is presented under a “Information from” heading. If several link files are merged, they are all listed here until the next *Save* operation. If a local link file is used (see “Local Link File” on page 429), both the master link file (read only) and the local link file are listed.

If the information in the Link Manager is not yet saved, “on-line editing” will be displayed to indicate that endpoints have been created in an editor or in the Organizer.

The main part of the drawing area displays all endpoints and links as *link trees*. Every endpoint is a root node, and the associated links and endpoints are added to that root. Link trees can be collapsed, and endpoints and links can be hidden.

Below the link trees, some statistics are presented under a “Statistics” heading. The number of endpoints and links is displayed, including the number of hidden endpoints and links, as in the following example:

```
Statistics:
10 endpoints (2 not shown)
```

```
4 links (1 not shown)
```

Endpoint Icons

The Link Manager uses the same icons for endpoints as the Entity Dictionary. See "Entity Icons" on page 436 for more information.

The icons can have different layouts indicating the state of the associated endpoint:

Normal
The normal state of the icon. Information is not modified.

Invalid
An endpoint is marked invalid if, after a *Check Endpoints* operation, it is not present in the document where it was supposed to be.

Dirty
The endpoint is modified or newly created from an editor, but the link file is not yet saved.

Dashed
The endpoint is already displayed on a higher level in the same tree, or it belongs to the *TO* group after a *Consistency Check*.

The endpoints are added as new root symbols below the last link tree as they are created. The order of the icons can be changed by using the quick buttons *Move Down* and *Move Up*.

Presentation Views and Link Trees

The Link Manager has two main methods of displaying endpoints, using an *Endpoint view* or an *Entity view*. There is also a *Consistency view*, used for presenting the results after a consistency check has been performed (see "Consistency Check" on page 476). When there is no selection in the drawing area, the name of the currently displayed view is shown in the status bar.

In Endpoint view, a link tree looks like this:

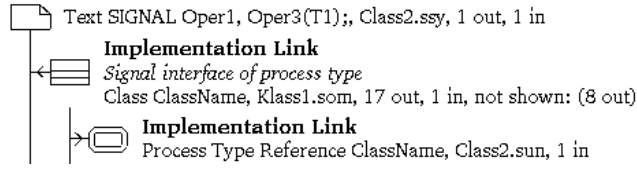

Figure 144: Link tree in Endpoint view

To the right of each endpoint icon, the following information identifying the endpoint is displayed (depending on the options set in *Options > Endpoint*):

- The endpoint type, i.e. the type of the endpoint object.
- The name of the endpoint, in a plain type face. For endpoints containing a name, such as diagram symbols, this name is listed. For other symbols and text fragments, the first 25 characters are shown.
- The file the endpoint resides in. The file name is shown with or without its absolute path depending on the setting in the Organizer.
- The link cardinality; the number of “out” links followed by the number of “in” links.
- The number of hidden links, if any, within parenthesis.

For each link in a link tree, the name of the link is displayed above the endpoint information, in **bold face**. The link name display can be switched on or off by the menu choice *Options > Link*.

The link comment, if it is used, is shown directly below the link name, in *italics*. The comment display can be switched on or off by the menu choice *Options > Link*.

In Entity view, all endpoints representing the same entity are collected into one symbol, and the number of endpoints represented by that entity is presented to the right of the name of the entity, preceded by an asterisk ‘*’. Also, instead of displaying the filename the endpoint resides in, the scope the entity resides in is displayed. The scope is either a filename or a module. An example of an endpoint in Entity view:

Figure 145: An entity in Entity view

Link Manager operations on endpoints also apply to entities. If there is a difference in the behavior of a menu choice depending on the view, this will be pointed out in the descriptions of the operations.

Double-Clicks

Double-clicking on an icon invokes the menu choice *Show in Editor*. In Entity view, if the selected entity corresponds to several endpoints, they will be selected one at a time for each double-click.

Menu Bar

This section describes the menu bar of the Link Manager window and all the available menu choices.

The menu bar contains the following menus:

- *File Menu*
- *Edit Menu*
- *View Menu*
- *Tools Menu*
- *Help Menu*
  (see "Help Menu" on page 15 in chapter 1, *User Interface and Basic Operations*).

File Menu

The *File* menu contains the following menu choices:

- *New*
- *Open*
- *Merge*
- *Save*
- *Save As*
- *Print*
- *Close*

The menu choices are described in "File Menu" on page 8 in chapter 1, *User Interface and Basic Operations*, except *Print*, which is described in "The Print Dialogs in the SDL Suite and in the Organizer" on page 316 in chapter 5, *Printing Documents and Diagrams*, and *Merge*, which is described below.

Merge

This menu choice opens an existing link file, and merges the contents of that file with the information already in the Link Manager. It works in a similar way to *Open*, but keeps the current endpoint and link information.

If two links are equal (i.e. they have the same source and destination endpoints and the same name) but they have different link comments, the new comment will consist of the old comments separated by a newline character.

Edit Menu

The *Edit* menu contains the following menu choices:

- *Highlight Endpoint*
- *Replace Endpoint*
- *Create Link*
- *Link Details*
- *Clear Link*.

Highlight Endpoint

This menu choice highlights an endpoint. Highlighting an endpoint is the first step to replace an endpoint or create a link. The highlighting is presented as a frame around the highlighted endpoint.

The first time this menu choice is used, the selected endpoint will be highlighted. The second time this menu choice is used for the same endpoint the highlighting will be removed. There is at most one highlighted endpoint. If another endpoint already was highlighted, the highlighting is moved to the selected endpoint.

Replace Endpoint

This menu choice replaces an endpoint with another endpoint. This operation is useful if an endpoint has become Invalid and the user has found a replacement endpoint that all links should be moved to.

One endpoint is defined with the *Highlight Endpoint* menu choice, the other endpoint is defined by the selection.

All links going to or from the replaced endpoint will be updated to go to or from the other endpoint instead. If the replaced endpoint was invalid, the user is given the option to delete the replaced endpoint.

The following dialog appears:

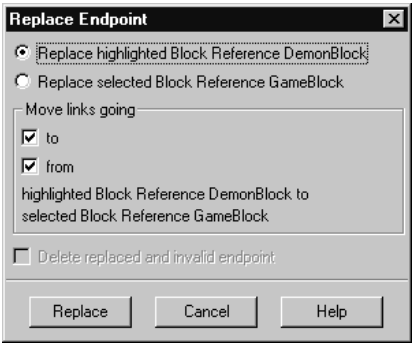

Figure 146: The Replace Endpoint dialog

- *Replace highlighted* `<endpoint>`
- *Replace selected* `<endpoint>`

  Depending on the setting of the radio button, either the highlighted or the selected endpoint will be replaced.

- *Move links going to/from*

  These options are used to select if links going to the replaced endpoint, or links going from the replaced endpoint, will be moved.

- *Delete replaced and invalid endpoint*

  If the endpoint to be replaced is invalid, it can optionally be deleted. If any links going to the deleted endpoint are not moved, they will also be deleted.

Create Link

This menu choice creates a link between the highlighted endpoint and the selected endpoint.

One endpoint is defined with the *Highlight Endpoint* menu choice, the other is defined by the selection.

The Create Link dialog appears, see Figure 135 on page 443.

Link Details

This menu choice displays information about the link above the selected endpoint; the name, the comment, and the direction of the link. All these attributes can be edited.

The following dialog appears:

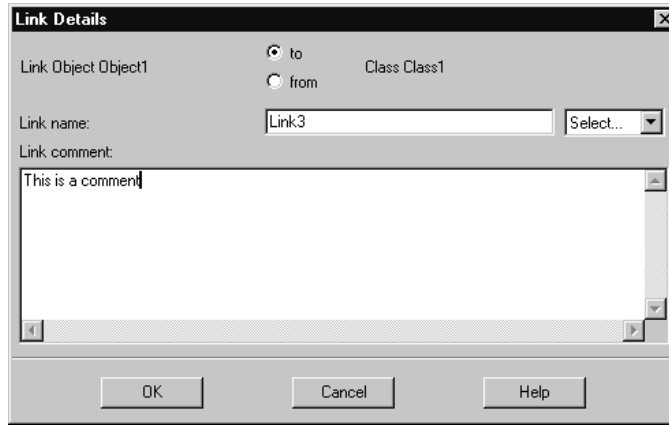

Figure 147: The Link Details dialog

The dialog works in the same way as the Create Link dialog, see Figure 135 on page 443.

Clear Link

This menu choice clears (deletes) the link above the selected endpoint. Only the link will be cleared, not the associated endpoints. You will be asked to confirm or cancel the deletion.

View Menu

The *View* menu contains the following menu choices:

- *Expand*
- *Expand Substructure*
- *Collapse*
- *Options > Window*
- *Options > Link*
- *Options > Endpoint*
- *Filter*
- *Set Scale*.

Expand

This menu choice expands the endpoint structure tree one level down for the selected endpoint. If any endpoints one level down are hidden, they will still be hidden after this operation. (Use the *Filter* menu choice to show or hide endpoints).

The menu choice is dimmed if:

- No endpoint is selected
- The selected icon is a leaf (no children icons)
- The selected icon is already expanded

Expand Substructure

This menu choice expands the endpoint structure tree the whole way down for the selected endpoint. If there is no selection, all endpoint trees will be expanded.

Collapse

This menu choice collapses the selected endpoint, i.e. the sub symbols are not shown after this operation. A collapsed endpoint has a small triangle drawn below the icon to indicate that it is collapsed. If there is no selection, everything will be collapsed.

Options > Window

This menu choice sets options for controlling the appearance of the Link Manager window.

The following dialog appears:

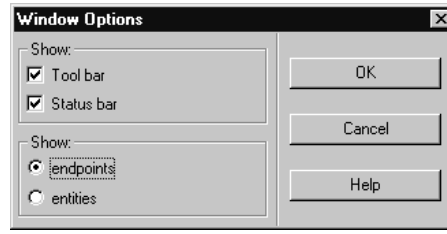

Figure 148: The Window Options dialog

- *Show: Tool Bar*
- *Show: Status Bar*

  These options control whether the tool bar and the status bar should be displayed or not.

- *Show: endpoints/entities*

  By using this radio button, Endpoint or Entity view is selected (see "Presentation Views and Link Trees" on page 464).

Options > Link

This menu choice sets options for controlling the appearance of links in the drawing area.

The following dialog appears:

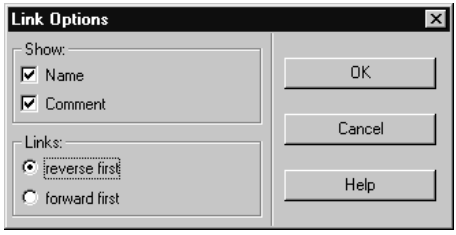

Figure 149: The Link Options dialog

- *Show: Name*

  Show/hide the name of all links.

- *Show: Comment*

  Show/hide the comment for all links.

- *Links: reverse first/forward first*

  This setting controls whether links going to a root endpoint (*reverse first*) or links going from a root endpoint (*forward first*) will be displayed first in the link trees.

Options > Endpoint

This menu choice sets options for controlling the appearance of endpoints in the drawing area.

The following dialog appears:

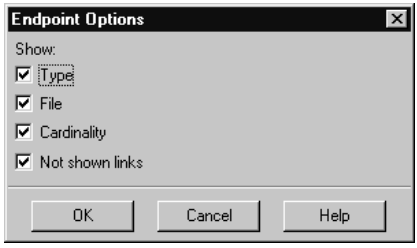

Figure 150: The Endpoint Options dialog

- *Show: Type*

  Show/hide the type of the endpoints.

- *Show: File*

  Show/hide the file name (or module) of the endpoints.

- *Show: Cardinality*

  Show/hide the cardinality, i.e. the number of links going to and from an endpoint.

- *Show: Not shown links*

  Show/hide the number of hidden links going to and from an endpoint.

Filter

This menu choice is used for filtering out endpoints and/or links which will not be shown. The filter is set in a modeless dialog, i.e. the Link Manager continues working without waiting for the dialog to be closed.

If an endpoint is hidden, all links associated to it will be hidden. If a link is hidden, the endpoints associated to it will still be visible.

The following dialog appears:

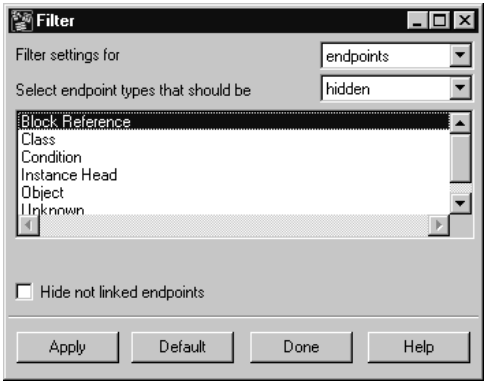

Figure 151: The Filter dialog

- *Filter settings for links/endpoints/documents*

  By using this option menu, filtering can be done on endpoint types, link names, and document file names. All filters are active simultaneously, i.e. for the filter to take effect, all three filter conditions must be true.

  The multiple-selection list in the dialog contains all link names, endpoint types or file names in the loaded link file, depending on the current setting of the option menu. By default, nothing is selected.

- Select <type of filter> that should be hidden/shown

  Depending on this option menu choice, the selected links/endpoints/documents will either be hidden or shown.

- *Hide not linked endpoints*

  If this option is set, all endpoints which are not linked will be hidden. This option is dimmed if filtering is not done on endpoint types.

- Pressing *Default* will set all the lists to their default values, but the filter is not applied until *Apply* is pressed.

Set Scale

Issues a dialog where the scale may be set.

Tools Menu

The *Tools* menu contains the following menu choices:

- *Show Organizer*
  (see "Show Organizer" on page 15 in chapter 1, *User Interface and Basic Operations*)

- *Search*
- *Search Again*
- *Consistency Check*
- *Check Endpoints*
- *Show in Editor*.

Search

This menu choice searches for a text string in endpoints or links.

The searching is based on ASCII character matching. All texts related to the endpoints and links are searched, i.e. endpoint types and names, link names and comments.

The search will start from the selected endpoint, or from the first endpoint if nothing is selected.

The following dialog appears:

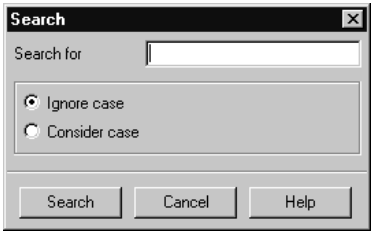

Figure 152: The Search dialog

- *Search for*

  The text string to search for. If a search already has been done, the previous search text is used by default.

- *Ignore Case/Consider case*

  Depending on the radio button setting, the search will either be case sensitive or not.

Search Again

This menu choice searches again for the same text string as the last performed search.

The menu choice is dimmed if a search has not yet been done.

Consistency Check

This menu choice is used for checking the consistency between a group of documents (the *FROM* group) and another group of documents (the *TO* group).

In Entity view, there are two types of consistency checks to choose from. The following dialog appears:

Figure 153: The Link Check/Entity Match dialog

- *Link check*

  Check that all endpoints/entities in the *FROM* group are linked with at least one endpoint/entity in the *TO* group.

- *Entity match*

  Check that all entities (not endpoints) in the *FROM* group has matching entities (not endpoints) in the *TO* group.

The above dialog is not opened in Endpoint view, in which case a link check always is performed.

First, the documents in the *FROM* group must be selected. The following dialog appears:

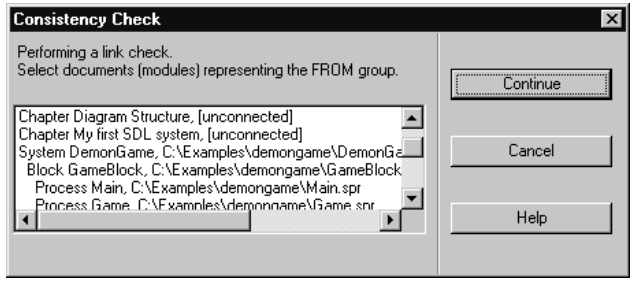

Figure 154: Selecting the FROM group

In the list of Organizer documents and modules, one or several documents must be selected. Selecting/deselecting a module will select/deselect all the documents in that module. Selecting/deselecting an SDL system will select/deselect all documents in that system. Individual documents in the module/system can then be selected/deselected without affecting the other documents.

When all *FROM* documents are selected, the *Continue* button is used to close the dialog and continue to the next dialog.

Then, the documents in the *TO* group must be selected. The following dialog appears:

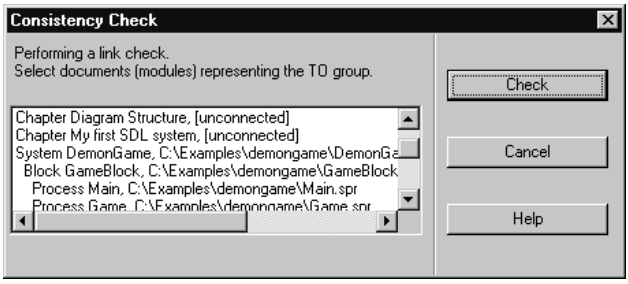

Figure 155: Selecting the TO group

The list of Organizer documents and modules works in the same way as when selecting the *FROM* documents. When all *TO* documents are selected, the *Check* button is used to close the dialog and start the consistency check operation.

The result of the consistency check is presented as a special view in the drawing area. This *Consistency view* only shows endpoints/entities from the two defined groups of documents. Endpoints/entities from the *FROM* group are shown in the normal way, and endpoints/entities from the *TO* group are shown as Dashed symbols.

The Consistency view is only showing links going from the *FROM* group of entities/endpoints to the *TO* group. After a link check, the links shown are the “real” links, as defined by the user. After an entity match, the links shown are only temporary links created by the Link Manager to indicate matching entities. The link name for such links are “Matching” and the link comment is “(Temporary link)”.

By selecting Endpoint or Entity view in *Options > Window*, the view will return to the selected normal view. By pressing the quick button *Show Endpoints or Entities*, the view will return to the previously used view.

Check Endpoints

This menu choice checks if there are endpoints in the Organizer or in the editors that do not exist in the Link Manager, or if there are invalid endpoints in the Link Manager. This menu choice could be used to remove any inconsistencies between the document endpoints in the system and the information in the Link Manager.

The information in the saved files is used for the checking, so if there are unsaved changes in an editor, these will not be taken into account in the checking. If there are any documents in the Organizer which have not been saved, the following dialog appears:

First, the Organizer and all documents in the system are checked. The following dialog appears:

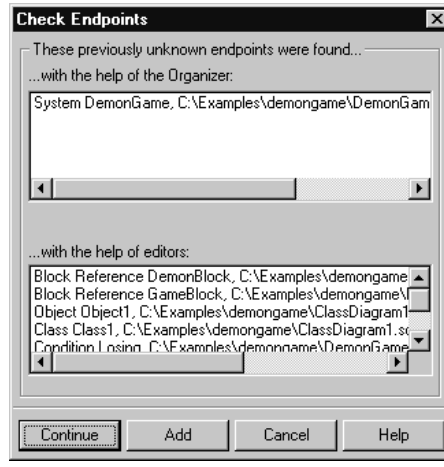

Figure 156: The first Check Endpoints dialog

In the upper multiple selection list, all endpoints that were found in the Organizer, but do not exist in the Link Manager, are listed. In the lower multiple selection list, all endpoints that were found in the documents belonging to the system, but do not exist in the Link Manager, are listed. It is possible to select one or more of the endpoints in the lists, with the purpose of adding them to the Link Manager.

- *Continue*

  Closes the dialog and continues to the next dialog. Any selected endpoints are **not** added to the Link Manager.

- *Add*

  Adds the selected endpoints to the Link Manager. The dialog is not closed until the *Continue* button is pressed.

Then, the endpoints in the Link Manager are checked. If any non-existing endpoints are found, they will be marked as Invalid. The following dialog appears:

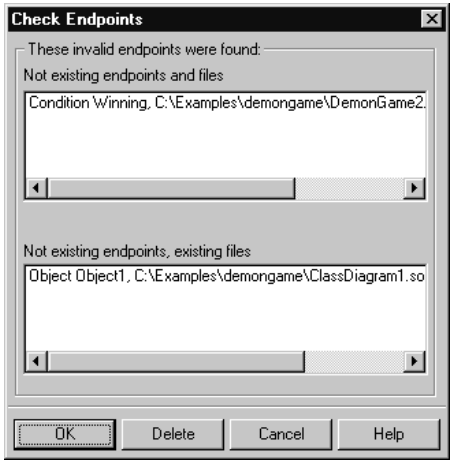

Figure 157: The second Check Endpoints dialog

In the upper multiple selection list, all Link Manager endpoints which reside in files that have been deleted are listed. In the lower multiple selection list, all Link Manager endpoints that no longer are present in the files they are supposed to be in are listed. It is possible to select one or more of the endpoints in the lists, with the purpose of deleting them from the Link Manager.

- *OK*

  Closes the dialog and returns to the main window. Any selected endpoints are **not** deleted from the Link Manager.

- *Delete*

  Deletes the selected endpoints from the Link Manager. The dialog is not closed until the *OK* button is pressed.

Show in Editor

This menu choice will show the symbol which corresponds to the selected endpoint in an editor.

In Entity view, each entity can represent more than one endpoint. In that case, the menu choice will be replaced by *Show 1 in Editor*, *Show 2 in Editor*, etc.

If there are more than nine endpoints, the menu choice *Show in Editor* will invoke the following dialog, where it is possible to select the appropriate endpoint:

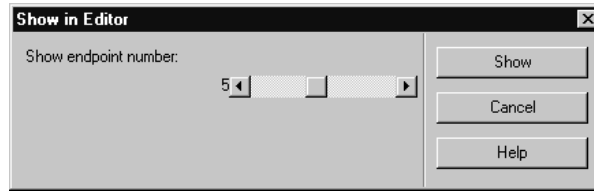

Figure 158: The Show in Editor dialog

Popup Menus

There are two popup menus available in the Link Manager:

On Endpoints

Highlight Endpoint	"Highlight Endpoint" on page 467
Replace Endpoint	"Replace Endpoint" on page 467
Create Link	"Create Link" on page 468
Link Details	"Link Details" on page 469
Clear Link	"Clear Link" on page 469
Expand	"Expand" on page 470
Expand Substructure	"Expand Substructure" on page 470
Collapse	"Collapse" on page 470
Show in Editor	"Show in Editor" on page 480

On the Background

Consistency Check	"Consistency Check" on page 476
Check Endpoints	"Check Endpoints" on page 478
Expand Substructure	"Expand Substructure" on page 470
Collapse	"Collapse" on page 470
Options > Window	"Options > Window" on page 471
Options > Link	"Options > Link" on page 472
Options > Endpoint	"Options > Endpoint" on page 473
Filter	"Filter" on page 474
Search	"Search" on page 475
Search Again	"Search Again" on page 476
Show Organizer	"Show Organizer" on page 15 in chapter 1, *User Interface and Basic Operations*

Keyboard Accelerators

In addition to the standard keyboard accelerators, described in "Keyboard Accelerators" on page 35 in chapter 1, *User Interface and Basic Operations*, the following accelerators can be used in the Link Manager:

Accelerator	Reference to corresponding command or quick button
`Ctrl+E`	"Show in Editor" on page 480
`Ctrl+1`	"Show Organizer" on page 15 in chapter 1, *User Interface and Basic Operations*
`Del`	"Clear Link" on page 469
`Arrow up`	Select the endpoint one step up (move the selection)
`Shift+arrow up`	"Move Up" on page 484
`Arrow down`	Select the endpoint one step down (move the selection)
`Shift+arrow down`	"Move Down" on page 484

Quick Buttons

Except for some of the general quick buttons (see "General Quick-Buttons" on page 24 in chapter 1, *User Interface and Basic Operations*) the following quick buttons are included the Link Manager.

Show Endpoints or Entities
Switches between the Endpoint and the Entity views; see "Options > Window" on page 471.

Consistency Check
Performs a consistency check operation; see "Consistency Check" on page 476.

Highlight Endpoint
Highlights the selected endpoint; see "Highlight Endpoint" on page 467.

Create Link
Creates a link between the highlighted and the selected endpoint; see "Create Link" on page 468.

Switch Link Direction
Changes the order of the links going to or from the (root) endpoint; see "Options > Link" on page 472.

Show or Hide Unused Endpoints
Toggles between showing and hiding endpoints that are not linked; see "Filter" on page 474.

Move Down
Moves the selected (root) endpoint one step down in the Link Manager view.

Move Up
Moves the selected (root) endpoint one step up in the Link Manager view.

The Link File

The Link Manager maintains a link file that contains a list of all endpoints and links in the system. The link file is a line-oriented, human-readable text file, with the default file name extension `.sli`.

The file has the following format:

```
<link file> ::= <endpoints> <links> $

<endpoints> ::= [ENDPOINTS] <endpoint>*
<endpoint> ::= <endpoint id> <endpoint format>
<endpoint id> ::= <integer>
```

A unique integer identifying the endpoint in the link file.

```
<endpoint format> ::= '(' <format> , <file name>
                      (, <anchor> | $) ')' <name>
                      <type>
<format> ::= SDL | OM | MSC | TEXT | WORD

<file name> ::= <string>
```

Name of the document file.

```
<anchor> ::= <string>
```

A unique string identifying the endpoint in the document. If the endpoint refers to the whole file, i.e. the endpoint is created in the Organizer, the anchor is set to an empty string ("").

```
<name> ::= <quoted string>
```

The name of the endpoint, in quotes.

```
<type> ::= <integer>
```

Type of document.

```
<links> ::= [LINKS] <link>*
<link> ::= <endpoint id> <endpoint id> <link name>
           <link comment>
<link name> ::= <quoted string>
```

The name of the link, in quotes.

```
<link comment> ::= <quoted string>
```

The link comment, in quotes.

Chapter 9 Implinks and Endpoints

Chapter

10 *The PostMaster*

This chapter is a reference to the internal communication mechanism between tools in SDL Suite and TTCN Suite, the PostMaster. The functionality of the PostMaster makes it possible to integrate applications by using a well-defined means of communication.

Introduction to the PostMaster

Caution!

The PostMaster was originally designed and implemented for integrating tools in the SDL Suite environment. Currently it integrates tools in the SDL Suite and the TTCN Suite environment. Our experience is that the PostMaster is also suitable for integrating external tools and applications with SDL Suite or TTCN Suite applications; one application area is for instance quick prototyping.

However, IBM Rational does not support using the PostMaster as a communication mechanism between real-time applications, in a run-time environment.

The PostMaster is the mechanism used for communication between the different tools in SDL Suite and TTCN Suite. A C program generated by the SDL Suite or the TTCN Suite tools can also take advantage of this communication mechanism. It can communicate with any application connected to the PostMaster that send messages according to a defined format. This makes it possible for an SDL simulator to communicate with, for instance, a user interface process for the Simulator.

The PostMaster also provides the basic means for an open public interface concept, see chapter 11, *The Public Interface*.

The PostMaster provides the following functionality:

- Starting an application and connecting to it
- Letting an application connect itself
- Letting an application send messages to a given recipient
- Making a “broadcast” of a message.

The PostMaster is a message passing service based on a selective broadcasting mechanism. It will distribute a copy of each message it receives to the tools subscribing to that type of message. By this, the PostMaster provides an integration mechanism between tools without the hard coupling between them that follows from conventional two part communication mechanisms.

Figure 159 illustrates some of the PostMaster concepts. The PostMaster maintains a list of which messages each tool subscribes to. Each tool has a PostMaster part for sending and receiving messages. In the figure, tool F broadcasts a message, i.e. the message is sent to the PostMaster. The

subscription lists of tool A and C (but not the lists of B and F) contains the message type. Accordingly the PostMaster broadcasts the message to tool A and C.

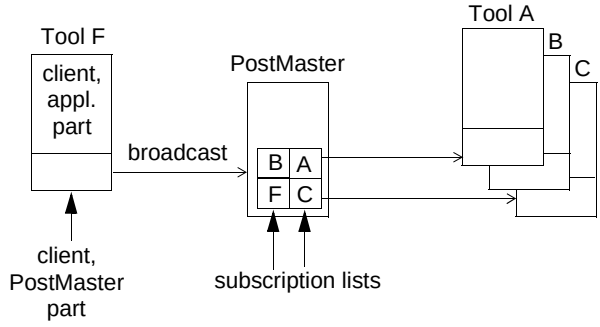

Figure 159: Example of a PostMaster broadcast

The PostMaster configuration is a file that informs the PostMaster about what tools and messages exist in the current context, i.e. it contains the message subscription lists. To include new tools or add new messages, the configuration must be edited.

For detailed information on the configuration, see "The PostMaster Configuration" on page 490.

PostMaster Reference

This section describes the external interface to the PostMaster, including messages to send and their format, contents of the configuration, and functions to call.

> **Note:**
>
> In order to promote a high throughput, it is strongly recommended that the PostMaster messages are consumed as soon as they are available.

PostMaster Messages

The PostMaster configuration defines a large number of messages that can be utilized in an SDL Suite or TTCN Suite system. A broad range of these messages are public, that is, they can be used externally. A description of these are found in *chapter 11, The Public Interface*.

All messages contain information about the identity of the sender, the time it was sent, the message type, and the size of an optional data part.

The optional data part can be seen as parameters to the message and is not interpreted by the PostMaster.

> **Note:**
>
> It is the responsibility of the tools using the PostMaster to define the format of the data part and to interpret it correctly.

The PostMaster Configuration

The PostMaster can be configured either statically at start up or dynamically during runtime. When a dynamic configuration is performed, the services Add Tool or Add Tool Subscription is used. The PostMaster is configured statically using the PostMaster configuration file(s)

The PostMaster configuration file(s) informs the PostMaster about what tools and messages exist in the current context. These files are often referred to as simply the *configuration*.

At start-up the PostMaster reads an environment variable `POSTPATH` which is a list of directories separated by colons **(on UNIX)** or semicolons **(in Windows)**. In these directories, the PostMaster searches for configuration files.

Such files should be named `post.cfd` and are read by the PostMaster whenever it is invoked, for instance when the SDL Suite or the TTCN Suite is started.

It is not possible to use C preprocessor statements or symbols in the configuration file.

Caution!

The file `post.cfd` residing in `$telelogic/sdt/bin` and `$telelogic/itex/bin` **(on UNIX)**, or in the installation directory **(in Windows)**, defines the existing tools in the environment and must not be edited; otherwise unpredictable behavior may occur.

It is possible to have local configurations which extends the standard PostMaster configuration set up by SDL Suite and TTCN Suite by simply defining the `POSTPATH` variable with a directory holding the extended configuration.

File Contents and Syntax

The configuration is a list of tool identities. Each tool identity is bound to an executable, a subscription list of messages and optionally a limit of instances of that tool. Each tool in the file is described in the following way:

```
Tool <tool number>:<executable>:<instance limit>
<message number>;
<message number>;
...
```

Description

- `<tool number>`

  is an integer defined by `SET_` symbols in the file `sdt.h`, and by `IET_` symbols in the file `itex.h`. The number 27000 (`SET_SDLENV`) is used for tools acting as an SDL environment.

- `<executable>`

  is the name of the executable file associated with the tool. It is used by the PostMaster after receiving an `SESTART` message when a tool is to be started.

  A file path may prefix the filename of the executable in order to explicitly tell where to find the tool. In this case the complete file description (path + filename) should be surrounded by a pair of quotes (i.e. `"/home/sdt/demo/demotool"` **(on UNIX)** or `"c:\sdt\demo\demotool"` **(in Windows)**).

- `<instance limit>`

  is the maximum number of concurrent running instances of the tool. It may be wildcarded with a '*' to a default value (`SPMAXNOOFINSTANCES`).

- `<message number>`

  is an integer defined by the symbols starting with `SE` in `sdt.h`. It is normally specified as `<tool number> + <nr>`. Symbols which are used in the TTCN Suite have the prefix `IE` and are defined in `itex.h`.

Adding Tools and Messages

To include new tools or add new messages, the configuration file must be edited. However, the tools and subscription lists existing in the original configuration must not be changed.

To **include a new tool**, follow the steps below. Note that it is not required to include a new tool in the configuration if it only serves as an SDL/TTCN environment that does not need to be started from other tools by using the Start service.

1. Select a tool number not conflicting with the ones already existing in the configuration, preferably a number greater than 100,000. The number chosen must be equally divisible by 1,000.
2. Make a new tool description in the configuration, using the syntax described above.
3. Define a new `SET_` (`IET_`) symbol in the file `sdt.h` (`itex.h`) so that the tool number can be easily accessed in the code.

Example 27 ----------

```
#define SET_MYTOOL   110000
```

To **add a new message**, follow these steps:

1. Decide upon a tool that the new message “belongs to” or “is defined by,” which should not be one of the pre-defined tools in the original configuration.
2. Define a new `SE` (`IE`) symbol in the file `sdt.h` (`itex.h`) as the tool symbol plus an ordinal number, not conflicting with any other message symbol.

Example 28 ----------

```
#define SEMYMESSAGE   SP_MESSAGE(SET_MYTOOL+1)
```

---

3. Use the numeric value of the message symbol when adding the new message to a subscription list in the configuration.

Example 29 ----------

```
110000+1;
```

Environment Variables

The PostMaster recognizes a number of environment variables setting the context in which the PostMaster is to operate. They are read when the PostMaster starts.

PostMaster Environment Variables

The following environment variables are recognized by the PostMaster:

- `POSTPORT`

  UNIX only: Should be set to a valid TCP port number. Causes the PostMaster to try to listen to this port number for possible connections. Makes it possible to connect applications running on other hosts than the PostMaster is running on. Is used in combination with the client side environment variables `POSTHOST` and `POSTPORT`.

- `POSTPATH`

A list of directories separated by colons **(on UNIX)** or semicolons **(in Windows)**, where to search for configuration files named `post.cfd`.

- `POSTDEBUG`

  If set, the PostMaster will log active tools and sent messages as an MSC log. The environment variable takes two optional parameters. The first tells the filename to put the log on. If the parameter is set to `'-e'` the log is put on `stdout`. The second parameter tells the log level. Normally only public messages are logged. But if set to a value > 2 all messages will be logged.

  If no parameters are submitted, the log will be stored on the file `post.mpr`

  See also "Start MSC Log" on page 596

- `STARTTIMEOUT`

  When the PostMaster executes its start service it assumes that the started client will connect, via SPInit, within a certain amount of time. This timeout (in seconds) sets the limit when the PostMaster considers the start having failed. Default is 60 seconds.

  If the SDL Suite and TTCN Suite tools environment is running on slow computer or on a network which is heavily loaded, start-up of a tool might fail due to this timeout. In such case, this environment variable should be increased to an appropriate value.

PostMaster Application Library Environment Variables

The following environment variables are recognized by the PostMaster application library. These environment variables are read in the SPInit function.

- `POSTHOST`

  UNIX only: Should be set to a hostname, on which a PostMaster runs. This PostMaster should be started with the environment variable `POSTPORT` set.

- `POSTPORT`

  UNIX only: Should be set to a valid TCP port which is allocated to a PostMaster. Corresponds to `POSTPORT` set for the PostMaster.

- `POSTPID`

  This environment variable is only of interest if multiple PostMasters are simultaneously active. If it is desired to make a connection to one particular PostMaster, this environment variable should be set to the process id corresponding to that PostMaster.

  If only one PostMaster is active, the application library automatically finds the PostMaster.

  If more than one PostMaster is running and this environment variable is not set, a connection is made to the PostMaster instance having the highest process id value.

Functional Interface

Communication with the PostMaster is based on a small set of fundamental functions:

SPInit	initialization
SPExit	termination
SPBroadcast	output message, broadcast
SPSendToTool	output message, sent to a certain tool
SPSendToPid	output message, sent to a certain PId
SPRead	input message
SPFree	frees memory allocated by SPRead or SPFindActivePostMasters
SPConvert	translate a symbolic message to an id
SPErrorString	Error string conversion
SPRegisterPMCallback	Message notification **(Windows only)**
SPQuoteString	Quoting strings
SPUnquoteString	Unquoting strings
SPFindActivePostMasters	find all PostMasters

Every function returns a value denoting success or failure of the associated operation.

Calling Conventions

The PostMaster functions should be called in the following ways from the external tool:

- The first thing to do is to initiate the connection with the PostMaster itself by calling SPInit. This is preferably done early in the main program. This initiation is private to the client and the PostMaster.
- When having successfully called SPInit, the tool should listen to the PostMaster message port and read the incoming messages by SPRead. The tool should then act upon the messages it subscribes on.
- If so desired, the tool should send messages by calling SPSendToTool, SPSendToPid or SPBroadcast.
- When the tool decides to terminate, it should broadcast the standard message SESTOPNOTIFY by calling SPBroadcast. Then it should disconnect from the PostMaster by calling SPExit.
- Every call to a PostMaster function should check the return value and act properly if an error is detected.

Variables

The following variables are defined.

```
extern INT16 sperrno;

extern INT16 spPortNO; (on UNIX)
extern int spPortNO; (in Windows)
```

sperrno contains an error code when a call to a PostMaster function failed. The error codes are defined in sdt.h and should be self-explanatory.

On UNIX, spPortNO contains a descriptor to the port where incoming messages from the PostMaster are found. **In Windows**, spPortNO contains a process identifier associated with the current process. The state of the variable prior to the call of SPInit is undefined.

These variables are found in the file post.h.

Caution!

Windows only: When linking with the PostMaster's dynamically linked libraries (`post.lib` and `post.dll`), the environment variable `USING_DLL` must be defined before including `post.h`. Example:

```
#define USING_DLL
#include "post.h"
#undef USING_DLL
```

Error Codes

When a function returns `SPERROR` which indicates an error or an not expected result of the function. In this case `sperrno` is set to one of the following values.

Error Code	Explanation
`SPNOSESSION`	The function `SPInit` has not been called successfully
`SPALREADYCONNECTED`	When calling `SPInit` more than once without disconnecting
`SPNOPOSTMASTER`	No PostMaster could be found when trying to connect
`SPNOCHANNEL`	The contact with the PostMaster is lost.
`SPNOMESSAGE`	No message available when trying to read by polling or after a timeout.
`SPTIMEDOUT`	The connection to the PostMaster timed out.
`SPNOSUCHPID`	Sending to a PId with a non positive value (<=0)
`SPNOMEMORY`	Cannot allocate anymore dynamic memory (rare)
`SPTOOLNOTFOUND`	When sending to a tool, this tool is not found in PostMaster configuration list

Error Code	Explanation
SPINVALIDMESSAGE	Sending a message with a NULL parameter but specifying the length greater than 0.
SPBADMESSAGE	A not supported message was to be sent.
SPMANYPOSTMASTERS	Many PostMasters running. Could not decide which one to connect to. **(Windows only)**
SPOLDPOSTMASTER	Old PostMaster running. **(Windows only)**

Functional Description

The available PostMaster functions are described on the following pages. The descriptions use the following format.

First, the function declaration is shown, including data types of parameters, followed by a short explanation of what the function does.

After that, in- and out parameters are described, together with possible return values and error codes.

SPInit

```
int SPInit(int toolType,
           char * argv0,
           *SPMList list);
```

`SPInit` initiates a session and establishes a connection with the PostMaster. See "Multiple PostMaster Instances" on page 518 for information on how to connect to a specific instance of the PostMaster.

Inparameters

- `toolType`

  The tool number identifies the tool and should be a value available in the PostMasters subscription list. For tools acting as an SDL/TTCN environment, it should be set to `SET_SDLENV`. See "Run-Time Considerations" on page 515 for more information.

- `argv0`

  The name of the executable (specified with its path). Normally argv[0] as passed to the program could be used.

- `list`

  Defines a list of predefined messages allowed to send. It also provides a set of mappings between textual strings and integer values for tools and messages. Normally the list provided in `sdt.h` (`itex.h`) is used. This list is later used by the function `SPConvert`, which translates between a textual string and the corresponding identifier.

Returns

- `>0`

  On UNIX, the PId of the calling process. Normally this PId corresponds to an UNIX PId. But if the PostMaster is started with the environment variable `POSTPORT` set, the PostMaster decides what PId value each client should get. In this case the numbering scheme gives the first started client 1, the next 2 and so on.

  In Windows, an identifier ("PId") which is used internally by the PostMaster in order to uniquely identify the calling process.

  This value could be used when sending messages and in comparisons with PIds contained in received messages.

- SPERROR

  SPInit failed, sperrno is set.

Errors

SPNOPOSTMASTER
SPTIMEDOUT
SPALREADYCONNECTED
SPNOMEMORY
SPMANYPOSTMASTERS
SPOLDPOSTMASTER

SPExit

```
int SPExit(void);
```

SPExit exits a session and disconnects the connection with the PostMaster. Subsequent calls to PostMaster functions will return the error code SPNOSESSION until a new SPInit is performed.

Returns

- SPOK

  Status OK.

- SPERROR

  SPExit failed, sperrno is set.

Errors

SPNOCHANNEL
SPNOSESSION

SPSendToTool

```
int SPSendToTool(int tool,
                 int event,
                 void * data,
                 int size);
```

`SPSendToTool` sends a message to the process of kind `tool`.

Inparameters

- `tool`

  Type of tool identifying the tool to send the message to. If such a tool is not running a service reply is sent by the PostMaster.

- `event`

  Type of message

- `data`

  Handle to an information block

- `size`

  Size of data.

Returns

- `SPOK`

  Status OK.

- `SPERROR`

  `SPSendToTool` failed, `sperrno` is set.

Errors

`SPNOCHANNEL`
`SPNOSESSION`
`SPNOMEMORY`
`SPBADMESSAGE`
`SPINVALIDMESSAGE`
`SPTOOLNOTFOUND`
`SPBADMESSAGE`
`SPNOSUCHPID`

SPSendToPid

```
int SPSendToPid(int pid,
                int event,
                void * data,
                int size);
```

`SPSendToPid` sends a message to the process which has process id `toPid`.

Inparameters

- `pid`

  PId of the message's receiver. If the specified PId does not exist, an `SEOPFAILED` message or a service reply is sent by the PostMaster.

- `event`

  Type of message.

- `data`

  Handle to an information block.

- `size`

  Size of data.

Returns

- `SPOK`

  Status OK.

- `SPERROR`

  `SPSendToPid` failed, `sperrno` is set.

Errors

`SPNOCHANNEL`
`SPNOSESSION`
`SPNOMEMORY`
`SPBADMESSAGE`
`SPINVALIDMESSAGE`
`SPTOOLNOTFOUND`
`SPNOSUCHPID`

SPBroadcast

```
int SPBroadcast(int event,
                void * data,
                int size);
```

`SPBroadcast` sends a message to all processes that subscribes on the message type.

Inparameters

- `event`

  Type of message.

- `data`

  Handle to an information block.

- `size`

  Size of data.

Returns

- `SPOK`

  Status OK.

- `SPERROR`

  `SPBroadcast` failed, `sperrno` is set.

Errors

SPNOCHANNEL
SPNOSESSION
SPNOMEMORY
SPBADMESSAGE
SPINVALIDMESSAGE

SPRead

```
int SPRead(int timeOut,
           int * pid,
           int * message,
           void ** data,
           int * len);
```

SPRead reads a message from the queue of unread messages that the PostMaster has sent. When the message is read, it is also consumed, i.e. removed from the queue. The function allocates the necessary amount of memory needed for the data component in the message. The application using this function is responsible for freeing the allocated memory with SPFree when it is no longer needed.

Inparameters

- timeOut

  Maximum amount of time (in milliseconds) that the function waits for a message. If a message has not arrived when timeOut expires, the function returns with return value SPERROR and sperrno is set to SPNOMESSAGE. If a message arrives, the function reads the message and returns immediately. If the desired behavior is to wait until a message arrives, which could mean forever, timeOut should be set to SPWAITFOREVER.

Outparameters

- pid

  PId of the tool sending the message.

- message

  Message identifier.

- data

  Pointer to data associated with the received message. SPFree should be used to free memory.

  Length of allocated data. If ASCII data is received, it is not assured that data is terminated by a ASCII NUL (‘\0’). The application should test if data[len-1] is ‘\0’.

Returns

- SPOK

Status OK.

- SPERROR

  SPRead failed, sperrno is set.

Errors

SPNOCHANNEL
SPNOMESSAGE
SPNOSESSION
SPNOMEMORY

SPFree

```
void SPFree (void * ptr)
```

SPFree should be used to free the memory allocated by SPRead. This is necessary when different compilers with different memory management are used.

Inparameters

- ptr

  A pointer to the memory block to be freed.

Returns

N/A.

SPErrorString

```
char * SPErrorString(int code);
```

Converts an error code into a textual string description of a tool or a message from the corresponding integer value.

Inparameters

- code

  Error code. Typically set by sperrno.

Returns

An descriptive error string corresponding to the error code.

SPConvert

```
int SPConvert(char * str);
```

Converts a textual description of a tool or a message to the corresponding integer value as provided by the parameter `list` in `SPInit`.

Inparameters

- `str`

  Textual description of the tool or message. The list provided in `SPInit` is used when searching for a mapping.

Returns

An integer value for the tool or message. If no mapping is found, `SPERROR` is returned.

SPRegisterPMCallback

```
typedef void (* SP_PM_MessageCallback) (void);
void SPRegisterPMCallback (SP_PM_MessageCallback
cb);
```

Windows only: Registers a callback function that gets called every time a new PostMaster message arrives. Registering this callback enables (32-bit) Windows applications to function correctly. Console applications need not use this function.

Inparameters

- `cb`

  The function to be called when a new PostMaster message is present. If `cb` is `NULL` the current callback is removed; otherwise the callback is replaced.

Returns

N/A.

SPQuoteString

```
int SPQuoteString(char *stringToQuote,
                  char *buffer,
                  int bufferLength,
                  int append)
```

`SPQuoteString` quotes a string. The following operations are performed:

- A quote is added to the beginning and end of the string.
- All quotes and backslashes in the string are escaped, i.e. a backslash character is added before them.

The quoted string can later be unquoted with a call to SPUnquoteString.

Inparameters

- `stringToQuote`

  Pointer to a null-terminated string. This is the string that should be quoted.

- `bufferLength`

  The size of the buffer (see the outparameter `buffer` below).

- `append`

  If the value of append is non-zero, `buffer` is supposed to already contain a null-terminated string. The result of the quoting operation will be appended to this string at the end.

  If several quoted strings are concatenated, they can be extracted and unquoted one at a time with calls to the SPUnquoteString function.

Outparameters

- `buffer`

  Pointer to a buffer where the resulting, quoted string will be returned. The buffer must be large enough to contain all the characters of the quoted string plus a trailing null character. The maximum buffer size needed can be quoted with the following formula:

  maximum buffer size = unquoted string size * 2 + 3

This includes space for escaping every character in the string, plus three bytes for quotes and null character. A larger buffer might of course be needed when appending (see `append` above).

The size of the buffer is given in `bufferLength`. If the quoted string does not fit in the buffer, the function will fail and return zero (further explained in the next section).

Returns

- `1`

  The call was successful.

- `0`

  The function call failed. The buffer was not large enough to contain the quoted representation of the string. The contents of the buffer are undefined.

SPUnquoteString

```
int SPUnquoteString(char *quotedString,
                    int inputLength,
                    char *buffer,
                    int bufferLength,
                    int position)
```

`SPUnquoteString` unquotes a string previously quoted with SPQuoteString, ignoring leading white-space characters. The following operations are performed:

- Any white-space characters in the beginning of the string are ignored. If the string is empty or contains only white-space characters, the function call fails and returns zero (see "Returns" on page 510).
- If the first character after white-spaces is a quote, the function assumes that this quote starts a string quoted with SPQuoteString. In this quoted string, backslashes escape the following character. The string is ended with a non-escaped quote.

  The returned string will have the escaping backslashes and the leading and closing quotes removed.
- If the first character after white-spaces is **not** a quote, the function will simply extract and return a substring up to but not including the next white-space character. If no further white-space characters are found, the rest of the string is returned. Backslashes and quotes have no special meaning when unquoting strings in this way.

Several concatenated quoted strings can be extracted with subsequent calls to this function by using the value returned in the `position` out parameter, see below.

Inparameters

- `quotedString`

  Pointer to a string containing the string previously quoted with SPQuoteString. The string should either be null-terminated or `inputLength` below should have a meaningful value.
- `inputLength`

  The maximum number of characters of `quotedString` that will be scanned. If `quotedString` is known to be null-terminated, a very large number should be supplied here.

- `bufferLength`

  The size of the buffer (see the outparameter `buffer` below).

Outparameters

- `buffer`

  A pointer to a buffer where the unquoted string will be returned. The buffer must be large enough to contain the resulting, unquoted string, including null character. A buffer one character larger than `inputLength` will always suffice. If the buffer is too small, the function call will fail and return zero (see "Returns" on page 510). The size of the buffer is given in `bufferLength`.

  `buffer` can also be null, in which case no unquoting will be performed. The value of `position` can still be interesting, though.

- `position`

  If this pointer is non-null it should point to an integer that will be filled in with the index of the character in the input string immediately following the extracted substring. This will be the character following a closing quote or a whitespace character or the terminating null character.

Returns

- `1`

  The function call was successful.

- `0`

  The function call failed. The supplied string might not be a valid quoted string according to the rules given above. The buffer might not be large enough to contain the result. The contents of the buffer and `position` are undefined.

SPFindActivePostMasters

```
int SPFindActivePostMaster (int *bufferPid,
                            char** bufferText,
                            int maxBufferlength);
```

Finds all PostMasters available for the application on the computer. Information retrieved is process id and a description in plain text.

Inparameters

- `maxBufferlength`

  The size of the arrays `bufferPid` and `bufferText`.

Outparamters

- `bufferPid`

  Pointer to an array where all process ids will be stored.

- `bufferText`

  Pointer to an array of strings telling when the PostMaster was started. `SPFindActivePostMaster` will allocate memory for all strings and the application must call SPFree in order to free the memory.

Returns

Number of PostMasters found.

Java Interface

The file `postmaster.java` contains a java class that encapsulates the postmaster interface for java programmers. The class contains a few fundamental methods.

`Init`	initialization
`SendToTool`	output message, sent to a certain tool
`SendToPid`	output message, sent to a certain Pid
`Broadcast`	output message, broadcast
`Read`	read a message
`Exit`	termination

Init

```
int Init(int toolType);
```

`SPInit` initiates a session and establishes a connection with the PostMaster. See "Multiple PostMaster Instances" on page 518 for information on how to connect to a specific instance of the PostMaster.

Inparameters

- `toolType`

  The tool number identifies the tool and should be a value available in the PostMasters subscription list.

Returns

See functional description for the C interface

SendToTool

```
int SendToTool(int toolType, int message,
               String data);
```

`SPSendToTool` sends a message to the process of kind `tool`.

Inparameters

- `toolType`

  Type of tool identifying the tool to send the message to. If such a tool is not running a service reply is sent by the PostMaster.

- `message`

  Type of message

- `data`

  Data to send

Returns

See functional description for the C interface

SendToPid

```
int SendToPid(int pId, int message, String data);
```

`SPSendToPid` sends a message to the process which has process id `toPid`.

Inparameters

- `pid`

  PId of the message's receiver. If the specified PId does not exist, an `SEOPFAILED` message or a service reply is sent by the PostMaster.

- `message`

  Type of message

- `data`

  Data to send

Returns

See functional description for the C interface

Broadcast

```
int Broadcast(int message, String data);
```

`SPBroadcast` sends a message to all processes that subscribes on the message type.

Inparameters

- `message`

  Type of message

- `data`

  Data to send

Returns

See functional description for the C interface

Read

```
int Read(int timeOut);
```

`SPRead` reads a message from the queue of unread messages that the PostMaster has sent. When the message is read, it is also consumed, i.e. removed from the queue. The data read by the last `Read` is copied to the `Sender`, `Message` and `Data` members of the class `postmaster`.

Inparameters

- `timeOut`

Maximum amount of time (in milliseconds) that the function waits for a message. If a message has not arrived when `timeOut` expires, the function returns with return value `SPERROR` and `sperrno` is set to `SPNOMESSAGE`. If a message arrives, the function reads the message and returns immediately. If the desired behavior is to wait until a message arrives, which could mean forever, `timeOut` should be set to `SPWAITFOREVER`.

Returns

See functional description for the C interface

Exit

```
int Exit();
```

`SPExit` exits a session and disconnects the connection with the PostMaster. Subsequent calls to PostMaster functions will return the error code `SPNOSESSION` until a new `SPInit` is performed.

Returns

See functional description for the C interface

Run-Time Considerations

Starting Up the PostMaster (in Windows)

When SDL Suite or TTCN Suite is started **in Windows**, an instance of the PostMaster is automatically started. No additional commands are needed for the PostMaster. There might however be situations when it is necessary to start the PostMaster stand-alone. This is described in the following sections. The examples only handle how the SDL Suite is started from the “DOS” command prompt, but in many cases a shortcut with the analogous parameters can be created.

Start-Up

There are several possible ways to start the PostMaster itself and the tools that wish to communicate via the PostMaster. In principle, there are two main alternatives:

- Starting the tools when the PostMaster is running
- Starting them without having the PostMaster running.

We will exemplify the start-up methods by using the DemonGame simulator and a User Interface to the DemonGame simulator.

> **Note:**
>
> The PostMaster **must be started first**, but the communicating tools may be started in any order. An SDL simulator must also execute the commands Start-SDL-Env and Go **before communication** with another tool can start.

Starting When the PostMaster Is Present

When the SDL Suite is started from the “DOS” or UNIX prompt, an instance of the PostMaster is automatically started. No additional commands are needed for the PostMaster in this case.

The DemonGame simulator is preferably started from the SDL Suite, thus giving access to all simulation features. It can also be started directly from the “DOS” or UNIX prompt.

Starting from the “DOS” Prompt

Use the following command from the “DOS” prompt:

```
DemonGame.exe -post
```

Note:

In Windows, the simulator is a Windows GUI application and not a Console application. It is therefore not possible to run the simulator stand-alone, i.e. without `-post`.

Starting from the UNIX Prompt

Use the following command from the UNIX prompt:

```
DemonGame.sct -post
```

(Without the parameter, the simulator runs stand-alone, which is not desired in this case.) Starting the simulator this way restricts the possibilities of the simulation since there is no connection to the SDL Suite tools. For instance, graphical trace is disabled.

The UI is preferably started directly from the UNIX prompt. It can also be started from the DemonGame simulator with the command Start-ITEX-Com, but this **requires** that the executable is named `sdtenv`. This is the name specified in the configuration for tool number 27000.

Starting Without the PostMaster

The SDL Suite must be started directly from the “DOS” or UNIX prompt with the command:

```
$telelogic/bin/sdtpm <arg> &
```
(on UNIX)

```
<Installation Directory>\sdt <arg>
```
(in Windows)

(using one of the start-up arguments, see below).

The DemonGame simulator must also be started directly from the “DOS” or UNIX prompt, as described above.

Note:

On UNIX: If activating the PostMaster this way, the environment variable `POSTPATH` **must** be set to include the directory where the executables resides, typically `$sdtbin`.

The UI can be started in the same way as when the PostMaster is running (see above). It can also be started indirectly when starting the PostMaster by using the “DOS” or UNIX command:

```
$telelogic/bin/sdtpm -clients 27000 & (on UNIX)

<Installation Directory>\sdt -clients 27000 (in Windows)
```

This **requires** that the executable is named `sdtenv`, the name specified in the configuration for tool number 27000.

> **Note:**
>
> A tool communicating through the PostMaster can also be started from another tool by using the `SESTART` message. This requires that the tool to be started is specified in the configuration.

Start-Up Arguments

The PostMaster recognizes the following arguments at start-up. Normally they are not needed, but could be used for special purposes

- `-clients <toolid>` Used if the PostMaster should invoke a certain tool at start-up. `<toolid>` is set to the logical tool number of a tool to start as defined in `post.cfd`.
- `-noclients` Used if only the PostMaster is to be invoked without starting any clients. In this case the PostMaster enters an idle state where it waits for a client to connect

All other arguments are passed to the tool started.

SDT-2 Connections (UNIX only)

Applications or tools linked with an SDT 2.X PostMaster application library will not be compatible with SDT 3.X PostMaster. Trying to connect such an old application to an SDT 3.X PostMaster will result in an error message:

```
Postmaster cannot connect SDT2 tool:<tool> with pid:
<pid>
```

on standard output, if externally started, or as a service reply, if started via the start service, and the connection is aborted.

Version 3.4 PostMaster (Windows only)

If an old PostMaster (version 3.4 or older) is used the SPInit function will fail. The error code is SPOLDPOSTMASTER.

Applications or tools linked with an SDT 3.4 PostMaster application library will not be compatible with the SDT 3.6 PostMaster. Trying to connect such an old application to an SDT 3.6 PostMaster with the SPInit function will fail. The error code is SPNOPOSTMASTER.

Multiple PostMaster Instances

It is possible to have multiple instances of the PostMaster running, for instance when more than one SDL Suite or TTCN Suite has been started. In this case it should be made sure that the communicating tools are connected to the correct instance of the PostMaster.

On UNIX, the function `SPInit` by default looks for the PostMaster instance with the **highest process id** (PId) number and connects to it.

On Windows, the function `SPInit` by default fails if more than one PostMaster is found.

To connect to another PostMaster instance, you can set the environment variable `POSTPID` to the PId number of the desired PostMaster. If this variable is set, `SPInit` connects to the PostMaster instance with that PId number.

Configuration and Tool Search

The PostMaster configuration is read whenever a PostMaster instance is invoked. The environment variable `POSTPATH` defines a list of directories where the PostMaster looks for a configuration file named `post.cfd`.

The user can extend the normal configuration by defining the `POSTPATH` variable to a directory containing an extended configuration. When SDL Suite or TTCN Suite is started normally, the directories containing the binaries are put as the first directories in the `POSTPATH` variable.

The same search order is applied when the start service is used. The supplied tool number is matched against the name of an executable in the configuration, which is then searched for as above.

Chapter

11 *The Public Interface*

This chapter introduces the Public Interface and describes a message based interface by which external tools and applications could be integrated with SDL Suite and TTCN Suite tools.

Three conceptually different facilities are provided:

- **By controlling the behavior of the tools and by modifying the data that are handled by the tools in SDL Suite and in TTCN Suite.**
- **By listening to important events of status change in SDL Suite and TTCN Suite.**
- **By integrating an external application with SDL simulators.**

The Public Interface uses the PostMaster as transport. This chapter assumes the reader to be familiar with the PostMaster; see chapter 10, *The PostMaster*.

In *chapter 12, Using the Public Interface*, you may find examples of how to use the Public Interface.

General Concepts

Introduction

Significant steps have been made to increase the openness of SDL Suite and TTCN Suite tools by the introduction of the *Public Interface*. Openness is provided both in terms of diverse ways of controlling the tools and the way data handled by the tools is made visible.

Application Areas

Two different kinds of usage of the Public Interface could be foreseen:

- As an alternate or complementary means to access functionality provided by the tools, compared to the normal graphical interface. Such usage could be to integrate simulators generated by the tools with dedicated user interfaces, or to use the tools batch facilities using make or print in a large “build” environment.
- Integrating SDL Suite and TTCN Suite tools with other tools forming a larger environment.

The Public Interface

The public interface has been made possible due to the modularity of the tools and thanks to the well defined interfaces by which the tools have been built.

The public interface is made available using two different mechanisms.

- Via a programming interface, providing message based services and notifications. The rest of this section provides a description of these services and notifications and their usage.
- Via applications executed via the OS command line interface. By using this interface:
  - Important services could be executed running in a *batch* mode.
  - A Service Encapsulator could be run, which allows message based services to be issued. This tool is also made available as a an example application. For more information, see “The Service Encapsulator” on page 537.

The PostMaster

The PostMaster forms an integral mechanism to integrate tools in the SDL Suite and TTCN Suite tools environment (a reference to the PostMaster is provided in chapter 10, *The PostMaster*).

It is also used as a low level mechanism to physically integrate SDL Suite and TTCN Suite tools with external tools. The PostMaster provides three basic facilities:

- It maintains a list on known tools. Such tools could be connected to the PostMaster and thereby taking part of message sending
- It provides means to broadcast messages to a list of subscribers
- It contains functionality to send a message to a certain recipient.

These facilities are used to implement the concepts provided by the SDL Suite and the TTCN Suite tools services. These are built up of *Services* and *Notifications*. A special case of service is *Communication with SDL Simulators*.

It is important to note that the interface provided could be extended for client-client usage outside SDL Suite and TTCN Suite as long as the conventions described in this document are followed.

Services

Services provides access to functionality within the SDL Suite and the TTCN Suite. Such functions could be used by an external tool to exercise control, to integrate SDL Suite or TTCN Suite with external tools or have SDL Suite and TTCN Suite take part in a larger environment.

Services adopts the client-server concept where a *request* is sent by a client to a server, which returns with a *reply*. Service request and service reply take both advantage of message sending from one tool to another.

Notifications

These are broadcast messages which are spontaneously emitted when a significant event takes place in SDL Suite or TTCN Suite. Often these notifications are caused by a service being successfully processed.

Communication with SDL Simulators

When external applications are to communicate with SDL Simulators, the message `SESDLSIGNAL` is used. It is asynchronously sent/broadcast-

er into the system. All simulators subscribes on this message. As a parameter to this message is the receiver (in the context of SDL) provided.

Overview of Available Services

The following services are provided for external usage. A service is normally supported by a specific tool or a few of the tools. Some of the services correspond to a menu choice or an operation performed by a user using the tools's graphical interface.

In the following services, the Configuration Services and the System File Services are applicable to SDL Suite and TTCN Suite, and the TTCN Suite Services are only applicable to the TTCN Suite. All other services are only applicable to SDL Suite.

Configuration Services

Service	Servers	Graphical correspondence
Start Tool	PostMaster	Start a new tool
Stop Tool	All tools	*Exit* menu choice
Get Tool Type	PostMaster	N/A
Get Tool Pid	PostMaster	N/A
Add Tool	PostMaster	N/A
Add Tool Subscription	PostMaster	N/A

System File Services

Service	Servers	Graphical correspondence
List System Files	Organizer	N/A
New System	Organizer	*New* quick button
Open System	Organizer	*Open* quick button
Save System	Organizer	*Save* quick button
Add Existing	Organizer	*Add Existing* menu choice

Link File Services

Service	Servers	Graphical correspondence
Add Local Link File	Organizer	N/A

Service	Servers	Graphical correspondence
Merge Local Link File	Organizer	N/A

TTCN Suite Services

Service	Servers	Graphical correspondence
Convert to GR	ITEX	N/A
Opened Documents	ITEX	N/A
Fetch Buffer Identifier Given the Database	ITEX	N/A
Fetch Buffer Identifier Given MP File Path	ITEX	N/A
Convert to MP	ITEX	N/A
Convert Selection to MP	ITEX	N/A
Merge Document	ITEX	N/A
Analyze Document	ITEX	N/A
Close Document	ITEX	N/A

Service	Servers	Graphical correspondence
Show Position	TE	N/A
Select Text	TE	N/A

Client Interface

A client which would like to make an integration using these facilities should consult the following interface:

- A programming interface to communicate with the PostMaster
- A description of the provided services
- A description of the available notifications

External Client types

Clients connecting to the PostMaster must be known by the PostMaster. This can be accomplished in a number of ways:

1. By defining a configuration file containing the extended configuration, name this file to `post.cfd` and to set the environment variable `POSTPATH` to include the directory where the file is stored.

   A change in this file is kind of static nature, since the configuration files are read every time the PostMaster is started.

2. By modifying the configuration dynamically. Requires a PostMaster to be running. The PostMaster provides services for dynamically changing a configuration, adding tools and adding subscriptions. This is easily done via a script and does only affect the current session.

New tool types or message types added to the PostMaster tool and subscription list should be set in a range not conflicting with SDL Suite and TTCN Suite. New tools and messages should use values above `100000`. Exact numbering should follow the scheme used by the SDL Suite and the TTCN Suite:

Item	Description
Tools	Use values in steps of 1000
Service Request	Base the value on the tool providing the service and add local base of 100. Then sequentially number the services
Service Reply	Base the value on the corresponding service request and add 100.

Item	Description
Notifications	Base the value on the tool broadcasting the notification and add the messages sequentially.

Message Based Services

Introduction

Using a message based service requires the client to be connected to the PostMaster. To invoke a service, the application sends a service request message to the tool providing the service. A service request message will normally cause a reply message to be sent to the client. An exception is if the server unexpectedly terminates while processing the service.

The client could choose whether to wait for the reply message (emulating a remote procedure call) or to continue working and intercept the reply message via a callback routine.

The client does not need to subscribe on service request messages or service reply messages. However the client itself must be present in the configuration list.

A server can only process one service at time. If additional services are requested from that particular server when being occupied processing the first service, the server is said to be *busy* and a service error reply is returned to the requester. Other kinds of messages received by server during the processing of a service request are queued up and will be processed as soon as the service has completed.

Service Request

A *service request* normally takes advantage of the `SPSendToTool` function. If more than one instance of a tool is active the function `SPSendToPid` will be more appropriate. The reply is fetched with the `SPRead` function. The client must however verify that the read message is the reply message. The macro `SP_MATCHREPLY` could be used to determine whether the received message is the desired reply.

Service Reply

The first parameter in the *service reply* informs about the result of the service request. The following codes are used:

Status Code	Value	Description
`OK`	`0`	The service was successfully processed. Optional parameters are provided in the reply message.
`Busy`	`1`	The server is *busy* and cannot process the service. The service request is aborted. An additional message might be provided.
`ErrorString`	`2`	The server failed to process the service. The remaining parts of the message contain an error message.
`ErrorCode`	`3`	The server failed to process the service, the next parameter in the service reply is a code indicating the error.

In the detailed description of each service, the reply format is only specified for the normal case returning `OK`. For services replying errors in the `ErrorString` format, the text may be context sensitive and only major error causes are specified.

Error Handling

Error handling takes place at two different levels.

1. **The service request failed to be issued**.

   Service Request message couldn't be sent. In such case the `SPSendToTool`, `SPSendToPid` returns false and the variable `sperrno` indicates the error. It also means that a service reply message will not be sent.

2. **While processing the service**.

   In this case the service request reaches the server but cannot be processed or the processing of the service fails. In such a case, an error code is provided in the service reply message. The error is either provided as a code or as explanatory text.

How to decode the service reply is described in the section below.

Common Errors

These errors are common to all services. They all use the `ErrorString` format. Where applicable, an additional explanatory text is added to the strings below:

```
Bad parameters
Server busy
Service not supported
Server locked
```

SDT Reference Errors

When a service request refers to an SDT reference, the following errors may occur:

```
Reference must contain paranthesis
Reference must start with #SDTREF
Invalid reference
Garbage after reference
Embedded value not terminated
Illegal value in paranthesis after token <token-nr>
Junk after embedded value
Incomplete reference lacking trailing paranthesis
Unsupported reference type <token>
Symbol must be integer >= 0
Malformed coordinate
```

For a reference to the syntax of references, see chapter 18, *SDT References*.

Notifications

Certain services will broadcast notifications as the service is processed in order to inform other participants than the service issuer that an operation has been performed by the server or that the state of the server has changed.

Message Parameters

Normally a message (a service request, a service reply, a notification or other) uses one or more parameters. Generally all such parameters are stored in a PostMaster message's data part.

- Parameters are normally separated by a blank (' ') character.
- A parameter that has an additional '*' character is a shorthand for none or a number of this type, each one separated by a blank ' ' or a newline '\n'.
  - The character '+' might also appear as an alternative. The difference is that one or more is expected.
- A preceding attribute tells how many items to expect.

The following parameter types are used:

Type	Description
`integer`	32 bit integer in ASCII form.
`bool`	Logical. True = 1, False = 0
`string`	ASCII string. If the string contains one or more spaces, it is surrounded by double quotes (i.e. "The string"). If a quote character appears in the string, it is preceded by a backslash ('\'). A backslash character is doubled ('\\'). An empty string is also double quoted ("").
`QString`	ASCII string surrounded by double quotes (i.e. "The string"). If a quote character appears in the string it is preceded by a backslash. ('\').
`ByteString`	Byte string. Is always preceded by an attribute telling the length of the byte string.

Files

- The files `sdt.h` and `itex.h` provides two lists of the available services and notifications in terms of message definitions. It also defines a list (see "Adding Tools and Messages" on page 492 in chapter 10, *The PostMaster*) providing a textual definition of messages.
- The file `sdtsym.h` provides the definitions necessary when working with editors and defines values for diagram types, pages types and symbol types.
- **In Windows**, the file `post.dll` is the DLL that contains the external PostMaster interface. It needs either reside in the same directory as the application that is utilizing it, or in a directory that is in the current `PATH`.

The files are found in the directory `$sdtdir/INCLUDE` **(on UNIX)**, or `%SDTDIR%\include` **(in Windows)**.

Interpretation of a Service Description

Below is an explanation of the different sections found in the service descriptions in "Tool Services" on page 539.

Description

A brief textual description of the service.

Tools Supporting the Service

The tool type(s) providing the service. Corresponds to definitions in the file `sdt.h/itex.h`; see "Files" on page 535.

Service Request

Message name. Corresponds to a definition in the file `sdt.h/itex.h`; see "Files" on page 535.

The service request is presented in a table of service parameters, with the appearance below. The parameters must appear in the order they are listed in the table. Usually, a parameter cannot be omitted. If it is optional, this is explicitly mentioned. See also "Message Parameters" on page 534.

Parameter	Type	Description
`symbolic parameter name`	`parameter type`	Brief description of the parameters.

Service Reply

Message name. Corresponds to a definition in the file `sdt.h/itex.h`; see "Files" on page 535.

The table below is similar to the service request parameter table above. A service reply always contains a status code in the first parameter. Additional parameters are only valid if the status code was OK (0). See also "Message Parameters" on page 534.

Parameter	Type	Description
`status`	`integer`	Service reply status.

Errors

Errors additional to the common errors are listed in this section; see "Common Errors" on page 533.

Emitted Notifications

Notifications emitted as a result of the service being successfully processed; see "Notifications" on page 521.

The Service Encapsulator

The Service Encapsulator application enables access to SDL Suite and TTCN Suite services from the Operating System command line prompt.

Basically the tool connects to the Postmaster, sends a service request message and waits for an answer. When the answer arrives, it is printed on standard output. Finally the application exists.

The Service Encapsulator is also available in source code form to show how the Postmaster's Functional Interface could be used. A description of the internal design of the Service Encapsulator is found in *chapter 12, Using the Public Interface*. The source code of the Service Encapsulator is found in

`$telelogic/examples/public_interface` **(on UNIX)**

`<installation directory>\examples\public_interface` **(in Windows)**

The Service Encapsulator binary is invoked by:

On UNIX: `$telelogic/bin/serverpc <tool> <service> <params>`

In Windows: `<installation directory>\sdtbin\serverpc <tool> <service> <params>`

where <tool> is the tool that should perform the service, and <service> is the service itself.

The `<tool>` and `<service>` arguments could either be entered as a symbolic value or as the assigned integer value. These definitions are found in `sdt.h`

If the service takes parameters, these should be provided in `<params>`

Care should be taken in order to enter parameters correctly. In particular if the service uses quoted string parameters:

- **On UNIX**, surrounding quotes should be doubled since the shell from which the tool is invoked, consumes one pair of quotes.
- **In Windows**, surrounding quotes should be prefixed with a back-slash (\) since the "DOS" shell from which the tool is invoked, consumes the quotes otherwise.

The tool allows carriage return `"\n"` and line-feed `"\r"` to be used.

The tool does not allow <params> to contain binary data. Therefore, the SDL Suite services accepting binary data must only contain ASCII characters.

The tool returns 0 on success and -1 if an error occur. Such errors correspond to errors when calling Postmaster functions, see SPInit, SPSendToTool, SPRead in Functional Interface for possible errors.

Tool Services

Configuration Services

Start Tool

Description

This service will start the specified tool. **On UNIX**, start means that a new UNIX process is “fork’ed” and “exec’ed”. **In Windows**, start means that the applications is started using the Windows API function CreateProcess.

The Service adds “`-post`” to the `argv[1]` variable.

The parameters are recognized by the started tool in the `argv[]` variable starting from index 2.

The started tool inherits the environment used by the PostMaster.

The service behaves somewhat differently from other services since it is performed both in the PostMaster and in the PostMaster library in the started tool. The service is initiated in the PostMaster creating the new tool, but the service is recognized to be completed when the started tool calls the PostMaster function `SPInit`. This call causes a `SESTARTNOTIFY` message to be sent. This message is recognized by the PostMaster which upon reception of the `SESTARTNOTIFY` also sends a `SESTARTREPLY` to the issues of the start service.

The service is also different in its nature since it will cause a time-out to expire if the started tool does not call the `SPInit` function within a certain time limit.

The started tool must have an entry in the PostMaster configuration and the associated file containing the tool to start must exist.

The service will return to the caller:

- When the `SESTARTREPLY` message is received by the caller.
- If the tool is only available in one instance and is already instantiated. In this case the process id of the already instantiated tool is returned.

- If the tool cannot be started or if the tool is not recognized by the PostMaster within a time-out. (The started tool calls `SPInit`.)

The following MSC diagram shows the protocol when a tool is started normally (the Organizer starts the editor).

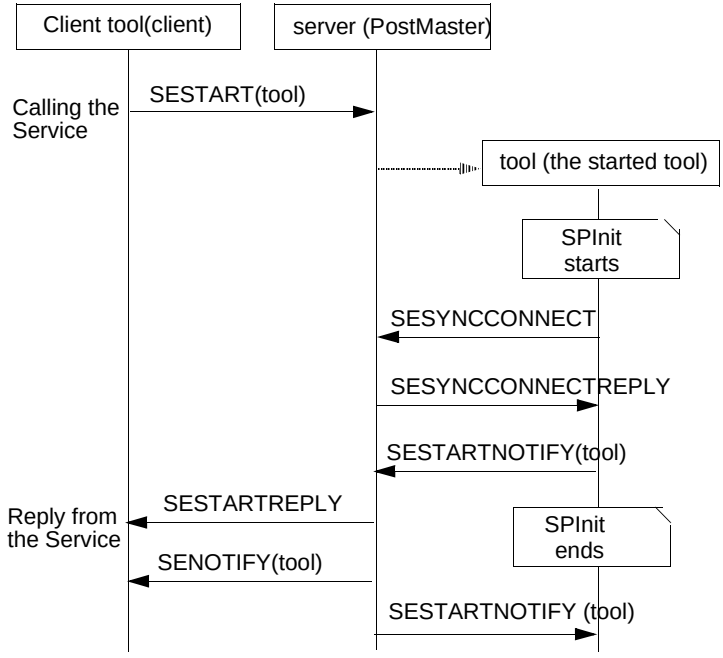

Figure 160: Protocol to start a tool

The SESYNCCONNECT and the SESYNCCONNECTREPLY messages are not present in the **Windows** *implementation.*

Tools Supporting the Service

`SET_POST`

Service Request

SESTART

Parameter	Type	Description
toolType	integer	Tool type to be started
params	string	Optional. Parameters for the started tool. More than one parameter allowed. If separated with blanks, each item will be inserted into the argv[] string list for the started application. The PostMaster will add a parameter -post as the first parameter in the argv[] list.

Service Reply

SESTARTREPLY

Parameter	Type	Description
status	integer	Service reply status.
pId	integer	A PId identifying the tool type of which the corresponding type is started.

Errors

No such tool
Max instances of tool
Already started
File not found
+ Operating System file access and process creation error messages

Emitted Notifications

Notification	Description
SESTARTNOTIFY	Broadcast by the started application when calling SPInit.

Stop Tool

Description

The tool disconnects from the Postmaster and then terminates.

Tools Supporting the Service

`All tools`

Service Request

`SESTOP`

Parameter	Type	Description
`force`	`bool`	If *false*, the tool is allowed to reject the request. If *true*, the tool is expected to terminate

Service Reply

`SESTOPREPLY`

Parameter	Type	Description
`status`	`integer`	Service reply status
`cancelled`	`bool`	*True* if the tool did not accept the Stop request.

Errors

-

Get Tool Type

Description

Returns the process type for a given process id.

Tools Supporting the Service

SET_POST

Service Request

SEGETTOOLTYPE

Parameter	Type	Description
pId	integer	A PId identifying the tool type of which the corresponding type is wanted.

Service Reply

SEGETTOOLTYPEREPLY

Parameter	Type	Description
status	integer	Service reply status.
noOfToolType	integer	Number of tools corresponding to the PId value. If the requested tool type was not found in the configuration, noOfToolType is set to 0.
toolType	integer	The type of tool. If the requested PId is not found, toolType 0 is returned

Errors

-

Get Tool Pid

Description

Returns the process id for the requested tool type. If multiple instances of the tool type exist, all PId values are returned.

Tools Supporting the Service

SET_POST

Service Request

SEGETTOOLPID

Parameter	Type	Description
toolType	integer	An identifier for the tool type of which the corresponding PIds) are wanted.

Service Reply

SEGETTOOLPIDREPLY

Parameter	Type	Description
status	integer	Service reply status.
noOfPid	integer	Number of PId values corresponding to the toolType. If the requested tool type was not found in the configuration, noOfPid is set to 0.
pId	integer	A PId value corresponding to toolType

Errors

-

Add Tool

Description

Dynamically adds a tool type to the PostMaster configuration.

Tools Supporting the Service

SET_POST

Service Request

SEADDTOOL

Parameter	Type	Description
toolType	integer	An identifier for the tool. Should be a value within the allowed range.
filename	string	The filename of the executable tool. Should be a pure filename and **must not** include a directory path. The file should be stored on a directory that is included in the directories designated by the environment variable POSTPATH.

Service Reply

SEADDTOOLREPLY

Parameter	Type	Description
status	integer	Service reply status.
exist	bool	Returns false if the tool was inserted, true if it already existed.

Errors

Operation failed

Add Tool Subscription

Description

Dynamically adds a message to a tool's subscription list.

Tools Supporting the Service

`SET_POST`

Service Request

`SEADDTOOLSUBSCRIPTION`

Parameter	Type	Description
`tooltype`	`integer`	The tool type to which a message subscription should be added.
`message`	`integer`	The message to add to the subscription list.

Service Reply

`SEADDTOOLSUBSCRIPTIONREPLY`

Parameter	Type	Description
`status`	`integer`	Service reply status.
`exist`	`bool`	Returns `false` if the message was inserted, `true` if it already existed.

Errors

```
No such tool
Operation failed
```

System File Services

List System Files

Description

Lists the files currently held in the Diagram Structure chapter in the Organizer. The files will be returned in the order they are found in the Organizer (i.e. top-down, left-right).

Tools Supporting the Service

SET_ORGANIZER

Service Request

SELISTSYSTEMFILES

Parameter	Type	Description
-	-	N/A.

Service Reply

SELISTSYSTEMFILESREPLY

Parameter	Type	Description
status	integer	Service reply status.
noOfFiles	integer	Number of returned files.
file(s)	string	A list of files, with a complete directory path. Each file specification is ended by a newline.

Errors

-

New System

Description

Clear the Organizer content and create a new system. Corresponds to the Organizer menu choice *New*.

Tools Supporting the Service

`SET_ORGANIZER`

Service Request

`SENEWSYSTEM`

Parameter	Type	Description
`forceQuit`	`bool`	If *true*, quit modified diagrams. If *false* and there were one or more modified diagrams, the service is denied.

Service Reply

`SENEWSYSTEMREPLY`

Parameter	Type	Description
`status`	`integer`	Service reply status.
`cancelled`	`bool`	*True*, if the service was cancelled.

Errors

```
Service request denied. No license available.
```

Open System

Description

Opens a system file and displays the file contents in the Organizer. Corresponds to the Organizer menu command *Open*.

Tools Supporting the Service

`SET_ORGANIZER`

Service Request

`SEOPENSYSTEM`

Parameter	Type	Description
`filename`	`string`	The system file to open.
`forceQuit`	`bool`	If `true`, quit modified diagrams. If `false` and modified diagram(s) exist(s), the service is denied.

Service Reply

`SEOPENREPLY`

Parameter	Type	Description
`status`	`integer`	Service reply status.
`toolType`	`integer`	The type of tool. If the requested PId is not found, `toolType` 0 is returned.

Errors

```
Service request denied. No license available
Cannot open, system modified
Error opening system A message box displays the
error
```

Save System

Description

Corresponds to the Organizer menu command *Save*. Unconnected diagrams are saved in default file names; for more information, see "Save in file" on page 63 in chapter 2, *The Organizer*.

Tools Supporting the Service

`SET_ORGANIZER`

Service Request

`SESAVEALL`

Parameter	Type	Description
`systemStructureOnly`	`bool`	True, both the system files and diagram files are saved; False, only diagram files are saved.

Service Reply

`SESAVEALLREPLY`

Parameter	Type	Description
`status`	`integer`	Service reply status.

Errors

```
Service request denied. No license available
Error save all A message box displays the error
```

Add Existing

Description

Adds an existing document to the Organizer and optionally displays it in an editor. The type of document to be added and its corresponding editor depends on the extension of the given filename. This is the same mechanism as in the GUI-based equivalent. Corresponds to the Organizer menu choice *Add Existing*.

Tools Supporting the Service

`SET_ORGANIZER`

Service Request

`SEADDEXISTING`

Parameter	Type	Description
`filename`	`string`	The document to add in the Organizer.
`selected Filename`	`string`	If there is a document connected to this file in the Organizer, the document will be selected before the *Add Existing* operation. In this case, the added document will be inserted before the selected document. An empty string means no selection.
`start Editor`	`bool`	If *true*, the added document will be popped up in an editor.
`expand Substructure`	`bool`	If *true*, the substructure diagrams to the added SDL diagram are added as well.

Service Reply

`SEADDEXISTINGREPLY`

Parameter	Type	Description
`status`	`integer`	Service reply status.
`ok`	`bool`	Returns *true* if the operation could be performed.

Errors

-

Link File Services

Add Local Link File

Description

Prepares a personal link file for a user. Any changes in endpoint and link information after this service is called are saved into this file. The master link file can be read only for the user at this time.

Tools Supporting the Service

SET_ORGANIZER

Service Request

SEADDLOCALLINKFILE

Parameter	Type	Description
filename	string	File name.

Service Reply

SEADDLOCALLINKFILEREPLY

Parameter	Type	Description
status	integer	Service reply status.

Errors

-

Merge Local Link File

Description

Merges the changes saved into the personal link file into the master link file. After a successful merge, the local link file information is cleared.

Tools Supporting the Service

SET_ORGANIZER

Service Request

SEMERGELOCALLINKFILE

Parameter	Type	Description
-	-	N/A.

Service Reply

SEMERGELOCALLINKFILEREPLY

Parameter	Type	Description
status	integer	Service reply status.

Errors

-

TTCN Suite Services

Convert to GR

Description

Converts a MP file to TTCN-GR. One document file is generated in the specified destination directory. The document filename is generated by the TTCN Suite. The name of the destination directory is given. The parameter *ignore page number* indicates that any included page numbers in the MP file will be ignored.

The generated names are displayed in the Organizer log. For more information, see "Importing a TTCN-MP Document" on page 1157 in chapter 24, *The TTCN Browser (on UNIX)*.

Tools Supporting the Service

`IET_BASE`

Service Request

`IEBXCONVERTTOGR`

Parameter	Type	Description
`filename`	`QString`	The name of the MP file
`destination`	`QString`	The name of the destination directory
`ignore page number`	`bool`	Ignoring the included page numbers

Service Reply

`IEBXCONVERTTOGRREPLY`

Parameter	Type	Description
`status`	`integer`	Service reply status
`itexfile`	`QString`	The filename of the generated document.

Errors

```
The MP file does not exist
Illegal MP file
The file has no read permission
Unable to generate document files in the destination
```

Load Document

Description

Given a source file path this function load the document. Then this document may be shown in the TTCN Browser using "Show" service. The source file may have MP format or TTCN GR format.

Note

Available on Windows only.

Tools Supporting the Service

`IET_BASE`

Service Request

`SELOAD`

Parameter	Type	Description
`filename`	`QString`	The filename

Service Reply

SELOADREPLY

Parameter	Type	Description
`status`	`integer`	Service reply status (zero if the operation does not fail).
`buffid`	`integer`	The document's buffer identifier

Errors

```
No such file or directory
Syntax error
```

Show Document

Description

Show the given document in the TTCN Browser.

Tools Supporting the Service

IET_BASE

Service Request

SESHOW

Parameter	Type	Description
buffid	integer	The document's buffer identifier

Service Reply

SESHOWREPLY

Parameter	Type	Description
status	integer	Service reply status (zero if the operation does not fail).

Errors

Invalid buffer identifier

Opened Documents

Description

Retrieves information about open documents known to TTCN Suite. The EBNF follows:

```
DocInfoList ::= empty | DocInfoList '<NewLine>'
                DocInfo
DocInfo     ::= documentidentifier ':' buffid ':'
                itexfile ':' backupfile
```

Tools Supporting the Service

IET_BASE

Service Request

IEBXOPENEDDOCUMENTS

Service Reply

IEBXOPENEDDOCUMENTSREPLY

Parameter	Type	Description
`status`	`integer`	Service reply status (zero if the operation does not fail).
`infolist`	`EBNF`	The list of open documents identifiers, buffer identifiers and database file.

Errors

-

Fetch Buffer Identifier Given the Database

Description

Given a database, this function fetches the document buffer identifier if the document is open.

Tools Supporting the Service

IET_BASE

Service Request

IEBXGETBUFFIDFROMPATH

Parameter	Type	Description
itexfile	QString	The database path in the local system syntax.

Service Reply

IEBXGETBUFFIDFROMPATHREPLY

Parameter	Type	Description
status	integer	Service reply status (zero if the operation does not fail).
buffid	integer	The document's buffer identifier

Errors

Unable to find database

Fetch Buffer Identifier Given MP File Path

Description

Given a MP file path this function fetches the document buffer identifier if there is any database generated from this MP and the document in the database is open.

Tools Supporting the Service

IET_BASE

Service Request

IEBXGETBUFFIDFROMMPPATH

Parameter	Type	Description
mpfile	QString	The MP file path in the local system syntax.

Service Reply

IEBXGETBUFFIDFROMMPPATHREPLY

Parameter	Type	Description
status	integer	Service reply status (zero if the operation does not fail).
buffid	integer	The document's buffer identifier

Errors

Unable to find database

Convert to MP

Description

Generates a MP file for the given system node. This converts the entire document source (all TTCN objects) and does not consider the selection. The document must be connected but not necessarily open.

For more information, see "Exporting a TTCN Document to TTCN-MP" on page 1152 in chapter 24, *The TTCN Browser (on UNIX)*.

Tools Supporting the Service

```
IET_BASE
```

Service Request

```
IEBXCONVERTTOMP
```

Parameter	Type	Description
buffid	integer	The document's buffer identifier
standard flag	bool	Indicates if the MP shall be TTCN standard. (True if standard MP is required.)
filename	QString	The MP filename

Service Reply

```
IEBXCONVERTTOMPREPLY
```

Parameter	Type	Description
status	integer	Service reply status

Errors

```
Invalid buffer identifier
The document is not connected
Unable to write file
```

Convert Selection to MP

Description

Generates a MP file for the given system node. It converts only the selected parts of the document which means that the document needs both to be connected and open.

For more information, see "Exporting a TTCN Document to TTCN-MP" on page 1152 in chapter 24, *The TTCN Browser (on UNIX)*.

Tools Supporting the Service

`IET_BASE`

Service Request

`IEBXCONVERTSELTOMP`

Parameter	Type	Description
`buffid`	`integer`	The document's buffer identifier
`standard flag`	`bool`	Indicates if the MP shall be TTCN standard. (True if standard MP is required.)
`filename`	`QString`	The MP filename

Service Reply

`IEBXCONVERTSELTOMPREPLY`

Parameter	Type	Description
`status`	`integer`	Service reply status

Errors

```
Invalid buffer identifier
The document is not connected
The document is not open
Unable to write file
```

Merge Document

Description

This function is used to merge one document into another document. Both the source and the destination documents must be available to the TTCN Suite environment, i.e. both documents must be loaded. Furthermore a selection must exists in the source document.

For more information, see "Merging TTCN Documents" on page 1144 in chapter 24, *The TTCN Browser (on UNIX)*.

Tools Supporting the Service

IET_BASE

Service Request

IEBXMERGEDOCUMENT

Parameter	Type	Description
srcbuffid	integer	The source document's buffer identifier
destbuffid	integer	The destination document's buffer identifier

Service Reply

IEBXMERGEDOCUMENTREPLY

Parameter	Type	Description
status	integer	Service reply status (zero if the operation does not fail).

Errors

Unable to merge documents

Analyze Document

Description

Analyze the given system node.

For more information, see chapter 26, *Analyzing TTCN Documents (on UNIX)*, or chapter 31, *Analyzing TTCN Documents (in Windows)*.

Tools Supporting the Service

IET_BASE

Service Request

IEBXANALYZE

Parameter	Type	Description
buffid	integer	The document's buffer identifier
forced analysis	bool	Set if forced analysis should be in effect
verbose	bool	Indicates if verbose mode is to be on
errorlimit	integer	Max number of errors before aborting

Service Reply

IEBXANALYZEREPLY

Parameter	Type	Description
status	integer	Service reply status

Errors

Invalid buffer identifier
The document is not connected

Close Document

Description

This function closes the document and all open tables in it.

Tools Supporting the Service

IET_BASE

Service Request

IEBXCLOSEDOCUMENT

Parameter	Type	Description
buffid	integer	The document's buffer identifier

Service Reply

IEBXCLOSEDOCUMENTREPLY

Parameter	Type	Description
status	integer	Service reply status (zero if the operation does not fail).

Errors

Invalid buffer identifier
Unable to close document

Save Document

Description

Given the buffer identifier of the document the corresponding system node is saved in the given filename.

Tools Supporting the Service

IET_BASE

Service Request

IEBXSAVE

Parameter	Type	Description
buffid	integer	The document reference
filename	QString	The filename where the document source must be saved.

Service Reply

IEBXSAVEREPLY

Parameter	Type	Description
status	integer	Service reply status.

Errors

```
No such tool
Invalid buffer identifier
Couldn't write file
```

Selector

Description

Given restrictions and a database this function selects all objects which fulfill the restrictions. For more information, see "Using More Complex Selections" on page 1124 in chapter 24, *The TTCN Browser (on UNIX)*.

Note

Available on UNIX only.

Tools Supporting the Service

`IET_BASE`

Service Request

`IEBXSELECTOR`

Parameter	Type	Description
`buffid`	`integer`	The document's buffer identifier
`namerestr`	`string`	The name restriction.
`typerestr`	`string`	The content restriction.
`contentrestr`	`string`	The type restriction.
`selectormode`	`string`	The selector mode (restrict, extend or replace REL where REL is references, references_recursive or referenced_by)
`analysestatus`	`string`	The analysis status (not_analyzed, error_analyzed or ok_analyzed)

Service Reply

`IEBXSELECTORREPLY`

Parameter	Type	Description
`status`	`integer`	Service reply status (zero if the operation does not fail).

Errors

`No such tool`

```
Invalid buffer identifier
```

SelectAll

Description

Select all objects in the document.

Tools Supporting the Service

```
IET_BASE
```

Service Request

```
IEBXSELECTALL
```

Parameter	Type	Description
buffid	integer	The document's buffer identifier

Service Reply

```
IEBXSELECTALLREPLY
```

Parameter	Type	Description
status	integer	Service reply status (zero if the operation does not fail).

Errors

```
Invalid buffer identifier
```

DeselectAll

Description

Remove all selections in the document.

Tools Supporting the Service

IET_BASE

Service Request

IEBXDESELECTALL

Parameter	Type	Description
buffid	integer	The document's buffer identifier

Service Reply

IEBXDESELECTALLREPLY

Parameter	Type	Description
status	integer	Service reply status (zero if the operation does not fail).

Errors

Invalid buffer identifier

IsSelected

Description

This function checks if there is any object selected in the document.

Tools Supporting the Service

IET_BASE

Service Request

IEBXISSELECTED

Parameter	Type	Description
buffid	integer	The document's buffer identifier

Service Reply

IEBXISSELECTEDREPLY

Parameter	Type	Description
status	integer	Service reply status (zero if the operation does not fail).
selectstate	bool	Indicates if there is any selected objects in the document.

Errors

Invalid buffer identifier

Get Modify Time

Description

This function fetches the modify time of a document.

Tools Supporting the Service

IET_BASE

Service Request

IEBXGETDOCUMENTMODIFYTIME

Parameter	Type	Description
buffid	integer	The document's buffer identifier

Service Reply

IEBXGETDOCUMENTMODIFYTIMEREPLY

Parameter	Type	Description
status	integer	Service reply status (zero if the operation does not fail).
modifytime	QString	The modify time of the document.

Errors

Invalid buffer identifier

Get Path

Description

Given a document buffer identifier this function fetches the corresponding database path.

Tools Supporting the Service

IET_BASE

Service Request

IEBXGETPATH

Parameter	Type	Description
buffid	integer	The document's buffer identifier

Service Reply

IEBXGETPATHREPLY

Parameter	Type	Description
status	integer	Service reply status (zero if the operation does not fail).
itexfile	QString	The database path in the local system syntax.

Errors

Invalid buffer identifier

Get MP Path

Description

Given a document bufferid this function fetches the corresponding MP file path.

Tools Supporting the Service

IET_BASE

Service Request

IEBXGETMPPATH

Parameter	Type	Description
buffid	integer	The document's buffer identifier

Service Reply

IEBXGETMPPATHREPLY

Parameter	Type	Description
status	integer	Service reply status (zero if the operation does not fail).
mpfile	QString	The MP file path in the local system syntax.

Errors

Invalid buffer identifier

Find Table

Description

Given the buffer identifier of the selected document and a table identifier, TTCN Suite searches for the table. The found table is displayed in the Table Editor.

Tools Supporting the Service

IET_BASE

Service Request

IEBXFINDTABLE

Parameter	Type	Description
buffid	integer	The document's buffer identifier
tableid	QString	The name of the table to find

Service Reply

IEBXFINDTABLEREPLY

Parameter	Type	Description
status	integer	Service reply status

Errors

Invalid buffer identifier
Unconnected document

Close Table

Description

Close the given table.

Tools Supporting the Service

IET_BASE

Service Request

IEBXCLOSETABLE

Parameter	Type	Description
buffid	integer	The document's buffer identifier
tableident	QString	The table identifier.

Service Reply

IEBXCLOSETABLEREPLY

Parameter	Type	Description
status	integer	Service reply status (zero if the operation does not fail).

Errors

```
Invalid buffer identifier
No such object
```

Get Table State

Description

This function returns the status of a given table. The status a table indicates if the table is open or close.

Tools Supporting the Service

IET_BASE

Service Request

IEBXGETTABLESTATE

Parameter	Type	Description
buffid	integer	The document's buffer identifier
tableident	QString	The table identifier.

Service Reply

IEBXGETTABLESTATEREPLY

Parameter	Type	Description
status	integer	Service reply status (zero if the operation does not fail).
tablestate	QString	Returns open, close, row_in_open or row_in_close.

Errors

Invalid buffer identifier
No such object

Get Row Number

Description

Given the name of a row this function returns the number (position) of it in the table. The row can be a row in a single or multiple table.

Tools Supporting the Service

IET_BASE

Service Request

IEBXGETROWNUMBER

Parameter	Type	Description
buffid	integer	The document's buffer identifier
tableident	QString	The table identifier.
rowname	identifier	The name of the row.

Service Reply

IEBXGETROWNUMBERREPLY

Parameter	Type	Description
status	integer	Service reply status (zero if the operation does not fail).
rownumber	integer	The number of the given row. The first row has number one.

Errors

```
Invalid buffer identifier
No such object
No such row
```

Select Row

Description

This function modifies the selection status of a given row in a table.

Tools Supporting the Service

IET_BASE

Service Request

IEBXSELECTROW

Parameter	Type	Description
buffid	integer	The document's buffer identifier
tableident	QString	The table identifier.
rownumber	integer	The number of the row.
selectstate	bool	The select status of the row to be modified.

Service Reply

IEBXSELECTROWREPLY

Parameter	Type	Description
status	integer	Service reply status (zero if the operation does not fail).
exist	bool	Returns false if the message was inserted, true if it already existed.

Errors

```
Invalid buffer identifier
No such object
No such rownumber
```

Clear Selection

Description

This function removes all row selections in a table.

Tools Supporting the Service

IET_BASE

Service Request

IEBXCLEARSELECTION

Parameter	Type	Description
buffid	integer	The document's buffer identifier
tableident	QString	The table identifier.

Service Reply

IEBXCLEARSELECTIONREPLY

Parameter	Type	Description
status	integer	Service reply status (zero if the operation does not fail).

Errors

Invalid buffer identifier
No such object

Rows Selected

Description

Given the buffer identifier and the table identifier, this function returns the numbers of the selected rows in a table (the first row has number 1).

Tools Supporting the Service

IET_BASE

Service Request

IEBXROWSSELECTED

Parameter	Type	Description
buffid	integer	The document's buffer identifier
tableident	QString	The table identifier.

Service Reply

IEBXROWSSELECTEDREPLY

Parameter	Type	Description
status	integer	Service reply status (zero if the operation does not fail).
nonezero*	integer	A list of selected row numbers. The list is empty if no row is selected.

Errors

Invalid buffer identifier
No such object

Menu Manipulation Services

Introduction

All graphical tools in the SDL Suite support customizable menus. These user-defined menus will be appended to the menu bar of the tool. The exact location will be defined by the tool, depending on the abilities of the graphical framework the tool is built upon.

The intention is to have an external tool to configure a tool in order to provide the necessary UI. SDL Suite and TTCN Suite could also take advantage of these extendable menus.

The following operations are available through a set of well defined PostMaster messages:

- Creating a menu
- Creating a menu choice
- Deleting a menu

Each menu choice can be associated to any of the following:

- A PostMaster message
- An operating system command

Add Menu

Description

Adds a new menu to the menu bar.

Tools Supporting the Service

SET_ORGANIZER
SET_SDLE
SET_MSCE
SET_OME
SET_TE

Errors

-

1. **In Windows**, the SDL Simulator/Explorer UI's can **not** read menu-definition files.

Add Item to Menu

Description

Adds a menu choice to the specified menu. The menu choice could either perform an OS command or issue a PostMaster notification when selected. The OS command to perform or the message to broadcast could be sensitive on a selected symbol.

The description of the service parameters below is generic to all tools supporting the service. Some tools have special interpretations of some parameters. Some tools also allow *format codes* to be used in the command string or as message parameter, providing additional context sensitive information. Both these tool-specific issues are described separately in the following sections:

- "Add Item to Menu – Organizer" on page 588
- "Add Item to Menu – Text Editor" on page 592
- "Add Item to Menu – Graphical Editors" on page 593

SET_HELPVIEWER
```

1. **In Windows**, the SDL Simulator/Explorer UI's can **not** read menu-definition files.

Service Request

SEMENUADDITEM

Parameter	Type	Description
menuName	string	The menu in which an item should be added.
menuItem	string	Name of menu item to add.
separator	bool	If a separator should precede the item.
statusText	string	The status text to show when the menu item is selected.
notUsed1 lastAction ProprietaryKey (tool-specific)	integer	The interpretation of this parameter is tool-specific; see the separate tool descriptions later. If not used, this parameter should be set to 0.
notUsed2 AttributeKey (tool-specific)	integer	The interpretation of this parameter is tool-specific; see the separate tool descriptions later. If not used, this parameter should be set to 0.
scope	integer	Indicates when the menu item should be dimmed. The possible values are tool-specific; see the separate tool descriptions later. If not used, this parameter should be set to:
		ALWAYS (0) The menu choice will always be available, independently of the selection in the tool's active window.

Parameter	Type	Description
`confirmText`	`string`	If no text is provided, no confirmation is assumed. A non-empty text denotes confirmation; a two button dialog will be issued with the choices *OK* and *Cancel*. The dialog text is defined in `confirmText`. In an associated user editable field, the expanded action to perform is displayed.
`actionType`	`integer`	The value controls the last part of the message which is variant. 0 = PostMaster message 1 = OS command.

- If `actionType` above sets the variant part to be a **PostMaster message**, the last two parameters are:

Parameter	Type	Description
`message`	`integer`	Interpreted as the PostMaster message to send.
`params`	`string`	Interpreted as the parameters to the PostMaster message. Tool-specific context sensitive format codes are evaluated; see the separate tool descriptions later.

- If `actionType` above sets the variant part to be an **OS command**, the last two parameters are:

Parameter	Type	Description
`OSblock`	`bool`	Whether to wait for the command to finish before giving control to the user.

Parameter	Type	Description
OScommand	string	The OS command to perform. Tool-specific context sensitive format codes are evaluated; see the separate tool descriptions later.

`SEMENUADDITEM`

Format Codes

The following format codes are recognized. There are format modifiers for some of the basic formats:

- B – the base filename
- D – the directory part of the full filename
- R – the filename, relative to the *source directory*

Format code	Description
`%b` `%Bb,` `%Db` `%Rb`	The file name of the system file associated to the Organizer window.
`%f` `%Bf` `%Df` `%Rf`	The name of the file that contains the selected object.
`%F` `%BF` `%DF` `%RF`	All files in the substructure of the selected object (including the selected object).
`%l` `%Bl` `%Dl` `%Rl`	The name of the link file loaded in the Organizer.
`%o` `%Bo` `%Do` `%Ro`	The name of the Control Unit file for the selected object.

Format code	Description
%r	Perform the command recursively on all files in the substructure of the selected object (including the selected object).
%u	The source directory.
%v	The target directory.

Parameters

Apart from providing a set of format codes, the Organizer gives special interpretation to the lastAction and scope parameters.

Parameter	Type	Description
lastAction	integer	Controls what happens when a dynamic menu command has been performed. Only available when actionType is OS Command. This attribute should be one of the following:
		NOTHING (0) Perform no action.
		CHECK_FILE (1) A check file operation is performed on the selected object when the OS command is completed. If the OS command is non-blocking, the command is performed as soon as the OS command has been issued.
		CHECK_FILE_ON_RECURSIVE (2) This flag works as the CHECK_FILE flag but is used only with a %r command.

Parameter	Type	Description
		`CM_UPDATE (4)` Perform a CM_UPDATE operation on the closest *.scu file.
		`SHOW_LOG (8)` Show the Organizer Log window (where textual output from the OS command is presented).

Parameter	Type	Description
scope	integer	This attribute could be one of the following:
		ALWAYS (0) The menu choice will always be available, independently of the selection in the tool's active window.
		ONE_SELECTED_OBJECT (1) The menu choice is available if one object is selected.
		SELECTED_OBJECT_NOT_IN_EDITOR (4) The menu choice is available if one object is selected and the selected object is not loaded in an editor.
		VALID_SELECTED_OBJECT (5) The menu choice is available if one object is selected and the object is not marked invalid.
		SELECTED_GROUP_NOT_IN_EDITOR (6) The menu choice is available if one object is selected and **no diagram** of the document group for the selected object is loaded in an editor.

Add Item to Menu – Text Editor

Description

Identical to the description of *Add Item to Menu*, except that the semantics of the parameters and supported format codes for the service differ.

Tools Supporting the Service

```
SET_TE
```

Service Request

```
SEMENUADDITEM
```

Format Codes

The following format codes are recognized.

Format code	Description
`%f`	The filename of the document.
`%u`	The source directory
`%s`	The selected text
`%S`	The entire text of the document.

Add Item to Menu – Graphical Editors

Description

Identical to the description of *Add Item to Menu*, except that the semantic of the parameters and supported format codes for the service differ.

Tools Supporting the Service

```
SET_SDLE
SET_MSCE
SET_OME
```

Service Request

```
SEMENUADDITEM
```

Format Codes

The following format codes are recognized.

Format code	Description
`%a`	The absolute name of the file associated with the selected object. Extracted from the SDT reference.
`%b`	The absolute name of the file associated to the window.
`%c`	If the selected object uses extended data, the `comment` is extracted.
`%d`	If the selected object uses extended data, the data part is extracted.
`%e`	The text in the object. (Only in the SDL Editor.)
`%f`	The name of the file that contains the object.
`%g`	The SDT reference to the object.
`%p`	The page name currently shown in the window (not applicable to the MSC Editor).
`%s`	The name of the file shown in the window.
`%t`	The page name for the object (not applicable to the MSC Editor). Extracted from the SDT reference.

Parameters

Apart from providing a set of format codes, the graphical editors give special interpretation to the `lastAction`, `ProprietaryKey` and `AttributeKey` parameters.

Parameter	Type	Description
`ProprietaryKey`	`integer`	The keys `ProprietaryKey` and `AttributeKey` are used to determine whether or not a menu choice should be available (i.e. dimmed or not). See "Editor – Object Services" on page 610 for more information.
`AttributeKey`	`integer`	See description of `ProprietaryKey`.

Parameter	Type	Description
scope	integer	This attribute should be one of the following:
		ALWAYS (0) The menu choice will always be available, independently of the selection in the tool's active window. The keys ProprietaryKey and AttributeKey are handled as don't care.
		ONE_SELECTED_OBJECT[a] (1) The menu choice is available only if exactly one object is selected. The keys ProprietaryKey and AttributeKey are handled as don't care.
		MATCHING_KEYS (2) The menu choice is available only if at least one of the selected objects has an attribute that matches the keys above.
		MATCHING_KEYS_ONE_SELECTED_OBJECT (3)[a.] The menu choice is available only if exactly one object is selected and it has an attribute that matches the keys above.

a. Each tool should define and adopt conventions for when exactly one object only is considered as selected. For instance, selecting a task symbol in an SDL Editor also selects the from and to lines. However, attaching information to these lines does not fill any meaningful purpose; the SDL Editor considers the situation as if one object only (i.e. the task symbol) was selected.

Logging Services

Start MSC Log

Description

Starts the logging of messages sent by tools connected to the PostMaster. The format used by the log is event-oriented MSC/PR.

Tools Supporting the Service

SET_POST

Service Request

SESTARTTRACE

Parameter	Type	Description
filename	string	The name of the file on which the log should be stored. If the parameter is omitted, the default log file post.mpr will be used. If the parameter is set to "-e", logging is done on standard error.
logMode	integer	If not set, only public messages are logged. If set to a value > 2 all messages are logged.

Service Reply

SESTARTTRACEREPLY

Parameter	Type	Description
status	integer	Service reply status.

Errors

-

Stop MSC Log

Description

Stops the logging of messages sent by PostMaster tools.

Tools Supporting the Service

SET_POST

Service Request

SESTOPTRACE

Parameter	Type	Description
-	-	N/A.

Service Reply

SESTOPTRACEREPLY

Parameter	Type	Description
status	integer	Service reply status.

Errors

-

SDT Reference Services

Show Source

Description

Selects the SDT reference in an editor. A reference could be:

- An SDL reference.

  The reference is shown in an SDL Editor.

- An MSC reference.

  The reference is shown in an MSC Editor.

- An OM reference.

  The reference is shown in an OM Editor.

- A text reference

  The reference is shown in a text editor. The text editor is chosen by the preference SDT*TextEditor.

For a complete description of the format of an SDT reference, please see chapter 18, *SDT References*.

Tools Supporting the Service

`SET_ORGANIZER`

Service Request

`SESHOWREF`

Parameter	Type	Description
`SDTRef`	`string`	A valid SDT reference.

Service Reply

`SESHOWREFREPLY`

Parameter	Type	Description
`status`	`integer`	Service reply status.

Errors

`SDT Reference Errors`

Emitted Notifications

Notification	Description
SELOADNOTIFY	If any editor loaded the required diagram.
SESDLELOADNOTIFY	If the SDL Editor loaded the required diagram.
SEOMELOADNOTIFY	If the OM editor loaded the required diagram.
SESTARTNOTIFY	If the editor was started.

Obtain GR Reference

Description

Returns the SDT references for the current selection(s) in the editors.

Tools Supporting the Service

SET_SDLE
SET_MSCE
SET_OME

Service Request

SEOBTAINGRREF

Parameter	Type	Description
-	-	N/A

Service Reply

SEOBTAINGRREFREPLY

Parameter	Type	Description
status	integer	Service reply status.
NoOfRef	integer	The number of references found.
ref*	string	A complete SDT reference.

Errors

SDT Reference Errors
Illegal use of qualifier
Illegal reference type

Editor – Diagram Services

The Buffer Concept

The editor defines the concept buffer, which basically identifies a diagram currently loaded in the editor. Each buffer is identified with a *buffer id* which is unique within one session of the editor as long as the editor is not stopped)

A buffer id is returned when an existing diagram is successfully loaded in an editor or a new diagram is created and implicitly loaded in the editor. Then, most services manipulating diagrams in editors, refer to the buffer containing the diagram via the buffer id.

Load Diagram

Description

Loads a diagram or text document specified by filename in an editor buffer. If the diagram was already loaded, the existing buffer id will be returned.

Tools Supporting the Service

SET_SDLE
SET_MSCE
SET_OME
SET_TE

Service Request

SELOAD

Parameter	Type	Description
filename	string	The diagram file to load specified with the full directory path.

Service Reply

SELOADREPLY

Parameter	Type	Description
status	integer	Service reply status.
bufId	integer	Refers to an allocated buffer in the editor.
type	integer	The type of diagram.
name	string	The name of the loaded diagram.

Errors

Can not read file <filename> <error message>
SDLE is busy, syntax error in text *(SDLE only)*

Emitted Notifications

Notification	Description
SELOADNOTIFY	If the diagram was loaded.
SESDLELOADNOTIFY	If an SDL diagram was loaded.
SEOMELOADNOTIFY	If an OM, SC or HMSC diagram was loaded.

Unload Diagram

Description

Unloads a diagram from an editor.

Tools Supporting the Service

SET_SDLE
SET_MSCE
SET_OME
SET_TE

Service Request

SEUNLOAD

Parameter	Type	Description
bufId	integer	Refers to a buffer in the editor.
forceUnload	bool	If true, the editor will force a modified diagram to be unloaded. If false, the editor will not unload the diagram if it is modified.

Service Reply

SEUNLOADREPLY

Parameter	Type	Description
status	integer	Service reply status.

Errors

Invalid diagram buffer id
Diagram is changed *If force Unload is false*
SDLE is busy, syntax error in text *(SDLE only)*

Emitted Notifications

Notification	Description
SEUNLOADNOTIFY	If the diagram was unloaded.

Show Diagram

Description

The service will raise a window in the editor showing the specified buffer.

Tools Supporting the Service

```
SET_SDLE
SET_MSCE
SET_OME
SET_TE
```

Service Request

```
SESHOW
```

Parameter	Type	Description
bufId	integer	Refers to a buffer in the editor.
pageName	string	Name of the page to show. If the string is empty, the last recently used, or if no such page exist, the default page will be shown. Applicable all diagrams except MSC and text documents. For MSC diagrams this parameter may be omitted or left empty. For text document (loaded in the TE), this option is ignored.

Service Reply

```
SESHOWREPLY
```

Parameter	Type	Description
status	integer	Service reply status.

Errors

```
Invalid diagram buffer id
Unable to open page   (SDLE/OME only)
SDLE is busy, syntax error in text   (SDLE only)
```

Emitted Notifications

Notification	Description
SESHOWNOTIFY	If the diagram was raised.

Save Diagram

Description

The service will save the diagram in the specified file. If not a valid filename or if there is no permission to save the file, an error will be returned. When saved, the editor buffer is marked as not edited.

Tools Supporting the Service

```
SET_SDLE
SET_MSCE
SET_OME
SET_TE
```

Service Request

```
SESAVE
```

Parameter	Type	Description
bufId	integer	Refers to a buffer in the editor.
filename	string	The file where to save the buffer.

Service Reply

```
SESAVEREPLY
```

Parameter	Type	Description
status	integer	Service reply status.
saveok	bool	Returns `true` if the buffer was successfully saved.

Errors

```
Invalid diagram buffer Id
Diagram is new. Filename is missing.
Cannot save file <filename> <error message>
SDLE is busy, syntax error in text    (SDLE only)
```

Emitted Notifications

Notification	Description
SESAVENOTIFY	If the diagram was saved.

Create SDL Diagram

Description

Creates an empty SDL diagram in a new buffer. The diagram gets an unconnected status. Corresponds to SDL Editor command *New*.

Tools Supporting the Service

`SET_SDLE`

Service Request

`SESDLECREATEDIAGRAM`

Parameter	Type	Description
`virtuality`	`integer`	Kind of virtuality. Only applicable to typed diagrams. Other diagrams should use the value `NOVIRTUAL` Possible values are: `NOVIRTUAL` `VIRTUAL` `REDEFINED` `FINALIZED` These values are defined in `sdtsym.h`
`DiagramType`	`integer`	Diagram type. See `sdtsym.h` for valid diagram types.
`name`	`string`	Diagram name.
`qualifier`	`string`	SDL qualifier. Could be empty.
`pageType`	`integer`	Type of the first page in the diagram. See `sdtsym.h` for valid page types. Note that the `pageType` must correspond with the `diagramType`.
`pageName`	`string`	Name of the first page in the diagram.

Service Reply

SESDLECREATEDIAGRAMREPLY

Parameter	Type	Description
status	integer	Service reply status.
bufId	integer	Refers to a buffer in the editor.

Errors

SDLE is busy, syntax error in text

Emitted Notifications

Notification	Description
SESDLECREATENOTIFY	As a result of creating the diagram.
SEPAGENOTIFY	As a result of creating a page.

Create MSC Diagram

Description

Creates an empty MSC diagram in new buffer. Corresponds to MSC Editor command *New*.

Tools Supporting the Service

SET_MSCE

Service Request

SEMSCECREATEDIAGRAM

Parameter	Type	Description
diagramType	integer	Diagram type. Defined in sdtsym.h. The value MSCDIAGRAM (16) should be used.
name	string	Name of the diagram to create.
qualifier	string	For future use. Should be empty.

Service Reply

SEMSCECREATEDIAGRAMREPLY

Parameter	Type	Description
status	integer	Service reply status.
bufId	integer	Refers to a buffer in the editor.

Errors

-

Emitted Notifications

Notification	Description
SEMSCENEWNOTIFY	As a result of creating the diagram.

Create OM Diagram

Description

Creates an empty OM diagram in new buffer. Corresponds to OM Editor command *New*.

Tools Supporting the Service

SET_OME

Service Request

SEOMECREATEDIAGRAM

Parameter	Type	Description
diagramType	integer	Diagram type. Defined in sdtsym.h. The value CLASSDIAGRAM (21) should be used.
name	string	Name of the diagram to create.
pageType	integer	Page type Defined in sdtsym.h. The value CLASSPAGE (16) should be used
pageName	string	name of the first page

Service Reply

SEOMECREATEDIAGRAMREPLY

Parameter	Type	Description
status	integer	Service reply status.
bufId	integer	Refers to a buffer in the editor.

Errors

-

Emitted Notifications

Notification	Description
SEOMENEWNOTIFY	As a result of creating the diagram.

Create Text Diagram

Description

Creates an empty text diagram in new buffer. Corresponds to Text Editor command *New*.

Tools Supporting the Service

SET_TE

Service Request

SETECREATEDIAGRAM

Parameter	Type	Description
diagramType	integer	Diagram type. See sdtsym.h for valid diagram types.
name	string	Name of the diagram to create.

Service Reply

SETECREATEREPLY

Parameter	Type	Description
status	integer	Service reply status.
bufId	integer	Refers to a buffer in the editor.

Errors

-

Emitted Notifications

Notification	Description
SETENEWNOTIFY	As a result of creating the diagram.

Editor – Object Services

Select Object

Description

The *Select Object* service will highlight an object in a diagram. Note that this command does not show the buffer and the selected object in a window. The difference between this service and the *Obtain GR Reference* service is that the *Select Object* service does not require the diagram to be saved on a file.

Tools Supporting the Service

```
SET_SDLE
SET_MSCE
SET_OME
```

Service Request

```
SESELECTOBJECT
```

Parameter	Type	Description
bufId	integer	Buffer referencing the diagram in which an object should be shown.
objectid	integer	Identifier to the object to show.
row	integer	The row where to put the text cursor.
column	integer	The column where to put the text cursor in the row.
keepSelections	bool	Flag indicating if old selections should be kept.

Service Reply

```
SESELECTOBJECTREPLY
```

Parameter	Type	Description
status	integer	Service reply status.

Errors

```
Invalid diagram buffer id
Invalid object id
SDLE is busy, syntax error in text    (SDLE only)
```

Show Object

Description

The *Show Object* service will make sure that the specified object is visible in a window. This means that it will display the buffer in a window and if necessary scroll into the position where the object is. Often used in combination with *Select Object*.

Tools Supporting the Service

```
SET_SDLE
SET_MSCE
SET_OME
```

Service Request

```
SESHOWOBJECT
```

Parameter	Type	Description
bufId	integer	Buffer referencing the diagram in which an object should be shown.
objectId	integer	Identifier to the object to show.

Service Reply

```
SESHOWOBJECTREPLY
```

Parameter	Type	Description
status	integer	Service reply status.

Errors

```
Invalid diagram buffer id
Invalid object id
SDLE is busy, syntax error in text    (SDLE only)
```

Insert SDL Object

Description

Adds an object to the SDL diagram.

Tools Supporting the Service

SET_SDLE

Service Request

SESDLEINSERTOBJECT

Parameter	Type	Description
bufId	integer	Buffer in which to insert the object.
pageName	string	Page to insert the object on.
shiftIsDown	bool	Emulate behavior of having <Shift> pressed when inserting an symbol.
objectType	integer	Type of object. Valid objects depend on the type of diagram and if syntax checking is on. Corresponds to available symbols in the editor symbol menu. **NOTE: SDL reference symbols are not possible to add using this service**. Definitions of symbols are found in sdtsym.h.
objectText	string	Text in object.

Service Reply

SESDLEINSERTOBJECTREPLY

Parameter	Type	Description
status	integer	Service reply status.

Errors

```
Invalid diagram buffer id
Invalid object id
A reference symbol containing text\
cannot be inserted in diagram <diagram>
Object type <objectType> is not allowed\
in diagram <diagram>
Unable to open page
The page is too small to insert the object
SDLE is busy, syntax error in text
```

Insert MSC Object

Description

The *Insert Object* service will create a new object in the diagram identified by the parameter and return an object identification (an integer) to the client. It will not display the new object.

For a full specification of how to specify the object to insert, the specification of Message Sequence Charts Z.120 should be consulted or the document “MSC Trace and Log Format 2.0 Specification” available from IBM Rational.

Tools Supporting the Service

`SET_MSCE`

Service Request

`SEINSERTOBJECT`

Parameter	Type	Description
`bufId`	`integer`	Buffer in which to insert the object.
`afterObject`	`integer`	Only object id 0 is allowed, and adds the object as the last object.
`objectDescription`	`string`	Description of the object to insert. The description should be in accordance with Z.120 using *event oriented* PR. Only one object at the time can be inserted.

Service Reply

`SEINSERTOBJECTREPLY`

Parameter	Type	Description
`status`	`integer`	Service reply status.
`objectId`	`integer`	Identifier to object.

Errors

`Invalid diagram buffer id`
`Errors from parsing objectDescription`

Remove Object

Description

The *Remove Object* service will delete an object in a diagram.

Tools Supporting the Service

SET_MSCE

Service Request

SEREMOVEOBJECT

Parameter	Type	Description
bufId	integer	Buffer referencing the diagram in which an object should be removed.
objectId	integer	The object to remove.

Service Reply

SEREMOVEOBJECTREPLY

Parameter	Type	Description
status	integer	Service reply status.

Errors

```
Invalid diagram buffer id
Invalid object id
Object can not be removed   (MSCE only)
```

Get Object Text

Description

The service will extract all texts for a given object.

Tools Supporting the Service

```
SET_SDLE
SET_MSCE
SET_OME
```

Service Request

```
SEGETOBJECTTEXT
```

Parameter	Type	Description
`bufid`	`string`	A buffer referencing the diagram where the object exists.
`objectId`	`integer`	Identifier to the object.

Service Reply

```
SEGETOBJECTTEXTREPLY
```

Parameter	Type	Description
`status`	`integer`	Service reply status.
`objectType`	`integer`	The type of the object. Definitions of possible object types are found in `sdtsym.h`.
`textnumber`	`integer`	The number of the text strings.
`texts`	`stringlist`	All the texts associated to the object.

Errors

```
Invalid diagram buffer id
No page found with this object id
No object with this id found
```

Editor – Object Attribute Services

Introduction

It is possible to extend the data associated to an object managed by the SDL Suite with the user's own data. How this is done is described in Figure 161.

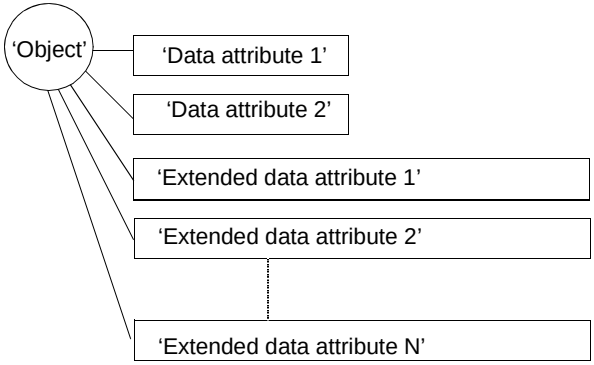

Figure 161: Extending the attributes associated to a symbol

The object can have any number of attributes associated to it, not necessarily 2 as illustrated. The number of extended data attributes is arbitrary.

An object is potentially any item that is handled as a source component by the SDL Suite, or any of the sub-components of which it consists. Objects are thus:

- SDL diagram
- MSC diagram
- OM, SC, HMSC diagram
- SDL Page
- OM, SC, HMSC page
- SDL symbol
- MSC symbol
- OM, SC, HMSC symbol

The purpose of the *extended data attribute* is:

- To allow the user to add his own-defined data to diagrams managed by the SDL Suite.

- In addition, data extensions can by connected to operations to be performed on that data. Operations are performed through PostMaster messages or Operating System commands.

Extended Data Attribute

An extended data attribute defines a number of fields. Below is a few of them further elaborated.

- `ProprietaryKey`

  Provides a means to tag extensions with the originating company / organization. Should normally be set to 0.

- `AttributeKey`

  Up to the user's preference when deciding how to use this key.

- `data_length`

  Provides information about how many bytes of data the `variant_data` union consists of. Generally, all elements of variable length need to have their length specified, since the user must be able to store hex 0 as data.

- `data_interpretation` and `data`

  In the SDL Suite, data is always interpreted as *raw data*. The SDL Suite have no knowledge about the format and meaning of the data. *Raw data* may consist of information produced by an external tool. Its format is not known by the SDL Suite. Thus, operation of any sort applied on that data, cannot be performed.

- `comment_length`

  How many bytes the comment consists of.

- `comment`

  Gives the possibility to attach a (preferable) readable comment in plain text. The comment could assist the user in understanding the meaning of data that he has attached to the object.

Display Key

Description

Request to display, i.e. select, all symbols referred by `SDTRef`, that have at least one associated attribute that matches the keys `ProprietaryKey` and `AttributeKey`.

- `AttributeKey` will be omitted if it has value 0
- If `ProprietaryKey` is 0 both keys will be omitted.

`SDTRef` is typically a diagram, but could also be a page or a specific symbol. The symbols that match the criteria will be marked as selected in the drawing area. Other symbols will be de-selected.

- If `SDTRef` is empty, display all symbols is all diagrams that are read by the tool, and that match the keys
- If `SDTRef` denotes a diagram, display all symbols in the diagram that match the keys
- If `SDTRef` denotes a page, display all symbols in the page that match the keys
- If `SDTRef` denotes a symbol, display the symbol if it matches the keys.

Tools Supporting the Service

SET_SDLE

Service Reply

SEDISPLAYKEYREPLY

Parameter	Type	Description
status	integer	Service reply status.

Errors

SDT Reference Errors

List Key

Description

Request to list all objects referred by SDTRef, that have at least one associated attribute that matches the keys ProprietaryKey and AttributeKey.

- AttributeKey will be omitted if it has value 0.
- If ProprietaryKey is 0 both keys will be omitted.

SDTRef is typically a diagram, but could also be a page or a specific symbol. The response is a count and a list of SDTRef to all objects that match the keys.

- If SDTRef is NULL, list all symbols is all diagrams that are read by the tool, and that match the keys.
- If SDTRef denotes a diagram, return SDTRef to all objects in the diagram that match the keys.
- If SDTRef denotes a page, return SDTRef to objects in the page that match the keys.
- If SDTRef denotes an object, return the SDTRef to the object if it matches the keys.

Load Definition File

Description

Loads a file containing external signal definitions into the Information Server. The contents of such a file are then made available via the *Signal Dictionary* functionality found in the SDL Editor.

The Information Server could read any ASCII file, but for efficient usage, the format of the files should contain one signal definition per line.

Tools Supporting the Service

`SET_INFOSERVER`

Service Request

`SELOADDEFINITIONMAP`

Parameter	Type	Description
`fileName`	`string`	Name of the file to load.
`tag`	`integer`	Is used to either add or remove a file. 0 = Add definition 1 = Remove definition.

Service Reply

`SELOADDEFINITIONMAPREPLY`

Parameter	Type	Description
`status`	`integer`	Service reply status.

Errors

```
File already added
File was not added before
```

SDL Editor Services

GRPR

Description

Generate PR for a given binary file. Optionally, GR references and CIF comments could be generated.

If the file is already being edited the PR generated will be from the internal version in the SDL Editor and not from the data in the file.

If the diagram is not being edited it will be unloaded after the PR generation.

Tools Supporting the Service

`SET_SDLE`

Service Request

`SEGRPRP`

Parameter	Type	Description
`fileName`	`string`	The file where the SDL/GR is stored.
`fileName`	`string`	The file where the PR is written
`append`	`bool`	If *true*, the PR will be appended to the file.
`generateGRRef`	`bool`	If *true*, the generated PR will also contain graphical references, that are used in the Analyzer to backtrace errors.
`generateCIF`	`bool`	If *true*, the PR will also contain CIF comments.

Service Reply

`SEGRPRREPLY`

Parameter	Type	Description
`status`	`integer`	Service reply status.

Errors

```
Invalid file name
SDLE is busy, syntax error in text    (SDLE only)
```

Tidy Up

Description

The *Tidy Up* service will perform a tidy up on a specified diagram. The functionality is identical to the *Tidy Up* command available in the SDL Editor.

Tools Supporting the Service

SET_SDLE

Service Request

SETIDYUP

Parameter	Type	Description
bufid	integer	Buffer referencing the diagram to tidy up.

Service Reply

SETIDYUPREPLY

Parameter	Type	Description
status	integer	Service reply status.

Errors

Invalid diagram buffer id

SC Editor Services

Get Diagram Info

Description

Get information about the symbols and lines of a SC diagram. The format of the returned *infoList* is:

```
Symbols: <noOfSymbols>
<type> <id> <superstateId> <noOfTexts> <text1> ...
...
Lines: <noOfLines>
<type> <fromSymbolId> <toSymbolId> <noOfTexts> <text1> ...
...

Where:
<type> ::=      An integer denoting the type of symbol or line
                Types can be found in sdtsym.h
<id> ::=        An integer identifying a symbol
```

Invalid diagram type

MSC Editor Services

MSC GRPR

Description

Generate PR for a given MSC binary file. Optionally, GR references can be generated.

If the file is already being edited, the generated PR will be from the internal version in the MSC Editor and not from the data in the file.

If the diagram is not being edited it will be unloaded after the PR generation.

Tools Supporting the Service

SET_MSCE

Service Request

SEMSCGRPR

Parameter	Type	Description
fileName	string	The file where the MSC/GR is stored.
fileName	string	The file where the PR is written.
mscDocName	string	The name of the MSC document. If empty the PR will be appended to PR file.
generateGRRef	bool	If *true*, the generated PR will also contain graphical references, that are used in the Analyzer to backtrace errors.

Service Reply

SEMSCGRPRREPLY

Parameter	Type	Description
errors	integer	Number of errors in the GR file.
warnings	integer	Number of warnings in the GR file.
errorLog	string	Description of errors and warnings, with GR references.

MSC Generate cui script

Description

Generate cui script for a given MSC diagram.

If the file is already being edited, the generated script will be from the internal version in the MSC Editor and not from the data in the file.

If the diagram is not being edited it will be unloaded after the script generation.

The input script will be generated as a .cui file with the same name as the input MSC diagram. The .cui file will be located in the same directory as your input MSC.

Tools Supporting the Service

`SET_MSCE`

Service Request

`SEGENERATEINPUTSCRIPT`

Parameter	Type	Description
`fileName`	`string`	The file where the MSC/GR is stored.

Parameter	Type	Description
fileName	string	The file where the HMSC/GR is stored.
fileName	string	The file where the PR is written.
mscDocName	string	The name of the HMSC document. If empty the PR will be appended to PR file.
generateGRRef	bool	If *true*, the generated PR will also contain graphical references, that are used in the Analyzer to backtrace errors.

Service Reply

SEHMSCGRPRREPLY

Parameter	Type	Description
errors	integer	Number of errors in the GR file.
warnings	integer	Number of warnings in the GR file.
errorLog	string	Description of errors and warnings, with GR references.

CIF Services

The CIF services enables the user to create diagrams where the graphical objects and texts could be positioned in a controlled manner.

These services enables the user to build converters to SDL Suite diagram formats.

The diagram types which are supported are:

- Block interaction diagrams,
- Process interaction diagrams

where the services are supported by the SDL Editor, and

- OM diagrams,

where the services are supported by the OM Editor.

Create SDL Diagram

Description

Creates an empty SDL diagram in a new buffer. Corresponds to the SDL Editor command *New*. The defaults applied to the created page are defined for the *Create SDL Page* service.

The texts for the package reference and the headings will be shown on every page in the diagram. The package reference symbol and the heading symbols will be automatically created, but their size can be changed by using the *Insert SDL Object* service for these symbols, (see "Object Specific Parameters" on page 641).

The kernel heading will be parsed to extract the necessary attributes like the virtuality, diagram type and diagram name. If this parsing fails the service will return an error.

The splitting of the SDL heading into a kernel heading and an additional heading is done according to the rules in section 2.2.5 'Partitioning of diagrams' in Z.100 with some necessary exceptions. Normally the kernel heading contains the heading up to, and including the diagram name,

```
<kernel heading> ::= [<virtuality>] <diagram kind>
{<diagram name> | <diagram identifier>}
```

The following exceptions to this rule apply:

For a type based system diagram the kernel heading contains the complete definition except for the ending <end> clause.

```
<kernel heading> ::= <typebased system heading>
```

For a process diagram the <number of process instance> might be included in the kernel heading.

For a procedure diagram the kernel heading is

```
<kernel heading> ::= <procedure preamble> procedure
{<procedure name> | <procedure identifier>}
```

Tools Supporting the Service

SET_SDLE

Service Request

SESDLECIFCREATEDIAGRAM

Parameter	Type	Description
packageReferenceText	string	The text that will appear in the package reference symbol
kernelHeadingText	string	The text that will appear in the kernel heading symbol
AdditionalHeadingText	string	The text that will appear in the additional heading symbol
pageType	integer	Type of the first page in the diagram. See sdtsym.h for valid page types. Note that the pageType must correspond with the diagramType.
pageName	string	Name of the first page in the diagram.
pageWidth	integer	The width of the page.
pageHeight	integer	The height of the page.
gridWidth	integer	The grid width.

Parameter	Type	Description
gridHeight	integer	The grid height.
autonumbered	bool	If true the page is an auto-numbered page.
showMeFirst	bool	If true this page is set as the ShowMeFirst page.
scale	integer	The scale used when shown, 100 means a 1:1 scale.

Service Reply

SESDLECIFCREATEDIAGRAMREPLY

status	integer	Service reply status.
bufid	integer	Refers to a buffer in the editor.

Errors

```
The pagename is empty
Illegal diagram kernel heading
```

Emitted Notifications

Notification	Description
SESDLENEWNOTIFY	As a result of creating the diagram.
SEPAGENOTIFY	As a result of creating a page.

Create SDL Page

Description

The *Create Page* service will create a new page in an existing diagram. The new page will be inserted as the last page in the diagram. The created page will have a frame symbol with margins to the page border as defined by the actual preference file. The kernel heading, additional heading and page number symbols exists and are placed automatically relative to the frame symbol. The package reference symbol exists, automatically placed, if the page type is a system page or a package page. The frame symbol can be changed to another position by using the Insert SDL Object service.

If a page already exists with the given page name, the service will be ignored and the return status is OK. This can be used for convenience to always send Create Page for all pages including the one already sent in the *Create SDL Diagram*.

The grid values should be multiples of 5 mm. If the values are zero or less than zero this means that the preferences values are used for the grid values.

A page can be set to be autonumbered. When this is used a page name must be given as well. For consecutive autonumbered pages these names must be “1”, “2”, “3” and so on. It will be checked that the given page name is the same as the generated page name. If not an error will be returned.

If the *ShowMeFirst* attribute is set for a new page it will override an already existing ShowMeFirst page.

Tools Supporting the Service

`SET_SDLE`

Service Request

`SESDLECIFCREATEPAGE`

Parameter	Type	Description
`bufId`	`integer`	Buffer referencing the diagram in which the page will be created.

Parameter	Type	Description
pageType	integer	Type of the page in the diagram. See sdtsym.h for valid page types. Note that the pageType must correspond with the diagramType.
pageName	string	Name of the new page in the diagram.
pageWidth	integer	The width of the page.
pageHeight	integer	The height of the page.
gridWidth	integer	The grid width.
gridHeight	integer	The grid height.
autonumbered	bool	If true the page is an autonumbered page.
showMeFirst	bool	If true this page is set as the ShowMe-First page.

For autonumbered pages, the given pagename "2" must
be the same as the generated page name "1"
```

Emitted Notifications

Notification	Description
SEPAGENOTIFY	As a result of creating a page.

Insert SDL Object

Description

The *Insert Object* service will insert an object in a specified position at a specific page. The return value is the object id for the inserted object. Lines connected to the inserted symbol should refer to the *objectId* returned by this service.

The following checks are applied on parameters:

- If a line is inserted the symbols connecting the line must already have been inserted.
- For lines it is an error if there are less than two breakpoints.
- The object type must be a known symbol or line.

The following is a non-exhaustive list of restrictions, applied inside SDLE when manipulating with symbols, that are **not** checked by this service:

- Ratio for process symbols, should be 1:2 (height vs. width).
- Positions outside the page area.
- Text syntax for reference symbols.
- Illegal texts on flowlines.
- Sizes less than minimum allowed.
- That lines are connected to symbols with the correct syntax.
- That line endpoints fall on enclosing rectangle of the symbol it is connected to.
- Symbols placed on pages where they should not appear, e.g. a task on a system page.
- Overlapping symbols

Tools Supporting the Service

`SET_SDLE`

Service Request

SESDLECIFINSERTOBJECT

Parameter	Type	Description
bufId	integer	Buffer referencing the diagram in which an object should be shown.
pagename	string	An existing page within the diagram.
objectType	integer	Identify the type of object to insert. Valid values for all symbols are given in sdtsym.h. For lines the values are listed below.
updateFlag	bool	If this flag is true a routine will be called for this page to fix some attributes for the objects. This fixing must be done before the page is saved. If this flag is false this fix will not be done.
object specific parameters	varying	One or more parameters defining the inserted object.

Service Reply

SESDLECIFINSERTOBJECTREPLY

Parameter	Type	Description
status	integer	Service reply status.
objectId	integer	Identifier to the inserted object.

Errors

```
Invalid diagram buffer id
Invalid pagename
Invalid fromSymbol id for a line:
Invalid toSymbol id for a line:
Invalid fromSymbol. The fromSymbol is a line:
Invalid toSymbol. The toSymbol is a line:
Number of points in line < 2 :
Invalid objectId for ConnectionPoint line:
Invalid object type:
```

Object Specific Parameters

For each object type the needed parameters are listed. All coordinates are given in 1/10 mm units in the coordinate system with the upper left corner of the page as origo and the y-coordinate having the positive direction going downwards.

A given coordinate will be adjusted to fall on a grid. For symbols this grid is given by a grid net of 5 x 5 mm. For line breakpoints and text positions the grid net is 2.5 x 2.5 mm.

The *Pagenumber* symbol (objectType number 53) has no extra specific parameters. When inserted there will not be a new symbol created as the pagenumber symbol is always created when the page is created. The text for the pagenumber symbol is generated automatically. The only use of inserting this symbol is to force an update of the page by having the *updateFlag* set to *true*.

- **Process Interaction diagram symbols**

```
Start(1), ProcedureStart(2), MacroInlet(3), Stop(4),
ProcedureReturn(5), MacroOutlet(6), State(7),
InputRight(8), InputLeft(9), PriorityInputRight(10),
PriorityInputLeft(11), ContinuousSignal(12),
EnablingCondition(13), Task(14), OutputRight(15),
OutputLeft(16), PriorityOutputRight(17),
PriorityOutputLeft(18), ProcedureCall(19),
InConnector(20), CreateRequest(21), Decision(22),
TransitionOption(23), MacroCall(24),
OutConnector(25), Save(26)
```

Parameter	Type	Description
`left`	`integer`	The x coordinate for the left side.
`top`	`integer`	The y coordinate for the top side.
`width`	`integer`	The width of the symbol.
`height`	`integer`	The height of the symbol.
`text`	`string`	The text in the symbol. The text is automatically aligned according to the built-in routines in SDLE

- **Block Interaction diagram symbols**

```
Procedure(27), Service(41), Process(42), Block(43),
BlockSubstructure(45), ChannelSubstructure(46),
SystemType(47), BlockType(48), ServiceType(49),
ProcessType(50), Operator(56).
```

Parameter	Type	Description
left	integer	The x coordinate for the left side.
top	integer	The y coordinate for the top side.
width	integer	The width of the symbol.
height	integer	The height of the symbol.
dashed	bool	If true the symbol will be dashed, this is valid for block, process and service symbols.
text	string	The text in the symbol.
XtextPosition	integer	The x coordinate for the left top position of the text.
YtextPosition	integer	The y coordinate for the left top position of the text.

There is no check that the text will fall inside the symbol boundary.

- **TextSymbol**(28)

Parameter	Type	Description
left	integer	The x coordinate for the left side.
top	integer	The y coordinate for the top side.
width	integer	The width of the symbol.
height	integer	The height of the symbol.
text	sString	The text in the symbol.

An automatically sized *TextSymbol* shall have the *width* and *height* set to zero. If values are given this means that the symbol will be clipped using the given sizing values.

- **Comment**(29), **CommentLeft**(30), **TextExtension**(31) and **TextExtensionLeft**(32)

Parameter	Type	Description
`left`	`integer`	The x coordinate for the left side (Comment, TextExtension) or the right side (CommentLeft, TextExtensionLeft)
`top`	`integer`	The y coordinate for the top side.
`text`	`string`	The text in the symbol.

For a *CommentLeft* or *TextExtensionLeft* the position gives the right top corner of the symbol. The size is automatically adjusted.

- **FrameSymbol**(44)

Parameter	Type	Description
`left`	`integer`	The x coordinate for the left side.
`top`	`integer`	The y coordinate for the top side.
`width`	`integer`	The width of the symbol.
`height`	`integer`	The height of the symbol.

A default *FrameSymbol* will always exist on a created page. This service will replace the existing Frame with a new frame symbol at the given position with the new size. The existing *heading symbols*, *package reference symbol* and the *pagenumber symbol* will be automatically adjusted.

- **AdditionalHeading**(52), **PackageReference**(55)

Parameter	Type	Description
`width`	`integer`	The width of the symbol.
`height`	`integer`	The height of the symbol.

For automatically sized symbols the values for the *width* and the *height* should be zero. If values different from zero are given this means that the symbol will be clipped.

Note that it might be necessary to insert this symbol for every page. This is so because these symbols might have a unique size for every page. If the symbols are not clipped there is no need to insert the symbol as they will be automatically generated as an unclipped symbol.

The size of the kernel heading cannot be changed.

- **FlowLine**(101)

Parameter	Type	Description
fromID	integer	The objectId for the symbol where the line starts.
toID	integer	The objectId for the symbol where the line ends.
textExists	bool	Is *true* if there is text on the flow line.
text	string	Optional text in the message. Only exists if textExists is true.
XtextPosition	integer	Optional text position in the message. Only exists if textExists is true. x coordinate for the left top corner of the text.
YtextPosition	integer	Optional text position in the message. Only exists if textExists is true. y coordinate for the left top corner of the text.
dashed	bool	If *true* the line will be dashed.
numPoints	integer	The number of breakpoints for the line. There must be at least 2.
x	integer	x coordinate for a point.
y	integer	y coordinate for a point.

It is checked that symbols exist having the given *fromID* and *toID*. The text and text position shall only exist if the *textExists* flag is *true*. *Flowlines* after *Decision*, *TransitionOption* and *MacroCall*

should always have text. There will be *numPoints x* and *y*-values at the end of the message. Line coordinates are adjusted to the nearest grid point but it will not be checked whether line endpoints are placed on the symbol boundaries, as they are expected to be.

- **SignalRoute**(102)

Parameter	Type	Description
fromID	integer	The objectId for the symbol where the line starts. Zero means ENV.
toID	integer	The objectId for the symbol where the line ends. Zero means ENV.
name	string	The name of the signal route.
signalList	string	The text in the signal list.
XnamePosition	integer	The x coordinate for the left top position of the name.
YnamePosition	integer	The y coordinate for the left top position of the name.
XsignalListPosition	integer	The x coordinate for the left top position of the signal list.
YsignalListPosition	integer	The y coordinate for the left top position of the signal list.
numPoints	integer	The number of breakpoints for the line. There must be at least 2.
x	integer	x coordinate for a point.
y	integer	y coordinate for a point.

It is checked that symbols exists having the given *fromID* and *toID*. There will be *numPoints x* and *y*-values at the end of the message. Text position and line coordinates are adjusted to the nearest grid point but it will not be checked whether line endpoints are placed on the symbol boundary (the rectangle enclosing the symbol), as they are expected to be. Extra line segments needed for e.g. a signal route entering a service will be automatically generated.

- **DoubleSignalRoute**(103)

Parameter	Type	Description
`fromID`	`integer`	The objectId for the symbol where the line starts. Zero means ENV.
`toID`	`integer`	The objectId for the symbol where the line ends. Zero means ENV.
`name`	`string`	The name of the signal route.
`signalList1`	`string`	The text in the signal list in the direction from fromID to toID.
`signalList2`	`string`	The text in the signal list in the reversed direction.
`XnamePosition`	`integer`	The x coordinate for the left top position of the name.
`YnamePosition`	`integer`	The y coordinate for the left top position of the name.
`XsignalList1Position`	`integer`	The x coordinate for the left top position of the first signal list.
`YsignalList1Position`	`integer`	The y coordinate for the left top position of the first signal list.

Parameter	Type	Description
XsignalList2Position	integer	The x coordinate for the left top position of the second signal list.
YsignalList2Position	integer	The y coordinate for the left top position of the second signal list.
numPoints	integer	The number of break-points for the line. There must be at least 2.
x	integer	x coordinate for a point.
y	integer	y coordinate for a point.

- **Channel**(104)

Parameter	Type	Description
fromID	integer	The objectId for the symbol where the line starts. Zero means ENV.
toID	integer	The objectId for the symbol where the line ends. Zero means ENV.
name	string	The name of the channel.
signalList	string	The text in the signal list.
XnamePosition	integer	The x coordinate for the left top position of the name.
YnamePosition	integer	The y coordinate for the left top position of the name.
XsignalListPosition	integer	The x coordinate for the left top position of the signal list.

Parameter	Type	Description
YsignalListPosition	integer	The y coordinate for the left top position of the signal list.
XarrowPosition	integer	The x coordinate for the arrow.
YarrowPosition	integer	The y coordinate for the arrow.
noDelay	bool	If true the channel is a non delaying channel.
numPoints	integer	The number of breakpoints for the line. There must be at least 2.
x	integer	x coordinate for a point.
y	integer	y coordinate for a point.

It is checked that symbols exists having the given *fromID* and *toID*. There will be *numPoints x* and *y*-values at the end of the message. Text position and line coordinates are adjusted to the nearest grid point but it will not be checked whether line endpoints are placed on the symbol boundary (the rectangle enclosing the symbol), as they are expected to be. The arrow position are automatically adjusted to be placed at the line as close as possible to the given arrow point. The angle of the arrow is automatically calculated. For a non delaying channel the arrow position is ignored and it will be automatically placed at the last breakpoint.

- **DoubleChannel**(104)

Parameter	Type	Description
fromID	integer	The objectId for the symbol where the line starts. Zero means ENV.
toID	integer	The objectId for the symbol where the line ends. Zero means ENV.
name	string	The name of the channel.
signalList1	string	The text in the signal list in the direction from fromID to toID.
signalList2	sString	The text in the signal list in the reversed direction.
XnamePosition	integer	The x coordinate for the left top position of the name.
YnamePosition	integer	The y coordinate for the left top position of the name.
XsignalList1Position	integer	The x coordinate for the left top position of the first signal list.
YsignalList1Position	integer	The y coordinate for the left top position of the first signal list.
XsignalList2Position	integer	The x coordinate for the left top position of the second signal list.
YsignalList2Position	integer	The y coordinate for the left top position of the second signal list.
Xarrow1Position	integer	The x coordinate for the first arrow.

Parameter	Type	Description
Yarrow1Position	integer	The y coordinate for the first arrow.
Xarrow2Position	integer	The x coordinate for the second arrow.
Yarrow2Position	integer	The y coordinate for the second arrow.
noDelay	bool	If true the channel is a non delaying channel.
numPoints	integer	The number of breakpoints for the line. There must be at least 2.
x	integer	x coordinate for a point.
y	integer	y coordinate for a point.

- **CreateLine**(106), **ChannelSubstructureLine**(107)

Parameter	Type	Description
fromID	integer	The objectId for the symbol where the line starts. This object is a channel for the ChannelSubstructureLine.
toID	integer	The objectId for the symbol where the line ends.
numPoints	integer	The number of breakpoints for the line. There must be at least 2.
x	integer	x coordinate for a point.
y	integer	y coordinate for a point.

It is checked that symbols exists having the given *fromID* and *toID*. There will be *numPoints x* and *y*-values at the end of the message. Line coordinates are adjusted to the nearest grid point but it will not be checked whether line endpoints are placed on the symbol boundary, as they are expected to be. For a *ChannelSubstructureLine* the starting is adjusted to be placed on the channel.

- **GateIn**(109), **GateOut**(110)

Parameter	Type	Description
X	integer	The x coordinate for the gate position on the FrameSymbol boundary.
Y	integer	The y coordinate for the gate position on the FrameSymbol boundary.
dashed	bool	If true the gate is dashed.
name	string	The name of the gate.
signalList	string	The text in the signal list.
constraint	string	The text in the constraint symbol connected to the gate.
XnamePosition	integer	The x coordinate for the left top position of the name.
YnamePosition	integer	The y coordinate for the left top position of the name.
XsignalListPosition	integer	The x coordinate for the left top position of the signal list.
YsignalListPosition	integer	The y coordinate for the left top position of the signal list.

The length of the gate is automatically calculated, so also the arrow position. The point will be adjusted such that it is guaranteed to stay on the Frame boundary. If the frame symbol is inserted after a gate, the gate might be positioned outside the frame. The correct positions will be fixed in the update that must be performed before saving the page.

- **DoubleGate**(111)

Parameter	Type	Description
X	integer	The x coordinate for the gate position on the FrameSymbol boundary.
Y	integer	The y coordinate for the gate position on the FrameSymbol boundary.
dashed	bool	If true the gate is dashed.
name	string	The name of the gate.
signalList1	string	The text in the signal list in the direction into the diagram.
signalList2	string	The text in the signal list in the direction out of the diagram.
constraint	string	The text in the constraint symbol connected to the gate.
XnamePosition	integer	The x coordinate for the left top position of the name.
YnamePosition	integer	The y coordinate for the left top position of the name.
XsignalList1Position	integer	The x coordinate for the left top position of the first signal list.
YsignalList1Position	integer	The y coordinate for the left top position of the first signal list.

Parameter	Type	Description
XsignalList2Position	integer	The x coordinate for the left top position of the second signal list.
YsignalList2Position	integer	The y coordinate for the left top position of the second signal list.

- **ConnectionPoint**(112)

Parameter	Type	Description
objectID	integer	The objectId for the symbol where the ConnectionPoint exists. Zero means ENV.
X	integer	The x coordinate for the ConnectionPoint.
Y	integer	The y coordinate for the ConnectionPoint.
name	string	The name of the ConnectionPoint.
XnamePosition	integer	The x coordinate for the left top position of the name.
YnamePosition	integer	The y coordinate for the left top position of the name.

A *ConnectionPoint* is used for gate names on the Frame symbol (ENV), channel names in block diagrams for graphical connect statements and for gate names inside block/process/service instances of block/process/service types. The *objectID* must be a valid symbol. The coordinate is adjusted such that the point will fall on the symbol boundary. If the frame symbol is inserted after a connection point residing on the frame, it might be positioned outside the frame. The correct positions will be fixed in the update that must be performed before saving the page.

Create OM Diagram

Description

Creates an empty OM diagram in a new buffer. Corresponds to the OM Editor command *New*. The defaults applied to the created page are defined for the Create OM Page service.

Create OM Page

Description

The *Create Page* service will create a new page in an existing diagram. The new page will be inserted as the last page in the diagram. The heading and page number symbols exists and are placed automatically relative to the frame symbol. The frame symbol can not be changed to another position.

If a page already exists with the given page name, the service will be ignored and the return status is OK. This can be used for convenience to always send Create Page for all pages including the one already sent in the Create OM Diagram service.

The grid values should be multiples of 5 mm. If the values are zero or less than zero this means that the preferences values are used for the grid values.

A page can be set to be autonumbered. When this is used a page name must be given as well. For consecutive autonumbered pages these names must be “1”, “2”, “3” and so on. It is considered an error if the given page name not is the same as the generated page name when this flag is set.

If the *ShowMeFirst* attribute is set for a new page it will override an already existing ShowMeFirst page.

Tools Supporting the Service

`SET_OME`

Service Request

`SEOMECIFCREATEPAGE`

Parameter	Type	Description
`bufId`	`integer`	Buffer referencing the diagram in which the page will be created.
`pageName`	`string`	Name of the new page in the diagram.
`pageWidth`	`integer`	The width of the page.
`pageHeight`	`integer`	The height of the page.

Parameter	Type	Description
gridWidth	integer	The grid width.
gridHeight	integer	The grid height.
autonumbered	bool	If true the page is an autonumbered page.
showMeFirst	bool	If true this page is set as the Show-MeFirst page.
scale	integer	The scale used when shown, 100 means a 1:1 scale.

Service Reply

SEOMECIFCREATEPAGEREPLY

Parameter	Type	Description
status	integer	Service reply status.

Errors

```
Invalid diagram buffer id
The pagename is empty
For an autonumbered page the given name must be the
same as the generated pagename: "<gen.pagename>"
```

Emitted Notifications

Notification	Description
SEPAGENOTIFY	As a result of creating a page.

Insert OM Object

Description

The *Insert Object* service will insert an object in a specified position at a specific page. The return value is the object id for the inserted object. Lines connected to the inserted symbol should refer to the objectId returned by this service.

The following parameter checks are performed:

- If a line is inserted the symbols connecting the line must already have been inserted.
- For lines it is an error if there are less than two breakpoints.
- The object type must be a known symbol or line.

The following is a non-exhaustive list of restrictions, applied inside OME when manipulating with symbols, that are **not** checked by this service:

- Positions outside the page area.
- Text syntax for class and instance symbols. However, when an object is inserted with the *updateFlag* set there will be a syntactic check and all eventual syntax errors will be marked in the normal way.
- That lines are connected to symbols with the correct syntax.
- That line endpoints fall on or inside the enclosing rectangle of the symbol it is connected to.
- Overlapping symbols

Tools Supporting the Service

`SET_OME`

Service Request

SEOMECIFINSERTOBJECT

Parameter	Type	Description
bufId	integer	Buffer referencing the diagram in which an object should be shown.
pagename	string	An existing page within the diagram.
objectType	integer	Identify the type of object to insert. Valid values for all symbols are given in sdtsym.h. For lines the values are listed below.
updateFlag	bool	If this flag is true a routine will be called for this page to fix some attributes for the objects. This fixing must be done before the page is saved. If this flag is false this fix will not be done.
object specific parameters	varying	One or more parameters defining the inserted object.

Service Reply

SEOMECIFINSERTOBJECTREPLY

Parameter	Type	Description
status	integer	Service reply status.
objectId	integer	Identifier to the inserted object

Errors

```
Invalid diagram buffer id
Invalid pagename
Invalid fromSymbol id for a line:
Invalid toSymbol id for a line:
Invalid fromSymbol. The fromSymbol is a line:
Invalid toSymbol. The toSymbol is a line:
Number of points in line < 2 :
Invalid objectId for ConnectionPoint line:
Invalid object type:
```

Object Specific Parameters

For each object type the needed parameters are listed below. All coordinates are given in 1/10 mm units in the coordinate system with the upper left corner of the page as origo and the y-coordinate having the positive direction going downwards.

A given coordinate will be adjusted to fall on a grid. For symbols this grid is given by a grid net of 5 x 5 mm. For line breakpoints and text positions the grid net is 2.5 x 2.5 mm.

The *Pagenumber* symbol (objectType number 53) have no extra specific parameters. When inserted there will not be a new symbol created as the pagenumber symbol is always created when the page is created. The text for the pagenumber symbol is generated automatically. The only use of inserting this symbol is to force an update of the page by having the *updateFlag* set to true

- **Class**(57)

Parameter	Type	Description
`left`	`integer`	The x coordinate for the left side.
`top`	`integer`	The y coordinate for the top side.
`nameText`	`string`	The name text part of the symbol.
`attributeText`	`string`	The attribute text part of the symbol.
`operationText`	`string`	The operation text part of the symbol.
`stereotypeText`	`string`	The stereotype text part of the symbol.
`propertiesText`	`string`	The properties text part of the symbol.
`collapsed`	`bool`	If this is true the symbol is collapsed.

- **Instance**(58)

Parameter	Type	Description
left	integer	The x coordinate for the left side.
top	integer	The y coordinate for the top side.
nameText	string	The name text part of the symbol.
attributeText	string	The attribute text part of the symbol.
stereotypeText	string	The stereotype text part of the symbol.
propertiesText	string	The properties text part of the symbol.
collapsed	bool	If this is true the symbol is collapsed.

- **TextSymbol**(28)

Parameter	Type	Description
left	integer	The x coordinate for the left side.
top	integer	The y coordinate for the top side.
text	string	The text in the symbol.
collapsed	bool	If this is true the symbol is collapsed

- **AssociationLine**(113), **AggregationLine**(114)

Parameter	Type	Description
fromID	integer	The objectId for the symbol where the line starts.
toID	integer	The objectId for the symbol where the line ends.
haveName	bool	Flag set if the line has forward name attributes

Parameter	Type	Description
`name`	`string`	Only if *haveName* set: The forward name of the line.
`nameArrow`	`bool`	Only if *haveName* set: Arrow on the forward name.
`XPosition`	`integer`	Only if *haveName* set: The x coordinate for the left top position of the name.
`YPosition`	`integer`	Only if *haveName* set: The y coordinate for the left top position of the name.
`haveRevName`	`bool`	Flag set if the line has reversed name attributes.
`revName`	`string`	Only if *haveRevName* set: The reversed name of the line.
`revNameArrow`	`bool`	Only if *haveRevName* set: Arrow on the reversed name.
`XPosition`	`integer`	Only if *haveRevName* set: The x coordinate for the left top position of the reversed name.
`YPosition`	`integer`	Only if *haveRevName* set: The y coordinate for the left top position of the reversed name.
`haveRoleName`	`bool`	Flag set if the line has role name attributes.
`roleName`	`string`	Only if *haveRoleName* set: The forward role name of the line.
`XPosition`	`integer`	Only if *haveRoleName* set: The x coordinate for the left top position of the forward role name.
`YPosition`	`integer`	Only if *haveRoleName* set: The y coordinate for the left top position of the forward role name.

Parameter	Type	Description
haveRevRoleName	bool	Flag set if the line has reversed role name attributes.
revRoleName	string	Only if *haveRevRoleName* set: The reversed role name of the line.
XPosition	integer	Only if *haveRoleName* set: The x coordinate for the left top position of the reversed role name.
YPosition	integer	Only if *haveRoleName* set: The y coordinate for the left top position of the reversed role name.
haveMultText	bool	Flag set if the line has multiplicity text attributes.
multText	string	Only if *haveMultText* set: The forward multiplicity text of the line.
XPosition	integer	Only if *haveMultText* set: The x coordinate for the left top position of the multiplicity text.
YPosition	integer	Only if *haveMultText* set: The y coordinate for the left top position of the multiplicity text.
haveRevMultText	bool	Flag set if the line has reversed multiplicity text attributes.
revMultText	string	Only if *haveRevMultText* set: The reversed multiplicity text of the line.
XPosition	integer	Only if *haveRevMultText* set: The x coordinate for the left top position of the multiplicity text.
YPosition	integer	Only if *haveRevMultText* set: The y coordinate for the left top position of the multiplicity text.

Parameter	Type	Description
haveQualText	bool	Flag set if the line has qualifier text attributes.
qualText	string	Only if *haveQualText* set: The forward qualifier text of the line.
haveRevQualText	bool	Flag set if the line has reversed qualifier text attributes.
revQualText	string	Only if *haveRevQualText* set: The reversed qualifier text of the line.
haveConstText	bool	Flag set if the line has constraint text attributes.
constraintText	string	Only if *haveConstText* set: The constraint text of the line.
XPosition	integer	Only if *haveConstText* set: The x coordinate for the left top position of the constraint text.
YPosition	integer	Only if *haveConstText* set: The y coordinate for the left top position of the constraint text.
haveOrdered	bool	Flag set if the line has the Ordered attribute.
XPosition	integer	Only if *haveOrdered* set: The x coordinate for the left top position of the Ordered text.
YPosition	integer	Only if *haveOrdered* set: The y coordinate for the left top position of the Ordered text.
haveSorted	bool	Flag set if the line has the Sorted attribute.
XPosition	integer	Only if *haveSorted* set: The x coordinate for the left top position of the Sorted text.

Parameter	Type	Description
YPosition	integer	Only if *haveSorted* set: The y coordinate for the left top position of the Sorted text.
haveRevOrdered	bool	Flag set if the line has the reversed Ordered attribute.
XPosition	integer	Only if *haveRevOrdered* set: The x coordinate for the left top position of the reversed Ordered text.
YPosition	integer	Only if *haveRevOrdered* set: The y coordinate for the left top position of the reversed Ordered text.
haveRevSorted	bool	Flag set if the line has the reversed Sorted attribute.
XPosition	integer	Only if *haveRevSorted* set: The x coordinate for the left top position of the reversed Sorted text.
YPosition	integer	Only if *haveRev* Sorted set: The y coordinate for the left top position of the reversed Sorted text.
derived	bool	Flag set if the line shall be marked as derived.
numPoints	integer	The number of breakpoints for the line. There must be at least 2.
x	integer	x coordinate for a point.
y	integer	y coordinate for a point.

It is checked that symbols exists having the given *fromID* and *toID*. There will be *numPoints x* and *y*-values at the end of the message. Text position and line coordinates are adjusted to the nearest grid point but it will not be checked whether line endpoints are placed on the symbol boundary (the rectangle enclosing the symbol), as they

are expected to be. Extra line segments needed for e.g. a signal route entering a service will be automatically generated.

- **GeneralizationLine**(115)

Parameter	Type	Description
fromID	integer	The objectId for the symbol where the line starts.
toID	integer	The objectId for the symbol where the line ends.
haveName	bool	Flag set if the line has a name attribute.
name	QuotedString	Only if *haveName* set: The name of the line.
XnamePosition	integer	Only if *haveName* set: The x coordinate for the left top position of the name.
YnamePosition	integer	Only if *haveName* set: The y coordinate for the left top position of the name.
numPoints	integer	The number of breakpoints for the line. There must be at least 2.
x	integer	x coordinate for a point.
y	integer	y coordinate for a point.

It is checked that symbols exists having the given *fromID* and *toID*. There will be *numPoints x* and *y*-values at the end of the message. Text position and line coordinates are adjusted to the nearest grid point.

- **Class LinkLine**(123)

Parameter	Type	Description
`fromID`	`integer`	The objectId for the line where the link line starts.
`toID`	`integer`	The objectId for the symbol where the line ends.
`numPoints`	`integer`	The number of breakpoints for the line. Always 2 since no breakpoints are allowed on this line.
`x`	`integer`	x coordinate for a point.
`y`	`integer`	y coordinate for a point.

It is checked that symbols exists having the given *fromID* and *toID*. Observe that the *fromID* must denote an association or aggregation line. Note that *numPoints* always must be 2, and consequently there will be two *x* and *y* coordinates.

Text Editor Services

Show Position

Description

The *Show Position* service makes sure that a certain character specified by line and column is visible in a text editor window:

- If no window is displaying the document identified by bufferId, the buffer is displayed in a window according to the user's window re-use policy.
- A window is brought to the front.
- The text in the window is re-centered so that the indicated character is displayed.

Note that the actual display position after re-centering is undefined if the line and/or column values do not make sense.

Tools Supporting the Service

SET_TE

Service Request

SETESHOWPOSITION

Parameter	Type	Description
bufid	integer	Identifies the buffer
line	integer	Indicates the line that should be shown
column	integer	Indicates which character on the line which should be shown

Service Reply

SETESHOWPOSITIONREPLY

Parameter	Type	Description
status	integer	Service reply status.

Errors

Buffer id does not exist

Select Text

Description

The *Select Text* service selects a range of text in a window displaying a given text buffer.

- If no window is displaying the document identified by bufferId, the buffer is displayed in a window according to the user's window re-use policy.
- A window is brought to the front.
- The text in the window is re-centered so that the indicated character is displayed.

Note that the actual selection is undefined if one or more of the line and/or column values do not make sense.

Tools Supporting the Service

`SET_TE`

Service Request

`SETESELECTTEXT`

Parameter	Type	Description
`bufid`	`integer`	Identifies the buffer
`line1`	`integer`	Indicates where the selection should start
`column1`	`integer`	Indicates the character where the selection should start.
`line2`	`integer`	Indicates the line where the selection should end.
`column2`	`integer`	Indicates the character where the selection should end.

Service Reply

`SETESELECTTEXTREPLY`

Parameter	Type	Description
`status`	`integer`	Service reply status.

Errors

`Buffer id does not exist`

Notifications

The *notifications* inform the environment when something significantly happens. Notifications are only available as PostMaster messages.

To receive a notification one must subscribe on that particular notification (or on all notifications). This is accomplished either statically, by an entry in an additional configuration file, or dynamically by the services *Add Tool* and *Add Tool Subscription*.

Overview of Available Notifications

Tool notifications

Message	Description
SESTARTNOTIFY	When a tool is started.
SESTOPNOTIFY	When a tool is stopped.

Diagram notifications

Message	Description
SELOADNOTIFY	When a diagram is loaded.
SEUNLOADNOTIFY	When a diagram is unloaded.
SEDIRTYNOTIFY	When a diagram becomes modified.
SESAVENOTIFY	When a diagram is saved.
SESDLENEWNOTIFY	When an SDL diagram is created.
SEMSCENEWNOTIFY	When an MSC diagram is created.
SEOMENEWNOTIFY	When an OM diagram is created.
SETENEWNOTIFY	When a text diagram is created.

Start Notify

Description

This message is broadcast when a new tool is started. That is, when it connects to the PostMaster. It is sent automatically by the SPInit function.

Tools Issuing the Notification

`The started tool`

Notification

`SESTARTNOTIFY`

Parameter	Type	Description
`toolType`	`integer`	The kind of tool that was started.
`argv0`	`string`	The filename (with a complete path) of the started tool as obtained by reading `argv[0]`.

Stop Notify

Description

This message is broadcast when the tool disconnects from the PostMaster and terminates.

Tools Issuing the Notification

`The tool which stops`

Notification

`SESTOPNOTIFY`

Parameter	Type	Description
`toolType`	`integer`	The kind of tool that stopped.

Load Notify

Description

Broadcast when the diagram is loaded in an editor.

Tools Issuing the Notification

```
SET_SDLE
SET_MSCE
SET_OME
SET_TE
```

Notification

```
SELOADNOTIFY
```

Parameter	Type	Description
bufId	integer	Buffer id of the loaded diagram.
fileName	string	Name of the loaded file.
diagramType	integer	Diagram type of the loaded diagram.
diagramName	string	Diagram name of the loaded diagram.

Unload Notify

Description

Broadcast when the diagram is unloaded in the editor. No assumptions could be made whether or not the diagram was saved. The buffer id of the unloaded diagram is then not longer valid and cannot be used anymore.

Tools Issuing the Notification

```
SET_SDLE
SET_MSCE
SET_OME
SET_TE
```

Notification

```
SEUNLOADNOTIFY
```

Parameter	Type	Description
bufId	integer	Buffer id of the unloaded diagram.

Dirty Notify

Description

Broadcast when a diagram becomes dirty, i.e. when the user has modified the diagram.

Tools Issuing the Notification

```
SET_SDLE
SET_MSCE
SET_OME
SET_TE
```

Notification

```
SEDIRTYNOTIFY
```

Parameter	Type	Description
bufId	integer	Buffer id of the diagram that became dirty.

Save Notify

Description

The message is broadcast when a diagram is saved.

Tools Issuing the Notification

```
SET_SDLE
SET_MSCE
SET_OME
SET_TE
```

Notification

```
SESAVENOTIFY
```

Parameter	Type	Description
bufId	integer	Buffer id of the saved diagram.
fileName	string	The filename in which the diagram was saved.

SDL New Notify

Description

Broadcast when a diagram is created in the SDL Editor. In this case a *Load Notify* is not broadcast.

Tools Issuing the Notification

SET_SDLE

Notification

SESDLENEWNOTIFY

Parameter	Type	Description
bufId	integer	Buffer id of the new diagram.
virtuality	string	Kind of virtuality
diagramType	integer	Type of diagram.
diagramName	string	Name of the diagram.
qualifier	string	A qualifier for the new diagram. The qualifier is not a full qualifier, since it does not include the diagram path to the root diagram.

MSC New Notify

Description

Broadcast when a diagram is created in the MSC Editor. In this case a *Load Notify* is not broadcast.

Tools Issuing the Notification

SET_MSCE

Notification

SEMSCENEWNOTIFY

Parameter	Type	Description
bufId	integer	Buffer id of the new diagram.
diagramName	string	Name of the new diagram.

OM New Notify

Description

Broadcast when a diagram is created in the OM Editor. In this case a *Load Notify* is not broadcast.

Tools Issuing the Notification

SET_OME

Notification

SEOMENEWNOTIFY

Parameter	Type	Description
bufId	integer	Buffer id of the new diagram.
diagramName	string	Name of the new diagram.

TE New Notify

Description

Broadcast when a diagram is created in the Text Editor. In this case a *Load Notify* is not broadcast.

Tools Issuing the Notification

SET_TE

Notification

SETENEWNOTIFY

Parameter	Type	Description
bufId	integer	Buffer id of the new diagram.
diagramName	string	Name of the new diagram.

Auxiliary Messages

Communicating with Simulators

Description

SESDLSIGNAL is sent by an SDL simulator when it sends an SDL signal to its SDL environment. Other simulators (or any applications connected to the PostMaster) can then receive the message and send back messages of the same type.

The PIds consist of a UNIX PId **(on UNIX)**, or an identifier ”pid” known by the PostMaster **(in Windows)**, in both cases an integer, and an SDL process instance number (a hex number), which normally is used only in comparisons. The PIds may be used to uniquely identify a single receiver if several receivers exist, but can be ignored if only two tools are communicating

Tools Issuing and Recognizing the Message

SET_SDLENV

Message

SESDLSIGNAL

Parameter	Type	Description
signalName	integer	SDL name of the sent signal
globalReceiverPid	integer	See above.
localReceiverPid	string	See above.
globalSenderPid	integer	See above.
localsenderPid	string	See above.
signalParam	string	Sea above.

PostMaster Operation Failed

Description

SEOPFAILED is sent by the PostMaster when an internal problem inhibited a message to be handled properly. Three major categories of errors exists:

- Communication error, i.e. the underlying network (e.g. UNIX socket) reported an error
- An explicit address did not exist
- An operation requested from the PostMaster failed.

Tools Issuing and Recognizing the Message

SET_POST

Message

SEOPFAILED

Parameter	Type	Description
message	integer	The message causing the error.
severity	integer	Kind of error.
pid	integer	The PId of the subscriber (if a specific subscriber was involved).
errorCode	integer	The error itself.
messageParam	string	The remaining information is the data (or the first part of the data) of the message causing the error.

Chapter 11 The Public Interface

Chapter

12

Using the Public Interface

This chapter contains a number of examples of how the use the features provided by the Public Interface.

For a reference to the topics that are exemplified in this chapter, see *chapter 11, The Public Interface*.

Introduction

The first example shows a simple application, the *Service Encapsulator*, by which it is possible to request SDL Suite or TTCN Suite tools services from the Operating Systems command line. The example shows how to use the PostMaster interface.

The second example uses the Service Encapsulator and shows the usage of some SDL Suite Services. Since the “DOS” command prompt is rather weak in its scripting capabilities, no example script file is included **for Windows** in this example.

The third example uses the Service Encapsulator and shows the usage of some TTCN Suite Services.

The final example exemplifies how to integrate an SDL simulator and a separate user interface **(UNIX only)**. How to design such a user interface is described in a detailed example. It is assumed that the reader has experience of creating and running SDL simulators.

The Service Encapsulator

Introduction to the Service Encapsulator

This section shows an application, the Service Encapsulator, implementing a command line service request encapsulation. That is, services as made available by the Public Interface, could be obtained from the command line.

The purpose of this example is to show:

- How the PostMaster interface is used when working with services in SDL Suite and TTCN Suite.
- By using the Service Encapsulator, show the usage of a number of services.

The application is general in the sense that it does not require any SDL Suite or TTCN Suite tool to be running (only the PostMaster is required to be running), but in this context it exemplifies a number of services.

From the outside world the application behaves like a tool providing *remote procedure call* functionality. That is, when the service is request-

ed, the application synchronously waits for the service reply, before returning (the application exits).

The example is found in the SDL Suite and TTCN Suite distribution in the subdirectory `examples` and then `public_interface`.

The Service Encapsulator is also available as a tool in the SDL Suite and TTCN Suite environment, see *"The Service Encapsulator" on page 537 in chapter 11, The Public Interface*.

Design

In this section is a few important aspects in the design and implementation of the *Service Encapsulator* given. The source file is named `serverpc.c` and the executable is named `serverpc`.

The tool connects to the PostMaster by issuing:

```
SPInit(SET_EXTERN, argv[0], spMList) (in SDL Suite)
SPInit(IET_EXTERN, argv[0], ipMList) (in TTCN Suite)
```

The first parameter gives the type of application. In this case `SET_EXTERN` or `IET_EXTERN` is used. This application type is a predefined tool type for external applications connecting to SDL Suite and TTCN Suite. The variable `spMList` or `ipMList` gives the possibility to convert between textual (symbolic) values and integers.

If `SPInit` succeeds, `SPInit` broadcasts a `SESTARTNOTIFY`, indicating to all other tools in the environment that an additional tool is connected.

```
if ((tool=atoi(argv[1])) == 0 )
  tool = SPConvert(argv[1]);
```

If the parameter `<tool>` was given textually, the function `SPConvert` converts it to the corresponding integer value. If a mapping cannot be found, -1 is returned. This is an error and will be detected in the `SPSendToTool` function, see below.

```
if ((sendEvent=atoi(argv[2])) == 0 )
   sendEvent = SPConvert(argv[2]);
```

Allocating memory for the message parameter is done as follows:

```
for (i=3;i<argc;i++) {
  p = realloc(p, strlen(p) + strlen(argv[i]) + 2);
  if (strlen(p)>0)
    p = strcat(p, " ");
  p = strcat(p, argv[i]);
}
```

The `handleescape` function allows carriage return "`\n`", "`\r`" and "`\0`" to be used when sending messages:

```
p = handleescape(p);
```

A normal service request is issued by:

```
status=SPSendToTool(tool, sendEvent, p, strlen(p)+1;
```

The last parameter tells the length of the parameter provided by `argv[3]` and must be extended by 1 to include the terminating `\0` character.

Now the service request message is sent to the PostMaster which forwards it to the server application. If not busy, the Service application starts to process the service request and when finished it replies with a service reply message to the issues. However, during the processing other messages can be sent or broadcast to the *Service Encapsulator* (the service issuer). Therefor we must enter a loop where we stay until the reply message is received. Other kind of messages are dropped.

```
do {
   if (( status=SPRead(SPWAITFOREVER, &pid,
         &replyEvent,(void*)&replyMessage, &len))!=0
)
      OnError("Error reading from postmaster: ");
} while ( ! SP_MATCHREPLY(sendEvent, replyEvent) );
```

The function `SPRead` reads a message form the PostMaster. The first parameter, the timeout, could be set to wait indefinitely until a message arrives, using the value `SPWAITFOREVER`.

This simple application has a drawback: if something unexpectedly happens to the server, it might be that no service reply will be sent which means that we block in `SPRead` forever. The behavior could be enhanced by setting a timeout, and when the timeout expires, check the state of the server (Use the PostMaster service Get Tool Pid).

If the service `readattribute` was issued, special care must be taken to handle the answer, since it contains binary data. The length of the data part ends the `replyMessage`. The end is indicated by an ASCII 0. The

data part immediately follows the ASCII 0 character and might contain non-ASCII characters. Our printout assumes ASCII data.

```
if ( sendEvent == SEREADATTRIBUTE ) {
   printf("%s", replyMessage+1);
  printf("%s\n", replyMessage+ strlen(replyMessage)
          +1);
}
```

The macro `SP_MATCHREPLY` compares the issued service request message and the reply message and returns true if the correct received message was the correct service reply message.

The service reply is then printed on standard output. The following prints the service reply data:

```
int i;
for( i=2;i<len;i++ )
  putchar(replyMessage[i]);
putchar('\n');
```

Counting starts at position 2, omitting the service reply status.

```
free (replyMessage);
```

`replyMessage` was dynamically allocated using malloc in `SPRead`, so it must be freed.

Before terminating the application, notify all other applications in the environment that it is going to break its connection to the PostMaster

```
SPBroadcast(SESTOPNOTIFY, NULL, 0);
```

Finally we terminate the PostMaster connection by calling:

```
SPExit ();
```

Generating the Application for the SDL Suite

To generate the application do the following:

1. Change the current directory to the sub directory containing the example:

   On UNIX: `cd <Installation Directory>/examples/public_interface`

   In Windows: `cd <Installation Directory>\examples\public_interface`

2. Set the environment variable `telelogic` to point to the right directory. This is platform dependent.

   On UNIX: `setenv telelogic <Installation Directory>`

   In Windows: `set telelogic=<Installation Directory>`

3. Generate the application:

   On Solaris: `make -f Makefile.solaris`

   In Windows using Microsoft: `nmake /f Makefile.msvc`

Using the SDL Suite Services

Introduction

This section exemplifies the usage of some SDL Suite services. The examples take advantage of the *Service Encapsulator* described in the previous section.

In these examples, we only use textual values of the parameters `<tool>` and `<service>`. Available textual values is found in the `spMList` variable in `sdt.h`.

In the examples below, the *Service Encapsulator* is executed from a `csh` shell **(on UNIX)**, or from the "DOS" prompt **(in Windows)**. If another shell is used, the examples below might need to be modified in order to supply the parameters correctly. Take care how to supply the quoted strings.

> **Note:**
>
> Due to limitations in DOS, this Service Encapsulator example is not as extensive in Windows as the UNIX version.

Load External Signal Definitions into the Information Server

For this service to be available, the Information Server must be started. This could be done by either starting the Type Viewer from the Organizer, by requesting *Signal Dictionary* support in the SDL Editor or by using the *Start service*. For a complete service description, See *"Start Tool" on page 539 in chapter 11, The Public Interface*.

Requesting the Service

It is assumed that a file `a.pr` is to be loaded. Note that the file to be loaded must be specified with a full directory path.

On UNIX: `serverpc info loaddefinition /usr/ab/a.pr`

In Windows: `serverpc info loaddefinition c:\sdt\ex\a.pr`

If the Information Server is started, the following reply message is returned:

```
Reply status is OK
```

If the Information Server is not started, we get the following reply message.

```
Error sending to postmaster:  server not connected
to postmaster
```

The external files loaded into the SDL Infoserver should have the following appearance e.g.:

```
signal sig1
signal sig2
signal sig3
```

Obtain Source (SDL/GR Reference)

Returns a complete SDT reference of each of the selected symbols in the specified editor.

```
serverpc sdle obtainsource
```

If the editor was already started and there was a selection the reply message might look like:

```
Reply status is OK
 1
"#SDTREF(SDL,c:\IBM\Rational\SDL_TTCN_Suite6.3\sdt\e
xamples\demongam\demon.spr(1),125(30, 70))"
```

Note that the reference returns a complete file path of the diagram file in which the selection was made.

If the editor did not contain any selection, the reply becomes:

```
Reply status is OK
```

```
0
```

For a complete description of the service, see *"Obtain GR Reference" on page 599 in chapter 11, The Public Interface*.

Show Source

Selects the object given by the parameters in an editor. The editor is started if necessary as a side effect. A system must however be opened in the Organizer containing the specified reference.

To test this service we could now deselect all selections in the SDL Editor and use the reference extracted by `obtainsource` to select this symbol again. Note how the SDT reference is quoted to pass it from the shell into the tool.

On UNIX:
```
serverpc organizer showsource \
  """#SDTREF(SDL,/usr/sdt-inst/examples/simulator- \
  integration/sunos4/demon.spr(1),125(30,70))"""
```

In Windows:
```
serverpc organizer showsource
\"#SDTREF(SDL,c:\IBM\Rational\SDL_TTCN_Suite6.3\sdt\
examples\demongam\demon.spr(1),125(30, 70))\"
```

If the reference is found the following message is replied:

```
Reply status is OK
```

For a complete description of the service, see *"Show Source" on page 598 in chapter 11, The Public Interface*.

For a complete description of how to specify a SDT reference, see "Syntax" on page 917 in chapter 18, *SDT References*.

Dynamic Menus

The following example shows how a dynamic menu is created and how a number of menu items are inserted in the dynamic menu. The script `dyn-menu` in the example directory performs the example below.

For a complete description of the services, see "Add Menu" on page 581, "Delete Menu" on page 582, "Clear Menu" on page 583 and *"Add Item to Menu – Graphical Editors" on page 593 in chapter 11, The Public Interface*.

Add a new menu to the SDL Editor:

```
serverpc sdle menuadd \"dyn-menu\"
```

Reply:

```
Reply status is OK
```

Add a menu item which executes the OS command `ls` **(on UNIX)** or `DIR` **(in Windows)** after a confirmation from the user:

On UNIX:
```
serverpc sdle menuadditem  \
\"dyn-menu\" \"ls\" 0 \
\"Perform OS command ls\"  0 0 0 \
\"OK to perform ls!\" 1 1 \"ls\"
```

In Windows:
```
serverpc sdle menuadditem \"dyn-menu\"
\"DIR\" 0 \"Perform OS command DIR\" 0 0 0 \"OK to
perform OS command DIR!\" 1 1 \"CMD /C DIR /W\"
```

Reply:

```
Reply status is OK
```

Then a menu item is added displaying the SDT reference of the selected symbol on standard output **(on UNIX)**, or in the Organizer Log window **(in Windows)**:

On UNIX:
```
serverpc sdle menuadditem  \
\"dyn-menu\" \"SDT-ref\" 1 \
\"export SDT ref\"  0 0 1 \
\"\" 1 1 \"echo \'%g\'\"
```

In Windows:
```
serverpc sdle menuadditen \"dyn-menu\"
\"SDT-ref\" 1 \"export SDT-ref\" 0 0 1 \"\" 1 1
\"CMD /C echo %%g\"
```

Reply:

```
Reply status is OK
```

Note that only dimmed if more than one item is selected. Normally a selected symbol includes a selection of in-going and out-going flowlines. These flowlines must be de-selected in order to get the SDT reference of the symbol.

Finally display the file containing the selected symbol on standard output **(on UNIX)**, or in the Organizer Log window **(in Windows)**:

On UNIX:
```
serverpc sdle menuadditem  \
\"dyn-menu\" \"filename\" 0 \
\"export filename\"  0 0 1 \
\"\" 1 1 \"ls -ls %a\"
```

In Windows:
```
serverpc sdle menuadditem \"dyn-menu\"
\"filename\" 0 \"export filename\" 0 0 1 \"\" 1 1
\"CMD /C DIR %%a\"
```

Reply:

```
Reply status is OK
```

Extended Object Data Attributes (UNIX only)

The SDL Suite allows external attributes to be added to SDL Suite objects. These extensions are persistent. That is, they are stored in the normal SDL diagram files and could be used at subsequent sessions. This **UNIX only** example gives a brief introduction to such extended attributes.

An description of extended attributes are found in "Extended Data Attribute" on page 617 in chapter 11, *The Public Interface*. Extended attributes are handled as binary data by the SDL Suite. As such, their services are preferably accessed via C program interface, in which binary data is easily handled.

However, in this example extended attribute services are accessed via the *Service Encapsulator*, which works for simple examples.

The example assumes one selection in an SDL Editor. This reference is saved in a shell variable

```
set ref=`serverpc sdle obtainsource`
```

If we have exactly one selection, we set the extended attribute. Parameter 9 will give us the SDT reference.

```
serverpc sdle createattribute 0 0 $ref[9] 0 \
  \"myComment\" \"\"  6"\0"MyData
```

Note that the length of data (`MyData)` must be manually calculated and that the data part must be preceded by a "\0".

We get the reply:

```
Reply status is OK
```

Now we extract the extended attribute on the selection.

```
serverpc sdle readattribute 0 0 $ref[9]
```

Which replies:

```
Reply status is OK
0 "myComment" "" 6MyData
```

Note that data immediately follows its' length without any spaces. In the reply message, there is a ASCII 0 character after the length, preceding the data part.

Then we update the attribute by;

```
serverpc sdle updateattribute 0 0 $ref[9] 0
\"newComment\" \"\" 7"\0"NewData
```

Reply:

```
Reply status is OK
```

Finally we read the extended attribute and should receive the updated value.

```
serverpc sdle readattribute 0 0 $ref[9]
```

Which replies:

```
Reply status is OK
0 "NewComment" "" 7NewData
```

The script `extended-attributes` performs the above described actions.

Using TTCN Suite Services

This section is meant to exemplify the usage of a few TTCN Suite services. The examples are made using the Service Encapsulator described in a previous section. For the complete list of supported services, see "TTCN Suite Services" on page 554 in chapter 11, *The Public Interface*.

Opened Documents

This command retrieves a list of information about the opened TTCN documents.

```
serverpc itex openeddocuments
```

This will yield a list of open TTCN documents (not necessarily shown) that looks like this (see complete list for description of the list format):

```
Reply status is OK
Doc1:1:/path/doc1.itex:/path/#doc1.itex
Doc2:2:/path/doc2.itex:/path/#doc2.itex
```

If the TTCN environment is not yet started the message will be:

```
Error sending to postmaster: server not connected to
postmaster
```

Find Table

To use this command the TTCN document in which the table is located must be open.

To invoke the service the following Service Encapsulator command is made:

```
serverpc itex findtable 1 \"Foo\"
```

which will search for the table named `Foo` in the open TTCN document with buffer identifier 1 and open it the Table Editor.

If the table is found the table will be shown and the following message will be returned:

```
Reply status is OK
```

If the table can not be found, an error message is issued:

```
Unable to find object 1 Foo
```

Integrating Applications with SDL Simulators

An example of utilizing the functionality of the PostMaster is to connect a simulator generated by the SDL Suite to another application, typically a user interface (UI). The section "Example of Use (UNIX only)" on page 692 presents a detailed description of such an example **(UNIX only)**. The sections below concentrate on overall design issues and serves as an introduction to that example.

The communication between an SDL simulator and another application is handled by the PostMaster, and can be seen as occurring on two levels:

- Sending and receiving SDL signals
- Sending and receiving PostMaster messages, containing the SDL signals

These two levels of communication are described further below.

Transferring SDL Signals

A simulator communicates with the world outside by sending and receiving SDL signals to/from its environment. For another application to communicate with the simulator, it must also be able to interpret those SDL signals, and to send and receive them. This includes mapping the information contained in the SDL signal (name and parameters) to components and actions in the UI, e.g. invoking a command or changing the contents of an output field.

To ensure successful communication with an SDL simulator, the SDL signal interface to the environment should be designed with regard to the connected applications. Decisions made when designing a UI can influence the design of the simulator interface, and vice versa. It is important to have a clearly defined signal interface to the applications that will communicate with the simulator.

Transferring PostMaster Messages

The PostMaster communicates with different tools by sending messages of a defined format. The SDL signals must therefore be transformed to PostMaster messages before they can be transferred between the tools. A few predefined PostMaster messages are available for the purpose of handling SDL signals.

Each tool designed to communicate by using SDL signals must have an interface to the PostMaster that handles the transformation to and from an appropriate message.

In the case of an SDL simulator, this interface is generated automatically. To invoke the transformation, so that SDL signals to and from the environment are transferred using the PostMaster, the monitor command Start-SDL-Env is to be used.

For other tools, the interface to the PostMaster must be implemented separately. The interface must use functions described later in this section to connect to the PostMaster, and to send and receive PostMaster messages containing SDL signals. This includes packing the information contained in the SDL signal (name and parameters) so that it can be sent using a PostMaster message, and unpacking the same information of a received message. See *"Input and Output of Data Types" on page 2137 in chapter 49, The SDL Simulator* for more information on suitable data formats.

Example of Use (UNIX only)

This section describes an example of how to connect a user interface (UI) to an existing SDL simulator. The simulated system used in the example is the well-known Demon game, described in "The Demon Game" on page 41 in chapter 3, *Tutorial: The Editors and the Analyzer, in the SDL Suite 6.2 Getting Started*. All necessary code for the example is provided with the release.

The DemonGame simulator is connected through the PostMaster to a control program, consisting of two parts; an interface to the PostMaster and a user interface (see Figure 162).

The PostMaster interface establishes a connection to the PostMaster and communicates with the DemonGame simulator. Messages are sent via the PostMaster to the simulator where they are seen as SDL signals coming from the environment. Correspondingly, SDL signals to the en-

vironment are sent via the PostMaster as messages back to the PostMaster interface.

The UI facilitates sending and receiving of the SDL signals sent to and from the environment in the Demon game. A command-based UI (written in C) is implemented. However, the ideas are general and could be used if a graphical user interface is to be used. The UI must be able to forward the SDL signals Newgame, Endgame, Probe and Result, and to present the SDL signals Win, Lose and Score.

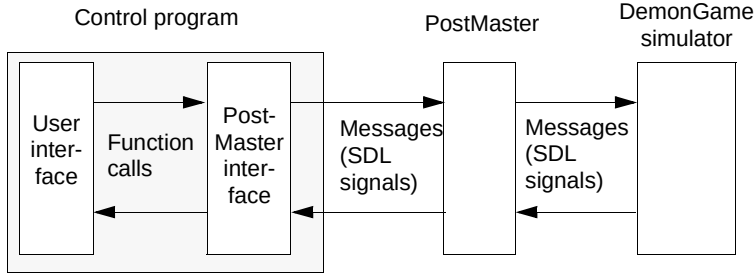

Figure 162: System parts and their communication

Note:

The simulator and the control program have the **same communication interface** to the PostMaster. The simulator's interface to the PostMaster is **generated** automatically by the SDL Suite.

All C functions, C preprocessor symbols and PostMaster messages used in this example are described in "PostMaster Reference" on page 490 in chapter 10, *The PostMaster*.

The PostMaster Interface

All communication with the DemonGame simulator is handled by the interface to the PostMaster, a C program called `env.c`. This program contains the functions `Init`, `Send_to_PM`, `Receive` and `Exit_PM`, all of which must be called by the UI. Please note that the error handling in this program is very simple and does not comply with the design recommendations mentioned above.

Functions in env.c

- `Init` establishes a connection to the PostMaster by calling `SPInit`, identifying this tool as an SDL environment. The function broadcasts the message `SESTARTNOTIFY` to inform other tools that this tool has started. Finally it calls `Init_UI`, a function in the UI.
- `Send_To_PM` takes the name of an SDL signal as parameter and broadcasts this signal as an `SESDLSIGNAL` message to the simulator.
- `Receive` calls `SPRead` to wait for messages from the PostMaster, and acts suitably:
  - If the message contains an SDL signal from the simulator (Score, Lose or Win), it is passed on to the UI by calling `Send_To_UI`, a function in the UI to present the receipt of the signal. It also returns true in these cases.
  - If the message is a request to stop executing (`SESTOP`), it is accepted by calling `Exit_UI`, a function in the UI that in turn calls `Exit_PM`.
  - If the message is `SEOPFAILED`, the PostMaster has failed to handle a message properly. You should then decode the message's parameters by calling
- `Exit_PM` broadcasts the message `SESTOPNOTIFY` and breaks the connection to the PostMaster by calling `SPExit`

Command-Based User Interface

The command-based UI prompts for and recognizes the commands "Newgame", "Endgame", "Probe", and "Result", corresponding to the SDL signals. When any of the SDL signals Score, Win or Lose are received, this information is printed. The command "Exit" exits the program.

The C program for the command-based UI is called `command.c`. It contains the functions:

- `main`
- `GetInput`
- `Appl_Receive`
- `Init_UI`
- `Exit_UI`
- `Send_To_UI`

Functions in command.c

- `main` calls `Init` in the PostMaster interface, prompts for input and examines the reading state of the file descriptors for the keyboard and the PostMaster message port. If input comes from the keyboard, `GetInput` is called and any valid SDL signal is sent by calling `Send_To_PM` in the PostMaster interface. If input comes from the message port, the message is read by calling `Appl_Receive`.
- `GetInput` reads the keyboard and compares the entered string with the available commands. If it is an SDL signal, the function returns true. If "exit" is entered, `Exit_UI` is called.
- `Appl_Receive` simply calls `Receive` in the PostMaster interface. It is included to make the functional interfaces equivalent for both user interfaces.
- `Init_UI` sets a file descriptor for the PostMaster message port and initializes unbuffered terminal output.
- `Exit_UI` calls `Exit_PM` in the PostMaster interface and exits the program.
- `Send_To_UI` prints the name of the received signal and any signal parameters on the terminal.

The figures below show how the different functions and other parts in the DemonGame UI communicate with each other.

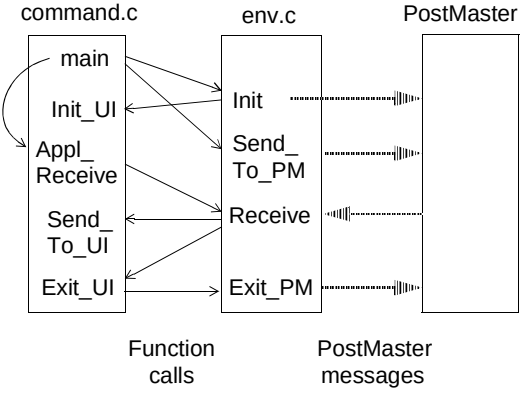

Figure 163: Communication diagram

Running the Example

To be able to build and execute the example program, the software provided on the distribution media must first be properly installed.

Building the Tools

This section describes how to build the tools that will communicate via the PostMaster, i.e. the DemonGame simulator and the UI to the simulator.

The tools are provided in source code form and in binary form for the architecture on which you have purchased the SDL Suite.

The DemonGame Simulator

In the original implementation of DemonGame provided on the installation CD (in the `examples/demongame` directory), a design error has deliberately been introduced into the game definition. See *"Dynamic Errors" on page 153 in chapter 4, Tutorial: The SDL Simulator, in the SDL Suite 6.2 Getting Started* for more information.

For the example program to execute correctly, this error must be corrected. New diagrams for the block GameBlock (`gameblock.sbk`) and the process Main (`main.spr`) are therefore provided, and are to be used to generate a new simulator. You can find the necessary files in the directory named `sdt/examples/simulatorintegration`.

1. Either replace the above diagrams in the original DemonGame implementation, or copy the DemonGame diagrams to a new directory.
2. Re-generate the simulator from the Organizer in the usual way.
3. Change to the directory containing the files `env.c`, `command.c`, and `makefile`.
4. Build the application with the UNIX `make` command. An executable named `command` is now created.

Executing a Session

This section describes how to start the communicating tools and initiate a session.

1. Make sure you have the SDL Suite running, so that an instance of the PostMaster is started.
2. Start the newly generated DemonGame simulator from the Organizer.
3. Give the following commands to the simulator, preferably by including the provided command file `init.sim`.

   `Start-SDL-Env`

   Start handling of the SDL environment. See *"Start-SDL-Env" on page 2178 in chapter 49, The SDL Simulator*.

   `Set-Trace 1`

   Restrict trace output to show only signals sent to and from the SDL environment.

   `Go`

   Start executing the simulation.
4. Start the command-based UI (`command`) from the UNIX prompt.
5. Send SDL signals from the UI by entering the signal name or pushing the corresponding button. (See the description earlier in this section.) Note the trace output in the simulator and the output in the UI.
6. Exit by entering "exit" or using the *File* menu.

Chapter 12 Using the Public Interface

Chapter

13 *The ASN.1 Utilities*

The ASN.1 Utilities perform three main functions:

- **They can translate an ASN.1 module to an SDL package. This makes it possible to use ASN.1 types and values in SDL.**
- **They make it possible for the TTCN Suite to retrieve external ASN.1 types and values that are used in TTCN.**
- **They produce type information for BER coders in SDL.**

> **Note: ASN.1 support in the TTCN Suite**
>
> **The TTCN to C compiler supports only a limited subset of ASN.1. See "TTCN ASN.1 BER Encoding/Decoding" on page 40 in chapter 1, *Compatibility Notes, in the Release Guide* for further details on the restrictions that apply.**

This chapter is the reference manual for the ASN.1 Utilities.

Introduction

This chapter describes the ASN.1 Utilities. It is assumed that the reader is familiar with ASN.1.

Application Areas for the ASN.1 Utilities

The main foreseen applications of the ASN.1 Utilities are the following:

- A lot of telecommunication protocols and services are defined using ASN.1. The ASN.1 Utilities make it easier to specify and implement these with SDL.
- The ASN.1 Utilities enable the SDL Suite and the TTCN Suite to share common data types by specifying these in a separate ASN.1 module.
- The ASN.1 Utilities generate type information for BER encoding/decoding for the SDL Suite.

Overview of the ASN.1 Utilities

The ASN.1 Utilities support the following main functions:

1. Perform syntactic and semantic analysis of ASN.1 modules.
2. Generate SDL code from ASN.1 modules.
3. Extract the ASN.1 types and values which are referred in the TTCN Suite.
4. Generate type information for BER encoding and decoding for the SDL Suite.

For further information about BER encoding and decoding, see chapter 58, *ASN.1 Encoding and De-coding in the SDL Suite, in the User´s Manual*.

In normal cases, the ASN.1 Utilities are completely hidden for the user by the SDL Analyzer and the TTCN Analyzer.

From the user's point of view, an ASN.1 module is very similar to an SDL package: ASN.1 data types can be defined in a module, and then be used within SDL, using operators that are defined in ITU Recommendation Z.105. When an SDL system containing ASN.1 modules is

analyzed, the Analyzer will order the ASN.1 Utilities to translate these modules into corresponding SDL packages.

In the TTCN Suite, indirect use of the ASN.1 Utilities is made by the ASN.1-by-reference table. When such a table is analyzed, the TTCN Suite orders the ASN.1 Utilities to extract the ASN.1 types and values in a specified ASN.1 module. For more information about this functionality, see "ASN.1 External Type/Value References" on page 1197 in chapter 26, *Analyzing TTCN Documents (on UNIX)*.

Using the ASN.1 Utilities

The ASN.1 Utilities are implemented in the executable `asn1util`. `asn1util` can be used in two ways:

1. Stand-alone from the organizer (command-line interface).
2. Via the PostMaster

Command-Line Interface

Usage: `asn1util [options] { <file> [options] }*`

Option	Meaning
`-h`	display a help message
`-v`	display version
`-q`	be quiet, suppress some output messages
`-c`	generate encode/decode type information for the SDL Suite and asn1_cfg.h configuration file
`-g`	generate coder information for TTCN Suite
`-B`	set BER as default encoding
`-P`	set PER as default encoding
`-N <name>`	set <name> as default encoding
`-m`	include module name in encode/decode type nodes and macros

Option	Meaning
`-n <name>`	use <name> for the name of the interface (*.ifc) files
`-S <config>`	use <config> for type names configuration in (*.ifc) files
`-s <file>`	generate SDL output in `<file>`
`-a`	append the output to an existing file instead of creating a new file
`-b`	generate SDL body only, i.e. do not generate package headings (makes it possible to import generated SDL with #INCLUDE)
`-r`	generate references (#SDTREF) to source file
`-e`	generate all operators for the SDL enumerated type as listed in Z.105. Default is to emit some of the operators in Z.105
`-O`	generate values for SDL Make operator with optional and default support
`-u <package>`	add “use <package>;“ to all generated SDL packages
`-J <name> <files>`	Join all ASN.1 modules from <files> into one SDL package <name> (see Example 32 on page 703)
`-K <file>`	Perform substitution for keywords listed in <file> (see “Keywords substitution” on page 705)
`-i <file>`	generate TTCN output to <file>
`-l <file>`	take command line from <file>
`-post`	wait for commands via the PostMaster (see “PostMaster Interface” on page 704)
`-T<dir>`	put generated code in directory `<dir>`

Example 30 ----------

```
asn1util -r -s myfile.pr -c myfile.asn
(myfile.asn contains ASN.1 module MyModule)
```

The command in the example translates the module MyModule in file myfile.asn to an SDL package MyModule in file 'myfile.pr'. The generated package will contain backward references to the source file 'myfile.asn'. Encode/decode type nodes are generated in C-source file 'MyModule_asn1coder.c' and C-header file 'MyModule_asn1coder.h'. A configuration file “asn1_cfg.”' with compile switches for coder related files is generated.

Example 31 ----------

```
asn1util AsnModule1.asn AsnModule2.asn
```

If no options are specified, then asn1util only performs syntactic and global semantic analysis for AsnModule1.asn and AsnModule2.asn, no output is generated.

If no input file is specified, then asn1util does nothing except showing help or version number if correspondent options are specified.

Example 32 Joining modules ----------

```
asn1util -J Join-Module -s my.pr my1.asn my2.asn
```

The ASN.1 modules from the files my1.asn and my2.asn will be joined together in the SDL package Join_Module. Name clashes may occur if the same name is available in different ASN.1 modules the filed are joined. These problems are resolved according to a set of name clash resolving rules, see “Joining modules” on page 708.

Configuration file generation

For the `-c` option encode and decode type information is generated to C-files. Also asn1util performs the analysis of ASN.1 types and some features used in the specification and generates file `asn1_cfg.h`.

This file contains compile switches that are referenced from inside the coders code. When `asn1_cfg.h` is used by the build process the preprocessor automatically throws away useless parts of the code from encod-

ing and decoding related files. This helps to reduce the code size and improve the performance of encoding and decoding procedures.

For example, if the ASN.1 file does not contain OCTET STRING and SET OF types in the module, the following definitions

```
#ifdef CODER_AUTOMATIC_CONFIG
#define CODER_NOUSE_OCTET_STRING
#define CODER_NOUSE_SET_OF
#endif
```

will be included in the configuration file.

This feature can be turned on by the `CODER_AUTOMATIC_CONFIG` compile switch. For more information about available compile switches for the configuration see "Encoding configuration" on page 2894 in chapter 58, *ASN.1 Encoding and De-coding in the SDL Suite*.

PostMaster Interface

The ASN.1 Utilities can also be invoked via the PostMaster. An example of this is when an SDL system that uses ASN.1 modules is analyzed. The Analyzer will then order the ASN.1 Utilities, via the PostMaster, to perform a translation of the ASN.1 modules to SDL packages. For a complete description of the PostMaster, see chapter 10, *The PostMaster*.

On UNIX, the PostMaster communication may also be invoked by starting `asn1util` with the `-post` command-line option. `asn1util` will then wait for commands sent to it from the PostMaster.

Translation of ASN.1 to SDL

This section describes the detailed translation rules from ASN.1 to SDL that are implemented in the ASN.1 Utilities. The translation rules all conform to Z.105, except for the cases described in "Restrictions to Z.105" on page 15 in chapter 1, *Compatibility Notes, in the Release Guide*.

General

- Case sensitivity is according to Z.105, i.e. ASN.1 names are converted directly to SDL names. This implies that in rare cases, correct ASN.1 modules may cause name conflicts when used in SDL.

Note:

Since named numbers, named bits, and integer values are all mapped to integer synonyms, the same name should not be used more than once, because this will lead to name conflicts in SDL.

- '-' (dash) in ASN.1 names is transformed to '_' (underscore), e.g. `long-name` in ASN.1 is transformed to `long_name` in SDL.
- In accordance with Z.105, tag information is ignored in the translation to SDL.
- As SDL does not have "in-line types", one ASN.1 type may be mapped to more than one SDL type. The generated in-line types get dummy names.
- External type/value references are mapped to qualifiers. For example `A.a` is mapped to `<<package A>> a`. Also a use clause (`use A;`) is generated.

Keywords substitution

ASN.1 generators can be configured to be sensitive to a certain number of identifiers. There is a special text file named 'asn1util_kwd.txt' that contains a list of identifiers and a list of their substitution during mapping. By default this file is used to configure target languages keywords substitution. It can be edited to get another functionality or another set of keywords to be replaced.

'asn1util_kwd.txt' should contain pairs of identifiers where the first one is the identifier from original ASN.1 specification that will be replaced by the second identifier during generation. 'asn1util_kwd.txt' should conform to the following syntax:

Example 33 Configuration file syntax

```
<identifier1>   <identifier1 substitution>
<identifier2>   <identifier2 substitution>
                ...
<identifierN>   <identifierN substitution>
```

ASN.1 Utility reads the first configuration file it finds. It searches for the 'asn1util_kwd.txt' file first in the current folder, then in the home folder and finally in the installation. If a configuration file named 'asn1util_kwd.txt' is put in the home folder or in the current working

folder, it will override the default configuration file from the installation. The configuration file to be used can also be specified in the Analyze dialog or from the command line with the '-K' option (see "Command-Line Interface" on page 701).

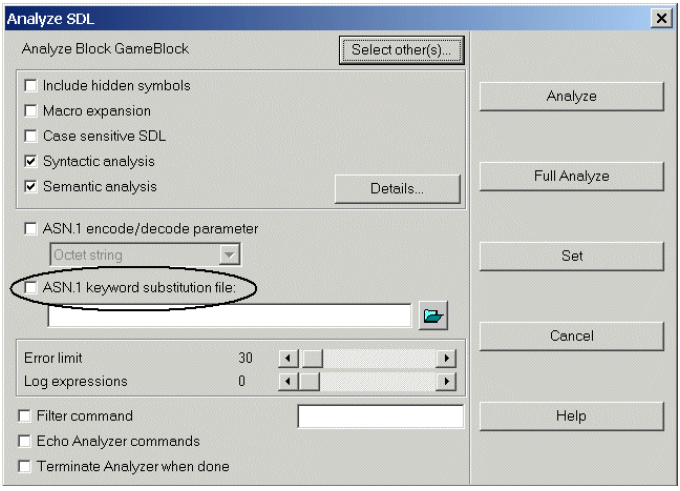

Figure 164: Keywords substitution

'asn1util_kwd.txt' is always present in the installation and it is configured to replace keywords from SDL, TTCN, C and C++ languages: the ASN.1 identifier `name`, that is a keyword in SDL, TTCN or C++, is replaced by `name_SDL_KEYWORD`, `name_TTCN_KEYWORD` or `name_CPP_KEYWORD` to avoid syntax errors in the target languages (see "Appendix A: List of recognized keywords" on page 759). If an original ASN.1 identifier has been modified, a warning message is reported. See "ERROR 2077 ASN.1 identifier #1 is a keyword, it will be replaced by #2" on page 758).

Note: Keywords recognition

ASN.1 in case-sensitive language and target language keywords are also recognized in case-sensitive mode. If generated SDL is analyzed in case-insensitive mode, there could still be keyword problems left. For example, ASN.1 contains the type named `Start` and it will not be recognized to be an SDL keyword, because the keyword `start` will be compared, but in case-insensitive mode `Start` is still a keyword in SDL, which will result in syntax errors.

Example 34 Keywords default substitution ––––––––––––––––––––

For these ASN.1 definitions:

```
CASE ::= ENUMERATED { upper, lower }

T ::= SEQUENCE {
        int INTEGER,
        explicit BOOLEAN,
        case     CASE,
        signal   INTEGER
}

value1 T ::= {
        int 5,
        explicit TRUE,
        case lower,
        signal 27 }
```

With default keywords substitution file the following SDL is generated:

```
newtype CASE_TTCN_KEYWORD
  literals upper,lower
  operators
    ordering;
endnewtype;

newtype T struct
  int_CPP_KEYWORD  Integer;
  explicit_CPP_KEYWORD  Boolean;
  case_CPP_KEYWORD  CASE_TTCN_KEYWORD;
  signal_SDL_KEYWORD  Integer;
endnewtype;

synonym value1 T = (. 5, true, lower, 27 .);
```

––

A configuration file allows the user to control the set of keywords to be replaced. Removing lines with TTCN keywords, for example, will

switch off TTCN keywords sensitivity. Providing an empty configuration file will result in switching off keywords substitution completely.

Module

- An ASN.1 module is translated to an SDL package as specified in Z.105. The `DefinitiveIdentifier` (object identifier after module name) is ignored. The tag default is also ignored.
- `EXPORTS` is mapped to a corresponding `interface`-clause.
- `IMPORTS` is mapped to a corresponding package reference clause. The `AssignedIdentifier` (object identifier after module name) is ignored.

> **Note:**
>
> **On UNIX**, the `-b` option disables generation of package/endpackage, interface and use clauses. Files that have been generated this way can be included in SDL with the #INCLUDE directive, see *"Including PR Files" on page 2506 in chapter 54, The SDL Analyzer*.

Example 35 ----------

```
MyModule DEFINITIONS ::= BEGIN

EXPORTS A, b, C;
IMPORTS X, Y, z FROM SomeModule { iso 3 0 8 }
...
END
```

is mapped to

```
package MyModule;
interface newtype A, synonym b, newtype C;
use SomeModule / newtype X, newtype Y, synonym z;
...
endpackage;
```

Joining modules

Mapping for ASN.1 original module structure can be changed by applying joining module functionality. Several ASN.1 modules can be generated into one SDL package, if ASN.1 modules are arranged into groups in the Organizer. Joining modules can also be controlled from the command line (see "Command-Line Interface" on page 701).

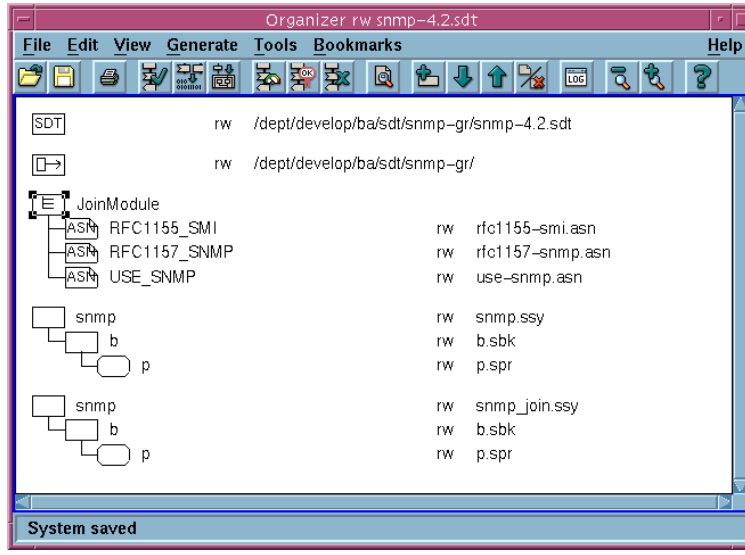

Figure 165: Joining modules

Joining means throwing away all import/export clauses and module headers and generating all module bodies into one big package with the name specified in the Organizer or command line interface.

When joining definitions from several ASN.1 modules into one SDL package, names in the resulting SDL package change according to the following rules:

- Clashed names are prefixed by the original ASN.1 module name
- Package names in the external references are replaced by the join package name

Example 36 ----------

```
M1
DEFINITIONS ::=
BEGIN

IMPORTS S2 FROM M2;

T ::= SET OF SEQUENCE { a S2 }
S1 ::= IA5String
```

```
END

M2
DEFINITIONS ::=
BEGIN

T ::= SEQUENCE OF SEQUENCE OF M1.S1
S2 ::= BOOLEAN

END
```

without joining applied ASN.1 modules M1 and M2 are mapped to

```
use M2/
  newtype S2;
package M1; /*#ASN.1 'M1'*/

newtype T
   Bag(T_INLINE_0)
endnewtype;

newtype T_INLINE_0 /*#SYNT*/ struct
  a  S2;
endnewtype;

syntype S1 = IA5String endsyntype;

endpackage M1;

package M2; /*#ASN.1 'M2'*/

newtype T
   String (T_INLINE_0, emptystring)
endnewtype;

newtype T_INLINE_0 /*#SYNT*/
   String (<<package M1>>S1, emptystring)
endnewtype;

syntype S2 = Boolean endsyntype;

endpackage M2;
```

with joining to package Join-Package applied ASN.1 modules are mapped to

```
package Join_Package; /*#ASN.1 'Join_Package'*/

newtype M1_T
  Bag(M1_T_INLINE_0)
endnewtype;
newtype M1_T_INLINE_0 /*#SYNT*/ struct
```

```
  a  S2;
endnewtype;
syntype S1 = IA5String endsyntype;

newtype M2_T
   String (M2_T_INLINE_0, emptystring)
endnewtype;
newtype M2_T_INLINE_0 /*#SYNT*/
   String (<<package Join_Package>>S1, emptystring)
endnewtype;
syntype S2 = Boolean endsyntype;

endpackage Join_Package;
```

General Type and Value Assignment

A type assignment is mapped to a newtype or a syntype, depending on the type on the right-hand side of the ‘::=’. Tags are ignored. An ASN.1 value assignment is mapped to a synonym.

Example 37

```
T1 ::= INTEGER
T2 ::= [APPLICATION 28] T1
a BOOLEAN ::= TRUE
```

is mapped to

```
syntype T1 = Integer endsyntype;
syntype T2 = T1 endsyntype;
synonym a Boolean = True;
```

Inline types naming

The ASN.1 language can use type definitions inside composite types, which are called inline types. Inline types are not allowed in SDL. In SDL, only named types can be used in a composite type. Implicit names are assigned to ASN.1 inline types and they are referenced by this name in SDL.

Implicit names for generated SDL have the following syntax: <parent_definition_name>_INLINE_<counter>, where parent_definition_name is either the name of the parent type or the name of the parent value, depending on if inline type exists in type or value assignment construct in ASN.1.

Example 38 ----------

```
T1 ::= SEQUENCE {
        a SET OF INTEGER,
        b CHOICE { x BIT STRING,
                   y OCTET STRING },
        c ENUMERATED { sat, sun } }

For type T the following inline types will be
generated to SDL

newtype T1 struct
  a  T1_INLINE_0;
  b  T1_INLINE_1;
  c  T1_INLINE_2;
endnewtype;

newtype T1_INLINE_0 /*#SYNT*/
   Bag(Integer)
endnewtype;

newtype T1_INLINE_1 /*#SYNT*/ choice
  x  Bit_string;
  y  Octet_string;
endnewtype;

newtype T1_INLINE_2 /*#SYNT*/
  literals sat,sun
  operators
    first: T1_INLINE_2 -> T1_INLINE_2;
    last:  T1_INLINE_2 -> T1_INLINE_2;
    succ:  T1_INLINE_2 -> T1_INLINE_2;
    pred:  T1_INLINE_2 -> T1_INLINE_2;
    num:   T1_INLINE_2 -> Integer;
    ordering;

  <operator definitions>

endnewtype;
```

Example 39 ----------

```
T2 SEQUENCE OF INTEGER ::= { {1,1} | {2,2} }

For T2 the following inline types will be generated
to SDL

newtype T2 /*#SYNT*/
   String (Integer, emptystring)
   constants ((. 1, 1 .)), ((. 2, 2 .))
endnewtype;
```

Example 40

```
val BIT STRING ( SIZE(3) ) ::= '101'B

synonym val val_INLINE_0 = bitstr('101');

syntype val_INLINE_0 = Bit_string constants size (3)
endsyntype;
```

Note:

SDL inline names can change if you change within the parent type or value in the ASN.1 specification, the counter can differ. If these names are used within an SDL system, then you must update the SDL system.

Boolean, NULL, and Real

`BOOLEAN`, `NULL` and REAL are mapped to the corresponding SDL types. Value notations for these types are mapped as follows

ASN.1 type	ASN.1 value	Corresponding SDL value
ANY		not supported (conform Z.105)
BOOLEAN	TRUE FALSE	True False
NULL	NULL	NULL
REAL	0 PLUS-INFINITY MINUS-INFINITY { mantissa 31416, base 10, exponent -4 }	0.0 PLUS_INFINITY MINUS_INFINITY 3.1416

If a REAL value has an exponent bigger than 1000 and if the mantissa is not zero, then it is mapped to PLUS_INFINITY or MINUS_INFINITY. If a REAL value has an exponent less than -1000, then it is mapped to 0.

Bit String

BIT STRING is mapped to the Z.105-specific type Bit_string. Named bits are mapped to integer synonyms. Values for bit strings are mapped to hexstr/bitstr expressions.

Example 41 ----------

```
B ::= BIT STRING { bit0(0), bit23(23) }

b1 BIT STRING ::= '011 1110'B
b2 BIT STRING ::= '3AFC'H
```

is mapped to

```
syntype B = Bit_string endsyntype;
synonym bit0 Integer = 0;
synonym bit23 Integer = 23;

synonym b1 Bit_string = bitstr('0110 1110');
synonym b2 Bit_string = hexstr('3AFC');
```

Note:

Bit_string, as opposed to most other string types in SDL, has indices starting with 0!

Type Bit is a Z.105 specific type with literals 0 and 1, and with boolean operators.

Available operators:

```
bitstr    : Charstring             -> Bit_string;
     /* converts a Charstring consisting of '0' and
        '1'-s to a Bit_string */
hexstr    : Charstring             -> bit_string;
     /* converts a Charstring consisting of
        hexadecimal characters to a bit_string */
"not"     : Bit_string             -> Bit_string;
"and"     : Bit_string, Bit_string -> Bit_string;
"or"      : Bit_string, Bit_string -> Bit_string;
"xor"     : Bit_string, Bit_string -> Bit_string;
"=>"      : Bit_string, Bit_string -> Bit_string;
     /* bitwise logical operators */
mkstring  : Bit                    -> Bit_string;
length    : Bit_string             -> Integer;
first     : Bit_string             -> Bit;
last      : Bit_string             -> Bit;
"//"      : Bit_string, Bit_string -> Bit_string;
extract   : Bit_string, Integer    -> Bit;
modify!   : Bit_string, Integer, Bit-> Bit_string;
substring : Bit_string, Integer, Integer ->
```

```
                                                Bit_string;
        /* normal String operators, except that index
           starts with 0;
           see also "Sequence of Types" on page 720 */
```

Character Strings

`PrintableString`, `NumericString`, `VisibleString`, and `IA5String` (i.e. all ASN.1 character string types with character sets that are a subset of ASCII) are mapped to syntypes of SDL `Charstring`. Values for these strings are mapped to corresponding `Charstring` synonyms in SDL.

The same operators as for `Charstring` are available for these types, and values of these types can be assigned freely to each other without need for conversion operators.

For example, in SDL an `IA5String` value can be assigned to a `NumericString` variable (given that the `IA5String` only contains numeric characters).

Choice Types

A `CHOICE` type is mapped to the choice-construct that is described in more detail in "Choice" on page 2670 in chapter 56, *The Cadvanced/Cbasic SDL to C Compiler*.

Example 42 ----------

```
C ::= CHOICE {
        a INTEGER,
        b BOOLEAN}

c C ::= a:7
```

is mapped to

```
newtype C choice
   a Integer;
   b Boolean;
endnewtype;

synonym c C = a:7
```

The operators that are available for a `CHOICE` type are (assuming that `C` is defined as in Example 42 above):

```
aextract!       : C -> Integer;
```

```
     /* e.g. c!a returns 7 */
bextract!       : C -> Boolean;
     /* but c!b gives dynamic error! */
amake!          : Integer -> C;
bmake!          : Boolean -> C;
     /* build choice value, e.g. in SDL
        it is possible to write b:True */
amodify!        : C, Integer -> C;
     /* e.g. var!a := -5 */
bmodify!        : C, Boolean -> C;
presentextract! : C -> xxx;
     /* returns the selected field.
        xxx is an anonymous type with values a and
b.
        E.g. c!present gives a */
```

Enumerated Types

An ENUMERATED type is mapped to a newtype with a set of literals plus some operators. By default only ordering operators are generated, use command line option -e to get the rest. The list of literals that is generated is reordered in accordance with the associated integer values.

Example 43 ----------

```
N ::= ENUMERATED { yellow(5), red(0), blue(6) }
```

is mapped to (only signature of operators shown)

```
newtype N
  literals red, yellow, blue
  /* note that the literals have been reordered! */
operators
   ordering;
   first: N -> N;
   last: N -> N;
   succ: N -> N;
   pred: N -> N;
   num: N -> Integer;
 endnewtype,
```

The operators that are available for an ENUMERATED type are (assuming that N is defined as in Example 43 above):

```
num : N -> Integer;
     /* num(yellow)=5, num(red)=0, num(blue)=6 */
"<" : N, N -> Boolean;
"<=": N, N -> Boolean;
">" : N, N -> Boolean;
">=": N, N -> Boolean;
    /* comparison based on num, i.e. red < yellow */
```

```
pred: N -> N;
succ: N -> N;
     /* predecessor/successor based on num, i.e.
        succ(red)=yellow, succ(yellow)=blue,
        pred(red) gives a dynamic error */
first: N -> N;
last : N -> N;
     /* first/last element based on num, i.e.
        first(red)=red, last(red)=blue */
```

Integer

`INTEGER` is mapped to the SDL `Integer` type, and ASN.1 integer values are mapped to corresponding SDL values.

Named numbers are mapped to synonyms.

Example 44 ----------

```
A ::= INTEGER { a(5), b(7) }
```

is mapped to

```
syntype A = Integer endsyntype;
synonym a Integer = 5;
synonym b Integer = 7;
```

Object Identifier

`OBJECT IDENTIFIER` is mapped to the Z.105-specific type `Object_Identifier`. The normal String operators are available for `Object_Identifier`, listed also in "Sequence of Types" on page 720. Indices start as usual with 1.

Octet String

OCTET STRING is mapped to the Z.105-specific type Octet_string. Octet_string is based on type Octet. This type is further described in "SDL Predefined Types" on page 2658 in chapter 56, *The Cadvanced/Cbasic SDL to C Compiler*. The mapping for the octet string value notation to SDL is identical to bit strings, see "Bit String" on page 714.

> **Note:**
>
> Octet_string, has indices starting with 1.

Operators available:

```
bitstr      : Charstring       -> Octet_string;
hexstr      : Charstring       -> Octet_string;
     /* conversion from Charstring to Octet_string,
        see also "Bit String" on page 714*/
bit_string  : Octet_string     -> Bit_string;
octet_string: Bit_string       -> Octet_string;
     /* conversion operators
        Octet_string <-> Bit_string */
mkstring    : Octet            -> Octet_string;
length      : Octet_string     -> Integer;
first       : Octet_string     -> Octet;
last        : Octet_string     -> Octet;
"//"        : Octet_string, Octet_string ->
                                    Octet_string;
extract!    : Octet_string, Integer -> Octet;
modify!     : Octet_string, Integer, Octet ->
                                    Octet_string;
substring   : Octet_string, Integer, Integer ->
                                    Octet_string;
     /* normal String operators, see also
        "Sequence of Types" on page 720 */
```

Sequence/Set Types

SEQUENCE and SET are both mapped to SDL *struct*. From an SDL point of view there is no difference between SEQUENCE and SET. In order to support optional and default components, SDL has been extended with corresponding concepts.

> **Note:**
>
> Optional and default fields in *struct* are both non-standardized extensions to SDL.

Values are mapped to the "(. ... .)" construct (= `Make!` operator). Values for optional and default components are not supported. Instead, SDL tasks should be used to assign optional and default components.

Example 45 ----------

```
S ::= SEQUENCE {
        a INTEGER OPTIONAL,
        b BOOLEAN,
        c IA5String DEFAULT "xyz" }

s S ::= { b TRUE }
```

is mapped to

```
newtype S struct
   a Integer optional;
   b Boolean;
   c IA5String := 'xyz';
endnewtype;

synonym s S = (. True .);
```

The operators that are available for a `SEQUENCE` or `SET` type are (assuming that `S` is defined as in Example 45 above):

```
make!    : Boolean -> S;
     /* builds a value for S */
aextract!: S -> Integer;
bextract!: S -> Boolean;
cextract!: S -> IA5String;
   /* Extract operators. Note that aextract! gives
      dynamic error if the field has not been set */
amodify! : S, Integer -> S;
bmodify! : S, Boolean -> S;
cmodify! : S, IA5String -> S;
     /* Modify operators change one component
        in a Sequence/Set */
apresent : S -> Boolean;
     /* gives True if component a has been assigned
        a value, e.g. aPresent(s) = False */
```

Sequence of Types

SEQUENCE OF is mapped to the String generator. Values are mapped to corresponding synonyms.

Example 46 ----------

```
S ::= SEQUENCE OF INTEGER
s1 S ::= { 3, 2, 5 }
s2 S ::= {}
```

is mapped to

```
newtype S
   String (Integer, Emptystring)
endnewtype;

synonym s1 S = (. 3, 2, 5 .);
synonym s2 S = (. .);
```

The normal String operators are available for Sequence types. Indices start at 1.

The operators that are available for a SEQUENCE OF type are (assuming that S is defined as in Example 46 above):

```
mkstring  : Integer             -> S;
     /* make a sequence of one item */
length    : S                   -> Integer;
     /* returns number of elements in sequence */
first     : S                   -> Integer;
     /* returns first element in sequence */
last      : S                   -> Integer;
     /* returns last element in sequence
"//"      : S, S                -> S;
     /* returns concatenation of two sequences */
extract!  : S, Integer          -> Integer;
     /* returns the indexed element */
modify!   : S, Integer, Integer -> S;
     /* modify the indexed element */
substring : S, Integer, Integer -> S;
     /* Substring(S, i, l) returns substring of S
        of length l, starting at index i */
make!     : * Integer           -> S;
      /* adds the included elements to the string,
       * corresponds to (. .) */
append    : in/out S, Integer;
      /* appends one element to the string */
```

Set of Types

`SET OF` is mapped to the Z.105 specific `Bag` generator. For a more complete description of the Bag generator, see *"Bag" on page 2673 in chapter 56, The Cadvanced/Cbasic SDL to C Compiler*.

Example 47 ----------

```
S ::= SET OF INTEGER
s1 S ::= { 2, 2, 5 }
s2 S ::= {}
```

is mapped to

```
newtype S
   Bag (Integer)
endnewtype;

synonym s1 S = (. 2, 2, 5 .);
synonym s2 S = (. .);
```

The operators that are available for a `SET OF` type are (assuming that `S` is defined as in Example 47 above):

```
incl     : Integer, S    -> S;
     /* add an element to the bag */
del      : Integer, S    -> S;
     /* delete one element */
incl     : Integer, in/out S;
del      : Integer, in/out S;
length   : S              -> Integer;
     /* returns number of elements */
take     : S              -> Integer;
     /* return some element from the bag */
take     : S,   Integer   -> Integer;
     /* return the indexed element in the bag */
makebag  : Integer        -> S;
     /* build a bag of one element */
"in"     : Integer, S     -> Boolean;
     /* gives true if the element is in the bag */
"<"      : S, S           -> Boolean;
">"      : S, S           -> Boolean;
"<="     : S, S           -> Boolean;
">="     : S, S           -> Boolean;
     /* subset/superset comparison operators */
"and"    : S, S           -> S;
"or"     : S, S           -> S;
     /* intersection/union operators */
make!    : * Integer      -> S;
     /* adds the included elements to the bag,
      * corresponds to (. .) */
```

Useful Types

The types `GeneralizedTime` and `UTCTime` have been defined in terms of ASN.1 as specified in X.680. It follows from their definition in X.680, together with the information about the translation rules given in this chapter, which operators are available in SDL for these types.

Constrained Types

Constrained types are mapped to sdl syntypes of the associated parent sort. Value constraints are mapped to sdl range condition.

When specifying ASN.1 value constraints, several constructs can be used that are not supported in the SDL Suite, such as ALL EXCEPT,INCLUDES <subtype> and value range with MIN or MAX endpoint. Possible values for such a type are computed and mapped to syntype with range condition represented by a sequence of open and closed ranges.

Example 48 ----------

```
T  ::= INTEGER ( (1..10) EXCEPT 8 )

T1 ::= INTEGER ( INCLUDES T EXCEPT (3..<6) )
```

is mapped to

```
syntype T = Integer
            constants 9 : 10, 1 : 7
endsyntype;

syntype T1 = Integer
             constants 9 : 10, 6 : 7, 1 : 2
endsyntype;
```

“COMPONENTS OF” and “WITH COMPONENT” constraints are mapped by using extra inline types. If the present constraint is applied to the parent type, then the new type is generated excluding fields marked as ABSENT and including fields marked as PRESENT.

Example 49 ----------

```
T  ::= SEQUENCE {
         a INTEGER,
         b IA5String
}

T1 ::=  T ( WITH COMPONENTS {
              a (-5..5),
```

```
                b (SIZE (7))
} )
```

is mapped to

```
newtype T struct
    a  Integer;
    b  IA5String;
endnewtype;

newtype T1 struct
    a  T1_INLINE_0;
    b  T1_INLINE_1;
endnewtype;

syntype T1_INLINE_0 = Integer constants -5 : 5
endsyntype;

syntype T1_INLINE_1 = IA5String constants size(7)
endsyntype;
```

Example 50 ----------

```
T  ::= SET OF BIT STRING

T1 ::= T ( WITH COMPONENT (SIZE (5)) )
```

is mapped to

```
newtype T
    Bag(Bit_string)
endnewtype;

syntype T1 = T1_INLINE_0 endsyntype;

newtype T1_INLINE_0 /*#SYNT*/
    Bag(T1_INLINE_1)
endnewtype;

syntype T1_INLINE_1 = Bit_string
    constants size (5)
endsyntype;
```

Example 51 ----------

```
T ::= SET {
       a INTEGER OPTIONAL,
       b REAL OPTIONAL
}
```

```
T1 ::= T ( WITH COMPONENTS {
             a (0..<MAX) PRESENT,
             b ABSENT
} )
```

is mapped to

```
newtype T struct
   a  Integer  optional;
   b  Real  optional;
endnewtype;

newtype T1 struct
    a  T1_INLINE_0;
endnewtype;

syntype T1_INLINE_0 = Integer constants >=0
endsyntype;
```

Note:

According to ASN.1, the types T and T1 are compatible, because they are derived from each other. In SDL these are different types and values of type T can not be assigned to type T1.

ASN.1 SET OF and SEQUENCE OF types with SIZE or single value constraints are mapped to one SDL type with constraint without introducing any extra inline types.

Example 52 ----------

```
T1 ::= SEQUENCE SIZE (5..15) OF INTEGER

T2 ::= SEQUENCE ( { 1 } | {} ) OF INTEGER

T3 ::= SET (SIZE (MIN .. <100) ) OF BOOLEAN

T4 ::= SET (SIZE (15) | { ''B } ) OF BIT STRING
```

is mapped to

```
newtype T1
   String(Integer, emptystring)
   constants size (5 : 15)
endnewtype;

newtype T2
   String(Integer, emptystring)
   constants ((. .)), ((. 1 .))
endnewtype;

newtype T3
```

```
   Bag(Boolean)
   constants size (<=99)
endnewtype;

newtype T4
   Bag(Bit_string)
   constants ((. bitstr('') .)), size (15)
endnewtype;
```

Extensibility

Extensibility was introduced in X.680 (1997). In ASN.1 extensibility is represented with extension markers and extension addition groups, that can be specified inside SET, SEQUENCE, CHOICE, ENUMERATED types and constraints.

Extension markers are not visible in SDL translations. All square brackets are ignored and all components from extension addition groups are translated into SDL as individual fields. All required components from extension additions, individual or from extension addition groups are mapped to optional ones.

Example 53

```
S1 ::= SET
{
  x [100] INTEGER,
  ... ,
  [[
     gr11 REAL
  ]],
  t BIT STRING,
  [[
     gr21 BOOLEAN OPTIONAL,
     gr22 SET OF INTEGER
  ]],
  ... ,
  y INTEGER
}
```

is mapped to SDL

```
newtype S1 struct
  x  Integer;
  gr11  Real  optional;
  t  Bit_string optional;
  gr21  Boolean  optional;
  gr22  S1_INLINE_1  optional;
  y  Integer;
```

```
endnewtype;

newtype S1_INLINE_1 /*#SYNT*/
   Bag(Integer)
endnewtype;
```

Note:

SDL translation removes the borders of additional groups and makes all required components optional.The semantics for assigning values to types with additional groups are: either the whole addition group ([[....]]) is absent, or it is all present unless components inside the group are optional. This is not checked in SDL tools but inconsistency will cause errors in ASN.1 encoding.

Extension markers are ignored in constraints. If both root and additional constraints are present, they are translated to the union constraint.

Example 54

```
T1 ::= INTEGER ( 1..10 ^ 2..20, ... , 12 )

is mapped to SDL

syntype T1 = Integer constants 12, 2 : 10
endsyntype;

T2 ::= INTEGER (1 | 3, ... )

is mapped to SDL

syntype T2 = Integer constants 3, 1 endsyntype;
```

Information from Object Classes, Objects and Object Sets

Object classes, object and objects sets are not translated to SDL. Only types and values are translated to SDL, but it is possible in ASN.1 to use information from object classes, objects and object sets when specifying types and values. This information is translated into SDL.

ObjectClassFieldType

ObjectClassFieldType is a reference to object class and a field in that class. The translation to SDL depends on the kind of field name used.

An open type is defined if the field name references a type field, a variable type value field or variable type value set field. An open type can be any ASN.1 type. Open types are translated to Octet_string types in SDL.

Example 55 ----------

```
OPERATION ::= CLASS {
   &ArgumentType,
   &arg &ArgumentType
}

T1 ::= SEQUENCE { a OPERATION.&ArgumentType }
```

is translated to SDL

```
newtype T1 struct
  a  T1_INLINE_0;
endnewtype;

syntype T1_INLINE_0 = Octet_string endsyntype;

T2 ::= OPERATION.&arg
```

is translated to SDL

```
syntype T2 = Octet_string endsyntype;
```

If the field name in the class references a fixed type value or fixed type value set fields, then the fixed type is used when translated to SDL.

Example 56 ----------

```
OPERATION ::= CLASS {
      &ValueSet INTEGER
   }

T ::= OPERATION.&ValueSet
```

is translated to SDL

```
syntype T = Integer endsyntype;
```

ObjectClassFieldType with table constraint (object set constraint)

Table constraint applied to ObjectClassFieldType restricts the set of possible types or values to those specified in a column of the table. A table corresponds to an object set. The columns of the table correspond to the object class fields and the rows correspond to the objects in the set.

If the field name in ObjectClassFieldType is a type field and constrained with a table, then it is translated to a CHOICE type with fields of the types specified in the table column. The names of the fields in the choice are the same as the names of the types in the column but the first letter is changed from upper case to lower case.

Note: Field names

If the type in the field is inline then the name in the field will be an implicitly generated inline name, like t_INLINE_4.

If the field name in ObjectClassFieldType is a fixed type value or a fixed type value set, then this is translated to a constrained type where only values that are specified in the table column are permitted.

If the field name in ObjectClassFieldType is a variable type value or variable type value set field, then this is translated to a CHOICE type with types, that are constrained to have values specified in the corresponding cell in the same row of the table.

Example 57 ––

```
OPERATION ::= CLASS {
       &ArgumentType,
       &operationCode INTEGER UNIQUE,
       &ValueSet INTEGER,
       &ArgSet &ArgumentType
   }
```

The My-Operations object set

Object name	&ArgumentType	&operationCode	&ValueSet	&ArgSet
operationA	INTEGER	1	{1 | 2 | 5 .. 8}	{ 111..444 }

Object name	&ArgumentType	&operationCode	&ValueSet	&ArgSet
operationB	SET OF INTEGER	2	{ 2 .. 8 }	{ {1,2,3} | { 888 } }

```
C1 ::= OPERATION.&ArgumentType ( {My-Operations} )
```

is translated to SDL

```
newtype C1 choice
  integer  Integer;
  c1_INLINE_2  C1_INLINE_1;
endnewtype;

newtype C1_INLINE_1 /*#SYNT*/
   Bag(Integer)
endnewtype;
```

```
C2 ::= OPERATION.&operationCode ( {My-Operations} )
```

is translated to SDL

```
syntype C2 = Integer constants 2, 1 endsyntype;
```

```
C3 ::= OPERATION.&ValueSet ( {My-Operations} )
```

is translated to SDL

```
syntype C3 = Integer constants 2 : 8, 1, 5 : 8, 2
endsyntype;
```

```
C4 ::= OPERATION.&ArgSet ( {My-Operations} )
```

is translated to SDL

```
newtype C4 choice
  c4_INLINE_1  C4_INLINE_1;
  c4_INLINE_1  C4_INLINE_2;
endnewtype;

syntype C4_INLINE_1 = Integer constants 111 : 444
endsyntype;

syntype C4_INLINE_2 /*#SYNT*/
  Bag(Integer)
  constants ((. 888 .)), ((. 1, 2, 3 .))
endsyntype;
```

If an open type is constrained by the table for which all type settings are omitted, then it is translated to SDL Octet_string instead of an empty CHOICE type.

Example 58 ----------

```
MY-CLASS ::= CLASS {
       &id INTEGER,
       &OpenType OPTIONAL
   }
```

The My-Set object set:

Object name	&id	&OpenType
object1	1	-
object2	2	-

```
S ::= SEQUENCE {
        id  MY-CLASS.&id({My-Set}),
        val MY-CLASS.&OpenType({My-Set}{@id})
}
```

is translated to SDL

```
newtype S struct
  id  S_INLINE_0;
  val  S_INLINE_2;
endnewtype;

syntype S_INLINE_0 = Integer constants 2, 1
endsyntype;

syntype S_INLINE_2 = Octet_string endsyntype;
```

TypeFromObject

TypeFromObject is a reference to an object and a type field in that object. This is simply translated to that type in SDL. If the field is optional in the class and not set in the object, then TypeFromObject cannot be translated.

Example 59 ----------

```
OPERATION ::= CLASS {
       &ArgumentType,
```

```
        &ResultType
    }

operationA OPERATION ::= {
      &ArgumentType INTEGER,
       &ResultType BOOLEAN
    }

O1 ::= operationA.&ArgumentType
```

is translated to SDL

```
syntype O1 = Integer endsyntype;

O2 ::= operationA.&ResultType
```

is translated to SDL

```
syntype O2 = Boolean endsyntype;
```

ValueSetFromObject

ValueSetFromObject is a reference to an object and a field with a set of values in that object. This is translated to a constrained type in SDL, allowing only values from the value set.

Example 60 ----------

```
OPERATION ::= CLASS {
        &ValueSet INTEGER
    }

operationA OPERATION ::= {
        &ValueSet { 1 | 2 | 5..8 }
  }

V1 ::= operationA.&ValueSet
```

is translated to SDL

```
syntype V1 = Integer constants 2, 5 : 8, 1
endsyntype;
```

ValueFromObject

ValueFromObject is a reference to an object and a field with a value in that object. This is translated to the same value in SDL.

Example 61 ----------

```
OPERATION ::= CLASS {
      &operationCode INTEGER UNIQUE
   }

operationA OPERATION ::= { &operationCode 1 }

val2 INTEGER ::= operationA.&operationCode
```

is mapped to SDL

```
synonym val2 Integer = 1;
```

CONSTRAINED BY notation

CONSTRAINED BY is treated like a comment and is not translated to SDL.

Parameterization

Wherever a parameterized type or value is used, it is translated to SDL after all dummy references are replaced by the actual parameters. A parameterized value is also translated after all dummy references are replaced by the actual parameters.

Parameterized assignments are ignored when translating to SDL.

Example 62 ----------

```
Container { ElemType, INTEGER : maxelements } ::=
       SET SIZE (0..maxelements ) OF ElemType

Intcontainer ::= Container {INTEGER, 25}
```

is first internally mapped to

```
Intcontainer ::= SET SIZE( 0..25 ) OF INTEGER
```

and then translated to SDL. Container is not translated to SDL.

Support for External ASN.1 in the TTCN Suite

The ASN.1 Utilities are also used by the TTCN Suite if a TTCN test suite contains data types and constraints that are defined in the tables “ASN.1 Type Definitions By Reference” and “ASN.1 Constraints By Reference”. For more information, see “ASN.1 External Type/Value References” on page 1197 in chapter 26, *Analyzing TTCN Documents (on UNIX)*.

Since TTCN is based on the older X.228 standard, while the ASN.1 Utilities are based on the new X.680 standard, users should be careful to use the common subset of X.680 and X.228 if an ASN.1 module is to be used in TTCN. In particular there are a number of differences:

- In `ENUMERATED` types, a value must be supplied for all values. For example:

  ```
  E ::= ENUMERATED { a, b }
  ```

  should be replaced by

  ```
  E ::= ENUMERATED { a(0), b(1) }
  ```

- X.680 offers more possibilities for specifying constraints than X.228 does. X.228 does not have the keywords `ALL`, `EXCEPT`, `UNION`, and `INTERSECTION`.

- For ASN.1 types that have components (e.g. `SET` or `SEQUENCE`), an identifier must be provided for every component (according to X.680), while in X.228 identifiers can be omitted. For example:

  ```
  S ::= SEQUENCE { INTEGER } -- valid X.228
  ```

  This is invalid according to X.680. The following should be used instead:

  ```
  S ::= SEQUENCE { field1 INTEGER }
  ```

General

- ‘-’ (dash) in ASN.1 names is transformed to ‘_’ (underscore), e.g. `long-name` in ASN.1 is transformed to `long_name` in TTCN.

- In general ASN.1 to TTCN translation look like pretty printing of ASN.1 modules into TTCN tables for most of the constructs, but not

all of them. Some ASN.1 concepts are not supported in TTCN Suite, they have to be modified during TTCN generation:

- Concepts defined in X.681, X.682 and X.683 (see "Information from Object Classes, Objects and Object Sets" on page 740, "CONSTRAINED BY notation" on page 745 and "Parameterization" on page 745)
- automatic tagging (see "Keywords substitution" on page 734)
- COMPONENTS OF Type notation (see "COMPONENTS OF Type notation" on page 737)
- selection types (see "Selection types" on page 738)
- enumerated types without numbers for enum identifiers (see "Enumerated types" on page 738)
- extensibility (see "Extensibility" on page 725)

Keywords substitution

ASN.1 generators can be configured to be sensitive to a certain number of identifiers. There is a special text file named 'asn1util_kwd.txt' that contains a list of identifiers and a list of their substitution during mapping. By default this file is used to configure target languages keywords substitution. It can be edited to get another functionality or another set of keywords to be replaced.

'asn1util_kwd.txt' should contain pairs of identifiers where the first one is the identifier from the original ASN.1 specification that will be replaced by the second identifier during generation. 'asn1util_kwd.txt' should conform to the following syntax:

Example 63 Configuration file syntax ----------

```
<identifier1>   <identifier1 substitution>
<identifier2>   <identifier2 substitution>
                ...
<identifierN>   <identifierN substitution>
```

ASN.1 Utility reads the first configuration file it finds. It searches for 'asn1util_kwd.txt' file first in the current folder, then in the home folder and finally in the installation. If a configuration file named 'asn1util_kwd.txt' is put in the home folder or in the current working

folder, it will override the default configuration file from the installation. The configuration file to be used can also be specified in the command line with the '-K' option (see "Command-Line Interface" on page 701), for example,

Example 64 Configuration file specification ––––––––––––––––––––

```
asn1util -K my_config.txt -i File.ttcn File.asn
```

––

'asn1util_kwd.txt' is always present in the installation and it is configured to replace keywords from the SDL, TTCN, C and C++ languages: the ASN.1 identifier `name`, that is a keyword in SDL, TTCN or C++, is replaced by `name_SDL_KEYWORD`, `name_TTCN_KEYWORD` or `name_CPP_KEYWORD` to avoid syntax errors in the target languages (see "Appendix A: List of recognized keywords" on page 759). If an original ASN.1 identifier has been modified, a warning message is reported. See "ERROR 2077 ASN.1 identifier #1 is a keyword, it will be replaced by #2" on page 758).

Example 65 Keywords default substitution ––––––––––––––––––––

For these ASN.1 definitions:

```
CASE ::= ENUMERATED { upper, lower }

T ::= SEQUENCE {
        int INTEGER,
        explicit BOOLEAN,
        case     CASE,
        signal   INTEGER
}

value1 T ::= {
        int 5,
        explicit TRUE,
        case lower,
        signal 27 }
```

With default keywords substitution file the following TTCN is generated:

```
CASE_TTCN_KEYWORD ::=
  ENUMERATED {upper(0), lower(1)}

T ::= SEQUENCE {
        int_CPP_KEYWORD INTEGER,
        explicit_CPP_KEYWORD BOOLEAN,
```

```
        case_CPP_KEYWORD CASE_TTCN_KEYWORD,
        signal_SDL_KEYWORD INTEGER
}

value1 T ::= {
  int_CPP_KEYWORD 5,
  explicit_CPP_KEYWORD TRUE,
  case_CPP_KEYWORD lower,
  signal_SDL_KEYWORD 27
}
```

A configuration file allows user to control the set of keywords to be replaced. Removing lines with SDL keywords, for example, will switch off SDL keywords sensitivity. Providing an empty configuration file will result in switching off keywords substitution completely.

Automatic tagging

If 'AUTOMATIC TAGS' is written in the header of an external ASN.1 module, then implicit tags are inserted into SET, SEQUENCE and CHOICE types. During the TTCN generation they are inserted in the type definitions explicitly.

Example 66

```
M1
DEFINITIONS AUTOMATIC TAGS ::=
BEGIN
T ::= SEQUENCE
{
   a INTEGER OPTIONAL,
   b INTEGER DEFAULT 5
}

C ::= CHOICE
  {
    x INTEGER,
    y BOOLEAN,
    z REAL
  }
END

is translated to TTCN

SEQUENCE
{
  a [0] INTEGER OPTIONAL,
  b [1] INTEGER DEFAULT 5
}
```

```
CHOICE
{
  x [0] INTEGER,
  y [1] BOOLEAN,
  z [2] REAL
}
```

COMPONENTS OF Type notation

COMPONENTS OF Type can appear in SET or SEQUENCE field types. Instead of COMPONENTS OF Type a list of components of the referenced type is included, except extension addition components.

Example 67

```
 S1 ::= SEQUENCE
{
  x INTEGER,
  g NULL,
  ... ,
  [[
     y BOOLEAN,
     z BIT STRING
  ]],
  [[
     c IA5String
  ]],
  d SET OF
    INTEGER OPTIONAL,
  ... ,
  f REAL
}

S2 ::= SEQUENCE
 {
   a IA5String,
   COMPONENTS OF S1,
   b OCTET STRING
 }

Type S2 is translated to TTCN

SEQUENCE
{
  a IA5String,
  x INTEGER,
  g NULL,
  f REAL,
  b OCTET STRING
}
```

Selection types

A selection type is mapped to the type it denotes.

Example 68 ----------

```
C ::= CHOICE
 {
   a INTEGER,
   b BOOLEAN
 }

T1 ::= a < C

T1 is translated to TTCN

INTEGER

T2 ::= b < C

T2 is translated to TTCN

BOOLEAN
```

Enumerated types

Enumerated items can be defined using “identifier” notation or “identifier and number” notation. For “identifier” notations, implicit numbers are assigned to the identifiers according to the rules described in X.680 (1997), 19.

For TTCN, all enumeration items are generated with their corresponding numbers using “identifier and number” notation, and they are arranged according to their number values in ascending order in the generated enumeration.

Extension markers are ignored.

Example 69 ----------

```
A ::= ENUMERATED { a, b, c(0), d, e(2) }

is translated to TTCN

ENUMERATED { c(0), a(1), e(2), b(3), d(4) }

B ::= ENUMERATED { a, b(3), ... , c(1) }

is translated to TTCN
```

```
ENUMERATED { a(0), c(1), b(3) }
```

Extensibility

Extensibility was introduced in X.680 (1997). In ASN.1 extensibility is represented with extension markers and extension addition groups, that can be specified inside SET, SEQUENCE, CHOICE, ENUMERATED types and constraints.

Extension markers are not visible in TTCN translation. All square brackets are ignored and all components from extension addition groups are translated into TTCN as individual fields. All required components from extension additions, individual or from extension addition groups, are mapped to optional ones.

Example 70

```
S1 ::= SET
{
  x [100] INTEGER,
  ... ,
  [[
     gr11 REAL
  ]],
  t BIT STRING,
  [[
     gr21 BOOLEAN OPTIONAL,
     gr22 SET OF INTEGER
  ]],
  ... ,
  y INTEGER
}

is translated to TTCN

SET
 {
   x [100] INTEGER,
   gr11 REAL OPTIONAL,
   t BIT STRING OPTIONAL,
   gr21 BOOLEAN OPTIONAL,
   gr22 SET OF INTEGER OPTIONAL,
   y INTEGER
 }
```

Note:

TTCN translation removes the borders of additional groups and makes all required components optional. The semantics for assigning values to types with additional groups is: either the whole addition group ([[....]]) is absent, or it is all present unless components inside the group are optional. This is not checked in TTCN tools but inconsistency will cause errors in ASN.1 encoding.

```
Extension markers are ignored in constraints. If
both root and additional constraints are present,
they are translated to the union constraint.
```

Example 71 ----------

```
T1 ::= INTEGER ( 1..10 ^ 2..20, ... , 12 )

is translated to TTCN

INTEGER (( 1..10 ^ 2..20 ) | ( 12 ) )

T2 ::= INTEGER (1 | 3, ... )

is translated to TTCN

INTEGER (1 | 3 )
```

Information from Object Classes, Objects and Object Sets

Object classes, object and objects sets are not translated to TTCN. Only types and values are translated to TTCN, but it is possible in ASN.1 to use information from object classes, objects and object sets when specifying types and values. This information is translated into TTCN.

ObjectClassFieldType

ObjectClassFieldType is a reference to an object class and a field in that class. The translation to TTCN depends on the kind of field name used.

An open type is defined if the field name references a type field, a variable type value field or variable type value set field. An open type can be any ASN.1 type. Open types are translated to OCTET STRING types in TTCN.

Example 72 ----------

```
OPERATION ::= CLASS {
   &ArgumentType,
   &arg &ArgumentType
}

T1 ::= SEQUENCE { a OPERATION.&ArgumentType }
```

is translated to TTCN

```
SEQUENCE { a  OCTET STRING }

T2 ::= OPERATION.&arg
```

is translated to TTCN

```
OCTET STRING
```

If the field name in the class references a fixed type value or fixed type value set fields, then the fixed type is used when translated to TTCN.

Example 73 ----------

```
OPERATION ::= CLASS {
      &ValueSet INTEGER
   }

T ::= OPERATION.&ValueSet
```

is translated to TTCN

```
INTEGER
```

ObjectClassFieldType with table constraint (object set constraint)

A table constraint applied to ObjectClassFieldType restricts the set of possible types or values to those specified in a column of the table. A table corresponds to an object set. The columns of the table correspond to the object class fields and the rows correspond to the objects in the set.

If the field name in ObjectClassFieldType is a type field and constrained with a table, then it is translated to a CHOICE type with fields of the types specified in the table column. The names of the fields in the choice are the same as the names of the types in the column but the first letter is changed from upper case to lower case.

Note:

If the type in the field is inline then the name in the field will be an implicitly generated inline name, like t_INLINE_4.

If the field name in ObjectClassFieldType is a fixed type value or a fixed type value set, then this is translated to a constrained type where only values that are specified in the table column are permitted.

If the field name in ObjectClassFieldType is a variable type value or variable type value set field, then this is translated to a CHOICE type with types, that are constrained to have values specified in the corresponding cell in the same row of the table.

Example 74 ––

```
OPERATION ::= CLASS {
       &ArgumentType,
       &operationCode INTEGER UNIQUE,
       &ValueSet INTEGER,
       &ArgSet &ArgumentType
   }
```

The My-Operations object set:

Object name	&ArgumentType	&operationCode	&ValueSet	&ArgSet
operationA	INTEGER	1	{1 | 2 | 5 .. 8}	{ 111..444 }
operationB	SET OF INTEGER	2	{ 2 .. 8 }	{ {1,2,3} | { 888 } }

```
C1 ::= OPERATION.&ArgumentType ( {My-Operations} )
```

is translated to TTCN

```
CHOICE {
  integer INTEGER,
  c1_INLINE_2 SET OF INTEGER
}
```

```
C2 ::= OPERATION.&operationCode ( {My-Operations} )
```

is translated to TTCN

```
INTEGER ( 1 | 2 )
```

```
C3 ::= OPERATION.&ValueSet ( {My-Operations} )
```

is translated to TTCN

```
INTEGER ( ( 1 | 2 | 5..8 ) | ( 2..8 ) )
```

```
C4 ::= OPERATION.&ArgSet ( {My-Operations} )
```

is translated to TTCN

```
CHOICE {
  c4_INLINE_1 INTEGER ( (111..444) ),
  c4_INLINE_2 SET OF INTEGER ( ( {1,2,3} | {888} ) )
}
```

If an open type is constrained by the table for which all type settings are omitted, then it is translated to TTCN OCTET STRING instead of an empty CHOICE type.

Example 75 ----------

```
MY-CLASS ::= CLASS {
       &id INTEGER,
       &OpenType OPTIONAL
   }
```

The My-Set object set:

Object name	&id	&OpenType
object1	1	-
object2	2	-

```
S ::= SEQUENCE {
        id  MY-CLASS.&id({My-Set}),
        val MY-CLASS.&OpenType({My-Set}{@id})
}
```

is translated to TTCN

```
SEQUENCE {
  id    INTEGER ( 1 | 2 ),
  val   OCTET STRING
}
```

TypeFromObject

TypeFromObject is a reference to an object and a type field in that object. This is simply translated to the that type in TTCN. If the field is optional in the class and not set in the object, then TypeFromObject cannot be translated.

Example 76 ----------

```
OPERATION ::= CLASS {
       &ArgumentType,
       &ResultType
   }

operationA OPERATION ::= {
      &ArgumentType INTEGER,
       &ResultType BOOLEAN
   }

O1 ::= operationA.&ArgumentType
```

is translated to TTCN

```
INTEGER

O2 ::= operationB.&ResultType
```

is translated to TTCN

```
BOOLEAN
```

ValueSetFromObject

ValueSetFromObject is a reference to an object and a field with a set of values in that object. This is translated to a constrained type in TTCN, allowing only values from the value set.

Example 77 ----------

```
OPERATION ::= CLASS {
       &ValueSet INTEGER
   }

operationA OPERATION ::= {
       &ValueSet { 1 | 2 | 5..8 }
  }

V1 ::= operationA.&ValueSet
```

is translated to TTCN

```
INTEGER ( 1 | 2 | 5..8 )
```

ValueFromObject

ValueFromObject is a reference to an object and a field with a value in that object. This is translated to the same value in TTCN.

Example 78

```
OPERATION ::= CLASS {
      &operationCode INTEGER UNIQUE
   }

operationA OPERATION ::= { &operationCode 1 }

val2 INTEGER ::= operationA.&operationCode
```

is translated to TTCN

```
val2 of type INTEGER equal to 1
```

CONSTRAINED BY notation

CONSTRAINED BY is treated like a comment and is not translated to TTCN.

Parameterization

Wherever a parameterized type or value is used, it is translated to TTCN after all dummy references are replaced by the actual parameters. A parameterized value is also translated after all dummy references are replaced by the actual parameters.

Parameterized assignments are ignored when translating to TTCN.

Example 79

```
Container { ElemType, INTEGER : maxelements } ::=
       SET SIZE (0..maxelements ) OF ElemType

Intcontainer ::= Container {INTEGER, 25}
```

is mapped to TTCN

```
SET SIZE ( 0..25 ) OF INTEGER
```

Error and Warning Messages

This section contains a list of the error and warning messages in the ASN.1 Utilities. Each message has a short explanation and, where applicable, a reference to the appropriate section of the recommendations X.680,X.681,X.682, X.683 or Z.105.

Some messages include a reference to the object that is the source of the diagnostic. These messages adhere to the format adopted in the SDL Suite. See chapter 18, *SDT References* for a reference to this format and for examples.

WARNING 2000 Unknown option '#1'

This warning message indicates that the ASN.1 Utilities were started with an unknown option. See "Command-Line Interface" on page 701 for an overview of the valid options.

WARNING 2001 No #1 specified after '#2' option

This warning message indicates that the ASN.1 Utilities were started with an illegal combination of options. See "Command-Line Interface" on page 701 for an overview of the valid options.

For example,

```
asn1util -s -r MyModule.asn
```

In this case no output file for sdl generation is specified after '-s' option.

ERROR 2002 Too many errors

This error message indicates that the maximum number of errors was reached when analyzing an ASN.1 module. The analysis has been aborted by the ASN.1 Utilities.

ERROR 2003 Multiple #1 paths

This warning message indicates an incorrect usage of the options of the ASN.1 Utilities.

For example,

```
asn1util -Tdir1 -Tdir2 -s MyModule.pr MyModule.asn
```

Multiple target directories provide a warning message

WARNING 2004 Option missing

This warning message indicates that no option is specified after dash.

ERROR 2005 Can not open #1

This error message indicates that an error occurred when the ASN.1 Utilities attempted to open a file. Modify, if necessary, the file protection and try to run the ASN.1 Utilities again. If the error persists, contact IBM Rational Customer Support. Contact information for IBM Rational Customer Support can be found in "How to Contact Customer Support" on page *iv in the Release Guide*.

For example,

```
asn1util -Tdir -i MyModule.ttcn MyModule.asn
```

This command line can cause an error message "Can not open air/MyModule.ttcn" if there is no target directory 'dir' in the catalogue from which asn1util is called.

ERROR 2006 Illegal characters in bstring

This message indicates that an ASN.1 binary string item (used in BIT STRING and OCTET STRING) contains illegal characters. The only characters allowed are `0', `1' and white space characters. (X.680: 9.9)

ERROR 2007 Illegal characters in hstring

This message indicates that an ASN.1 hexadecimal string item (used in BIT STRING and OCTET STRING) contains illegal characters. The only characters allowed are `0'-'9', `A'-'F' and white space characters. (X.680: 9.10)

For example: 'F30C 973D'H is a valid hexadecimal string item.

ERROR 2008 'H' or 'B' expected

This error message indicates that an ASN.1 BIT STRING or OCTET STRING value is not ended with a `B or an `H. (X.680: 9.9 and 9.10).

For example: '0110'B or '1AFC'H are valid values for BIT STRING and OCTET STRING, '01110' is illegal.

ERROR 2009 Unclosed #1 string

This error is reported when there is no closing apostrophe at the end of string

WARNING 2010 Unknown token `#1'

This warning indicates a syntax error in the ASN.1 module.

ERROR 2011 Syntax error

This message indicates a syntax error in the ASN.1 module with syntax from standard X.680-X.683. This could be caused by a misspelling. It could also be caused by X.228 constructs that are not part of X.680.

ERROR 2012 Out of memory

This message indicates that the ASN.1 Utilities ran out of memory. Try to make the ASN.1 module smaller or supply more memory. If the error persists, contact IBM Rational Customer Support. Contact information for IBM Rational Customer Support can be found in "How to Contact Customer Support" on page *iv in the Release Guide*.

WARNING 2013 No semantic support for `#1'

This warning indicates that an ASN.1 construct is used that is not supported by the ASN.1 Utilities. The construct will be ignored by the ASN.1 Utilities.

ERROR 2014 Export-file `#1' corrupt

This message indicates that the export file format of an ASN.1 module was corrupt or unknown. This error should normally not occur. Contact IBM Rational Customer Support. Contact information for IBM Rational Customer Support can be found in "How to Contact Customer Support" on page *iv in the Release Guide*.

ERROR 2015 Old ASN1,#1

This message indicates that an ASN.1 construct of the older X.228 recommendation is used that has been superseded in the X.680 Recommendation.

For example:

```
S ::= SEQUENCE { INTEGER }
```

is old ASN.1. Correct X.680 ASN.1 is:

```
S ::= SEQUENCE { field1 INTEGER }
```

ERROR 2016 Recursive expansion of COMPONENTS OF in type #1

This error message indicates that the ASN.1 type uses directly or indirectly COMPONENTS OF itself.

ERROR 2017 Recursive #1

This message indicates that the ASN.1 construct is recursively defined.

For example: `T1::=T2, T2::=T1; T::=SET OF T`, or v T ::= v

ERROR 2018 Recursive #1 constraint

This error message indicates that type being constrained is recursively used in applied constraint.

For example: `I ::= INTEGER ( 1 .. 10 | INCLUDES I)`

ERROR 2019 Field '#1' should be initialized by #2

This message is reported when you assign wrong kind of value for the field in the object, for example when you try to assign a value for the type field in the object

ERROR 2020 Value for `#1' can not be #2

This error message indicates a semantic error in the ASN.1 module.

For example, `T ::= BIT STRING { a(-1)}` causes the error “Value for 'named bit' can not be negative”

WARNING 2021 Construct `#1' has no mapping in SDL

This warning indicates that an ASN.1 construct is used that can not be mapped to SDL.

For example:

```
S1 SEQUENCE ::= { }
       -- empty SEQUENCE/SET
    s SEQUENCE { a INTEGER OPTIONAL } ::= {}
         -- value for SEQUENCE/SET without components
```

ERROR 2022 Ambiguous reference, symbol `#1' imported more than once

A value is used that is imported more than once. Use an external value reference to specify unambiguously the module of the value that you want to use.

ERROR 2023 Multiple definition of #1

This error message appears, when the same identifier appears more then once on the right side of assignment.

For example, `X ::= INTEGER, X ::= SET OF REAL`

ERROR 2024 Exported symbol #1 not defined

This error message is reported when symbol is exported, but it is neither defined in the module nor imported to it

ERROR 2025 Ambiguous export, symbol #1 is imported more than once

This error message indicates that it is impossible to decide which symbol to export, because two symbols with the name #1 are imported to the module

ERROR 2026 Ambiguous export, symbol #1 is defined and imported

This error message indicates that it is impossible to decide which symbol to export, because symbol #1 is defined in the module and imported to it at the same time

ERROR 2027 Nothing known about module #1

This message appears when module referenced from imports clause does not exist. You should specify all modules from which symbols are imported to the analyzed module in the same command line, otherwise it is impossible to perform global semantic analysis

ERROR 2028 Import from empty module #1

This message appears when importing symbols from a module, that does not contain any definitions

ERROR 2029 Module does not export symbols

This message appears when you are trying to import symbols from module with empty export: “EXPORTS ;”

ERROR 2030 Imported symbol #1 is not exported from module #2

This message appears when symbol #1 is present in imports from module #2 clause, but it is not exported from #2. `"EXPORTS ;"` indicates that nothing is exported, while empty exports clause indicates that all definitions are exported from the module.

ERROR 2031 Imported symbol #1 is not defined in module #2

This error situation occurs when symbol is imported from module that exports all, but symbol is not defined there

ERROR 2032 Ambiguous import, symbol #1 imported more than once to module #2

This indicates that all symbols are exported from module #2, but it is impossible to import symbol #1 from module #2 because symbol #1 is imported more than once to #2. The symbols have the same name, but defined in different modules.

ERROR 2033 Ambiguous import, symbol #1 defined and imported to module #2

This indicates that all symbols are exported from module #2, but it is impossible to import symbol #1 from module #2 due to ambiguity between symbol #1defined in module #2 and symbol #1 imported to module #2.

For example;

```
M1 DEFINITIONS ::= BEGIN
   IMPORTS a FROM M2;
END

M2 DEFINITIONS ::= BEGIN
   IMPORTS a FROM M3;
   a INTEGER ::=5
END

M3 DEFINITIONS ::= BEGIN
   EXPORTS a;
  a BOOLEAN ::= TRUE

END
```

In the above case you can not import a to M1, although a is exported from M2.

ERROR 2034 Multiple declaratiom of module name #2

Module name shall appear only once in IMPORTS clause.

For example

IMPORTS a , b FROM X c FROM X; is wrong ASN.1 declaration

ERROR 2035 Recursive import for #1

This error message is reported, for example, when module A imports T from B, and B imports T from A at the same time

ERROR 2036 Multiple occurance of #1 '#2' in #3

This error is reported when some types are defined incorrectly - they have the same identifier, for example enumeration can not have the same identifiers, named number list for INTEGER type can not have the same identifiers in the list, #2 is a string

ERROR 2037 Multiple occurance of #1 #2 in #3

The same class of error as ERROR 2036 above, but #2 is an integer value.

ERROR 2038 External references are not allowed

When imports clause looks like “IMPORTS ;”,no external references are allowed from the module (X.680, 10.14, d), NOTE 2)

ERROR 2039 Referenced #1 '#2' not defined

This error is reported when you use reference that is not assigned value or type anywhere.

ERROR 2040 Value of type #1 needed

This error message indicates that value does not correspond to the type. For example `x INTEGER ::= TRUE` - this results in an error “Value of type INTEGER needed”

ERROR 2041 #1 type needed after COMPONENTS OF

The type after in COMPONENTS OF expansion should be either SET or SEQUENCE, and it should be the same as the type to which it is extracted.

For example SET { a INTEGER, b COMPONENTS OF T }, where T is SEQUENCE type is wrong usage of COMPONENTS OF notation(X.680, 22.4, 24.2)

ERROR 2042 Field names in type after COMPONENT OF already declared

After performing the COMPONENTS OF transformation, all field names should be distinct.

For example, type S1 is wrong (it has two fields named 'a')

```
S ::= SET { a INTEGER, b REAL }
S1 ::= SET { a SET OF IA5String, COMPONENTS OF S }
```

ERROR 2043 #1 type needed

This error is reported when type in selection type is not choice.

For example x < INTEGER does not satisfy that requirement

ERROR 2044 No alternative named #1 in Choice type

This error is reported when type notation is “#1 < type”, type is a CHOICE type, but it does not have alternative named #1

ERROR 2045 Too many components

This error message appears when you are trying to assign extra components, which are not defined in the type, when specifying the value of SET or SEQUENCE

ERROR 2046 No such field '#1' in #2 type

This error indicates that type #2 does not have field named #1, but you are trying to assign it a value.

ERROR 2047 Missing values for non-optional #1 fields : #2

This message indicates that not all required #1 components have been initialized in the value, and #2 is the list of names of fields, for which values are missing. The example S ::= SET { a INTEGER, b REAL, c

NULL OPTIONAL }, s S ::= { a 57 } results in error message “Missing values for non-optional SET fields: ’b’”.

ERROR 2048 More than one #1 for the field '#2'

This error occurs when you are trying to assign more then one component to one field.

For example

```
T ::= SET { a IA5String , b NULL }
t T ::= { a "val1", b NULL, a "val2" }
```

ERROR 2049 Nothing known about bit named '#1'

This error is reported when bitstring value contains identifier that is not declared in the correspondent type definition

ERROR 2050 Value for #1 should be #2

If you specify table for the value of IA5String, TableColumn should be in the range from 0 to 7, if this constraint is violated then the above error message is reported

ERROR 2051 Type is required to be derived from #1

This error indicates that type used in SubtypeConstraint is not derived from the type being constrained and thus does not satisfy X.680,45.3.2

ERROR 2052 Can not apply #1 constraint to #2 type

Not all constraints can be applied to every type, X.680, Table 6 describes which constraints can be applied to which types, if the requirements declared in Table 6 are not satisfied, the above error message is reported

ERROR 2053 There shall be at most one #1

Two presents constraints are not allowed when constraining a CHOICE type.

For example:

```
C ::= CHOICE { a T1 , b T2 } (WITH COMPONENTS {a PRESENT,
b PRESENT} )
```

causes the error message

ERROR 2054 Wrong value : out of constraint

This error is reported when value does not correspond to the constraint applied to the type.

For example: `x INTEGER (1..10) ::= -1`, x is out of constraint

ERROR 2055 The same tags for #1 components

This error message indicates that type does not correspond to the requirements for distinct tags specified in X.680, 22.5, 24.3, 26.2; If you use AUTOMATIC TAGS in the module, requirement for distinct tags will always be satisfied if automatic tagging has been applied

ERROR 2056 OBJECT IDENTIFIER value should have at least two components

`x OBJECT IDENTIFIER ::= { iso }` is wrong object identifier value because encode/decode functions require at least two components for object identifier value

WARNING 2057 Construct #1 has no mapping in SDL

This warning is reported if no mapping to sdl exist but it does not prevent further code generation.

ERROR 2058 Construct #1 has no mapping in SDL

This error indicates that no mapping to sdl exist and is fatal for further code generation.

WARNING 2059 Value given for #1 component

This warning indicates that a value has been given to an optional or default component of an ASN.1 SEQUENCE or SET type. Values for optional and default components cannot be translated to SDL.

WARNING 2060 Constraint could have been extended when mapped to sdl

This warning indicates that constraint transformation has been applied when mapping complex ASN.1 constraints to sdl but the sdl type can allow more values than the ASN.1 type. This can occur when there is no exact mapping of ASN.1 constraints.

ERROR 2061 INTERNAL ERROR in #1

This message indicates an error in the implementation in the utilities. Please send a report to IBM Rational Customer Support, especially if the error can be reproduced as the only error message of an analysis. Contact information for IBM Rational Customer Support can be found in "How to Contact Customer Support" on page *iv in the Release Guide*

ERROR 2062 Code generation : #1

Error in the generation of SDL, TTCN or encode/decode output.

WARNING 2063 Too big exponent

Exponent in a real value is too big to translate to SDL. This warning message is shown if the exponent is bigger than 1000 or less than -1000.

WARNING 2064 Duplicate synonym name, this synonym will not be mapped to SDL

This message indicates that there are synonym name clashes between named numbers and named bits from INTEGER and BIT STRING types and ASN.1 values if they all will be mapped to SDL (see "Integer" on page 717 and "Bit String" on page 714), and in order to avoid errors only one synonym will be mapped, others are ignored.

ERROR 2065 Number #1 is already assigned to previously defined enumeration item

This error message is reported when NamedNumber alternative is used in an enumerated type definition in an addition enumeration after extension marker and the number #1 has already been assigned to identifier from root enumeration, for example A ::= ENUMERATED {a,b, ... , c(0)} First corresponding numbers are assigned to identifiers in root enumeration, and then in additional enumeration. The above case is invalid, since both 'a' and 'c' are equal to 0.

ERROR 2066 Value for the field '#1' needed #2

This message indicates that value for the field '#1' is missing, but it should be present in #2

ERROR 2067 #1 omitted in #2

Indicates that #1 is omitted, but it should be present in #2

ERROR 2068 #1 should reference #2

This message indicates that a field name references an object class field that is not allowed to be referenced.

ERROR 2069 Wrong object specification

This message indicates that an object specification is incorrect

ERROR 2070 #1 of class #2 needed

This message indicates that an object or object set does not match the governing object class specified in object or object set's definitions

ERROR 2071 Wrong defined syntax

This message indicates that an error in defined syntax for the object definition

ERROR 2072 #1 can not be used in object set specification

This message indicates that an illegal construct is used in the object set specification

ERROR 2073 #1 in the field '#2' is not specified in the #3

This message is reported when information, for example, type or value, is extracted from object field that has not been initialized in the object. This can occur when the field is optional or default in the object class.

WARNING 2074 #1 is not supported in the encoders / decoders

This warning message is reported when ASN.1 notation is used that the encoder / decoder library cannot support

ERROR 2075 #1 can be used only for #2

This message is reported when #1 is used in a component relation constraint but is not allowed to be used in that context.

ERROR 2076 #1

This is used for several different messages concerning component relation constraint, each message is listed and explained below:

Referenced component should refer to the same object class as the referencing one

This message indicates that the referenced and referencing components in a component relation constraint do not stem from the same object class.

Only fixed type value fields are allowed to be specified in a referenced component

This message indicates that a referenced component in a component relation constraint is not a fixed type value field, for example

```
SET {
      a MY-CLASS.@id ({My-set}),
      b MY-CLASS.@TypeField ({My-set})
    }
```

For the field a, @id should reference fixed type value field in class 'MY-CLASS'

Only values of INTEGER types can be used as component relation identifiers";

This message is reported when a referenced fixed type value field is not an INTEGER, only INTEGERS are supported.

```
SET {
      a MY-CLASS.@id ({My-set}),
      b MY-CLASS.@TypeField ({My-set})
    }
```

In the example above @id should be derived from an INTEGER.

Wrong referenced component

This message indicates that a wrong type of component is referenced in a component relation constraint, for example not using ObjectClass-FieldType notation.

Referenced components should be constrained by the same object set as the referencing one

This message indicates that the referenced and referencing component are not constrained with the same object sets.

ERROR 2077 ASN.1 identifier #1 is a keyword, it will be replaced by #2

This message is reported when an ASN.1 identifier is a keyword in one of the target languages and will be changed according to the keywords

configuration file during mapping for avoiding syntax errors in the target languages.

ERROR 2078 Module #1 has got name clashes within joined modules group '#2'

This message is reported when an ASN.1 definition name causes name clashes within joined SDL package and will be prefixed by the original ASN.1 module name during mapping to avoid errors in SDL (see "Joining modules" on page 708).

Restrictions

The ASN.1 Utilities handle all constructs of ASN.1 as defined in ITU-T recommendations X.680, X.681, X.682, X.683, X.690, X.691. There is no support for features defined in the old ASN.1 version X.208 that have been superseded in X.680.

For a list of restrictions see "ASN.1 Utilities" on page 13 in chapter 1, *Compatibility Notes, in the Release Guide*.

Appendix A: List of recognized keywords

By default target language keywords are recognized among ASN.1 identifiers and a postfix `'_<language>_KEYWORD'` is added at the end of the identifier when SDL (`<language> = SDL`), TTCN (`<language> = TTCN`) or C (`<language> = CPP`) is generated. This appendix describes lists of supported keywords for all supported target the target languages.

SDL keywords

```
active, adding, all, alternative, and, any, as, atleast,
axioms, block, break, call, channel, choice, comment,
connect, connection, constant, constants, continue, cre-
ate, dcl, decision, default, else, endalternative, end-
block, endchannel, endconnection, enddecision, endgener-
ator, endmacro, endnewtype, endoperator, endpackage,

Chapter

14 *The CPP2SDL Tool*

The CPP2SDL tool is a C/C++-to-SDL translator that makes it possible to access C or C++ declarations in SDL. The tool takes a set of C/C++ header files as input and generates SDL declarations for a configurable set of the C/C++ declarations in these files.

CPP2SDL is the new generation of the H2SDL utility. Compared to its predecessor, CPP2SDL offers a comprehensive C++ support as well as superior translation configurability. CPP2SDL is fully integrated in SDL Suite, but can also be executed as a stand-alone utility from the command shell.

This chapter is the reference manual for CPP2SDL. The reader is assumed to be familiar with C/C++ and SDL.

Introduction

The overall purpose of the CPP2SDL tool is to provide a convenient means of making external C or C++ declarations available in an SDL context. This is accomplished by translating the C/C++ declarations into representing SDL declarations. These resulting declarations can be injected at an arbitrary level in the SDL scope hierarchy, and may then be used just as if they actually were declared at that scope level. When target code is generated for the SDL system, the Code Generator produces C or C++ code for usages of generated SDL declarations that matches the original C/C++ declarations. The picture below depicts the data flow when using CPP2SDL, and the context of the tool.

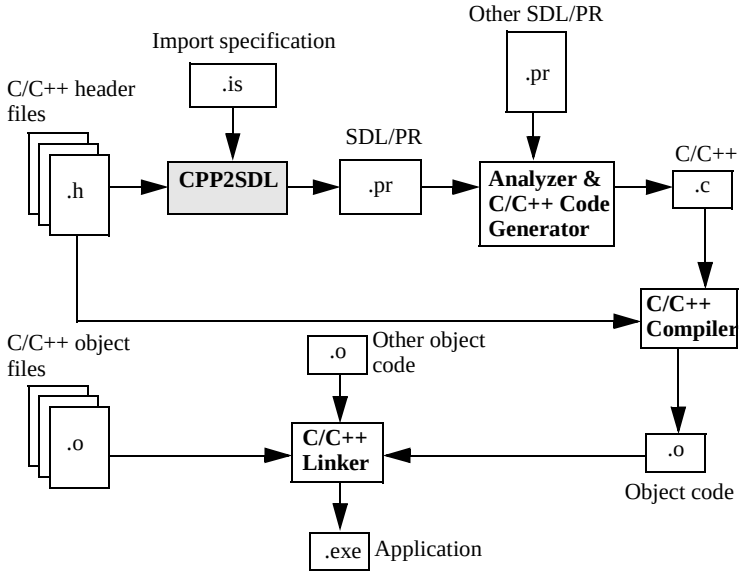

Figure 166 CPP2SDL Data Flow and Context

As can be seen in the figure, the input to CPP2SDL is a set of C/C++ header files and, optionally, an import specification. From this input CPP2SDL generates an SDL/PR file containing SDL representations for the declarations in the header files, or for a subset of these declarations according to what is specified in the import specification. The generated SDL/PR is analyzed together with other SDL/PR, e.g. the

SDL/PR for the SDL system. The Code Generator then generates target C/C++ code which is compiled by a C/C++ compiler. Note that the original C/C++ headers are used in this compilation. The resulting object code is linked together with the object files belonging to the C/C++ headers. Other object files are also included, e.g. the precompiled SDL kernel that is to be used. The result is an executable application.

CPP2SDL translates from C/C++ to SDL according to certain translation rules. These translation rules have been designed to be as simple and intuitive as possible. A user that is familiar with C/C++ should find it straight-forward to use a C/C++ declaration from SDL. The translation rules are described in full detail in "C/C++ to SDL Translation Rules" on page 785. Although CPP2SDL supports translation of a major part of the C and C++ languages, not everything is supported. The limitations of CPP2SDL are listed in "CPP2SDL" on page 27 in chapter 1, *Compatibility Notes*.

Executing CPP2SDL

Normally, CPP2SDL is automatically invoked by the SDL Analyzer as part of the make process. Input header files and tool options are then specified in the Organizer. However, CPP2SDL may also be executed as a stand-alone tool from a command shell, and in that case input headers and tool options are given as command line options.

This section begins with a description of the integration with the Organizer and the Analyzer. Then how to execute CPP2SDL from the command line is described. Finally, follows a section on how to run the tool through the PostMaster.

Execution from the Organizer

The most common way to execute CPP2SDL should be from the Organizer. In fact CPP2SDL will be started automatically by the Analyzer once for each import specification symbol it finds in the Organizer view (see "Import Specifications" on page 776 to learn about import specifications). The Analyzer executes CPP2SDL by means of the PostMaster as described in "Execution from the PostMaster" on page 775. All messages that are output during the execution will be printed in the Organizer Log Window.

Example 80: Executing CPP2SDL from the Organizer ----------

Consider a simple SDL system with one block and one process that needs to access some C++ declarations. At system level certain declarations of the C++ header file `general.h` is used, and at process level declarations of the files `f1.h` and `f2.h` are needed. Figure 167 below shows how the Organizer view of this SDL system could look like.

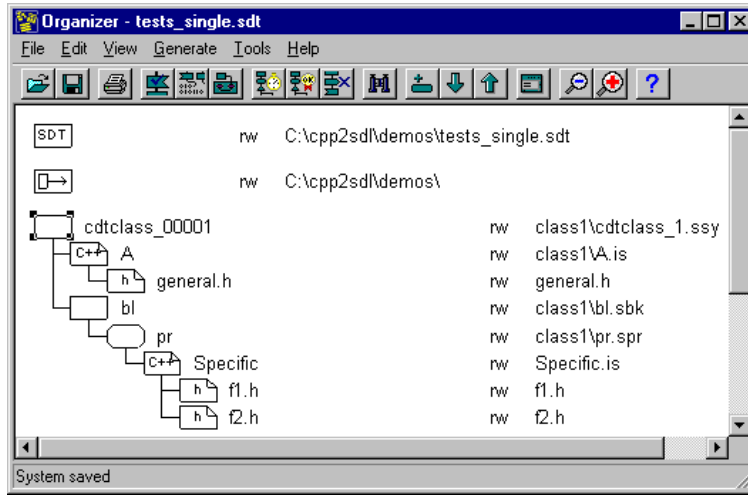

Figure 167 Organizer view with headers to be translated by CPP2SDL

When this system is analyzed, the Analyzer will execute CPP2SDL once for the file `general.h`, and once for the files `f1.h` and `f2.h`. The result of the first translation is a set of SDL declarations that are injected at system level, and thus will be accessible in all scopes. The result of the second translation is a set of SDL declarations that are injected at process level and thus are not accessible in the system or in the block scope.

Adding Import Specifications to the Organizer view

The first step in accessing C/C++ declarations from SDL is to insert a PR symbol at the place in the SDL specification where the C/C++ declarations are to be used. The PR symbol represents the inclusion of the SDL PR that is the translation of the C/C++ declarations.

To specify that this should be an import specification, double-click the PR symbol either in the Organizer or in the SDL Editor to open the Edit Document dialog. In the dialog it is possible to select either C Import Specification or C++ Import Specification.

An import specification can be edited manually by means of the Text Editor (see "Import Specifications" on page 776 to learn about import

specifications). However, an import specification can also be edited in the CPP2SDL Options dialog described below.

After adding an import specification it is necessary to specify which C/C++ header files are to be translated. This is done by selecting the import specification in the Organizer and then use the Add Existing and Add New commands to select or create C/C++ header files respectively.

Setting CPP2SDL Options in the Organizer

Required options to CPP2SDL may be specified in the Organizer for each import specification by using the CPP2SDL Options dialog. This dialog may be opened from the menu that appears when the right mouse button is pressed on an import specification symbol. Figure 168 shows this dialog.

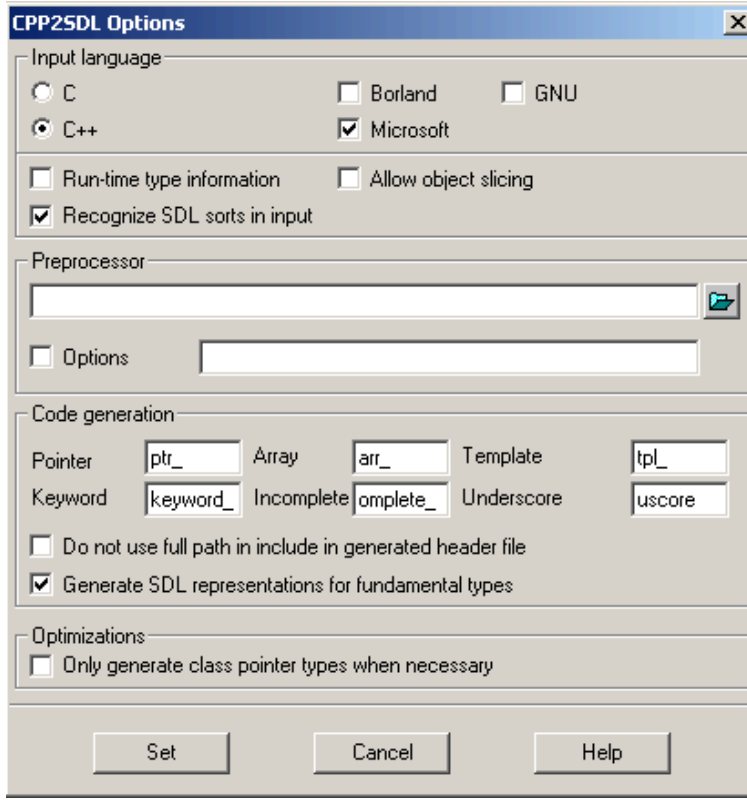

Figure 168 The CPP2SDL Options Dialog

The fields and buttons of the CPP2SDL Options dialog correspond directly to the command line options described in "Command Line Options" on page 769:

- *Language*

  These radio buttons select the input language. If C is selected, CPP2SDL will be executed in C mode, i.e. as with the `-c` command line option.

- *Dialect*

These check boxes determine what dialects to support in the input, and correspond to the `-dialects` command line option. If no check-boxes are marked, the ANSI C/C++ dialect is supported.

- *Run-Time Type Information*

  This check box should be set if Run-Time Type Information (RTTI) is available in C++ and should be supported in the SDL translation. It corresponds to the `-rtti` command line option.

- *Allow object slicing*

  This check box should be set if object slicing should be supported in the SDL translation. It corresponds to the `-slicing` command line option.

- *Recognize SDL sorts in input*

  This check box should be set if SDL sorts should be recognized in the input. It corresponds to the `-sdlsorts` command line option.

- *Preprocessor*

  This field is used to specify the preprocessor to use for preprocessing the input. It corresponds to the `-preprocessor` command line option. This field also has a browse button that makes it possible to select the preprocessor from a file selection dialog.

- *Preprocessor options*

  This field should contain the options to the preprocessor. It corresponds to the `-cppoptions` command line option.

- *Pointer, Array, Template, Keyword, Incomplete, Underscore*

  These fields specify the prefixes and suffixes that are used when C/C++ names must be modified in the SDL translation. They correspond to the `-prefix` and `-suffix` command line options.

- *Do not use full path in include in generated header file*

  Checking the box will prevent usage of path in the includes and make it easier to move files to other directory locations. It corresponds to the `-noabsolutepath` command line option.

- *Generate SDL representations for fundamental types*

This check box should be set if SDL representations for fundamental C/C++ types should be included in the translation. It corresponds to the `-generatecpptypes` command line option.

- *Only generate class pointer types when necessary*

  If this check box is set, CPP2SDL will optimize the generation of class pointer types. It corresponds to the `-optclasspointers` command line option.

Execution from Command Line

CPP2SDL is invoked from the command prompt by the command:

```
cpp2sdl [options] <C/C++ header files>
```

Unless the `-post` option is set, all messages that are output by the tool, e.g. errors and warnings, will be printed on the standard error stream (`stderr`).

CPP2SDL will translate the declarations in the specified C/C++ header files, or a subset of these declarations if a suitable import specification is used (see "Import Specifications" on page 776). The resulting SDL declarations will be saved in a file called *`name`*`.pr`, where *`name`* is the name of the import specification used. If no import specification is used, *`name`* will be the name of the first input header file.The output file will be placed in the same directory from where CPP2SDL is executed.

There is a possibility when running in batch mode to be able to change the CPP2SDL options used in an SDL system. See "Batch Facilities" on page 208 in chapter 2, *The Organizer*.

Normally CPP2SDL options are saved in an import ("`.is`") file. These options will in batch be superseded by CPP2SDL options given in a batch "`.sdt`" option file.

Command Line Options

The command line options recognized by CPP2SDL are listed and explained below. Note that an option may be abbreviated as indicated by the underlined part of the option name.

- `-append`

Append the generated SDL declarations to the file that is specified with the `-output` option. If that file does not exist, this option will be ignored and CPP2SDL will create a new file for the output as usual.

- `-c`

  Execute in C mode. CPP2SDL will assume that no C++ specific constructs are encountered in the input headers. If this assumption does not hold, the result of the translation is undefined. See "Special Translation Rules for C Compilers" on page 846 for a detailed description of translation rule modifications that are caused by using this option.

- `-cppoptions <optionsstring>`

  Send the specified option string to the preprocessor. If the string contains white spaces, it must be quoted.

- `-dialects <dialect> <dialect> ... <dialect>`

  Accept the specified C/C++ dialects in the input headers. Supported dialects are

  – ANSI (ANSI C/C++)

  – GCC (Gnu C/C++)

  – MSVC (Microsoft Visual C/C++)

  – ALL (all supported C/C++ dialects)

  If this option is not used, CPP2SDL will assume that the input headers conform to the ANSI C/C++ dialect.

- `-errorlimit <number>`

  Set the maximum number of errors to report before terminating the translation. The default it to terminate when 5 errors have been found.

- `-extsyn`

  Will not generate for constants with numeric expressions, external synonyms with its value (if the expression can be calculated during translation). Default, i.e. without this option, the value is translated.

- `-generatecpptypes`

Include SDL representations for fundamental C/C++ types in the translation. See "SDL Library for Fundamental C/C++ Types" on page 848 for more information about what actually is generated when this option is used.

- `-help`

  Print a help message about CPP2SDL. No translation will be performed.

- `-importspecification <file>`

  Use the specified file as import specification for the translation. Import specifications are described in "Import Specifications" on page 776.

- `-noabsolutepath`

  Prevent usage of path in the includes to make it easier to move files to other directory locations.

- `-nocheckinput`

  Do not check that all input headers are existing and readable before trying to translate them. The use of this option could make it easier to use CPP2SDL from scripts.

- `-nodepend`

  Do not translate depending declarations when using an import specification. Only the identifiers that are explicitly present in the import specification will be translated. If this option is set, CPP2SDL cannot guarantee that the resulting set of SDL declarations is complete and consistent. See "Import Specifications" on page 776 for more information.

- `-noinclude`

  Ignore definitions #included into imported header file by the preprocessor. Only definitions that are explicitly present in the original header file will be translated, and may be some others if the -nodepend option is not set.

  This option allows having several separate import specifications for several imported header files, even if these files include each other. Although, conflicts in SDL are still possible if the same depending definitions are imported for different import specifications. So, to achieve the best result, the -noinclude option should often be used

together with the -nodepend option. Both options are not present in "CPP2SDL Options..." dialog window and should be specified directly in the *.is file.

To avoid build errors when using several import specifications for several header files that include each other, do not forget to use protection macros #ifndef-#define-#endif in the header files.

- `-novariables`

  Do not generate external variables. This option is needed since the rules for where SDL allows declarations of external variables are more restrictive than for other declarations. For example, SDL does not allow external variables declared at system or block level. If this option is used, CPP2SDL will output a warning if it finds a construct that otherwise would be translated to an external variable.

- `-optclasspointers`

  Optimize the generation of class pointer types so that they are only generated when they appear in the input headers. If this option is not used, CPP2SDL will automatically generate a pointer type to all translated classes. Read more about this in "Classes, Structs and Unions" on page 803.

- `-output <file>`

  Write the resulting SDL declarations to the specified file. If the `-append` option is set, the result will be appended to the file. Otherwise a new file will be created, overwriting an existing file with the same name, if any.

  Note that all files that CPP2SDL generates will be placed in the same directory as the generated SDL/PR file.

- `-post`

  Start CPP2SDL as a PostMaster client waiting for requests from the PostMaster. The PostMaster messages that are handled by CPP2SDL are described in "Execution from the PostMaster" on page 775.

- `-prefix "ptr=<string> arr=<string> keyword=<string> incomplete=<string> tpl=<string>"`

  Use the specified name prefixes when generating SDL. CPP2SDL uses name prefixes when the original C/C++ names for some reason cannot be used in SDL. This option makes it possible to fully con-

figure how such modified names are generated. This is often useful in order to avoid name clashes in SDL.

- `-preprocessor <executable>`

  Use the specified executable for preprocessing the input headers. The executable should be a preprocessor or C/C++ compiler that is supported by CPP2SDL:

  – 'cl' (Microsoft Visual C/C++ Compiler), **in Windows**.

  – 'cpp' (C/C++ Preprocessor), **on Unix**.

  – 'cc' and 'CC' (Sun Workshop C and C++ Compilers), **on Unix**.

  – 'gcc' and 'g++' (GNU C and C++ Compilers), **on Unix**.

  If this option is not used, CPP2SDL will attempt to use 'cl' **in Windows**, and 'cpp' **on Unix**.

  Note that CPP2SDL uses name matching of the specified filename, with the file name extension stripped, to determine what preprocessor or compiler to use for preprocessing. If the specified name does not match the name of any supported preprocessor or compiler on the current platform, CPP2SDL will attempt to call the executable like this:

  ```
  <executable> <options> <input file> <output file>
  ```

  `<options>` are the option string specified with the `-cppoptions` options.
  If this call fails, CPP2SDL does not know how to preprocess the input headers and terminates.

Hint:

If you want to preprocess the input headers using a preprocessor that is not supported by CPP2SDL, you can write a simple shell script that wraps the call to the desired preprocessor. The script should conform to the call style that CPP2SDL uses for unknown preprocessors. Then execute CPP2SDL, using the `-preprocessor` option to specify the script as the preprocessor to use.

- `-ref`

Include source references in the generated SDL. The format of these source references is described in "Source and Error References" on page 783.

- `-rtti`

  Assume Run-Time Type Information, and support dynamic casting. See "Run-Time Type Information and Dynamic Cast" on page 827 for more information what this means.

- `-sdlsorts`

  Recognize SDL sorts in input. CPP2SDL will translate C/C++ types that are prefixed with 'SDL_' to the corresponding SDL sort. Refer to "SDL Sorts in C/C++" on page 844 for an example on how this feature can be used.

- `-slicing`

  Generate SDL cast operators to support slicing of C++ objects. See "Type Compatibility between Inherited Classes" on page 823 for more information.

- `-sortmembers`

  Sort struct members in SDL newtypes alphabetically.

- `-suffix "uscore=<string>"`

  Use the specified name suffixes in the generated SDL. CPP2SDL uses name suffixes when the original C/C++ name for some reason cannot be used in SDL. This option makes it possible to fully configure how such modified names are generated.

- `-targetdir <directory>`

  Set the target directory for generated files. CPP2SDL produces one single header file which includes all the header files that are to be translated. If this option is used, this generated header file is placed in the specified target directory. Otherwise the file will be placed in the same directory as the generated SDL/PR file.

- `-version`

  Show version information.

Example 81: Executing CPP2SDL from the command line

```
% cpp2sdl -preprocessor /usr/ccs/lib/cpp -output
result.pr -prefix "ptr=p arr=a" -rtti -ref input.h
```

This command will translate the input header `input.h` to SDL and write the resulting SDL declarations to the file `result.pr`. The specified preprocessor 'cpp' will be used to preprocess the input. If the input contains pointer or array types, the corresponding SDL names will be prefixed with 'p' and 'a' respectively. Source references to the declarations in `input.h` will be generated by CPP2SDL, and Run-Time Type Information is assumed so that dynamic cast operators are generated.

Execution from the PostMaster

As mentioned above, CPP2SDL may be started as a PostMaster client by using the `-post` option at the command line. As a PostMaster client, CPP2SDL will handle two different PostMaster events.

- SESTOP
- SECPP2SDLCOMMAND <optionstring>

The reception of a SESTOP event has the expected behavior; CPP2SDL ceases to be a PostMaster client and terminates.

The SECPP2SDLCOMMAND event has an option string as argument. The event will cause CPP2SDL to execute according to the options specified in that string. The format of the option string is the same as when CPP2SDL is executed from the command line (see "Execution from Command Line" on page 769). All messages that are output by the tool will be broadcast to the PostMaster.

After the execution of a SECPP2SDLCOMMAND event a reply is sent:

SECPP2SDLCOMMANDREPLY <#errors> <#warnings> <status>

The <#errors> and <#warnings> arguments tell the number of errors and warnings that occurred during the translation, and <status> is a text string with the same information in a more readable form.

Example 82: Executing CPP2SDL from the PostMaster

A single PostMaster may be started with this command:

```
% sdt -noclients
```

Then CPP2SDL is started as a PostMaster client:

```
% cpp2sdl -post &
```

CPP2SDL is now waiting for requests to come from the PostMaster. By using for example the SERVERPC application, events can be sent to it.

```
% serverpc 58000 58101 "-rtti -ref input.h"
```

58000 is the tool id of CPP2SDL, and 58101 is the event id for the SECPP2SDLCOMMAND event. As a result the following reply event could for example be received:

SECPP2SDLCOMMANDREPLY 0 2 “0 errors and 2 warnings”

Finally, CPP2SDL is terminated using the SESTOP event (id 58303):

```
% serverpc 58000 58303
```

Import Specifications

A simple but powerful way of configuring the translation of a set of C/C++ declarations is to use an import specification. As the name suggests, an import specification specifies how to import external code into SDL. An import specification for CPP2SDL is a textfile written in a simple C/C++-style syntax. The file consists of two sections that both are optional:

- `CPP2SDLOPTIONS`

  This section may contain options to the CPP2SDL tool. The syntax is the same as when CPP2SDL is executed as a stand-alone tool from the command line. See “Command Line Options” on page 769.

- `TRANSLATE [ALL]`

  This section may contain a list of C/C++ identifiers. CPP2SDL will attempt to make these identifiers available in SDL by translating the corresponding declarations.

  Optional keyword ALL tells that, in spite of provided list of identifiers, all objects from the source files should be imported.

Options and identifiers in an import specification are delimited by newlines.

The example below shows a simple import specification where the identifiers `func`, `C` and `myint` are made available in SDL.

Example 83: A simple import specification ––––––––––––––––––––

```
CPP2SDLOPTIONS {
   -preprocessor /usr/ccs/lib/cpp
}

TRANSLATE {
   func
   C
   myint
   // C++ style comment (if supported by preproc.)
   /* C style comment */
}
```

––

The import specification file will be preprocessed by CPP2SDL with the same preprocessor and preprocessor options that are used when preprocessing the input C/C++ headers. This makes it possible to use, for instance, C/C++ comments and macros in an import specification.

> **Note:**
>
> Some preprocessors will refuse to preprocess files that have an unknown file name extension (for example `.is`). In that case the import specification file must be given a file name extension that is known to the preprocessor (for example `.h`).

If an identifier in an import specification refers to a declaration that depends on other declarations, CPP2SDL will, by default, translate all these depending declarations as well. This principle is applied recursively to all declarations that depend on depending declarations, thereby making sure that the resulting SDL declarations are complete and consistent. If the `-nodepend` option is set, depending declarations will not be translated automatically. Then the tool cannot guarantee that the resulting set of SDL declarations is complete and consistent.

Example 84: Translation of depending declarations––––––––––––

File `data.h`:

```
typedef int myint;

class C {
public:
  myint* mvar;
```

```
};
```

File `import.is`:

```
TRANSLATE {
   C
}
```

Execution of CPP2SDL from the command line,

```
% cpp2sdl -importspecification import.is data.h
```

will produce resulting SDL declarations in the file `import.pr`:

```
SYNTYPE myint = int
ENDSYNTYPE myint;EXTERNAL 'C++';
NEWTYPE ptr_myint Ref( myint);
  OPERATORS
    ptr_myint : -> ptr_myint;
    ptr_myint : ptr_myint -> ptr_myint;/
ENDNEWTYPE ptr_myint;EXTERNAL 'C++';
NEWTYPE ptr_C Ref( C);
  OPERATORS
    ptr_C : -> ptr_C;
    ptr_C : ptr_C -> ptr_C;
ENDNEWTYPE ptr_C;EXTERNAL 'C++';
NEWTYPE C
  STRUCT
    mvar ptr_myint;
  OPERATORS
    C : -> C;
    C : C -> C;
ENDNEWTYPE C;EXTERNAL 'C++';
```

Here, the import specification only specifies that the class `C` shall be translated, but since the declaration of `C` depends on `myint*`, which in turn depends on `myint`, these declarations will be translated as well.

Note:

CPP2SDL will only translate those identifiers in an import specification that refer to declarations in namespaces (including the global namespace). If an identifier refers to another kind of declaration, for example a class member, it will be ignored and CPP2SDL will issue a warning.

Advanced Import Specifications

Besides from specifying which identifiers that should be translated to SDL, there are some more advanced constructs that may be used in an import specification.

Type Declarators

It is possible to append type declarators to identifiers that represent types. The same type declarators as in C/C++ are allowed, i.e. pointer (*), array ([]), and reference (&). Prefix and postfix declarators are separated by a dot (.).

Example 85: Type declarators in import specification ––––––––––––

```
TRANSLATE {
   char*         // A pointer to char.
   MyClass.[8]   // An array of 8 MyClass.
   mytype&       // A reference to mytype.
   C*.[10]       // An array of 10 pointers to C.
}
```

––

Prototypes for Ellipsis Functions

The translation rule for a function with unspecified arguments (a.k.a an ellipsis function) requires that information is provided about which versions of the function that should be made available in SDL (see "Unspecified Arguments" on page 796). This information may be given in an import specification by specifying prototypes for the function.

Example 86: Prototypes for ellipsis functions in import specification

Input declaration:

```
int printf(const char*, ...);
```

Import specification:

```
TRANSLATE {
   printf
   printf(int)
   printf(double, char)
}
```

Resulting SDL declarations:

```
NEWTYPE global_namespace_ImpSpec /*#NOTYPE*/
```

```
  OPERATORS
    printf : ptr_char, double, char -> int;
    printf : ptr_char, int -> int;
    printf : ptr_char -> int;
ENDNEWTYPE global_namespace_ImpSpec;EXTERNAL 'C++';

NEWTYPE ptr_char Ref( char);
  OPERATORS
    ptr_char : -> ptr_char;
    ptr_char : ptr_char -> ptr_char;/
ENDNEWTYPE ptr_char;EXTERNAL 'C++';
```

Template Instantiations

Similar to ellipsis functions, the translation of templates requires additional information about how the templates should be instantiated (see "Templates" on page 838). This information may be specified in an import specification, using the same syntax as when templates are instantiated in C++.

Example 87: Template instantiations in import specification

Input declarations:

```
template <class C, int i> class S {
public:
  C arr[i];
};

template <class D> D func(const D& p1);
```

Import specification:

```
TRANSLATE {
   S<double, 5>
   func<unsigned int>
}
```

Resulting SDL declarations:

```
NEWTYPE global_namespace_ImpSpec /*#NOTYPE*/
  OPERATORS
    tpl_func_unsigned_int /*#REFNAME 'func<unsigned
int >'*/ : unsigned_int -> unsigned_int;
ENDNEWTYPE global_namespace_ImpSpec;EXTERNAL 'C++';

NEWTYPE arr_5_double CArray( 5, double);
ENDNEWTYPE arr_5_double;EXTERNAL 'C++';

NEWTYPE ptr_tpl_S_double_5 Ref( tpl_S_double_5);
  OPERATORS
```

```
    ptr_tpl_S_double_5 : -> ptr_tpl_S_double_5;
    ptr_tpl_S_double_5 : ptr_tpl_S_double_5 ->
    ptr_tpl_S_double_5;
ENDNEWTYPE ptr_tpl_S_double_5;EXTERNAL 'C++';

NEWTYPE tpl_S_double_5 /*#REFNAME 'S<double, 5 >'*/
  STRUCT
    arr arr_5_double;
  OPERATORS
    tpl_S_double_5 /*#REFNAME 'S'*/ : ->
    tpl_S_double_5;
   tpl_S_double_5 /*#REFNAME 'S'*/ : tpl_S_double_5
-> tpl_S_double_5;
ENDNEWTYPE tpl_S_double_5;EXTERNAL 'C++';
```

Note that since class template instantiations define types, it is possible to use type declarators for them.

Providing additional import information in the TRANSLATE section

For the cases when all objects from the input header files should be imported, and at the same time additional information for the import should be provided (for example, information on ellipsis function prototypes), TRANSLATE ALL section can be used.

The "TRANSLATE ALL { }" section contains a list of objects, but it does not limit the number of translated objects to the listed ones. All objects from the source file are translated, the translate section provides additional information for translation of advanced objects, such as ellipsis functions, templates, etc.

Example 88: Use of TRANSLATE

f1.h contains types X, Y and f2.h contains types Z, printf

When translating both header files with the following import specification:

```
TRANSLATE {
  X
  printf(int)
}
```

the imported PR Files will contain type X and one prototype of printf(...)

For the import specification:

```
TRANSLATE ALL {
  X
  printf(int)
}
```

the imported PR file will contain all types (X, Y, Z) and one prototype for the ellipsis function

---

Source and Error References

A source reference is a reference from a generated SDL declaration to the corresponding original C/C++ declaration. Source references are placed in the generated SDL/PR file.

An error reference is also a reference to a declaration in the input header file, but is used to point out an error (or a warning) in that file. Error references are therefore printed as messages to the standard error stream or to the Organizer Log Window.

CPP2SDL uses the #SDTREF format both for source and error references. See chapter 18, *SDT References* for more about #SDTREF.

Source References

When CPP2SDL is executed from the Organizer, or from the command line with the `-ref` option set, the generated SDL/PR file will contain references to the input source files. Such a reference occurs just before a generated SDL declaration, and is on the form

```
/*#SDTREF(TEXT,filename,line)*/
```

where

- `filename` is the name of the input file where the corresponding C/C++ declaration can be found.
- `line` is the line number in that input file where the C/C++ declaration starts.

A source reference is shown in Example 89 below.

Example 89: Source references ----------

```
/*#SDTREF(TEXT,input.h,226)*/
NEWTYPE S STRUCT
  a int;
OPERATORS
  get_a: S -> int;
ENDNEWTYPE S;EXTERNAL 'C++';
```

Error References

Error references have a similar format as source references but with a column position added after the line number:

```
/*#SDTREF(TEXT,filename,line,column)*/
```

CPP2SDL prints error references when errors or warnings are found during the translation. They are output to the standard error stream (`stderr`) or to the Organizer Log Window depending upon whether CPP2SDL is executed from the command line or from the PostMaster.

Problems with error references may arise because of the preprocessor. Among other things, the preprocessor expands macros, and a typical problem is illustrated in Example 90 below.

Example 90: Error References ––––––––––––––––––––––––––––––

File `def.h`:

```
#define init InitializingFunction

void init(undefinedType *, int);
```

If CPP2SDL translates this file, the following error message will be printed:

```
#SDTREF(TEXT,def.h,3,27)
ERROR 3200 Syntax error.
```

Here the syntax error occurs at position (3,11) in the source file, but because of the macro expansion of `init` to `InitializingFunction`, CPP2SDL will report the error at position (3,27) instead. Thus the column position is several characters off the target in the original file. When using the Organizer Log's *Show Error* function (see "Show Error" on page 187 in chapter 2, *The Organizer*) to view the source of this error message, the cursor will be placed at `int` instead of at `undefinedType`. CPP2SDL calculates both source and error references from the preprocessed source code, and this may lead to reference problems when macros are involved.

––

C/C++ to SDL Translation Rules

The general idea behind the CPP2SDL tool is to take a set of C/C++ header files, preprocess them, and translate some or all of the declarations in these headers into SDL/PR representations. This section describes the rules for this translation process.

Each C/C++ construct is described in a subsection of its own. First, a general rule for the translation of the construct is presented. Then follows a description of exceptions to this rules, and rationals for these exceptions.

Before proceeding, it should be noted that the translation rules have been designed to support both C and C++ target compilers. To a large extent the translation rules are actually independent of whether a C or C++ target compiler is used. However, there are some differences, so when CPP2SDL executes in "C mode" (i.e. with the `-c` option set) a few translation rules are slightly modified. These modifications are described in "Special Translation Rules for C Compilers" on page 846.

Names

Rule: The name of a C/C++ identifier is the same in SDL.

The naming rules of identifiers in SDL and C/C++ are rather similar but differs in two important aspects:

- SDL is a case-insensitive language, while C/C++ is case-sensitive.
- SDL has some restrictions for how underscores may be used in names. C/C++ has no such restrictions.

To overcome these differences tool specific extensions have been made in the supported SDL dialect. The Analyzer has an option to handle case sensitive SDL (see "Set-Case-Sensitive" on page 2486 in chapter 54, *The SDL Analyzer*), and most of the restrictions with underscores have been removed. However, the rule that a name that ends with an underscore should be concatenated with the following name, makes it necessary to modify such names in the SDL mapping. This is done by appending a string suffix to such names. This string is by default "uscore" but may be configured to an arbitrary string be means of the CPP2SDL option
`-suffix`.

Another case where a name in C/C++ cannot be retained in the SDL translation is when the name is an SDL keyword. Such names are prefixed with a user-configurable string that by default is `keyword_`. The option `-prefix` can be used to configure this string.

Example 91 below gives some examples of the translation rules for names.

Example 91: Translation of names ----------

C++:

```
int ABC, abc;   // Case sensitivity
char u__sc, _w, x_; // Unrestricted use of
underscores
double signal;  // SDL keyword
```

SDL:

```
DCL ABC int; EXTERNAL 'C++';
DCL abc int; EXTERNAL 'C++';
DCL u__sc char; EXTERNAL 'C++';
DCL _w char; EXTERNAL 'C++';
DCL x_uscore /*#REFNAME 'x_'*/ char; EXTERNAL 'C++';
DCL keyword_signal /*#REFNAME 'signal'*/ double;
EXTERNAL 'C++';
```

Note the #REFNAME directive that passes the original C/C++ name to the Code Generator for names that are modified in the SDL translation.

Fundamental Types

Rule: A fundamental C/C++ type is mapped to an SDL sort with the same name.

The SDL sorts that represent fundamental C/C++ types are not generated by CPP2SDL but are defined in special SDL/PR files that are included if the `-generatecpptypes` option is set. The SDL sorts in these files are normally syntypes of predefined SDL sorts. Refer to "SDL Library for Fundamental C/C++ Types" on page 848 for more information.

The table below shows how the fundamental C/C++ types are translated to SDL sorts, and what predefined SDL sort that correspond to these SDL sorts.

C/C++ Fundamental Type	SDL Sort	Predefined SDL Sort
signed int int	int	Integer
unsigned int unsigned	unsigned_int	Integer
signed long int signed long long int long	long_int	Integer
unsigned long int unsigned long	unsigned_long_int	Integer
signed short int signed short short int short	short_int	Integer
unsigned short int unsigned short	unsigned_short_int	Integer
signed long long int signed long long long long int long long	long_long_int	Integer
unsigned long long int unsigned long long	unsigned_long_long_int	Integer
char	char	Character
signed char	signed_char	Character
unsigned char	unsigned_char	Octet
wchar_t	wchar_t	N/A
float	float	Real
double long double	double	Real
bool	bool	Boolean
void	N/A	N/A

Note that the `wchar_t` type has no counterpart in SDL, and thus is represented by a newtype rather than a syntype of a predefined sort.

Also note that the special `void` type is not represented explicitly in SDL. Instead this type is translated by omitting input and result arguments to operators as described in "Functions" on page 793.

Type Declarators

There are two different type declarators in C; pointer (*), and array ([]). C++ has one additional type declarator; reference (&).

Pointers

Rule: A type with a pointer declarator is translated by applying the `Ref` generator on the SDL sort that corresponds to that type.

The name of the generated newtype for the pointer is prefixed with a user-configurable string that by default is `ptr_`. The option `-prefix` can be used to configure this string.

Untyped pointers (`void*`) are translated to a special SDL sort called `ptr_void`. See "SDL Library for Fundamental C/C++ Types" on page 848 for more information about the `Ref` generator and the special `ptr_void` sort.

Example 92: Translation of pointers ----------

C++:

```
typedef int* p_int;
extern void* generalp;
```

SDL:

```
NEWTYPE ptr_int Ref( int);
  OPERATORS
    ptr_int : -> ptr_int;
    ptr_int : ptr_int -> ptr_int;
ENDNEWTYPE ptr_int;EXTERNAL 'C++';
SYNTYPE p_int = ptr_int
ENDSYNTYPE p_int;EXTERNAL 'C++';
DCL generalp ptr_void; EXTERNAL 'C++';
```

Arrays

Rule: A type with an array declarator is translated by applying the `CArray` generator on the SDL sort that corresponds to that type.

There is one important exception to this rule. Array declarators that do not specify the size of the array are translated in the same way as pointers (see "Pointers" on page 788).

The name of the generated newtype for an array type with a specified size is prefixed with a user-configurable string that by default is "arr_". The option `-prefix` can be used to configure this string. The name also contains the size of the array, since the size is used in the `CArray` generator instantiation and thus is significant in SDL. This makes SDL array sorts of different sizes type incompatible, but this is normally not a big problem since the elements of the arrays are type compatible.

> **Note:**
>
> SDL array sorts corresponding to C/C++ arrays with different sizes are normally type incompatible.

Example 93: Translation of arrays ----------

C++:

```
extern char c_arr1[20];
extern char c_arr2[];
```

SDL:

```
NEWTYPE arr_20_char CArray( 20, char);
ENDNEWTYPE arr_20_char;EXTERNAL 'C++';
DCL c_arr1 arr_20_char; EXTERNAL 'C++';
NEWTYPE ptr_char Ref( char);
  OPERATORS
    ptr_char : -> ptr_char;
    ptr_char : ptr_char -> ptr_char;
ENDNEWTYPE ptr_char;EXTERNAL 'C++';
DCL c_arr2 ptr_char; EXTERNAL 'C++';
```

References

Rule: A type with a reference declarator is translated as normal, i.e. the reference declarator is not translated to SDL.

A C++ reference can be looked upon as a constant pointer that is automatically de-referenced each time it is used. This makes a reference an alternative name for an object. Since no difference will be made between an object and a reference to an object in the SDL mapping, references will appear to be objects in SDL.

Example 94: Translation of references ----------

C++:

```
extern int i; /* i is initialized elsewhere */
extern int& r; /* r is initialized to i elsewhere
                                              (int& r =
i;), i.e. r and i refers to
                    the same int. */
```

SDL:

```
DCL i int; EXTERNAL 'C++';
DCL r int; EXTERNAL 'C++';/* N.B. C++ reference! */
```

Note that if `r` in this example is assigned a value in SDL, it is in fact the object that `r` refers to (i.e. `i`) that gets a new value. This could be confusing if only the SDL translation of `r` is considered, and to avoid this a comment is attached to the declaration of `r` that tells that it is a reference in C++.

References could also appear as specifiers for formal function arguments. Such arguments will be translated to operator arguments marked with the IN/OUT keyword if they are non-constant (see "Argument Passing and Return Value" on page 794).

Enumerated Types

Rule: An enumerated type is translated to a newtype with literals corresponding to the enum literals.

A special case is when the enumerated type has no literals. Such a type can be treated as an integer in C/C++, and is consequently translated to a syntype of `int`.

Example 95: Translation of enumerated types----------

C/C++:

```
enum {} v;
enum E2 {};
enum E1 {a, b, c=10};
```

SDL:

```
DCL v int; EXTERNAL 'C++';
SYNTYPE E2 = int
ENDSYNTYPE E2;EXTERNAL 'C++';
NEWTYPE E1
```

```
    LITERALS a, b, c;
    OPERATORS
      IntToEnum /*#REFNAME '(E1)'*/ : int -> E1;
      EnumToInt : E1 -> int; /*#OP(PY)*/
      ORDERING;
ENDNEWTYPE E1;EXTERNAL 'C++';
```

By using the “type conversion” operators `EnumToInt` and `IntToEnum` integer arithmetic and comparisons become available in SDL also for enumerations. As can be seen from the #REFNAME directive in the example above, the generated code for calls to the `IntToEnum` operator will be a C style cast from `int` to `enum`. This explicit type conversion should be acceptable by all target compilers. Also note that the #OP(PY) directive means that there will be no generated code for calls to the `EnumToInt` operator, which is desired since that type conversion is implicit in C/C++.

If the enumerated type is incomplete, i.e. if the enum tag is missing, the translation rule is slightly modified according to the translation rules for incomplete types (see “Incomplete Types” on page 830). For enumerations, these rules have the following impact:

· The name of the generated newtype follows the naming rules for incomplete types described in “Incomplete Types” on page 830.

· The newtype will not be external, since it does not correspond to a C/C++ type that may be referred to.

· The `IntToEnum` operator will not be generated for the same reason.

Typedef Declarations

Rule: A typedef declaration is translated to an SDL syntype declaration.

There are two exceptions to this rule:

- A typedef declaration of a tagged type[1], where the typedef name is the same as the name of the tag.
- A typedef declaration where the typedef name has been omitted. This is a legal but not very common case.

1. A tagged type is a class, struct, union or enum type with a tag.

In these cases the typedef declarations do not define new typenames, and thus no syntypes need to be generated.

Another special case is when a synonym for `void` is introduced by means of a typedef declaration. Such a typedef declaration is not translated, but the typedef name will be remembered. References to the typedef name will then be translated in the same way as `void` would have been translated in that context.

Example 96: Translation of typedef declarations ––––––––––––––––

C++:

```
typedef int MyInt;
typedef struct r {
                int a;
} r; // Typedef name is the same as the tag name!
typedef struct s {
  MyInt a;
}; // Omitted typedef name - legal but rare!
typedef void myvoid;
typedef myvoid myvoid2;
myvoid f(myvoid2);
```

SDL:

```
NEWTYPE global_namespace_ImpSpec /*#NOTYPE*/
  OPERATORS
    f :;
ENDNEWTYPE global_namespace_ImpSpec;EXTERNAL 'C++';
SYNTYPE MyInt = int
ENDSYNTYPE MyInt;EXTERNAL 'C++';
NEWTYPE ptr_r Ref( r);
  OPERATORS
    ptr_r : -> ptr_r;
    ptr_r : ptr_r -> ptr_r;
ENDNEWTYPE ptr_r;EXTERNAL 'C++';
NEWTYPE r
  STRUCT
    a int;
  OPERATORS
    r : -> r;
    r : r -> r;
ENDNEWTYPE r;EXTERNAL 'C++';
NEWTYPE ptr_s Ref( s);
  OPERATORS
    ptr_s : -> ptr_s;
    ptr_s : ptr_s -> ptr_s;
ENDNEWTYPE ptr_s;EXTERNAL 'C++';
NEWTYPE s
  STRUCT
    a MyInt;
  OPERATORS
```

```
    s : -> s;
    s : s -> s;
ENDNEWTYPE s;EXTERNAL 'C++';
```

Note:

Typedefs of function types are not supported by CPP2SDL, and will not be translated to SDL.

Functions

Rule: A function prototype is translated to an SDL operator signature.

This rule is valid both for member and non-member functions. Operators that result from functions that are members of a class will be placed in the newtype that is the translation of that class. Operators that result from non-member functions will be placed in a special newtype called `global_namespace_ImpSpec`[1].

Member functions are described in "Members" on page 807, and the rest of this section will focus on non-member functions.

Example 97: Translation of non-member functions

C++:

```
char myfunc1(char);
int myfunc1();
void myfunc2();
void myfunc2(int);
```

SDL:

```
NEWTYPE global_namespace_ImpSpec /*#NOTYPE*/
  OPERATORS
    myfunc1 : char -> char;
    myfunc1 : -> int;
    myfunc2 :;
    myfunc2 : int;
ENDNEWTYPE global_namespace_ImpSpec;EXTERNAL 'C++';
```

Note that functions without input arguments or return value, will be translated to operators without input arguments or return value. Such operators are not allowed according to the SDL96 standard, but are accepted by the SDL Analyzer as a tool specific language extension.

1. This name indicates that the newtype represents the global scope in C/C++. In C++ terminology this scope is often called the global namespace.

Overloaded Functions

Rule: Overloaded functions are translated to overloaded SDL operators.

The semantics of overloaded functions in C++ differs slightly from the semantics of overloaded operators in SDL. For example, C++ allows overloading on constant arguments which is not possible in SDL. A C++ header file may therefore contain overloaded functions that cannot be translated to SDL. Normally this is not a problem since the C++ compiler resolves generated calls to these functions correctly anyway.

Example 98: Translation of overloaded functions

C++:

```
int f0();
int f0(double);
int f1(int&);
int f1(const int&);
```

SDL:

```
NEWTYPE global_namespace_ImpSpec /*#NOTYPE*/
  OPERATORS
    f0 : -> int;
    f0 : double -> int;
    f1 : int -> int;
ENDNEWTYPE global_namespace_ImpSpec;EXTERNAL 'C++';
```

Argument Passing and Return Value

Rule: Function arguments that are passed by reference are translated to IN/OUT operator arguments in SDL.

There is one exception to this rule; arguments that are references to constants do not translate to IN/OUT arguments since C++ allows these arguments to take variables as well as constant values.

Example 99: Translation of function arguments and return value

C++:

```
int f1 (int p1, int &p2, const int &p3, const int
*p4, int *const p5);
int &f2();
const int &f3();
```

SDL:

```
NEWTYPE global_namespace_ImpSpec /*#NOTYPE*/
  OPERATORS
    f1 : int, IN/OUT int, int, ptr_int, ptr_int ->
int;
    f2 : -> int;
    f3 : -> int;
ENDNEWTYPE global_namespace_ImpSpec;EXTERNAL 'C++';
NEWTYPE ptr_int Ref( int);
  OPERATORS
    ptr_int : -> ptr_int;
    ptr_int : ptr_int -> ptr_int;
ENDNEWTYPE ptr_int;EXTERNAL 'C++';
```

The example shows that information about constant arguments is lost in the SDL mapping. Also note that no difference will be made in SDL between functions that return data by value, data by reference, or constant data by reference.

Finally note that IN/OUT arguments to operators is a tool specific SDL extension.

Default Arguments

Rule: A function with default arguments are translated to several overloaded SDL operators.

This translation is reasonable given the fact that each C++ function with default arguments may be rewritten to an equivalent set of overloaded C++ functions.

Example 100: Translation of functions with default arguments

C++:

```
int func(int a, int b = 5, int c = 7);
int func(int a); // Ambiguous function!
```

SDL:

```
NEWTYPE global_namespace_ImpSpec /*#NOTYPE*/
  OPERATORS
    func : int, int, int -> int;
    func : int, int -> int;
    func : int -> int;
ENDNEWTYPE global_namespace_ImpSpec;EXTERNAL 'C++';
```

In C++, ambiguities between overloaded functions are allowed provided that the functions are never called. SDL is, however, more strict, and

operator resolution is made from the declarations of the operators. The second version of `func` in the example above is therefore not accessible in the SDL mapping.

Unspecified Arguments

Rule: The translation of a function with unspecified arguments (a.k.a. an ellipsis function) requires the usage of an import specification that specifies the types of the unknown arguments.

See "Prototypes for Ellipsis Functions" on page 779 for information about how an import specification can be used to "expand" ellipsis functions.

Inline Functions

Rule: A function that is declared to be inline is translated as an ordinary function.

This is natural since the `inline` keyword on functions can be seen as a directive to the C++ compiler, which only affects the way that calls to these functions are generated. This is of course nothing that needs to be visible in SDL.

Example 101: Translation of inline functions

C++:

```
inline int fac(int n){/*...*/};
```

SDL:

```
NEWTYPE global_namespace_ImpSpec /*#NOTYPE*/
  OPERATORS
    fac : int -> int;
ENDNEWTYPE global_namespace_ImpSpec;EXTERNAL 'C++';
```

Function Pointers

Rule: A function pointer is translated to an untyped pointer in SDL, i.e. to `ptr_void`.

This translation rule makes it possible to represent a function pointer in SDL, but it is not possible to call the function that it points to, or to assign the address of another function to it. That has to be done with inline C/C++ code, for example by means of the #CODE operator.

Example 102: Translation of function pointers ––––––––––––––––––

C++:

```
typedef int (*fp)(int, char);
fp g(double);
```

SDL:

```
NEWTYPE global_namespace_ImpSpec /*#NOTYPE*/
  OPERATORS
    g : double -> fp;
ENDNEWTYPE global_namespace_ImpSpec;EXTERNAL 'C++';
SYNTYPE fp = ptr_void
ENDSYNTYPE fp;EXTERNAL 'C++';
```

––

The special `ptr_void` sort is described in "SDL Library for Fundamental C/C++ Types" on page 848.

Scope Units

Rule: A C/C++ scope unit is translated to an SDL newtype.

Note that the global scope (known as the global namespace in C++) is also translated to an SDL newtype. This newtype is called `global_namespace_`<ImpSpec> (where <ImpSpec> is the name of the import specification file) and is a container for all operators that are the translation of non-member or global functions in the program. Other global declarations are however placed directly in the SDL scope that is the context of the translation.

Example 103: Translation of the global namespace ––––––––––––––

C++:

```
int i;
void op(unsigned int);
```

SDL:

```
NEWTYPE global_namespace_ImpSpec /*#NOTYPE*/
  OPERATORS
    op : unsigned_int;
ENDNEWTYPE global_namespace_ImpSpec;EXTERNAL 'C++';
DCL i int; EXTERNAL 'C++';
```

––

The most important scope units that may be found in a C/C++ header file are:

- Namespaces
- Classes, structs and unions
- Template classes

In C++ these scope units may be nested to arbitrary depth, but since nested newtypes are not allowed in SDL, the translation of a nested scope unit will be a newtype that has a name that is prefixed with a scope qualification prefix. This prefix consists of the names of all enclosing scope units separated by underscores ("_").

Example 104: Translation of nested scope units

C++:

```
class C {
public:
          int ci;
  class CC {
  public:
    int op();
  };
};
```

SDL:

```
NEWTYPE ptr_C_CC Ref( C_CC);
  OPERATORS
    ptr_C_CC : -> ptr_C_CC;
    ptr_C_CC : ptr_C_CC -> ptr_C_CC;
ENDNEWTYPE ptr_C_CC;EXTERNAL 'C++';
NEWTYPE C_CC /*#REFNAME 'C::CC'*/
  OPERATORS
    op : C_CC -> int;
    C_CC /*#REFNAME 'CC'*/ : -> C_CC;
    C_CC /*#REFNAME 'CC'*/ : C_CC -> C_CC;
ENDNEWTYPE C_CC;EXTERNAL 'C++';
NEWTYPE ptr_C Ref( C);
  OPERATORS
    ptr_C : -> ptr_C;
    ptr_C : ptr_C -> ptr_C;
ENDNEWTYPE ptr_C;EXTERNAL 'C++';
NEWTYPE C
  STRUCT
    ci int;
  OPERATORS
    C : -> C;
    C : C -> C;
ENDNEWTYPE C;EXTERNAL 'C++';
```

Compare the name "C_CC" of the nested class CC in this example, with the fully qualified name "C::CC" of this class in C++. The latter name is provided in a #REFNAME directive as information to the Code Generator.

Namespaces

Rule: A namespace is translated to a newtype that may not be instantiated in SDL.

Classes, structs, unions and template classes not only define scope units, but also types. They may thus be instantiated in for example variable declarations. Namespaces, on the other hand, are plain scope units and may not be instantiated. This is indicated in the SDL mapping by means of a Code Generator directive called #NOTYPE. This directive enables the Code Generator to catch attempts to instantiate newtypes that originates from namespaces.

Example 105: Translation of namespaces ––––––––––––––––––––

C++:

```
namespace N {
          const int ci;
  class CC {
  public:
    int op();
  };
  int f(char);
}
```

SDL:

```
SYNONYM N_ci /*#REFNAME 'N::ci'*/ int = EXTERNAL
'C++';
NEWTYPE ptr_N_CC Ref( N_CC);
  OPERATORS
    ptr_N_CC : -> ptr_N_CC;
    ptr_N_CC : ptr_N_CC -> ptr_N_CC;
ENDNEWTYPE ptr_N_CC;EXTERNAL 'C++';
NEWTYPE N_CC /*#REFNAME 'N::CC'*/
  OPERATORS
    op : N_CC -> int;
    N_CC /*#REFNAME 'CC'*/ : -> N_CC;
    N_CC /*#REFNAME 'CC'*/ : N_CC -> N_CC;
ENDNEWTYPE N_CC;EXTERNAL 'C++';
NEWTYPE N /*#NOTYPE*/
  OPERATORS
    N_f /*#REFNAME 'N::f'*/ : char -> int;
```

```
ENDNEWTYPE N;EXTERNAL 'C++';
```

Note that the newtype that corresponds to the namespace only contains the operators that are the translation of the functions declared in that namespace. This is analogous to how the global namespace is translated (see Example 103). Other declarations in the namespace will appear outside the newtype. All SDL declarations that are generated from namespace declarations will be prefixed with the name of the newtype that is the translation of that namespace. Also, their fully qualified C++ name is given in #REFNAME directives.

Variables

Rule: A variable is translated to an external variable if it is a non-member or global variable, or to a newtype field if it is a member variable.

Newtype fields that result from member variables of a class will be placed in the newtype that is the translation of that class. Member variables are described in "Members" on page 807, and the rest of this section will focus on non-member variables.

Example 106: Translation of non-member variables

C++:

```
int ivar, jvar;
class X {
        int j;
public:
  int Get() { return j;};
} xvar;
```

SDL:

```
DCL ivar int; EXTERNAL 'C++';
DCL jvar int; EXTERNAL 'C++';
NEWTYPE ptr_X Ref( X);
  OPERATORS
    ptr_X : -> ptr_X;
    ptr_X : ptr_X -> ptr_X;
ENDNEWTYPE ptr_X;EXTERNAL 'C++';
NEWTYPE X
  OPERATORS
    Get : X -> int;
    X : -> X;
    X : X -> X;
ENDNEWTYPE X;EXTERNAL 'C++';
```

```
DCL xvar X; EXTERNAL 'C++';
```

External variables are a tool-specific SDL extension that are similar to external synonyms.

External variables may only be declared in a process, procedure, service or operator diagram. Since CPP2SDL does not know the SDL context where the translation takes place, it has a command line option called `-novariables` that tells whether external variables may be generated or not. When CPP2SDL is executed from the Organizer, this option is set automatically. If the option is set, and a C/C++ construct is found that would map to an external variable, CPP2SDL will print a warning.

Constants

Rule: A constant is translated to an external synonym.

This rule applies for all true C/C++ constants, i.e. constants that have been declared using the `const` type specifier. It is not uncommon, especially in older C API:s, to use macros to represent constants. Such constants will not be directly accessible in SDL since the preprocessor expands them before CPP2SDL begins the translation. However, simple macro constants may often be accessed by using inline target code, for example by means of the #CODE operator. As an alternative external synonyms could be declared to represent such macros.

> **Note:**
> With the option `-extsyn` the translation of constants differs some. For constants with numeric expressions that can be calculated during translation, the default transformation rule is that also the constant value is translated. If `-extsyn` is switched on, translation is always an external synonym without its value.

Example 107Translation using -extsyn

C++:

```
const int FOO = 1;
const float ScoobieDoo = FOO/4;
const bool YOU;
```

SDL without -extsyn option (default behavior):

```
SYNONYM FOO int = 1;
SYNONYM ScoobieDoo float = 0.25;
```

```
SYNONYM YOU bool = EXTERNAL 'C++';
```

SDL with -extsyn option:

```
SYNONYM FOO int = EXTERNAL 'C++';
SYNONYM ScoobieDoo float = EXTERNAL 'C++';
SYNONYM YOU bool = EXTERNAL 'C++';
```

Example 108: Translation of constants ––––––––––––––––––––––––

C++:

```
class MyClass;
const double pi = 3.1415;
const MyClass m(7, 'x');
```

SDL:

```
SYNONYM pi double = 3.1415;
NEWTYPE MyClass /*#NOTYPE*/
ENDNEWTYPE MyClass;EXTERNAL 'C++';
SYNONYM m MyClass = EXTERNAL 'C++';
```

––

Constant Expressions

Rule: Constant expressions are evaluated while translated to SDL.

Constant expressions may be encountered at a number of places in a C/C++ header, for example as constant initializers, or as size specifiers of array declarators or bitfields. If a constant expression has to be translated to SDL, CPP2SDL attempts to evaluate it during the translation in order to simplify its representation in SDL.

Example 109: Translation of constant expressions ––––––––––––––

C++:

```
enum e {a, b, c=10};
const int i = (2+c)*b;
struct s{
  int f1 : (2+c)*b;
};
typedef int intarr[sizeof(int)+1];
```

SDL:

```
NEWTYPE e
  LITERALS a, b, c;
  OPERATORS
    IntToEnum /*#REFNAME '(e)'*/ : int -> e;
```

```
    EnumToInt : e -> int; /*#OP(PY)*/
    ORDERING;
ENDNEWTYPE e;EXTERNAL 'C++';
SYNONYM i int = 12;
NEWTYPE ptr_s Ref( s);
  OPERATORS
    ptr_s : -> ptr_s;
    ptr_s : ptr_s -> ptr_s;
ENDNEWTYPE ptr_s;EXTERNAL 'C++';
NEWTYPE s
  STRUCT
    f1 int : 12;
  OPERATORS
    s : -> s;
    s : s -> s;
ENDNEWTYPE s;EXTERNAL 'C++';
NEWTYPE arr_2_int CArray( 2, int);
ENDNEWTYPE arr_2_int;EXTERNAL 'C++';
SYNTYPE intarr = arr_2_int
ENDSYNTYPE intarr;EXTERNAL 'C++';
```

Note that not all the constant expressions in this example are visible in the SDL translation, and thus need not be evaluated by CPP2SDL.

Most constant expressions can be evaluated by CPP2SDL, but not all. In particular, expressions containing the `sizeof()` operator are difficult to evaluate since CPP2SDL has no information about what compiler that will be used to compile the generated C/C++ code. Some standard assumptions are therefore used when a `sizeof()` operator is encountered, and a warning will be issued to encourage manual inspection of the translation.

Classes, Structs and Unions

Rule: A class, struct or union is translated to an SDL newtype.

This rule follows from the fact that classes, structs and unions are scope units (see "Scope Units" on page 797).

This section mainly uses classes in the discussions and examples, but since the translation rules make no difference between classes, structs and unions, the same is valid for structs and unions. Example 110 shows the translation of an empty class, struct and union.

Example 110: Translation of classes, structs and unions ----------

C++:

```
class C {};
struct S {};
union U {};
```

SDL:

```
NEWTYPE ptr_C Ref( C);
  OPERATORS
    ptr_C : -> ptr_C;
    ptr_C : ptr_C -> ptr_C;
ENDNEWTYPE ptr_C;EXTERNAL 'C++';
NEWTYPE C
  OPERATORS
    C : -> C;
    C : C -> C;
ENDNEWTYPE C;EXTERNAL 'C++';
NEWTYPE ptr_S Ref( S);
  OPERATORS
    ptr_S : -> ptr_S;
    ptr_S : ptr_S -> ptr_S;
ENDNEWTYPE ptr_S;EXTERNAL 'C++';
NEWTYPE S
  OPERATORS
    S : -> S;
    S : S -> S;
ENDNEWTYPE S;EXTERNAL 'C++';
NEWTYPE ptr_U Ref( U);
  OPERATORS
    ptr_U : -> ptr_U;
    ptr_U : ptr_U -> ptr_U;
ENDNEWTYPE ptr_U;EXTERNAL 'C++';
NEWTYPE U
  OPERATORS
    U : -> U;
    U : U -> U;
ENDNEWTYPE U;EXTERNAL 'C++';
```

In the example above three C++ types translate to six SDL sorts. The reason for this is that when CPP2SDL generates a newtype for a class, it will also, by default, generate a newtype that represents a pointer type for this class. This is convenient since pointers to a class often are needed. If the class inherits other classes this pointer newtype is in fact necessary, since it then holds cast operators to the base types of the class (see "Type Compatibility between Pointers to Inherited Classes" on page 824). If the command line option `-optclasspointers` has been set, CPP2SDL will not generate this extra newtype unless a pointer to the class is explicitly present in the input code.

If the class, struct, or union has no tag, it is an incomplete type declaration. The translation rules for incomplete types are described in "Incomplete Types" on page 830.

When importing a C/C++ union, the imported PR code will contain a /*#UNIONC*/ directive for the newtype representing that union.

Anonymous Unions

Rule: An anonymous union is translated by making its members become fields of the newtype that represents the enclosing scope unit.

This translation rule is natural since an anonymous union is no scope unit.

Example 111: Translation of Anonymous Unions

C++:

```
struct S {
        int i;
  union {
    int j;
    int k;
  };
};
```

SDL:

```
NEWTYPE ptr_S Ref( S);
  OPERATORS
    ptr_S : -> ptr_S;
    ptr_S : ptr_S -> ptr_S;
ENDNEWTYPE ptr_S;EXTERNAL 'C++';
NEWTYPE S
  STRUCT
    j int;/* member of anonymous union */
    k int;/* member of anonymous union */
    i int;
  OPERATORS
    S : -> S;/*implicit parameter-less constructor*/
    S : S -> S;/* implicit copy constructor */
ENDNEWTYPE S;EXTERNAL 'C++';
```

Note that an anonymous union is not an incomplete type declaration, although the syntax is similar. An anonymous union is not used to declare a type nor a variable, and does not define a type at all. Consequently, the translation rules for anonymous unions and incomplete types differ significantly. Compare with "Incomplete Types" on page 830.

Constructors

Rule: A constructor for a class is translated to an operator with the same name as the newtype that represents the class.

The return sort of the operator will be the sort defined by the newtype for the class, and the operator will of course also be placed in that newtype.

There are two different kinds of constructors in C++:

- User-defined constructors. These constructors are manually declared and implemented.
- Implicit constructors. These constructors are implicitly declared and are auto-generated by the C++ compiler, provided that they are not already declared by the user.

While a class may contain an arbitrary number of user-defined constructors, it may at the most contain two auto-generated ones; a parameter-less (or default) constructor and a copy constructor. A parameterless constructor is available only if the class has no user-defined constructors, and a copy constructor is available only if no user-defined copy constructor is declared.

CPP2SDL will generate operators both for user-defined and implicit constructors. Example 112 below shows a class with three user-defined constructors, and one implicit copy constructor.

Example 112: Translation of constructors ––––––––––––––––––––––

C++:

```
class C {
public:
  C();
  C(int i);
  C(char c);
  ~C();
};
```

SDL:

```
NEWTYPE ptr_C Ref( C);
  OPERATORS
    ptr_C : -> ptr_C;
    ptr_C : ptr_C -> ptr_C;
ENDNEWTYPE ptr_C;EXTERNAL 'C++';
NEWTYPE C
  OPERATORS
```

```
    C : -> C;
    C : char -> C;
    C : int -> C;
    C : C -> C;/* implicit copy constructor */
ENDNEWTYPE C;EXTERNAL 'C++';
```

Destructors

Rule: A destructor is not translated to SDL.

The reason why a class destructor is not made accessible in SDL, is that it normally should not be called explicitly. Instead it will be called automatically when an object of the class goes out of scope or is deleted. See Example 112 for an example of how a destructor disappears in the SDL mapping.

Members

Rule: Member variables of a C++ class are translated to fields in the newtype that is the translation of that class, and member functions are translated to operators in the same newtype.

Other declarations than variables and functions in a class, for example type declarations, are also sometimes called members of the class, but they are not translated according to the translation rule above. Instead they are considered to be declarations on their own, but defined in an enclosing scope unit (i.e. the class). See "Scope Units" on page 797 for more information.

Example 113: Translation of class members

C++:

```
class C {
public:
  int mv1; // Member variable
  void mf1(long long p1); // Member function
  enum e {a,b,c}; // "Member" type declaration
};
```

SDL:

```
NEWTYPE C_e /*#REFNAME 'C::e'*/
  LITERALS a, b, c;
  OPERATORS
    IntToEnum /*#REFNAME '(C::e)'*/ : int -> C_e;
    EnumToInt : C_e -> int; /*#OP(PY)*/
    ORDERING;
```

```
ENDNEWTYPE C_e;EXTERNAL 'C++';
NEWTYPE ptr_C Ref( C);
  OPERATORS
    ptr_C : -> ptr_C;
    ptr_C : ptr_C -> ptr_C;
ENDNEWTYPE ptr_C;EXTERNAL 'C++';
NEWTYPE C
  STRUCT
    mv1 int;
  OPERATORS
    mf1 : C, long_long_int;
    C : -> C;/* implicit parameter-less constructor
*/
    C : C -> C;/* implicit copy constructor */
ENDNEWTYPE C;EXTERNAL 'C++';
```

Note that the operator that represents a member function will have an additional initial formal argument. This argument has the sort of the newtype that represents the class where the member function is declared. Member functions are called from SDL in a functional style, where the first actual argument to the member function operator is the class instance on which the member function is to be invoked.

Member Access Specifier

Rule: Only members with public access specifier are translated to SDL.

This rule follows from the fact that public members of a class are the only members that are accessible from outside that class or its derived classes.

Example 114: Translation of members with different access specifiers

C++:

```
class C {
private:
        int i;
protected:
  int j;
public:
  int k;
  int GetI();
  int GetJ();
  int Calc (int x, int y);
};
```

SDL:

```
NEWTYPE ptr_C Ref( C);
```

```
  OPERATORS
    ptr_C : -> ptr_C;
    ptr_C : ptr_C -> ptr_C;
ENDNEWTYPE ptr_C;EXTERNAL 'C++';
NEWTYPE C
  STRUCT
    k int;
  OPERATORS
    Calc : C, int, int -> int;
    GetI : C -> int;
    GetJ : C -> int;
    C : -> C;
    C : C -> C;
ENDNEWTYPE C;EXTERNAL 'C++';
```

Virtual Member Functions

Rule: A virtual member function is translated in the same way as an ordinary member function.

In C++, virtual functions of a base class may be redefined in derived classes. Although this means that there is only one version of a particular virtual function in a derived class, the version defined in the base class may still be called by means of explicit qualification. Both versions of the function must thus be present in the SDL translation, exactly as is the case for non-virtual functions. See "Inheritance" on page 814 for more about how C++ inheritance is represented in SDL.

Example 115: Translation of virtual member functions

C++:

```
class CPen {
public:
  virtual void Draw(); // Virtual member function
  double GetRep(); // Non-virtual member function
};
class CPenD : public CPen {
public:
  virtual void Draw(); // Redefinition of
CPen::Draw()
};
```

SDL:

```
NEWTYPE ptr_CPen Ref( CPen);
  OPERATORS
    ptr_CPen : -> ptr_CPen;
    ptr_CPen : ptr_CPen -> ptr_CPen;
ENDNEWTYPE ptr_CPen;EXTERNAL 'C++';
```

```
NEWTYPE CPen
  OPERATORS
    Draw : CPen;
    GetRep : CPen -> double;
    CPen : -> CPen;
    CPen : CPen -> CPen;
ENDNEWTYPE CPen;EXTERNAL 'C++';
NEWTYPE ptr_CPenD Ref( CPenD);
  OPERATORS
    cast : ptr_CPenD -> ptr_CPen; /*#OP(PY)*/
    ptr_CPenD : -> ptr_CPenD;
    ptr_CPenD : ptr_CPenD -> ptr_CPenD;
ENDNEWTYPE ptr_CPenD;EXTERNAL 'C++';
NEWTYPE CPenD
  OPERATORS
    Draw : CPenD;
    CPen_Draw /*#REFNAME 'CPen::Draw'*/ : CPenD;/*
Inherited from CPen */
    GetRep : CPenD -> double;/* Inherited from CPen
*/
    CPenD : -> CPenD;/
    CPenD : CPenD -> CPenD;
ENDNEWTYPE CPenD;EXTERNAL 'C++';
```

Pure Virtual Member Functions

Rule: A pure virtual member function is translated in the same way as an ordinary member function.

Although “pure virtuality” does not affect the translation of the member function itself, it will have impact on how the containing class, which is an abstract class, is translated. The reason is that special translation rules apply for abstract classes. See “Abstract Classes” on page 826 for more information and an example on how pure virtual member functions are translated.

Static Members

Rule: A static member is translated both as an ordinary member, and as if it was declared in the global namespace.

There will thus be two representations in SDL of a static C++ member. The additional representation is caused by the fact that a static member is accessible without having an instance of the class where it is defined.

As shown in Example 116 below, a static member variable will be translated both to a newtype field and an external variable (see “Variables” on page 800), while a static member function will result in both

an operator in the newtype for the class and an operator in the special `global_namespace_ImpSpec` newtype (see "Functions" on page 793).

Example 116: Translation of static members

C++:

```
class C {
public:
  static int k;
  static void InitI(int);
};
```

SDL:

```
NEWTYPE global_namespace_ImpSpec /*#NOTYPE*/
  OPERATORS
    C_InitI /*#REFNAME 'C::InitI'*/ : int;
ENDNEWTYPE global_namespace_ImpSpec;EXTERNAL 'C++';
DCL C_k /*#REFNAME 'C::k'*/ int; EXTERNAL 'C++';
NEWTYPE ptr_C Ref( C);
  OPERATORS
    ptr_C : -> ptr_C;
    ptr_C : ptr_C -> ptr_C;
ENDNEWTYPE ptr_C;EXTERNAL 'C++';
NEWTYPE C
  STRUCT
    k int;
  OPERATORS
    InitI : C, int;
    C : -> C;
    C : C -> C;
ENDNEWTYPE C;EXTERNAL 'C++';
```

If the resulting SDL declarations are to be inserted in an SDL context where external variables are not allowed (i.e. if CPP2SDL executes with the `-novariables` option set), static member variables cannot be translated to external variables. In that case only the standard translation of class members can be applied. Naturally, CPP2SDL will issue a warning if this happens.

Constant Members

Rule: A constant member is translated as an ordinary member, but with a #CONSTANT directive attached.

The semantics of a constant member variable is that it may not be written to after its initialization, and a constant member function may not change the state of its object. There is no way to express these restric-

tions in SDL, so the Analyzer will not be able to detect if they are violated. However, by attaching the #CONSTANT directive to SDL declarations that result from constant members, the Code Generator can do the necessary checks.

Example 117: Translation of constant members ––––––––––––––––––

C++:

```
class C {
public:
  const int cm; // constant member
  C(int k) : cm(k) {};
  void Do(double);
                          void Undo(double) const; //
constant member function
};
```

SDL:

```
NEWTYPE ptr_C Ref( C);
  OPERATORS
    ptr_C : -> ptr_C;
    ptr_C : ptr_C -> ptr_C;
ENDNEWTYPE ptr_C;EXTERNAL 'C++';
NEWTYPE C
  STRUCT
    cm /*#CONSTANT*/ int;
  OPERATORS
    C : int -> C;
    Do : C, double;
    Undo : C, double; /*#CONSTANT*/
    C : C -> C;
ENDNEWTYPE C;EXTERNAL 'C++';
```

––

Member Constants

Rule: A member constant is translated both as an ordinary member with a #CONSTANT directive attached, and as if it was declared in the global namespace.

This translation rule is a combination of the translation rules for static and constant members, which is natural since a member constant is declared both to be constant and static in C++.

Example 118: Translation of member constants ––––––––––––––––––

C++:

```
class X {
public:
  static const int i = 99; // member constant
};
const int X::i; // definition of i
```

SDL:

```
SYNONYM X_i /*#REFNAME 'X::i'*/ int = EXTERNAL
'C++';
NEWTYPE ptr_X Ref( X);
  OPERATORS
    ptr_X : -> ptr_X;
    ptr_X : ptr_X -> ptr_X;
ENDNEWTYPE ptr_X;EXTERNAL 'C++';
NEWTYPE X
  STRUCT
    i /*#CONSTANT*/ int;
  OPERATORS
    X : -> X;
    X : X -> X;
ENDNEWTYPE X;EXTERNAL 'C++';
```

Mutable Member Variables

Rule: A mutable member variable is translated as an ordinary member variable.

The `mutable` keyword in C++ can be looked upon as some kind of compiler directive, and needs therefore not be visible in the SDL translation.

Bitfield Member Variables

Rule: A bitfield member variable is translated to an SDL bitfield.

This rule applies for all bitfields that have a name. Bitfields without name are not translated to SDL.

It would have been possible to translate bitfields to ordinary newtype fields. However, by including the bitfield size in the SDL translation, the Analyzer is given a possibility to check that these fields are not assigned values that will not fit in the corresponding bitfield.

Example 119: Translation of bitfields ––––––––––––––––––––––––––

C++:

```
struct A {
  unsigned int i : 12;
  int : 3;
```

```
  bool dirty : 1;
};
```

SDL:

```
NEWTYPE ptr_A Ref( A);
  OPERATORS
    ptr_A : -> ptr_A;
    ptr_A : ptr_A -> ptr_A;
ENDNEWTYPE ptr_A;EXTERNAL 'C++';
NEWTYPE A
  STRUCT
    dirty bool : 1;
    i unsigned_int : 12;
  OPERATORS
    A : -> A;
    A : A -> A;
ENDNEWTYPE A;EXTERNAL 'C++';
```

Note that bitfields are a tool-specific SDL extension.

Friends

Rule: Friend declarations will not be translated to SDL.

Friendship between a class C and another declaration D only affects what members of C that the implementation of D may access. It is therefore uninteresting to supply this information in the SDL translation of the class C.

Inheritance

Rule: C++ inheritance is represented in SDL by adding the translation of all public base class members to the newtype that represents a derived class.

This rule simply means that the C++ inheritance hierarchy is flattened in the SDL newtype representation. The reason for choosing this translation strategy, instead of using SDL inheritance between newtypes, is that the semantics of C++ and SDL inheritance is quite different.

All public member variables and member functions (but not constructors) of direct or indirect bases of a class will be generated in the newtype that is the translation of that class. Such an inherited field or operator will normally have the same name in SDL as in C++, but in some cases it is necessary to prefix the name with the name of the class from which it is inherited[1]. This happens when the name of the inherited member is the same as the name of one of the members in the derived

class. Example 120 below shows how such ambiguities between inherited members are handled.

Example 120: Translation of inheritance ––––––––––––––––––––––

C++:

```
class A {
public:
  int am;
  A(char);
};
class B : public A {
public:
  char bm;
  virtual void calc();
  void set();
};
class C : public B {
public:
  int am;
  double cm;
  void calc(); // Redefines B::calc()
  void set();
};
```

SDL:

```
NEWTYPE ptr_A Ref( A);
  OPERATORS
    ptr_A : -> ptr_A;
    ptr_A : ptr_A -> ptr_A;
ENDNEWTYPE ptr_A;EXTERNAL 'C++';
NEWTYPE A
  STRUCT
    am int;
  OPERATORS
    A : char -> A;
    A : A -> A;
ENDNEWTYPE A;EXTERNAL 'C++';
NEWTYPE ptr_B Ref( B);
  OPERATORS
    cast : ptr_B -> ptr_A; /*#OP(PY)*/
    ptr_B : -> ptr_B;
    ptr_B : ptr_B -> ptr_B;
ENDNEWTYPE ptr_B;EXTERNAL 'C++';
NEWTYPE B
  STRUCT
    am int;/* Inherited from A */
    bm char;
  OPERATORS
    calc : B;
```

1. This naming rule is generalized in "Multiple Inheritance" on page 818.

```
    keyword_set /*#REFNAME 'set'*/ : B;
    B : B -> B;
ENDNEWTYPE B;EXTERNAL 'C++';
NEWTYPE ptr_C Ref( C);
  OPERATORS
    cast : ptr_C -> ptr_A; /*#OP(PY)*/
    cast : ptr_C -> ptr_B; /*#OP(PY)*/
    ptr_C : -> ptr_C;
    ptr_C : ptr_C -> ptr_C;
ENDNEWTYPE ptr_C;EXTERNAL 'C++';
NEWTYPE C
  STRUCT
    am int;
    B_am /*#REFNAME 'B::am'*/ int;/* Inherited from
A */
    bm char;/* Inherited from B */
    cm double;
  OPERATORS
    calc : C;
    B_calc /*#REFNAME 'B::calc'*/ : C;/* Inherited
from B */
    keyword_set /*#REFNAME 'set'*/ : C;
    B_keyword_set /*#REFNAME 'B::keyword_set'*/ :
C;/* Inherited from B */
    C : C -> C;
ENDNEWTYPE C;EXTERNAL 'C++';
```

In C++, it is always possible to use a fully qualified name when accessing a class member, even if the name of the member is unambiguous without qualification. In the example above, the member variable `bm` in `C` that is inherited from `B`, may be referred to both as `bm` and `B::bm`. To avoid getting too many fields and operators in the generated newtypes, only the unqualified name can be used from SDL. This is natural since qualification in C++ normally only is done when necessary to resolve ambiguities.

There are more cases where C++ allows a member to be accessed by more than one name, while the SDL translation only supplies one of these possible names. For example, this applies for inherited types and static members as shown in Example 121 below.

Example 121: Translation of inherited types and static members ----

C++:

```
class B {
public:
        static int mv;
  static char mf(double);
  struct s {
```

```
    int y;
  } ms;
};
class D : public B {
};
```

SDL:

```
NEWTYPE global_namespace_ImpSpec /*#NOTYPE*/
  OPERATORS
    B_mf /*#REFNAME 'B::mf'*/ : double -> char;
ENDNEWTYPE global_namespace_ImpSpec;EXTERNAL 'C++';
NEWTYPE ptr_B Ref( B);
  OPERATORS
    ptr_B : -> ptr_B;
    ptr_B : ptr_B -> ptr_B;
ENDNEWTYPE ptr_B;EXTERNAL 'C++';
NEWTYPE B
  STRUCT
    ms B_s;
    mv int;
  OPERATORS
    mf : B, double -> char;
    B : -> B;
    B : B -> B;
ENDNEWTYPE B;EXTERNAL 'C++';
DCL B_mv /*#REFNAME 'B::mv'*/ int; EXTERNAL 'C++';
NEWTYPE ptr_B_s Ref( B_s);
  OPERATORS
    ptr_B_s : -> ptr_B_s;
    ptr_B_s : ptr_B_s -> ptr_B_s;
ENDNEWTYPE ptr_B_s;EXTERNAL 'C++';
NEWTYPE B_s /*#REFNAME 'B::s'*/
  STRUCT
    y int;
  OPERATORS
    B_s /*#REFNAME 's'*/ : -> B_s;
    B_s /*#REFNAME 's'*/ : B_s -> B_s;
ENDNEWTYPE B_s;EXTERNAL 'C++';
NEWTYPE ptr_D Ref( D);
  OPERATORS
    cast : ptr_D -> ptr_B; /*#OP(PY)*/
    ptr_D : -> ptr_D;
    ptr_D : ptr_D -> ptr_D;
ENDNEWTYPE ptr_D;EXTERNAL 'C++';
NEWTYPE D
  STRUCT
    ms B_s;/* Inherited from B */
    mv int;/* Inherited from B */
  OPERATORS
    mf : D, double -> char;/* Inherited from B */
    D : -> D;
    D : D -> D;
ENDNEWTYPE D;EXTERNAL 'C++';
```

The declarations `B::mv`, `B::mf` and `B::s` in this example may in C++ also be referred to by means of the names `D::mv`, `D::mf` and `D::s`. This is not possible in the SDL translation, i.e. there are no declarations called `D_mv`, `D_mf` or `D_s`. CPP2SDL will choose the first version of the names since the members are declared in `B`.

Multiple Inheritance

The translation rule for C++ inheritance works also when a class inherits from more than one base class. However, the naming strategy described in "Inheritance" on page 814 for handling ambiguous inherited members have to be generalized to also cover the case when a class inherits the same base class more than once.

Example 122: Translation of multiple inheritance ––––––––––––––––

C++:

```
class A {
public:
  int m;
};
class B {
public:
  int m;
  int n;
};
class C: public A, public B {
};
```

SDL:

```
NEWTYPE ptr_A Ref( A);
  OPERATORS
    ptr_A : -> ptr_A;
    ptr_A : ptr_A -> ptr_A;
ENDNEWTYPE ptr_A;EXTERNAL 'C++';
NEWTYPE A
  STRUCT
    m int;
  OPERATORS
    A : -> A;
    A : A -> A;
ENDNEWTYPE A;EXTERNAL 'C++';
NEWTYPE ptr_B Ref( B);
  OPERATORS
    ptr_B : -> ptr_B;
    ptr_B : ptr_B -> ptr_B;
ENDNEWTYPE ptr_B;EXTERNAL 'C++';
NEWTYPE B
  STRUCT
```

```
    m int;
    n int;
  OPERATORS
    B : -> B;
    B : B -> B;
ENDNEWTYPE B;EXTERNAL 'C++';
NEWTYPE ptr_C Ref( C);
  OPERATORS
    cast : ptr_C -> ptr_B; /*#OP(PY)*/
    cast : ptr_C -> ptr_A; /*#OP(PY)*/
    ptr_C : -> ptr_C;
    ptr_C : ptr_C -> ptr_C;
ENDNEWTYPE ptr_C;EXTERNAL 'C++';
NEWTYPE C
  STRUCT
    A_m /*#REFNAME 'A::m'*/ int;/* Inherited from A
*/
    B_m /*#REFNAME 'B::m'*/ int;/* Inherited from B
*/
    n int;/* Inherited from B */
  OPERATORS
    C : -> C;
    C : C -> C;
ENDNEWTYPE C;EXTERNAL 'C++';
```

The names of the generated fields and operators correspond to the qualified names that must be used in C++ to access the members in question. The rule is to qualify an ambiguous member with the most specialized base class that makes the name of the member unique. In most cases this base class is the class where the ambiguous member is declared, but when the inheritance hierarchy forms a graph rather than a tree (see Example 123) it might be necessary to qualify with the name of a class further down on the inheritance path.

Note that in some extraordinary inheritance hierarchies, it is possible that a member of a base class is inaccessible in a derived class. This happens when the inherited member cannot be unambiguously qualified according to the naming rule described above. If this happens, CPP2SDL will not translate the member to SDL, and a warning will be printed.

Virtual and Non-Virtual Inheritance

Rule: Virtual inheritance is translated in the same way as ordinary inheritance.

Virtual inheritance affects the way data is replicated when multiple inheritance is used. As shown in “Multiple Inheritance” on page 818

members that are inherited more than once from the same base class need to be prefixed in SDL.

Since data from a base class is not replicated in derived classes that inherit from the base class with virtual inheritance, it would be possible to avoid prefixing the name of the members that are virtually inherited from the base class. However, since a virtually inherited member in general may be accessed using many alternative prefixes (corresponding to possible paths for reaching the member in the inheritance graph), and none of these prefixes can be said to be more natural to use than the others, all versions of the member's name are included in the SDL translation. This is the reason why no difference is made between virtual and non-virtual inheritance in SDL.

Example 123: Translation of virtual inheritance ––––––––––––––––––

C++:

```
class A {
public:
  int a;
};
class C : public A {
};
class D : public virtual A {
};
class E : public virtual A {
};
class G : public C, public D, public E {
};
```

SDL:

```
NEWTYPE ptr_A Ref( A);
  OPERATORS
    ptr_A : -> ptr_A;
    ptr_A : ptr_A -> ptr_A;
ENDNEWTYPE ptr_A;EXTERNAL 'C++';
NEWTYPE A
  STRUCT
    a int;
  OPERATORS
    A : -> A;
    A : A -> A;
ENDNEWTYPE A;EXTERNAL 'C++';
NEWTYPE ptr_C Ref( C);
  OPERATORS
    cast : ptr_C -> ptr_A; /*#OP(PY)*/
    ptr_C : -> ptr_C;
    ptr_C : ptr_C -> ptr_C;
ENDNEWTYPE ptr_C;EXTERNAL 'C++';
```

```
NEWTYPE C
  STRUCT
    a int;/* Inherited from A */
  OPERATORS
    C : -> C;
    C : C -> C;
ENDNEWTYPE C;EXTERNAL 'C++';
NEWTYPE ptr_D Ref( D);
  OPERATORS
    cast : ptr_D -> ptr_A; /*#OP(PY)*/
    ptr_D : -> ptr_D;
    ptr_D : ptr_D -> ptr_D;
ENDNEWTYPE ptr_D;EXTERNAL 'C++';
NEWTYPE D
  STRUCT
    a int;/* Inherited from A */
  OPERATORS
    D : -> D;
    D : D -> D;
ENDNEWTYPE D;EXTERNAL 'C++';
NEWTYPE ptr_E Ref( E);
  OPERATORS
    cast : ptr_E -> ptr_A; /*#OP(PY)*/
    ptr_E : -> ptr_E;
    ptr_E : ptr_E -> ptr_E;
ENDNEWTYPE ptr_E;EXTERNAL 'C++';
NEWTYPE E
  STRUCT
    a int;/* Inherited from A */
  OPERATORS
    E : -> E;
    E : E -> E;
ENDNEWTYPE E;EXTERNAL 'C++';
NEWTYPE ptr_G Ref( G);
  OPERATORS
    cast : ptr_G -> ptr_E; /*#OP(PY)*/
    cast : ptr_G -> ptr_D; /*#OP(PY)*/
    cast : ptr_G -> ptr_C; /*#OP(PY)*/
    ptr_G : -> ptr_G;
    ptr_G : ptr_G -> ptr_G;
ENDNEWTYPE ptr_G;EXTERNAL 'C++';
NEWTYPE G
  STRUCT
    C_a /*#REFNAME 'C::a'*/ int;/* Inherited from A
*/
    D_a /*#REFNAME 'D::a'*/ int;/* Inherited from A
*/
    E_a /*#REFNAME 'E::a'*/ int;/* Inherited from A
*/
  OPERATORS
    G : -> G;
    G : G -> G;
ENDNEWTYPE G;EXTERNAL 'C++';
```

Inheritance Access Specifier

Rule: Only members that are inherited using public inheritance are translated to SDL.

When the inheritance is private or protected, the members of the base class are not accessible from outside the class. It is therefore natural to exclude members, that are inherited from private and protected bases, in the newtype that represents the derived class.

Example 124: Translation of inheritance with different access specifiers ––

C++:

```
class X {
public:
  int a;
  void f();
};
class Y1 : public X {};
class Y2 : protected X {};
class Y3 : private X {};
```

SDL:

```
NEWTYPE ptr_X Ref( X);
  OPERATORS
    ptr_X : -> ptr_X;
    ptr_X : ptr_X -> ptr_X;
ENDNEWTYPE ptr_X;EXTERNAL 'C++';
NEWTYPE X
  STRUCT
    a int;
  OPERATORS
    f : X;
    X : -> X;
    X : X -> X;
ENDNEWTYPE X;EXTERNAL 'C++';
NEWTYPE ptr_Y1 Ref( Y1);
  OPERATORS
    cast : ptr_Y1 -> ptr_X; /*#OP(PY)*/
    ptr_Y1 : -> ptr_Y1;
    ptr_Y1 : ptr_Y1 -> ptr_Y1;
ENDNEWTYPE ptr_Y1;EXTERNAL 'C++';
NEWTYPE Y1
  STRUCT
    a int;/* Inherited from X */
  OPERATORS
    f : Y1;/* Inherited from X */
    Y1 : -> Y1;
    Y1 : Y1 -> Y1;
ENDNEWTYPE Y1;EXTERNAL 'C++';
```

```
NEWTYPE ptr_Y2 Ref( Y2);
  OPERATORS
    ptr_Y2 : -> ptr_Y2;
    ptr_Y2 : ptr_Y2 -> ptr_Y2;
ENDNEWTYPE ptr_Y2;EXTERNAL 'C++';
NEWTYPE Y2
  OPERATORS
    Y2 : -> Y2;
    Y2 : Y2 -> Y2;
ENDNEWTYPE Y2;EXTERNAL 'C++';
NEWTYPE ptr_Y3 Ref( Y3);
  OPERATORS
    ptr_Y3 : -> ptr_Y3;
    ptr_Y3 : ptr_Y3 -> ptr_Y3;
ENDNEWTYPE ptr_Y3;EXTERNAL 'C++';
NEWTYPE Y3
  OPERATORS
    Y3 : -> Y3;
    Y3 : Y3 -> Y3;
ENDNEWTYPE Y3;EXTERNAL 'C++';
```

The inheritance access specifier also affects how casting from the derived type to the base type can be done. This is described in "Type Compatibility between Inherited Classes" on page 823 and in "Type Compatibility between Pointers to Inherited Classes" on page 824.

Type Compatibility between Inherited Classes

Rule: An object of a derived class may be assigned to an object of a base class by using an explicit cast operator in SDL.

The above assignment (known as slicing) is type-compatible in C++ without the use of a cast operator. Since only the common members are copied in the assignment, this operation is somewhat dangerous and is not generally recommended. Therefore, the cast operators that are needed in SDL to do slicing between objects, are only generated when the `-slicing` option is set.

Example 125: Generation of operators for slicing----------

C++:

```
class C {};
class D {};
class CD : public C, public D {};
```

SDL:

```
NEWTYPE ptr_C Ref( C);
  OPERATORS
```

```
    ptr_C : -> ptr_C;
    ptr_C : ptr_C -> ptr_C;
ENDNEWTYPE ptr_C;EXTERNAL 'C++';
NEWTYPE C
  OPERATORS
    C : -> C;
    C : C -> C;
ENDNEWTYPE C;EXTERNAL 'C++';
NEWTYPE ptr_D Ref( D);
  OPERATORS
    ptr_D : -> ptr_D;
    ptr_D : ptr_D -> ptr_D;
ENDNEWTYPE ptr_D;EXTERNAL 'C++';
NEWTYPE D
  OPERATORS
    D : -> D;
    D : D -> D;
ENDNEWTYPE D;EXTERNAL 'C++';
NEWTYPE ptr_CD Ref( CD);
  OPERATORS
    cast : ptr_CD -> ptr_D; /*#OP(PY)*/
    cast : ptr_CD -> ptr_C; /*#OP(PY)*/
    ptr_CD : -> ptr_CD;
    ptr_CD : ptr_CD -> ptr_CD;
ENDNEWTYPE ptr_CD;EXTERNAL 'C++';
NEWTYPE CD
  OPERATORS
    cast : CD -> D; /*#OP(PY)*/
    cast : CD -> C; /*#OP(PY)*/
    CD : -> CD;
    CD : CD -> CD;
ENDNEWTYPE CD;EXTERNAL 'C++';
```

Note that the inheritance access specifier affects how these cast operators are generated. A cast operator from a class `D` to a class `B` will only be generated if `B` is a public unambiguous base of `D`. If it is private or protected, or is an ambiguous base for `D`, it is not allowed to cast from `D` to `B`.

Type Compatibility between Pointers to Inherited Classes

Rule: A pointer to an object of a derived class may be assigned to a pointer to an object of a base class by using an explicit cast operator in SDL.

The above assignment is type-compatible in C++, i.e. “up-casts” in a class hierarchy are implicit in C++. This is an important property of object-oriented languages that support for example polymorphism. In SDL, however, the newtypes for a base class and a derived class will be unrelated and thus type incompatible. To support up-casting in SDL,

explicit cast operators are generated in the newtype that represents the pointer type to a derived class.

Example 126: Generation of cast operators for up-casting ––––––––––

C++:

```
class C {};
class D {};
class CD : public C, public D {};
```

SDL:

```
NEWTYPE ptr_C Ref( C);
  OPERATORS
    ptr_C : -> ptr_C;
    ptr_C : ptr_C -> ptr_C;
ENDNEWTYPE ptr_C;EXTERNAL 'C++';
NEWTYPE C
  OPERATORS
    C : -> C;
    C : C -> C;
ENDNEWTYPE C;EXTERNAL 'C++';
NEWTYPE ptr_D Ref( D);
  OPERATORS
    ptr_D : -> ptr_D;
    ptr_D : ptr_D -> ptr_D;
ENDNEWTYPE ptr_D;EXTERNAL 'C++';
NEWTYPE D
  OPERATORS
    D : -> D;
    D : D -> D;
ENDNEWTYPE D;EXTERNAL 'C++';
NEWTYPE ptr_CD Ref( CD);
  OPERATORS
    cast : ptr_CD -> ptr_D; /*#OP(PY)*/
    cast : ptr_CD -> ptr_C; /*#OP(PY)*/
    ptr_CD : -> ptr_CD;
    ptr_CD : ptr_CD -> ptr_CD;
ENDNEWTYPE ptr_CD;EXTERNAL 'C++';
NEWTYPE CD
  OPERATORS
    CD : -> CD;
    CD : CD -> CD;
ENDNEWTYPE CD;EXTERNAL 'C++';
```

––

Note that the inheritance access specifier is taken into consideration so that a cast operator from `Ref(D)` to `Ref(B)` only will be generated if the class `B` is a public unambiguous base of the class `D`.

Sometimes it is necessary to do down-casts, or even cross-casts, in a class hierarchy. Such casts (known as dynamic casts) are explicit both

in C++ and SDL. See "Run-Time Type Information and Dynamic Cast" on page 827 for more information.

Abstract Classes

Rule: An abstract class is translated to a newtype without constructor operators.

This translation rule makes it possible to declare pointers to an abstract class, but no objects of such a class may be allocated since there are no constructor operators that can be used as argument to the `new` operator (see "Dynamic Memory Management" on page 832).

Example 127: Translation of abstract classes ––––––––––––––––––––

C++:

```
class C {
public:
  virtual int f(int) = 0; // pure virtual member
function
  C() {};
};
class D : public C {
};
```

SDL:

```
NEWTYPE ptr_C Ref( C);
ENDNEWTYPE ptr_C;EXTERNAL 'C++';
NEWTYPE C
  OPERATORS
    f : C, int -> int;
ENDNEWTYPE C;EXTERNAL 'C++';
NEWTYPE ptr_D Ref( D);
  OPERATORS
    cast : ptr_D -> ptr_C; /*#OP(PY)*/
ENDNEWTYPE ptr_D;EXTERNAL 'C++';
NEWTYPE D
  OPERATORS
    f : D, int -> int;/* Inherited from C */
ENDNEWTYPE D;EXTERNAL 'C++';
```

––

Note from the example above that abstractness is inherited to a derived class if not each pure virtual member function of all its base classes are redefined in the derived class.

Run-Time Type Information and Dynamic Cast

Rule: A pointer to an object of a base class may be assigned to a pointer to an object of a derived class, or to a pointer to an object of a base class of such a derived class, by using an explicit cast operator in SDL.

The above assignments require a dynamic cast in C++, which is done with an explicit cast operator that supports down-casts and cross-casts in an inheritance hierarchy. Since these casts require run-time type information (RTTI) about the dynamic type of an object, most C++ compilers have an option that must be set to safely support dynamic casts. For the same reason, CPP2SDL also has such an option called `-rtti`. If it is set, cast operators will be generated that enable the type conversions that are possible in C++ using dynamic casts.

The source type of a dynamic cast must be polymorphic, i.e. contain one or more virtual member functions, possibly inherited ones. For each such polymorphic class `X`, cast operators will be generated that convert from `Ref(X)` to `Ref(Y)`, for each class `Y` that either inherits from `X` (down-casts), or is a public base class of a class that inherits from `X` (cross-casts).

Example 128 below illustrates this translation rule. It is assumed that all classes in the example contain virtual functions and thus are polymorphic.

Example 128: Generation of cast operators for dynamic casting ––––

C++:

```
class A {};
class B: public A {};
class E {};
class D: protected E {};
class C: public B, public D {};
```

SDL:

```
NEWTYPE ptr_A Ref( A);
  OPERATORS
    ptr_A : -> ptr_A;
    ptr_A : ptr_A -> ptr_A;
ENDNEWTYPE ptr_A;EXTERNAL 'C++';
NEWTYPE A
  OPERATORS
    A : -> A;
    A : A -> A;
ENDNEWTYPE A;EXTERNAL 'C++';
NEWTYPE ptr_B Ref( B);
```

```
  OPERATORS
    cast /*#REFNAME 'dynamic_cast<B*>'*/ : ptr_A ->
ptr_B;
    cast : ptr_B -> ptr_A; /*#OP(PY)*/
    ptr_B : -> ptr_B;
    ptr_B : ptr_B -> ptr_B;
ENDNEWTYPE ptr_B;EXTERNAL 'C++';
NEWTYPE B
  OPERATORS
    B : -> B;
    B : B -> B;
ENDNEWTYPE B;EXTERNAL 'C++';
NEWTYPE ptr_E Ref( E);
  OPERATORS
    ptr_E : -> ptr_E;
    ptr_E : ptr_E -> ptr_E;
ENDNEWTYPE ptr_E;EXTERNAL 'C++';
NEWTYPE E
  OPERATORS
    E : -> E;
    E : E -> E;
ENDNEWTYPE E;EXTERNAL 'C++';
NEWTYPE ptr_D Ref( D);
  OPERATORS
    ptr_D : -> ptr_D;
    ptr_D : ptr_D -> ptr_D;
ENDNEWTYPE ptr_D;EXTERNAL 'C++';
NEWTYPE D
  OPERATORS
    D : -> D;
    D : D -> D;
ENDNEWTYPE D;EXTERNAL 'C++';
NEWTYPE ptr_C Ref( C);
  OPERATORS
    cast /*#REFNAME 'dynamic_cast<A*>'*/ : ptr_D ->
ptr_A;
    cast /*#REFNAME 'dynamic_cast<B*>'*/ : ptr_D ->
ptr_B;
    cast /*#REFNAME 'dynamic_cast<D*>'*/ : ptr_A ->
ptr_D;
    cast /*#REFNAME 'dynamic_cast<D*>'*/ : ptr_B ->
ptr_D;
    cast /*#REFNAME 'dynamic_cast<C*>'*/ : ptr_D ->
ptr_C;
    cast : ptr_C -> ptr_D; /*#OP(PY)*/
    cast /*#REFNAME 'dynamic_cast<C*>'*/ : ptr_A ->
ptr_C;
    cast : ptr_C -> ptr_A; /*#OP(PY)*/
    cast /*#REFNAME 'dynamic_cast<C*>'*/ : ptr_B ->
ptr_C;
    cast : ptr_C -> ptr_B; /*#OP(PY)*/
    ptr_C : -> ptr_C;
    ptr_C : ptr_C -> ptr_C;
ENDNEWTYPE ptr_C;EXTERNAL 'C++';
NEWTYPE C
```

```
  OPERATORS
    C : -> C;
    C : C -> C;
ENDNEWTYPE C;EXTERNAL 'C++';
```

Note that no cast operators are generated that cast to `ptr_E` since `E` is a protected base of `D`. But in fact there are no cast operators that cast from `ptr_E` neither. The somewhat subtle reason for this is that those operators cannot be used in practice, since the protected inheritance makes it impossible to have a variable with `ptr_E` as static type and `ptr_C` as dynamic type. CPP2SDL will therefore not generate these cast operators.

In C++ dynamic casts work both for pointers and references to objects. In SDL, however, it is only possible to do dynamic casts between pointers, since references are not explicitly represented in the translation (see "References" on page 789).

Forward Declarations

Rule: A forward declaration is not translated to SDL.

This rule is valid for all forward declarations for which there are definitions later on in the header file. This is the most common case, and the purpose of such forward declarations is simply to make an identifier known to the C/C++ compiler so that it may be used before it is defined.

However, it is possible to make a forward declaration for which no definition exists in the header file. In that case CPP2SDL must generate an extra newtype to represent the missing definition. Since this extra newtype does not correspond to a real C/C++ type, it is marked with a #NOTYPE directive.

Example 129 below contains two forward declarations, one of which has no corresponding definition (`class C`).

Example 129: Translation of forward declarations ————————————

C++:

```
typedef struct S *fwdS;
class C *fwdC;
struct S {
        int a;
};
```

SDL:

```
SYNTYPE fwdS = ptr_S
ENDSYNTYPE fwdS;EXTERNAL 'C++';
NEWTYPE C /*#NOTYPE*/
ENDNEWTYPE C;EXTERNAL 'C++';
NEWTYPE ptr_C Ref( C);
  OPERATORS
    ptr_C : -> ptr_C;
    ptr_C : ptr_C -> ptr_C;
ENDNEWTYPE ptr_C;EXTERNAL 'C++';
DCL fwdC ptr_C; EXTERNAL 'C++';
NEWTYPE ptr_S Ref( S);
  OPERATORS
    ptr_S : -> ptr_S;
    ptr_S : ptr_S -> ptr_S;
ENDNEWTYPE ptr_S;EXTERNAL 'C++';
NEWTYPE S
  STRUCT
    a int;
  OPERATORS
    S : -> S;
    S : S -> S;
ENDNEWTYPE S;EXTERNAL 'C++';
```

Incomplete Types

Rule: An incomplete type declaration is translated to a newtype that may not be instantiated in SDL. This rule applies to all incomplete types even if they are declared within complete types. For example a tagless type within a container type will not be correctly instantiated in SDL.

Compare this translation rule with the one for namespaces (see "Namespaces" on page 799). While a namespace does not define a type at all, an incomplete type declaration defines an incomplete type that may not be referred to. That is the reason why such a newtype must not be instantiated in SDL.

C/C++ allows declarations of incomplete classes, structs, unions and enums, i.e. all types having a tag. Incomplete types are therefore also called tag-less types.

Incomplete types can be used in

- data declarations (i.e. variables, constants etc.)
- type declarations (i.e. typedefs)
- "useless" declarations (i.e. without declaring data or type)

Example 130: Translation of incomplete types ––––––––––––––––––

C++:

```
typedef struct {
  int i;
} r;
struct S {
  int i;
  struct {
    int j;
  } ss1, *ss2, ss3[2]; // Data declarations
};
typedef enum {
  a, b, c
} ss1, *ss2, ss3[2]; // Type declarations
typedef struct {
        int i;
}; // Missing type name - "useless" declaration
struct {
        int i;
}; // Missing variable name - "useless" declaration
```

SDL:

```
NEWTYPE r
  STRUCT
    i int;
ENDNEWTYPE r;EXTERNAL 'C++';
NEWTYPE S_incomplete_ss3
  STRUCT
    j int;
ENDNEWTYPE S_incomplete_ss3;
NEWTYPE ptr_S_incomplete_ss3 Ref( S_incomplete_ss3);
  OPERATORS
    ptr_S_incomplete_ss3 : -> ptr_S_incomplete_ss3;
    ptr_S_incomplete_ss3 : ptr_S_incomplete_ss3 ->
    ptr_S_incomplete_ss3;
ENDNEWTYPE ptr_S_incomplete_ss3;EXTERNAL 'C++';
NEWTYPE arr_2_S_incomplete_ss3 CArray(2,
S_incomplete_ss3);
ENDNEWTYPE arr_2_S_incomplete_ss3;EXTERNAL 'C++';
NEWTYPE ptr_S Ref( S);
  OPERATORS
    ptr_S : -> ptr_S;
    ptr_S : ptr_S -> ptr_S;
ENDNEWTYPE ptr_S;EXTERNAL 'C++';
NEWTYPE S
  STRUCT
    i int;
    ss1 S_incomplete_ss3;
    ss2 ptr_S_incomplete_ss3;
    ss3 arr_2_S_incomplete_ss3;
  OPERATORS
    S : -> S;
```

```
    S : S -> S;
ENDNEWTYPE S;EXTERNAL 'C++';
NEWTYPE incomplete_ss3
  LITERALS a, b, c;
  OPERATORS
    EnumToInt : incomplete_ss3 -> int; /*#OP(PY)*/
    ORDERING;
ENDNEWTYPE incomplete_ss3;EXTERNAL 'C++';
NEWTYPE ptr_incomplete_ss3 Ref( incomplete_ss3);
  OPERATORS
    ptr_incomplete_ss3 : -> ptr_incomplete_ss3;
    ptr_incomplete_ss3 : ptr_incomplete_ss3 ->
    ptr_incomplete_ss3;

ENDNEWTYPE ptr_incomplete_ss3;EXTERNAL 'C++';
SYNTYPE ss2 = ptr_incomplete_ss3
ENDSYNTYPE ss2;EXTERNAL 'C++';
NEWTYPE arr_2_incomplete_ss3 CArray( 2,
incomplete_ss3);
ENDNEWTYPE arr_2_incomplete_ss3;EXTERNAL 'C++';
SYNTYPE ss3 = arr_2_incomplete_ss3
ENDSYNTYPE ss3;EXTERNAL 'C++';
```

As can be seen in the example, incomplete types that are used in data or type declarations will have the name of the last declared variable or type, prefixed with a user-configurable string that by default is “incomplete_”. The option `-prefix` can be used to configure this string.

Incomplete types in “useless” declarations will not be translated to SDL, and CPP2SDL will issue warnings that the declarations were ignored.

Note that the translation of incomplete enum declarations differs from the normal translation rule of an enum declaration. The differences are listed in “Enumerated Types” on page 790.

Finally note that incomplete classes, structs and unions define scope units although they are incomplete. Their names thus follows the rules for naming of scope units described in “Scope Units” on page 797.

Dynamic Memory Management

Rule: The C/C++ primitives for dynamic memory management is represented in SDL by means of special operators.

Dynamic memory management is done differently in C and C++. How C or C++ data is dynamically allocated and deallocated in SDL there-

fore depends on whether CPP2SDL executes in C or C++ mode (controlled by the option `-c`). In both cases dynamic memory management is done by means of special SDL operators that are defined in the `Ref` generator. However, the definition of the `Ref` generator is different in C and C++ mode (see "SDL Library for Fundamental C/C++ Types" on page 848).

C Mode

The following operators are used to support dynamic memory management of C data from SDL:

- `Make!`
  Enables dynamic allocation of simple C data.
- `free`
  Enables dynamic deallocation of data that was allocated by the `Make!` operator.

Example 131: Dynamic memory management of C data from SDL ---

C:

```
struct S {
  int i;
  double j;
};
```

SDL:

```
NEWTYPE ptr_S Ref( S);
ENDNEWTYPE ptr_S;EXTERNAL 'C';
NEWTYPE S /*#REFNAME 'struct S'*/
  STRUCT
    i int;
    j double;
ENDNEWTYPE S;EXTERNAL 'C';
```

SDL Usage:

```
dcl var s, ptrs ptr_s;
task {
  ptrs := (. var .);
  ptrs*>!i := 4;
  free(ptrs);
};
```

C++ Mode

The following operators are used to support dynamic memory management of C++ data from SDL:

- `new`[1]
  Enables dynamic allocation of scalar C++ data of, for example, class type, fundamental type, or pointer type. It corresponds to the C++ operator with the same name.

- `delete`
  Enables dynamic deallocation of data that was allocated by the `new` operator. It corresponds to the C++ operator with the same name.

- `new_array`
  Enables dynamic allocation of arrays of C++ data of, for example, class type, fundamental type, or pointer type. It corresponds to the C++ operator `new[]`.

- `delete_array`
  Enables dynamic deallocation of data that was allocated by the `new_array` operator. It corresponds to the C++ operator `delete[]`.

Example 132: Dynamic memory management of C++ data from SDL –

C++:

```
struct S {
  int i;
  double j;
};
```

Import Specification:

```
TRANSLATE {
  S**
  int*
}
```

SDL:

```
NEWTYPE ptr_int Ref( int);
  OPERATORS
    ptr_int : -> ptr_int;
    ptr_int : ptr_int -> ptr_int;
ENDNEWTYPE ptr_int;EXTERNAL 'C++';
NEWTYPE ptr_ptr_S Ref( ptr_S);
```

1. In fact the `Make!` operator can also be used in C++ mode. In that case it behaves exactly like the `new` operator.

```
  OPERATORS
    ptr_ptr_S : -> ptr_ptr_S;
    ptr_ptr_S : ptr_ptr_S -> ptr_ptr_S;
ENDNEWTYPE ptr_ptr_S;EXTERNAL 'C++';
NEWTYPE ptr_S Ref( S);
  OPERATORS
    ptr_S : -> ptr_S;
    ptr_S : ptr_S -> ptr_S;'
ENDNEWTYPE ptr_S;EXTERNAL 'C++';
NEWTYPE S
  STRUCT
    i int;
    j double;
 OPERATORS
    S : -> S;
    S : S -> S;
ENDNEWTYPE S;EXTERNAL 'C++';
```

SDL Usage:

```
dcl ptrs ptr_s, ptrptrs ptr_ptr_s, ptri ptr_int;
task {
  ptrs := new(s);
  ptrs*>!i := 4;
  ptrptrs := new(ptr_s);
  ptri := new(int);
  delete(ptrs);
  delete(ptrptrs);
  delete(ptri);
  ptri := newArray(int, 5);
  deleteArray(ptri);
};
```

The input to the `new` and `new_array` operators must be an operator that corresponds to a constructor in C++. To enable dynamic allocation of data with non-class types, there must thus exist constructor operators for these types. These operators correspond to the implicit parameter-less and copy constructors, which exist for each C++ type. The definition of these constructor operators are part of the non-generated SDL declarations that are included when the `-generatecpptypes` option is set (see "SDL Library for Fundamental C/C++ Types" on page 848).

Overloaded Operators

Rule: An overloaded C++ operator is translated to a corresponding overloaded SDL operator.

Since the sets of operators that may be overloaded are different in C++ and SDL, not all overloaded C++ operators can be translated to SDL.

The table below shows which C++ operators that can be translated to SDL

:

C++ operator	Description	SDL operator
+	(binary) Addition	+
-	(binary) Subtraction	-
*	(binary) Multiplication	*
*	(unary prefix) Dereference	*>
/	(binary) Division	/
%	(binary) Modulo	rem
!	(unary prefix) Not	not
<	(binary) Less	<
>	(binary) Greater	>
<<	(binary) Left Shift	<
>>	(binary) Right Shift	>
==	(binary) Equal	=
!=	(binary) Not Equal	/=
<=	(binary) Less Equal	<=
>=	(binary) Greater Equal	>=
&&	(binary) And	and
||	(binary) Or	or

Note that even if there is a corresponding SDL operator to translate to, a C++ operator could be declared in a way that would make it necessary to qualify its SDL name, which is not possible. This happens for example if the operator is declared to be static, or declared inside a namespace (see "Scope Units" on page 797 for more about scope name qualifications). It may also happen due to name qualification rules for inherited members (see "Multiple Inheritance" on page 818). CPP2SDL will issue a warning if it encounters an overloaded operator that cannot be translated.

The table above shows that the translation of the less and greater operators (<, >) is the same as the translation of the shift operators (<<, >>). Obviously, this may lead to ambiguities if both these operator pairs are overloaded in a class. In that case, the less and greater operators will have precedence, and CPP2SDL will issue a warning that the overloaded shift operators cannot be translated to SDL.

Example 133: Translation of overloaded operators ––––––––––––––

C++:

```
class ostream {
public:
  ostream& operator<(const char* p1);
  ostream& operator<<(const char* p1);
  ostream& operator>>(const char* p1);
  static int operator%(int p1);
  bool operator!();
};
```

SDL:

```
NEWTYPE ptr_char Ref( char);
  OPERATORS
    ptr_char : -> ptr_char;
    ptr_char : ptr_char -> ptr_char;
ENDNEWTYPE ptr_char;EXTERNAL 'C++';
NEWTYPE ptr_ostream Ref( ostream);
  OPERATORS
    ptr_ostream : -> ptr_ostream;
    ptr_ostream : ptr_ostream -> ptr_ostream;
ENDNEWTYPE ptr_ostream;EXTERNAL 'C++';
NEWTYPE ostream
  OPERATORS
    "not" /*#REFNAME 'operator!'*/ : ostream ->
bool;
    "rem" /*#REFNAME 'operator%'*/ : ostream, int ->
int;
    "<" /*#REFNAME 'operator<'*/ : ostream, ptr_char
-> ostream;
    ostream : -> ostream;
    ostream : ostream -> ostream;
ENDNEWTYPE ostream;EXTERNAL 'C++';
```

Conversion Operators

Rule: A conversion operator is translated to a special `conv` operator in SDL.

In C++, a conversion operator is implicitly called by the compiler when a matching type conversion is needed. The `conv` operator, however, must be called explicitly in SDL.

Example 134: Translation of conversion operators

C++:

```
class Tiny {
public:
  operator int(); // Implicit conversion from Tiny
to int
};
```

SDL:

```
NEWTYPE ptr_Tiny Ref( Tiny);
  OPERATORS
    ptr_Tiny : -> ptr_Tiny;
    ptr_Tiny : ptr_Tiny -> ptr_Tiny;
ENDNEWTYPE ptr_Tiny;EXTERNAL 'C++';
NEWTYPE Tiny
  OPERATORS
    conv : Tiny -> int; /*#OP(PY)*/
    Tiny : -> Tiny;
    Tiny : Tiny -> Tiny;
ENDNEWTYPE Tiny;EXTERNAL 'C++';
```

Note that the `conv` operator returns the target type of the type conversion specified by the conversion operator. The #OP(PY) directive tells the Code Generator that the operator is implicitly called in C++.

Templates

Rule: A template declaration is translated to SDL by instantiating it.

A template declaration as such cannot be translated to SDL. Only specified instantiations of the template can be translated. CPP2SDL will print a warning about this when a template declaration is encountered.

A template instantiation may of course be present in the input headers. In that case CPP2SDL will translate the template instantiation by substituting all formal template arguments in the template declaration with the actual template arguments used in the template instantiation. If the input headers contain no suitable instantiation of a certain template, an import specification may be used to provide such an instantiation. See "Template Instantiations" on page 780 to learn more about that.

There are two main kinds of template declarations in C++; class templates and function templates.

Class Templates

Rule: An instantiation of a class template is translated in the same way as the non-template class that is obtained if all formal arguments of the class template declaration are substituted with the actual arguments of the class template instantiation.

This translation rule implies that class template instantiations will become newtypes in SDL. The name of such a newtype will consist of the name of the template class, followed by the names of all actual template arguments of the template instantiation. The name will also be prefixed with a string that by default is “tpl_”. The option `-prefix` can be used to configure this string.

Example 135: Translation of class template instantiations ––––––––

C++:

```
template <class T> class C {
public:
        T t;
  T f();
  C(T v);
};
typedef C<int> mytype; // Class template
instantiation
```

SDL:

```
NEWTYPE ptr_tpl_C_int Ref( tpl_C_int);
  OPERATORS
    ptr_tpl_C_int : -> ptr_tpl_C_int;
    ptr_tpl_C_int : ptr_tpl_C_int -> ptr_tpl_C_int;
ENDNEWTYPE ptr_tpl_C_int;EXTERNAL 'C++';
NEWTYPE tpl_C_int /*#REFNAME 'C<int >'*/
  STRUCT
    t int;
  OPERATORS
    tpl_C_int /*#REFNAME 'C'*/ : int -> tpl_C_int;
    f : tpl_C_int -> int;
    tpl_C_int /*#REFNAME 'C'*/ : tpl_C_int ->
tpl_C_int;
ENDNEWTYPE tpl_C_int;EXTERNAL 'C++';
SYNTYPE mytype = tpl_C_int
ENDSYNTYPE mytype;EXTERNAL 'C++';
```

––

Note that a #REFNAME directive passes the C++ name of the class template instantiation to the Code Generator.

Function Templates

Rule: An instantiation of a function template is translated in the same way as the non-template function that is obtained if all formal arguments of the function template declaration are substituted with the actual arguments of the function template instantiation.

This translation rule implies that function template instantiations will become operators in SDL. The name of such an operator will consist of the name of the template function, followed by the names of all actual template arguments of the template instantiation. The name will also be prefixed with a string that by default is “tpl_”. The option `-prefix` can be used to configure this string.

Since a function template is instantiated when called, a C++ header file will normally not contain any function template instantiations. Instead an import specification should be used to provide the necessary instantiations (see “Template Instantiations” on page 780). In Example 136 below an import specification is used to instantiate the template function with the type `int*`.

Example 136: Translation of function template instantiations ––––––––

C++:

```
template <class T> T func(T t);
```

Import Specification:

```
TRANSLATE {
  func<int*>
}
```

SDL:

```
NEWTYPE global_namespace_ImpSpec /*#NOTYPE*/
  OPERATORS
    tpl_func_ptr_int /*#REFNAME 'func<int* >'*/ :
ptr_int
-> ptr_int;
ENDNEWTYPE global_namespace_ImpSpec;EXTERNAL 'C++';
NEWTYPE ptr_int Ref( int);
  OPERATORS
    ptr_int : -> ptr_int;
    ptr_int : ptr_int -> ptr_int;
```

```
ENDNEWTYPE ptr_int;EXTERNAL 'C++';
```

As can be seen from the translation of the example above, the #REFNAME directive contains the C++ name of the template instantiation written on the so called explicit form[1]. This makes the Code Generator use this explicit form when the template function is called from SDL.

> **Note:**
>
> Calling a function template from SDL requires that the target C++ compiler can handle calls using the explicit form of the function template instantiation.

Default Template Arguments

Rule: An instantiation of a template declaration with default arguments is translated in the same way as an ordinary template instantiation, where omitted actual arguments in the instantiation are substituted with the specified default types or values.

This translation rule is very similar to the one used for functions with default arguments (see "Default Arguments" on page 795).

Example 137: Translation of templates with default arguments

C++:

```
template <class T, class U = char, int i = 5> class
C {
public:
        T t[i];
  T f();
  C(U p1);
};
C<int> var1; // Using all the default values
C<int, bool> var2; // Using the default value for i
C<int, bool, 5> var3; // Not using any default value
```

SDL:

```
NEWTYPE ptr_tpl_C_int_char_5 Ref( tpl_C_int_char_5);
  OPERATORS
```

1. In the explicit form of a function template instantiation, all actual template arguments are provided explicitly in the instantiation rather than being deduced from the types of the actual arguments in a call to the function template.

```
    ptr_tpl_C_int_char_5 : -> ptr_tpl_C_int_char_5;
    ptr_tpl_C_int_char_5 : ptr_tpl_C_int_char_5 ->
    ptr_tpl_C_int_char_5;
ENDNEWTYPE ptr_tpl_C_int_char_5;EXTERNAL 'C++';
NEWTYPE tpl_C_int_char_5 /*#REFNAME 'C<int, char, 5
>'*/
  STRUCT
    t arr_5_int;
  OPERATORS
    tpl_C_int_char_5 /*#REFNAME 'C'*/ : char ->
tpl_C_int_char_5;
    f : tpl_C_int_char_5 -> int;
    tpl_C_int_char_5 /*#REFNAME 'C'*/ :
tpl_C_int_char_5
-> tpl_C_int_char_5;
ENDNEWTYPE tpl_C_int_char_5;EXTERNAL 'C++';
DCL var1 tpl_C_int_char_5; EXTERNAL 'C++';
DCL var2 tpl_C_int_bool_5; EXTERNAL 'C++';
NEWTYPE arr_5_int CArray( 5, int);
ENDNEWTYPE arr_5_int;EXTERNAL 'C++';
NEWTYPE ptr_tpl_C_int_bool_5 Ref( tpl_C_int_bool_5);
  OPERATORS
    ptr_tpl_C_int_bool_5 : -> ptr_tpl_C_int_bool_5;
    ptr_tpl_C_int_bool_5 : ptr_tpl_C_int_bool_5 ->
    ptr_tpl_C_int_bool_5;
ENDNEWTYPE ptr_tpl_C_int_bool_5;EXTERNAL 'C++';
NEWTYPE tpl_C_int_bool_5 /*#REFNAME 'C<int, bool, 5
>'*/
  STRUCT
    t arr_5_int;
  OPERATORS
    tpl_C_int_bool_5 /*#REFNAME 'C'*/ : bool ->
tpl_C_int_bool_5;
    f : tpl_C_int_bool_5 -> int;
-> tpl_C_int_bool_5;
ENDNEWTYPE tpl_C_int_bool_5;EXTERNAL 'C++';
DCL var3 tpl_C_int_bool_5; EXTERNAL 'C++';
```

Note that although the template instantiations of `var2` and `var3` in the example above look different, they evaluate to the same template type both in C++ and in the SDL translation.

Miscellaneous

This section covers some miscellaneous issues that have not been discussed so far. They are divided into constructs that are part of the C or C++ languages, and constructs that are not part of the languages as such, but that nevertheless may be found in an input C/C++ header file.

Language Constructs

Volatile

Rule: A volatile declaration is translated in the same way as an ordinary declaration.

The `volatile` specifier can be looked upon as some kind of compiler directive, and needs therefore not be visible in the SDL translation.

Linkage

Rule: The linkage of a C/C++ identifier is not visible in the SDL translation of the identifier.

There is one important exception to this rule; static linkage of class members affects their translation as described in "Static Members" on page 810.

In general, the linkage of a C/C++ identifier can be specified to be internal or external using the keywords `static` or `extern` (although the former is a deprecated feature in C++ for all declarations but class members). In C++ it is also possible to use the `extern` keyword to specify that a set of declarations have C linkage, i.e. belong to a translation unit that is compiled with a C compiler.

Example 138: Translation of identifiers with different linkage–––––––

C++:

```
extern int a; // Declaration of a
extern int a; // Legal redeclaration of a
int a; // Definition of a
extern "C" {
  struct S {
    int x;
  };
}
```

SDL:

```
DCL a int; EXTERNAL 'C++';
NEWTYPE ptr_S Ref( S);
  OPERATORS
    ptr_S : -> ptr_S;
    ptr_S : ptr_S -> ptr_S;
ENDNEWTYPE ptr_S;EXTERNAL 'C++';
NEWTYPE S
  STRUCT
    x int;
```

```
  OPERATORS
    S : -> S;
    S : S -> S;
ENDNEWTYPE S;EXTERNAL 'C++';
```

Note that the `extern "C"` directive in this example does not affect the mapping of `S` at all. For example, it will be possible to instantiate `S` using the `new` operator.

Non-Language Constructs

Macros

Rule: Macros are not translated to SDL.

The reason for not translating macros is that they are not part of the C or C++ languages. Macros are expanded and removed by the preprocessor before CPP2SDL performs the translation.

Some header files (especially C headers) contain numerous macros that could be useful or even essential to access in SDL. Fortunately most macros can actually be accessed from SDL, although they are not translated by CPP2SDL. Refer to "Constants" on page 801 for more information.

SDL Sorts in C/C++

Rule: A C/C++ type called "SDL_<sort>", where <sort> is a predefined SDL sort, is translated to that SDL sort.

Since this translation rule restricts the way ordinary C/C++ types may be named, it is only respected by CPP2SDL if the `-sdlsorts` option is set.

Example 139: Translation of types referring to SDL sorts

C++:

```
SDL_Real func(SDL_Integer, int);
```

SDL:

```
NEWTYPE global_namespace_ImpSpec /*#NOTYPE*/
  OPERATORS
    func : Integer, int -> Real;
ENDNEWTYPE global_namespace_ImpSpec;EXTERNAL 'C++';
```

The feature of referring to SDL sorts from a C/C++ header file may be useful if the header has been designed to be used from SDL exclusively.

Special Translation Rules for C Compilers

CPP2SDL by default assumes that its input is C++ code, and that the target compiler is a C++ compiler. In order to also support C code and C target compilers, the translation rules have to be slightly modified. CPP2SDL does this if the `-c` option is set. The tool then executes in “C mode”.

A general difference is how the external specifier for all SDL declarations will be generated. Normally this specifier is followed by the string ‘C++’ to tell the Code Generator that the declaration was translated from a C++ declaration. In C mode the string will instead be ‘C’.

Example 140: Different external specifier in C mode ––––––––––––

C++:

```
const int a;
```

SDL:

```
SYNONYM a int = EXTERNAL 'C';
```

––

In C, a struct or a union is not a scope unit, which means that declarations inside a struct or a union should be treated as ordinary declarations. This means that the #REFNAME directive that normally is used for specifying the qualified name of for example a nested struct declaration, will not be printed in C mode.

Instead, a #REFNAME directive will be inserted after the name of newtypes that represent tagged types (i.e. structs, unions and enums). The reason is that C, contrary to C++, does not allow such types to be referenced only with the name of the tag. Another place where the “full” type name is required in C mode is in the C style cast that is generated by means of a #REFNAME directive for `IntToEnum` operators (see “Enumerated Types” on page 790).

Example 141: Differences in translation of structs, unions and enums

C++:

```
struct S {
  int a;
  struct SS {
    int b;
  };
};
```

```
typedef enum E {e1, e2, e3} Etype;
```

SDL:

```
NEWTYPE ptr_SS Ref( SS);
ENDNEWTYPE ptr_SS;EXTERNAL 'C';
NEWTYPE SS /*#REFNAME 'struct SS'*/
  STRUCT
    b int;
ENDNEWTYPE SS;EXTERNAL 'C';
NEWTYPE ptr_S Ref( S);
ENDNEWTYPE ptr_S;EXTERNAL 'C';
NEWTYPE S /*#REFNAME 'struct S'*/
  STRUCT
    a int;
ENDNEWTYPE S;EXTERNAL 'C';
NEWTYPE E /*#REFNAME 'enum E'*/
  LITERALS e1, e2, e3;
  OPERATORS
    IntToEnum /*#REFNAME '(enum E)'*/ : int -> E;
    EnumToInt : E -> int; /*#OP(PY)*/
    ORDERING;
ENDNEWTYPE E;EXTERNAL 'C';
SYNTYPE Etype = E
ENDSYNTYPE Etype;EXTERNAL 'C';
```

Finally, note that memory allocation is done differently in C and C++. This is reflected in SDL by using a different definition of the `Ref` generator when CPP2SDL executes in C mode, where for example the `new`, `delete`, `new_array`, and `delete_array` operators are not present. See "Dynamic Memory Management" on page 832 and "SDL Library for Fundamental C/C++ Types" on page 848 for more information.

SDL Library for Fundamental C/C++ Types

The SDL declarations that are generated by CPP2SDL will normally not be semantically correct on their own. They typically contain several references to SDL sorts that represent fundamental C/C++ types, for example `int`, `char` and `bool`, and type declarators such as pointers (`*`) and arrays (`[]`). The SDL representations of all fundamental C/C++ types and type declarators are defined in a library consisting of a few SDL/PR files. The table below lists these files and their contents.

SDL/PR file	Contents
BasicCTypes.pr *Contains SDL representations of fundamental C types. Also contains representations for an untyped pointer (void*) and the array type declarator ([]).*	SYNTYPE int = Integer ENDSYNTYPE int; SYNTYPE unsigned_int = Integer ENDSYNTYPE unsigned_int; SYNTYPE long_int = Integer ENDSYNTYPE long_int; SYNTYPE unsigned_long_int = Integer ENDSYNTYPE unsigned_long_int; SYNTYPE short_int = Integer ENDSYNTYPE short_int; SYNTYPE unsigned_short_int = Integer ENDSYNTYPE unsigned_short_int; SYNTYPE char = Character ENDSYNTYPE char; SYNTYPE signed_char = Character ENDSYNTYPE signed_char; SYNTYPE unsigned_char = Octet ENDSYNTYPE unsigned_char; SYNTYPE float = Real ENDSYNTYPE float; SYNTYPE double = Real ENDSYNTYPE double; NEWTYPE ptr_void LITERALS Null; DEFAULT Null; ENDNEWTYPE ptr_void; GENERATOR CArray (CONSTANT Length, TYPE Itemsort) OPERATORS modify!: CArray, Integer, Itemsort -> CArray; extract!: CArray, Integer -> Itemsort; ENDGENERATOR CArray;

SDL/PR file	Contents
BasicC++Types.pr *Contains SDL representations of fundamental C++ types. Also contains operators representing implicit constructors for fundamental types.* *Note that this file includes the files BasicCtypes.pr and ExtraCTypes.pr.*	/*#INCLUDE 'BasicCTypes.pr'*/ /*#INCLUDE 'ExtraCTypes.pr'*/ SYNTYPE bool = Boolean ENDSYNTYPE bool; NEWTYPE wchar_t ENDNEWTYPE wchar_t; NEWTYPE __ConstructorOperators /*#NOTYPE*/ OPERATORS int: -> int; int: int -> int; unsigned_int: -> unsigned_int; unsigned_int: unsigned_int -> unsigned_int; long_int: -> long_int; long_int: long_int -> long_int; unsigned_long_int: -> unsigned_long_int; unsigned_long_int: unsigned_long_int -> unsigned_long_int; short_int: -> short_int; short_int: short_int -> short_int; unsigned_short_int: -> unsigned_short_int; unsigned_short_int: unsigned_short_int -> unsigned_short_int; char: -> char; char: char -> char; signed_char: -> signed_char; signed_char: signed_char -> signed_char; unsigned_char: -> unsigned_char; unsigned_char: unsigned_char -> unsigned_char; float: -> float; float: float -> float; double: -> double; double: double -> double; ptr_void: -> ptr_void; ptr_void: ptr_void -> ptr_void; bool: -> bool; bool: bool -> bool; wchar_t: -> wchar_t; wchar_t: wchar_t -> wchar_t; ENDNEWTYPE __ConstructorOperators;EXTERNAL 'C++';

SDL/PR file	Contents
ExtraCTypes.pr *Contains SDL representations of additional fundamental C types.*	`SYNTYPE long_long_int = Integer` `ENDSYNTYPE long_long_int;` `SYNTYPE unsigned_long_long_int = Integer` `ENDSYNTYPE unsigned_long_long_int;`
ExtraC++Types.pr *Contains SDL representations of additional fundamental C++ types.*	`NEWTYPE__ExtraConstructorOperators` `long_long_int : -> long_long_int;` `long_long_int : long_long_int -> long_long_int;` `unsigned_long_long_int : ->` `unsigned_long_long_int;` `unsigned_long_long_int : unsigned_long_long_int -` `> unsigned_long_long_int` `ENDNEWTYPE__ExtraConstructorOperators`
CPointer.pr *Contains SDL representation of the C pointer type declarator (*).*	`GENERATOR Ref (TYPE Itemsort)` `LITERALS Null, Alloc;` `OPERATORS` `  modify!  : Ref, Integer, Itemsort -> Ref;` `  extract! : Ref, Integer -> Itemsort;` `  "*>"     : Ref, Itemsort -> Ref;` `  "*>"     : Ref -> Itemsort;` `  "&"      : Itemsort -> Ref;` `  make!    : Itemsort -> Ref;` `  free     : in/out Ref;` `  "+"      : Ref, Integer -> Ref;` `  "-"      : Ref, Integer -> Ref;` `  cast     : Ref -> ptr_void;` `  cast     : ptr_void -> Ref;` `DEFAULT Null;` `ENDGENERATOR Ref;`

SDL/PR file	Contents
C++Pointer.pr *Contains SDL representation of the C++ pointer type declarator (*).*	GENERATOR Ref (TYPE Itemsort) LITERALS Null; OPERATORS modify! : Ref, Integer, Itemsort -> Ref; extract! : Ref, Integer -> Itemsort; "*>" : Ref, Itemsort -> Ref; "*>" : Ref -> Itemsort; "&" : Itemsort -> Ref; new : Itemsort -> Ref; delete : Ref; new_array : Itemsort, Integer -> Ref; delete_array : Ref; "+" : Ref, Integer -> Ref; "-" : Ref, Integer -> Ref; cast : Ref -> ptr_void; cast : ptr_void -> Ref; DEFAULT Null; ENDGENERATOR Ref;

If the option `-generatecpptypes` is set, CPP2SDL will include some of the files from the table above in the SDL translation. Which files that are included depends on if CPP2SDL executes in C or C++ mode (controlled by the `-c` option).

The following files will be included in C mode:

- `BasicCTypes.pr`
- `CPointer.pr`

The following files will be included in C++ mode:

- `BasicC++Types.pr`
- `C++Pointer`

The reason for breaking out the types `long long int` and `unsigned long long int` into separate files, is that not all compilers support these types. These files must be manually included if these types are present in the input headers.

Hint:

The syntype definitions of the SDL sorts that represent fundamental C/C++ types can easily be changed. For example, the definitions of the SDL sorts ‘char’ and ‘unsigned char’ could be swapped if the target platform specifies that a simple ‘char’ is unsigned rather than signed.

Example usage of some C/C++ functionality

Overloaded Operators

This example illustrates how to call an operator which has been made accessible by CPP2SDL. There are two operators defined and used, the first being a member operator, and the second a non-member operator. Also see “Overloaded Operators” on page 853.

C++:

```
class CInt {
  int val;
        public:
  CInt() : val(0) {};
  CInt(int i) : val(i) {};
  int value() const { return val; };

  int operator+(const int& i){val+= i; return val;};
};

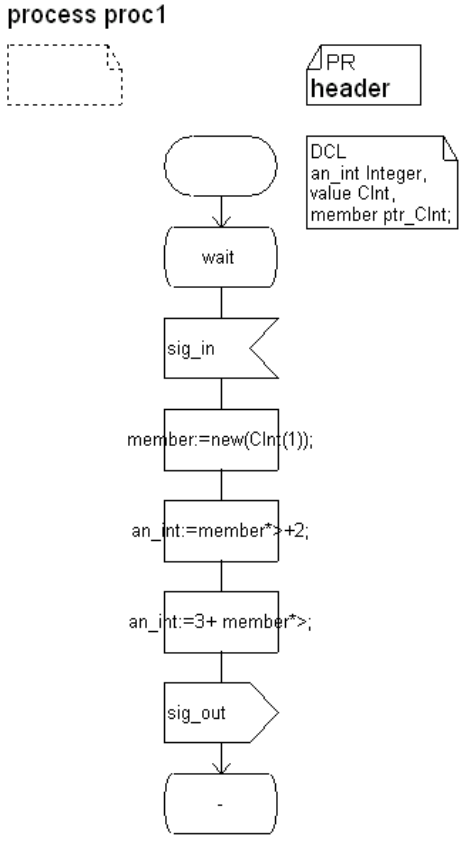
int operator+(const int& left, const CInt& right)
{return right.value()+left;};
```

SDL:

```
NEWTYPE global_namespace_ImpSpec /*#NOTYPE*/
  OPERATORS
    "+" /*#REFNAME 'operator+'*/ : int, CInt -> int;
ENDNEWTYPE global_namespace_ImpSpec;EXTERNAL 'C++';
NEWTYPE ptr_CInt Ref( CInt);
  OPERATORS
    ptr_CInt : -> ptr_CInt;
    ptr_CInt : ptr_CInt -> ptr_CInt;
ENDNEWTYPE ptr_CInt;EXTERNAL 'C++';
NEWTYPE CInt
  OPERATORS
    "+" /*#REFNAME 'operator+'*/ : CInt, int -> int;
    CInt : -> CInt;
    CInt : int -> CInt;
```

```
    value : CInt -> int; /*#CONSTANT*/
    CInt : CInt -> CInt;
ENDNEWTYPE CInt;EXTERNAL 'C++';
```

Use in SDL:



String handling

It is possible to do C-style string handling in SDL, by using the standard C header **`string.h`**. By including '`string.h`' and '`stdio.h`' we are given access to the functions defined within them in SDL. You may notice that strcpy is defined in the hand written header as well as in '`string.h`'. The former definition allows us to assign the string "good-

bye" to empty, without using the return value of strcpy, and importing it to SDL. Also needed is an allocate and deallocate function. An example allocate function has been defined in the header, a deallocate function should also be done in the practice to avoid memory leaks.

C:

```
#include<string.h>
#include<stdio.h>

#ifdef __CPP2SDL__
void strcpy(char*,char*);
#endif

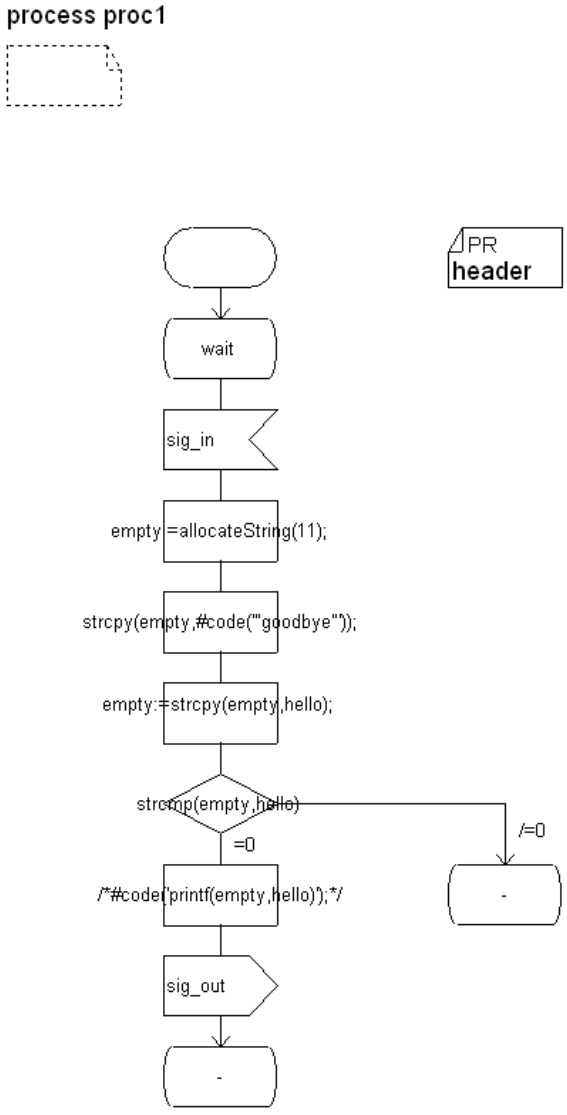
typedef char* string;
char ara[10];
string hello= "hello";
string empty;

char* allocateString(int length) {
  return (char*) calloc(length,sizeof(char));
}
```

SDL:

```
NEWTYPE global_namespace_ImpSpec /*#NOTYPE*/
  OPERATORS
    memcpy : ptr_void, ptr_void, size_t -> ptr_void;
    memcmp : ptr_void, ptr_void, size_t -> int;
    memset : ptr_void, int, size_t -> ptr_void;
    _strset : ptr_char, int -> ptr_char;
    strcpy : ptr_char, ptr_char -> ptr_char;
    strcat : ptr_char, ptr_char -> ptr_char;
    strcmp : ptr_char, ptr_char -> int;
    strlen : ptr_char -> size_t;
    ....
    unlink : ptr_char -> int;
    strcpy : ptr_char, ptr_char;
    allocateString : int -> ptr_char;
ENDNEWTYPE global_namespace_ImpSpec;EXTERNAL 'C';
...
SYNTYPE string = ptr_char
ENDSYNTYPE string;EXTERNAL 'C';
/*#SDTREF(TEXT,header_CPP2SDL.i,728,6)*/
NEWTYPE arr_10_char CArray( 10, char);
ENDNEWTYPE arr_10_char;EXTERNAL 'C';
/*#SDTREF(TEXT,header_CPP2SDL.i,728,6)*/
DCL ara arr_10_char; EXTERNAL 'C';
/*#SDTREF(TEXT,header_CPP2SDL.i,729,8)*/
DCL hello string; EXTERNAL 'C';
/*#SDTREF(TEXT,header_CPP2SDL.i,730,8)*/
DCL empty string; EXTERNAL 'C';
```

Use in SDL:

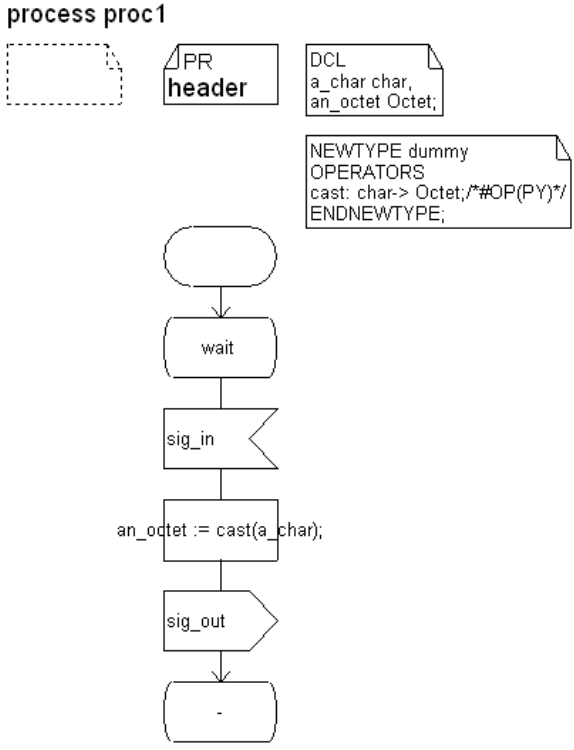


process proc1
PR
header
wait
sig_in
empty:=allocateString(11);
strcpy(empty,#code("goodbye"));
empty:=strcpy(empty,hello);
strcmp(empty,hello)
=0
/=0
/*#code("printf(empty,hello)");*/
-
sig_out
-

Type conversion

Some type conversions are easier in C/C++ than in SDL, in particular those that are implicit. An implicit type conversion must often be explicit in SDL, by introducing a simple cast operator that performs the conversion. For example, by using the mapping of SDL sorts between unsigned_char and char we can create a cast operator in SDL that converts a char to an Octet. (See "Fundamental Types" on page 786 for more information). This corresponds to the implicit conversion in C/C++ between char and unsigned char.

Use in SDL:



Error Handling

The input headers to CPP2SDL have in many cases been compiled with a C/C++ compiler previously, and it should then be relatively uncommon that CPP2SDL will have to issue any error messages. However, differences in language support, and inappropriate preprocessor settings, are common sources for error reports also from input files that otherwise are perfectly correct.

If CPP2SDL finds an error in the input, a message will be printed that briefly describes the reason for the error.

> **Note:**
>
> The error messages produced by CPP2SDL are often less descriptive than the corresponding error messages from a C/C++ compiler. If CPP2SDL reports errors in a header file, it is therefore a good idea to run a C/C++ compiler on the same header file to get more information about the reason for the error.

The format of printed error messages are described in "Source and Error References" on page 783.

CPP2SDL performs a complete syntactic analysis of the input C/C++ code, and syntax errors are reported as shown in Example 142 below.

Example 142: Syntax errors ----------

File syn.h:

```
int f(};
conts int i = 7;
```

Command Prompt:

```
% cpp2sdl syn.h
Parsing C/C++ input...
Syntax errors found. Cannot perform SDL translation.
#SDTREF(TEXT,syn.h,1,7)
ERROR 3200 Syntax error.
#SDTREF(TEXT,syn.h,2,7)
ERROR 3200 Syntax error.
2 errors and 0 warnings.
```

CPP2SDL will proceed with semantic analysis only if no errors were found during the syntactic analysis. The semantic analysis that is done

by CPP2SDL is not complete according to the C/C++ standards, but only a limited number of semantic tests are performed:

- The type of variables, constants, typedefs, functions, function arguments, actual template arguments, and base classes are checked. If a type is undeclared, or if it depends on an undeclared type[1], an error message will be issued.
- The actual arguments of a template instantiation are checked against the formal arguments of the template definition. If there are too few or too many actual arguments, or if there are type mismatches between actual and formal arguments, an error message will be issued.

Example 143: Semantic errors ––––––––––––––––––––––––––––––

File sem.h:

```
template <class U, int d> class S {
public:
  U arr[d];
};
typedef unknown T; // T depends on undeclared type
const unknown a = 3;
T f(int, char);
S<T, 3> var;
typedef S<> t1; // Too few actual arguments
typedef S<char, 5, 5> t2; // Too many actual
arguments
typedef S<int, int> t3; // Argument type mismatch
```

Command Prompt:

```
% cpp2sdl -errorlimit 10 sem.h
Parsing C/C++ input...
Translating C/C++ to SDL...
Generating SDL...
#SDTREF(TEXT,sem.h,11,9)
ERROR 3263 Illegal instantiation of template 'S'.
#SDTREF(TEXT,sem.h,10,9)
ERROR 3263 Illegal instantiation of template 'S'.
#SDTREF(TEXT,sem.h,9,9)
ERROR 3263 Illegal instantiation of template 'S'.
#SDTREF(TEXT,sem.h,8,3)
ERROR 3261 The type 'T' is undeclared, or is
depending on an undeclared type.
#SDTREF(TEXT,sem.h,7,3)
ERROR 3261 The type 'T' is undeclared, or is
```

1. One example of such a type dependency is when the source type of a typedef type is undeclared. Usages of the typedef type will then be considered to be undeclared.

```
depending on an undeclared type.
#SDTREF(TEXT,sem.h,6,15)
ERROR 3261 The type 'unknown' is undeclared, or is
depending on an undeclared type.
#SDTREF(TEXT,sem.h,5,17)
ERROR 3261 The type 'unknown' is undeclared, or is
depending on an undeclared type.
#SDTREF(TEXT,sem.h,1,33)
WARNING 3211 Cannot translate template declaration.
The declaration will be ignored.
7 errors and 1 warnings.
```

Note that the command line option `-errorlimit` can be used to set a limit for the number of errors to report before terminating a translation.

CPP2SDL Messages

CPP2SDL may produce three kinds of messages during the translation of a set of header files.

- Error messages are printed if CPP2SDL finds any syntactic or semantic errors in the input header files. See "Example usage of some C/C++ functionality" on page 853 for more information about how CPP2SDL handles errors in the input.
- Warnings are given if CPP2SDL finds language constructs that for some reason cannot be fully translated. The tool also prints warnings if it has to make assumptions about a construct that not necessarily are valid.
- Information messages are all other messages that are printed.

The rest of this section lists and explains all errors and warnings that may be issued by CPP2SDL.

Errors

`ERROR 3200 Syntax error.`

An error was found during the syntactic analysis of the input. CPP2SDL will not continue with semantic analysis and translation to SDL, since the program is not correct.

> **Note:**
> If this error message is printed for a program that is accepted by a C/C++ compiler, make sure that the correct language dialect has been set to CPP2SDL by means of the `-dialect` option.

`ERROR 3260 The identifier <identifier name> is undeclared.`

An identifier is undeclared, i.e. the program is not semantically correct and will therefore not be translated to SDL.

`ERROR 3261 The type <type name> is undeclared, or is depending on an undeclared type.`

A type is undeclared, or depends on a type that is undeclared. A type defined by a typedef of an undeclared type is an example of a type that depends on a undeclared type. Since the program is not semantically correct, it will not be translated to SDL.

```
ERROR 3262 The base <base class name> is undeclared.
```

A class inherits from a base class that is undeclared. This is a semantic error, and the program will thus not be translated to SDL.

```
ERROR 3263 Illegal instantiation of template <template
name>.
```

A template instantiation is semantically incorrect. Make sure that the number of actual arguments in the template instantiation matches the number of formal arguments in the template declaration, and that the kinds of the arguments are correct. Since the program is not semantically correct, it will not be translated to SDL.

Warnings

```
WARNING 3201 Static member variable <variable name> will
not be globally accessible since no SDL variables are al-
lowed.
```

A static member variable cannot be fully translated, since no external variables are allowed in the context where the generated SDL declarations are to be injected. The static variable will still be accessible as an ordinary member variable, but not as a globally accessible variable. Unset the option `-novariables` to allow generation of external SDL variables.

```
WARNING 3202 Static overloaded operator <operator name>
will not be globally accessible.
```

A static overloaded operator cannot be fully translated, since it is not possible to qualify the name of an overloaded operator in SDL which otherwise would be required. The static operator will still be accessible as an ordinary member overloaded operator, but not as a globally accessible overloaded operator. Refer to "Overloaded Operators" on page 835.

```
WARNING 3203 Cannot translate incomplete type declara-
tion without declared objects. The declaration will be
ignored.
```

An incomplete type declaration that is not used as the type of at least one object (e.g. variable, constant, or type) is a useless declaration that will not be translated to SDL. See "Incomplete Types" on page 830 for more about useless incomplete type declarations.

```
WARNING 3204 Cannot translate overloaded operator, since
it is declared in a namespace.
```

An overloaded operator declared in a namespace cannot be translated to SDL, since it is not possible to qualify the name of an overloaded operator in SDL which otherwise would be required. Refer to "Overloaded Operators" on page 835.

```
WARNING 3205 Cannot translate overloaded shift operator,
since the '<' or '>' operator also is overloaded in this
scope.
```

The translation rule for overloaded operators only supports translation of either the < and > operators or the << and >> operators. This warning is given if an operator from both these operator pairs are overloaded in a certain scope. See "Overloaded Operators" on page 835 for more information.

```
WARNING 3206 Cannot translate overloaded operator, since
no corresponding SDL operator exists.
```

An overloaded operator cannot be translated to SDL, since no appropriate SDL operator exists that could represent it. The table in "Overloaded Operators" on page 835 shows what overloaded C++ operators that may be represented in SDL.

```
WARNING 3207 Unable to evaluate sizeof expression prop-
erly.
```

A constant expression contains a usage of the `sizeof()` operator, and could therefore not be safely evaluated by CPP2SDL. The translation of the constant expression may thus be incorrect, and should be manually reviewed. See "Constant Expressions" on page 802 for more information about constant expressions.

```
WARNING 3208 The member <member name> of <class name> in-
herited via <base class names> is inaccessible and will
not be translated.
```

An inherited class member cannot be accessed in C++ due to a combination of multiple inheritance and base classes with members having the same name. The member will thus not be translated to SDL.

```
WARNING 3209 Cannot translate function pointer type. It
will be represented by ptr_void.
```

This warning is given when a function pointer type is encountered in the input. The support for function pointers is limited (see "Function Pointers" on page 796), and they will be represented as untyped pointers in SDL (i.e. `ptr_void`).

```
WARNING 3210 Cannot translate typedef of function type.
The declaration will be ignored.
```

A typedef declaration where the source type is a function type cannot be translated to SDL, since there is no translation rule for function types.

```
WARNING 3211 Cannot translate template declaration. The
declaration will be ignored.
```

A template declaration cannot be translated to SDL. Only instantiations of a template declaration can be translated. Note that this warning is given also when a template instantiation has been specified in an import specification (see "Template Instantiations" on page 780). In that case the warning could be ignored.

```
WARNING 3212 Cannot fully translate ellipsis function.
Unspecified function arguments will be ignored.
```

A function with unspecified arguments (a.k.a. an ellipsis function) cannot be fully translated to SDL, since no information has been provided about the unspecified arguments. The function will be translated, but without taking the unspecified arguments into consideration. See "Prototypes for Ellipsis Functions" on page 779 to learn how to use an import specification to provide CPP2SDL with actual arguments for unspecified formal arguments of ellipsis functions.

```
WARNING 3213 The typedef name <name> conflicts with the
name of another non-compatible type. The declaration
will be ignored.
```

A typedef declaration cannot be translated to SDL, since the typedef name is the same as another type that is not type compatible with the type defined by the typedef itself. This warning may be given for typedefs of pointers or arrays of tagged types. For example:

```
typedef struct T {
  int i;
} *T;
```

This declaration, which is illegal in C++ but legal in C, contains two types called `T` that are type incompatible. CPP2SDL will make the type

`struct T` available in SDL (called `T` there), while the type `T` will not be translated.

It is recommended to change the name of either the typedef name or the type tag to enable CPP2SDL to translate both types, and thus avoid getting this warning.

```
WARNING 3290 The identifier <identifier name> does not
refer to a declared object. It will be ignored.
```

This warning is given if CPP2SDL finds an identifier in an import specification that does not exist in the input program. The identifier will be ignored.

```
WARNING 3291 Cannot translate the identifier <identifier
name>, since it is a class member.
```

This warning is given if CPP2SDL finds an identifier in an import specification that refers to a class member in the input program. The identifier will not be translated, since only declarations in namespaces may be translated (see "Import Specifications" on page 776).

Chapter 14 The CPP2SDL Tool

Chapter

15 *CPP2SDL Migration Guide*

This chapter is a practical guide on how to convert an SDL specification that uses the H2SDL tool, which is not supported any longer, into an equivalent specification that uses the new CPP2SDL tool.

A complete description of the CPP2SDL tool can be found in "The CPP2SDL Tool" on page 761 in chapter 14, *The CPP2SDL Tool* .

Introduction

The purpose of this chapter is to help H2SDL users to smoothly migrate from the obsolete H2SDL tool to CPP2SDL. In addition, IBM Rational Customer Support will be happy to assist in solving any migration problems not covered by this chapter.

The H2SDL tool provided automated support for accessing C code from within the SDL Suite. The CPP2SDL tool works according to the same fundamental principle, i.e. by automatically translating C/C++ declarations into SDL representations.

However, due to the difference between the C and C++ languages, CPP2SDL is not entirely backward compatible with H2SDL. This means that existing SDL systems that use H2SDL, may need to be updated when upgrading to CPP2SDL.

Reasons to Migrate

Apart from H2SDL being obsolete, there are several reasons to migrate from H2SDL to CPP2SDL:

- CPP2SDL has superior language support. Not only does it support C++, but it also covers a larger set of the C language.
- CPP2SDL allows the user to configure the translation from C/C++ to SDL by means of import specifications. This is a technique which often cuts the build time significantly, when large APIs are interfaced from SDL.
- With H2SDL, the user often has to edit input header files, to make them suitable for translation. This need is significantly reduced with CPP2SDL, since the import specification mechanism lets the user configure the translation of each C/C++ declaration individually.
- Translation rules implemented by CPP2SDL are considerably improved, compared to the ones implemented by H2SDL. These improvements are due to the implementation of language extensions oriented towards SDL2000.
- CPP2SDL has an improved reference generator, allowing more precise analysis.
- The SDL package generated by H2SDL may only be used at system level, while the SDL declarations generated by CPP2SDL may be injected at any level in the SDL hierarchy. This is possible by means of a new SDL-PR symbol in the SDL Editor.
- CPP2SDL supports a wider range of preprocessors and compilers to be used for preprocessing input header files.
- CPP2SDL is built with state-of-the-art compiler technology on top of a commercial C/C++ parser. This provides for rapid incorporation of future extensions to C/C++.

Migration Guidelines

This section describes the procedure of upgrading an SDL system from H2SDL to CPP2SDL usage. Required changes are grouped into subsections corresponding to the main reasons for the changes.

Note:

The CPP2SDL tool takes advantage of SDL2000 being case-sensitive, therefore you should make sure that your SDL system is possible to analyze in case-sensitive mode prior to starting the migration work.

The SDL Suite includes a tool that helps you convert your SDL system into a case-sensitive SDL system (see Update to case-sensitive SDL.

Update to case-sensitive SDL

The following steps will help you convert your SDL system into case-sensitive mode.

1. Make sure you use the standard Text Editor for editing text files in the SDL Suite.
2. Files should be write enabled. If not, the files will be updated but stored with the extension `.keep`.
3. Check the correctness of the system with the batch commands described in "Checking diagrams for duplicated object IDs" on page 212 in chapter 2, *The Organizer*.

   You should now be ready to convert to case-sensitive mode. Start with creating an extended cross reference file and a file with references to all keywords in the system.
4. Issue the following command:

   ```
   sdtbatch[.bat] -a systemPath/systemname.sdt -options
   optionFile.txt
   ```

   The file `optionFile.txt` should include the following lines of options to the Analyzer:

   ```
   [ANALYSEROPTIONS]
   SDLKeywordFile=True
   SetPredefinedXRef=True
   XRef=True
   CaseSensitiveSDL=False
   ```

   Two files will be created in the target directory of the system. They are called `casesensitive.xrf` and `casesensitive.key` and should be used in the next step.

5. Now you can start the update of the system by invoking the following command.

   ```
   sdtbatch[.bat] -changecase
   targetDir/casesensitive.xrf
   ```

   The result of the operation is sent to `sdtout` and contains information about what have been done, problems that have arisen and finally which files that was updated and saved. Since it is a lot of information you should probably pipe the output to a file.

   When the case is updated we recommend that you analyze the system again. Proceed as follow:

6. Change the last row in the `optionFile.txt` from above. The last row should now be:

   ```
   CaseSensitiveSDL=True
   ```

7. If your system uses the ctypes package and H2SDL you will need to use a special ctypes package that makes it possible to analyze in case-sensitive mode. Open the system in the Organizer and connect ctypes package to the file `<installation directory>/sdt/include/ADT/ctypes_migration.sun`.

8. Analyze the system by issuing the following command:

   ```
   sdtbatch[.bat] -a systemPath/systemname.sdt -options
   optionFile.txt
   ```

   There are known restrictions that may make it necessary to manually make further changes of the case in some places in the system. Known problems are:

   – Text in class symbols are ignored.

   – Words spanning two symbols using the possibility to divide a word with '_' are not updated.

   – When generating SDL PR files from SDL GR files some words are trimmed for spaces. Those may not be handled correctly.

We recommend that you update the system further until you have no known errors in the system when running in case-sensitive mode before continuing the process to migrate to CPP2SDL.

Changed Tool Integration

CPP2SDL is integrated with the Organizer and the SDL Editor in a slightly different way than H2SDL is. Instead of placing the header files one by one at root level in the Organizer view, it is now possible to define a set of header files which will be translated by CPP2SDL as a group. Each such set is organized by an import specification which controls what declarations should be translated and how they should be translated. The SDL/PR file that results from the processing of an import specification is represented by means of a PR symbol in the SDL Editor.

1. Remove all header files from the root level in the Organizer view. Also remove the symbol for the ctypes package.
2. In the extended heading of the SDL system diagram, remove the use clauses of the packages, which were generated by H2SDL for the header files. Also remove the use clause of the ctypes package.

> **Note:**
>
> The ctypes package must not be used with CPP2SDL as it is designed exclusively for H2SDL. A set of SDL/PR files plays the same role as the ctypes package and will be included by selecting an option in an import specification as described in step 5.

Now all dependencies on H2SDL have been removed, and the specification may be set up for using CPP2SDL instead.

3. Add an import specification at system level in the Organizer view. Do this by placing a PR symbol in the SDL system diagram. Then double-click the PR symbol, and select it to be a C import specification in the dialog that appears.
4. Add the removed header files to the import specification, by selecting the import specification and using the Add Existing command in the Organizer. The symbols for the added header files will appear below the import specification symbol in the Organizer.
5. Go to the CPP2SDL Options dialog for the import specification and set the option[1] to generate SDL representations for fundamental types.

When the above steps have been performed, the SDL specification should be equivalent to the original specification from a tool integration

point-of-view. However, while doing these changes there are a few optimizations that are enabled by CPP2SDL which should be considered. We will look at these later in "Configuring CPP2SDL Translation" on page 880.

Differences in Translation Rules

Although the translation rules implemented by CPP2SDL in many ways are similar to the ones implemented by H2SDL, they are not identical. Therefore, it may be necessary to do some modifications in the SDL specification.

The following sections follow the presentation in chapter 14, *The CPP2SDL Tool*.

Names

The names of generated SDL identifiers may differ in prefixes and suffixes. All references to such identifiers from the SDL specification should be updated, if needed.

1. Remove suffixes generated by H2SDL to handle case-sensitivity. These suffixes have the format "_*i*", where *i* is a natural number.
2. Remove prefixes generated by H2SDL to handle combinations of underscores that previously were not supported. These prefixes have the format "zz_UScr_*ij*_", where *i* and *j* are natural numbers. Also change the name of these identifiers to be the same as the corresponding C identifiers.
3. Change prefixes generated by H2SDL to handle SDL keywords. These prefixes have the format "zz_CCod_" and should be replaced with "keyword_".

Hint:

An alternative to changing all keyword prefixes manually, is to set the keyword prefix to be "zz_CCod_" in the CPP2SDL Options dialog.

1. This option plays the same role as the ctypes package did for H2SDL. When it is set, the generated SDL will include suitable SDL/PR files with SDL representations of fundamental C/C++ types and type declarators (e.g. int, char, pointers and arrays). If set at more than one specification, errors will occur. Therefore, set this option at the broadest scope in which it will be used.

Fundamental Types

The ctypes package used by H2SDL, is replaced by one of two sets of SDL/PR files, depending on the used input language; BasicCTypes and CPointer, or BasicC++Types and C++Pointer. They are included automatically in the SDL generated by CPP2SDL if the *Generate SDL representations for fundamental types* is set. Refer to "Fundamental Types" on page 786 in chapter 14, *The CPP2SDL Tool* for more information.

The table below describes the differences between the H2SDL ctypes package and the corresponding CPP2SDL SDL/PR files. The most obvious difference is that the SDL names of the sorts that represent fundamental C/C++ types are more consistent and intuitive when CPP2SDL is used.

Also note that the `CharStar` and `VoidStarStar` sorts of ctypes (representing `char*` and `void**` in C/C++) are not predefined in the CPP2SDL included SDL/PR files. See "Predefined Pointer Types" on page 877 and "Predefined Operators" on page 877.

C/C++ Fundamental Type	SDL Sort when using H2SDL	SDL Sort when using CPP2SDL
`signed int` `int`	`Integer`	`int`
`unsigned int` `unsigned`	`UnsignedInt`	`unsigned_int`
`signed long int` `signed long` `long int` `long`	`LongInt`	`long_int`
`unsigned long int` `unsigned long`	`UnsignedLongInt`	`unsigned_long_int`
`signed short int` `signed short` `short int` `short`	`ShortInt`	`short_int`
`unsigned short int` `unsigned short`	`UnsignedShortInt`	`unsigned_short_int`

C/C++ Fundamental Type	SDL Sort when using H2SDL	SDL Sort when using CPP2SDL
signed long long int signed long long long long int long long	LongLongInt	long_long_int
unsigned long long int unsigned long long	UnsignedLongLongInt	unsigned_long_long_int
char	Character	char
signed char	Character	signed_char
unsigned char	Octet	unsigned_char
char *	CharStar	N/A
float	Float	float
double long double	Real	double
bool	N/A	bool
wchar_t	N/A	wchar_t
void *	VoidStar	ptr_void
void **	VoidStarStar	N/A

4. Update all references to sorts corresponding to fundamental types, with the names of the corresponding SDL sorts generated by CPP2SDL.

Hint:

An alternative to changing all these references manually is to define a set of syntypes mapping the old names to the new ones.

Type Declarators

The names of SDL sorts representing pointer and array types have been changed to be more intuitive and shorter when CPP2SDL is used.

5. Update all references to sorts corresponding to pointer types by changing the old pointer prefix “Ref_*filename*_” to “ptr_”.

6. Update all references to sorts corresponding to array types by changing the old array prefix “CA_*filename_i*_X_” to “arr_*i*_”, where *i* is the number of elements in the array.

As the H2SDL array prefix “CA_*filename_i*_X_” would result in very long SDL sort names when translating multi-dimensional arrays, H2SDL generates syntypes to shorten the sort names. These syntypes are named “MA_*filename_j*”, where *j* is a natural number. Example 144 gives an example of this technique and the corresponding CPP2SDL translation.

Example 144: H2SDL translation of multi-dimensional array compared to CPP2SDL translation ––––––––––––––––––––––––––––––––––––

C header:

```
int func(int[2][3][4]);
```

H2SDL translation:

```
newtype CA_filename_4_X_Integer /*#SYNT*/
  CArray(4,Integer);
endnewtype CA_filename_4_X_Integer;

newtype CA_filename_3_X_CA_filename_4_X_Integer
/*#SYNT*/
  CArray(3,CA_filename_4_X_Integer);
endnewtype CA_filename_3_X_CA_filename_4_X_Integer;

syntype MA_filename_0 /*#SYNT*/ =
 CA_filename_3_X_CA_filename_4_X_Integer
endsyntype;

newtype CA_filename_2_X_MA_filename_0 /*#SYNT*/
  CArray(2,MA_filename_0);
endnewtype CA_filename_2_X_MA_filename_0;

procedure func;
  fpar
    fpar_0 CA_filename_2_X_MA_filename_0;
  returns Integer;
external;
```

CPP2SDL translation:

```
NEWTYPE global_namespace_ImpSpec /*#NOTYPE*/
  OPERATORS
    func : arr_2_arr_3_arr_4_int -> int;
/*#ADT(A(S) E(S) K(H))*/
ENDNEWTYPE global_namespace_ImpSpec;EXTERNAL 'C++';
NEWTYPE arr_4_int CArray( 4, int);
/*#ADT(A(S) E(S) K(H))*/
```

```
ENDNEWTYPE arr_4_int;EXTERNAL 'C++';
NEWTYPE arr_3_arr_4_int CArray( 3, arr_4_int);
/*#ADT(A(S) E(S) K(H))*/
ENDNEWTYPE arr_3_arr_4_int;EXTERNAL 'C++';
NEWTYPE arr_2_arr_3_arr_4_int CArray( 2,
arr_3_arr_4_int);
/*#ADT(A(S) E(S) K(H))*/
ENDNEWTYPE arr_2_arr_3_arr_4_int;EXTERNAL 'C++';
```

7. If syntypes for multi-dimensional arrays are present ("MA_*filename_j*"), replace them with one "arr_*i*_" prefix for each array dimension.

Predefined Pointer Types

The H2SDL ctypes package includes the definition of the SDL sorts `CharStar` and `VoidStarStar` corresponding to the C/C++ pointer types `char*` and `void**`. These predefined sorts are not supported by CPP2SDL. Instead CPP2SDL will translate these pointer types using the `Ref` generator as they are needed.

8. Update all references to the obsolete sort `CharStar` to the translated sort `ptr_char`.

9. Update all references to the obsolete sort `VoidStarStar` to the translated sort `ptr_ptr_void`.

Predefined Operators

The ctypes package also defines a number of obsolete conversion operators for the `Ref` generator and the `CharStar` and `VoidStarStar` sorts, these are replaced with the `cast` operator according to the table below.

H2SDL operator	CPP2SDL operator	Comment
`ref2vstar`	`cast`	
`vstar2ref`	`cast`	
`ref2vstarstar`	`N/A`	Use `cast(cast( ))` instead, i.e `<type>*` to `void*` to `void**`
`cstar2cstring`	`cast`	Defined in CharConvert.pr
`cstring2cstar`	`cast`	Defined in CharConvert.pr

H2SDL operator	CPP2SDL operator	Comment
cstar2vstar	cast	
vstar2cstar	cast	
cstar2vstarstar	N/A	Use cast(cast( )) instead, i.e <type>* to void* to void**
vstarstar2vstar	cast	
vstar2vstarstar	cast	

10. If the cstar2cstring or cstring2cstar operators are used, add a PR symbol and connect it to the file <installation directory>/include/ADT/CharConvert.pr.

11. Replace all occurrences of the obsolete conversions operators with the cast operator according to the table above.

Enumerated Types

H2SDL has two alternative translations of enum declarations; using integer synonyms or using newtype literals. CPP2SDL only supports the latter of these alternatives.

If H2SDL was configured to translate enum literals to integer synonyms instead of newtype literals, and such a generated SDL synonym is used as an arithmetic expression, then the EnumToInt operator generated by CPP2SDL should be invoked on the newtype literal that corresponds to that synonym. See "Enumerated Types" on page 790 in chapter 14, *The CPP2SDL Tool* for more information.

Another difference in the translation of enumerated types is that H2SDL adds an Enum_ prefix to the generated newtype, while CPP2SDL uses the name as it is.

12. Remove all Enum_ prefixes from identifiers in references to newtypes representing enumerated types.

Functions

While H2SDL translates function prototypes to SDL procedures, CPP2SDL translates them to operators.

13. Convert all calls to procedures that represent C functions into operator calls by removing the `call` keyword.

14. If the Procedure call symbol is used to call procedures representing C functions, replace the Procedure call symbol with a Task symbol.

Note:

A procedure without parameters is called differently than an operator without parameters:

```
/* Calling a procedure p without parameters. */
task call p();
/* Calling an operator o without parameters. */
task o;
```

Variables

H2SDL does not translate C variables directly, but generates two procedures for getting and setting the value of the variable. CPP2SDL, on the other hand, generates external SDL variables, which is a tool-specific SDL extension.

15. For each accessed variable `v`, replace all procedure calls to `Set_v(`*`value`*`)` with the assignment `v := `*`value`*. Replace procedure calls to `Get_v()` with the variable name `v`.

Note:

CPP2SDL will only translate variables when the Import Specification is placed in a SDL diagram that allows declaration of variables.

Structs and Unions

With CPP2SDL, the names of newtypes generated from structs and unions are retained, while H2SDL adds a `Struct_` or a `Union_` prefix to these names.

16. Remove all `Struct_` and `Union_` prefixes from identifiers in references to newtypes representing structs or unions.

Dynamic Memory Management

The definition of the Ref generator that was used with H2SDL only contained an operator (`Make!`) or literal (`Alloc`) for instance allocation,

while instance deallocation was made with a `Free` procedure, defined outside the generator. With CPP2SDL, the `Free` procedure has been replaced with a `free` operator in the Ref generator.

17. Convert all calls to the `Free` procedure into calls to the `free` operator by removing the **call** keyword and changing `Free` to `free`.

Configuring CPP2SDL Translation

While H2SDL performs a full translation of all supported C constructs to the system scope of the SDL specification, the Import Specification makes it possible to define what CPP2SDL translates and where to import it.

Additionally, it is also possible to use multiple Import Specifications to import C declarations to different scopes in the SDL specification.

> **Note:**
>
> The SDL language does not contain any construct like the C `#ifdef` construct, so take care not to import any declarations more than once if you are planning to use multiple Import Specifications.

Where to place the Import Specifications

For example, instead of always placing an import specification at system level, it should be placed at the most narrow scope that encloses all SDL usages of the declarations in the header files that are present under that import specification.

CPP2SDL Options

H2SDL used a centralized setting controlling which preprocessor and what preprocessor options to use for preprocessing input headers. CPP2SDL is more flexible, and makes it possible to specify these settings for each import specification.

1. Open the CPP2SDL Options dialog for each import specification, and enter the preprocessor and preprocessor options to use for preprocessing the headers grouped by that import specification.

Also note that H2SDL defines the macro `__H2SDL__` while preprocessing the C header files. When using CPP2SDL this macro is replaced by the `__CPP2SDL__` macro.

2. If the __H2SDL__ macro is used in your C headers change this to __CPP2SDL__.

> **Hint:**
>
> An alternative to changing the __H2SDL__ macro is to use the pre-processor options in the CPP2SDL Options dialog to define the __H2SDL__ macro.

For more information on the options available in the CPP2SDL Options dialog please refer to "Setting CPP2SDL Options in the Organizer" on page 766 in chapter 14, *The CPP2SDL Tool*.

What to Translate

The TRANSLATE section of the Import Specification controls which C identifier that should be translated, by default CPP2SDL will also translate any declarations that these identifiers are depending on.

With the TRANSLATE section it is also possible to add type declarators to types and supply prototypes for ellipsis functions making these available in SDL.

Read more about the TRANSLATE section in "Import Specifications" on page 776 in chapter 14, *The CPP2SDL Tool*.

New Build Options

Contrary to H2SDL, CPP2SDL requires the generated SDL to be analyzed as case sensitive SDL.

3. In the Analyzer Options dialog, set the Case sensitive SDL option.

It should now be possible to analyze the SDL specification.

When the SDL specification has been accepted by the Analyzer, it should also be possible to generate code without further modification. Note, however, that using the Targeting Expert is the recommended way of generating code when CPP2SDL is used. This means that if a makefile or makefile template was used with H2SDL to link the external object files to the generated application, this could now be achieved in an easier way using the Targeting Expert. For more information, see "Generated Makefile" on page 2997 in chapter 59, *The Targeting Expert*.

Chapter 15 CPP2SDL Migration Guide

Chapter

16 *CIF Converter Tools*

This chapter is a reference manual for the CIF2SDT and SDT2CIF converter tools. The CIF2SDT tool converts CIF (the Common Interchange Format as defined in the Z.106 recommendation) files to binary format files, while SDT2CIF tool converts binary files or system files to CIF files.

CIF is a human readable text format for storing SDL diagrams, making it possible to store SDL diagrams in version control systems that only accept text files. In addition, it provides a base for converting diagrams to and from other SDL toolsets. The CIF2SDT and SDT2CIF tools bring the advantage of CIF to the SDL Suite tools.

Introduction

Common Interchange Format

CIF (Common Interchange Format) is a text format specified by ITU-T (International Telecommunication Union) in the recommendation Z.106 to ease the interchange of graphical SDL specifications. SDL-CIF is an extension to SDL/PR and is based on the SDL/PR syntax and can be read and written by tools as well as users. The CIF constructs are expressed as comments preceding the PR code. The advantages of such a text format are:

- SDL diagrams may be stored in version control systems that only accept text files.
- The format is human readable.
- It makes it possible to convert diagrams, including their layout, to and from other SDL toolsets that support CIF.
- It also makes it possible to revert to previous versions of the SDL Suite, by using CIF as an intermediate format and re-opening the CIF files in an older version of the SDL Suite to become SDL-GR.

However, CIF cannot be used as a storage format for files in the SDL Suite as it is required that specification stored in CIF file must be complete and correct.

CIF <-> SDT Converters

The CIF2SDT and SDT2CIF converters make the advantages of the CIF format available to the SDL Suite tools. The converters are implemented as a binary that can be run in a textual, command-line mode from the OS prompt, or as separate applications with graphical user interfaces **(in Windows)**. The converter tools can also be launched from the Organizer using the menu choices *Convert GR to CIF* and *Convert CIF to GR* from the *Generate* menu.

The conversion between CIF and the binary format is performed as follows:

- When converting to CIF, the tool SDT2CIF is used. CIF comments will be generated close to the corresponding SDL/PR code.

- When converting from CIF, the tool CIF2SDT is used. Both CIF comments and SDL/PR code are considered. CIF comments control conversion, while the text for symbols is extracted from the SDL/PR code.

Note:

The CIF2SDT or SDT2CIF tools require the SDL Suite environment when running; meaning that there should be enough licenses available to be able to convert to/from CIF.

On UNIX, when running the CIF converters without having started the SDL Suite tools, the environment variable $`telelogic` must be set. This will be set by souring the file `telelogic.sou` in the installation directory.

Generally, one CIF file contains several SDL diagrams. However, the placement of generated diagrams can be specified by the user.

CIF2SDT Converter Tool

The CIF2SDT tool converts CIF files to binary format files. It can convert one or more specified CIF files or all CIF files in a specified directory.

The CIF2SDT converter never overwrites existing data files. If the converter finds that the file it was going to write already exists, it generates a new name for the output file by replacing the two last characters at the end of the file name.

The CIF2SDT converter can be started in the following ways:

- From the OS command line; see "Command Line Syntax" on page 886.
- As a separate application with a graphical user interface **(Windows only)**; see "Graphical User Interface (Windows only)" on page 890.
- From the Organizer's *Generate* menu choice *Convert CIF to GR*.
  - **On UNIX**, a dialog is then opened; see "Convert CIF to GR Dialog (UNIX only)" on page 889.
  - **In Windows**, the separate application is then started; see "Graphical User Interface (Windows only)" on page 890.

Command Line Syntax

The CIF2SDT tool can be invoked from the OS prompt as follows:

```
cif2sdt [-v[ersion]] [-h] [-r] [-k]
[ -o <output file name> ]
( <CIF file> | <directory> )*
```

The meaning of the command-line options is given in the following sections.

(Windows only) When started without options or with -r option only, the Graphical User interface will be started, otherwise the application will execute as a command line application. However, to be able to get the output in the command window when run as a command line application you must use the special application conspawn as a wrapper (assuming `C:\IBM\Rational\SDL_TTCN_Suite6.3` is the installation directory)

```
C:\IBM\Rational\SDL_TTCN_Suite6.3\bin\wini386\conspawn.exe -b

C:\IBM\Rational\SDL_TTCN_Suite6.3\bin\wini386\cif2sdt.exe
myciffile
```

When using the converter as a command line application and invoking it within emacs path names in input files are lost. Therefore be sure to do a “cd” to the directory where the files are before invoking the converter.

Command Line Options

- `-v` or `-version` (show the version)

  This option displays the version number of the tool.

- `-h` (show the command line syntax)

  This option displays a help message about the command line syntax.

- `-r` (reuse a started session)

  This option allows to reuse and connect to an already started session if it exists. The default behavior is to start a new session.

- `-k` (keep original file name)

  If the CIF file being converted was converted from an SDL diagram, the converter will use the original file name for the output file.

Note:

This option will only work if the CIF file contains the CIF comment OriginalFileName.

- `-o` (save the generated files under the name specified)

  When given this option, the SDT2CIF converter will save the generated diagrams in the file named `<output file name>`.

Examples of Usage

Example 145 ————————————————————————————

```
cif2sdt myfile.cif
```

The CIF2SDT tool will convert the diagrams contained in the CIF file `myfile.cif` to the file `myfile.sif` (if a file named `myfile.sif` does

not already exist), `myfile01.sif` (if a file named `myfile.sif` already exists, but the file `myfile01.sif` does not), `myfile02.sif` and so on.

Example 146 ----------

```
cif2sdt -o lift.sbk lift.cif
```

The CIF2SDT tool will convert the diagrams contained in the CIF file `lift.cif` to binary format and put it into an SDL block file named `lift.sbk` (again, if the file named `lift.sbk` does not already exist – otherwise, the name will be modified and a corresponding message issued).

Example 147 ----------

```
cif2sdt mycifdir
```

(where `mycifdir` specifies a directory name)

The CIF2SDT tool will search for CIF files in the directory named `mycifdir`, convert all CIF files found to binary format files.and put the converted diagrams in the directory `mycifdir`. For information on how the search for CIF files is done, see "How the Converter Works" on page 892.

Example 148 ----------

```
cif2sdt myblock.cbk myprocss.cpr myservce.csv
```

The CIF2SDT tool will convert the CIF files `myblock.cbk`, `myprocss.cpr` and `myservce.csv` and put the converted diagrams into the binary files `myblock.sbk`, `myprocss.spr` and `myservce.ssv`.

Example 149 ----------

```
cif2sdt mysystem.csy mycifdir
```

(where `mycifdir` specifies a directory name)

The CIF2SDT tool will convert the CIF file `mysystem.csy` and put the converted diagrams into an system file, then it will search the directory `mycifdir` and convert all CIF files found in this directory.

Convert CIF to GR Dialog (UNIX only)

On UNIX, the CIF2SDT converter can also be started by selecting *Convert CIF to GR* from the Organizer's *Generate* menu. This opens the *Convert CIF to GR* dialog:

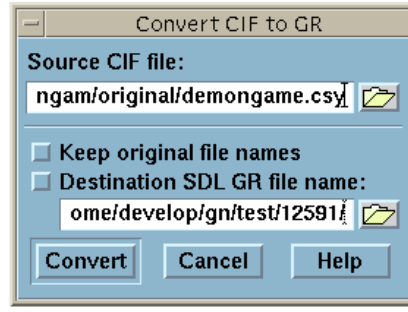


Figure 169: The Convert CIF to GR dialog

The dialog functions as a front-end to the `cif2sdt` converter described in "Command Line Syntax" on page 886. The only functionality **not** supported by the dialog is the possibility to specify a directory name as input to the conversion.

- *Source CIF file*

  This text field specifies the name of the CIF file to be converted (a directory name **cannot** be specified). To select a file using a standard file selection dialog box, press the folder button located to the right of the text field.

- *Keep original file names*

  If this option is enabled, the converter will preserve the original file name (i.e. the file from which this CIF file was generated).

> **Note:**
> This option will only work if the CIF file contains the CIF comment OriginalFileName.

- *Destination SDL/GR file name*

  This text field specifies the name of the file which will contain the converted diagrams. To select a file using a standard file selection

dialog box, press the folder button located to the right of the text field.

- *Convert*

  Clicking this button will initiate the conversion, using the options currently displayed in the dialog. Messages issued by the converter will appear in the Organizer Log window. The possible messages are listed in "Messages from CIF2SDT Converter" on page 893.

Graphical User Interface (Windows only)

In Windows, the CIF2SDT converter is either started outside the SDL Suite by using the `cif2sdt` executable in the release, or by selecting *Convert CIF to GR* from the Organizer's *Generate* menu. It provides a graphical user interface to control the conversions:

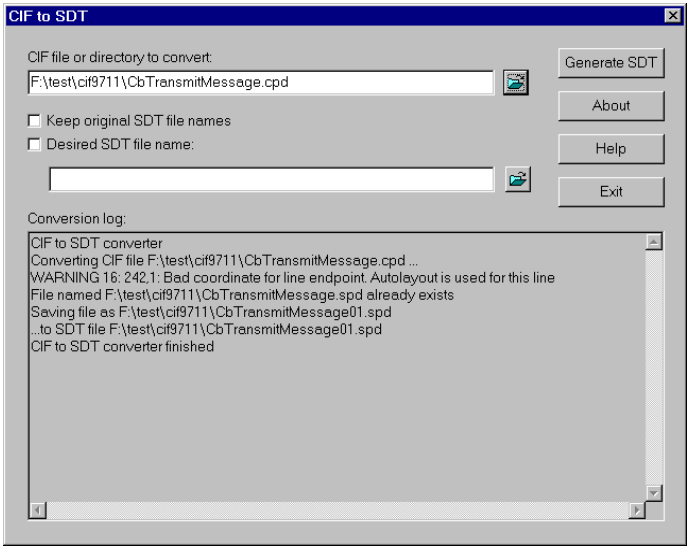

Figure 170: CIF2SDT Graphical User Interface

To convert a CIF file or all CIF files in a directory, perform the following steps:

1. Type a CIF file or directory name in the text field under *CIF file or directory to convert*.
   - To select a file using a standard dialog box, click the folder button which is located to the right of the text field.
2. Specify the desired options by clicking on check boxes which specify conversion options; look for option explanations in "Converter Options" on page 891.
3. Click the *Generate SDT* button.

After these steps, the conversion will proceed, possibly printing warning/errors/information messages into the *Conversion log* text box.

After the conversion has been performed, the CIF2SDT converter can be used again to convert more CIF files or directories.

Converter Options

- *CIF file or directory to convert*

  This text field specifies the name of the CIF file or directory to be converted. To select a file using a standard file selection dialog box, press the folder button located to the right of the text field.

- *Keep original SDT file names*

  If this option is enabled, the converter will preserve the original file name (i.e. the file from which this CIF file was generated).

> **Note:**
> This option will only work if the CIF file contains the CIF comment OriginalFileName.

- *Desired SDT file name*

  This text field specifies the name of the file which will contain the converted diagrams. To select a file using a standard file selection dialog box, press the folder button located to the right of the text field.

- *Conversion log*

This text box contains warning/error/information messages issued by the converter during the last conversion. The possible messages are listed in "Messages from CIF2SDT Converter" on page 893.

- *Generate SDT*

  Clicking this button will initiate the conversion, using the options currently displayed in the window.

- *Exit*

  Clicking this button exits the converter.

How the Converter Works

First of all, the converter analyzes the input and builds a list of files to convert. If one or a set of files was specified, it adds all the files specified to the list of files to convert. If a directory was specified, the converter searches in the specified directory for files with the extensions `.cif, .cun, .csy, .cbk, .csu, .cpr, .csv, .cpd, .cmc, .cst, .cbt, .cpt, .cvt, .cop` (which are assumed to contain CIF diagrams) and adds the files found to the list of files to convert. The extension for the output file is formed by replacing the first character of the extension of the input file with the character 's'.

When the list of files to convert is ready, the converter tries to convert each file in the list. The file being converted is parsed, analyzed, transformed, and saved. During parsing, CIF comments take precedence over the PR text, which is supposed to contain additional attributes for CIF objects. If the converter finds an error in the PR text, it proceeds by printing a warning message about that fact, using only the information extracted from the CIF comments.

The advantage of the CIF2SDT converter is that it supports incomplete PR text. For example, it can handle empty text of symbols, empty signal lists, and empty gate constraints. However, there is an exception when the PR text is required to be correct: after the "Diagram Start" CIF comment.

If a line is found that does not have the correct breakpoints (to be correct, it should be a point on the symbol border), an auto layout method is used to place the line.

The converter never overwrites any existing files. If the file to be written gets the same name as an existing file, a new name is generated for the output file to avoid overwriting existing files.

Messages from CIF2SDT Converter

The CIF2SDT converter issues an *information message* when it needs to inform the user about something; for example, when it changes the output file name in order not to overwrite an existing file. It also issues a *warning message* when some non-fatal error is found; for example, when some symbol on a diagram occurs in a wrong context. It prints an *error message* when it is not possible to continue the conversion; for example, when the input file is wrong or corrupt.

Message Format

The general format for warning/error messages is the following:

```
ERROR <error code>: [<line>, <column>:] <error text>
<additional information>
WARNING <warning code>: [<line>, <column>:] <warning
text> <additional information>
```

The `<error code>` specifies the error code which can be used to find the warning/error explanation (see the following sections). The `<line>` and `<column>` specify a position in the source CIF file where the error has occurred. The `<error text>` gives a short explanation of what is wrong. The `<additional information>` specifies additional information about the error (for example, it can specify the name of an endpoint constraint that could not be bound).

The list of possible warning/error messages follows in the next sections.

List of Error Messages

`Error 1: Arguments required` (UNIX only)

This error indicates that no command-line arguments were given to the CIF2SDT converter, which thus cannot continue processing. To remedy the situation, specify one or more file/directory name(s) to convert.

`Error 2: Illegal option` **(UNIX only)**
This message is issued when an invalid option is found in the command line. To remedy the situation, supply an appropriate option instead of the invalid one.

`Error 3: Duplicate option` **(UNIX only)**
This message is issued when a duplicate command-line option is found. The command-line options can be specified only once. To remedy the situation, remove duplicated options from the command line.

`Error 4: Missing output file` **(UNIX only)**
This message is issued when the option `-o` has been specified, but no output file name follows. To remedy the situation, supply an output file name after the `-o` option.

`Error 5: Illegal command line syntax` **(UNIX only)**
This message is issued when the command line is found not to obey the command-line syntax. To remedy the situation, make the command line conform to the command-line syntax.

`Error 6: Impossible to connect to SDT PostMaster`
This message is issued when the CIF2SDT converter cannot connect to the PostMaster.

In Windows, the CIF2SDT converter requires the PostMaster to be running in order to perform conversion. Start the Organizer and try again.

On UNIX, the most likely cause of this message is that either the path to the SDL Suite tools is not in the search path, or the maximum number of licenses is reached. To remedy the situation, ensure that the SDL Editor can be started (i.e. it is in the search path) and that there are enough licenses available.

`Error 7: Error creating diagram`
This message is issued when the CIF2SDT converter cannot create a diagram in the SDL Editor. This message is most probably caused by a corrupt input CIF file. To remedy the situation, correct the CIF file.

Error 8: Error creating page

This message is issued when the CIF2SDT converter cannot create a page in the SDL Editor. This message is most probably caused by a corrupt input CIF file. To remedy the situation, correct the CIF file.

Error 9: Error creating symbol

This message is issued when the CIF2SDT converter cannot create a symbol in the SDL Editor. This message is most probably caused by a corrupt input CIF file. To remedy the situation, correct the CIF file.

Error 10: Error saving diagram in file

This message is issued when the CIF2SDT converter cannot save the resulting diagram on the output file. This message may be caused by an invalid output path/file name. If this is the case, specify a valid path. This message may also be caused by insufficient disk space available. If this is the case, free some disk space.

Error 11: Size of symbol is not specified

This message is issued when the CIF2SDT converter encounters a symbol without an explicit size specified and without any default size specified in a diagram in the input CIF file. This is illegal according to the Z.106 standard. To remedy the situation, correct the source CIF file.

Error 12: Cannot bind gate reference

This message is issued when the CIF2SDT converter cannot bind a gate reference to a list of connections. This means the input file is corrupt. To remedy the situation, correct the source CIF file.

Error 13: Cannot bind connect for...

This message is issued when the CIF2SDT converter cannot bind a connection statement with a list of channels/signal routes. This means the input file is corrupt or illegal. To remedy the situation, correct the source CIF file.

Error 14: Cannot bind FROM endpoint for...

This message is issued when the CIF2SDT converter cannot bind a FROM endpoint of a channel or signal route to a block or process. This means that the input CIF file is corrupt or illegal. To remedy the situation, correct the CIF file.

Error 15: Cannot bind TO endpoint for...

This message is issued when the CIF2SDT converter cannot bind a TO endpoint of a channel or signal route to a block or process. This means that input CIF file is corrupt or illegal. To remedy the situation, correct the CIF file.

Error 16: Cannot bind endpoint of line

This message is issued when the CIF2SDT converter encounters a flow line statement and cannot find symbols which are supposed to be connected. To remedy the situation, correct the CIF file.

Error 17: Dashed should be used if keyword Adding is used for gate

Error 18: Wrong first endpoint in gate

Error 19: Gate constraint symbol is omitted for gate

These three messages mean that the source CIF file contains contradictory CIF comments and SDL/PR and is thus corrupt. To remedy the situation, correct the CIF file.

Error 20: Wrong page name

This message is issued when the CIF2SDT converter encounters a CIF PageSwitch comment in a source file that references an undefined page in the diagram. To remedy the situation, correct the CIF file.

Error 21: Wrong number of points in pointlist for gate

This message is issued when the CIF2SDT converter encounters a CIF Gate comment with a pointlist consisting of more than two points. This is a violation of the Z.106 standard, the input file is thus corrupt. To remedy the situation, correct the CIF file.

Error 22: Create line can occur only inside block (type) without decomposition

This message means that the source CIF file is corrupt. To remedy the situation, correct the source CIF file.

Error 23: Flowline can occur only inside diagrams with process body

This message means that the source CIF file is corrupt. To remedy the situation, correct the source CIF file.

Error 24: Symbol cannot occur in this context

This message means that the CIF2SDT converter encountered a graphical symbol in a wrong context in the source diagram (for example, a start symbol in a system diagram). To remedy the situation, correct the source CIF file.

Error 25: Syntax error

This message means that the CIF2SDT converter encountered a violation of the CIF syntax in the source CIF file. To remedy the situation, correct the source CIF file.

Error 26: Illegal name of output file

This message means that either no unique name was found for the output file or there was an input/output error during saving of the output file. To remedy the situation, try to convert the diagrams to a file with a different name (**on UNIX**, see the `-o` option).

Error 27: Cannot bind connection point text position

This message means that the position of text in a connection statement could not be bound. To remedy the situation, try to move the text of connection symbol in the source diagram, then re-run the converter.

Error 28: Wrong page type(s) on the diagram

This message means that the CIF2SDT converter found a process diagram with several pages of different types, which is a violation of the Z.106 standard. To remedy the situation, correct the CIF file.

Error 29: Analysis of CIF failed

This message means that the CIF2SDT converter failed to analyze the input CIF file. In this case nothing is generated in the output file. To remedy the situation, correct the CIF file.

Error 30: Wrong syntax of extended task

This message means that the CIF2SDT converter found a syntax error in the PR text of an extended task symbol. The incorrect text is printed as the rest of the error message. Either the left or right curly bracket is missing or they appear in the wrong place in the PR text. To remedy the situation, correct the CIF file.

List of Warning Messages

Warning 2: No input files

This warning is issued when the CIF2SDT converter finds out that no valid file or directory names were specified on the command line. To remedy the situation, ensure that the specified path/file names are correct.

Warning 3: Cannot convert file or directory

This warning is issued when the CIF2SDT converter cannot determine if the specified file is a CIF file or a directory. This is most probably caused by an invalid file/path name. To remedy the situation, ensure that the specified path/file names are correct.

Warning 4: SDLE says: ...

This warning is issued when the CIF2SDT converter receives a reply from the SDL Editor with a message explaining the reason of the error. To see the more detailed explanation of the reason for the error, see the text following the colon.

Warning 5: Empty diagram

This warning means that no diagrams are contained in the source CIF file.

Warning 6: Sorry, Select symbol is not supported in SDT SDLE

Since Select symbol is not supported in the SDL Editor, the converter has no option but to ignore it.

Warning 7: ... cannot contain ... text position specification, specification ignored

Warning 7: ... text placement specification is already specified, ignoring extra specification

Warning 8: This is location of previous specification

These warning messages mean that the source CIF file is corrupt. To remedy the situation, correct the CIF file.

Warning 9: Parsing of PR has failed

This means that there is incorrect SDL/PR after some CIF comment in the source CIF file. To remedy the situation, correct the CIF file.

Warning 10: Dashed attribute synthesized

Warning 11: Dashed attribute ignored

Warning 12: Ignoring gate references

These three messages mean that there are errors in source CIF file that have been automatically corrected.

Warning 13: Integer value expected, zero assumed

This message means that some other text was encountered instead of integer number in the source CIF file, thus the value has been assumed to be zero.

Warning 14: PR is not allowed in ...

This message means that the CIF2SDT converter encountered SDL/PR where it is not allowed to be. This also indicates that the source CIF file is corrupt. To remedy the situation, correct the CIF file.

Warning 15: Descriptors are not allowed (in typebased system)

This means that the source CIF file contained a type based system diagram with some symbols in it, which is a violation of the Z.106 standard. These symbols have been ignored.

```
Warning 16: Bad coordinate for line endpoint.
Autolayout is used for this line
```

This means that a coordinate for a line endpoint has been found but this coordinate does not fall on the perimeter of the symbol that is connected to the line. Autolayout of the line will be used to place the line.

SDT2CIF Converter Tool

The SDT2CIF tool converts binary format files to CIF files. It can convert one or more specified binary format files, SDL system files or all SDL diagram files in a specified directory.

The SDT2CIF converter also supports the mixed platform feature of the SDL Suite (for more information on this topic, see "Windows and UNIX File Compatibility" on page 215 in chapter 2, *The Organizer*. If the converter finds a `[DRIVES]` section during the conversion of an SDL system file, it assumes that this system file is used on mixed platforms. This makes the converter change all characters in output file name to lower case **(on UNIX)** or replace the part of the path by the drive letter **(in Windows)**.

The SDT2CIF converter never overwrites existing data files. If the converter finds that the file it was going to write already exists, it generates a new name for the output file by replacing the two last characters at the end of the file name.

The SDT2CIF converter can be started in the following ways:

- From the OS command line; see "Command Line Syntax" on page 901.
- As a separate application with a graphical user interface **(Windows only)**; see "Graphical User Interface (Windows only)" on page 906.
- From the Organizer's *Generate* menu choice *Convert GR to CIF*.
  - **On UNIX**, a dialog is then opened; see "Convert GR to CIF Dialog (UNIX only)" on page 904.
  - **In Windows**, the separate application is then started; see "Graphical User Interface (Windows only)" on page 906.

Command Line Syntax

On UNIX, the SDT2CIF tool can be invoked from the OS prompt as follows:

```
sdt2cif [-v[ersion]] [-h] [-r] [-g] [-i] [-s]
[-o <output file name>] ( <binary diagram file> |
<system file> | <directory> )*
```

(Windows only) When started without options or with -r option only, the Graphical User interface will be started, otherwise the application will execute as a command line application. However, to be able to get the output in the command window when run as a command line application you must use the special application conspawn as a wrapper (assuming `C:\IBM\Rational\SDL_TTCN_Suite6.3` is the installation directory)

```
C:\IBM\Rational\SDL_TTCN_Suite6.3\bin\wini386\conspawn.exe -b

C:\IBM\Rational\SDL_TTCN_Suite6.3\bin\wini386\cif2sdt.exe
myciffile
```

When using the converter as a command line application and invoking it within emacs path names in input files are lost. Therefore be sure to do a “cd” to the directory where the files are before invoking the converter.

The meaning of the command-line options is given in the following sections.

Command Line Options

- `-v` or `-version` (show the version)

  This option displays the version number of the tool.

- `-h` (show the command line syntax)

  This option displays a help message about the command line syntax.

- `-r` (reuse a started session)

  This option allows to reuse and connect to an already started session if it exists. The default behavior is to start a new session.

- `-g` (include graphical SDT references)

  This option directs the SDT2CIF converter to include graphical SDT references into the generated CIF file. If `-g` is given, graphical references are stored as SDL/PR comments; otherwise they are omitted.

- `-i` (omit CIF comments)

  When using this option, only SDL/PR will be generated by SDT2CIF.

- `-s` (single file)

  When using this option, all diagrams will be saved on one single file. The name of the file is the same name as the first CIF file would get after conversion if this option was not used.

- `-o` (save the generated files under the name specified)

  When given this option, the SDT2CIF converter will save the generated diagrams in the file named `<output file name>`.

Examples of Usage

Example 150 ––

```
sdt2cif mysystem.sdt
```

where `mysystem.sdt` has the following diagrams:

```
myblock.sbk
myprocss.spr
myservce.ssv
myproced.spd
```

The SDT2CIF tool will convert all the diagrams referred to in the system file and save them in the CIF format under transformed names:

```
myblock.sbk    -> myblock.cbk
myprocss.spr   -> myprocss.cpr
myservce.ssv   -> myservce.csv
myproced.spd   -> myproced.cpd
```

Example 151 ––

```
sdt2cif mysdtdir
```

(where `mysdtdir` specifies a directory name)

The SDT2CIF tool will look in the directory `mysdtdir` and convert all binary files (but not system files – this would cause double conversion) to the corresponding CIF files.

Example 152 ––

```
sdt2cif myblock.sbk myprocss.spr myservce.ssv
```

The SDT2CIF tool will convert the three binary files to the CIF files `myblock.cbk`, `myprocss.cpr` and `myservce.csv`.

Example 153 ----------

```
sdt2cif -o blocks.cif block_a.sbk block_b.sbk
block_c.sbk
```

The SDT2CIF tool will convert the three binary files `block_a.sbk`, `block_b.sbk`, `block_c.sbk` and put all diagrams converted into the file `blocks.cif`.

Example 154 ----------

```
sdt2cif -s block_a.sbk block_b.sbk block_c.sbk
```

The SDT2CIF tool will convert the three binary files `block_a.sbk`, `block_b.sbk`, `block_c.sbk` and put all diagrams converted into the file named `blocks_a.cbk` (resulting from the name under which the first file in the list of files to convert would be saved if the `-s` switch was not specified).

Convert GR to CIF Dialog (UNIX only)

On UNIX, the SDT2CIF converter can also be started by selecting *Convert GR to CIF* from the Organizer's *Generate* menu. This opens the *Convert GR to CIF* dialog:

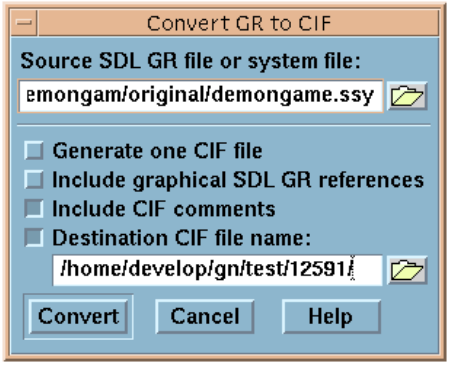

Figure 171: The Convert GR to CIF dialog

The dialog functions as a front-end to the `sdt2cif` converter described in "Command Line Syntax" on page 901. The only functionality **not**

supported by the dialog is the possibility to specify a directory name as input to the conversion.

- *Source SDL/GR file or system file*

  This text field specifies the name of the SDL/GR file or system file to be converted (a directory name can **not** be specified). To select a file using a standard file selection dialog box, press the folder button located to the right of the text field.

- *Generate one CIF file*

  If this option is enabled, the converter will save all converted diagrams into one file. The name of this file is determined from the *Destination CIF file name* check box state. If the check box is not selected, the name of the file will be the same as the name the first file being converted would get. This option is disabled by default. If the check box is selected, the name of the file with diagrams will be the name specified in the *Destination CIF file name* text field.

- *Include graphical SDL/GR references*

  This option directs the SDT2CIF converter to include graphical SDT references in the generated CIF files (see chapter 18, *SDT References* for more information on this topic). If this option is enabled, graphical SDT references are stored as SDL/PR comments; otherwise they are omitted. This option is disabled by default.

- *Include CIF comments*

  If this option is disabled, only SDL/PR will be generated to output file; otherwise CIF comments will be included. This option is enabled by default.

- *Destination CIF file name*

  This text field specifies the name of the file that will contain the converted diagrams. To select a file using a standard file selection dialog box, press the folder button located to the right of the text field.

- *Convert*

  Clicking this button will initiate the conversion, using the options currently displayed in the dialog. Messages issued by the converter will appear in the Organizer Log window. The possible messages are listed in "Messages from SDT2CIF Converter" on page 908.

Graphical User Interface (Windows only)

In Windows, the SDT2CIF converter is either started outside the SDL Suite by using the `sdt2cif` executable in the release, or by selecting *Convert GR to CIF* from the Organizer's *Generate* menu. It provides a Graphical User Interface to control the conversions:

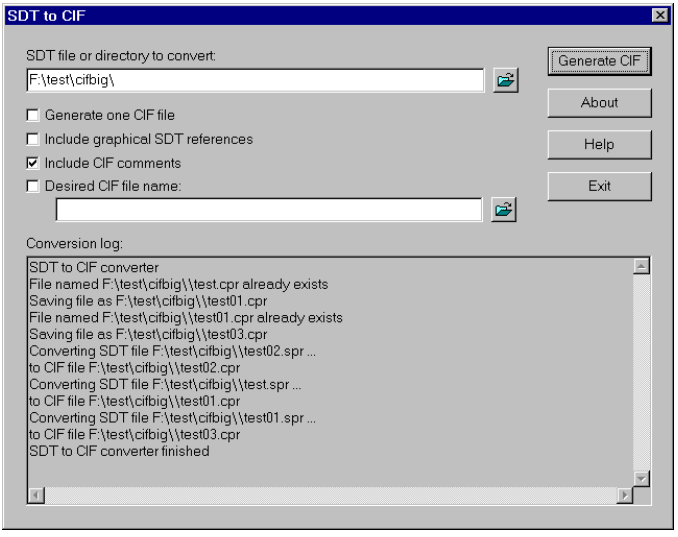

Figure 172: SDT2CIF Graphical User Interface

To convert a single binary file, system file or all binary files in a directory, perform the following steps:

1. Type an file or directory name in the text field under *file or directory to convert*.
   - To select a file using a standard dialog box, click the folder button which is located to the right of the text field.
2. Specify the desired options by clicking on check boxes which specify conversion options; look for option explanations in the following subsections.
3. Click the *Generate CIF* button.

After these steps, the conversion will proceed, possibly printing warning/errors/information messages into the *Conversion log* text box.

After the conversion has been performed, the SDT2CIF converter can be used again to convert more files or directories.

Converter Options

- *file or directory to convert*

  This text field specifies the name of the file or directory to be converted. To select a file using a standard file selection dialog box, press the folder button located to the right of the text field.

- *Generate one CIF file*

  If this option is enabled, the converter will save all converted diagrams into one file. The name of this file is determined from the *Desired CIF file name* check box state. If the check box is not selected, the name of the file will be the same as the name the first file being converted would get. This option is disabled by default. If the check box is selected, the name of the file with diagrams will be the name specified in the *Desired CIF file name* text field.

- *Include graphical SDT references*

  This option directs the SDT2CIF converter to include graphical SDT references in the generated CIF files (see chapter 18, *SDT References* for more information on this topic). If this option is enabled, graphical SDT references are stored as SDL/PR comments; otherwise they are omitted. This option is disabled by default.

- *Include CIF comments*

  If this option is disabled, only SDL/PR will be generated to output file; otherwise CIF comments will be included. This option is enabled by default.

- *Desired CIF file name*

  This text field specifies the name of the file that will contain the converted diagrams. To select a file using a standard file selection dialog box, press the folder button located to the right of the text field.

- *Conversion log*

  This text box contains warning/error/information messages issued by the converter during the last conversion. The possible messages are listed in "Messages from SDT2CIF Converter" on page 908.

- *Generate CIF*

  Clicking this button will initiate the conversion, using the options currently displayed in the dialog.

- *Exit*

  Clicking this button will exit the converter.

Messages from SDT2CIF Converter

The SDT2CIF converter issues an *information message* when it needs to inform the user about something; for example, when it changes the output file name so as not to overwrite an existing file. It also issues a *warning message* when some non-fatal error is found; for example, when some symbol on a diagram occurs in a wrong context. It prints an *error message* when it is not possible to continue the conversion; for example, when the input file is wrong or corrupt.

Message Format

The general format for warning/error messages is the following:

```
ERROR <error code>: <error text> <additional
information>
WARNING <warning code>: <warning text> <additional
information>
```

The `<error code>` specifies the error code which can be used to find the warning/error explanation (see the following sections). The `<error text>` gives a short explanation of what is wrong. The `<additional information>` specifies additional information about the error (for example, it can specify the name of an endpoint constraint that could not be bound).

The list of possible warning/error messages follows in the next sections.

List of Error Messages

`Error 1: Arguments required` **(UNIX only)**
This error indicates that no command-line arguments were given to the SDT2CIF converter, which thus cannot continue processing. To remedy the situation, supply one or more file/directory name(s) to convert.

`Error 2: Illegal option` **(UNIX only)**
This message is issued when an invalid option is found in the command line. To remedy the situation, supply an appropriate option instead of the invalid one.

`Error 3: Duplicate option` **(UNIX only)**
This message is issued when a duplicate command-line option is found. The command line options can be specified only once. To remedy the situation, remove duplicated options from the command line.

`Error 4: Missing output file` **(UNIX only)**
This message is issued when the option `-o` has been specified, but no output file name follows. To remedy the situation, supply an output file name after the `-o` option.

`Error 5: Illegal command line syntax` **(UNIX only)**
This message is issued when the command line is found not to obey the command-line syntax. To remedy the situation, make the command line conform to the command-line syntax.

`Error 6: Impossible to connect to SDT PostMaster`
This message is issued when the SDT2CIF converter cannot connect to the PostMaster.

In Windows, the SDT2CIF converter requires the PostMaster to be running in order to perform conversion. Start the Organizer and try again.

On UNIX, the most likely cause of this message is that either the path to the SDL Suite tools is not in the search path, or the maximum number of licenses is reached. To remedy the situation, ensure that the SDL Editor can be started (i.e. it is in the search path) and that there are enough licenses available.

Error 7: SDLE cannot convert the file

This message means that either the file is corrupt or the SDL Editor cannot read the source file or write to output file. To remedy the situation, ensure that the source file is valid and that there is enough disk space. Try to Restart the SDL Suite and re-run the converter.

List of Warning Messages

Warning 1: No input files (UNIX only)

This message means that the SDT2CIF converter did not find any suitable file for conversion among those specified on the command line. To remedy the situation, ensure the specified file/path names are correct.

Warning 2: Cannot convert file or directory

This message is most probably caused by a path/file name misspelling. To remedy the situation, ensure that the specified file/path names are correct.

Warning 3: SDLE says: ...

This warning is issued when the SDT2CIF converter receives reply from the SDL Editor with message explaining the reason of the error. To see the more detailed explanation of the reason for the error, see the text following the colon.

Chapter

17 *The Information Server*

This chapter is a reference to the error messages that are issued by the Information Server.

General

The Information Server is an application that serves the SDL Suite tools as a response to the following requests:

- Type Viewer request to list SDL diagram types along with their relationships and their instantiations. See chapter 45, *The SDL Type Viewer* for more information.
- SDL Editor request to list SDL signals according to the options selected in the Signal Dictionary options. See "Specifying the Signal Dictionary Options" on page 1986 in chapter 43, *Using the SDL Editor*.

The Information Server has no user interface and its operation is managed under the supervision of the SDL Suite, beyond user control.

Information Server Error Messages

This section is a reference to the error messages that may be produced by the Information Server.

Some messages contain a '#' followed by a number, which is used to indicate where information, specific to the error situation, will be included.

Some messages include a reference to the object that is the source of the diagnostic. These messages adhere to the format adopted in the SDL Suite. See chapter 18, *SDT References* for a reference to this format and for examples.

`ERROR 1000 #1 #2 contains parse error at '#3'`

The message contains a reference to an entity that could not be parsed by the Information Server. It is likely that the symbol contains syntactically incorrect information. The error message also contains a reference to the object where the error was detected.

`ERROR 1001 #1 #2 is not connected to a file`

#1 and #2 refer to the type and name of a diagram that is not connected in the Organizer structure. Use the Organizer command *Connect* (see "Connect" on page 92 in chapter 2, *The Organizer*) to connect the diagram to a suitable file.

ERROR #1002 Inheritance for #1 #2 is circular

#1 and #2 refer to the type and name of a diagram that contain a circular inheritance. Circular inheritance is not supported by the SDL Suite. The error message also contains a reference to the object where the error was detected.

ERROR 1003 Could not create temporary filename, status: #1

The Information Server failed when creating the name of a temporary file. #1 contains more information about what operation failed.

ERROR 1004 Could not create temporary file, status: #1

The Information Server failed when creating a temporary file. #1 provides additional information about the error code.

ERROR 1005 #1 #2 contains yacc stack overflow at '#3'

The message contains a reference to an entity which caused the parser stack to overflow. This message may occur when the parsers processes statements that contain a large amount of lexical elements. Break down the expression. The error message also contains a reference to the object where the error was detected.

Chapter 17 The Information Server

Chapter

18 *SDT References*

This chapter contains a reference to the syntax used by the SDL Suite when referring to entities managed by the SDL Suite.

Through these references, the SDL Suite environment provides a means to:

- **Obtain a graphical trace back from Analyzer diagnostics to the source SDL diagrams**
- **Trace simulations in graphical mode**
- **Obtain a trace back from generated MSCs to the source SDL diagrams**
- **Navigate between SDL type diagrams, cross-reference diagrams, coverage charts and the source SDL diagrams**
- **Navigate between the generated PR or C files and the source SDL diagrams.**

General

The concept “GR reference”, introduced in the SDT 2.X tool family, has been extended in order to support references to virtually all entities that are managed in an SDT 3.X environment (or will be managed in future versions):

- SDL diagrams
- SDL pages
- SDL symbols
- Text within an SDL symbol
- SDL Overview diagrams
- SDL/PR files
- OM, SC, MSC, HMSC diagrams
- OM, SC, HMSC pages
- OM, SC, MSC, HMSC symbols
- Text within an MSC symbol
- Text within an OM symbol[1]
- Cross-reference files
- Coverage files
- C files
- ASN.1 files
- Other ASCII text files

The term *GR reference* has been replaced by the term *SDT reference*. It is possible to retrieve SDT references from the SDL Suite tools using commands such as *Show GR Reference* in the SDL Editor, and to show the source that matches a reference using commands such as *Go To Source* in the Organizer.

1. This refers to the text in the name compartment in class definition and class instance symbols. Text in the operation and attributes compartments are not possible to refer to in this version.

Syntax

Below follows the syntax for an SDT reference:

```
<SDT_Reference> ::=
  '#SDTREF' '('
  ( <SDT_GR_Ref> | <SDT_Textfile_Ref>
  | <SDT_MSC_Ref> | <SDT_HMSC_Ref> | <SDT_OM_Ref>
  | <SDT_SC_Ref> )
  ')'

<SDT_GR_Ref> ::=
   'SDL' ',' <FileName>
   [ '(' <PageName> ')' ]
   [ ',' <ObjectId> [ <Object_Coordinates> ]
   [ ',' <LineNumber> [ ',' <Column> ] ] ]

<SDT_Textfile_Ref> ::=
  'TEXT' ',' <FileName>
   [ ',' <LineNumber> [ ',' <Column> ] ]

<SDT_MSC_Ref> ::=
   'MSC' ',' <FileName>
   [ ',' <ObjectId>
   [ ',' <LineNumber> [ ',' <Column> ] ] ]

<SDT_HMSC_Ref> ::=
   'HMSC' ',' <FileName>
   [ '(' <PageName> ')' ]
   [ ',' <ObjectId> [ <Object_Coordinates> ]
   [ ',' <LineNumber> [ ',' <Column> ] ] ]

<SDT_OM_Ref> ::=
   'OM' ',' <FileName>
   [ '(' <PageName> ')' ]
   [ ',' <ObjectId> [ <Object_Coordinates> ]
   [ ',' <LineNumber> [ ',' <Column> ] ] ]

<SDT_SC_Ref> ::=
   'SC' ',' <FileName>
   [ '(' <PageName> ')' ]
   [ ',' <ObjectId> [ <Object_Coordinates> ]
   [ ',' <LineNumber> [ ',' <Column> ] ] ]

<FileName> ::=
  File name

<PageName> ::=
  name of a page according to SDT 3.X rules

<ObjectId> ::=
  integer, unique id for object
```

```
<Object_Coordinates> =
  '(' <x-coord> ',' <y-coord> ')'

<x-coord> ::=
   x coordinates in mm from upper left corner
<y-coord> ::=
   y coordinates in mm from upper left corner

<LineNumber> ::=
   line number within symbol or file

<Column> ::=
   column within the line
```

Examples

Below follow some examples of SDT references.

Example 155: SDL graphical references ––––––––––––––––––––––

Reference	Explanation
`#SDTREF(SDL,test.sbk)`	SDL diagram.
`#SDTREF(SDL,test.sbk(P1))`	SDL page
`#SDTREF(SDL,test.sbk(P1),10)`	SDL symbol
`#SDTREF(SDL,test.sbk,10)`	SDL symbol
`#SDTREF(SDL,test.sbk(P1),10(30,130))`	SDL symbol
`#SDTREF(SDL,test.sbk(P1),10,5)`	Line within symbol
`#SDTREF(SDL,test.sbk(P1),10(30,130),5)`	Line within symbol
`#SDTREF(SDL,test.sbk(P1),10,5,15)`	Column at line within symbol

Example 156: MSC graphical references ––––––––––––––––––––––

Reference	Explanation
`#SDTREF(MSC,test.msc)`	MSC
`#SDTREF(MSC,test.msc,10)`	Symbol in MSC
`#SDTREF(MSC,test.msc,10,5)`	Line within symbol
`#SDTREF(MSC,test.msc,10,5,15)`	Column at line within symbol

Example 157: OM graphical references ––––––––––––––––––––––––

Reference	Explanation
`#SDTREF(OM,test.som)`	OM diagram.
`#SDTREF(OM,test.som(P1))`	OM page
`#SDTREF(OM,test.som(P1),10)`	OM symbol
`#SDTREF(OM,test.som,10(30,130))`	OM symbol
`#SDTREF(OM,test.som,10,5)`	Line within symbol
`#SDTREF(OM,test.som(P1),10(30,130),5)`	Line within symbol
`#SDTREF(OM,test.som(P1),10,5,15)`	Column at line within symbol

Example 158: Textual references ––––––––––––––––––––––––––––

Reference	Explanation
`#SDTREF(TEXT,test.pr)`	Text file
`#SDTREF(TEXT,test.pr,10)`	Line in text file
`#SDTREF(TEXT,test.pr,10,15)`	Column at line within file

––

Chapter

19 *Using OM Access*

This chapter describes the OM Access feature.

OM Access is a module that provides the end user with access to the information in a diagram created by the OM Editor through a C++-interface, based on the UML Meta-model.

OM Access

OM Access is a C++ application programmer's interface to the OM Editor. It can be used in applications that uses the information contained in OM diagrams, such as:

- Code generators
- Documentation generators
- Report generators
- Statistics.

Note:

This chapter is an OM Access primer and is not intended to provide knowledge about C++ programming.

OM Access Files

These files can be found under the `<installation dir>/orca/omaccess/>` directory of your installation.

Filename	Description
`stlmini.h`	Minimal implementation of the standard C++ library, used by `omaccess.cc`
`uml.h`	Declarations of UML Meta-structure
`omaccess.h`	Header-file for `omaccess.cc`
`omaccess.cc`	Functions for accessing the data in an OM diagram
`pmtool.h`	Declarations for low-level communications with the OM Editor
`om2cpp.cc`	A small demo program that takes a diagram and makes a C++ include file
`trace.cc`	A small demo program that prints almost everything it gets from OM Access

General Concepts

The OM Access Application

An OM Access application is an application that uses the data in an OM Diagram. This OM Diagram is represented in the program by a data structure similar to UML's metamodel.

The first section introduces the basic methods.

Basic Methods

First of all there are some definitions needed; these can be found in the include file `omaccess.h`:

```
#include "omaccess.h"
```

This file also includes `uml.h` and `stlmini.h`. The file `uml.h` contains declarations for the UML metamodel, and `stlmini.h`[1] contains a minimal implementation of `string` and `list` classes in the standard C++ library used for handling the data.

An instance of the `OMModule` is needed to hold the information:

```
OMModule module;
```

To load the contents of a diagram into the module either `GetFile` or `GetBufID` can be used:

```
bool result = GetFile(module, filename);
bool result = GetBufID(module, bufid);
```

Returns `true` on success, false if failed to load the module.

1. `stlmini.h` can be replaced by the appropriate standard C++ headers `<list.h>` and `<string.h>` if you have access to an implementation of the standard C++ library.

Accessing the Information

The `OMModule` class keeps the information fetched from the OM Editor in lists. The lists are:

```
list<Class> classList
list<Generalization> generalizationList
list<AssociationClass> associationlist
```

Aggregations and associations are stored into the `associationList`, to simplify handling. To pick out the associations and aggregations separately, use the functions:

```
GetAggregations(OMModule&, list<AssociationClass>*)
GetAssociations(OMModule&, list<AssociationClass>*)
```

These functions fill the list in the second parameter with the associations and aggregations in the module.

The lists can be traversed using iterators. The following example shows how to print all the names of the classes in a module:

Example 159 ----------

```
for (list<Class>::iterator ci=omModule.classList.begin();
     ci != omModule.classList.end();
     ++ci) {
        const Class &omClass = *ci;
        cout << omClass.name << endl;
}
```

Relations

The links between associations/aggregations/generalizations and classes are represented as the names of classes, stored as `strings`.

Generalizations

The `Generalization` class contains the data members `subtype` and `supertype`. The names of the super- and subclass are stored as `string`.

The data member `discriminator` contains the discriminator, stored as `string`.

To list the superclasses and subclasses of a class, the following functions can be used:

```
GetSuperClassList(OMModule&, string&, list<string>*)
GetSubClassList(OMModule&, string&, list<string>*)
```

They put the names of the superclasses or subclasses belonging to the name of the class in `string`, into the `list`.

Aggregations/Associations

The `AssociationClass` class can contain both aggregations and associations as well as associations with association classes connected to them. The `boolean` member `isAggregation` can be used to determine if it is an aggregation or association.

To get a list of the names of the classes connected to the association/aggregation, the function

```
GetEndPoints(AssociationClass&, list<string>*)
```

can be used.

Example

Here follows a small example that shows how to access the class information. For each class in the diagram it prints the name of the class and the name of its subclasses.

Example 160: printclasses.cc ----------

```
#include <iostream.h>
#include "omaccess.h"

#include "stlmini.h"

int main(int argc, char *argv[]) {
        if (argc !=2) {
                cout << "Usage : printclasses <filename>" << endl;
                return EXIT_FAILURE;
        }

        OMModule omModule;

        // Retrieve the file from the OM Editor
        if(! GetFile(argv[1], &omModule) )
                return EXIT_FAILURE;

        // Iterate over the classes
        for (list<Class>::iterator ci=omModule.classList.begin();
             ci != omModule.classList.end();
             ++ci) {
                const Class &omClass = *ci;
                cout << omClass.name << endl;

                // Extract the subclassess
                list<string> classlist;
                GetSubClassList(omModule,omClass.name,&classlist);
                // And iterate through them
                for (list<string>::iterator ni=classlist.begin();
                     ni != classlist.end();
                     ++ni) {
                        const string &name = *ni;
                        cout << " Subclass: " << name << endl;
                        }
        }
        return EXIT_SUCCESS;
}
```

Files and Compiling

General

To use OM Access a C++ compiler that can handle templates is needed, such as g++ 2.95.2, or MSVC 6.

There are some Makefiles together with the examples (`$telelogic/orca/omaccess/examples`) that might be usable as templates.

OM Access is based on the Public Interface; see "PostMaster Reference" on page 490 in chapter 10, *The PostMaster*.

UNIX

The following files should be included into the compilation/linking phase for UNIX is:

```
$telelogic/orca/omaccess/src/omaccess.cc
$telelogic/orca/omaccess/src/pmtool.cc
$telelogic/lib/<platform>lib/post.o
```

where `$telelogic` refers to the installation path, and `<platform>` can be one of `linux` or `sunos5`.

Two paths to the include files is also necessary:

```
-I$telelogic/orca/omaccess/include
-I$telelogic/include/post
```

Example 161: Compile `printclasses.cc` with g++ on Solaris ––––––––––––––––––

```
g++ -o printclasses -I$telelogic/orca/omaccess/include \
        -I$telelogic/include/post \
        printclasses.cc \
        $telelogic/orca/omaccess/src/omaccess.cc \
        $telelogic/orca/omaccess/src/pmtool.cc \
        $telelogic/lib/sunos5lib/post.o
```

––

If Solaris is used, the switches `-lgen -lsocket -lnsl` have to be added.

Example 162: Compile `printclasses.cc` with g++ on Solaris

```
g++ -o printclasses -I$telelogic/orca/omaccess/includes \
        -I$telelogic/include/post \
        printclasses.cc \
        $telelogic/orca/omaccess/src/omaccess.cc \
        $telelogic/orca/omaccess/src/pmtool.cc \
        $telelogic/lib/sunos5lib/post.o -lgen -lsocket -lnsl
```

The OM Access files could also be copied to a local directory to ease up compilation.

Windows

> **Note:**
>
> During runtime the DLL `post.dll` (located in a subdirectory to `<installation directory>\sdt\sdtdir\wini386\include`) must either be in the path or the directory the application is started from.

Microsoft Visual C++

Add the files `omaccess.cc, pmtool.cc` (can be found in `<installation directory>\orca\src`) and `post.lib` (can be found in `<installation directory>\sdt\sdtdir\wini386\include\msvc50)` to the project.

Add `<installation directory>\orca\includes` and `<installation directory>\include\post` to the include path.

Using OM Access Together with the SDL Suite

Applications written with OM Access can easily be called from within the OM Editor, for example from a menu (for more info about defining your own menus see *"Defining Menus in the SDL Suite" on page 18 in chapter 1, User Interface and Basic Operations*.

The following example adds a choice to generate C++ code skeleton of an OM Diagram from the OM Editor and pops up a text editor with the generated file in it.

Example 163: `ome-menus.ini` ----------

```
SDT-DYNAMICMENUS-3.6
[MENU]
Name=&OM Access
[MENUITEM]
ItemName=Generate C++
Separator=off
StatusbarText=Generate C++ code skeleton
ProprietaryKey=1
AttributeKey=0
Scope=Always
ConfirmText=You might want to change the name of the output file
ActionInterpretation=OS_COMMAND
BlockCommand=off
FormattedCommand=om2cpp %b `basename %b .som`.h
[MENUEND]
```

Reference

The reference contains two parts:

- Data Model: information about the data model used. For each class, a description is provided and then the members of the class are presented in a table.
- Functions: information about the functions in OM Access. For each function, the definition is shown followed by a description and a table of the parameters.

Data Model

The data model in OM Access is based on the UML Metamodel. For more information about the UML Metamodel, see the “UML Semantics” chapter of the “Unified Modeling Language, version 1.1” documentation. This document can be found at:
`http://www-306.ibm.com/software/rational/uml/`

If not mentioned otherwise, the members are of type `string`.

OMModule

An instance of the `OMModule` class contains information about an OM Diagram.

Member	Description
`classList`	A list of `Class`, containing all of the classes.
`generalizationList`	A list of `Generalization`, containing all of the generalizations.
`associationList`	A list of `AssocationClass`, containing all of the associations/aggregations.

Class

An instance of the `Class` class contains information about a class.

Member	Description
`name`	The class name as a string.
`attributeList`	A list of `Attribute`, each entry representing one attribute in the class.
`operationList`	A list of `Operation`, each entry representing one attribute in the class.

Operation

An instance of the `Operation` class contains information about an operation.

Member	Description
`visibility`	Visibility of operation.
`name`	Name of operation.
`returnType`	Return type of operation.
`parameterList`	List of `Parameter` containing information about the operations parameters.

Parameter

An instance of the `Parameter` class contains information about a parameter.

Member	Description
`name`	Name of the parameter.
`type`	Type of the parameter.

Attribute

An instance of the `Attribute` class contains information about an attribute.

Member	Description
`visibility`	Visibility of attribute.
`name`	Name of attribute.
`type`	Type of the attribute.
`value`	Default value.

Generalization

An instance of the `Generalization` class contains information about a generalization.

Member	Description
`subtype`	The name of the subtype, ‘subclass’ of the generalization.
`supertype`	The name of the supertype, ‘superclass’ of the generalization.
`discriminator`	The discriminator of the generalization.

AssociationClass

An instance of the `AssociationClass` class contains information about an association/aggregation. The connection between the different classes is maintained by `fromEnd` and `toEnd`.

Member	Description
`fromEnd`	An `AssociationEnd` representing one of the ends of the association.
`toEnd`	An `AssociationEnd` representing the other end of the association.

Member	Description
isAggregation	A boolean that is true if the association is an aggregation.
hasAssociationClass	A boolean that is true if the association also have an AssocationClass.

If the association also has an associationclass, the class-information is contained in the instance, inherited from Class.

AssociationEnd

An instance of the AssociationEnd class contains information about a connection to a class, for example in an association.

Member	Description
name	Name of this end.
rolename	Role name of association.
type	Name of the class connected to.
multiplicity	Multiplicity of association.
qualifier	Qualifier of association.
constraint	Constraint of association.
aggregation	Represents the type of the association.
isSorted	True if the association is sorted.
isOrdered	True if the association is ordered.

Functions

GetFile

```
bool GetFile(filename, omModule, status)
```

Description

Loads the contents of `filename` into `omModule`. Returns `true` on success, `false` if failed to load the module.

Parameters

Parameter	Type	Description
`filename`	`string`	The (absolute) name of the file containing the diagram.
`omModule`	`OMModule *`	A pointer to the OMModule where the diagrams data will be put.
`status`	`string *`	(optional) If loading failed a diagnostic message is inserted into this string.

GetBufID

```
bool GetBufID(bufID,omModule,status)
```

Description

Loads the contents of the buffer `bufID` into `omModule`. Returns `true` on success, `false` if failed to load the module.

Parameters

Parameter	Type	Description
`bufID`	`string`	The bufferID of the diagram.
`omModule`	`OMModule *`	A pointer to the OMModule where the diagrams data will be put.
`status`	`string *`	(optional) If loading failed a diagnostic message is inserted into this string.

GetSuperClassList

```
GetSuperClassList(omModule,className,superClasses)
```

Description

Fills the list `superClasses` with the names of the superclasses to `className` in `omModule`.

Parameters

Parameter	Type	Description
`omModule`	`OMModule &`	The OMModule containing the diagram information.
`className`	`string`	The name of the class whose superclasses are searched for.
`superClasses`	`list<string> *`	The list to put the name of the superclasses in.

GetSubClassList

```
GetSubClassList(omModule,className,superClasses)
```

Description

Fills the list `subClasses` with the names of the subclasses to `class-Name` in `omModule`.

Parameters

Parameter	Type	Description
`omModule`	`OMModule &`	The OMModule containing the diagram information.
`className`	`string`	The name of the class whose subclasses are searched for.
`subClasses`	`list<string> *`	The list to put the name of the subclasses in.

SourceAggregationEnd

```
string SourceAggregationEnd(association)
```

Description

Returns the name of the class which starts the aggregation (the end with the square in it), the owner-part. (The `source` contains the `end`.)

Parameters

Parameter	Type	Description
`association`	`AssociationClass`	The association to check.

TargetAggregationEnd

```
string TargetAggregationEnd(association)
```

Description

Returns the name of the class that ends the aggregation (the end without the square in it), the owned-part. (The `source` contains the `end`.)

Parameters

Parameter	Type	Description
`association`	`AssociationClass`	The association to check.

GetEndPoints

```
void GetEndPoints(association, classes)
```

Description

Fills the classes list with the names of the classes that this association/aggregation is connected to.

Parameters

Parameter	Type	Description
`association`	`AssociationClass`	The association to check.
`classes`	`list<string> *`	The list to insert the names into.

HasEndpoint

```
bool hasEndPoint(association, name)
```

Description

Returns true if `association` has an endpoint at `name`.

Parameters

Parameter	Type	Description
`association`	`AssociationClass`	The association to check.
`name`	`string`	The class to check.

GetAggregations

```
void GetAggregations(omModule,aggregations)
```

Description

Fills `aggregations` with all the aggregations in `omModule`.

Parameters

Parameter	Type	Description
`omModule`	`OMModule`	The OMModule containing the diagram information.
`aggregations`	`list<AssociationClass>`	The list to fill with aggregations.

GetAggregations

```
void GetAggregations(comModule,aggregations,owner)
```

Description

Fills `aggregations` with all the aggregations in `omModule`, that has `owner` as source.

Parameters

Parameter	Type	Description
`omModule`	`OMModule`	The OMModule containing the diagram information.
`aggregations`	`list<AssociationClass>`	The list to fill with aggregations.
`owner`	`string`	the name of the class that has to be the owner.

GetAssociations

```
void GetAssociations(omModule, associations)
```

Description

Fills `associations` with all the associations in `omModule`.

Parameters

Parameter	Type	Description
`omModule`	`OMModule`	The OMModule containing the diagram information.
`associations`	`list<AssociationClass>`	The list to fill with associations.

GetAssociations

```
void GetAssociations(omModule, associations,
                     firstEnd)
```

Description

Fills `associations` with all the associations in `omModule`, that is connected to `firstEnd`, in some end.

Parameters

Parameter	Type	Description
`omModule`	`OMModule`	The OMModule containing the diagram information.
`associations`	`list<AssociationClass>`	The list to fill with associations.
`firstEnd`	`string`	The name of one of the classes that the association has to be connected to.

GetAssociations

```
void GetAssociations(omModule,associations,
                     firstEnd,secondEnd)
```

Description

Fills `associations` with all the associations in `omModule`, that is connected to `firstEnd`, and `secondEnd`.

Parameters

Parameter	Type	Description
`omModule`	`OMModule`	The OMModule containing the diagram information.
`associations`	`list<AssociationClass>`	The list to fill with aggregations.

Parameter	Type	Description
firstEnd	string	The name of one of the classes that the association has to be connected to.
secondEnd	string	The name of the second class that the association has to be connected to.

TraceModule

```
void TraceModule(omModule,os)
```

Description

Outputs a textual dump of `omModule` to `os`, with as much information as possible, useful for debugging purposes.

Parameters

Parameter	Type	Description
omModule	OMModule	The OMModule containing the diagram information.
os	ostream	The stream to output the dump to.

Chapter

20

Basic Compiling Theory

This chapter gives the ground basis for basic compiling theory. It will give an introduction to compiling theory as it is the corner-stone on which TTCN Access is built upon. See chapter 21, *TTCN Access*.

This chapter is intended to be read by developers of executable test suites, translator developers and test result analyzers.

Basic Compiling Theory

A programming language can be defined by describing what its programs look like (the *syntax* of the language) and what its programs mean (the *semantics* of the language).

For specifying the syntax of a language, such as TTCN, the widely used notation called *context-free grammar*, or BNF (Backus-Naur Form) is used. (A more precise definition of context-free grammar will be defined in "Syntax Definition" on page 944).

To describe the semantics of a language is more difficult, as no appropriate notation for semantic description is available. Consequently, when specifying the semantics of a language an informal description technique has to be used. TTCN uses *Semantic actions* that, in natural language, describes the actual semantic given a specific context.

Besides specifying the syntax of a language, a context-free grammar can be used to help guide the translation of a programs. A grammar oriented compiling technique, known as syntax-directed translation, is very helpful for organizing a compiler front end.

The Compiler

Conceptually, a compiler operates in phases, each of which transforms the source program from one representation to another. Often, some of the phases may be grouped together and the intermediate representation between the grouped phases need not be explicitly constructed.

The first three phases of a compiler, forming the bulk of the analysis portion is often called *front end*. The front end consist of those phases that depend primarily on the source language and are largely independent of the target language. This front end normally includes lexical and syntactic analysis, the creation of the symbol table, semantic analysis and the generation of intermediate code.

The last phases of a compiler, the *back end*, include those portions of a compiler that depend on the target language. In the back end, one will find code optimization, code generation along with the necessary error handling and symbol-table operation.

This chapter will discuss and explain the concept of the front end thoroughly. The back end will be mentioned just for completeness. The reason for this is quite obvious:

TTCN Access is the front end to a TTCN compiler.

Lexical Analyzer

The lexical analyze is the first phase of a compiler. Its main task is to read input characters and produce as output a sequence of tokens that the parser uses for the next phase, the *syntax* analysis.

Since the lexical analyzer is the part of a compiler that reads the source text, it may also perform certain secondary tasks at the user interface. One such task is stripping out comments and white space in the form of blank, tab, and newline character. Another is correlating error messages from the compiler with the source program. For example, the lexical analyzer may keep track of the number of newline characters seen, so that a line number can be associated with an error message.

In lexical analysis the stream of characters making up the program is read from left-to-right and grouped into tokens that are sequences of characters having a collective meaning.

Example 164 ––

For example, the characters in the assignment statement below:

```
position := initial + rate * 60
```

would be grouped into the following tokens:

1. The identifier `position`
2. The assignment symbol `:=`
3. The identifier `initial`
4. The plus sign
5. The identifier `rate`
6. The multiplicand sign
7. The number `60`

––

The blanks separating the characters of these tokens would normally be eliminated during lexical analysis.

Syntax Definition

In this section, a notation called a *context-free* grammar (grammar for short) is introduced. This notation is used for specifying the syntax of a language.

A grammar naturally describes the hierarchical structure of many programming language constructs. For example, an if-else statement in C has the form as below.

```
if ( expression ) statement else statement
```

That is, the statement is the concatenation of the keyword *if*, an opening parenthesis, an expression, a closing parenthesis, a statement, the keyword *else*, and another statement. Using the variables *expr* to denote an expression and the variables `stmt`, `stmt1` and `stmt2` to denote three (possible different) statements, this structuring rules can be expressed as

```
stmt -> if ( expr ) stmt1 else stmt2
```

in which the arrow may be read as “can have the form”. Such a rule is called a *production*. In a production lexical elements like the keyword **if** and the parentheses are called *tokens*. Variables like `expr` and `stmt2` represent sequence of tokens and are called *nonterminals*.

A *context-free grammar* has four components:

- A set of tokens, known as *terminal* symbols.
- A set of nonterminals.
- A set of productions where each production consists of a nonterminal, called the *left side* of the production, an arrow, and a sequence of tokens and/or nonterminals, called the *right side* of the production.
- A destination of one of the nonterminals as the *start* symbol.

Through this chapter, examples and pictures will be present in order to clarify a topic or explain a specific concept. As TTCN, at this stage, has a too large grammar definition to be included in this document, a language called SMALL is defined that in this chapter will be used for examples and discussions.

SMALL will be defined as a language only consisting of digits and the plus and minus signs, e.g., 9-5+2, 3-1 and 7. In the language SMALL, a plus or minus sign must appear between two digits, and expressions

as above will be referred to as “lists of digits separated by plus or minus sign”.

The following grammar specifies the syntax of this language with *list* as its start symbol:

```
1:list -> list + digit
2:list -> list - digit
3:list -> digit
4:digit -> 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9
```

From production (3), a single digit by itself is a *list*. Productions (1) and (2) express the fact that if one take any *list* and follow it by a plus or a minus sign and then another digit one has a new *list*. For example, it is possible to deduce that 9-5+2 is a list as follows:

a) 9 is a list by production (3), since 9 is a digit.

b) 9-5 is a list by production (2), since 9 is a list and 5 is a digit.

c) 9-5+2 is a list by production (1), since 9-5 is a list and 2 is a digit.

This reasoning is illustrated by the tree in the next figure. Each node in the tree is labelled by a grammar symbol. An interior node and its children correspond to a production; the interior node corresponds to the left side of the production, the children to the right side. Such trees are called *parse trees* and are discussed in the next chapter.

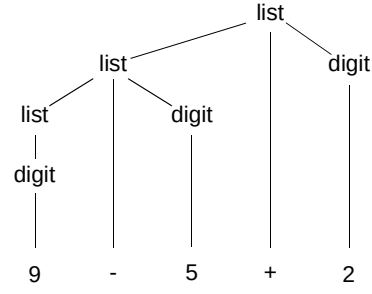

Figure 173: A parse tree for 9-5+2

Syntax Analyzer

Every programming language has rules that prescribe the syntactic structure of well-formed programs. In Pascal, for example, a program is made out of blocks, a block out of statement, a statement out of expressions, an expression out of tokens, and so on. The syntax of programming language constructs can be described by context-free grammars or BNF notation. Grammars offer significant advantages to both language designers and compiler writes:

- A grammar gives a precise, yet easy-to-understand, syntactic specification of a programming language.
- From certain classes of grammars it is possible to automatically construct an efficient parser that determines if a source program is syntactically well formed.
- A properly designed grammar imparts a structure to a programming language that is useful for translation of source programs into correct object code and for the detection of errors.
- Languages evolve over a period of time, acquiring new constructs and performing additional task. These new constructs can be added to a language more easily when there is an existing implementation based on a grammatical description of the language.

During syntax analysis the tokens of the source program are grouped into grammatical phrases that are used by a compiler to synthesis the output. Usually, the grammatical phrase of the source program is represented by a *parse tree*.

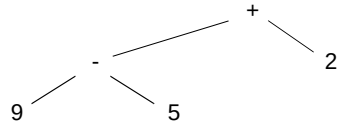

Figure 174: A syntax tree for the assign statement 9-5+2

Parse Trees

A parse tree pictorially shows how the start symbol of a grammar derives a string in the language. If nonterminal A has a production as:

```
A -> X Y Z
```

then a parse tree may have an interior node labelled A with three children labelled X, Y and Z, from left to right:

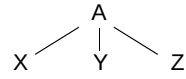

Figure 175: Parse tree

Formally, given a context-free grammar, a *parse tree* is a tree with the following properties:

1. The root is labelled by the start symbol.
2. Each leaf is labelled by a token or empty.
3. Each interior node is labelled by a nonterminal.
4. If A is the nonterminal labelling some interior node, and X1, X2, ..., Xn (where Xi are terminals or nonterminals) are the labels of the children of that node, then
   `A -> X1 X2 ..., Xn`
   is a production in the grammar.

The leaves of a parse tree read from left to right form the yield of the parse tree, which is the string *generated* or *derived* from the nonterminal at the root of the parse tree. Any tree imparts a natural left-to-right order to its leaves, based on the idea that if *a* and *b* are two children with the same parent, and *a* is to the left of *b*, then all descendants of *a* are to the left of descendants of *b*.

Another definition of a language generated by a grammar is as the set of strings that can be generated by some parse tree. The process of finding a parse tree for a given string of tokens is called *parsing* that string.

Parsing

Parsing is the process of determining if a string of tokens can be generated by a grammar. In discussing this topic, it is helpful to think of a parse tree being constructed, even though a compiler may not actually construct such a tree. However, a parser must be capable of constructing the tree, or else the translation cannot be guaranteed correct.

Intermediate Code

After syntax and semantic analysis, some compilers generate an explicit intermediate representation of the source program. This intermediate representation can be seen as a program for an abstract machine. In the context of the TTCN Suite and TTCN Access, the intermediate representation is the actual parse tree generated by the Analyzer. For more information see chapter 26, *Analyzing TTCN Documents (on UNIX)* and chapter 31, *Analyzing TTCN Documents (in Windows)*.

Code Generator

The final phase of a compiler is the generation of target code, that is transforming the intermediate code into something useful such as an executable. As TTCN Access is an application programmers interface towards the intermediate representation, the parse tree, it is the TTCN Access application that will define the actual transformation of the intermediate code. It can be an executable as well as a reporter, interpreter, etc.

The Phases of a Compiler

Conceptually, a compiler operates in phases, each of which transforms the source program from one representation to another. A typical decomposition of a compiler is shown in the next picture. In practice, some of the phases may be grouped together and the intermediate representation between the grouped phases need not be explicitly constructed.

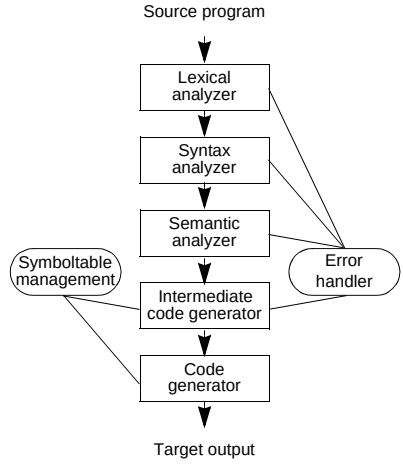

Figure 176: The phases of a compiler

The first three phases, forming the bulk of the analysis portion of a compiler has previously been discussed. Two other activities, symbol-table management and error handling, are shown interacting with the five phases of lexical analysis, syntax analysis, semantic analysis, intermediate code generation and code generation. Informally, the symbol-table management and the error handler are also called *phases*.

Symbol Table Management

An essential function of a compiler is to record the identifiers used in the source program and collect information about various attributes of each identifier. These attributes may provide information about the identifier as its type, its scope (where in the source program it is valid) and, in the case of procedure names, such things as the number and type of its arguments, the method for passing each argument (e.g., by reference), and the type returned, if any.

A *symbol table* is a data structure containing a record for each identifier, with fields for the attributes of the identifier. The data structure allows us to find the record for a specific identifier quickly and to store or retrieve data from that record.

When an identifier in the source program is detected by the lexical analysis, the identifier is entered into the symbol table. However, the attributes of an identifier cannot normally be determined during lexical analysis. The remaining phases enter information about identifiers into the symbol table and then use this information in various ways. For example, when doing semantic analysis, the compiler needs to know what types the identifiers have, so it can be checked that the source program uses them in a valid way.

Error Detection and Reporting

Each phase can encounter errors. However, after detecting an error, a phase must somehow deal with that error, so that compilation can proceed, allowing further errors in the source program to be detected.

The syntax and semantic analysis phase usually handle a large fraction of the errors detectable by the compiler. The lexical phase can detect errors where the characters remaining in the input do not form any token of the language. During semantic analysis the compiler tries to detect constructs that have the right syntactic structure but no meaning to the operations involved, e.g., when adding two identifiers, one of which is the name of an array and the other is a name of a procedure.

Chapter

21 *TTCN Access*

This chapter describes TTCN Access. It is intended to be read by developers of executable test suites, translator developers and test result analyzers. It requires some basic programming knowledge in C++ as TTCN Access is a C++ programming tool.

Introduction to TTCN Access

A TTCN test suite can be looked upon as a formal description of a collection of test sequences where each test sequence involves signals and values. The abstract test suite contains formal definitions of these signals and values as well as a structural description of each test sequence. A common formal notation used to describe these test sequences, as well as all the other items in an abstract test suite, is TTCN.

TTCN Access is a C++ application programmers interface towards an arbitrary abstract test suite written in TTCN and incorporated in the TTCN Suite. TTCN Access reveals the content of the test suite in a high level abstraction and allows various users to access the content in a read-only manner.

TTCN Access is a platform for writing applications related to an abstract test suite such as:

- Executable test suites
- Interpreters
- Encoders and decoders
- Analyzers
- Reporters

By using TTCN Access, a variety of applications can be implemented that will ease the maintenance of abstract test suites and the development of executable test suites. TTCN Access is an easy-to-use application programmers interface that provides the required functionality for applications in these areas.

Terms Used in This Document:

- ISO/IEC 9646-3 : 1991 is called *the TTCN standard*.
- ISO/IEC 8824 : 1990 is called *the ASN.1 standard*.
- Backus-Naur Format is called *BNF*.

General Concepts

The easiest, and simplest way of describing TTCN Access would be to state that TTCN Access is a TTCN compiler. Unfortunately this statement is not fully true and also somewhat misleading as it might, conceptually, bring the reader (and TTCN Access users) towards the domain of executable test suites and thereby not reveal all the other possibilities that TTCN Access brings. A more correct statement would thereby be

that TTCN Access is a half compiler, more precisely the first phase of a compiler, often called the *front-end*. For a general explanation of compiler theory and compiler front-ends, see chapter 20, *Basic Compiling Theory*. The fact is that the TTCN to C compiler is built on top of TTCN Access.

TTCN Access and the TTCN Analyzer

All the components and definitions mentioned in chapter 20, *Basic Compiling Theory*, together build up the basics for compiling theory. As mentioned, TTCN Access is a C++ application programmers interface towards a test suite written in TTCN. It reveals the content of the test suite in a high level abstraction and allows various users to access the content in a read-only manner.

This section will once again mention these components, but this time put them in the context of the TTCN Suite and the functionality that it provides, thereby explaining the relationship between the TTCN Suite and TTCN Access.

Lexical Analysis

The lexical analysis in the TTCN Suite is done in two phases, depending on the format of the abstract test suite.

- If the source code is in MP format, a basic lexical analysis is done at the import stage, verifying that the imported test suite is written in correct MP format. A full lexical analysis is done when using the Analyzer. The complete lexical analysis is the first phase in the analysis.

  For more information see "Importing a TTCN-MP Document" on page 1157 in chapter 24, *The TTCN Browser (on UNIX)*.

- If the source code is written directly into the TTCN Suite via one of the editors, a lexical analysis is done by using the Analyzer as mentioned above.

  For more information see chapter 26, *Analyzing TTCN Documents (on UNIX)* and chapter 31, *Analyzing TTCN Documents (in Windows)*.

Syntax Analysis

The syntax analysis is done when executing the Analyzer and it is done in the second phase. This second phase also contains a semantic analysis of the test suite, all in order to verify that the test suite complies with the standardized notations for TTCN and ASN.1.

Parse Tree

The last phase of the analysis is to generate a parse tree. This can only be done if the lexical and syntax analysis have been successfully completed.

Symbol Table Management

During execution of an TTCN Access application the symbol table is accessible at any time.

Example of TTCN Access Functionality

As TTCN Access looks upon a test suite as a parse tree, it provides the required primitives and functionality for parse tree handling. This includes parse tree traversing and hooks into the parse tree as well as templates for main() and several examples in source code format. The best way to visualize the functionality of TTCN Access is by using an example:

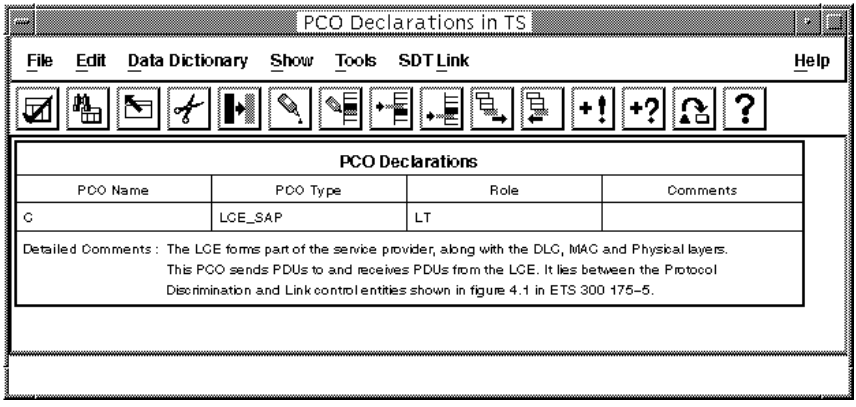

Figure 177: The PCO Declarations table

The PCO Declarations table, containing just one PCO declaration will generate the parse tree visualized below:

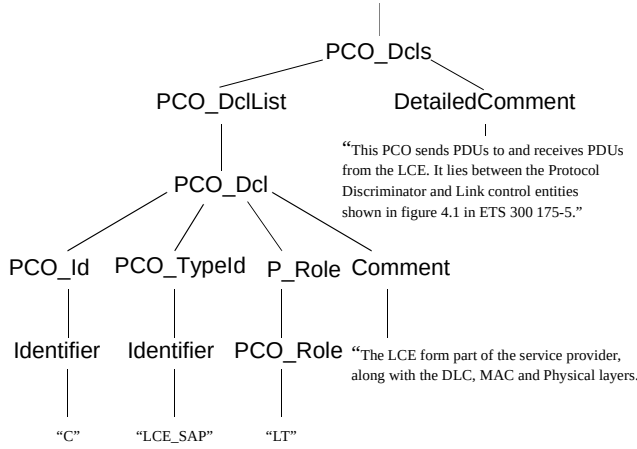

Figure 178: Parse tree

Traversing

The basics of parse tree functionality has to include traversing primitives. TTCN Access therefore provides a special *visitor* class with a *default traverser* that, given any node in the parse tree, traverses that parse tree in a *Left-Right-Depth-First* manner. In the parse tree previously described, the default traversing order for the sub tree *PCO_Dcl* will be:

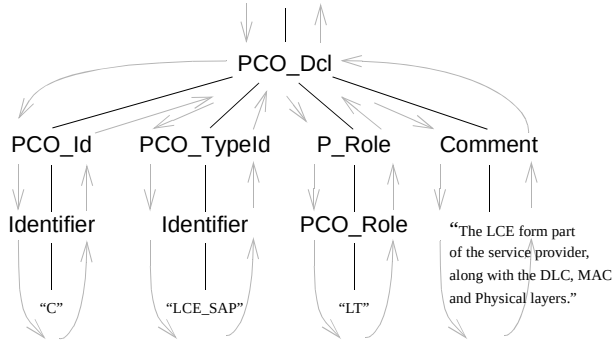

Figure 179: Default traversing tree

This default translating algorithm may be *customized* in order to fit any user specific traversing order. For the above example, a customized traverser could be implemented as traversing sub tree *PCO_TypeId* before sub tree *PCO_Id* and ignoring sub tree *Comment*.

Translating

The second most important functionality when discussing parse trees, is the possibility to access specific nodes in the parse tree in order to generate side effects, such as executing external code, print parse tree information, etc. By being able to modify the default traverser, TTCN Access provides the user with the possibility of defining such side effects.

Example of TTCN Access Usability

To visualize the strength of TTCN Access, this section will discuss a small TTCN Access application. The example is a generic encoder.

The Encoder

Transforming an abstract test suite into an executable test suite will eventually involve the problem of representing the actual ASP and PDU signals as bit patterns. The step from abstract syntax (TTCN) to transfer syntax (bit patterns) has to be provided and implemented by someone with vast knowledge of the actual protocol as well as the test system and the test environment.

The encoder described in this small example will assume the following:

- Elements of the same type are encoded identically.
- Encoding an ASP or PDU is performed by encoding its components recursively.

These assumptions tell us that encoding functions are data driven and that the encoding function has to be derived from the type definitions. It also tells us that the encoding of base types, that is INTEGER, BOOLEAN, etc., are identical.

Before looking at the algorithm for the generic encoder, let us have a look at a specific type and how the corresponding encoding function may be implemented. The type will be a small PDU as below:

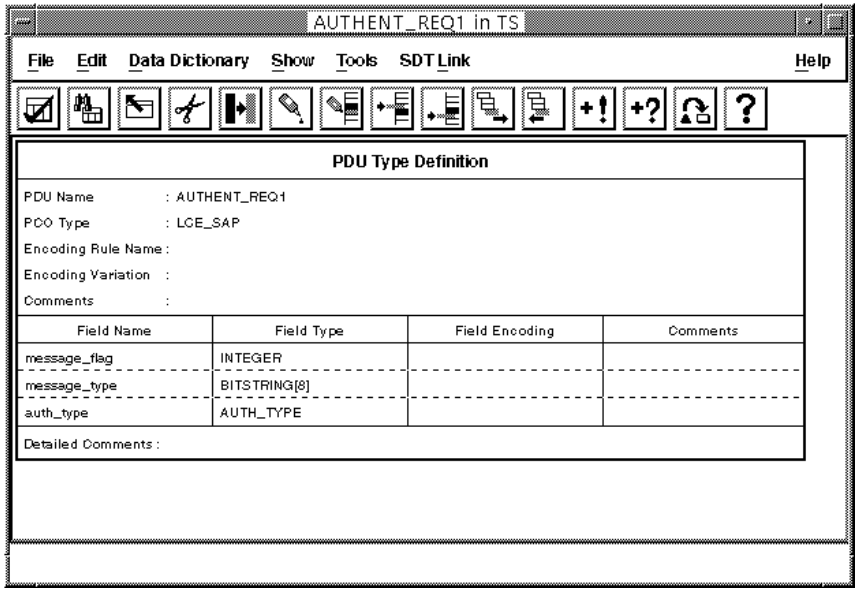

Figure 180: TTCN PDU type definition

The corresponding encoding function may look like:

```
void AUTHENT_REQ1_encode( AUTHENT_REQ1* me, char* enc_buf )
{
  INTEGER_encode( &me->message_flag, enc_buf );
  BITSTRING_encode( &me->message_type, enc_buf );
  AUTH_TYPE_encode( &me->auth_type, enc_buf );
}
```

It is a data driven encoding function that given any element of type `AUTHENT_REQ1` will encode them all identical. The first argument is a pointer to the element that shall be encoded, the second argument is the buffer where the result of the encoding shall be stored.

The function may of course contain more code and more information, but for this example, the above is the smallest encoder function needed.

The following example will give an algorithm for how the encode functions may be generated via TTCN Access. The algorithm is followed by a small TTCN Access application generating the actual encoder.

```
FUNCTION GenerateEncoder( type : typedefinition )
BEGIN
/* Generate encoder function header such as: */
/* void type_encode( type* me, char* enc_buf ) */
/* { */
FOR( "every element in the structured type" )
/* Generate a call to the element type encoder
/* function
/* such as: */
/* element_type_encode( &type->element, enc_buf );
END
/* Generate encoder function footer such as: */
/* } */
END
```

The above algorithm will generate generic encoders for any type. Of course, header files and base type encoder functions must be provided/generated as well. Below is a nearly complete TTCN Access application that generates encoders for any TTCN PDU type definition. Observe how the visitor class is customized to traverse and generate side effects for the specific parts we are interested in.

```
// Start by customizing the default visitor class

class Trav : public AccessVisitor
{
public:
  void VisitTTCN_PDU_TypeDef( const TTCN_PDU_TypeDef& Me );
  void VisitPDU_FieldDcl( const PDU_FieldDcl& Me );
};

void Trav::VisitTTCN_PDU_TypeDef( const TTCN_PDU_TypeDef& Me )
{
  // Generate the header part

  cout << Me.pdu_Identifier( ) << "_encode( const ";
  cout << Me.pdu_Identifier( ) << "& me, char* enc_buf )";
  cout << "\n{" << endl;

  // Traverse fields using default traverser

  AccessVisitor::VisitPDU_FieldDcls( Me.pdu_FieldDcls( ) );

  // Generate the footer part

  cout << "}" << endl;
}

void Trav::VisitPDU_FieldDcl( const PDU_FieldDcl& Me )
{
  Astring type = get_type( Me.pdu_FieldType( ) );
  Astring name = get_name( Me.pdu_FieldId( ) );

  cout << "void " << type << "_encode( me->"
       << name << "( ), enc_buf );" << endl;
}
```

All that remains now is a main function for the generic encode generator.

```
#include     <stdio.h>
#include     <iostream.h>
#include     <time.h>
#include     <ITEXAccessClasses.hh>
#include     <ITEXAccessVisitor.hh>

class Trav : public AccessVisitor
{
public:
  void VisitTTCN_PDU_TypeDef( const TTCN_PDU_TypeDef& Me );
  void VisitPDU_FieldDcl( const PDU_FieldDcl& Me );
};

int main( int argc, char **argv )
{
  //The actual suite

  AccessSuite suite;

  if ( argc != 2 )
    {
      fprintf( stderr, "usage: %s suitename\n", argv[ 0 ] );
      return 0;
    }

  /* Open the suite and go for it! */

  if ( suite.open( argv[ 1 ] ) )
    {
      Trav trav;

      trav.Visit( suite );
      suite.close( );
    }
}
```

The `get_type` and `get_name` functions can be simple or complex. See the example below:

```
Astring get_type( const PDU_FieldType& Me )
{
  TypeAndAttributes ta = Me.typeAndAttributes( );
  switch ( ta.choice( ) )
    {
    case Choices::c_TypeAndLengthAttribute:
      return get_type( ta.typeAndLengthAttribute( ) );
    default:
      cerr << "ERROR: Type not supported: "
           << Me.content( ) << endl;
      return "***#***";
    }
}

Astring get_type( const TypeAndLengthAttribute& Me )
{
  const TTCN_Type tt = Me.ttcn_Type( );

  switch ( tt.choice( ) )
    {
```

```
    case Choices::c_PredefinedType:
      if ( tt.predefinedType( ).choice( ) ==
           Choices::c_INTEGER )
        return "INTEGER";
      break;
    case Choices::c_ReferenceType:
      return tt.referenceType( ).identifier( );
    default:
      break;
    }
  cerr << "ERROR: Type not supported: "
       << Me.content( ) << endl;
  return "***#***";
}

Astring get_name( const PDU_FieldId& Me )
{
  const PDU_FieldIdOrMacro pfid = Me.pdu_FieldIdOrMacro( );
  if ( pfid.choice( ) != Choices::c_PDU_FieldIdAndFullId )
    {
      cerr << "ERROR: Slot name not supported: "
           << Me.content( ) << endl;
      return "***#***";
    }

  return pfid->pdu_FieldIdAndFullId( ).pdu_FieldIdentifier( );
}
```

TTCN Access in Relation to TTCN and ASN.1

TTCN Access is created for the purpose of accessing and traversing the contents of a TTCN test suite. As a basis for the development of TTCN Access, the TTCN-MP syntax productions in BNF [ISO/IEC 9646-3, appendix A] together with the ASN.1 standard [ISO/IEC 8824] have been used.

Differences

Every node in TTCN Access reflects a rule in the BNF. However there are some small differences between the BNF and TTCN Access:

The Present Nodes

The intention is to map the ASN.1 and TTCN standards as good as possible. In a perfect world this would mean that no extra nodes could be found in TTCN Access and that each rule in the standards would have exactly one corresponding node in TTCN Access. Some differences between the perfect world and our world are listed in detail below. Differences exist due to redundancies in the standardized grammar or design decisions made during the development of TTCN Access. The goal of any implementation of TTCN Access is to make as few changes compared to the perfect world as possible. However, some extra nodes have been added to TTCN Access, and in a few places the exact calling order of the pre/post functions has been altered to what we feel is a more straight forward approach for executable languages.

The SEQUENCE OF

The TTCN and ASN.1 notations at times allow for arbitrary many nodes to be grouped in lists of nodes or sequences of nodes. For example there is the SubTypeValueSetList rule of the ASN.1 standard and there is the AssignmentList rule of the TTCN standard. In both BNF notations a difference is made between lists that are allowed to be empty and those which must contain at least one element, corresponding to the {} and {}+ notation in the TTCN standard.

In TTCN Access no difference is made between the two forms of lists, since a well defined and simple access method is of prime interest. All lists are allowed to be empty, and it is the work of the Analyzer to ensure

non-empty lists where appropriate. In the ASN.1 standard the non-empty lists are sometimes written by re-grouping already existing rules. This re-grouped structure will not be represented in TTCN Access. The decision does not alter the number of nodes or the names of nodes, but merely the visiting order when traversing the nodes, i.e. SubTypeValueSetList before SubTypeValueSet.

Example 165 ----------

ASN.1 rule SubTypeSpec:

```
SubTypeSpec ::= ( SubTypeValueSet SubTypeValueSetList )
```

becomes:

```
SubTypeSpec ::= ( SubTypeValueSetList )
```

In the TTCN standard there are nodes which contain an implicit grouping.

Example 166 ----------

TTCN BNF rule:

```
TestStepLibrary ::= ({TestStepGroup | TestStep})
```

becomes:

```
TS_ConstDcls ::= {TS_ConstDcl}+ [Comment].
```

Furthermore there are nodes that contain groupings without the list postfix name convention.

Example 167 ----------

TTCN BNF rule:

```
TimerOps ::= TimerOp {Comma TimerOp}.
```

Whenever necessary, a grouping or/and choice node will be inserted between rules in the TTCN standard. When nodes are created without corresponding node in any of the standards, the nodes will be named according to the convention used in the ASN.1 standard, i.e. these nodes will have postfix “List”. Nodes which are a grouping but do not follow the naming convention will be left as they are.

OPTIONAL

In the BNF rules for TTCN-MP, the use of `[ abc ]` implies zero or one instance of `abc`. In the definition of TTCN Access the same effect is achieved by the use of the symbol “OPTIONAL” after the TTCN Access definition. If a TTCN Access element defined as “OPTIONAL” is not present in a specific instance, no TTCN Access representation for that specific field will be available. To detect whether or not a TTCN Access node defined as “OPTIONAL” is present or not, a boolean TTCN Access function will be necessary to apply to that TTCN Access node in order to verify the presence/absence of the parse tree related to the specific slotname.

FIELD

A difference between TTCN Access and the BNF rules is that TTCN Access views every BNF production reflecting a field in the TTCN-GR format to be optional even though the field is not defined as such in the BNF. The reason for this is that no TTCN Access tree can be built for a field unless a successful analysis has been performed on that field. If the analysis failed, the field will not carry any TTCN Access information and the field may not be accessed.

In TTCN Access all fields are marked with the symbol “FIELD”. This “FIELD” symbol implies that the field may be empty. The field may be empty even though the field is not defined as optional in the BNF. To detect whether or not a field is present or not present, a boolean TTCN Access function will be necessary to apply to that TTCN Access node in order to verify the presence/absence of the parse tree related to the specific field. This extension is applicable to all fields except if a field is implemented in TTCN Access as a node of type TERMINAL. All TERMINAL types are strings and TTCN Access sees the absence of a TERMINAL as an empty string.

The Value Notation

The Common Value Notation

The value notations of the two standards must be unified. Some values are clearly within one standard only (SetValue for instance), while others are in both standards (7 for instance). Those values that have the same syntax in both standards are considered to belong to the TTCN standard. Note that the ASN.1 standard might specify some other chain

of productions to reach such a value and that this chain of productions is not represented in TTCN Access.

The Expression Tree

The expression rule has been re-written since it is undesirable to have the flat representation from the standard. Instead a normal tree oriented representation of an expression is used. This means that the rules making up an expression are heavily changed.

The Base Nodes

Base nodes are the representation of the terminals in the TTCN Access tree. They can in most aspects be treated as strings, they can be printed directly for example. The base nodes are:

- Identifier
  Has an associated type
- Number
- All nodes having a single child of type BoundedFreeText (FullIdentifier or SO_SelExprId for example).
- Ostring, Cstring, Bstring and Hstring

Note:

The Keyword class in ITEX Access 1.0 does not exist in ITEX Access 2.0. Neither of the standards has the notion of a keyword class/rule, and therefore there is no node/class named Keyword in ITEX Access 2.0. It has been replaced with ITEX Access node TERMINAL.

Tree Traversing in the Dynamic Part

An extension to the BNF adds the possibility to access the content of test cases, test steps and defaults, by using the logical tree structure of the test. This is achieved by adding a slot in the node type definition BehaviourLine named “children”. By accessing that slot an TTCN Access object is returned that holds a vector of children to the current statement line. A child is a BehaviourLine with a level of indentation one greater that the preceding BehaviourLine.

Naming Conventions

As a basis for naming TTCN Access nodes, the names in the BNF for TTCN and ASN.1 have been used. There are some differences though, and they will be discussed and explained in this subsection.

- No slot name, type name or type definition contains the symbol “&” as it is a reserved symbol in C++. It is replaced with “and” or “And” where appropriate.
- All type definitions start with an upper case letter (and are written in bold).
- All slot names start with a lower case letter.
- All type names start with an upper case letter.

The TTCN Access Notation

The notation used to describe a node in TTCN Access is described as below (a simple BNF for an example node):

```
Node           ::= TypeReference Assign TypeAssignment
TypeReference  ::= Identifier
             --has to start with an upper case letter
Assign         ::= "::="
TypeAssignment ::= ClassType ClassBody | "TERMINAL"
ClassType      ::= "SEQUENCE" | "SEQUENCE OF" |
"CHOICE"
ClassBody      ::= "{" { Slot }+ "}"
Slot           ::= SlotName TypeReference
                   [ "OPTIONAL" | "FIELD"]
SlotName       ::= Identifier
              --has to start with a lower case letter
```

Example 168 ——————————————————————————————

```
StructTypeDef ::= SEQUENCE {
    structId          FullIdentifier  FIELD
    comment           Comment         FIELD
    elemDcls          ElemDcls
    detailedComment   DetailedComment FIELD
}
```

——

- A TTCN Access node type is defined in **Bold** starting with an upper case letter.
- A node can be of type SEQUENCE, SEQUENCE OF or CHOICE. A SEQUENCE contains an ordered collection of elements, a SE-

QUENCE OF a vector of elements (possibly empty) and a CHOICE is a collection of possible elements.

- Each slot in a *TypeAssignment* starts with a *SlotName* followed by a *SlotType*. Each *SlotType* has a corresponding node in TTCN Access.
- The *SlotType* can be followed by a `FIELD` symbol meaning that the slot is associated with a field in the TTCN-GR format.
- The *SlotType* can be followed by a `OPTIONAL` symbol meaning that the slot can be absent.
- Each slot is followed by a page reference to the node corresponding to the *SlotType*. This page reference is not a part of the Abstract Data Structure.

For more information see chapter 23, *The TTCN Access Class Reference Manual*.

TTCN Access Primitives

Each node in TTCN Access is translated to a C++ class definition. Each instance of a specific C++ class definition contains one or more elements as defined in the specific C++ class definition. For each type definition there are a collection of TTCN Access functions.

In this chapter names written in *italic* are referred to as meta names. Words written in `courier` are taken from the definition of TTCN Access.

> **Note:**
>
> For further details see the TTCN Access include file `access.hh`.

General TTCN Access Functions Description

- For every node definition with assignment of type SEQUENCE or SEQUENCE OF there exists a general method

  SlotType TypeReference.SlotName()

  that returns an object of type *SlotType*. This type is the type of the corresponding slot in TTCN Access.

  Example 169 ––

  ```
  Attach MyRepeat.attach()
  ```

  where MyRepeat is of type Repeat and the return value is of type Attach.

  ––

- For every *TypeAssignment* of type CHOICE there is a general method

  Choices::choice TypeReference.choice()

  that returns the allowed SlotName type for current object. It is then possible to use the general method

  SlotType TypeReference.SlotName()

  that returns an object of type SlotType.

  Example 170 ––

```
switch ( MyEvent.choice() ) {
        case Choice::c_send:
                do_something( Me.send() );
                break;
        case Choice::c_receive:
                do_something( Me.receive() );
                break;
        case Choice::c_otherwise:
                do_something( Me.otherwise() );
                break;
        case Choice::c_timeout:
                do_something( Me.timeout() );
                break;
        case Choice::c_done:
                do_something( Me.done() );
                break;
        default:
                do_something_default();
                break;
}
```

––

- For every node of type SEQUENCE OF there is a general method

  SlotTypeList TypeReference.SlotName()
  that returns an object of type *SlotTypeList* which is a vector of elements of type *SlotType*.

  Example 171 ----------

  Assume that MyEvent.choice() in the previous example returned the value Choice::c_done. Then, TTCN Access method MyEvent.done().tcompIdList will then be a valid method and return an object of type TCompIdList.

- Every object of type *SlotTypeList* has a method

  int *Object*.nr_of_items()
  that returns the number of elements in the vector. The elements can be accessed with the method

  SlotType Object[index]
  where *Object* is an element of type *SlotTypeList* and index starts with 0 for the first element. It returns an element of type *SlotType.*

  Example 172 ----------

  According to the above example the method MyTCompIdList.nr_of_items() returns an integer value of the number if items in the vector object MyTCompIdList and MyTCompIdList[2] will return the third element in the vector.

- For slots with ending OPTIONAL or FIELD there is a general method

  Boolean *TypeReference*.is_present_*SlotName*()
  used for verifying if an object is present or not. It is the responsibility of the TTCN Access programmer to ensure that all calls to optional slots are preceded with a call to the is_present method of that slot. It is a fatal error to attempt to access a non-present optional slot.

- For slots with ending `FIELD` and slots residing in a sub tree to a field there is a general method

  `Astring` *`Node`*`.content()`

  that returns an object of type `Astring` holding the content of the current field in a vector of characters.

Example 173 ––

The following C++ code will print out the content of a behavior line:

```
BehaviourLine BLine = MyLine;

  cout << BLine.line( ).content() << endl;
```

––

Terminal Nodes in TTCN Access

Every TTCN Access node that represents a leaf in the parse tree is considered to be a *terminal* TTCN Access node. A terminal TTCN Access node is a node that does not have any TTCN Access child nodes and can therefore not be accessed any further.

Terminal TTCN Access children are nodes containing identifiers, strings, keywords as well as numbers (i.e. TTCN Access nodes of type `Identifier`, `IA5String`, `INTEGER`, `NUMBER`, etc.). However, the content of such terminal nodes can be accessed through the methods supplied by the inherited class `Astring`.

TTCN Access Class Astring

Every terminal TTCN Access node carries information in string format. In order to access that information, every terminal TTCN Access node inherits a class named `Astring`. This class contains various methods for treating string information.

For terminal TTCN Access nodes, the following operations are available:

- Initialization operations

Example 174 ----------

The following C++ code will create and initiate a variable of type `Astring`:

```
Astring tmp1;              // tmp1 is empty
Astring tmp2( "test1" );   // tmp2 contains "test1"
Astring tmp3 = "test2";    // tmp3 contains "test2"
Astring tmp4 = tmp2;       // tmp4 contains "test1"
```

- Relational operations

Example 175 ----------

The following relational operations are available between Astring elements:

```
==, !=
```

- `Astring` objects are type cast equivalent with `const char*`

Example 176 ----------

The following code is valid C++ code:

```
Astring myString( "test" );

cout << myString;
printf( "%s", ( const char* ) myString );
```

- Address the nth character in the string, starting with 0.

Example 177 ----------

The following is valid C++ code:

```
char c = myString[ 2 ]; // save the third character
of the string
```

Note:

For further details see class `Astring` in TTCN Access include file `ITEXAccessClasses.hh`.

Direct Access

AccessSuite

The `AccessSuite` object is the TTCN Access representation of a TTCN test suite. The test suite is in turn contained in a TTCN Suite data base. The *AccessSuite* services include opening and closing the TTCN Suite data bases as well as services to start an TTCN Access application and accessing the symbol table manager.

Example 178 ––

Opening and closing the test suite *Test.itex* for use in TTCN Access:

```
AccessSuite suite;

Boolean ok_open = suite.open( "Test.itex" );
if( ok_open )
{
   // do something
   Boolean ok_close = suite.close();
}
```

––

After opening a test suite for TTCN Access use, it is possible to use the following methods to get a handle to the contents of the data base file:

- Get a handle to the root node of the document.

  Example 179 ––

  Getting a handle to the root object of a document:

```
AccessSuite suite;
Boolean ok_open = suite.open( "Test.itex" );
if( ok_open ) {
    const AccessNode node = suite.root();
    // do something with NSAPaddr
    Boolean ok_close = suite.close();
}
```

  ––

> **Note:**
>
> For further details see class `AccessSuite` in TTCN Access include file `access.hh`.

- Ask the AccessSuite object for a specific TTCN Access object in the test suite. The object asked for must be a global object in the test suite. This is performed by using TTCN Access class AccessNode.

Example 180 ----------

Find the TTCN Access object NSAP in test suite *Test.itex*:

```
AccessSuite suite;
Boolean ok_open = suite.open( "Test.itex" );
if( ok_open ) {
    const AccessNode node = suite.find("NSAPaddr");
    // do something with NSAPaddr
    Boolean ok_close = suite.close();
}
```

The AccessNode object now holds the TTCN Access item corresponding to the name NSAPaddr, if any.

To gain access to the data in an AccessNode, you must now find out the runtime type of the object. Based on that type, you will be able to use the conversion routine for an object of the corresponding type:

Example 181 ----------

Find the type of the TTCN Access node corresponding to a name:

```
extern void HandleSimpleType( const SimpleType * );

AccessSuite suite;
Boolean ok_open = suite.open( "Test.itex" );
if( ok_open ) {
   AccessNode node = suite.find( "SomeName" );
   switch( node.choice() ) {
     case Choice::_SimpleType:
       HandleSimpleType(node.SimpleType());
       break;
     default:
       break;
   }}
```

Note:

For further details see class AccessNode in TTCN Access include file access.hh

The AccessVisitor Class

TTCN Access is a large class library, with over 600 classes, and therefore we also need suitable tools for simplifying the creation of TTCN Access applications. The preferred solution is the usage of the class AccessVisitor, which definition is available in the C++ header file `ITEXAccessVisitor.hh`.

The AccessVisitor class is a very close relative to the design pattern 'Visitor' (described by, for instance, Gamma, Helm, Johnson and Vlissides in 'Design Patterns - Elements of reusable software', Addison-Wesley1994). The difference is that the TTCN Access classes contain runtime type information which eliminates the need for them to have dependencies to the Visitor class (and therefore there is no need for 'Accept' methods in the visited classes).

An object of a class which is derived from the class AccessVisitor is later on referred to as a 'visitor'.

AccessVisitor Class Members

Common Classes

The AccessVisitor class has two methods for visiting objects of common classes AccessSuite and AccessNode. These are declared

```
public:
void Visit( const AccessNode );
void Visit( const AccessSuite & );
```

and calling them with, will start a chain of calls in the visitor which effectively is a pre-order traversal of the subtree of the AccessNode, or the complete syntactical tree of the AccessSuite.

TTCN/ASN.1 Derived Classes

The AccessVisitor class has one virtual member function for each TTCN and ASN.1 derived class in TTCN Access. Each of the member functions are declared

```
public:
virtual void Visit<class>( const <class> & );
```

Example 182 ----------

Visitor member method for an Identifier (excerpt from ITEXAccess-Visitor.hh):

```
class AccessVisitor
{
public:
    ...
  virtual void VisitIdentifier(const Identifier&);
  virtual void VisitVerdict(const Verdict&);
    ...
};
```

The base class implementation of this method calls the related Visit<child-class> function for all of the child objects to the current object.

If you need to change the behavior, for instance in order to generate some code or report from the TTCN Access Suite, just derive a new class from the AccessVisitor class and override the relevant method(s). Call the base class implementation of the method to traverse the children if needed.

Data Members

The AccessVisitor class contains no explicitly declared data members and is therefore stateless. It therefore makes program re-entrance possible, and several visitors may be active in the same tree/document at the same time if needed.

Using the AccessVisitor

The intended usage of the AccessVisitor class is by derivation. Derive one or several specialized classes for each of the purposes which you use TTCN Access. Override the relevant methods.

Use Case – Information Collection

It is simple to create a visitor class for collection of some kind of information from the test suite. The basic method for this is to have a handle or actual information in the visitor class.

Example 183 ----------

An information collecting visitor class:

```
#include <time.h>
#include <iostream.h>
#include <ITEXAccessClasses.hh>
#include <ITEXAccessVisitor.hh>

//
// A visitor which counts the number of testcases
// in a test suite.

class TestCounter : public AccessVisitor
{
public:
  TestCounter() : _count( 0 ) { }
  ~TestCounter() { cout << _count << endl; }
  void VisitTestCase(const TestCase&) { _count++; }
private:
  unsigned int _count;
};

// Small example usage, no real fault control...

int main( int argc, char ** argv )
{
  AccessSuite suite;
  if ( suite.open( argv[1] ) ) {
    TestCounter testCounter;
    testCounter.Visit( suite );
  }
  return 0;
}
```

Use Case – Code Generation

It is likewise simple to create a class for simple code generation. The following example is a class for generation of a c-style declaration which contains a list of all SimpleType names in a test suite.

Example 184 ----------

An information collecting visitor class:

```
#include <stdio.h>
#include <time.h>
#include <ITEXAccessClasses.hh>
#include <ITEXAccessVisitor.hh>

// A visitor which generate a c-style declaration
// of a null-terminated array of all Simple Type
// Declarations (identifiers) in a test suite.

class ListGenerator : public AccessVisitor
{
public:
  ListGenerator(FILE * f) : _file( f ) {
          printf( "const char *ids[]={\n");
        }
  void VisitSimpleTypeId(const SimpleTypeId& id) {
          printf( "  \"%s\",\n", (const char*)
                    id.simpleTypeIdentifier());
        }
  ~ListGenerator() {
          printf( "  NULL\n};\n");
        }
};

// Small example usage, no real fault control...

int main( int argc, char ** argv )
{
  AccessSuite suite;
  if ( suite.open( argv[1] ) ) {
    ListGenerator generator;
    generator.Visit( suite );
  }
  return 0;
}
```

The last two examples are not the most efficient implementations due to the fact that they traverse the whole tree even though we are only interested in small parts, and therefore we may want to improve the efficien-

cy. This may be done using any of the techniques described in "Optimizing Visitors" on page 978.

Advanced Use Case – Combined Visitors

More advanced designs may be possible by combining several visitors for performing more advanced tasks. You may for instance have visitors which are parameterized with other visitors for specialized tasks, where you still would want to maintain decent performance and yet not have trade-offs in clarity of the design.

Example 185 ––

A TTCN Interpreter would need a mechanism for building an internal representation of values. Values are always built by using the same structure, but you may wish to have several possible representations of atomic values. A visitor could be used to generate the value objects, where one visitor is used for building the overall structure, and another is used for building individual fields. There are at least two choices available in the design:

- To inherit the structure building class into the class which builds the atomic values
- To parameterize the structure building class with the atomic value handing class (which gives you a possibility to tune the behavior at runtime).

In this example, the value building class inherits from the AccessVisitor class and the Visit<xxx> functions are used to generate a new value. The class GciValueBuilder in the example, may visit any structured type and will on the Visit<class> function either create itself a data value, or if it is a structured type, create a dynamic array, and then invoke a new visitor for each of the fields, which results will later be assigned to each of the fields in the same array. The implementation is not present in the example. It is just outlined below.

The solution of using visitors for building the values, removes the switch statements, which otherwise would undoubtedly clobber an implementation which uses Direct Access as described in a previous section.

```
class GciValueBuilder : public AccessVisitor
{
  // basic structure for building/matching values
  virtual void VisitXxxx( const Xxxx & );
  ...
  // built value
  GciValue * _value;
};

class GciValueBinaryBuilder : public GciValueBuilder
{
  // suitable overrides for efficient binary value
  // handling
  ...
};

class GciValueBigNumBuilder : public GciValueBuilder
{
  // suitable ovverides for a 'bignum'
  // implementation
  ...
};
```

Optimizing Visitors

A visitor is a potentially inefficient way to find and process objects, since it in its unmodified version traverses the whole document, without regarding what parts of the document the inherited visitor is interested in. All optimizations are in the domain of limiting the subtree for which we are traversing. The following examples shows methods for avoiding unnecessary traversal and optimally, constant time access.

Example 186

Optimizing a visitor class to avoid traversal of all parts but the declarations part, may improve performance for suite traversal by over 100 times for some fairly representable suites (since most suites contain more and larger syntactical trees in the dynamic part than in all other parts, possibly with the exception of ASN.1 constraint declarations).

```
class DeclarationChecker : public AccessVisitor
{
 public:
  void VisitSuiteOverviewPart(
                const SuiteOverViewPart& ) { }
  void VisitConstraintsPart(
                const ConstraintsPart & ) { }
  void VisitDeclarationsPart (
                const DeclarationsPart & ) { }

  // Add the functions which actually do processing
  // below ...
};
```

Optimizing a visitor class to traverse only parts we are interested in, is also possible, by using one or a few levels of Direct Access instead of the default traversal.

Example 187 ----------

This example skips all traversal down to the Simple Type Definitions table, and only traverses those.

```
class SimpleTypeIdPrinter : public AccessVisitor
{
 public:
  void VisitASuite( const ASuite& );
  void VisitSimpleTypeId ( const SimpleTypeId & );
};

void
SimpleTypeIdPrinter::VisitASuite(const ASuite & s)
{
  VisitSimpleTypeDefs( s.declarationsPart().
                       definitions().
                       ts_TypeDefs().
                       simpleTypeDefs());
}

void
SimpleTypeIdPrinter::VisitSimpleTypeId( const
                                  SimpleTypeId & id )
{
  cout  << "Id: "
        << id.simpleTypeIdentifier()
        << endl;
}
```

Finally, you may combine several visitors into one visitor, thus avoiding multiple passes when processing a suite. This implies that you define several classes which are not truly visitors, and define a inherited class from AccessVisitor which calls methods in these classes.

Example 188 ----------

Two objects driven by a visitor, thus performing two passes on one traversal.

```
class IdOperation
{
 public:
  virtual void AtIdentifier(const Identifier&) = 0;
};

// A IdOperation

class IdCounter : public IdOperation
{
 public:
  IdCounter( ) : _count( 0 ) { }
  void AtIdentifier( const Identifier & id )
     { _count++; }
  ~IdCounter( ) { cout << _count << endl; }
 private:
  unsigned int _count;
};

// Another IdOperation

class IdPrinter : public IdOperation
{
  public:
   void AtIdentifier( const Identifier & id )
        { cout << id << endl; }
};

// A class which drives up to IdOpDriverMax
// IdOperations

const int IdOpDriverMax = 10;

class IdOpDriver : public AccessVisitor
{
 public:
  IdOpDriver() : _ops_used(0) { }
  void VisitIdentifier( const Identifier & id ) {
    for (unsigned int op = 0 ; op < _ops_used; ++op)
      _ops[op].AtIdentifier( id );
  }
  void AddIdOp( IdOperation * op )
        { _ops[_ops_used++] = op; }
```

```
 private:
  IdOperation  _ops[IdOpDriverMax];
  unsigned int _ops_used;
};

// Main routine which opens a suite and applies two
// IdOperations.

int main( int argc, char ** argv )
{
  AccessSuite suite;
  if ( suite.open( argv[1] ) ) {
    IdCounter  counter;
    IdPrinter  printer;
    IdOpDriver driver;
    driver.AddIdOp( &counter );
    driver.AddIdOp( &printer );
    driver.Visit( suite );
    suite.close( );
  }
  return 0;
}
```

Common Class Definitions

This part contains the declaration of the three common TTCN Access classes `AccessSuite`, `AccessNode` and `Astring`. For further information see TTCN Access include file `access.hh`.

AccessSuite

```
class AccessSuite
{
public:
  AccessSuite();
  ~AccessSuite();
  AccessSuite( const AccessSuite& orig );
  void operator=( const AccessSuite& orig );

  Boolean open( const char* suite_name );
  Boolean open( Suite* suite );
  Boolean close();

  const AccessNode root();
  const AccessNode find( const Identifier & id );
  const AccessNode find( const char* id );
 };
```

AccessNode

```
class AccessNode
{
public:
  AccessNode();
  AccessNode(NodeInfo nodeinfo);
  ~AccessNode();
  AccessNode(const AccessNode& Me);

  int operator==(const AccessNode& o) const;
  void operator=(const AccessNode& orig);

  Boolean is_equal(const AccessNode& o) const;
  Choices::Choice choice() const;
  Boolean ok() const;

};
```

Astring

```
class Astring
{
public:
  Astring();
  Astring(const char* s);
  // end should point to the char after the last
char
  Astring(const char* begin, const char* end);
  Astring(Field* field, PT* pt);
  Astring(const Astring& orig);

  ~Astring();

  //operators
  Astring* operator->();
  const Astring* operator->() const;
  operator const char*() const;
  char& operator[](unsigned i) ;
  char operator[](unsigned i) const ;

  void operator=(const Astring&);
  void operator=(const String&);
  void operator=(const char*);
  void operator=(const char);

  int operator==(const Astring& s) const;
  int operator!=(const Astring& s) const;
  int operator==(const char* cs) const;
  int operator!=(const char* cs) const;
};
```

Getting Started with TTCN Access

Setting Up the TTCN Access Environment

When building applications using TTCN Access, the compiler will need to find a few files, the `ITEXAccessClasses.hh` include file and the `libaccess.a` library file. Normally these files are found in the `.../itex/include/CC` and `.../itex/lib/CC` directory respectively. The include file must be included in every TTCN Access application and the library `libaccess.a` must be used when linking.

> **Note:**
>
> For further information, contact your system administrator.

TTCN Access operates on the TTCN Suite data bases. These data bases must have passed analysis and be saved before using TTCN Access. If the data base contains a TTCN test suite that is not analyzed, the TTCN Access application can not reach into the fields of the tables. The default behavior of TTCN Access is to simply skip those fields that are not analyzed. De-referencing a particular field in an non-analyzed data base, will result in undefined behavior.

TTCN test suite data bases are managed by the AccessSuite object, which has member functions for opening and closing the TTCN Suite data bases and also for starting traversing. From an AccessSuite object it is also possible to access tables in a random manner via the symbol table manager.

Using Example Applications

TTCN Access is delivered with some simple example applications. To compile the examples, the installation directory, where the `ITEXAccessClasses.hh` and `libaccess.a` files reside, must be known to the makefiles. Do this by setting the environment variable ACCESS or by explicitly filling in the local variable ACCESS in every makefile or using make with the syntax `make ACCESS=$telelogic/itex/access`.

Starting an TTCN Access Application

You have to retrieve the TTCN Access license when you start the TTCN Suite. To do this, start the TTCN Suite from the command line with the switch `-access`.

Then you can execute TTCN Access applications from the command line or from the window manager.

You can also select *Start Application* in the *Access* menu in the Browser. This will open a dialog in which you may change settings and start the TTCN Access application.

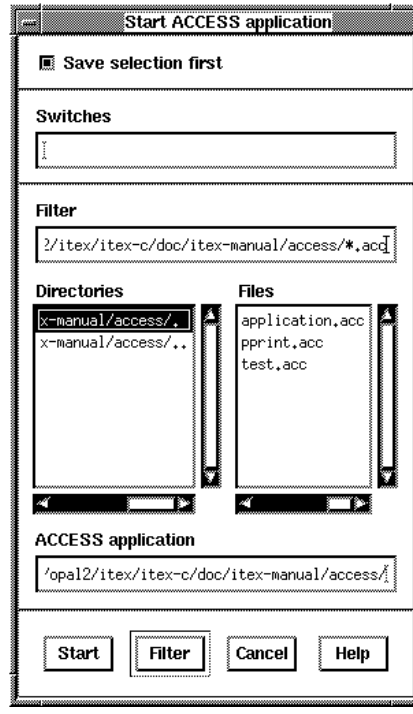

Figure 181: The Start Application dialog

Save selection first

Select this to save the current selection in the Browser before executing the TTCN Access application.

Switches

Switches may be passed to the chosen TTCN Access application. The switches are written as free text. As the last argument is the name of the the TTCN Suite database passed. This name is always passed to the TTCN Access application.

> **Note:**
>
> Observe that it is the name of the (working) *database* file and not the name of the test suite that is passed to the TTCN Access application.

Filter

Sets the filter for the files that will be displayed in the *Suites* list. There are no predefined naming conventions for TTCN Access applications.

For example the name filter `*.acc` will cause only those files whose names end with `.acc` to be displayed.

Access application

Displays the selected application.

Chapter

22

Creating a TTCN Access Application

This chapter is intended to be an introduction to how to create a TTCN Access application, and it is expected to be read sequentially. As TTCN Access is a C++ application programmers interface, this chapter will contain several TTCN Access applications written in C++. The chapter includes general TTCN Access application concepts as well as specific examples.

For reference, the test suite that is used as input to the various TTCN Access applications, is included in TTCN-GR form at the end of this chapter together with the source code for each example.

TTCN Access

TTCN Access is a C++ application programmers interface. It is a platform for writing applications related to TTCN test suites such as:

- Executable test suites
- Interpreters
- Encoders and decoders
- Reporters

TTCN Access is meant to be used by executable test suite developers, translator developers as well as test result analyzers.

In order to make this chapter as complete as possible and thereby cover as many different TTCN Access application domains as we can, this chapter contains several different examples, each described in its own section. However, before we start with the examples, we will explain some general concepts that apply to every TTCN Access application.

Note:

This chapter is an TTCN Access primer and is not intended to provide a chapter in C++ programming.

General Concepts

The TTCN Access Application

A TTCN Access application is typically an application that produces some kind of output during the traversing of an Access tree. The Access tree, tree for short, is a tree oriented representation of a test suite. This tree is stored in the database `<TestSuite>.itex` where `<TestSuite>` is the user given name of the database.

The first section introduces the basic methods. These include the main function and how to initialize a test suite in a TTCN Access application. The second section describes how the traversing is done.

Basic Methods

When executing a TTCN Access application there are some basic methods that have to be applied before and after traversing the tree. First of all, to be able to get all the definitions needed, the header files `ITEX-`

`AccessClasses.hh` and `ITEXAccessVisitor.hh` have to be included. These files must be included in all TTCN Access applications as shown below:

```
#include <ITEXAccessClasses.hh>
#include <ITEXAccessVisitor.hh>
```

Once this is done, we need to create an instance of the *AccessSuite* class. This can be done as follows:

```
AccessSuite suite;
```

The *AccessSuite* class can be seen as a handle to the Access tree and the symbol table. It will be used for opening and closing the database and for finding specific, named Access objects stored in the symbol table.

To open a database for reading, the following method has to be called:

```
Boolean open_ok = suite.open( arg );
```

where `arg` is a string containing the name of the database that shall be opened. This method must always be applied to the database before traversing the Access tree. The method returns a boolean value stating whether the database could be opened or not. To close a database the following method must be called:

```
Boolean close_ok = suite.close();
```

This method requires no database name to be given as the database that will be closed is associated with `suite`. The method returns a boolean value stating whether the database could be closed or not. Below is a generic TTCN Access main function where `argv[1]` contains the name of the database:

```
#include <ITEXAccessClasses.hh>
#include <ITEXAccessVisitor.hh>

int main( int argc, char **argv )
{
  AccessSuite suite;

  if ( suite.open( argv[ 1 ] ) )       // OK open database?
    {
      // Write your Access application here
      // Typically start the traverser

     if ( suite.close( ) )            // OK close database?
       return 1;
     else                             // Error close database!
       return 0;
     }
   else                               //Error open database!
       return -1;
}
```

Traversing the Access Tree

The traversing of a test suite is the “engine” that actually drives the TTCN Access application to execute.

The previous section was only concerned with opening and closing of the database. This section will describe and explain the different methods that TTCN Access provides for starting the actual TTCN Access application, i.e. starting the traversing from different nodes in the Access tree.

To be able to allow the user to traverse the tree in a simple way, TTCN Access provides a visitor class that can be customized in a flexible way by the user. The class is called *AccessVisitor* and provides different ways of traversing.

In all the examples discussed in the following sub sections, we assume that we have a global instance of the class *AccessSuite* called *suite, a global instance of the class AccessVisitor called visitor* and that a test suite has been opened as described in the previous section.

Traversing from the Root of the Tree

As TTCN Access can be seen as a huge tree, the basic method for traversing will be to start traversing from the root. This will result in a traversing that will traverse the full Access tree starting from top. This is performed by calling the method:

```
Boolean root_ok = visitor.Visit( suite );
```

It is an error to try to traverse a database that has not been previously opened.

Traversing by Reference

In some cases it is desirable to start traversing from a specific table, i.e. a test case or a type definition. TTCN Access provides means for this in terms of using its symbol table.

The symbol table handles global entities, that is elements that must be globally unique within a test suite according to the TTCN standard (9646-3). Such elements are all variable names, all type names, all test case names, etc.

To start traversing the Access tree from a specific element, TTCN Access provides a simple solution divided into four steps:

1. The first step is to get a handle to the symbol table:

   ```
   AccessNode node = suite.find( name );
   ```

   This method will return a handle to the symbol table.

2. The second step is to verify that this handle holds an element present in the symbol table. This is performed by applying the following method:

   ```
   Boolean symbol_table_ok = node.ok();
   ```

3. Assuming that the argument `name` was a global name in the test suite, we still do not know what kind of element it is. It could for example be a TTCN PDU type definition, a test case or a test step. The handle to the symbol table provides a method for finding the Access type of its corresponding element. The third step will be to ask the symbol table what type its corresponding element has:

   ```
   Choices::Choice type = node.choice();
   ```

   This method will return an enumerated value of type `Choices::Choice` revealing the type of the element. As there are several different Access types, this type check is best solved in a switch statements. Assuming that the name can be either a test case or a TTCN PDU type definition, the following switch statement will detect that.

   ```
   switch( node.choice( ) )
   {
     case Choices::c_TTCN_PDU_TypeDef:
           //
           // do something
           //
           break;
     case Choices::c_TestCase:
           //
           // do something else
           //
           break;
     default:
           //
           // do something default
           //
           break;
   }
   ```

4. The fourth step is to call the corresponding traverser function.

   Below is a complete example that will traverse a test suite starting from a specific element. The example assumes that the function `main( )` is called with two arguments where the first is the name of the database and the second is the name of the element that the traversing shall start from. This application can only handle TTCN PDU type definitions and test cases.

```
int main( int argc, char **argv )
{
  AccessSuite suite;
  AccessVisitor visitor;

  if ( suite.open( argv[ 1 ] ) )        // OK open database?
    {
      //Get the handle

      AccessNode node = suite.find( arg[ 2 ] );

      if ( node.ok( ) )                 // Handle ok?
        visitor.Visit( node );
      else                              // Error in symbol table
        return -2

      if ( suite.close( ) )             // OK close database?
        return 1;
      else                              // Error close database!
        return 0;
     }
   else                                 // Error open database!
     return -1;
}
```

Examples

This section provides all the examples in this chapter. It starts with a simple TTCN Access application and continues from there. Every example is discussed in its own subsection. In each subsection, only the interesting parts are discussed. A complete solution to every example can be found in "Solutions to the Examples" on page 1000.

Every TTCN Access application can be seen as an application providing a solution to a problem. These problems are related to TTCN test suites in general, such as reporters or style checkers, encoders and decoders. Therefore, every example in this chapter will be preceded with a small discussion of the actual problem that the corresponding TTCN Access application shall solve. Of course, the problems discussed in this chapter will mainly be of a fictive nature, but they will reflect the simplicity of TTCN Access and the different implementation techniques and methods that TTCN Access provides.

In all examples, we assume that there exist a global instance of the class *AccessSuite* called *suite*, a global instance of the class *AccessVisitor* called *visitor* and that a test suite has been opened.

The Identifiers

Objective

In every test suite there exists a set of identifiers. The objective of this example is to print out every identifier present in the test suite.

Solution 1

Every identifier present in an Access tree will be represented as an Access node of type Identifier. The solution will therefore only include one user defined method in the visitor class instance that, when entering the node Identifier, prints the content of that class. In this case it is the name of the identifier. The method is provided below.

```
void Trav::VisitIdentifier( const Identifier& Me )
{
  printf( "Identifier %s\n", (const char*) Me );
}
```

This method will be called from TTCN Access every time the traverser enters the Identifier node. The name `Identifier` is the name of the

Access node and the prefix tag `Visit` means that this is a visiting method.

As the task of a TTCN Access application is to traverse a test suite according to the traverser and call possibly user defined functions or methods, we need to create a traverser that will use the default traversing, but have the desired small change. This is done by sub classing as follows:

```
class Trav : public AccessVisitor
{
public:
  void VisitIdentifier( const Identifier& id );
};
```

As identifiers are present everywhere in the Access tree, no change to the traversing order needs to be done. The default traverser will be used and the traversing will start from root.

The full solution is found in "Solution 1" on page 1001.

Context

Objective

When executing the previous example, all identifiers in the given test suite will be printed. By looking at the output one might think that there should not be so many identifiers in the test suite, but the way in which the grammars are specified (both TTCN and ASN.1), nearly every grammar rule ends in a identifier. This example will explain the importance of calling the user defined function at their correct place, or to be more specific, in its right context.

Let us assume, with the previous example in mind, that we want to distinguish between TTCN PDU type definition identifiers and TTCN PDU constraint identifiers (the rest is of no concern). This can be achieved in several different ways. Below are two different solutions to this problem.

Solution 2

This first solution, looking at each identifiers type, will be implemented in the visiting method used in the previous example. However, it has to be extended to look at each identifier type and only print the appropriate ones. The updated method is found below.

```
void Trav::VisitIdentifier( const Identifier& Me )
{
  switch( Me.choice( ) )
    {
      case Choices::c_TTCN_PDU:
        printf( "Identifier '%s' is a TTCN PDU type\n",
                (const char*) Me );
        break;

      case Choices::c_TTCN_PDU_Cons:
        printf( "Identifier '%s' is a TTCN PDU constraint\n",
                (const char*) Me );
        break;

      default:
        break;
    }
}
```

Solution 3

The second solution will replace the used method with two new ones. The first method will print out every TTCN PDU type definition identifier. This will be done in the method `VisitTTCN_PDU_TypeDef`. The second, `VisitTTCN_PDU_Constraint`, will print out every TTCN PDU constraint identifier. In each method the Identifier Access node is reached by explicit addressing, that is, explicitly naming the path to the Access node Identifier. Their corresponding definitions are supplied below.

```
void Trav::VisitTTCN_PDU_TypeDef( const TTCN_PDU_TypeDef& Me )
{
  printf( "Identifier '%s' is a TTCN PDU type\n",
           (const char*) Me.pdu_Id( ).pdu_IdAndFullId( )
           .pdu_Identifier( ) );
}

void Trav::VisitTTCN_PDU_Constraint( const
TTCN_PDU_Constraint& Me)
{
  printf( "Identifier '%s' is a TTCN PDU constraint\n",
          (const char*) Me.consId( ).consIdAndParList( ).
          .constraintIdentifier( ) );
}
```

The definition of the visitor object is done as follows:

```
class Trav : public AccessVisitor
{
public:
  void VisitTTCN_PDU_TypeDef( const
TTCN_PDU_TypeDef& );
  void VisitTTCN_PDU_Constraint( const
TTCN_PDU_Constraint& );
};
```

Comments

When executing the two examples above with the test suite in the end of this chapter as input, one will find that the output is not equivalent. The first solution will have some more output lines that the second one. By adding the following line to each method, one will detect in which table the identifier was found.

```
printf( "In table '%s': ", (const char*) Me.table_name() );
```

One will find that the extra lines of output in the first solution are produced from the Constraints Part and the Dynamic Part. This is true due to the fact that the type identifiers are being used in each constraint and the constraint identifiers are being used in the Constraint Reference column in each test case and test step table.

The full solutions are found in "Solution 2" on page 1003 and "Solution 3" on page 1005.

Translating TTCN

A very common and useful TTCN Access application is to translate a test suite to another target language. Examples are C, C++, Pascal etc. By doing this translation we can thereby create an executable test suite. To achieve this, one needs a TTCN translator that translates a TTCN test suite to the specific source code. This example will not be a full translator, but will rather show how such a translator can be written by using TTCN Access.

Objective

In this example, we will translate TTCN PDU type definitions to C where each PDU will be a unique C type. To achieve this, we need to have some kind of mapping between TTCN and C. One way to do this is to do a case study. First we will look at a TTCN PDU type definition in the table format and from that table extract how the corresponding C representation shall be. Then, a generic representation of all TTCN PDUs in C will be defined. This generic representation will then be implemented in TTCN Access, and thereby a generic TTCN PDU type definition to C translator will be implemented.

Solution 4

Let us have a look at a TTCN PDU type definition in table format. The table below, the TTCN PDU type definition SEND, is taken from the test suite attached to the end of this chapter.

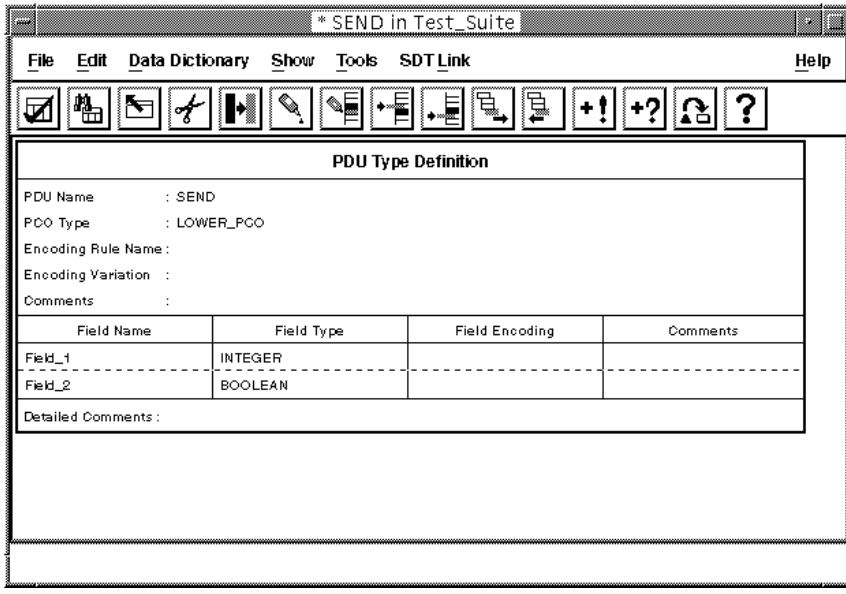

Figure 182: TTCN PDU Type Definition

A corresponding C representation of the above type could look something like:

```
typedef struct {
 INTEGER Field_1;
 BOOLEAN Field_2;
} SEND;
```

That is, a structured type holding the same number of elements as the corresponding TTCN type definition. In this example, no consideration is taken to the PCO type. This is only done for simplicity and can of course be included in the type as well.

As one can see in this example there are a lot similarities between the TTCN definition and the C representation in terms of names of elements

and their corresponding type. This helps us define a generic C representation of a TTCN PDU type definition as below:

```
typedef struct {
 Element1_Type Element1_Name;
 Element2_Type Element2_Name;
 ...
 ElementN_Type ElementN_Name;
} PDU_TypeName;
```

The type and name of each element is taken from the corresponding names in the TTCN type definition and the type defined is named as in TTCN.

Now, the next step is to implement this generic type in TTCN Access! To do this, we divide the generic C type into three distinct elements; the header, the body and the footer.

The Header and Footer

The visitor method that traverses the TTCN PDU type definitions, will be the one responsible for generating the header and footer of the generated C structure definition. The method may look something like this:

```
void Trav::VisitTTCN_PDU_TypeDef( const TTCN_PDU_TypeDef& Me )
{
  // Generate the header part

  cout << Me.pdu_Id( ) << "_encode( const ";
  cout << Me.pdu_Id( ) << "& me, char* enc_buf )";
  cout << "\n{" << endl;

  // Traverse fields using default traverser

  AccessVisitor::VisitPDU_FieldDcls(
Me.pdu_FieldDcls( ) );

  // Generate the footer part

  cout << "}" << endl;
}
```

This method will be called every time the traverser enters the Access node TTCN_PDU_TypeDef.

The Body

The body of the type definition, is a collection of rows where each row is translated identically. A row can be translated by defining the following method:

```
void Trav::VisitPDU_FieldDcl( const PDU_FieldDcl& Me )
{
  printf( "  %s %s;\n",
          (const char*) get_type_str( Me.pdu_FieldType( ),
          (const char*) get_id( Me.pdu_FieldId( ) );
}
```

where `get_type_str` and `get_id` are two functions returning the type and the name of the element respectively. This method shall be called every time the traverser enters the Access node PDU_FieldDcl.

The full solution is found in "Solution 4" on page 1006.

Summary

TTCN Access provides a platform for generating applications in the domain of TTCN, conformance testing and related applications such as translators, interpreters, analyzers, reporters, etc. TTCN Access is a C++ representation of the related grammars that spans the language TTCN. We hope that this chapter has revealed the basis of TTCN Access, the methods it supplies and how easy it is to use. All examples in this chapter have full solutions in "Solutions to the Examples" on page 1000.

Solutions to the Examples

This section contains fully implemented solutions to each example given in the "Examples" on page 993. It will also contain the expected output when executing each TTCN Access application with the example test suite as input.

Makefile

This generic Makefile has been used for compilation and linking:

```
#-------------------------------------------------------------
# Name: Makefile
#
# Destcription:
# Generic Makefile for Access applications
# Note that the makefile requires the variable
# itexaccess to be set.
#-------------------------------------------------------------

ACCESS-INCL = $(itexaccess)/include
ACCESS-LIB = $(itexaccess)/lib

TARGET = the name of the target
OBJS = $(TARGET).o

#-----------------------------------------------------------

$(TARGET) :$(OBJS)
        $(CCC) -L$(ACCESS-LIB) -Bstatic -o $@ $(OBJS) -laccess
        strip $@

#-----------------------------------------------------------

clean :
        /bin/rm $(TARGET) $(OBJS)

#-------------------------------------------------------------

.SUFFIXES: .cc .o

.cc.o :
        $(CCC) -I$(ACCESS-INCL) -c -o $@ $<
```

Solution 1

Code

```
#include <ITEXAccessClasses.hh>
#include <ITEXAccessVisitor.hh>

class Trav : public AccessVisitor
{
public:
  void VisitIdentifier( const Identifier& id );
};

void Trav::VisitIdentifier( const Identifier& Me )
{
  printf( "Identifier %s\n", (const char*) Me );
}

int main( int /* argc */, char **argv )
{
  AccessSuite suite;

  if( suite.open( argv[ 1 ] ) )   // OK open database?
   {
      Trav visitor;

      visitor.Visit( suite );

      if( suite.close( ) )       // OK close database?
        return 1;
      else                       // Error close database!
        return 0;
   }

  else                           // Error open database!
    return -1;
}
```

Output

```
> ./print-ids ../Example_Suite_A.itex
Identifier Example_Suite_A
Identifier Example_Suite_A
Identifier L
Identifier LOWER_PCO
Identifier SEND
Identifier LOWER_PCO
Identifier Field_1
Identifier Field_2
Identifier RECEIVE
Identifier LOWER_PCO
Identifier Field_1
Identifier Field_2
Identifier S1
Identifier SEND
Identifier Field_1
Identifier Field_2
Identifier R1
Identifier RECEIVE
Identifier Field_1
Identifier Field_2
Identifier TEST_CASE_1
Identifier L
Identifier SEND
Identifier S1
Identifier TEST_STEP_1
Identifier TEST_STEP_1
Identifier L
Identifier RECEIVE
Identifier R1
Identifier L
>
```

Solution 2

Code

```
#include <ITEXAccessClasses.hh>
#include <ITEXAccessVisitor.hh>

class Trav : public AccessVisitor
{
public:
  void VisitIdentifier( const Identifier& Me );
};

int main( int /* argc */, char **argv )
{
  AccessSuite suite;

  if( suite.open( argv[ 1 ] ) )   // OK open database?
   {
      Trav visitor;

      visitor.Visit( suite );

      if( suite.close( ) )       // OK close database?
        return 1;
      else                       // Error close database!
        return 0;
   }

  else                           // Error open database!
    return -1;
}

void Trav::VisitIdentifier( const Identifier& Me )
{
  switch( Me.choice( ) )
    {
      case Choices::c_TTCN_PDU:
        printf( "Identifier '%s' is a TTCN PDU type\n",
                (const char*) Me );
        break;

      case Choices::c_TTCN_PDU_Cons:
        printf( "Identifier '%s' is a TTCN PDU constraint\n",
                (const char*) Me );
        break;

      default:
        break;
    }
}
```

Output

```
> ./print-ids ../Example_Suite_A.itex

Identifier 'SEND' is a TTCN PDU type
Identifier 'RECEIVE' is a TTCN PDU type
Identifier 'S1' is a TTCN PDU constraint
Identifier 'SEND' is a TTCN PDU type
Identifier 'R1' is a TTCN PDU constraint
Identifier 'RECEIVE' is a TTCN PDU type
Identifier 'SEND' is a TTCN PDU type
Identifier 'S1' is a TTCN PDU constraint
Identifier 'RECEIVE' is a TTCN PDU type
Identifier 'R1' is a TTCN PDU constraint
>
```

Solution 3

Code

```
#include <access.hh>

void id_pre_TTCN_PDU_TypeDef(const TTCN_PDU_TypeDef& Me);
void id_pre_TTCN_PDU_Constraint(const TTCN_PDU_Constraint&
Me);

int main( int /* argc */, char **argv )
{
  AccessSuite suite;

  if( suite->open( argv[ 1 ] ) )   // OK open database?
    {
      // Setup the id writing functions
      pre_TTCN_PDU_TypeDef = id_pre_TTCN_PDU_TypeDef;
      pre_TTCN_PDU_Constraint = id_pre_TTCN_PDU_Constraint;

      // Start traversing from root.
      if( !suite->trav_root() )
        return 1;

      if( suite->close() )         // OK close database?
        return 0;
       else                        // Error close database!
        return 2;
    }

  else                             // Error open database!
   return -1;
}

void id_pre_TTCN_PDU_TypeDef(const TTCN_PDU_TypeDef& Me)
{
  printf( "Identifier '%s' is a TTCN PDU type\n",
           (const char*) Me->pdu_Id()->pdu_IdAndFullId()
           ->pdu_Identifier() );
}

void id_pre_TTCN_PDU_Constraint(const TTCN_PDU_Constraint& Me)
{
  printf( "Identifier '%s' is a TTCN PDU constraint\n",
          (const char*) Me->consId()->consIdAndParList()
          ->constraintIdentifier() );
}
```

Output

```
> print-ids ../Example_Suite_A.itex

Identifier 'SEND' is a TTCN PDU type
Identifier 'RECEIVE' is a TTCN PDU type
Identifier 'S1' is a TTCN PDU constraint
Identifier 'R1' is a TTCN PDU constraint
>
```

Solution 4

Code

```
#include <ITEXAccessClasses.hh>
#include <ITEXAccessVisitor.hh>

class Trav : public AccessVisitor
{
public:
  void VisitTTCN_PDU_TypeDef( const TTCN_PDU_TypeDef& Me );
  void VisitPDU_FieldDcl( const PDU_FieldDcl& Me );
};

Astring get_type_str(const AccessNode& n);
Astring get_id(const AccessNode& n);

int main( int /* argc */, char **argv )
{
  AccessSuite suite;

  if( suite.open( argv[ 1 ] ) )   // OK open database?
    {
      Trav visitor;

      visitor.Visit( suite );

      if( suite.close() )         // OK close database?
        return 0;
      else                        // Error close database!
        return 2;
    }

  else                            // Error open database!
    return -1;
}

void Trav::VisitTTCN_PDU_TypeDef( const TTCN_PDU_TypeDef& Me )
{
  // Generate the header part

  cout << Me.pdu_Id( ) << "_encode( const ";
  cout << Me.pdu_Id( ) << "& me, char* enc_buf )";
  cout << "\n{" << endl;

  // Traverse fields using default traverser

  AccessVisitor::VisitPDU_FieldDcls( Me.pdu_FieldDcls( ) );

  // Generate the footer part

  cout << "}" << endl;
}

void Trav::VisitPDU_FieldDcl( const PDU_FieldDcl& Me )
{
  printf( "  %s %s;\n",
          (const char*) get_type_str( Me.pdu_FieldType( ),
          (const char*) get_id( Me.pdu_FieldId( ) );
}
```

```
// Help functions

Astring get_type_str(const AccessNode& n)
{
  switch ( n.choice( ) )
    {
    case Choices::c_PDU_FieldType:
      return n.PDU_FieldType().content();

    default:
      fprintf( stderr, "Bad case in get_type %d\n",
               (int) n.choice( ) );
      abort();
    }
}

Astring get_id(const AccessNode& n)
{
  switch ( n.choice( ) )
    {
      case Choices::c_PDU_FieldId:
           if ( n.PDU_FieldId( ).pdu_FieldIdOrMacro( )
                .choice( )
                == Choices::c_MacroSymbol )
           return n.PDU_FieldId( ).pdu_FieldIdOrMacro( )
                   .macroSymbol( );
        else
           return n.PDU_FieldId( ).pdu_FieldIdOrMacro( )
                   .pdu_FieldIdAndFullId( )
                   .pdu_FieldIdentifier( );

      case Choices::c_PDU_Id:
        return n.PDU_Id( ).pdu_IdAndFullId( )
               .pdu_Identifier( );

      default:
        fprintf( stderr, "Bad case in get_id %d\n",
                 (int) n.choice( ) );
        abort( );
    }
}
```

Output

```
> ./pdu2c ../Example_Suite_A.itex

  INTEGER Field_1;
  BOOLEAN Field_2;
} SEND;

typedef struct {
  INTEGER Field_1;
  BOOLEAN Field_2;
} RECEIVE;
>
```

Chapter 22 Creating a TTCN Access Application

Chapter

23

The TTCN Access Class Reference Manual

This chapter contains the class definitions in TTCN Access.

The definitions are grouped into the following areas:

Static and Table Nodes

This section contains all static nodes and table nodes (that is those visible in the Browser) and also the nodes representing rows inside tables. Common for these nodes are that they are always present, there may be any number of them, but they are generally well defined and cannot just be missing.

Parse Tree Nodes

This section contains all nodes within the Parse Trees. The Parse Trees are the output of the Analyzer, and they are a representation of whatever code the Test Suite writer put into the fields. Being user written, this part is much less well behaved than, say, the Static part, nodes may or may not be present, fields may or may not be well analyzed and some nodes have different children in different places in the Parse Tree (choices). All this is well specified however, using the mechanisms of is_present, is_analyzed (for tables) and the choice member function, but it is up to the user of TTCN Access to be aware of these constructs.

Terminal Nodes

This section contains all the Terminal Nodes. A Terminal Node is defined to be a node without children in the Parse Tree, and they generally represents some actual piece of text in the field. The Identifier class is a good example of a Terminal Node. It is the Access representation of a name or identifier. The Terminal Nodes have some special properties, they can be printed directly, yielding the piece of text they represent, and their positions in the field string can be easily found. The Identifier is a special Terminal Node since all Identifiers have an type which is information about in what table the identifier was declared (or Unknown if this could not be found during analysis).

Impl. Note: Every Identifier has an associated type, which refers to the context where the Identifier was declared. If, for example, an Identifier refers to a TTCN ASP declaration table, then its type will be Choices::_TTCN_ASP, and if the Identifier refers to a parameter of a constraint or test step, then its type will be Choices::_FormalParam_Id. The associated type is reached through the member function Identifier::choice().

Chapter

24

The TTCN Browser (on UNIX)

This chapter contains a reference manual to the TTCN Browser. The Browser presents an overview of the TTCN document. In the Browser, it is possible to edit the TTCN document structure, to determine which parts of the document to view, and to apply different tools.

The functionality of the Browser, the menus, windows and quick buttons, are described in this chapter. The TTCN Table Editor is described in chapter 25, *The TTCN Table Editor (on UNIX)*. How to analyze and find tables is described in chapter 26, *Analyzing TTCN Documents (on UNIX)*.

For an overview of the TTCN Suite, see chapter 3, *Introduction to the TTCN Suite (on UNIX), in the TTCN Suite 6.2 Getting Started*.

> **Note: UNIX version**
>
> **This is the UNIX version of the chapter. The corresponding Windows chapter is chapter 30, *Editing TTCN Documents (in Windows)*.**

Introduction to the TTCN Browser

The TTCN Browser is the part of the TTCN Suite that presents TTCN document structures. When a new TTCN document is opened, place holders for the static parts of the document are already created. Then you can add and delete the dynamic parts.

The amount of information actually displayed in a Browser can be collapsed and expanded. It is also possible to display selected parts of the TTCN document in a sub Browser. You open a sub Browser from the main Browser or from another sub Browser.

The functionality of a menu choice is applied to all items or selections of items in the Browser. If an operation is invoked from the Organizer (see chapter 2, *The Organizer*), it is always applied to all items in the TTCN document.

Opening the Browser and a TTCN Document

You open the TTCN Browser by selecting a TTCN document already included in the Organizer followed by the menu choice *Edit*, or by double-clicking the TTCN document. You may also add a new TTCN document with *Add New* or *Add Existing* from the *Edit* menu, or start a Browser directly by selecting *Editors > TTCN Browser* from the *Tools* menu. See chapter 2, *The Organizer* for more information.

If you try to open a TTCN document that is already opened by any another user or in another TTCN Suite Browser, you will get a question informing that the file is opened by another user and ask to open it in read-only mode. In read-only mode you will not be able to save your changes (if any) in the same file, but free to save the TTCN document as another file. No other restrictions exist in read-only mode: you may browse, analyze, generate code, etc.

The question that the file is opened by another user is isuued because a read-lock file (with additional suffix '-read_lock') exists in the same directory as the document. This may also happen if the TTCN Suite or Windows has crashed. In this case just remove this file and try to open the TTCN document again.

Close the Browser and a TTCN Document

To close the Browser and all corresponded table editors, in the Browser *File* menu choose *Close*. The TTCN Suite will remain running, TTCN documents remains loaded and the license is not released in this case. The *Close* command means only that the Browser window is closed. To exit TTCN Suite Editor, go to the Browser *File* menu and choose *Exit*.

Exit the TTCN Suite Editor

To close all Browsers and table editors, you can in any Browser's *File* menu choose *Exit*. The TTCN Suite will then close all Browsers, release the license and finish. If any Browser contains any modified TTCN documents, you will be prompted to save your document.

The Browser User Interface

For a general description of the user interface in SDL Suite and TTCN Suite, see chapter 1, *User Interface and Basic Operations*.

The TTCN document in the Browser contains *items*. These are:

- *Static items*, common to every TTCN document, such as the declarations part or constraints part.
- *Dynamic items* – that is TTCN objects – such as tables, groups or objects in a table, for example test case variables.

The Browser displays all the static items in the order defined in the TTCN standard. This ordering cannot be changed. For example, it is not possible to have the constraints part coming before the declarations part. Only the dynamic items – the tables – may be added and deleted. The structure is indicated by indention.

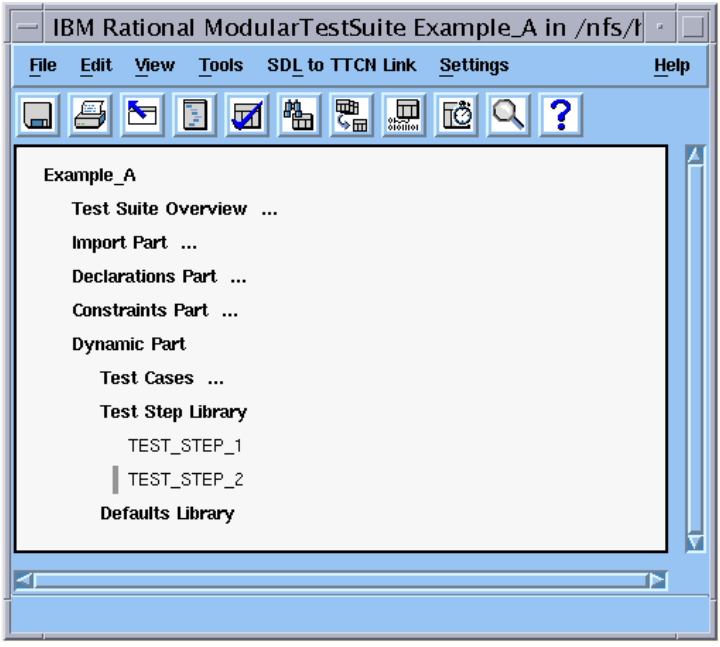

Figure 183: The the TTCN Browser window **on UNIX**

Figure 183 depicts the Browser window. The test suite overview, the import part, the declarations part, the constraints part, the test cases and the defaults library are collapsed. This is indicated by the three dots.

The dynamic part and the test step library are expanded. The test step library contains two test steps: `LT` and `UT`. `LT` has been edited but not analyzed. This is indicated by the shaded bar (gray on a color screen). The table icon indicates that `UT` is opened and the filled bar (red on a color screen) that `UT` has been analyzed and is erroneous. Items with no analysis bars have been analyzed and contain no errors.

Items in **bold** font represent the static (or structural) parts of the TTCN document and cannot be opened or edited. The items in normal font represent named TTCN tables which can be opened and edited.

Some of the static items may remain unused. For example, if *Test Case Variables* is not used it will still be displayed in the Browser. However, it will not be printed or output in the TTCN-MP format.

Controlling the Items in the Browser

Selecting Items

There is a difference between *selection* and *input focus*. Selection is an inverted item or text string. The input focus is indicated by a rectangular border surrounding the relevant item. Keyboard commands operate on the item with input focus, not the selection.

Point and click once to select a **single** item in a Browser – note that this also sets the input focus. Selecting a new item will deselect the previous item (if any).

To select **several** items, press `<Ctrl>` while selecting items. Note that the input focus is set to the last selected item. Pressing `<Ctrl>` while selecting items works in toggle mode: a selected item will be deselected and vice versa.

To select a range of items, select the first, and then press `<Shift>` and click on the last item in the range.

When clicking the **middle** mouse button, the input focus will be set to the new item. The selection will not be changed.

You can also select items by using:

- The popup menus, see "Using Popup Menus" on page 1123.
- Selector, see "Using More Complex Selections" on page 1124.
- Compare, see "Comparing TTCN Documents" on page 1137.

> **Hint:**
>
> Some of the commands in the TTCN Suite only work when a single item is selected in a Browser. Before applying such commands, it is recommended that you deselect all items before you select a single item.

Controlling What is Displayed

The *View* menu is used for deciding how much of the test suite that should be displayed in a Browser. This is useful when you work with large test suites. This menu also contains commands to access any opened Table Editor and to close all opened editors, as well as to access any loaded TTCN document.

View > Collapse

Hides all items under the marked item. A collapsed item is indicated by an ellipsis (...). A shortcut for *Collapse* is to type `<c>` without invoking the *View* menu.

View > Expand

Displays all items at the next level below the marked item. A short-cut for *Expand* is to type `<e>` without invoking the *View* menu.

View > Expand Tree

Displays all items at all levels below the marked item. A short-cut for *Expand Tree* is to type `<Shift+e>` without invoking the *View* menu.

View > Close All Editors

Closes all open Table Editors, regardless of which document they belong to.

View > Show Editor

This sub menu presents a list of all open Table Editors, in any TTCN document. By selecting an item in this list, the corresponding Table Editor is brought forward.

View > Show Document

This sub menu presents a list of all loaded TTCN documents. By selecting an item in this list, the main Browser of the corresponding document is brought forward.

Creating a Sub Browser

Sub Browsers may be created to display selected portions of a test suite. These selections may be made manually or with the Selector (see above).

This facility is useful when working with a large test suite or with items that fulfil certain criteria.

Tools > Browser

Causes a sub Browser to be displayed containing only the selected items from this Browser. There is no limit on the number of sub Browsers that may be displayed.

> **Note:**
> Closing the main Browser also closes any sub Browsers that are opened.

Editing the TTCN Document Structure

The TTCN Suite displays all the components of a TTCN document in the structured format of the Browser. Part of this structure is static and common to every TTCN document. This static structure is automatically generated when the TTCN document is first created.

To build an individual TTCN document, named tables (such as PDUs, Constraints and Behaviours) and named objects to the multi-object tables (such as Test Case Variables, PCOs and Timers) must be added to this static structure.

The *Edit* menu is used to add, delete, copy, cut, paste etc. *editable items* (i.e. groups, tables or objects in a multiple object table) in a Browser.

Adding and Inserting Items

Edit > Add

Adds a new table to the Browser or adds an object to a table in the Browser.

In the case of single-object tables, select the Browser item that "holds" the table. Choosing *Add* will add a new table to the end of the list of tables. The new table will be unnamed. Use the *Rename* command to give the table its correct name, or open the table and edit the name there.

Example 189 ––

To add a new TTCN PDU to a Browser, select the item *TTCN PDU Type Definitions* and apply *Add*.

––

In the case of multiple-object tables, select the item that is the name of the table. Choosing *Add* will add a new object to the end of the list of objects in this table. The new object will be unnamed. Use the *Rename* command to give the table its correct name, or open the table and edit the name there.

Example 190 ––

To add a new Test Case Variable to a Browser, select the item *Test Case Variables* item and apply *Add*.

––

Edit > Insert Before

Similar to *Add* but the new table (or object in a table) is inserted **before** a selected table (or selected object).

Note:

Only a single item should be selected.

Edit > Insert After

Similar to *Add* but the new table (or object in a table) is inserted **after** a selected table (or selected object).

Note:

Only a single item should be selected.

Adding and Inserting Groups

The following commands are used to add/insert new groups to the Test Case, Test Step and Default libraries.

Edit > Add Group

Adds a new Test (Case) Group, a new Test Step Group, a new Default Group in the Dynamic Part, or a new Group in Constraints Part. The new group is added at the **next level after** the selected group.

Use the *Rename* command to edit the temporary name *NoName*. Note that the trailing slash (/) is automatically added.

To add a table to a group, select the group and use the *Add* command.

Edit > Insert Group Before

Inserts a new group **before** a selected item.

Edit > Insert Group After

Inserts a new group **after** a selected item.

Adding and Inserting Compact Tables

It is possible to specify that all the Test Cases in a given group are displayed in the compact format (see Annex C, clause C.3 of ISO/IEC 9646-3). The following commands allow the insertion of compact groups in the test suite hierarchy:

Edit > Add Compact Group

Adds a compact group at the **next level after** the selected group.

Edit > Insert Compact Group Before

Inserts a compact group before a selected item.

Edit > Insert Compact Group After

Inserts a compact group after a selected item.

Sorting Items

The *Sort* command is applicable for any node that has dynamic subnodes.

Edit > Sort

The command sorts the sub-nodes in alphabetical order.

Cutting, Copying and Pasting Items

Editable items may be cut or copied to the clipboard. The contents of the clipboard may be pasted according to compatible classes, for example:

- Test Suite Parameters, Test Suite Constants, Test Suite Variables and Test Case Variables may be pasted into each other.
- TTCN ASP, PDU, Structured Type and CM Definitions may be pasted into each other and into TTCN ASP, PDU, Structured Type and CM Constraints (and vice versa).
- ASN.1 ASP, PDU, Structured Type and CM Definitions may be pasted into each other and into ASN.1 ASP, PDU, Structured Type and CM Constraints (and vice versa).
- Test Case, Test Step and Default Behaviours may be pasted into each other.

However, it is not possible to paste a Constraint for example as a Test Case Behaviour.

The *Paste* command is not available if the clipboard contains an object of an incompatible type to the selected object.

Note:

On the table row and text levels, no paste restrictions apply.

Edit > Cut

Deletes the selected items from the Browser and stores them in the clipboard.

Edit > Copy

Copies selected items from the Browser to the clipboard.

Edit > Paste Before

Pastes the contents of the clipboard before a selected item.

Edit > Paste After

Pastes the contents of the clipboard after a selected item.

Edit > Paste In

Pastes the contents of the clipboard to the end of a list of tables (or list of objects in a multi-object table).

Deleting Items

Editable items may be removed from the Browser.

Edit > Delete

Deletes selected items from the Browser.

> **Caution!**
>
> The TTCN Suite has no undo so this command is irreversible.

Browser Shortcut Keys for Navigation

The cursor and mouse may be used to set the input focus on an item in a Browser. However, you may find the following shortcut keys more useful:

- `<Down Arrow>` moves the input focus to the **next** item. This movement is not sensitive to the structure of a Browser.
- `<Shift+Down Arrow>` moves the input focus to the next item at the **same** level of indentation.
- `<Up Arrow>` moves the input focus to the **previous** item. This movement is not sensitive to the structure of a Browser.

- <Shift+Up Arrow> moves the input focus to the **previous** item at the **same** level of indentation.
- <Left Arrow> moves the input focus to the **previous** level of indentation.
- <Shift+Left Arrow> moves the input focus to the **previous** level of indentation and collapses that branch in a Browser.
- <Right> moves the input focus to the **first** item at the **next** level of indentation. If the next level is collapsed then it is automatically expanded.
- <Shift+Right Arrow> moves the input focus to the **last** item at the **next** level of indentation. If the next level is collapsed then it is automatically expanded.

Renaming Dynamic Items

The *Rename* command is used to give names to newly created Browser items that have the temporary name *NoName* or to rename existing Browser items. It is available in the popup menu for the item.

Rename

Renames the dynamic item. A text box with a cursor appears for the item. Type the new name and then press <Return>. It is also possible to copy, cut, paste and delete text.

- <Copy> or <L6> on a Sun keyboard copies selected text.
- <Cut> or <L10> on a Sun keyboard cuts selected text. <Ctrl+k> cuts text from the current position to the end of the line.
- <Paste> or <L8> on a Sun keyboard pastes text that is stored in the paste buffer. <Ctrl+y> pastes the most recently cut line at the current position.
- <Delete> or <Backspace> deletes one character to the left of the insertion point. <Ctrl+d> deletes one character to the right of the insertion point.

Note:

The TTCN Suite has no undo function. This means that <Undo> has no effect.

A shortcut for *Rename* is to type `<r>` without invoking the pop-up menu. The item with the input focus will then be renamed.

Opening a Table

A table is opened from a Browser when you double click on the specific item. Observe that this command has the additional effect of deselecting every item in the Browser. If this additional effect is undesirable, it can be inhibited by holding down `<Ctrl>` simultaneously.

In the case of single-object tables, point to the table name (e.g. Test Case name). To open a multiple-object table, point to a Browser item that is the title of the table (e.g. Test Case Variables) or to an object in the table (e.g. a Test Case Variable name).

In the case of collapsed items, point and double-click to expand the item (e.g. displaying all items at the next level below the pointed item). A double-click on a group table (regardless if it is collapsed or not) opens the group table. If the item pointed at is a leaf node that is not a table, the double-click will instead create a new item below it.

Alternatively, you may point and click once with the middle mouse button (i.e. set the input focus) and then press `<t>` to open the table. Note that the input focus can also be set with shortcut keys. See "Key and Button Bindings" on page 1163.

If a table has previously been opened, but it is for some reason hard to get at, it may be brought forward by selecting the name of the table in the submenu *Show Editor* of the menu *View*.

Printing a TTCN Document

To print a TTCN document:

- Select *Print* from the *File* menu.
  - The shortcut is `<Ctrl+P>`.

For more information, see "The Print Dialogs in the TTCN Suite" on page 333 in chapter 5, *Printing Documents and Diagrams*.

Requesting License Information

Help > License Info

The TTCN Suite consists of several tools and for running each tool it is required that the appropriate license is installed. The the TTCN Suite *License Information* dialog is used to list these licenses.

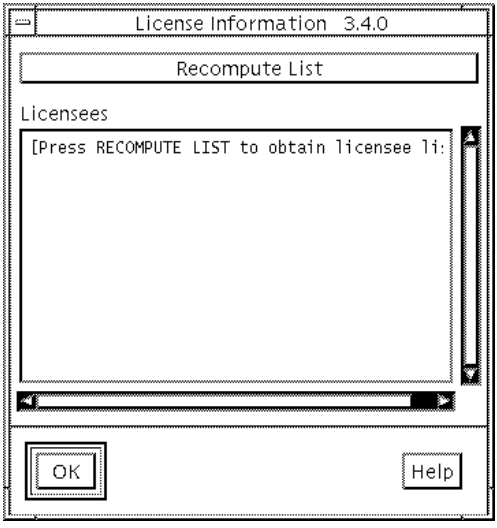

Figure 184: The Information dialog

- Clicking *Recompute List* retrieves the list of licensees and lists them in the scrollable area below.
- The *Licensees* area shows a list of licensees and the licenses available.

Using Popup Menus

Node Specific Popup Menu

This menu is shown when you point to an item in the Browser and click the right mouse button. Most of the commands are also available in the main menu bar. The commands in this menu are applied on the pointed item. Using this menu moves the input focus to the item pointed to, but does not change the selection.

Background Popup Menu

This menu is shown when you point to the background of the Browser and click the right mouse button. Using this menu does not affect the selection or the input focus.

Popup Menu Commands

The following commands in the popup menus are not available elsewhere.

Select All

Selects all items in the Browser. The same effect can be achieved by pressing `<Ctrl+/>`.

Deselect All

Deselects all selected items. The same effect can be achieved by pressing `<Ctrl+\>`.

Toggle Select

Toggles the selection state for the item. The same effect can be achieved by pressing `<Ctrl+space>`.

Toggle Select Tree

Toggles the selection state for the whole sub-tree below the item. The same effect can be achieved by pressing `<Ctrl+Shift+space>`.

Rename

Renames the item, see "Rename" on page 1120.

Using More Complex Selections

Apart from manually selecting items in the Browser, you can make more complex selections by using the Selector. These selections can then be displayed in a sub Browser.

The Selector tool is available from the Browser *Tools* menu. Like the other TTCN Suite tools, the Selector tool works on selections. The purpose of the Selector tool is to, from an existing selection, create a new selection.

With the Selector, you can make selections in three ways:

- By restricting the existing selection
- By making additions to the existing selection
- By replacing the existing selection

You can make selections by specifying restrictions on table names, restrictions on tables types and even restrictions on the contents of the tables.

Restrictions can also include the analysis status of the table, i.e. *not analyzed*, *error* and *OK*.

Selections can also be made depending on references between TTCN objects. A typical use of this feature might be to select (and perhaps later Convert to TTCN-MP) an entire Test Case, i.e. the Test Case Behaviour and all its associated declarations, constraints, Test Steps etc.

Note: UNIX only

The Selector is only available on UNIX.

Tools > Selector

Creates a new selection from a given selection. The Selector dialog is opened:

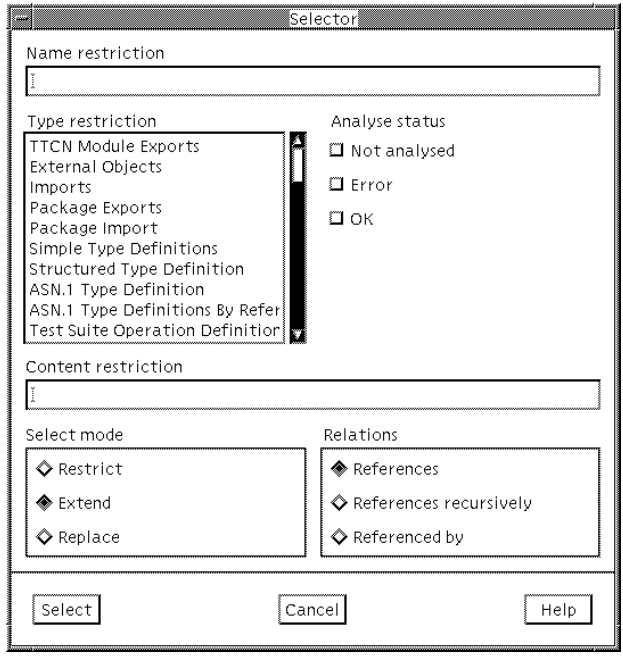

Figure 185: Selector dialog

Name Restriction

Enables the user to define the restrictions on the **identifiers** of the named TTCN tables (e.g. ASPs, PDUs, Constraints, Test Cases, Test Steps and Defaults) to be selected. This restriction is a regular expression (see "Regular Expressions" on page 1130). If the name restriction field is empty then no restrictions on the table names will apply.

Example 191 ––

The name restriction `^abc` will select all tables whose names begin with the string "abc".

––

Type Restriction

Enables the user to define the restrictions on which **kind** of TTCN tables that are to be selected. Click once to select one or more table types.

Example 192 ––

Suppose that the initial selection is the entire Dynamic Part. Choosing the table types Test Case Dynamic Behaviour and Test Step Dynamic Behaviour **together** with the name restriction `^abc` will select all test cases and test steps whose names begin with the string “abc”.

––

If no table types at all are selected then no type restrictions are assumed to apply (i.e. the same effect as selecting all table types).

Content Restriction

Enables the user to define the restrictions on the **contents** of TTCN tables that are to be selected. This restriction is a regular expression (see “Regular Expressions” on page 1130). If the content restriction field is empty then no restrictions on the contents of tables will apply.

Example 193 ––

Suppose that the initial selection is the entire TTCN document. Choosing the table type TTCN PDU Type Definition **together** with the Content restriction `^xyz` will select all TTCN PDUs which have a field beginning with the string “xyz”.

––

Select Mode

Enables the user to choose a select mode: *restrict*, *extend* or *replace*.

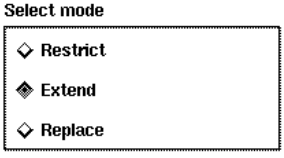

Figure 186: Selector mode

- In the *Restrict* mode the initial selection will be **reduced** to those items which fulfill the user supplied restrictions. The examples above illustrate the *Restrict* mode.

  Note that in this mode the *Relations* option is not available.

- In the *Extend* mode the initial selection will be **extended** with the items that 1) fulfill the references given by the *Relations* option and 2) fulfill the user supplied restrictions (if any).
- In the *Replace* mode items in the initial selection will be **replaced** by the items that 1) fulfill the references given by the *Relations* option and 2) fulfill the user supplied restrictions (if any).

Relations

When a TTCN document is analyzed, the TTCN Suite builds a symbol table of all the named TTCN objects that are in the TTCN document. If required, the Selector will perform a 'look-up' in this table in order to select referenced objects.

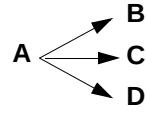
It is required that the TTCN document is analyzed before applying the Selector with the Relations option. This will ensure that the entries in the symbol table are consistent with the TTCN document on the screen.

There are three kinds of references: *References, References recursively* and *Referenced by*

- *References*

  Selects all other objects that are referenced by the initially selected objects. This new selection may be further restricted if any *Name* and/or *Type* and/or *Content* restrictions are chosen.

  In the first case, suppose that we have object A. Choosing *References* will select all the other objects, e.g. B, C and D that object A references.



Example 194 ––

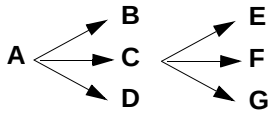
If the initial selection is a single test case and we make a type restriction of Test Step Dynamic Behaviour but no Name or Content restrictions, then choosing *Extend* and *References* will add to the current selection all the test steps (if any) that the selected test case references.

––

- *References recursively*

  Same as above except that all recursive references are also selected.

  The second case is the same as the first, except that the references are selected recursively, e.g. B, C, D, E, F and G.



Example 195 ––

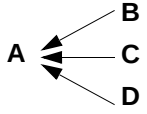
To extract an entire test, select the desired test case and apply *Extend* and *References recursively* without any other restrictions. The Selector will select the Test Case Behaviour and all its associated declarations, constraints, attached Test Steps (including any Test Steps that these Test Steps may attach), Defaults etc. The *Convert to MP* command can then be used to output this test case in TTCN-MP format.

––

- *Referenced by*

  Selects all objects that have references to the selected object. This new selection may be further restricted if any *Name* and/or *Type* and/or *Content* restrictions are chosen.

  In the third case suppose that we have object A. Choosing *Referenced by* will select all the other objects, e.g. B, C and D that reference object A.



Example 196 ––

If the initial selection is a single PDU definition, then choosing *Extend* and *Referenced by* without any other restrictions will select all the objects (e.g. constraints and behaviours) that use this PDU type.

––

Keeping and Retrieving a Selection

File > Keep Selection

Saves the current selection for later retrieval. This operation may, for example, be used when an Access application is to be applied on the TTCN document. To be able to retrieve the saved selection in another session the *Save Document* command needs to be issued after this command. For more information see "Getting Started with TTCN Access" on page 984 in chapter 21, *TTCN Access*.

File > Retrieve Selection

Retrieves the saved selection.

Searching by Using the Selector

A search pattern (regular expression) can be defined for either the complete content of a set of objects or only for the names.

A search always operates with a Browser selection as its scope. It will produce another selection as the result. By creating a sub Browser from the resulting selection a convenient environment for viewing the objects that fulfilled the search predicate is achieved.

Making Sub Browsers from Selections

Often, after making a selection, it is useful to make a sub Browser which only contains the items which are selected. This can easily be done by using the *Browser* command from the *Tools* menu of the Browser.

Example 197 ––

Applying the Selector on an entire TTCN document with the *Analyze status* option set to *error* will select all objects that have syntax and/or static semantic errors. Choosing the *Browser* command from the *Tools* menu of the Browser where the selection was applied will create a Sub-browser that only contains the error objects (including the structure needed to "glue" them together).

––

Regular Expressions

When you use the Selector or search from the Table Editor, string patterns are used for matching and searching for named objects or text strings. In UNIX terminology these patterns are called *regular expressions*. Regular expressions include symbols specifying the pattern to be searched for. Some of these symbols are:

```
\ < > ^ $ [ ] *
```

Use of these symbols in regular expressions involves a quite complicated syntax which can be very powerful. We illustrate some common uses below, but for full information we suggest that the user takes a look at the UNIX manual entry for regexp (do a *man regexp*), and look under the heading Regular Expressions.

Example 198 ----------

TTCN tables contain *fields*. Fields contain text *strings*. Text strings contain *words*.

The pattern `abc` will match all words that **include** the string “abc”, e.g. abcxyz xyzabc, xyzabcxyz, abc.

The pattern `\<abc\>` will match all **words that are exactly** “abc”. This is useful for finding TTCN identifiers embedded in strings and comments.

The pattern `^abc` will match any field that **begins** with the string “abc”, e.g. abcxyz abc, abcabc.

The pattern `abc$` will match any field that **ends** with the string “abc”, e.g. xyzabc, abc, abcabc.

The pattern `^abc$` will only match **fields containing exactly** “abc”.

The pattern `abc[1-5]$` will select all fields that end with “abc” and a single number between 1 and 5, e.g. abc1 and xyzabc4, but not abc7 or abc12.

Searching and Replacing

You specify the text to search for and the replacement text in the Table Editor, see "Searching and Replacing" on page 1176 in chapter 25, *The TTCN Table Editor (on UNIX)*. However, you can invoke the search from the Browser too and in this case, an empty Table Editor will be opened.

Edit > Find & Replace

Opens an empty Table Editor where you can specify what to search for.

Presenting Status Information

The Reporter presents status information on selected Browser items (i.e. TTCN objects) in the form of a simple list. This list can include such information as analyze status and modification dates etc. The Reporter also provides limited formatting of the list.

Reporter output may be stored to file for later use, for example printing or as input to an AWK script for further processing.

> **Note: UNIX only**
>
> The Reporter tool is only available on UNIX.

Constructing Lists with the Reporter

The Reporter tool is available from the Browser *Tools* menu.

Tools > Reporter

The Reporter tool is applied to selected items in a Browser, and presents them in the form of a simple list. Selections can either be made by using the mouse or by using the Selector tool (see "Using More Complex Selections" on page 1124).

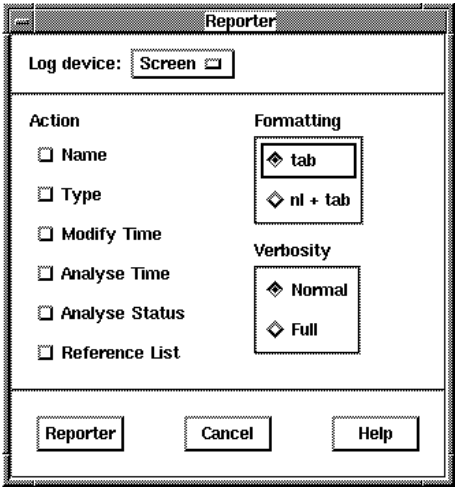


Figure 187: Reporter dialog

Log Device

Controls the log (output) device for the Reporter tool. The default value is *Screen*, but the log can be directed to a named file by choosing *File* or turn it off altogether by choosing *None*. The file extension for the reporter log is `.rpt`.

For a full description of this command see "The TTCN Suite Logs" on page 6 in chapter 1, *User Interface and Basic Operations*.

Action

The following options specify which information about each selected item shall appear in each Reporter list entry.

- *Name*

  The name of the item (e.g. ESTABLISH_CONNECTION)

- *Type*

  The type of the item (e.g. Test Step Dynamic Behaviour)

- *Modify Time*

  The date and time that the item was last modified (edited) (e.g. Thu Aug 20 13:05:55 1992).

- *Analyze Time*

  The date and time that the item was last analyzed (e.g. Thu Aug 20 13:08:35 1992).

- *Analyze Status*

  The analyze status of the item (e.g. error))

- *Reference List*

  The other objects that this object references. This information is used, for example, by the Selector when the References option is set (e.g. N_SAP:L:LT_DEFAULT:CR1:NDr:CR:CC1:NDi:CC).

Formatting

The list can be formatted using either *tab* or *nl + tab*, where *nl* stands for *new line*.

- *tab*

  In this format the components of each list entry are separated by a tab.

Example 199 ––

Part of a Reporter log showing two test steps. The list was generated using only the *Name* and *Type* option with the format option set to *tab*.

Figure 188: The TTCN Suite log for Reporter (tab)

––

- *nl + tab*

  In this format the components of each list entry each are printed on a new line. Each component, except the first component in the list entry, is preceded by a tab.

Example 200 ––

Part of a Reporter log showing two test steps. The list was generated using all the options and with the *nl + tab* format.

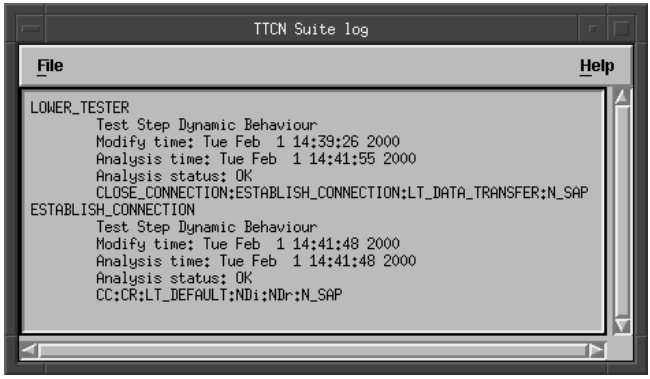

Figure 189: The TTCN Suite log for Reporter (nl+tab)

––

Verbosity

Full verbosity gives more detailed information. The following extra information is available with full verbosity:

- *Reanalysis*

  It is obvious that if the item is not OK (its analyze status), it needs to be reanalyzed. Even if the item has an OK status, the item may need to be reanalyzed since it may contain references to items which have been modified. The reporter with full verbosity will determine if the item need to be reanalyzed or not. This information is reported together with the analysis status.

- *Reference status*

  For each reference the following extra information is available with full verbosity:

  – If the reference does not exist (has been removed)
  – If it is not unique
  – If it is a named object
  – If the reference has been analyzed more recently

Revision Control

There is no integrated revision control system in the TTCN Suite. Since normal visible files are used to store the TTCN documents it is easy to integrate the TTCN Suite in a revision control system like SCCS or RCS. The `.itex` file format, being binary, is however not very suitable for that, it is better to use the TTCN-MP format to store in the revision control system.

Increased functionality is obtained if not only the TTCN-MP file is stored. The output from the Reporter contains useful information like modification dates and cross-reference lists.

By applying the following procedure whenever a check-point is desired the revision system becomes even more powerful:

1. Select the entire document.
2. Use the Convert to MP command to create a TTCN-MP file. Store it as e.g. `Test-Suite.mp`.
3. Use the Reporter, setting relevant options, to create a report. This report could now include modification date, cross-reference lists, etc. The *formatting* option *tab* should be chosen. This means that each TTCN object will occupy one line.
4. Store the log-window created by the reporter as e.g. `Test-Suite.rpt`.
5. Allow both files to be handled by the revision control system

It is now easy to obtain useful information about the difference between revisions by simply comparing the stored report files. A compare could be made using e.g. `sccs diff` (if SCCS is used).

Comparing TTCN Documents

The Compare tool is used for comparing two TTCN documents with respect to finding *similarities* that exist between them, i.e. two TTCN objects that have the same name. These objects need not necessarily be of the same type.

The Compare tool is accessed from a Browser and is applied to selections of items in that Browser.

Compare will check either only for similar names or for names **and** object type. The comparison can also include the contents of tables if required.

The Compare tool can also check the group structure of TTCN documents for similarities, i.e. it will indicate Test Group, Test Step Group and Default Group paths that are the same in both TTCN documents.

Any similarities that are found may be logged in a log file. There are three levels of log verbosity: *quiet*, *some* and *full*. Execution of the Compare tool may result in a new selection, which can be used to create a separate Browser if so wished.

One of the main uses of this tool will be to help remove conflicts from two TTCN documents prior to performing a merge operation.

Comparing by Using the Compare Tool

To use the Compare tool, you need two TTCN documents to operate on: the *destination* document and the *compare* document.

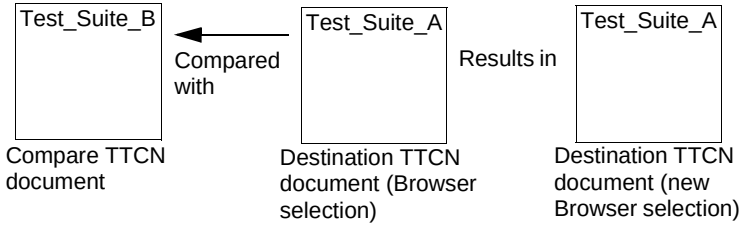

Figure 190: How Compare works

A selection from the *destination* document may be compared with the *compare* document. If any similarities are found between the two TTCN

documents this will result in the modification of the original selection in the *destination* TTCN document.

Tools > Compare

Compares a Browser selection from one TTCN document with another TTCN document with respect to similarities. Make the selection in a *destination* TTCN document Browser and call the Compare tool from the same Browser.

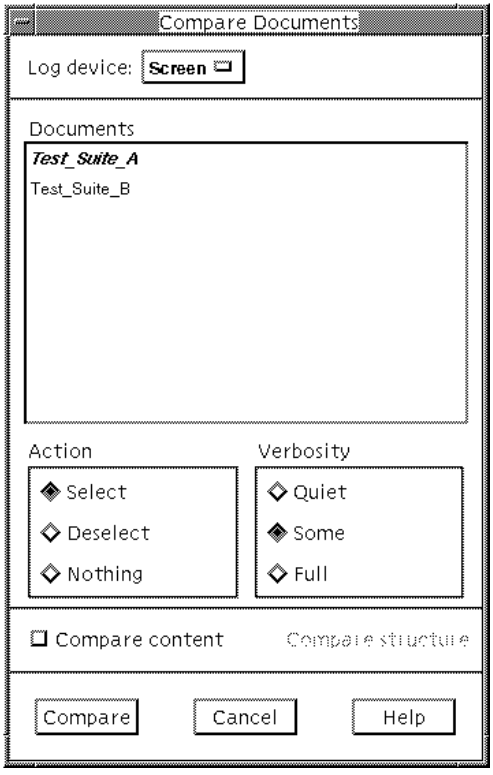

Figure 191: Compare Documents dialog

Log Device

Controls the log device for the Compare tool. The default value is *Screen*, but the log can be directed to a named file by choosing *File* or turn it off altogether by choosing *None*.

For a full description of this command see "The TTCN Suite Logs" on page 6 in chapter 1, *User Interface and Basic Operations*.

Documents

Presents a list of currently open documents. For Compare to work correctly at least two documents must be present in this list. The document name in bold italic font is the document from which the Compare tool was called, i.e. the destination document. The user must choose another document in this list, i.e. the *compare* document, in order to do a comparison.

Example 201 ––

In the dialog above the destination document is `Test_Suite_A` and hence the *compare* document may only be `Test_Suite_B`.

––

Action

Specifies the effect that the Compare operation will have on the original selection in the *destination* TTCN document.

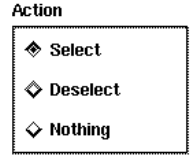

Figure 192: Compare: Action

- *Select*

  All items in the original selection that are similar to items in the compare TTCN document will **remain selected**, otherwise the items will be deselected.

In other words, the result of the Compare operation will result in a selection that shows the similarities between the destination and the *compare* TTCN documents.

- *Deselect*

  All items in the original selection that are similar to items in the compare TTCN document will be **deselected**, otherwise the items will remain selected.

  In other words, the result of the Compare operation will result in a selection that shows the differences between the TTCN documents.

- *Nothing*

  Means that the Compare operation will have no effect on the destination selection. However, the results of the Compare operation will still be recorded in the log, if this option is set.

Verbosity

Sets the verbosity level for the log file.

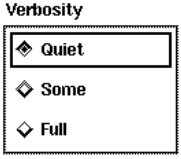

Figure 193: Compare: Verbosity

- *Quiet*

  Turns the log off. No information will be recorded in the log, even if the *Log Device* is on.

Note:

Using the *Nothing* action together with the *Quiet* option is rather meaningless!

- *Some*

  Causes the names of all identically named objects to be printed in the log.

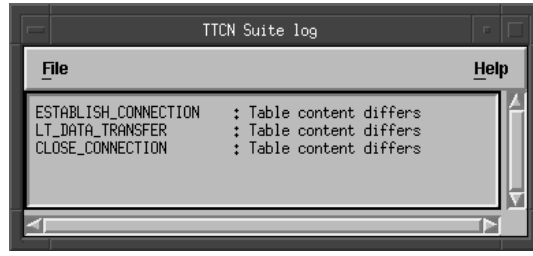

Figure 194: Compare: log (Verbosity: some)

If the *Content* switch is on, the log will also indicate that a difference has been detected.

- *Full*

  Causes the names of all identically named objects to be printed in the log. However, if the objects are of different types this will be indicated as well.

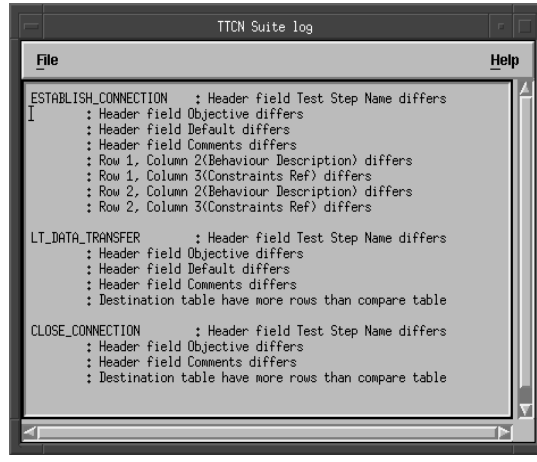

Figure 195: Compare: log (Verbosity: full)

If the *Compare Content* switch is on, the log will also indicate in detail the differences detected.

Compare Content

Extends the scope of the comparison to include the contents (down to the level of a single character) of the tables as well. Thus, two objects are considered to be identical if their names, object types and entire contents are identical. If the verbosity is full the differences are detailed.

Compare structure

Extends the scope of the comparison to include the Test Group, Test Step Group and Default Group references in the relevant behaviour tables. This option is only available when the Compare content option is chosen.

Comparing by Using itexdiff

A separate program, `itexdiff`, may also be used to quickly compare the contents of two TTCN Suite files. The tool is less powerful than the Compare tool, but it may be very useful when there is a need for quickly comparing two revisions of the same TTCN document for equality.

The program is run like:

```
itexdiff FooSuite.itex /home/user1/FooSuite.itex
```

This will test the content of the two TTCN documents for equality and report the result in a printout. To get a more elaborate compare, the `-d` switch may be added like:

```
itexdiff -d FooSuite.itex /home/user1/FooSuite.itex
```

This will give the output of running the program `diff` on the MP representation of the content of the two documents.

Running the program without any arguments will print out a terse usage message.

Using Compare Before Merging Two TTCN Documents

The Merge tool will always try to perform the merge operation, also when the two documents have conflicts. A conflict occurs if any TTCN objects in the TTCN documents have the same name.

One of the first things Merge does is to compare the two TTCN documents. Any conflicts found will be notified in the log and the Merge op-

eration will then continue. The Compare tool can be used to find and resolve the conflicts.

For a full description of this command see “Merging TTCN Documents” on page 1144.

Merging TTCN Documents

The Merge tool is used for merging one TTCN document (complete or partial) into another TTCN document.

A useful application of the Merge tool is to use the Selector tool and the Convert to MP tool to extract a complete test case (the Test Case Dynamic Behaviour together with its declarations, constraints etc.) and merge it with another TTCN document.

Preparing for a Merge

The merge tool requires that two TTCN documents are opened. We shall call them the *merge* TTCN document and the *destination* TTCN document or selection.

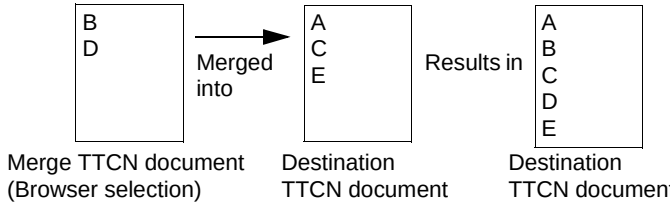

Figure 196: Shows how Merge works

The Merge tool will always try to perform the merge operation, also when the two documents have conflicts. A conflict occurs if any TTCN objects in the TTCN documents have the same name. If any name conflicts are detected, this will be logged and the conflict tables will not be merged.

One of the first things Merge does is to compare the two TTCN documents. Any conflicts found will be notified in the log and the Merge operation will then continue. The Compare tool can be used to find and resolve the conflicts.

For a full description of this command see "Comparing TTCN Documents" on page 1137.

Merging of constraint tables are handled specially. For example, a *merge* TTCN document may contain a TTCN ASP Constraint `constraint1` that refers to the type `type1`, where the `type1` Type

table is of the incompatible type TTCN PDU TypeDef. This will make the merge process insert a copy of `constraint1` as a table of type TTCN PDU Constraint instead of the original type. There are, however, limitations to this “type conversion”. The conversion will not convert an ASN.1 Constraint to a TTCN Constraint nor vice versa.

Merging Two TTCN Documents

Tools > Merge

Merges a selection into another TTCN document. Make the selection in the merge TTCN document and call the merge tool to merge the selected nodes into the destination document.

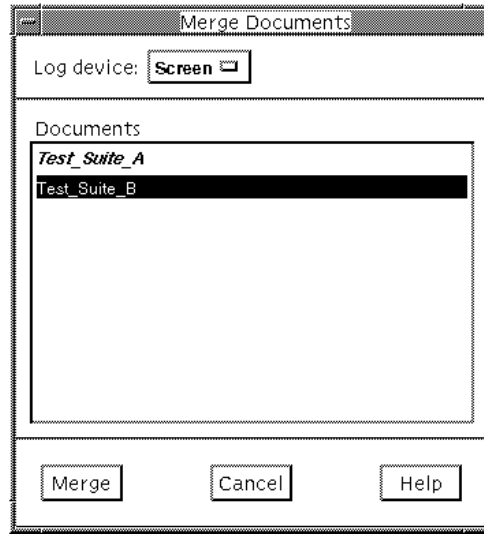

Figure 197: Merge Documents dialog

- *Log device*

  Enables the user to define the log device for the Merge tool. The default value is *Screen*, but the user can direct the log to a named file by choosing *File* or turn it off altogether by choosing *None*.

For a full description of this command see "The TTCN Suite Logs" on page 6 in chapter 1, *User Interface and Basic Operations*.

- *Documents*

  Presents a list of currently open documents. For Merge to work correctly at least two documents must be present in this list. The document name in bold italic font is the document from which the Merge tool was called, i.e. the merge document. The user must choose another document in this list, i.e. the destination document, in order to do a merge.

  In the dialog above the destination document is `Test_Suite_B` and the merge document is `Test_Suite_A`.

Creating Documents by Using the Merge Tool

The Merge Tool is not only useful when merging two documents together. It can also be used in the creation of a new document that needs to obtain some information from another document. The following procedure can be useful:

1. Create a new (empty) document.
2. Open the document containing objects that are to be copied.
3. Select the desired objects in the Browser (possibly aided by the Selector tool).
4. Merge them into the empty document.

There are also alternate ways of doing this. Copy/Paste between the documents or using the Convert to MP tool and the Convert to GR tool or the Merge from MP tool.

Merge from command line

`TTCNMerge` is a command-line tool for merging two or more TTCN documents into one.

Usage:

```
TTCNMerge <Destination TTCN Suite file> <Source file 1>
... <Source file n>
```

If `<Destination TTCN Suite file>` doesn't exist, it will be created.

Example 202 ––

```
TTCNMerge total.itex main.mp decl.mp initial.itex
```

––

The appearance order of source files in command line is significant such that files are being merged one by one in order of their appearance, and, if the table with the same name exists in several TTCN source documents, only the first appearance will be merged. All others will be skipped with warnings given.

Merging from MP Files

Use the menu choice *Merge from MP* or *Autolink Merge* for merging the content of an MP file into a TTCN document. For additional information on merging an Autolink generated MP file, see "Merging TTCN Test Suites in the TTCN Suite" on page 1398 in chapter 35, *TTCN Test Suite Generation*.

Four steps are involved in a merge from MP:

1. It first converts the MP file to a temporary GR format TTCN document, see "Importing a TTCN-MP Document" on page 1157 for details.
2. The second step is to use the Merge tool to copy all the content of the new document into the existing document, see "Merging TTCN Documents" on page 1144 for details (note the conflict resolution difference).
3. The third step is to remove the temporary document.
4. The optional fourth step is to analyze the destination document (this last step is mandatory if called under the name *AutoLink Merge*)

The Merge from MP tool requires that one TTCN document is open. We shall call it the *destination* TTCN document. This is where the merge from MP is called from.

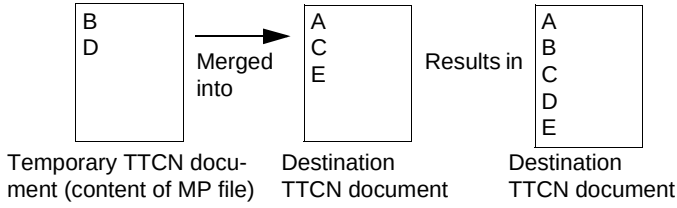

Figure 198: How a merge from MP works

Merge from MP will only work as depicted above if the two TTCN documents **do not conflict**. A conflict occurs if any TTCN object in the MP file has the same name as any TTCN object in the destination document. If such a conflict is detected, the conflicting object in the MP file will be skipped and the merge process continued.

Tools > Merge from MP

SDT Link > Autolink Merge

The menu choice *Merge from MP* in the *Tools* menu and *Autolink Merge* in the *SDT Link* menu makes it possible to merge the content of an MP file into the current TTCN document.

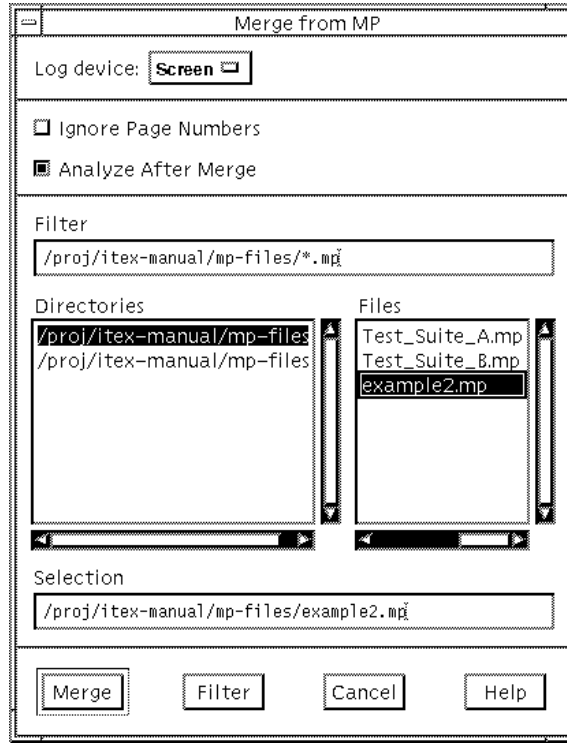

Figure 199: The Merge from MP dialog

- *Log device*

  Enables you to define the log device for the merge from MP. The default value is *Screen*, but the user can direct the log to a named file by choosing *File* or turn it off altogether by choosing *None*.

  For a full description of this command see "The TTCN Suite Logs" on page 6 in chapter 1, *User Interface and Basic Operations*.

- *Ignore Page Numbers*
  Ignore any page number information in the MP file if set.

- *Analyze After Merge*

  Runs the Analyzer on the whole destination document after successful merge if set. This option is not possible to disable when using *AutoLink Merge* and so is not displayed in that dialog.

- *Filter*

  Sets the filter for the files that will be displayed in the *Files* list. By convention TTCN-MP files are given the suffix `.mp`.

  Example 203 ––

  The name filter ***** `.mp` will cause only those files whose names end with `.mp` to be displayed, e.g. `example.mp`

  ––

- *Directories*

  Lists the directories in the current file system directory. To change directory, point to the required directory name and double-click.

- *Files*

  Lists the files (if any) that are in the current directory and which match the filter.

- *Selection*

  Displays the selected document.

- *Merge*

  Terminates the dialog and executes the merge from MP.

- *Filter*

  Updates the *Files* list according to the current filter.

Exporting a TTCN Document to TTCN-MP

TTCN-MP – the textual notation (*m*achine *p*rocessable) – can be used when you want to import a TTCN document into a non-TTCN Suite tool or make backups.

By using the menu command *Convert to MP*, you can convert a TTCN-GR document to TTCN-MP. However, note that it is also possible to simply use *Save Document As* for changing the format. The difference between the two menu commands is that *Convert to MP* gives the option to save as TTCN Suite MP or standard MP, while *Save As* produces TTCN Suite MP. How this differs from the standard MP format is described in "The TTCN Suite MP format" on page 1154.

There are no restrictions on the analysis state of the TTCN document with regards to its correctness, i.e. it will generate TTCN-MP even for TTCN documents that are neither complete nor error-free. This implies that the generated MP file may be, but is not necessarily, conformant to the standardized TTCN-MP format.

However, to ensure that a TTCN document that is output in TTCN-MP by the TTCN Suite can be read by a non-TTCN Suite tool, it is necessary to make sure that the TTCN document is correctly analyzed, that the test suite overview have been recently updated. You also have to select everything in the document before convert to MP. The TTCN Suite format option in the dialog will in most such cases have to be non-selected.

Convert to MP, invoked from the Browser, works on Browser selections, i.e. it is possible to output selected items (e.g. a single test case or just the constraints). Convert to MP will add the necessary keywords to the MP file to make it into a TTCN-MP that can be converted back into GR format.

An optional but non-standard TTCN-MP for compact tables and ASN.1 references is supported. Additional fields in dynamic tables (fields which are transferred to test suite overview tables) are also supported. This format is the recommended format for transferring TTCN document between the TTCN Suite instances, and also for making backups of the TTCN documents.

Convert to MP is accessible from the Browser *File* menu and from the Organizer *Generate* menu.

Converting to TTCN-MP in the TTCN Suite

The items selected in the Browser will be converted to TTCN-MP. Selections can be arbitrary – the TTCN Suite will add the necessary keywords to the MP file to make it into a TTCN-MP that can be converted back into GR format.

To convert an entire TTCN document, do a *Select All* and then select *Convert to MP* from the *File* menu, or invoke this operation from the Organizer. For more information, see "Convert to MP (TTCN)" on page 133 in chapter 2, *The Organizer*.

For example, to convert a complete test case, use the Selector, together with the *References recursively* option and then apply *Convert to MP* on the resulting selection.

File > Convert to MP

Presents a dialog in which you can convert the selected items to MP.

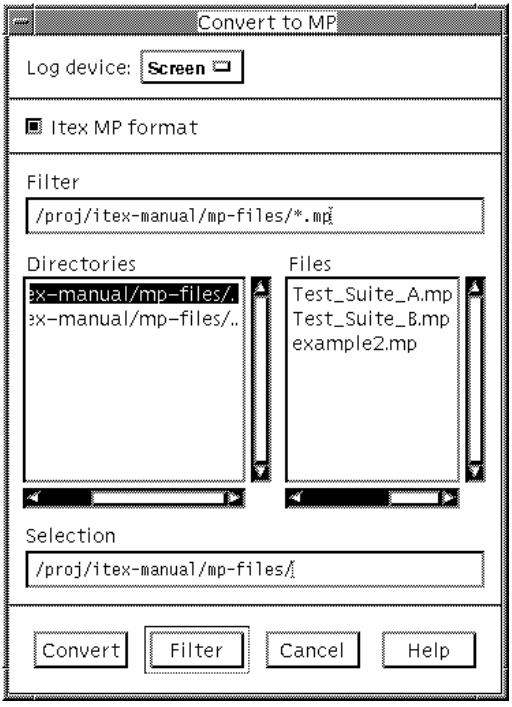

Figure 200: Convert to MP file dialog

Log Device

Controls the log device for the Convert to MP tool. The default value is *Screen*, but the log can be directed to a named file by choosing *File* or disabled by choosing *None*.

For a full description of this command see "The TTCN Suite Logs" on page 6 in chapter 1, *User Interface and Basic Operations*.

The TTCN Suite MP format

Enables the user to convert a TTCN document to a non-standard MP with the following extra information:

- *Compact tables*

Is intended for TTCN documents where the Test Case Dynamic Behaviours (i.e. compact test cases) table has been used. Check this option to generate an MP file that contains additional keywords that specifically identify compact tables. If this option is not used the TTCN Suite will output a standard TTCN-MP file where each test case in the compact test cases table is represented as a single test case (i.e. the information about the compact table is lost).

- *Additional fields in dynamic tables*

  If the *ITEX MP format* option is used, the TTCN Suite will convert the additional Selection Ref and Description fields in the behaviour tables.

- *ASN.1 reference tables*

  The additional field in ASN.1 type by reference and Test Suite Constant Declarations By Reference tables will be converted if this option is checked. These additional fields contain the definition of the ASN.1 type and value.

- *Import tables*

  The additional column fields in Import tables will also be converted if this option is checked.

Filter

Sets the filter for the files that will be displayed in the *Files* list. By convention TTCN-MP files are given the suffix `.mp`.

Example 204 ––

The name filter ***** `.mp` will cause only those files whose names end with `.mp` to be displayed, e.g. `example.mp`

––

Directories

Lists the directories in the current file system directory. To change directory, point to the required directory name and double-click.

Files

Lists the TTCN Suite TTCN-MP files (if any) that are in the current directory and which match the filter.

Selection

Displays the selected document.

Filter

Updates the *Files* list according to the filter.

Exporting by Using itex2mp

A separate program, `itex2mp`, may be used to quickly export the content of a TTCN Suite file. The generated MP format includes the TTCN Suite-specific extensions.

The program is run like:

```
itex2mp FooSuite.itex FooSuite.mp
```

This will export the content of the TTCN document into the specified MP file. You may notice that the program has the “style” of a specialized `cp` program.

Running the program without any arguments will print out a terse usage message.

Importing a TTCN-MP Document

By using the menu choice *Convert to GR* in the Organizer, you can convert a TTCN-MP document to TTCN-GR and open it in the TTCN Suite. However, note that it is also possible to simply open an MP document.

The Convert to GR tool is flexible, it will read any TTCN-MP file that has been successfully generated by the Convert to MP tool, even if the MP file only contain parts of a test suite. Convert to GR will also read TTCN-MP from other products which support TTCN assuming that this TTCN-MP follows the ISO standard.

For a full EBNF supported by the Convert to GR tool, see "The TTCN-MP Syntax Productions in BNF" on page 1574 in chapter 38, *Languages Supported in the TTCN Suite*.

An optional but non-standard TTCN-MP for converting TTCN documents that use compact tables and ASN.1 references with an explicit definition, is also supported.

Converting a TTCN Document

For a full description of this command see "Convert to GR (TTCN)" on page 136 in chapter 2, *The Organizer*.

MP File Format Problem

When converting certain TTCN documents, a problem with transferring the information (e.g. Description) in the Overview tables to the tables in Dynamic Part, may occur.

The TTCN standard allow path specifications to optionally include the document name first. This has the unfortunate effect that if the TTCN document contains a top level group with the same name as the TTCN document there is, in general, no way of knowing if the first part of the paths is a group identifier or the TTCN document identifier.

The TTCN Suite assumes that if the first part of the path is equal to the document name, it is the optional document name and, when converting, strips it away. When exporting, the document name is always added to the front of all paths. That way the TTCN Suite is always able to convert the MP files it exports. Note that ITEX 2.0 did not add the docu-

ment name at export, and therefore the problem described here may also apply when converting MP files exported by ITEX 2.0.

If the TTCN document contains top level group identifiers equal to the document name, and the TTCN Suite is unable to resolve the paths, temporarily change the document name in the MP file and change it back once inside the TTCN Suite.

Converting Fields Containing the Dollar Character

Normally the Convert to GR tool ignores the content of the fields of tables in the MP file but, to allow converting of non-BoundedFreeText fields (e.g. TS_VarValue field) with embedded dollar characters (e.g. “$”) the Convert to GR tool has been enhanced with a simple syntax checker of the fields. This has the implication that it is no longer possible to convert TTCN documents containing unmatched single or double quotes in non-BoundedFreeText fields, i.e. Convert to GR is less tolerant about syntax errors in the fields.

Generating the Test Suite Overview Tables

The TTCN Suite generates the contents of the Test Suite Overview tables (i.e. The Test Suite Structure, Test Case Index, Test Step Index and Default Index tables) and the TTCN Module Overview (i.e. The TTCN Module Structure and the index tables).

These tables are **not** editable. The extra information that they require (such as references to selection expressions and descriptions) are entered at the corresponding table rather than in the Test Suite Overview tables. This ensures consistency between the TTCN document and the contents of the Test Suite Overview.

Selection Expressions

The Test Case Dynamic Behaviour table displayed by the TTCN Table Editor has an additional field in the table header called: *Selection Ref.*

This field is used to hold the reference to a Selection Expression (if any) declared in the Test Case Selection Expression Definitions table. This reference will then appear in the *Selection Ref* column of the Test Case Index when the index is generated using the Generate tool.

If the Selection Reference needs to be edited this must be done in the relevant Test Case table and not in the Test Case Index table (which cannot be edited). The Test Suite Overview (or the TTCN Module Overview) must be re-generated in order to update any changes.

The additional *Selection Ref* field in the Test Case header is **not** printed in the TTCN-GR form. It is however exported in the TTCN Suite specific MP format.

Test Case, Test Step and Default Descriptions

The Test Case, the Test Step and the Default Dynamic Behaviour tables displayed by the TTCN Table Editor have an additional field in the table header called *Description*.

The *Description* field is used to hold the description of the behaviour table, which in many cases may simply be a copy or a shortened form of the Test Purpose or Test Step or Default Objective. This description will then appear in the Description column of the relevant index when it is generated using the Generate Overview tool.

If the Description needs to be edited this must be done in the relevant behaviour table and not in the index tables (which cannot be edited). The Test Suite Overview (or the TTCN Module Overview) must be re-generated in order to update any changes.

The additional Description field in the Test Case, Test Step and Default headers is **not** printed in the TTCN-GR form. It is however exported in the TTCN Suite specific MP format.

The Group Table

The TTCN Browser supports additional non-standard tables for groups. These tables are: the *Test Group* table, the *Test Step Group* table and the *Default Group* table. **None** of these tables are printed in the TTCN-GR form.

The Test Group table has two fields in its header that are used to hold information for the Test Suite Structure table. These fields are: *Selection Ref* and *Test Group Objective*.

The *Selection Ref* field is used to hold a reference to a Selection Expression (if any) declared in the Test Case Selection Expression Definitions table. This reference will then appear in the Selection Ref column of the Test Suite Structure when it is generated using the Generate tool.

The *Test Group Objective* field is used to hold the description of the Test Group. This description will then appear in the *Test Group Objective* column of the Test Suite Structure when it is generated using the Generate tool.

If either the Selection Reference or the Test Group Objective needs to be edited this must be done in the relevant Test Group table and not in the Test Suite Structure table (which cannot be edited). The Test Suite Overview must be re-generated in order to update any changes.

All of these fields are exported in the TTCN Suite specific MP format.

Generation of the Test Suite Overview and Indices

The Generate tool is available from the *Tools* menu in the Browser and the *Tools* menu in the Table Editor. Unlike other tools it does **not** require a selection: it always applies to the entire TTCN document and its action is the same whether it is invoked from a Browser or from a Table Editor.

Tools > Generate SO

Generates the Test Suite Overview (or the TTCN Module Overview) tables (i.e. The Test Suite Structure, TTCN Module Structure, Test Case Index, Test Step Index and Default Index tables). It makes use of the additional Group tables and the additional Selection Ref and Description fields in the behaviour tables.

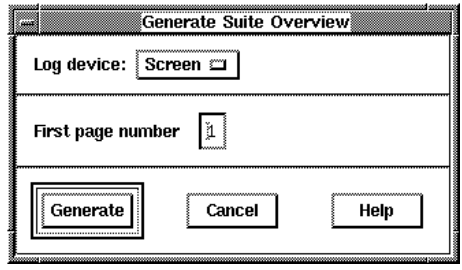

Figure 201: Generate Suite Overview dialog

- The *Log Device* option controls the log device for the Generate tool. The default value is *Screen*, but the log can be directed to a named file by choosing *File* or turn it off altogether by choosing *None*.

  For a full description of this command see "The TTCN Suite Logs" on page 6 in chapter 1, *User Interface and Basic Operations*.

- The *First Page Number* option enables setting the first page number of the TTCN document. The default value is 1.

Crash Recovery

In the event of a TTCN Suite crash, it is possible to recover up-to-the-minute changes. The auto-save content is stored in two “comma files”: `filename,s` and `filename,t`, where `filename` consists of the name of the file they are associated with and in some cases a '#' character and an integer number. The '#' character and the integer number are added when a file with the same name already exist. This can happens when a crash has occurred previously or when the Suite with the same filename is opened in another TTCN Suite Browser. The integer number is increased until a unique filename can be created. The files can be found in the designated temporary directory, usually `/var/tmp`. To be able to open those files, you need to concatenate them into a `.itex` format file. This is accomplished with the `iconcat` program.

The program is run like:

```
iconcat /var/tmp/FooSuite FooSuite-saved.itex
```

This will concatenate the content of the TTCN Suite files `/var/tmp/FooSuite,s` and `/var/tmp/FooSuite,t` into the `FooSuite-saved.itex` ITEX file. Note that the program will ignore a `/var/tmp/FooSuite` file, despite the argument syntax.

You may notice that the program has the “style” of a specialized `cp` program. Running the program without any arguments will print out a terse usage message.

Key and Button Bindings

Key	Action
Ctrl+Shift+space	Toggles the select status of all nodes in the subtree.
Ctrl+space	Toggles the select status of the focused node.
Shift+space	Set the select status of all nodes in the subtree. Remove select status on all others.
Space	Set the select status of the focused node. Remove select status on all others.
t	Open an editor on the focused node.
osfHelp	Get help on Browser.
c	Hide subtree.
e	Make children of the focused node visible.
Shift+e	Make whole subtree visible.
r	Rename the focused node.
Ctrl+c	Copy the focused node (for later paste).
Ctrl+x	Cut the focused node (for later paste).
Ctrl+v	Paste the content of the paste buffer before/above the focused node.
Ctrl+Shift+osfInsert	Add a new child to the focused node. It is placed last in the child list.
Ctrl+osfInsert	Add a new sibling before/above the focused node.
Ctrl+Meta+osfInsert	Add a new sibling after/below the focused node.
Ctrl+Shift+G	Add a new group child to the focused node. It is placed last in the child list.
Ctrl+g	Add a new group sibling before/above the focused node.
Ctrl+Meta+g	Add a new group sibling after/below the focused node.

Key	Action
F2	Move down in tree such that if we start on root node we come to “Test Cases”.
Ctrl+/	Select all nodes in browser.
Ctrl+\	Deselect all nodes in browser.
osfUp	Move focus to previous visible node.
osfDown	Move focus to next visible node.
osfLeft	Move focus to parent of the focused node.
osfRight	If the children of the focused node are hidden, make them visible. Then move focus to first child.
Shift+osfUp	Move focus to previous node at same level.
Shift+osfDown	Move focus to next node at same level.
Shift+osfLeft	Move focus to parent of the focused node, and hide the subtree.
Shift+osfRight	If the children of the focused node are hidden, make them visible. Then move focus to last child.
osfBeginLine	Move to first visible node of browser.
osfEndLine	Move to last visible node of browser.
Shift+F10	Show node popup menu.
Ctrl+Z	Run “Analyze & Stop” on page 1191 in chapter 26, *Analyzing TTCN Documents (on UNIX)*

Mouse button (OSF Names)	Action
`Button1`	Set focus to the node and set selection status of the node. Remove select status on all others.
`Ctrl+Button1`	Set focus to the node and toggle selection status of the node.
`Shift+Button1`	Set focus to the node and set selection status of the subtree. Remove select status on all others.
`Ctrl+Shift+Button1`	Set focus to the node and toggle selection status of the subtree.
`Button1` twice	Set focus to the node and start an editor on that node if that is at all reasonable. If the node is a static node, make its children visible or hidden. Remove select status on all nodes.
`Ctrl+Button1` twice	Set focus to the node and start an editor on that node.
`Button2`	Move focus to the node.
`Button3`	Show popup menu.

Chapter

25

The TTCN Table Editor (on UNIX)

This chapter contains reference information about the Table Editor, used for editing various TTCN tables.

The functionality of the Table Editor, the menus, windows and quick-buttons are described in this chapter. The TTCN Browser is described in chapter 24, *The TTCN Browser (on UNIX)*. How to analyze and find tables is described in chapter 26, *Analyzing TTCN Documents (on UNIX)*.

For an overview of the TTCN Suite, see chapter 3, *Introduction to the TTCN Suite (on UNIX), in the TTCN Suite 6.2 Getting Started*.

> **Note: UNIX version**
>
> **This is the UNIX version of the chapter. The corresponding Windows chapter is chapter 30, *Editing TTCN Documents (in Windows)*.**

Introduction to the TTCN Table Editor

The Table Editor is used for editing the various TTCN tables. It is possible to have any number of tables open for editing at any given time.

The TTCN Suite supports all of the standardized, non-compact tables that are defined in ISO/IEC 9646-3. The compact Test Case Dynamic Behaviour table (ISO/IEC 9646-3, clause C.3) and the concurrent TTCN tables are supported, as well as the modular TTCN tables to be added in the upcoming new TTCN version.

The compact tables for constraints (also in Annex C of ISO/IEC 9646-3) are not supported.

On screen, the TTCN Suite presents all tables exactly as defined in ISO/IEC 9646-3, apart from some minor additions to the regular dynamic behaviour tables (for test cases, test steps and defaults), to the compact test case dynamic behaviour table, to the ASN.1 type by reference tables, to the test suite constant declarations by reference, and to the import tables.

These changes have been introduced to aid the automatic generation of the TTCN document overview and index tables. For more information, see "Generating the Test Suite Overview Tables" on page 1159 in chapter 24, *The TTCN Browser (on UNIX)*. However, in the printed GR form the TTCN document is presented according to the ISO standard (that is, the additions are not present in the printed version).

As a visual aid, dotted lines separate rows in a table. Again, this is not present in the printed GR form.

The TTCN Suite always displays the optional comments column and comments footer of a table, even if they are empty.

You can use both menu choices and keyboard shortcuts for editing tables. It is also possible to search and replace text patterns. By providing a Data Dictionary, the Table Editor supports semi-automatic generation of send and receive statement lines. In the Data Dictionary, you select the components in a send or receive statement from lists of PCOs, types and constraints. The TTCN Suite prevents you from selecting incompatible items.

The Table Editor also shows the analysis status of the table contents.

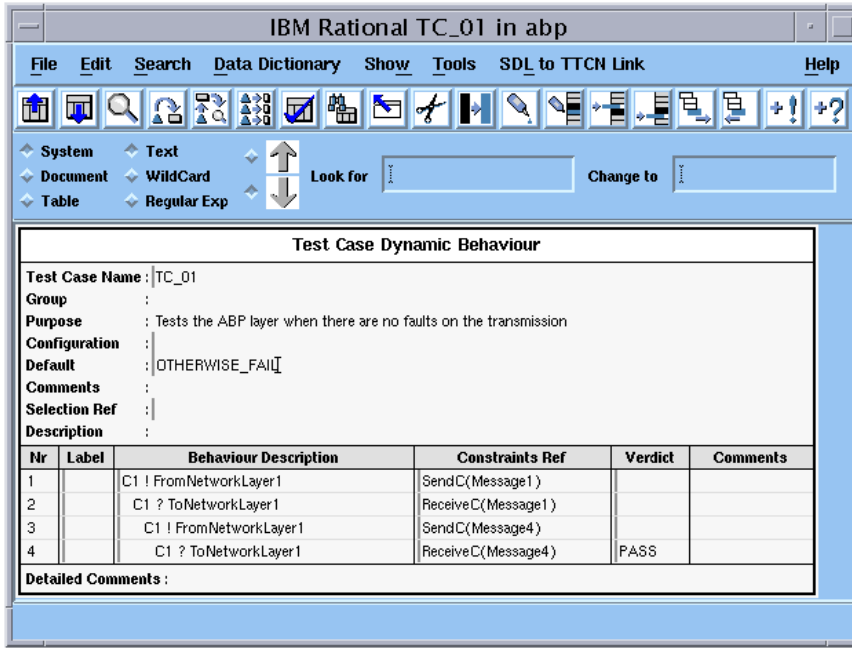

Figure 202: A TTCN Table Editor for a test case

Opening a Table

Tables are opened from a Browser when you double-click on a selected table name, or with the popup menu. For more detailed information see "Opening a Table" on page 1121 in chapter 24, *The TTCN Browser (on UNIX)*.

Renaming a Table

A table can be renamed either by using the *Rename* command in the Browser (for more information see "Renaming Dynamic Items" on page 1120 in chapter 24, *The TTCN Browser (on UNIX)*) or by editing the table name in the table itself. This choice also exists for objects in multiple-object tables.

Navigating and Editing Text in a Table

The Table Editor facilitates fast and efficient editing. The input focus determines which field is open for editing at any given time.

Setting the Input Focus

The input focus is automatically set on the name field of the table when it is opened. Reset the input focus by using the following shortcuts:

To move to:	Use this key combination:
Next field	<Tab>
Previous field	<Shift+Tab>
Next part of the table	<Ctrl+Tab>
Next field in same column	<Ctrl+down arrow>
Previous field in same column	<Ctrl+up arrow>
Field on the left	<Ctrl+left arrow>
Field on the right	<Ctrl+right arrow>

You can also use the mouse for setting the input focus. However, note that a middle-click only moves the focus to that field but it is not possible to edit text. To do this, you have to left-click in the field.

Editing Text in a Table

To edit the text in a field, you set the input focus and start typing. The table fields will expand automatically to accommodate the text and you can add a line break by simply pressing <Return>. To move the insertion point in the same field, you can either use the mouse or the following shortcuts:

To move the insertion point:	Use this key combination
Down	<Ctrl+N>, <down arrow>
Up	<Ctrl+P>, <up arrow>
Left	<Ctrl+B>, <left arrow>

To move the insertion point:	Use this key combination
Right	<Ctrl+F>, <right arrow>
To the beginning of the line	<Ctrl+A>
To the end of the line	<Ctrl+E>
Left and extending selection	<Shift+left arrow>
Right and extending selection	<Shift+right arrow>

If you initially type with very high speed, race problems may arise and you will be notified with a beep. This means that the text typed in will not appear correct in the buffer. If this happens often, you should make a brief pause between typing the first and consecutive characters.

Cut, Copy and Paste Text

To cut, copy and paste text in the fields, you can use the following shortcuts. Note that you do not use the same commands or shortcuts as when editing entire rows in a table.

To do this:	Use this key combination:
Delete one character forward	<Ctrl+D>
Cut selected text	<Cut>, <Shift+Delete>
Cut text to the end of the line	<Ctrl+K>
Copy selected text	<Copy>, <Ctrl+Insert>[a]
Paste cut or copied text	<Paste>, <Shift+Insert>
Paste the most recently cut line	<Ctrl+Y>

a. <Ctrl+Shift+Insert> also works.

Note:

The paste buffer for text is not the same as the one used for entire rows in the body of a table.

Caution!

The TTCN Suite has no undo function. This means that `<Undo>` has no effect.

Editing Rows in a Table

Rows can be added, deleted, copied, etc. in the bodies of all TTCN tables that contain more than one column. The ASN.1 tables only have a single column with a single row and therefore adding, deleting and copying rows is not applicable. However, you can still copy and paste the contents of these tables as text.

You cannot add or remove rows in table headers and footers, as the formats of these parts of a table are defined by the TTCN standard.

Selecting Rows in a Table

In the dynamic behaviour tables, you select a single row by clicking the row number.

You select a *behaviour tree* of rows by `<Ctrl+Shift>`-clicking.

You select rows in the body of a table by `<Ctrl>`-clicking. Selecting a row does not deselect other selected rows.

To deselect a row, you select it again.

> **Note:**
> Setting the input focus will also deselect all selected rows.

Cutting, Copying and Pasting Rows

Rows in a table may be cut, copied and pasted. This not only possible among tables of the same or similar type, but also across different types of tables.

Edit > Cut

Removes selected row or rows from the table and stores them in the clipboard.

Edit > Copy

Copies selected rows to the paste buffer. Any number of rows may be selected.

Note:

The paste buffer used for entire rows in the body of a table, is not the same as the one used for text.

Edit > Delete

Deletes the selected row or rows.

Caution!

The TTCN Suite has no undo so this command is irreversible.

Inserting Rows

Edit > Insert Row

Inserts a new row before a selected row. Only one row may be selected.

Edit > Insert Row After

Inserts a new row after a selected row. Only one row may be selected.

Edit > Insert Tree Header

Inserts a new Tree Header row before a selected row. Only one row may be selected. This command only works in dynamic behaviour tables.

Edit > Insert Tree Header After

Inserts a new Tree Header row after a selected row. Only one row may be selected. This command only works in dynamic behaviour tables.

The <Ins> Key

The `<Ins>` key (on the right-hand keypad) can be used for inserting rows. If you press this key while input focus is in the header or footer of a table, a new row is appended after the **last** row in the body of the table. If the input focus is set on a field in the body of the table, `<Ins>` will

insert a new row **after** the field that has the input focus. The input focus will be transferred to the corresponding field in the new row.

Indenting Rows in Behaviour Descriptions

TTCN *behaviour* tables include a number of commands and shortcut keys that simplify indenting behaviour lines.

> **Caution!**
>
> Do not use the <Tab> character to represent indentation in behaviour trees.

Edit > Increase Indent

Increases the indentation of selected behaviour lines by one position. This command can only be used to indent behaviour lines.

- Keypad <+>
  Pressing <+> (*Plus*) on the right-hand keypad (the normal <+> key does not have this effect) will indent the field that currently has the input focus.
- <Ctrl> + Keypad <+>
  Pressing <Ctrl> together with the *keypad* <+> key will cause **selected** behaviour lines to be indented one position, i.e. it has the same effect as the *Increase Indent* command.
- <Shift> + Keypad <+>
  Pressing <Shift> together with the *keypad* <+> key will cause an entire **branch** in the behaviour tree to be indented one position.

Edit > Decrease Indent

Decreases the indentation (i.e. *undent*) of the selected rows by one position. This command can only be used on behaviour lines.

- Keypad <->
  Pressing <-> (*Minus*) on the right-hand keypad (the normal <-> key does not have this effect) will undent the field that currently has the input focus.

- <Ctrl> + Keypad <->
  Pressing <Ctrl> together with the *keypad* <-> key will cause **selected** behaviour lines to be undented one position, i.e. it has the same effect as the *Decrease Indent* command.

- <Shift> + Keypad <->
  Pressing <Shift> together with the keypad <-> key will cause an entire **branch** in the behaviour tree to be undented one position.

Selecting Branches in Behaviour Descriptions

TTCN *behaviour* tables include the following short-cut key that simplifies the task of selecting behaviour lines.

- <Shift+Ctrl> + Left Mouse Button
  Pressing <Shift+Ctrl> together with the left mouse button while the cursor is pointing to a behaviour line, will select that behaviour line and all the subsequent behaviour lines that are in the same branch of the behaviour tree.

Showing the Indentation Level

Show > Show Indent

Causes the indentation level of behaviour lines to be displayed in the line number column of behaviour tables. Choosing this command again will cause the display to revert to line numbering.

Searching and Replacing

From the Table Editor, you can search for and replace text, either on system, document or table level. You specify the search in the search bar of the Table Editor and start the search (and replace) from menu choices in the *Search* menu.

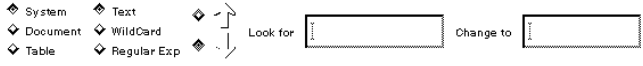

Figure 203: The TTCN Table Editor search bar

Specifying Search and Replace Settings

Delimiting the Scope of Search

You can search for text on three levels:

- *System* means all documents of the associated document – except for any Flat View document – or only the associated document if it is a Flat View.
- *Document* means the associated document only.
- *Table* means the current table only.

Selecting the Type of Search

There are three types of search patterns:

- *Text* means ordinary literal strings.
- *Wildcard* means a pattern with * and ?.
- *Regular Exp* means regular expression.

  See also "Regular Expressions" on page 1130 in chapter 24, *The TTCN Browser (on UNIX)*.

Selecting the Search Direction

The search direction can be forward (down arrow) or backward (up arrow).

Specifying the Text to Search For

You specify the text to search for in the *Look for* field. If you search for text using a regular expression, you will be notified if you try to use an incorrect regular expression.

Specifying the Replacement Text

You specify the replacement text (or replacement pattern, if the type of search is regular expression) in the *Change to* field.

If you search and replace using regular expressions, the replacement pattern must be compatible with the search pattern. If it is not, you will be notified.

Something important to note about regular expressions, is that the actual replacement text is a result of a combination of the search pattern, the match found and the replacement pattern. This means that the actual replacement text may not literally match the text in the *Change to* field. However, the actual replacement text will be presented in the status bar when you start searching and a match is found.

Starting the Search and Replace

Search > Search

Starts the search from the current position. If you search in the current table, selected text will be skipped. If the Table Editor is empty, the search will start from the beginning or end of the document or system, depending on the scope and direction that you have specified.

Search > Replace

Replaces currently selected text with the replacement text. If you searched using regular expressions, the replacement text will be presented in the status bar when a match is found.

You can also replace manually selected text. This only requires that *Text* or *Wildcard* is selected and that the *Change to* field contains some text. Note that you cannot manually make an empty selection, but it is possible to search and find an empty match that you can replace.

Search > Proceed

Searches for and replaces text sequentially. If text is selected, it will be replaced and after that the search will proceed.

Search > Replace All

Replaces selected text and then continues the search and replace from the current position. If the Table Editor is empty, the search will start from the beginning or end of the document or system, depending on the scope and direction that you have specified. The number of replacements will be presented in the status bar.

Exporting and Importing Objects

Generate Exports and *Generate Import* assist in the use of the Modular TTCN feature of exporting and importing objects to and from other documents.

Tools > Generate Exports

Fills the TTCN Exports table with rows that provide access to the objects of the current document. Only rows that are not already present will be added (at the end of the table), so it is supported to repeat this operation at a later time to detect if any object has been added since the last time. *Generate Exports* is only available when the Table Editor contains a TTCN Exports table.

Tools > Generate Import

Fills the Import table with rows that enables access to the objects of the document to import from. Only rows that are not already present will be added (at the end of the table), so it is supported to repeat this operation at a later time to detect if any object has been added since the last time. *Generate Import* is, naturally, only available when the Table Editor contains an Import table.

Browsing in the Table Editor

With the *Previous Table* and the *Next Table* commands, you can easily browse the contents of the TTCN document.

File > Previous Table

Replaces the table shown in the Table Editor with the previous table in the document. To open the table five tables before the current, use `<Ctrl>` + *Previous Table*.

File > Next Table

Replaces the table shown in the Table Editor with the next table in the document. To open the table five tables after the current, use `<Ctrl>` + *Next Table*.

See also "Context Sensitive Popup Menu" on page 1185 and "Finding Tables by Name" on page 1207 in chapter 26, *Analyzing TTCN Documents (on UNIX)*.

Generating Behaviour Statements

In TTCN *behaviour* tables it is possible to get lists of user defined objects (e.g. constraints, timers etc.). Through these lists, you can generate a statement.

When you invoke the following commands, a row in the table should have the input focus.

Data Dictionary > Add Send Statement

Generate a Send statement by selecting a PCO, a type and a constraint.

This functionality requires that the TTCN document is analyzed. The PCOs, types and constraints with major reference problems or missing type references will not be presented in these lists.

Each list is split in two parts. The upper part contains the items corresponding to the selected items in the other lists. The lower part contains the rest of the items.

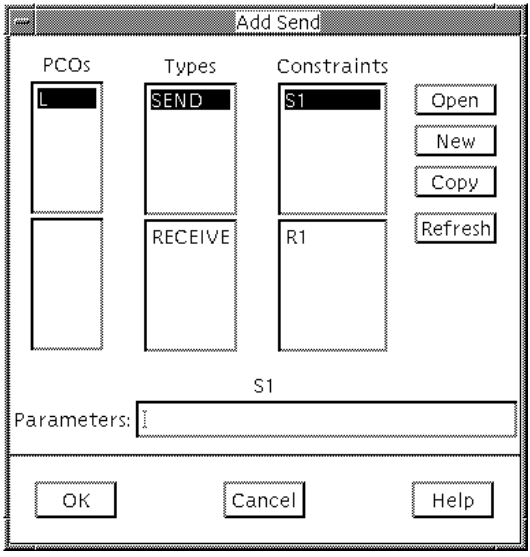

Figure 204: Add Send statement dialog (receive is analogous)

- *PCOs*

  Select a PCO or CP in this list and the *Types* and *Constraints* lists will be split accordingly.

- *Types*

  Select an ASP, PDU or CM type in this list and the corresponding constraints and *PCOs* lists will be split accordingly.

- *Constraints*

  Select a constraint in this list and the corresponding Types and PCOs will be split accordingly.

- *Open*

  The selected constraint will be opened.

- *New*

  A new constraint of the selected type is created. The new constraint will be opened.

- *Copy*

  A new constraint which is a copy of the selected constraint is created. The new constraint will be opened.

- *Refresh*

  Recompute the contents of the lists and re-display the dialog. The selection will be preserved.

- *Parameters*

  If the selected constraint has a parameter list, an actual parameter list is specified here.

- *OK*

  A Send statement is generated with the selected PCO (or CP), type and constraint.

Data Dictionary > Add Receive Statement

Generate a Receive statement by selecting a PCO, a type and a constraint.

A dialog which is analogous with *Add Send Statement* will be displayed.

Data Dictionary > Add StartTimer Statement

Generate a StartTimer statement by selecting a timer.

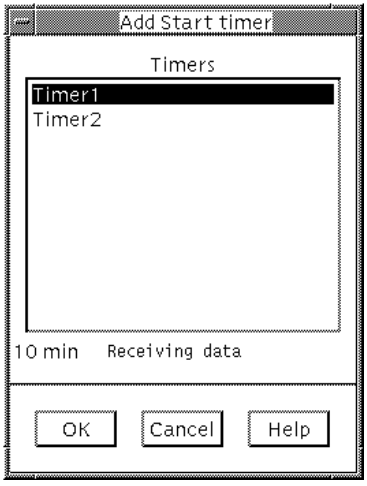

Figure 205: Add StartTimer Statement dialog

- When *OK* is clicked, a StartTimer statement is generated with the selected timer.

Data Dictionary > Add CancelTimer Statement

Generate a CancelTimer statement by selecting a timer.

A dialog which is analogous with *Add StartTimer Statement* will be displayed.

Data Dictionary > Add Attach Statement

Generate an Attach statement by selecting a test step and specifying an actual parameter list (if the test step has a formal parameter list).

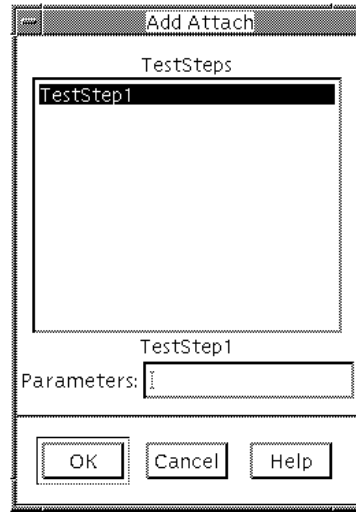

Figure 206: Add Attach Statement dialog

Data Dictionary > Add Timeout Statement

Generate a Timeout statement by selecting a timer.

A dialog which is analogous with *Add StartTimer Statement* will be displayed.

Reverting a Table

File > Revert

Causes all edits to the table **since it was last opened** to be discarded. In other words, the contents of the table are restored to what they were at the point when the table was opened.

This gives the TTCN Suite a **limited** undo capability. Note that the analyze status of the table may be set to *not analyzed* by this command.

Creating a New Constraint Table

The *Create Constraint* and *Copy Constraint* commands, facilitate the creation of Constraint tables:

Tools > Create Constraint

Creates a new Constraint table – related to the Type table currently shown in the Table Editor – in a new Table Editor window.

If you use `<Ctrl>` + *Create Constraint*, the new Constraint table will instead be shown in the current Table Editor.

Tools > Copy Constraint

Creates a new Constraint table – that is an exact copy of the Constraint table currently shown in the Table Editor – in a new Table Editor window.

If you use `<Ctrl>` + *Copy Constraint*, the new Constraint table will instead be shown in the current Table Editor.

Generating the Test Suite Overview Tables

The generation of Test Suite Overview Tables is described in "Generating the Test Suite Overview Tables" on page 1159 in chapter 24, *The TTCN Browser (on UNIX)*.

Using Popup Menus

The background popup menu is accessible when you click the right mouse button. When you click the right mouse button and <Ctrl>, the context sensitive menu will be available.

Context Sensitive Popup Menu

The context popup menu contains only one operation, *Find Table*, but in addition it also contains some of the content of the table to be opened by this Find Table operation. The identifier to use in the Find Table operation is retrieved from the field content under the mouse pointer when the context menu was invoked.

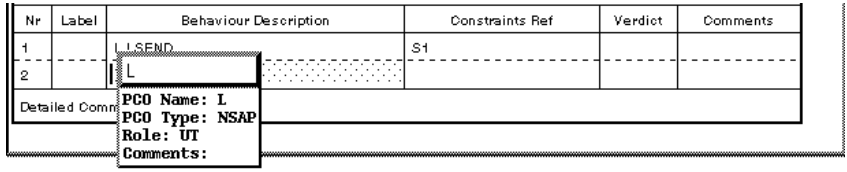

Figure 207: Example use of the TTCN Table Editor context popup menu

Background Popup Menu

The background popup menus are available in all the TTCN Suite tables but the appearance differs in accordance with the applicable operations. The popup menus in synchronized behaviour tables and desynchronized behaviour tables have a totally different appearance and will be described below:

Synchronized Behaviour Tables

If the Table Editor contains a behaviour table which is synchronized, the popup menu will display the same menu entries as the *SDT Link* menu. For an explanation of *synchronized* and the commands in the *SDT Link* menu see chapter 35, *TTCN Test Suite Generation*.

Desynchronized Behaviour Tables

If the Table Editor contains a behaviour table which is **not** synchronized, the popup menu will have a different appearance than in the previous case.

The popup menu will contain a sub menu containing all the menu entries of the *Data Dictionary* pull-down menu. It will also contain the following entries:

Cut Focused Row

Removes the focused row from the table and stores it in the clipboard.

Copy Focused Row

Copies the focused row to the paste buffer.

Paste Before Focused Row

Pastes the contents of the paste buffer **before** the focused row.

Delete Focused Row

Deletes the focused row.

Increase Indent

Increases the indentation of the **focused** behaviour line by one position.

Decrease Indent

Decreases the indentation of the **focused** behaviour line by one position.

Increase Sub Tree Indent

Increases the indentation of an entire **branch** in the behaviour tree by one position starting from the **focused** row.

Decrease Sub Tree Indent

Decreases the indentation of an entire **branch** in the behaviour tree by one position starting from the **focused** row.

Insert Row After

Insert a new row after the **focused** row.

Show Error Message

Displays the analysis status message (if any) of the **focused** field.

Find Table

Finds a named table.

Key and Button Bindings

Some bindings operate on the body rows as if they were organized as a tree (work only in the dynamic part of the TTCN document). The indentation level defines the tree structure.

Key	Action
`osfUp`	Move focus to a neighbor field.
`osfDown`	Move focus to a neighbor field.
`osfRight`	Move focus to a neighbor field.
`osfLeft`	Move focus to a neighbor field.
`Ctrl+osfUp`	Move focus to a neighbor field even when editing.
`Ctrl+osfDown`	Move focus to a neighbor field even when editing.
`Ctrl+osfRight`	Move focus to a neighbor field even when editing.
`Ctrl+osfLeft`	Move focus to a neighbor field even when editing.
`osfInsert`	Insert a new row, after focused row if already in body, otherwise last in body.
`osfHelp`	Get help on Table Editors.
`Ctrl+Z`	Run "Analyze & Stop" on page 1191 in chapter 26, *Analyzing TTCN Documents (on UNIX)*
`Ctrl+S`	Search forward with the current settings
`Ctrl+R`	Search backward with the current settings
`character keys`	Start editing field and then apply key.
`Delete`	Start editing field and then apply key.
`...`	Start editing field and then apply key.
`Tab`	Move focus to a neighbor field.
`Shift+Tab`	Same as `<Tab>` but in the opposite direction.

Key	Action
Ctrl+Tab	Navigate in the tool bar, the search bar, the scroll bars and the table
Ctrl+Shift+Tab	Same as <Ctrl+Tab> but in the opposite direction
Ctrl+space	Toggle selection of focused row
KP_Add	Increase indentation level of focused row
Ctrl+KP_Add	Increase indentation level of selected rows
Shift+KP_Add	Increase indentation level of focused subtree
Ctrl+Shift+KP_Add	Increase indentation level of subtree of single selected row
KP_Subtract	Decrease indentation level of focused row
Ctrl+KP_Subtract	Decrease indentation level of selected rows
Shift+KP_Subtract	Decrease indentation level of focused subtree
Ctrl+Shift+KP_Subtract	Decrease indentation level of subtree of single selected row
Ctrl+Shift+osfUp	Move focus to previous row at same indentation level
Ctrl+Shift+osfDown	Move focus to next row at same indentation level
Ctrl+Shift+osfRight	Move focus to last child row of focused row
Ctrl+Shift+osfLeft	Move focus to parent of focused row

Mouse button (OSF names)	Action
Button1	Set focus to the field, and start editing.
Button2	Move focus to the field.
Ctrl+Button1	Toggle selection status of the row
Ctrl+Shift+Button1	Toggle selection status of the subtree with the row as root, move the focus to the field under pointer

Chapter

26

Analyzing TTCN Documents (on UNIX)

This chapter contains a reference manual to the Analyzer in the TTCN Suite. A description of the *Find Table* command is also included. It can, for example, be used when you want to find erroneous tables that are displayed in the Analyzer log.

The TTCN Browser and the TTCN Table Editor are described in chapter 24, *The TTCN Browser (on UNIX)* and chapter 25, *The TTCN Table Editor (on UNIX)* respectively.

See chapter 3, *Introduction to the TTCN Suite (on UNIX), in the TTCN Suite 6.2 Getting Started* for an overview of the TTCN Suite tool-set.

> **Note: UNIX version**
>
> **This is the UNIX version of this chapter. The Windows version is chapter 31, *Analyzing TTCN Documents (in Windows)*.**

The TTCN Analyzer

The TTCN Analyzer in the TTCN Suite does a complete syntax check on both TTCN and ASN.1 (as it is used in TTCN). The Analyzer also performs a number of static semantic checks, mainly the uniqueness and existence of identifiers.

For implementation reasons, the Analyzer does not exactly follow the TTCN standard – some syntax restrictions and relaxations apply. These differences will not affect the vast majority of users, but for reference they are documented together with the standard syntax in chapter 38, *Languages Supported in the TTCN Suite*. This chapter also includes the static semantics supported by the TTCN Suite.

During analysis, the TTCN Suite compiles an extensive symbol table containing all named objects in the TTCN document and the references between them. This symbol table is used not only during the static semantic checks, but also by tools such as the Selector tool and the Compare tool.

The Analyzer can be called from various tools: from the Organizer, from a Browser, or from a Table Editor. It is possible to analyze an entire TTCN system, a whole TTCN document or just selected portions of a TTCN document (e.g. a single test case or all the PDU definitions).

The Analyzer considers a TTCN system to not contain any Flat View document, so it needs to be explicitly applied in order to analyze the flat view.

Using the Analyzer from the Organizer

Invoking the Analyzer from the Organizer is described in "Analyze TTCN" on page 118 in chapter 2, *The Organizer*.

Using the Analyzer from a Browser

The Analyzer works either on the entire TTCN system or on selected items in the Browser it is applied on. Selections can either be made by using the mouse or by using the Selector tool (see "Using More Complex Selections" on page 1124 in chapter 24, *The TTCN Browser (on UNIX)*.

Selections can be arbitrary – the TTCN Suite will analyze each selected item independently.

To analyze an entire TTCN document, do a *Select All* in the TTCN document browser and then apply the Analyzer. Alternatively apply the Analyzer on the TTCN document in the Organizer (see "Analyze TTCN" on page 118 in chapter 2, *The Organizer*).

Tools > Analyze

Conducts a syntax and static semantic check on the TTCN system or on the selected items (tables) in a Browser.

If an item is analyzed as incorrect, this will be recorded as an error message in the Analyzer log. Erroneous items are indicated by a black analysis bar in the Browser. On a color display this bar will be red.

Showing Progress

The Analyzer will, if invoked for a document or a whole system, display the progress made in the relevant Browser status window. This mechanism also provides the means to abort the analysis while it is running. Aborting is accomplished by clicking in the status window.

Tools > Analyze & Stop

Conducts a syntax and static semantic check on the TTCN system or on the selected items (tables) in a Browser but stops on the first found error and shows the table containing that error in a Table Editor.

- To execute this command via the quick-button, `<Ctrl>` must be pressed.

Using the Analyzer from a Table Editor

When used from the Table Editor the Analyzer will be applied to the contents of that particular table.

Tools > Analyze

Conducts a syntax and static semantic check on the table contents.

If a field in a table is analyzed as incorrect this will be recorded as an error message in the Analyzer log. Erroneous fields are indicated by a black status bar and the field is shaded grey (red on a color display).

Tools > Analyze & Stop

Conducts a syntax and static semantic check on the TTCN system but stops on the first found error and replaces the table in the Table Editor with the table containing the found error.

- To execute this command via the quick-button, `<Ctrl>` must be pressed.

Note:

When using the Table Editor, the *On Field* menu choice in the *Help* menu displays the TTCN BNF syntax applicable for the relevant field.

The *Analyzer* Dialog

The Analyzer uses the same dialog when started either from a Browser or a Table Editor:

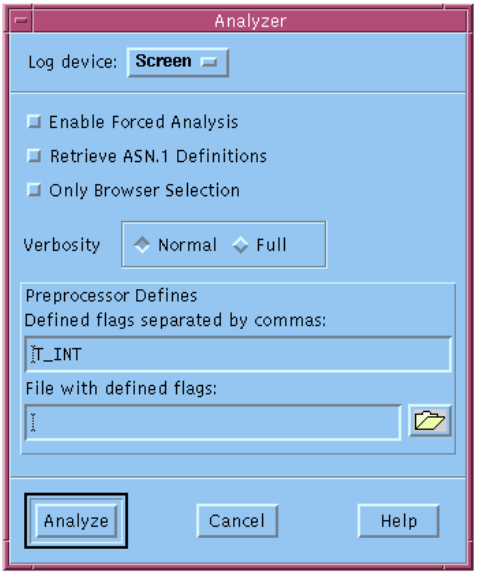

Figure 208: Analyzer dialog

Log Device

This option controls the log device for the Analyzer. The default value is *Screen*, but the log can be directed to a named file by choosing *File* or turned off altogether by choosing *None*.

For a full description of this command see "The TTCN Suite Logs" on page 6 in chapter 1, *User Interface and Basic Operations*.

Enable Forced Analysis

Indicates that all selected items are going to be analyzed and no item will be skipped. An item is normally skipped if it is OK.

Retrieve ASN.1 Definitions

Indicates that the definitions of encountered ASN.1 references should be retrieved. An ASN.1 definition is retrieved if this option is set or if the definition has not been fetched before.

Only Browser Selection

Check this item if the analysis shall be restricted to the Browser selection (this option is not applicable if started from a Table Editor).

Verbosity

Full verbosity gives more detailed information. The following extra information is available with full verbosity:

- Processing Cyclic references

  The items which will be left with incorrect references and incorrect analyze status are listed.

- Detect unused objects

  If applied on a complete test suite without finding any errors, an additional search for unused objects is performed.

Defined flags

The flags defined for the TTCN Suite preprocessor are separated by commas (see "TTCN Suite Preprocessor" on page 1205).

File with defined flags

This field can be used to point to a file with flags defined for the TTCN Suite preprocessor. Use comma (“,”) to separate the flags in this file.

Error Messages

Errors detected during analysis are recorded in the log. For the fields in the header of a table the error messages have the general format:

```
==================================
Table name and table type
Field type 1
Error message
Field type 2
Error message
:
:
Field type n
Error message
==================================
```

Example 205 ––

An error found in the Default Name (identifier) field of the Default Dynamic Behaviour called UT_DEFAULT:

```
==========================================
Analysis messages in table: UT_DEFAULT of type:
Default Dynamic Behaviour
 Default Name:
The referenced identifier UPPER_PCO is not declared.
UT_DEFAULT (p : UPPER_PCO)
----------------^
==========================================
```

––

In the body of a table (where the field type name does not uniquely define a field) the row number is also included:

- Row number
- Body type
- Error message

Example 206 ––

Errors found in a Test Step table header (the Default field) and in the body (rows 1 and 2 of the Behaviour Description):

```
==========================================
```

```
Analysis messages in table: ESTABLISH_CONNECTION of
type: Test Step Dynamic Behaviour
 Default:
Mismatched number of parameters: is 1, should be 0.
   Row: (#1)
      Behaviour Description:
The referenced identifier CR is of wrong type.
UPPER_PCO ! CR
------------^
   Row: (#2)
      Behaviour Description:
The referenced identifier CC is of wrong type.
UPPER_PCO ? CC
------------^
==========================================
```

Showing Error Messages

It is possible to display the Analyzer error message (if any) that is associated with the field in a table that has the current input focus. To do this, select *Error Messages* from the Table Editor *Show* menu.

Resolving Forward References

During analysis, the TTCN Suite does two main tasks:

- It checks the **syntax** of the abstract TTCN document.
- It checks some of the **static semantics** of the TTCN document.

The syntax of TTCN is defined in ISO/IEC 9646-3 Annex A as a list of BNF productions or rules. See also "The TTCN-MP Syntax Productions in BNF" on page 1574 in chapter 38, *Languages Supported in the TTCN Suite*. The TTCN Suite checks all these rules except for a very few minor deviations; for more information, see "The Restrictions in the TTCN Suite" on page 1570 in chapter 38, *Languages Supported in the TTCN Suite*). If a rule is not followed in the TTCN document then this will be reported as an error by the Analyzer.

The static semantic rules of TTCN are also defined in Annex A of ISO/IEC 9646. These are in the form of text statements which **limit** the use of some of the syntax rules, usually in a specific context. "TTCN Static Semantics" on page 1603 and "ASN.1 Static Semantics" on page 1619 in chapter 38, *Languages Supported in the TTCN Suite* describe the static semantics which are controlled by the Analyzer. The static semantics currently supported are mainly of the following types:

- Identifiers (names) are checked for uniqueness with respect to the scoping rules defined in ISO/IEC 9646-3
- The existence of referenced TTCN objects (e.g. a Test Step) from another TTCN object (e.g. Test Case) is verified
- Type control and type restriction control

In order to achieve this, the Analyzer constructs a symbol table of all the named TTCN objects that it finds during analysis, e.g. variable names, type identifiers, tables, etc.

This symbol table is used by some of the other tools, such as the Selector and the Reporter. This explains why it is necessary to ensure that the TTCN document is analyzed **before** applying these tools – the symbol table is updated each time the TTCN document is analyzed.

It is important to note that TTCN allows *forward reference*s. For example a Test Step may attach another Test Step that is declared **later** on in the TTCN document, that is, the referenced (i.e. attached) Test Step, appears **after** the Test Step that has done the attach.

The Analyzer has a feature called *back-pass* designed to resolve forward references. The back-pass is automatically invoked at certain points in the analysis process.

Forward references usually appear in the context of ASP/PDU definitions, constraints and as the result of attachment statements in behaviour trees. This is the reason that the Analyzer does not traverse the items to be analyzed in exactly the listed order. The Analyzer order deviates from the listed order in a few places:

- Items in the PDU Type Definitions sub-tree are analyzed before items in the ASP Type Definitions sub-tree.
- Items in the PDU Constraint Declarations sub-tree are analyzed before items in the ASP Constraint Declarations sub-tree.
- Items in the Defaults Library sub-tree are analyzed before items in the Test Step Library sub-tree and those are analyzed before items in the Test Cases sub-tree.
- Items in the Declarations Part, Constraints Part and Dynamic Part are analyzed before any items in the Import Part (where applicable) and overviews.

ASN.1 External Type/Value References

References to ASN.1 definitions in external ASN.1 modules can occur in the following four TTCN tables:

- Test Suite Constant Declarations By Reference
- ASN.1 Type Definitions By Reference
- ASN.1 ASP Type Definitions By Reference
- ASN.1 PDU Type Definitions By Reference

In these tables there are three important fields to consider:

- *Module Identifier* (set by user)
  The name of the ASN.1 Module. This should be the real name of the model, i.e. the name stated inside the module itself.
- *Type Reference/Value Reference* (set by user)
  This is the name of the desired type (or value).
- *Type Definition/Value* (set automatically when fetched)
  This is the field where the fetched type definition/value is copied into.

The term *definition* is used below both to denote an ASN.1 type definition and an ASN.1 value.

When an ASN.1 reference is analyzed, the referred definition must be available to the Analyzer. In the pro formas for this kind of reference in the TTCN Suite, there is an extra column where both the definition and the parse tree is stored.

Since the ASN.1 module is accessible from the Organizer the Analyzer can fetch the definition. If the Analyzer encounters any reference to a type/value, the definition is fetched, given the type/value name and the module identifier, and copied into the external field before the field is analyzed. The operation of fetching the definition of the reference is controlled by an option in the Analyzer dialog. Important to note is that the fields *Module Identifier* and *Type/Value Reference* are not parsed. This means that if a change is made in either of these two fields, the row will not be analyzed and thus no fetching will be made. The solution to this is to set the *Enable Forced Analysis* in the Analyzer dialog when altering a reference. See "The Analyzer Dialog" on page 1192.

To use external ASN.1 module references in the TTCN Suite, information about the referred ASN.1 module must be available. That is why the ASN.1 module must appear in the Organizer and a *dependency* must be defined from the ASN.1 Module to the TTCN document. See "Dependencies" on page 138 in chapter 2, *The Organizer*.

Analysis can be invoked either from the TTCN Suite or from the Organizer. The only difference, regarding dependencies, is that when the analysis is made from the TTCN Suite the dependencies are fetched explicitly while the Organizer always precedes an analysis with a dependency update.

Analyzing ASN.1 References

This is the general algorithm when encountering an ASN.1 in the analysis phase.

1. First of all, an attempted fetch is only made if no current definition exists or if the Analyzer fetching-option is selected.
2. The actual fetching is made, see "Retrieving External ASN.1 Definitions" on page 1198.
3. If the definition is successfully fetched, the identifiers in the definition is converted to TTCN compatible syntax, see "Syntactic Conversion" on page 1198.
4. Finally a possible update of the definition is made and the analysis is continued.

Retrieving External ASN.1 Definitions

From the ASN.1 module a simple parse tree is built to access its contents. The parse tree is (re-)built when either it has not been built before or the ASN.1 module has been modified since last access. The parse tree for an ASN.1 module "lives" for the duration of the whole analysis phase.

Syntactic Conversion

The received definition must be manipulated in the following sense. All identifiers must be syntactically checked and altered if they include any characters that is disallowed in TTCN. The rule is that all '-' (dash) characters in an ASN.1 name is replaced by a '_' (underscore).

No special care has to be considered to ASN.1 comments since they are ignored when the parse tree is built from the module.

External type references in the type definition (e.g "... Module.Type...") will only be converted like above and left for the Analyzer to deal with (see also "Restrictions" on page 1200).

Restrictions

These features are not supported in TTCN:

- External type reference identifiers on the form *ModuleIdentifier.Type/Valuereference* are not supported.
- Type/value references within the same ASN.1 module are not supported.

Furthermore there are restrictions in the ASN.1 Utilities when it is used to extract the external types and values. These restrictions are introduced in translating ASN.1 to SDL but since the same algorithm is used for extracting types and values, the restrictions are also relevant for the TTCN Suite. For more information, see "Translation of ASN.1 to SDL" on page 704 in chapter 13, *The ASN.1 Utilities*.

Error Handling

Any error that occurs while finding, parsing or accessing the ASN.1 module will cause the old definition to remain. Only when a completely successful fetch has been made, the definition will be updated. Possible errors could be:

- The ASN.1 Module not found among the dependencies.
- The ASN.1 Module file could not be found or was not readable.
- The ASN.1 Module file was not syntactically correct.
- The referred type/value could not be found in the module.

See chapter 13, *The ASN.1 Utilities* for a more general view on ASN.1 usage.

TTCN Static Type Restriction Control

The TTCN standard defines a set of semantic rules for type definitions. In particular it defines simple types as types which might contain a true subset of the values which the parent type might contain. The Analyzer now analyzes the TTCN type system and also reports violations of these rules. This analysis is implemented as a post-pass over the related tables, and is only applied when the previous passes have been successful.

Furthermore, restriction control is performed on a number of other constructs in the TTCN language, thus facilitating the task of writing semantically correct TTCN documents. Most of the TTCN types and values are checked and thereby reducing the chance of programming errors

slipping through to other tools which depends upon the correctness of the TTCN document.

Application of Static Type Restriction Control

Static Type Restriction Control is applied to at least the following TTCN tables and fields:

- Simple type definitions
- TTCN structured type / ASP / PDU / CM definitions
- Test Suite Constant Declarations
- Test Suite Variable Declarations
- TTCN Structured Type / ASP / PDU / CM Constraint declarations
- Actual constraint reference parameter lists
- Actual parameter lists

The Static Type Restriction Control also evaluates expressions in advance, where possible, and checks that the result does not violate the type restrictions of the field where the value is found. It operates on both types and values, regarding specific values as special cases of types.

Reducing Level of Restriction Control

Setting the environment variable `ITEX_RESTRICT_LEVEL` to the value `NONE` will disable the strict checking of type restrictions. This might be useful for allowing test suites with deliberate type errors pass through the analysis. A setting of `SOME` will relax the analysis somewhat, and is recommended before trying `NONE`. In order to get the most strict analysis (default), the value `STRICT` might be used.

Generating a Flat View

A Flat View is the part of the modular TTCN Suite environment that presents the tree structure of an expanded modularized TTCN source. This complete view includes all explicit defined objects in the TTCN system.

The Flat View interactive interfaces is similar to the Browser. Unlike the Browser, the Flat View is started (generated) from the Organizer.

The structure of the TTCN source in a Flat View is similar to a Test Suite. Neither the Import tables nor Export tables are displayed in a Flat View.

Generating a Flat View in a system, requires that at least the root document of the system to be connected to a file. The connected document must be of one of these types:

- Test Suite
- Modular Test Suite
- TTCN Module

If this condition is not fulfilled, the operation Generate Flat View fails. Also if the current Flat View is modified or is locked (by any user) the operation fails.

If a Flat View is edited by the user, it must be saved in another document file. The user is asked for a new file name. Otherwise, if the existing Flat View file is not modified, it is overwritten by the new generated Flat View if the generation is redone.

For each TTCN system in the organizer only one instance of Flat View can be generated. A Flat View can be regenerated. A Flat View includes all explicit defined objects in the system at the time of the (re)generation.

The first time the Flat View in a system is generated, the name of the Flat View file is the same as the file name of the root document in the system if the name is not already used. The file extension for a Flat View file is `.ifv`.

An already existing Flat View is always connected to a document file. If this existing Flat View is in the current target directory (and neither is modified nor locked) the Flat View file is reused (the Flat View is regenerated). Otherwise a new Flat View file in the current target directory is used.

Algorithm

When the command Generate Flat View is invoked the following cases may occur:

No Flat View is Available

In other words this is the first time a Flat View is generated for the given system. A new Flat View is generated in the target directory. The name of the document file is generated. This name is derived from the file name of the root document in the system. A Flat View icon is added to the selected TTCN system in the Organizer and it is connected to the generated document file.

A Flat View is Available

If the file connected to the existing Flat View either is locked or modified the operation fails. If the existing file is not in the target directory do as the previous case except not to add a Flat View system node.

Otherwise if the existing file is in the current target directory the file is reused (the current document file name must have been derived from the file name of the root document in the system).

If the Flat View is modified, the operation (Generate Flat View) fails and the user is asked to save the Flat View (into another file) before regenerating.

Save a Flat View

A user modified Flat View must be saved as a document of type (non-modular) Test Suite in another file than the Flat View file.

When the user invokes the save operation from the Organizer, a new file name must be given otherwise the save operation fails. If the user invokes the save operation from the TTCN Suite a file browser pops up and the user is asked for a file name.

Merging Objects into a Flat View

A Flat View contains a copy of all explicitly defined objects in a system. When a Flat View is generated for a TTCN system, explicitly defined objects in each system node is merged into the Flat View. The merged objects may have the same name.

Objects of the following types are treated special:

Overview Tables

The main table in the Overview Part is the Test Suite Structure table. Depending on the type of the root node in the system the Overview tables in the generated Flat View contain the following information.

Test Suite (Modular or Non-Modular)

This type of system nodes have a Test Suite Structure table. The header of the corresponding table in the Flat View inherits the information in the header of the root table.

The Detailed Comments in the index tables are copied to the index tables in the Overview part of the generated Flat View.

TTCN Module

In this case the TTCN Module Exports table is the corresponding table to the Test Suite Structure table in the Flat View. The TTCN Module Exports contains two extra header fields: Objective and TTCN ModuleRef. These two fields are ignored when the Flat View is generated.

The Detailed Comments in the index tables are copied to the index tables in the Overview part of the generated Flat View.

Package

In this case there is no corresponding table to the Test Suite Structure table in the generated Flat View.

Import and Export Tables

These tables contain no explicit defined object and therefore they are ignored.

External Tables

These tables contain no explicit defined object and therefore they are ignored.

Multiple Tables

The objects in the multiple tables are added to the corresponding multiple table in the generated Flat View. The Detailed Comment in the multiple table is added to the Detailed Comment in the corresponding multiple table.

Single Tables

Add each single table to the appropriate place in the generated Flat View.

Group Nodes

For each group node if it does not exist already in the generated Flat View create a new group node.

TTCN Suite Preprocessor

The TTCN Suite preprocessor is a text processor that manipulates the text of a TTCN table as part of the first phase of Analyzing. TTCN Suite preprocessor allows you to produce different ETS code depending on the flags set. The syntax of TTCN Suite preprocessor directives is similar to directives for a C preprocessor:

```
#if <expr>
....
[#else]
...
#endif

<expr> ::= defined(<flag>) | '!' <expr> | <expr>
'||' <expr> | <expr> '&&' <expr> | (expr)
```

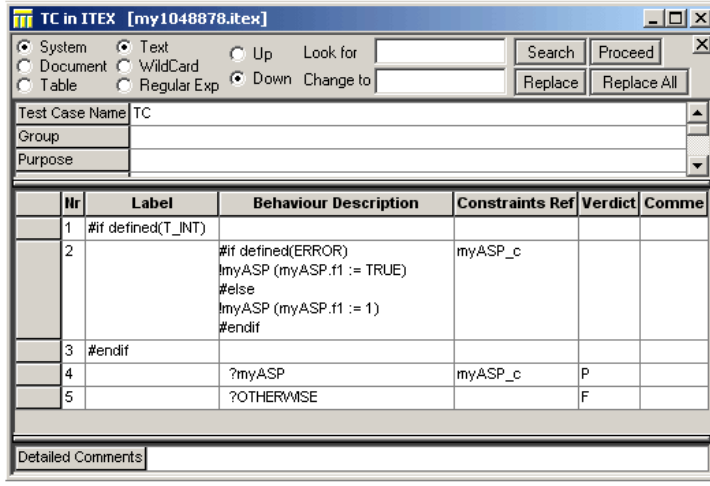

Figure 209: Example of preprocessor directives

These directives can be used in every editable field, not different from TTCN and ASN.1 definitions. The '`#if`' directive and its corresponding '`#endif`' directive must be placed within the same field, except when they are used in the body of a TTCN table that may consist of several rows. In this case it is allowed to use directives '`#if`', '`#else`' and '`#endif`' in separate rows, and only one such directive in the first field is allowed in such a row. The scope of such a directive will be all rows between.

The defined flags for Analysis and Code Generation are set in the Analyzer options (see "The Analyzer Dialog" on page 1192) The flags can also be set via options '-i' and '-I' from a command line session (see "Running the TTCN to C Compiler from the Command Line" on page 1323 in chapter 32, *The TTCN to C Compiler (in Windows)*).

Finding Tables

The Find Table tool searches for and displays named tables. The name searched for is given by the currently marked piece of text in any TTCN Suite window. This tool is very useful when debugging a TTCN document from an Analyzer log.

Finding Tables by Name

The Find Table tool is available from the *Tools* menu in the *TTCN* sub menu in the Organizer, from the *Tools* menu in a Browser and from the *Tools* menu in a Table Editor. Unlike most other tools it does **not** require a selection: it applies to the context given by where the tool is started (i.e. a TTCN table or a TTCN document), and its action is the same whether it is invoked from the Organizer, from a Browser or from a Table Editor.

Tools > Find Table

Finds a named table or the table in which a named object, such as a test case variable, is declared. The name searched for is given by the currently marked piece of text in a TTCN Suite window. If no text is marked Find Table will use the contents of the text clipboard (used for *Cut* and *Copy*).

A typical use of this tool would be to debug a TTCN document when analyzing. Erroneous tables identified in the Analyzer log window can be easily found by marking the names of these tables in the log window and applying the Find Table tool.

The Find Table tool is able to find named objects with the name specified as `<document name>::<object name>` (e.g. `Test_Suite_A::SEND`), where `<document name>` is the name of a document in the TTCN system and `<object name>` is the name of an object available in the context of that document. This may also be specified as `<document name>__<object name>` (i.e. with underscores instead of colons).

> **Note:**
>
> The Find Table tool will in fact use marked text as the look-up string from any X Window, not just TTCN Suite windows.

Example 207 ––

Marking the PDU name *CON_req* in, say, the behaviour line *L! CON_req (X:=1)* of a test step, and then choosing the Find Table tool will cause the PDU definition of CON_req to be displayed (assuming it exists).

On the other hand, marking the test case variable *X* in the same line would cause the Test Case Variables table, in which *X* is declared, to be displayed.

The TTCN to C Compiler (on UNIX)

This chapter describes what the TTCN to C compiler is used for, how to run it and the structure of the generated code.

When the TTCN to C compiler has translated TTCN into C code, the code must be adapted with the system that is to be tested. The adaption process is described in chapter 36, *Adaptation of Generated Code*.

Note: ASN.1 support

The TTCN to C compiler supports only a limited subset of ASN.1. See "Support for External ASN.1 in the TTCN Suite" on page 733 in chapter 13, *The ASN.1 Utilities, in the User´s Manual* for further details on the restrictions that apply.

Note: UNIX version

This is the UNIX version of the chapter. The Windows version is chapter 32, *The TTCN to C Compiler (in Windows)*.

Introduction to the TTCN to C Compiler

When developing new systems or implementations of any kind, the developing process is divided into well defined phases. Most commonly, the first phases involve some kind of specification and abstract design of the new system. After a while, the implementation phase is entered and finally, when all parts are joined together, the test phase is activated.

In any case when a system is tested, we want to make sure that its behavior conforms to a set of well defined rules. TTCN was developed for the specification of test sequences. Unfortunately, as very few systems interpret or compile pure TTCN, we need to translate the TTCN notation into a language which can be compiled and executed. In the case of the TTCN Suite, the TTCN to C compiler translates TTCN to ANSI-C.

Even after the TTCN code has been translated, there are a couple of things that need to be taken care of. In this case, we must *adapt* the generated code with the system it intends to test. This chapter describes how the TTCN to C compiler is used. The adaption process is described in chapter 36, *Adaptation of Generated Code*.

Getting Started

Unfortunately a test sequence description expressed in TTCN can not easily be executed as it is. This is because the test notation is not executable and only few test environments interpret pure TTCN. A different approach to create an executable test suite (ETS), is to translate the formal test description into a language which can be compiled into an executable format.

The TTCN to C compiler translates TTCN into ANSI-C which can be compiled by an ANSI-C compiler. Figure 210 depicts the first step in the process of creating an ETS using the TTCN to C compiler.

The generated code, called the TTCN runtime behavior, is only one of the two major modules of an ETS.

The second module which is needed includes test support functions which are dependent on the protocol used, the host machine, test equipment, etc. For this reason, it is up to the user to write this second module and in such way adapt the TTCN runtime behavior to the system he/she wants to test.

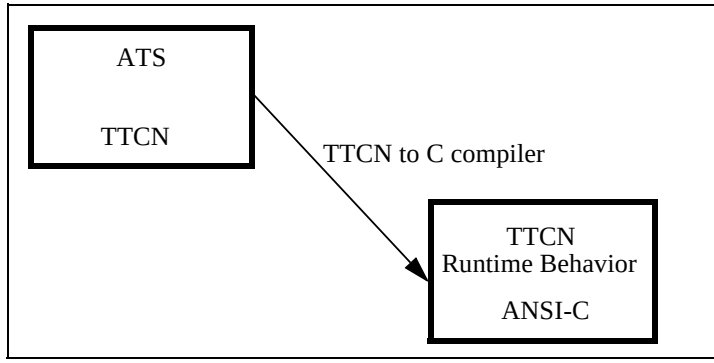

Figure 210: Translating TTCN to ANSI-C

The adaption process is described in chapter 36, *Adaptation of Generated Code*. Figure 211 displays the anatomy of the final result.

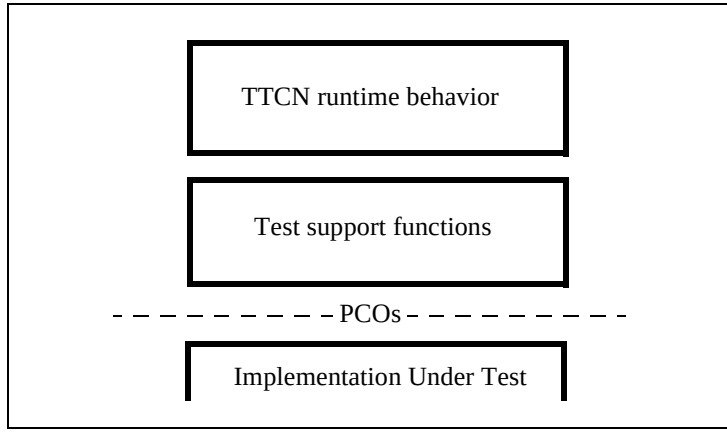

Figure 211: The anatomy of an ETS

Running the TTCN to C Compiler

The TTCN to C compiler can be activated either from the TTCN Browser, both as a quick button and a menu command, or from the Organizer when a TTCN test suite is selected.

> **Note:**
>
> Observe that the TTCN to C compiler is unable to function correctly if the test suite is not fully verified correct. This verification is accomplished by running the Analyzer tool on all the parts of the test suite.

Tools > Make

When you select *Make*, the TTCN Suite Make dialog is opened. The dialog contains two important toggle buttons, *Analyze & Generate* and *Compile & Link*.

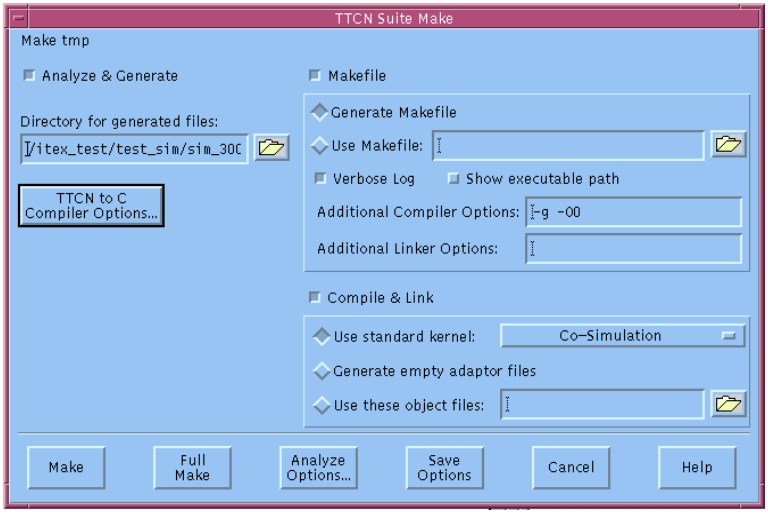

Figure 212: Dialog for starting the TTCN to C compiler

Analyze & Generate

If *Analyze & Generate* is set, the Analyzer will first be called to analyze the test suite before any code is generated. If errors are found, these will be reported and no code will be written to file. The generation phase

performed after the analysis phase will only generate code for the parts that need to be re-generated.

Directory for generated files

If code is generated, that code will reside in the directory specified in this field.

Makefile

If *Compile & Link* is set, the TTCN Suite will also take care of the making and linking of the generated code. At this point you have the possibility to specify how you want the code to be built. Either you can specify that the default generated makefile is to be used, or your own special makefile. This is done by setting the radio buttons in the field below the *Makefile* toggle button.

Verbose Log

The *Verbose Log* switches the logging between the default mode, which prints the result of the Make process as it goes along, and the *Verbose* mode, where all possible information is presented. The *Verbose* log is primarily intended for debugging.

The *Verbose* log contains the following information in addition to the default log:

- signal parameters, with an attempt to restore all names (for signal, fields, parameters, choices, etc.), even when these names are lost (which is the case when the user construct the signals directly in the adaptor). The default log can be made to show this if the Compilation flag /DSHOWSIGNALPARAMETERS is set.
- matching processes are presented *Verbose*. Each field shows how it was matched, using the indentation level for nested fields.

Show Executable Path

When *Show Executable Path* is selected, the lines in the ETS log will be prefixed by the path for the executing Test Case and Test Steps, like the following example:

```
Test Case:[line number]  Step_no:[line number] ... Test Step_n
```

Compilation flag /DSHOWSIGNALPARAMETERS

The flag `SHOWSIGNALPARAMETERS` is generated in the Makefile even when the log is not *Verbose*. With this compilation flag the default log will also contain the complete contents of all signals, just like when log is set to *Verbose*. When this is not desired, this flag can easily be removed from the Makefile.

Additional Compiler Options and Additional Linker Options

Here it is possible to specify any compiler and linker options that will be added into the generated Makefile.

Compile & Link

The compiler needs to know what files to link into the executable. Three different possibilities are at hand:

- You have not yet written an adaptor, but you want an empty template to allow compilation to go through successfully.
- You have already written an adaptor which you want to link into the executable.
- You want to link to a simulator kernel to allow you to simulate.

The TTCN to C compiler assumes the first case to be the default one. In this case the *Generate empty adaptor files* radio button is set. If you do not have adaptor files (`adaptor.c` and `adaptor.h`) in the target directory, these will be created, as empty templates, for you. If you already have generated and edited adaptor files these will of course not be overwritten.

If you already have your own compiled adaptor files elsewhere in the file system, these files, as object files, should be listed in the text field below the *Use the object files* dialog button. Observe that you should use absolute path names for the adaptor files to avoid problems for the makefile to find these files! An absolute path name is a path name that identifies a file uniquely from the root of the files system, for example `/home/myhome/myadaptor.o`.

Finally, if you want to generate code for simulation, the *Use standard kernel* radio button should be set with the option *Simulation*. This is the only available kernel at the moment so no other choice is valid here.

Make

If the *Make* button is pressed, the compiler will only generate code for the parts that really need to be re-generated.

Full Make

If the *Full Make* button is pressed, everything will be regenerated again.

When the generation phase is started, a new log window will be displayed where information about the compiler actions will be displayed.

TTCN to C Compiler Options

By pressing the *TTCN to C Compiler Options* button in the Make dialog, the dialog depicted in Figure 213 will be displayed.

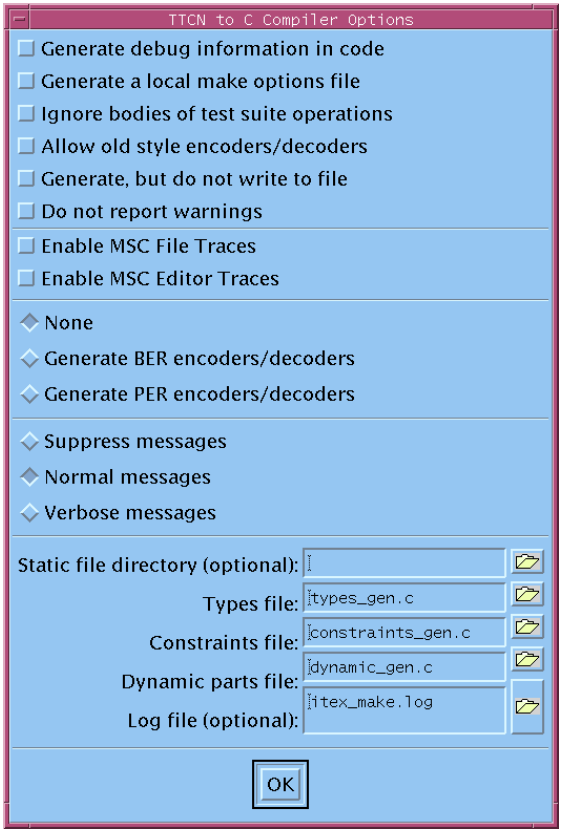

Figure 213: Setting extra TTCN to C compiler options

- If the *Generate debug information in code* button is set, the compiler will generate extra code for tracing and debugging.
- If the *Generate a local make options file* button is set, the compiler will generate a file called `makeopts` in the target directory. This file is used to define settings used by the makefile. You have the flexi-

bility to choose compiler and add extra information for the make process.

- If the *Ignore bodies of test suite operations* button is set, the compiler will ignore to generate code for test suite operations. This is useful if you already have a file with your own test suite operations that only need to be linked to the rest of the code. If the button is not set, the test suite operators will be generated and included in the file `tsop_gen.c`.
- If the *Allow old style encoders/decoders* button is set, the compiler will generate two extra files that will allow you to use an adaptor written for the old code generator to be used with the new one.
- If the *Generate, but do not write to file* button is on, the compiler will not generate code. This is useful for users that only wish to generate code when they know no generation errors will occur.
- If the *Do not report warnings* button is set, the compiler will not inform you about warnings.

MSC Trace

- *Enable MSC/PR file tracing*

  Generates MSC/PR format files that are saved in the current working directory. By default, the MSC file names will be on the form `log_<TestCaseId>_<SequenceNo>.mpr`, where `<TestCaseId>` is substituted by the test case name of the logged test case. `<SequenceNo>` is an integer that is started by 0000 and increased by one if there is already a version n in the working directory.

  The preprocessor constant MSC_FILE_MODE should be defined at compile-time of `mscgen.c` to get this mode. The constant GENMSC should be defined for compiling `globalvar.c` to activate appropriate calls.

  If the file cannot be created, a new attempt will be done at the start of the next test case. No file log will be created.

  The function `MscSetPrefix` can be used to change the path and prefix of generated files at runtime.

- *Enable MSC Editor tracing*

Creates a new diagram in the MSC Editor when a new test case is started and then appends and displays the events as they are executed. This mode assumes that an MSC Editor license is available and that TTCN Suite is running at the host where the ETS is running and provides run-time MSC logging.

The preprocessor constant MSC_MSCE_MODE should be defined at compile-time of `genmsc.c` to get this mode. The constant GENMSC should be defined for compiling `globalvar.c` for activation of the appropriate calls.

If the creation of events in the MSC Editor fails, it will be retried at the next event, possibly creating an inconsistent MSC.

This mode may also require access to the Public Interface libraries and include files that can be found in the installation.

For more information, see "TTCN Test Logs in MSC Format" on page 1328.

Encoders

- By selecting one of the radio buttons *None*, *Generate BER encoders/decoders* or *Generate PER encoders/decoders* the compiler will either omit generation of encoders/decoders or generate extra code for BER or PER encoding and decoding support. See chapter 58, *ASN.1 Encoding and De-coding in the SDL Suite, in the User´s Manual*.

Encoders

- By selecting one of the radio buttons *Suppress messages*, *Normal Messages* or *Verbose messages* you can set the level of verbosity when the compiler generates code. The default value is *Normal messages*.

Files

You can also choose the names of the files you want to use. This is done in the fields in the lower part of the TTCN to C compiler options dialog.

- The optional *Static file directory* field should only be used by users that brutally want to change the behavior of the compiler by using their own static files. For "normal" users it is recommended that this field is not set.

- The *Types file* field determines the name of the file to which type definitions from your test suite are generated. The default value is `types_gen.c`.
- The *Constraints file* field determines the name of the file to which constraint definitions from your test suite are generated. The default value is `constraints_gen.c`.
- The *Dynamic part file* field determines the name of the file to which the dynamic part from your test suite is generated. The default value is `dynamic_gen.c`.
- The *Log file* field determines the name of the file to which messages about the generation are to be written. Default is standard out.

Running the TTCN to C Compiler from the Command Line

Please see "Running the TTCN to C Compiler from the Command Line" on page 1323 in chapter 32, *The TTCN to C Compiler (in Windows)*.

What Is Generated?

In the case of the code generated from the compiler we also need a set of static functions which handle TTCN basics and other internal events. Even if these functions are vital for the successful compilation and execution of the generated code, the user should not have to worry about this part. These functions are gathered in a small set of static files which are compiled by the generated makefile and linked with the rest of the code.

The Code Files

The generated makefile is the file containing a definition of how the code should be compiled and linked.

The `adaptor.h` and `adaptor.c` files are the files that contain the adaptation code. If code is generated for the first time, these files will be generated by the compiler with empty function templates for the user to implement. On the other hand, if these files are present in the target directory the user does not have to worry about getting them overwritten.

The `*_gen.{c,h}` files contains the code generated for the TTCN test suite.

The `asn1ende.h` file contains the encode and decode functions for the ASN.1 Types. See chapter 58, *ASN.1 Encoding and De-coding in the SDL Suite, in the User´s Manual*. (Only generated if ASN.1 encoding/decoding support has been selected)

The Adaptation

We are now ready to deal in greater detail with the adaptation phase which is the final phase to create an executable test suite. The adaptation process is described in "Adaptation of Generated Code" on page 1487 in chapter 36, *Adaptation of Generated Code*.

TTCN Test Logs in MSC Format

Please refer to "TTCN Test Logs in MSC Format" on page 1328 in chapter 32, *The TTCN to C Compiler (in Windows)*.

Chapter

28

The SDL and TTCN Integrated Simulator (U)

This chapter describes theSDL and TTCN Integrated Simulator in the UNIX version of the TTCN Suite. It gives an introduction to the concept of the SDL and TTCN Integrated Simulator, as well as a guide to its functionality and an introduction to using the SDL and TTCN Integrated Simulator for controlling real Executable Test Suites.

> **Note: UNIX version**
>
> **This is the UNIX version of the chapter. The Windows version is chapter 33, *The SDL and TTCN Integrated Simulator (W)*.**

The SDL and TTCN Integrated Simulator

The SDL and TTCN Integrated Simulator allows you to:

- Execute a compiled test suite and inspect the results.
- Execute test cases and test groups by stepping through the TTCN lines or executing at full speed with the possibility to set breakpoints at given tables/lines.
- View the actions performed by the various parallel test components (PTCs) in multiple windows if needed when executing a concurrent test suite.

The possibilities to pinpoint the cause of the test result beyond the test verdict *fail* are vast, and will undoubtedly help in improving the time needed for testing in the development phase.

Performing a Integrated-Simulation

Given a test suite containing a set of tests you want to execute together with a simulated SDL system, the following steps are to be performed:

1. Analyze the test suite and make sure it contains no errors. (This can be done using the TTCN Suite *Make* dialog.)
2. Using the TTCN Suite *Make* dialog, build an executable test suite with the *Use standard kernel* radio button set, and with the *Integrated-Simulation* kernel selected.

3. Start the SDL and TTCN Integrated Simulator by pressing the integrated-simulation quick-button on the top of the TTCN Browser, or selecting *Start Integrated-Simulator* from the Browser *Tools* menu.

Setting Up an SDL and TTCN Integrated Simulation

A complete test of a system design can be performed prior to building a prototype by designing the system in SDL, and using the TTCN Suite to write test specifications in TTCN, or using a tool to automatically or semi-automatically generate test suites from a system description in any language. The actual testing is then a matter of connecting the two simulators.

To achieve the connection, follow these steps:

1. Generate and start the SDL Simulator.
2. Start the SDL and TTCN Integrated Simulator by selecting the Integrated-Simulator quick-button from the tool bar of the Browser.
3. When the SDL and TTCN Integrated Simulator has appeared, along with a selection of executable test cases and test groups, enter the command
   `start-itex` in the SDL Simulator.
4. Select one or more test cases or test groups in the SDL and TTCN Integrated Simulator Setup window, and click the *Run Test* button.
5. In the SDL Simulator, give any of the start commands (**`Forever`**, **`Go`**...).

The loaded SDL system is now being simulated on the SDL Suite side, and conformance tested from the TTCN Suite side with the SDL and TTCN Integrated Simulator.

The SDL and TTCN Integrated Simulator User Interface

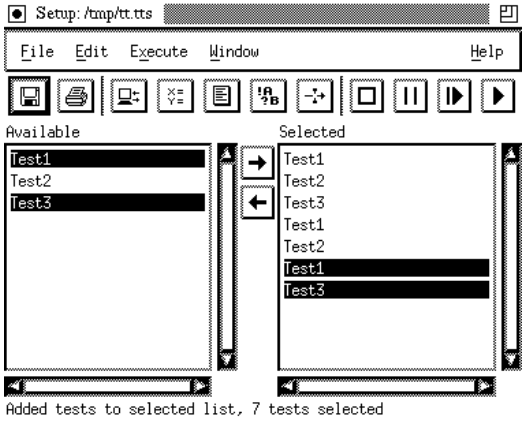

Figure 214: The SDL and TTCN Integrated Simulator Test Setup window

The Test Setup window is the main window of the SDL and TTCN Integrated Simulator. It manages an Executable Test Suite and a number of associated documents. The main part of the window is used for test selection. The left list depicts the currently available tests, and the right list depicts a selection of test cases and/or test groups.

Managing Setup Documents

The menu choices in the *File* menu are used for creating and saving documents. For information on the operations not mentioned here, see the general description of the *File* menu in "File Menu" on page 8 in chapter 1, *User Interface and Basic Operations*.

File > New

Creates a new Setup document. The new setup inherits the Executable Test Suite from the current Setup.

File > Open

Opens a previously saved Setup file in a new window.

File > Save

Saves the current Setup file. If the Setup was not previously saved, a name will be prompted for. A saved Setup consists of the file names of the associated documents, as well as the ETS name.

File > Save As...

Saves the Setup file with another file name. A running ETS might need to be restarted in order for changes to become effective.

File > Restart ETS

Restarts the Executable Test Suite / SDL and TTCN Integrated Simulator. This may compromise the consistency of running test cases, but might be necessary in order to make changes to the Setup effective.

File > Close

Closes the current view of the Setup document. If there are no more views of the Setup, the ETS will be terminated along with any test cases. If the Setup has been changed, a dialog will prompt for a file name for saving the Setup before it is closed. If the Setup is the only one currently open, the program will quit.

Selecting Test Cases and Groups

This section lists the SDL and TTCN Integrated Simulator commands available in the *Edit* menu.

Edit > Documents > Select ETS

Enables you to select another ETS for the test Setup. This might be useful for selecting a new ETS, using the same Setup as the old one.

Edit > Documents > Add Document

Enables you to add a document type to this Setup. A standard set of document types are provided by default at program start-up.

Edit > Show > Test Cases

Sends a command to the ETS such that it lists all Test Cases in the *Available* list.

Edit > Show > Test Groups

Sends a command to the ETS such that it lists the Test Groups.

Edit > Add All

Adds all tests from the set of available tests to the set of selected tests.

Edit > Add

Adds the tests currently selected in the *Available* list, to those present in the *Selected* list. Both test cases and test groups may be present in the *Selected* list at the same time.

Edit > Remove

Removes the selected tests from the *Selected* list.

Edit > Remove All

Removes all tests from the *Selected* list.

Executing a Test

This section lists the SDL and TTCN Integrated Simulator commands available in the *Execute* menu.

Execute > Test > Cancel

Cancels a test in progress. All information will be lost and the ETS returns to its initial state. This might compromise the consistency of a test since it might leave the IUT in any state.

Execute > Test > Pause

Temporarily pauses the test execution. This might be used to examine the state of the IUT or of the ETS.

Execute > Test > Step

Steps one line of TTCN code. In a simulated environment this is a well-defined operation, as opposed to a real test system. In the latter case, timing might be compromised.

Execute > Test > Run test

Runs/Continues a test at full speed until it is finished or until a breakpoint is reached.

Execute > Breakpoints > Breakpoints

Shows the breakpoint editor, as described in "The SDL and TTCN Integrated Simulator Editor" on page 1230. Notice: If the quick button is disabled, this is because no breakpoint document is currently associated with the Setup. Use this menu item to add such a breakpoint document to the Setup.

Execute > Breakpoints > Enable

Enables all breakpoints (default).

Execute > Breakpoints > Disable

Temporarily disables all breakpoints.

Execute > Monitor > PCOs

Monitors all PCO Queues in a separate monitor window.

Execute > Monitor > Timers

Monitors all Timers in a separate monitor window.

Execute > Monitor > PTCs

Monitors all CPs in a separate monitor window.

Execute > Monitor > CPs

Monitors all CPs in a separate monitor window.

Execute > Enable ITEX Tracking

Highlights the next statement line to be executed in the Table Editor. This is on condition that you are running an SDL and TTCN Integrated Simulator session and that the SDL and TTCN Integrated Simulator was started from within the TTCN Suite.

Viewing Documents

This section lists the SDL and TTCN Integrated Simulator commands available in the *Window* menu.

Window > New Window

Enables you to display a new view of the same Setup, with a possibly different test selection. No new Setup is created with this command.

Window > Execution Trace

Shows a new view of the Test Execution trace. If the item is not accessible, select *Document* and then *Add Trace Document* in the *Edit* menu to add a document of this type to the current Setup.

Window > Conformance Log

Shows a new view of the Test Conformance Log. If the item is not accessible, select *Document* and then *Add Log Document* in the *Edit* menu to add a document of this type to the current Setup.

Window > Configuration Editor

Shows a new editor for the Test Configuration, see "The SDL and TTCN Integrated Simulator Editor" on page 1230. If the item is not accessible, select *Document* and then *Add Configuration Document* in the *Edit* menu to add a document of this type to the current Setup. The Test configuration is system dependent and not used for integrated-simulation.

Window > Parameter Editor

Shows a new editor for the Test Suite Parameters, see "The SDL and TTCN Integrated Simulator Editor" on page 1230. If the item is not accessible, select *Document* and then *Add Parameter Document* in the *Edit* menu to add a document of this type to the current Setup.

The SDL and TTCN Integrated Simulator Editor

A generic editor is present for editing some of the documents, as for instance the Breakpoints, Parameter and the Configuration. It is of limited interest to those who are only interested in SDL and TTCN Integrated Simulation, but it might be of more interest if you consider using the GUI for running real executable test suites.

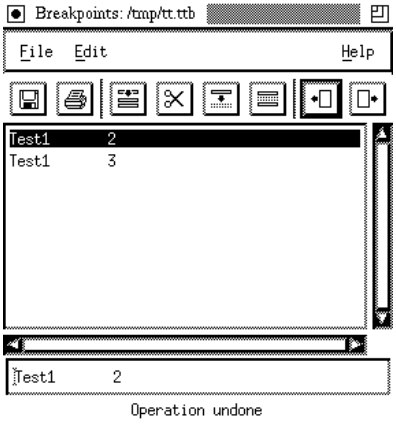

Figure 215: The SDL and TTCN Integrated Simulator editor for breakpoints

The editor is row oriented and the format of each row is determined by the current ETS. It is up to the ETS to warn the user for syntactic and/or semantic errors in the edited document. Please refer to the documentation of the ETS for more throughout definitions of the expected contents of each row.

Managing Documents in the SDL and TTCN Integrated Simulator Editor

The menu choices in the *File* menu are used for creating and saving documents. For more information, see the general description of the *File* menu in "File Menu" on page 8 in chapter 1, *User Interface and Basic Operations*.

Editing Documents in the SDL and TTCN Integrated Simulator Editor

The following section lists the SDL and TTCN Integrated Simulator Editor commands available in the *Edit* menu.

Edit > Undo

Undoes the last change of the document. This functionality is disabled when the document is saved or if a new document is opened. There are more than 200 undo steps.

Edit > Redo

Redoes the next undone change to the document. Applying a new operation removes any non-redone steps.

Edit > Cut

Cuts the currently selected row from the document. The row is placed in an internal clipboard.

Edit > Copy

Copies the currently selected row from the document to the internal clipboard.

Edit > Paste

Pastes the contents of the internal clipboard before the currently selected row.

Edit > Add

Inserts an empty row before the currently selected row.

Integrated-Simulation from command line

The generated ETS for Integrated-Simulation may be started from command line. Do this without any arguments in command line. In this case ETS has no any graphic interface. It reads commands from stdin and print the results of performed commands, Conformance Log, etc. to stdout. Extra debug output will be printed if the environment variable TTCN_SIMULATOR_DEBUG is set. The available commands are as follows:

breakpoint

`breakpoint <table name> <line number>`

Set the breakpoint in table `<table name>` on `<line number>`.

Example 208 ----------

```
breakpoint Init_step 1
```

---

breakpoints

`breakpoints`

List set of breakpoints.

cancel

`cancel`

Stop execution of test case.

delete

`delete [<table name> [<line number>]]`

Delete the breakpoint from table <table name> on the line <line number>. When <line number> is not set, all breakpoints from table <table name> will be removed. If <table name> also isn't set, all breakpoints will be removed.

Example 209 ----------

```
delete Init_step 1
```

---

gett

```
gett <value>
```

Print the value.

Example 210 ----------

gett VarX

---

glist

```
glist
```

List the available Test Groups.

list

```
list
```

List the available Test Cases.

pcos

```
pcos
```

List the available PCOs.

quit

```
quit
```

Exit the ETS.

run

```
run [<Test Case or Test Group>]
```

Start execution of the Test Case or Test Group. When Test Case is running and paused, may be used without arguments to continue Test Case execution.

Example 211 ----------

```
run TC
```

---

run-SDL (Windows only)

```
run-SDL <SDL Simulator executeable>
```

Start the SDL Simulator and redirect its input in order to pass commands to SDL Simulator. Wait until the SDL Simulator start and con-

nect to the Postmaster. When the TTCN Simulator exits, it automatically terminates any such started SDL Simulator.

Example 212 ----------

```
run-SDL cosim_smc.exe
```

SDL-command (Windows only)

`SDL-command <command>`

Passes the <command> to SDL Simulator, that previously has been started using the command `run-SDL`.

Example 213 ----------

```
SDL-command start-itex
```

---

sleep (Windows only)

`sleep <msecs>`

Pause the execution and sleep for <msecs> milliseconds.

Example 214 ----------

```
sleep 1000
```

---

step

`step [<Test Case or Test Group>]`

Start execution of the Test Case or Test Group and pause it after 1 step. When Test Case is running and paused, may be used without arguments to make 1 step in Test Case execution and pause it again.

Example 215 ----------

```
step TC
```

---

stop

`stop`

Pause Test Case execution.

timers

`timers`

List the available timers.

Files Handled by the SDL and TTCN Integrated Simulator

A total of 7 file types are handled by the SDL and TTCN Integrated Simulator user interface. Fortunately, most sessions involve only a subset of those file types. The file types and a short description are listed below:

- ETS file

  Executable Test Suite file. This is a file generated by the TTCN to C compiler. It might in particular be an integrated-simulator which has a specialized kernel for running in cooperation with an SDL Suite simulated system.

- Setup file (`.tts`)

  A Setup file is a collection of the other file types and is used to manage a particular test Setup such that it can easily be re-created.

- Log file (`.log`)

  A Conformance Log File consists of the output from an ETS, as specified in the ISO-9646 standard.

- Trace file (`.ttt`)

  A simplified version of the Log file, more corresponding to the actual TTCN tables contents.

- Test Suite Parameters file (`.ttp`)

  A file for transferring the test suite parameters to the ETS. Comparable to the PICS/PIXIT file of ISO-9646. For details, please see "Test Suite Parameters" on page 1347 in chapter 34, *The TTCN Exerciser*.

- Configuration file (`.ttc`)

  Test platform dependent file. Please see the ETS kernel implementators user guide for details.

- Breakpoints file (`.ttb`)

  A given set of breakpoints might be saved in the editor for later reuse.

Information Messages

The SDL and TTCN Integrated Simulator can present messages to the user in three forms:

- Informative messages
- Warning messages
- Error messages

Informative Messages

Informative messages are normally presented at the status bar. These might be for instance progress reports or other simple messages, which are only of a temporary interest (such as the tool tips).

Warnings Messages

Warnings, also known as “non-critical errors”, are events that indicate a problem during the preparation for an integrated-simulation, or during the actual integrated-simulation run. These are always presented in standard Motif warning dialogs. Warnings normally does not cause an integrated-simulation to halt.

Error Messages

Critical errors will halt the integrated-simulation. They are presented by an error dialog that appears in front of the application. The error dialog can often appear large and intimidating, but it simply gives a more verbose reason to why the error occurred, and what steps should be taken to avoid it.

Using the UI with an ETS

The user interface uses a publicly available format for communication with the ETS. Implementation of a management interface for an ETS is simple since the ETS only uses the standard I/O channels for communication with the GUI. Please request a protocol definition from IBM Rational if you consider adapting your own test suite using this GUI. It is currently unlicensed and might be started using this command:

```
$telelogic/itex/bin/${hosttype}bin/isimui -help
```

Type Mappings in Integrated-Simulation

This section specifies the data type mapping used by the integrated-simulation of the SDL Simulator and the SDL and TTCN Integrated Simulator. Specifically it identifies the transfer syntax used in the communication between the SDL Simulator and the SDL and TTCN Integrated Simulators for each supported data type.

TTCN Types

This subsection describes the mapping from TTCN types to SDL types. For each TTCN type the corresponding SDL type and some examples of the transfer syntax is given.

Predefined Types

TTCN Type	SDL Type	Transfer Syntax Example
INTEGER	integer	1 -3
BOOLEAN	boolean	true false
BITSTRING	bit_string	'0101'B
HEXSTRING	-	
OCTETSTRING	octet_string	'4BA0'O
NumericString	NumericString	'3295' (0..9 + space)
PrintableString	PrintableString	'ask38-'
TeletexString	-	
VideotextString	-	
VisibleString	VisibleString	'xy'
IA5String	charstring	'123 abc'
GraphicString	-	
GeneralString	-	

References Types

TTCN Type	SDL Type	Transfer Syntax Example
SimpleType	syntype	same as referenced type
Struct	struct	(. 1, true .)
PDU	struct	(. 1, true .)
ASP	- (ASPs maps to signals)	

ASN.1 Types

This subsection describes the mapping from ASN.1 types to SDL types. For each ASN.1 type the corresponding SDL type and some examples of the transfer syntax is given.

ASN.1 Type	SDL Type	Transfer Syntax Example
BOOLEAN	boolean	true false
INTEGER	integer	1 0 -55
ENUMERATED	enumeration types	The enumerated values
REAL	- (Not supported in the TTCN to C compiler)	
BIT STRING	bit_string	‘0100’B
OCTET STRING	octet_string	‘4BA0’O
NULL	null	Null
SEQUENCE	struct	(. 1, true .)
SEQUENCE OF	array, string	(: 1, 2 :)
SET	-	
SET OF	bag, powerset	[1, 2, 2]
CHOICE	choice	<name> : <value>
ANY	-	
OBJECT IDENTIFIER	-	

ASN.1 Type	SDL Type	Transfer Syntax Example
Selection type	-	
Tagged type	-	
SubType	syntype	same as referenced type

SDL Types

This subsection defines the mapping from SDL to TTCN and to ASN.1. For each SDL type first the TTCN type is given, then the ASN.1 type and finally an example of transfer syntax.

Predefined Sorts

SDL Type	TTCN Type	ASN.1 Type	Transfer Syntax Example
Bit	BITSTRING	BIT STRING (SIZE (1))	'1'B
Bit_String	BITSTRING	BIT STRING	'1010'B
Boolean	BOOLEAN	BOOLEAN	true false
Character	IA5String	IA5String (SIZE (1))	'a'
Charstring	IA5String	IA5String	'123 abc'
IA5String	IA5String	IA5String	'123 abc'
NumericString	NumericString	NumericString	'123'
PrintableString	PrintableString	PrintableString	'ask38-'
VisibleString	VisibleString	VisibleString	'xy'
Duration	-	-	
Time	-	-	
Integer	INTEGER	INTEGER	0 4 -66
Natural	INTEGER	INTEGER	0 55
Null	-	NULL	Null

SDL Type	TTCN Type	ASN.1 Type	Transfer Syntax Example
Object_Identifier	-	-	
Octet	OCTETSTRING	OCTET STRING (SIZE (1))	'FE'O
Octet_String	OCTETSTRING	OCTET STRING	'F0E2'O
PId	-	-	
Real	-	-	

User Defined Sorts

SDL Type	TTCN Type	ASN.1 Type	Transfer Syntax Example
Syntypes	SimpleTypes	SubType	same as referenced type
Enumeration Sorts	-	ENUMERATED	the enumerated values
Struct	struct	SEQUENCE	(. 1, true .)
Bit Fields	-	-	(. 2, 3, 0 .)
Optional	-	-	
Choice	-	CHOICE	C1 : 1

Predefined Generators

SDL Type	TTCN Type	ASN.1 Type	Transfer Syntax Example
Array	-	SEQUENCE OF	(: 1, 4, 7 :)
String	-	SEQUENCE OF	(: 1, 4, 7 :)
Powerset	-	SET OF	[1, 6, 8]
Bag	-	SET OF	[1, 6, 6]

Chapter 28 The SDL and TTCN Integrated Simulator (U)

Chapter

29

Customizing the TTCN Suite (on UNIX)

This chapter describes how to customize the TTCN Suite on UNIX. You can, for example, find information about how resources are read and how to customize key and button bindings.

The chapter does not contain information about how to configure the help environment. You can read about that in "Customizing the On-Line Help" on page 298 in chapter 4, *Managing Preferences*.

> **Note: UNIX version**
>
> **It is only possible to customize the TTCN Suite on UNIX with the facilities described in this chapter.**

Customizing the TTCN Suite

The TTCN Suite is an Xt based application (X11R5). Customizing is done by setting resources in the normal way for Xt applications. The default configuration is given in the file `$telelogic/X11/app-defaults/Itex`[1]. This file should be installed as part of the installation of the TTCN Suite.

Most of the resources in the global resource file for the TTCN Suite should never be overridden.

The resources that are most likely to be changed, will be mentioned in this chapter. For examples on how to set the resources see the file `Itex.sample` in the installation directory `$telelogic/itex`.

Note: UNIX only

Customizing the TTCN Suite is only possible **on UNIX**.

How Resources Are Read

At start-up, resources are read from a number of files in the standard way for Xt applications. There are a number of environment variables that control the way the program looks for resource files:

- `XFILESEARCHPATH`
- `XUSERFILESEARCHPATH`
- `XAPPLRESDIR`
- `XENVIRONMENT`

When the TTCN Suite is started, none of the environment variables above need to be set. The TTCN Suite will automatically find the resource file under the default name `$telelogic/itex/X11lib/app-defaults/Itex`.

To override some of the resources in the global resource file there are several possibilities:

- Give command line arguments to the TTCN Suite (see the man page `itex`).

1. `$telelogic` denotes the installation directory on your system.

- Set the environment variable `XENVIRONMENT` to a file containing resources for the TTCN Suite, or create a file `$HOME/.Xdefaults-<host>`.
- Set the value of the `RESOURCE_MANAGER` property with the program `xrdb`, or create a file `$HOME/.Xdefaults`.

The easiest way to set some personal resources is to create a file `.Xdefaults` in the home directory and add these resources to it.

For a more detailed description of how resources are found in an Xt based application see some suitable book on the subject, for example the *X Toolkit Intrinsics Programming Manual* from O'Reilly & Associates.

Customizing Key and Button Bindings

Key bindings are accomplished by translations in the resource file of the TTCN Suite. The translation tables that are relevant to add/change in are:

Itex*XmText.translations

Affect all places where text is edited in the TTCN Suite, for example rename of node in Browser and editing of field in the Table Editor. It is here the Emacs-like editing keys are defined.

Itex*textWindow*XmText.translations

Affect only key bindings in log windows. This is, by default, defined to contain the same key bindings as above but with the addition of a few bindings that have to do with scrolling.

Itex.browser*node.translations

Most of the keys in the Browser are defined here.

Itex.nodeTranslations

Some keys for traversing the Browser tree are defined here.

Itex.editor.headerFields.overrideTranslations

Defines the bindings available when focus is on a header field in the Table Editor.

Itex.editor.rowFields.overrideTranslations

Defines the bindings available when focus is on a body field in the Table Editor.

Itex.editor.fieldEditor.overrideTranslations

Defines editor specific bindings when editing a field in the Table Editor.

In the resource file there are comments that describe the action functions that can be used in translation tables. Changes to these tables must be done with caution, since much of the functionality of the TTCN Suite depends on these translations being set in a reasonable way.

Other Customizations

The following is a list of miscellaneous customizations. For examples, see the file `Itex.sample` in the installation directory `$telelogic/itex`.

Change of Paper Size

By default, the printout will be in A4 format. Other formats supported are Letter, Tabloid and Legal. For all formats it is possible to choose between portrait and landscape mode. The default is portrait mode.
See the file `Itex.sample` for an example.

Change of the Header/Footer in Printouts

By default, the header consists of a string containing the version, the document name and the string “user name @ host name”. It is possible to change the header and the footer.
See the file `Itex.sample` for an example.

Change of Font Size in Editor

By default, the font size used in fields in the Table Editor is 10 screen points. The same size is used in printouts. It is possible to change the

size of the Table Editor on the screen, without changing the paper size. See the file `Itex.sample` for an example.

Change of Font Family

By default, all text is from the Helvetica family. You can change this to another family supported by both X11 and Postscript (for example Times).
See the file `Itex.sample` for an example.

Changing Relative Widths of Columns in Editor

The total width of a table is divided among all columns. You can control this by specifying how wide different columns should be. It can be specified individually for each table type.
See the file `Itex.sample` for an example.

Hiding and Showing the Browser Toolbar

If you set the resource entry `Itex*browser.enableToolBar` to False, it is possible to hide the tool bar in the Browser window.

Configuring the Help Environment

The Help environment is configured via the Preference Manager, see "Customizing the On-Line Help" on page 298 in chapter 4, *Managing Preferences*.

Chapter 29 Customizing the TTCN Suite (on UNIX)

Chapter

30

Editing TTCN Documents (in Windows)

In the TTCN Suite, TTCN test components can be edited on table level as well as restructured on a hierarchical level. This chapter describes the editors and information managers in the TTCN Suite in Windows and how to use them.

For an overview of the TTCN Suite, see chapter 2, *Introduction to the TTCN Suite (in Windows), in the TTCN Suite 6.2 Getting Started*.

> **Note: Windows version**
>
> **This chapter is Windows only. The corresponding UNIX chapters are chapter 24, *The TTCN Browser (on UNIX)* and chapter 25, *The TTCN Table Editor (on UNIX)*.**

Introduction to the TTCN Suite

The TTCN Suite can be used for development, specification and compilation of test system components in the TTCN language. The functionality included will be described below.

The TTCN Suite supports all of the standardized, non-compact tables that are defined in ISO/IEC 9646-3. The compact test case dynamic behaviour table (ISO/IEC 9646-3, clause C.3) and concurrent TTCN tables are also supported. The compact tables for constraints (also in Annex C of ISO/IEC 9646-3) are not supported.

The general user interface concepts and common menu choices are described in chapter 1, *User Interface and Basic Operations*.

Different Views of the TTCN Document

The contents of a TTCN test suite can be viewed in *the Browser*, *the Finder* and *the Table Editor*:

- The Browser presents an overview of the TTCN tables. In the Browser it is possible to edit the TTCN table structure, to determine which parts of the test system component to view and to apply a number of operations on it. See "Using the Browser" on page 1253.
- The Table Editor presents TTCN tables for editing, referencing, and a number of table-specific operations. See "Editing Tables" on page 1262.
- The Finder presents a non-hierarchical view of the TTCN tables. Subsets of the total set of tables can be extracted, sorted according to various rules, and a number of operations can be performed on the resulting set of tables. See "Finding and Sorting Tables" on page 1282.

The Log Manager gives another view of the test suite. It presents log outputs from the currently loaded test system components. Information from various operations, such as analysis and simulation, will appear in the test component log in the Log Manager. See "Viewing Log Information" on page 1279.

Functionality to Apply on the TTCN Document

Building Test Components and Tables

- The Data Dictionary is used in conjunction with the Table Editor, and offers an easy way to build TTCN behavior statements from the declared test system components. For more information, see "Creating Behaviour Lines" on page 1269.
- SDL to TTCN Link is similar in use and appearance to the Data Dictionary. It utilizes a Link executable for an SDL system to interactively build the behavior of a TTCN test for that particular system. For more information, see chapter 35, *TTCN Test Suite Generation*.
- Autolink supports semi-automatic generation of TTCN test suites based on SDL specifications. For more information, see chapter 35, *TTCN Test Suite Generation*. The menu choice *Autolink Merge* in the *File* menu may be used for merging Autolink generated MP files into an opened test suite.

Analyzing, Verifying and Executing a Test

- The Analyzer verifies syntactic correctness of test components. For more information, see chapter 31, *Analyzing TTCN Documents (in Windows)*.
- The TTCN to C compiler generates C code from TTCN. For more information, see chapter 32, *The TTCN to C Compiler (in Windows)*.

  The Generic Compiler Interpreter interface is an interface for the adaption of the generated code to a specific target environment. For more information, see chapter 36, *Adaptation of Generated Code*.
- The Simulator allows execution and interactive debugging of test systems. For more information, see chapter 33, *The SDL and TTCN Integrated Simulator (W)*.

Starting the TTCN Suite

You can start the TTCN Suite from the Organizer in the following ways:

- Select *Tools > Editors > TTCN Browser* in the Organizer. This will also add an untitled TTCN document in the Organizer.
- Double-click on a TTCN document icon already included and connected in the Organizer (or select *Edit* from the *Edit* menu).
- Add a new TTCN document to the Organizer and make sure that the option *Show in editor* is checked in the *Add New* dialog.
- Add an existing TTCN document to the Organizer.

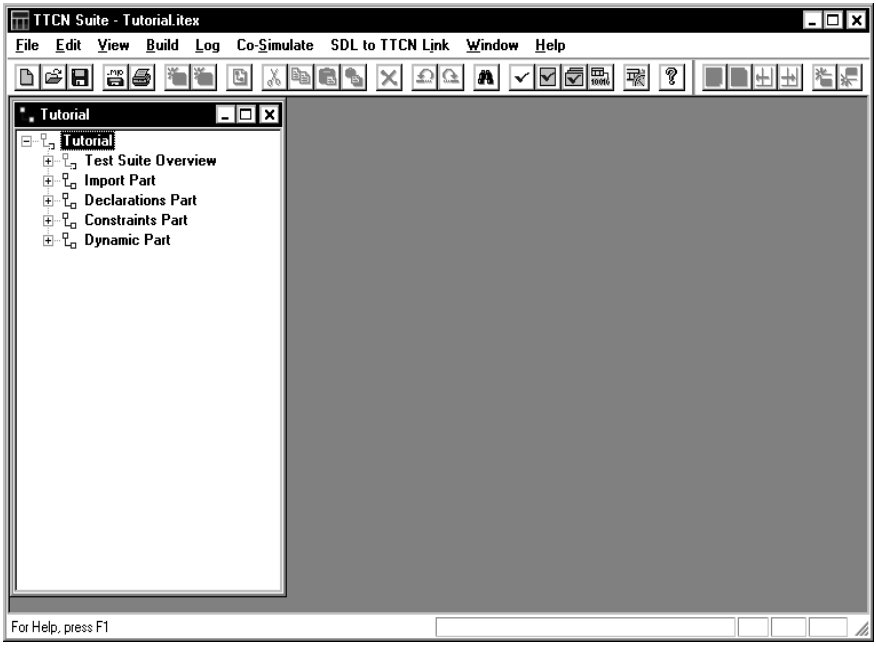

Figure 216:The TTCN Suite is started and the Browser displays a modular test suite

Using the Browser

When you open a TTCN document it will be displayed in the Browser. As the structure of TTCN is tree oriented, the Browser presents an overview of the test system component in tree form.

Multiple Browser views can be opened on a document and all editing performed in a Browser will be simultaneously reflected in the other opened Browser windows.

In addition to this, you may create sub Browsers. This means that you restrict the view to only display a few nodes. In combination with the possibility to have multiple Browsers open on the same test document, this enables you to keep just the interesting bits of information in a couple of small Browser windows.

By using the edit operations, such as *Add In* and *Delete*, you can manipulate the Browser structure to build a complete TTCN system component. You can control the amount of information actually displayed in a Browser, by collapsing and expanding sub trees.

Opening the Browser and a TTCN Document

You open the Browser and a TTCN document by selecting *New* or *Open* from the *File* menu. From the *File* menu, you can also select the four most recently used files.

> **Hint:**
>
> If you try to open very large test suites, for example containing extensive constraint declarations, you may get an error message about “scanner buffer overflow”. You can solve this by setting the environment variable ITEX_SCANNER_BUFFER_SIZE to a high value, for example 75 000 000.

To open additional Browsers for the same component:

- Make sure the Browser is active and select *File* > *New Window*.

The Browser is also opened automatically when the TTCN Suite is started from the Organizer, as described in “Starting the TTCN Suite” on page 1252.

If you try to open a TTCN document that is already opened by any another user or in another TTCN Suite Browser, you will get a question

informing that the file is opened by another user and ask to open it in read-only mode. In read-only mode you will not be able to save your changes (if any) in the same file, but free to save the TTCN document as another file. No other restrictions exist in read-only mode: you may browse, analyze, generate code, etc.

The question that the file is opened by another user is isuued because a read-lock file (with additional suffix '-read_lock') exists in the same directory as the document. This may also happen if the TTCN Suite or Windows has crashed. In this case just remove this file and try to open the TTCN document again.

The Browser User Interface

The initial structure of a TTCN tree contains place holders for the static parts of the system component. These *static nodes* are automatically created by the TTCN Suite whenever you create a new test system component. What you usually do when you build a test system component is to add *dynamic child nodes* to the static nodes, and fill them with test specification data. Examples of static nodes are the Declarations Part and the Constraints Part. Examples of dynamic nodes include tables, groups or objects in a table (e.g. test case variables).

The Browser displays all the static nodes in the order defined in the TTCN standard. This ordering cannot be changed. For example, it is not possible to have the Constraints Part coming before the Declarations Part. Only the dynamic items – the tables – may be added and deleted.

Static nodes are the only nodes that can become the root of a sub Browser.

Static Nodes in the Browser

Static nodes can take on four different appearances depending on the *parse status* of dynamic nodes below. Whenever you analyze a sub-tree, or parts of it, or edit it in a way such that the parse status of one or more dynamic nodes is altered, an abnormal parse status is indicated by the appearance of the static parent nodes.

This is an ordinary static node. All children to this node have been analyzed with status OK.

This is a static node where at least one of the dynamic nodes in the sub tree below has not yet been analyzed or is in need of analysis. There are no erroneous dynamic nodes.

This is a static node where at least one of the dynamic nodes in the sub tree below has been analyzed with an error or warning as result. In the actual view, the arrow is **red** for errors and **purple** for warnings.

To find a table that has to be corrected, you follow the marked nodes through the tree. Note that erroneous nodes have precedence over non-parsed ones, so even a single erroneous child to a static node will make it red no matter how many non-analyzed nodes there are in the sub-tree.

It may be that some of the static nodes will remain unused. A TTCN test system component is allowed to leave out the use of for example *Test Case Variables*. However, although this empty node will be displayed in the Browser, it will not be printed or output in the TTCN-MP format.

Dynamic Nodes in the Browser

A dynamic node is always associated with a table and can be accessed by the Table Editor. Two kinds of dynamic nodes can have children, namely *multiple tables* and *group tables.* Multiple tables look just like ordinary table icons, with the added feature of possible children, whereas group tables (referred to as *group nodes* in the Browser) have a different look to distinguish them somewhat from the others.

This is a group node with all dynamic nodes in its sub tree analyzed with status OK.

This is a group node with a sub-tree containing at least one non-analyzed dynamic node, but no erroneous ones.

This is a group node with a sub-tree containing at least one dynamic node analyzed with an erroneous status or a warning. In the actual view, the color is red for errors and purple for warnings.

This is a dynamic node (or multi-table) that is analyzed with status OK.

This is a dynamic node that needs to be analyzed.

This is a dynamic node that has been analyzed and contains one error. In the actual view, the cross is red for errors and purple for warnings.

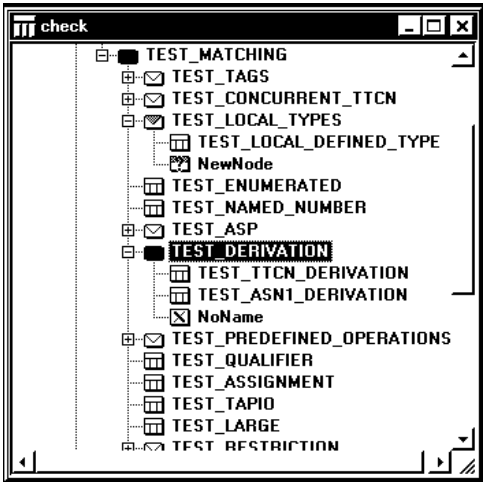

Figure 217: Different node types in a Browser

Controlling the Nodes in the Browser

As the Browser displays the information in a TTCN document in a tree oriented way, it is very simple to control the amount of information that the you want to see at a specific moment.

Expanding and Collapsing a Node

Nodes with sub-trees are possible to expand and collapse to show or hide the branch below it. This works in the same way that you expand and collapse directory levels in the Windows Explorer by double-clicking.[1]

- The shortcut for collapse is `<Left arrow>` when an expanded node is selected.

1. Note that test group nodes differ. Double-clicking a group node that is expanded always opens its associated table instead of collapsing it. Click on the minus sign to the left of the group icon instead.

- The shortcut for expand is <Right arrow> when a collapsed node is selected.

Selecting Nodes

Click a node to select it. <Ctrl>-click a node to extend the current selection.

Instead of using the mouse for navigation, you can use the following shortcuts:

- To move the selection to the next node, use <Down Arrow>.
- To move the selection to the previous node, use <Up Arrow>.

Renaming Dynamic Nodes

To rename a dynamic node:

- Click the name of a selected node, then type the new name and press <Enter>.
  – You can also change the name in the table itself.

Sorting Dynamic Nodes

The Sort command is applicable for any node that has dynamic subnodes. The command sorts the sub-nodes in alphabetical order.

To sort a dynamic node do one of the following:

- Right-click a node, then choose *Sort* from the shortcut menu.
- Select the node to sort. From the *Edit* menu choose *Sort.*

Creating a Sub Browser

To create a sub Browser:

- Select *Make Sub Browser* from the *View* menu. This replaces the contents of the active Browser with the selected node and its sub tree.

To get a Browser with the full TTCN document tree, select *New Window* from the *Window* menu.

Editing the Browser Structure

The static structure is automatically generated when a TTCN document is first created and cannot be edited. To build an individual TTCN system component, you need to add named tables – such as PDUs, constraints and behavior tables – and named objects to the multi-object tables – such as test case variables, PCOs and timers.

Use the *Edit* menu choices for adding, deleting, copying, pasting, etc, *editable nodes* – also called dynamic nodes – (that is, groups, tables or objects in a multiple object table) in the Browser.

Generating the Test Suite Overview

The test suite overview is a collection of tables that contain test suite structure, test case index and default index. These are used for reference in a printed copy of the system component, as described in the TTCN standard. The overview will be generated the first time you print the test suite, export it or open the overview tables. The generation may take a little while, but it is only needed once for each session, as the tables are automatically updated when you edit the test suite.

Adding Nodes

To add a new dynamic node as the last child of the selected node:

- Select *Add In* from the *Edit* menu.
  – The shortcut is `<Ctrl+Shift+A>`.

  In the case of multiple-object tables, select the node that represents the multiple-table. When you select *Add In*, a new node will be added as the last child node.

To add a new dynamic node before the selected node:

- Select *Add* from the *Edit* menu. As with *Add In*, the new table will be unnamed.
  – The shortcut is `<Ctrl+A>`.

Adding Groups

It is possible to add a new test case group, a new test step group or a new default group in the Dynamic Part, it is also possible to add a new Group for constraint declaration in the Constraints Part.

To add a new group as the last child to the selected node:

- Select *Add Group In* from the *Edit* menu.

To add a new group before the selected node:

- Select *Add Group* from the *Edit* menu.

To add a table to a group, select the group and *Add In*.

Adding Compact Tables

It is possible to specify that all the test cases in a given group are displayed in the compact format (see Annex C, clause C.3 of ISO/IEC 9646-3). The following commands allow the insertion of compact groups in the test suite hierarchy:

To add a compact group before the selected node:

- Select *Add Compact Group* from the *Edit* menu.

To add a compact group as the last child of the selected node:

- Select *Add Compact Group In* from the *Edit* menu.

Cutting, Copying and Pasting Nodes

You may cut or copy dynamic nodes. Dynamic nodes may also be pasted according to compatible classes, for example:

- Test suite parameters, test suite constants, test suite variables and test case variables may be pasted into each other.
- TTCN ASP, PDU, structured type and CM definitions may be pasted into each other and into TTCN ASP, PDU, structured type and CM constraints (and vice versa).
- ASN.1 ASP, PDU, structured type and CM definitions may be pasted into each other and into ASN.1 ASP, PDU, structured type and CM constraints (and vice versa).
- Test case, test step and default behaviors may be pasted into each other.

However, it is not possible to paste a constraint, for example, as a test case behaviour.

Paste is not available if the clipboard contains an object of an incompatible type to the selected object.

To cut the selected node and its sub tree:

- Select *Edit* > *Cut*.
  – The shortcut is `<Ctrl+X>`.

To copy the selected node and its sub tree:

- Select *Edit* > *Copy*.
  – The shortcut is `<Ctrl+C>`.

To paste a node before the selected node:

- Select *Edit* > *Paste*.

To paste a node as the last child to the selected node:

- Select *Edit* > *Paste In*.
  – The shortcut is `<Ctrl+V>`.

Creating Constraints

The most convenient way of creating a constraint is to copy the corresponding type and paste it as a constraint. Do this by copying the chosen type (ASP, PDU, CM or structured type), and then pasting it among the corresponding constraints. This works for both tabular constraints and for ASN.1 constraints.

The pasted table will have all its local names filled in. All that remains is to give the constraint a name and fill in the values.

Deleting Nodes

Dynamic nodes may be removed from the test document.

To delete the selected node and its sub tree:

- Select *Delete* from the *Edit* menu.

Undoing/Redoing Operations

All editing commands can be undone, and undone actions can be re-done.

- To revert the last edit step, select *Undo* from the *Edit* menu.
  – The shortcut is `<Ctrl+Z>`.

- To revert the last *Undo*, select *Redo* from the *Edit* menu.
  – The shortcut is `<Ctrl+Y>`.

Opening a Table

To open a table, either:

- Double-click a table node in the Browser.
- Select a table node and then press `<Enter>`
- Select a table node and then *Open Table Editor* from the *View* menu.

It is possible to open several tables at the same time, but if it is more than ten, you will be asked to confirm it.

Printing a TTCN Document

To print a TTCN document:

- Select *Print* from the *File* menu.
  – The shortcut is `<Ctrl+P>`.

For more information, see "The Print Dialogs in the TTCN Suite" on page 333 in chapter 5, *Printing Documents and Diagrams*.

Editing Tables

The Table Editor is used for editing various TTCN tables. It displays the tables in three different parts: the header, the body and the footer. Also, in the upper part, it displays the Search and Replace tool. Each part, as well as many fields, can be resized.The Table Editor is used for editing various TTCN tables. It displays the tables in three different parts: the header, the body and the footer. Each part, as well as many fields, can be resized.

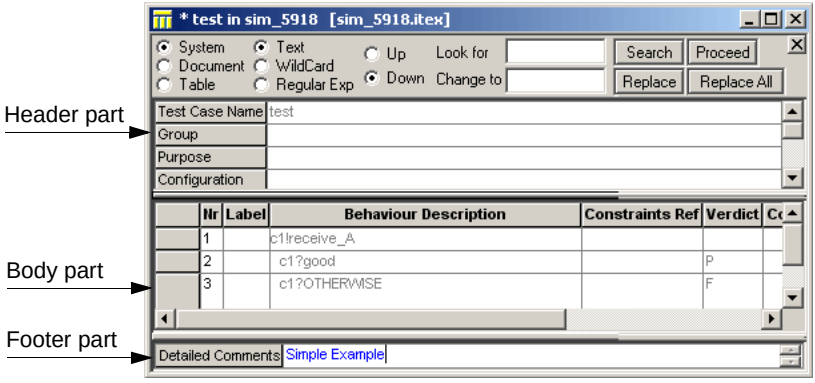

Figure 218: A Table Editor for a test case

Resizing Cells and Table Parts

The three parts of a table – header, body and footer – are separated by horizontal bars, which you can drag to change the relative size and to hide parts of the table from view.

You can change the individual height of rows by dragging the leftmost row separator. In the body part, you may also change the individual width of columns by dragging the separators of the header fields.

Note that changing the column width may have effect on the row height, as the row will change to display all information it contains.

When the Search and Replace tool is closed this affects all Table Editors opened in TTCN Suite. To restore the view of Search and Replace tool press the expand button that appear in upper-right part of Table Editor instead of the **Close Window** button.

Renaming a Table

To change the name of a table, you can either rename its node in the Browser or edit the table name in the table itself.

Setting the Input Focus

To set the input focus in another part of a table, either:

- Click in a cell in that part.
- Use `<left arrow>` and `<right arrow>` to move between the last field of one part and the first field of another part.

To set the input focus within a part, either point and click or use the arrow keys. There are also some shortcuts:

To Move to:	Use This Key Combination
Next field in same row	`<Tab>`
Previous field in same row	`<Shift+Tab>`
Last field in same column	`<Ctrl+Down arrow>`
First field in same column	`<Ctrl+Up arrow>`
First field	`<Ctrl+Home>`
Last field	`<Ctrl+End>`

Editing Text in a Table

When you have used the keyboard to move the input focus to a field, the contents of the field will be **replaced** with the new text when you start typing. To edit the existing text, you have to press `<Home>` or `<End>` first.

If you use the mouse to explicitly set the input focus in a field, you can start editing the existing text directly with the keyboard.

The table fields will expand automatically to accommodate the text. You can also add a line break in the text by using `<Return>`.

To cut, copy and paste text in the fields, you use the corresponding commands in the popup menu, the *Edit* menu or the standard Windows

shortcuts. However, note that it is only possible to paste text into a table field when the field contains a text pointer.

> **Note:**
> The paste buffer for text is not the same as the one used for entire rows in the body of a table.

Auto completion of identifiers

When editing tables, it is possible to auto-complete identifier table names while editing text in the Table Editor.

Start to type any identifier (a table with this name should already exist in the test suite). Type one or more letters, then press <CTRL-space>. TTCN Suite will find the tables that match the text typed. If one match is found, the typed name will be completed with the found one. If several matches are found, a pop-up window with a list of names will be displayed. It is possible to select one by using keyboard (“Up”, “Down” arrows for navigate, “Enter” to select, “ESC” for cancel) or mouse (double-click to select, click outside the window for cancel).

Editing Rows in the Body of a Table

You can add, delete, cut and copy rows in the body of all TTCN tables that contain more than one column. This is not possible in the headers and footers, since the formats of these parts of a table are defined by the TTCN standard.

The ASN.1 tables only have a single column with a single row and therefore adding, deleting, cutting and copying rows is not applicable. However, the contents of ASN.1 tables can still be copied, pasted, etc, as text.

Selecting and Deselecting Rows

- Select rows in the body of a table by clicking in the leftmost cell of a row (the “row button”). This deselects other selected rows.
- Select range of rows in the body by first selecting one row and then `<Shift>`-clicking another.
- Toggle the selection of a row by `<Ctrl>`-clicking the leftmost cell of the row.

Note:

Setting the input focus will also deselect all selected rows.

Cutting, Copying and Pasting Rows

Rows in the body of a table may be cut, copied and pasted. *Copy* and *Paste* work across all the different tables although the *Paste* command is mainly intended for use among tables of the same or similar types.

To cut selected row or rows from the table:

- Select *Edit* > *Cut*.
  - The shortcut is `<Ctrl+X>`.

To copy selected row or rows:

- Select *Edit* > *Copy*.
  - The shortcut is `<Ctrl+C>`.

To paste a row or rows:

- Select *Edit* > *Paste*.
  - The shortcut is `<Ctrl+V>`.

To paste a row or rows before the current row:

- Select *Paste In* from the *Edit* menu.

It is possible to paste a row when a body row or field is selected.

Note:

The paste buffer for entire rows in the body of a table, is not the same as the one used for text.

Deleting rows

To delete the selected row or rows, select *Delete* from the *Edit* menu.

Inserting Rows

To insert a new row before a selected row:

- Select *Insert New Row Before* from the *Edit* menu.

  Only one row may be selected. If no row is selected, the new row will be created first in the table.

  – The shortcut is `<Ctrl+Ins>`.

To insert a new row after a selected row:

- Select *Insert New Row After* from the *Edit* menu.

  Only one row may be selected. If no row is selected, the new row will be created last in the table.

  – The shortcut is `<Ins>`.

To insert a new tree header row before a selected row:

- Select *Insert Local Tree Before* from the *Edit* menu.

  Only one row may be selected. This command only works in dynamic behaviour tables. If no row is selected, the new row will be created first in the table.

To insert a new tree header row after a selected row:

- Select *Insert Local Tree After* from the *Edit* menu.

  Only one row may be selected. This command only works in dynamic behaviour tables. If no row is selected, the new row will be created last in the table.

You may also use `<Ins>` to insert rows. Where the row will be inserted depends on the input focus:

- If input focus is in the header or footer of a table, a new row is added after the last row in the body of the table.
- If input focus is set on a field in the body of the table, a new row is added after the field that has the input focus. The input focus will be transferred to the corresponding field in the new row.

- <Ctrl+Ins> gives the same effect as above but the new row is inserted **before** the row/field.

Indenting Behaviour Lines

The indention of behaviour lines can be increased and decreased:

To increase the indentation of a row in focus, or selected rows, by one position:

- Select *Increase Indention Level* from the *Edit* menu.

To decrease the indentation of row in focus, or the selected rows, by one position:

- Select *Decrease Indention Level* from the *Edit* menu.

Browsing in the Table Editor

If you right-click a table field containing an identifier, you may open the table representing the identifier from the pop-up menu:

- To save the current table in the history and display the definition of the selected identifier in the current Table Editor:
  - Select *Open <Identifier>* from the pop-up menu.
- To display a pop-up menu containing the header rows of the identified table:
  - <Control>-right-click the identifier.
- If the identifier is associated with a one-line table, the whole table is displayed in the pop-up. To select the identifier in the popup will have the same effect as *Open <Identifier>* (described above).
- To open the table associated with the identifier in a new Table Editor window:
  - Select *Open <Identifier> in New Window* from the popup menu.

    The new window gets a new (empty) history buffer and is completely independent of the table from which it was opened.

The Table Editor maintains a history of tables displayed with *Open <Identifier>* described above. This is similar to going back and forward in a web browser:

To go forward in the history of the Table Editor:

- Select *Go Forward* from the popup menu or the *View* menu.

To go back in the history of the Table Editor:

- Select *Go Back* from the popup menu or the *View* menu.

Editing Text with an External Editor

You may use any external text editor for editing text in TTCN Tables. The editor must have the possibility to read and save files in ASCII format (text only, without any formatting).

Specify the external editor executable in the TTCN Suite Options dialog (*Menu > Settings > Options...*). Right-click in any cell of TTCN Table, with no text selected in the cell, and point to the item *External Editor* in the shortcut menu. to start the editor which you specified. After you have edit the text, save and close the editor. This will import the modified text to the cell of TTCN Table. While the external editor is open no other operations in the TTCN Suite are available. The external editor must be closed before you continue.

Creating Behaviour Lines

The Data Dictionary gives you an alternative way of writing behaviour lines, by providing easy access to lists of PCOs, types, constraints, timers, etc, that you have already defined

Before you can use the Data Dictionary, the TTCN document has to be analyzed, because PCOs, types and constraints with major reference problems or missing type references will not be presented in the lists in the dialog.

Opening the Data Dictionary

To open the Data Dictionary:

1. Select a body row in a behaviour table.
   - If you have not inserted a behaviour line yet, the input focus should be somewhere in the header of the table.
2. Select *Data Dictionary* from the *View* menu.

It is only possible to have one *Data Dictionary* dialog opened.

The *Data Dictionary* dialog contains:

- Three different tabs: *Send/Receive*, *Timer* and *Attachment*, from which you can select different statements to generate.
- Three fields: *Behaviour Line*, *Constraint* and *Verdict*, whose contents will be inserted as a TTCN line in the table. It is also possible to edit the fields manually.
- Three buttons: *Apply*, *Clear* and *Close* (the first two only enabled when a body row of a behaviour table is selected):
  - Click the *Apply* button to add a new row – containing the contents of the *Behaviour Line*, *Constraint* and *Verdict* fields – to the table.
  - Click the *Clear* button to reset the dialog and deselect all selections in the current tab.

Generating a Send or Receive Statement

Generate a send or receive statement by selecting a PCO, a type and a constraint. You can also add a timer, assignment and qualifier.

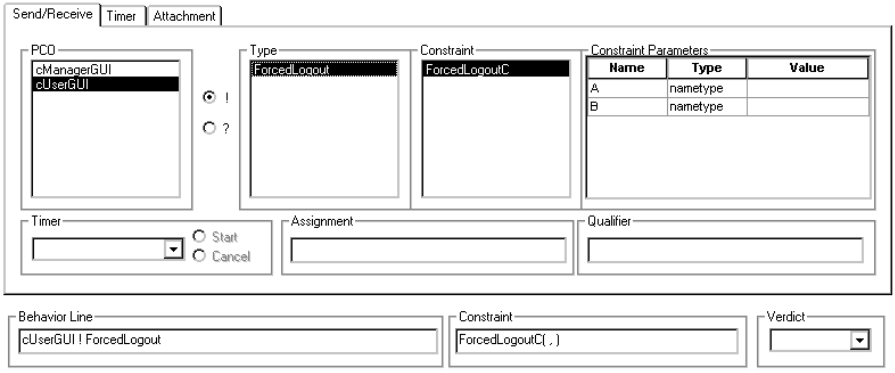

Figure 219: The Send/Receive tab in the Data Dictionary dialog

To add a send or receive statement:

1. Select the *Send/Receive* tab.
2. Select a PCO.

   The *Type* and *Constraints* list will be updated and only show the entries that are valid for the currently selected PCO.
3. Select the *!* radio button for a send statement or the *?* radio button for a receive statement.
4. Select an ASP or a PDU in the *Types* list.

   The *PCO* and *Constraints* lists will be updated accordingly.
5. Select a constraint.

   The *Type* and *Constraints* list will be updated.

   – If the constraint is a parametric constraint, a choice for each parameter will be displayed in the *Constraints Parameter* area, which you can select.

6. Optionally you can add a timer statement by selecting the *Start* or *Cancel* radio button.

   To insert a start statement, you also have to select a timer.

   It is not possible to select timeout or to specify a timeout value here. You have to do that in the *Timer* tab of the dialog.

7. Optionally, add assignments separated by commas and without parenthesis.

8. Optionally, add qualifier statements, without brackets.

9. Optionally, add a verdict.

10. Click *Apply*

    A new row – containing the contents of the *Behaviour Line*, *Constraint* and *Verdict* fields in the dialog – will be added after the currently selected row and the new row will be selected.

Adding a Timer Statement

In the *Timer* tab, you may generate a StartTimer, CancelTimer or a Timeout statement. As described above, you can also add timer statements from the *Send/Receive* tab. The difference is that from this tab you can also add Timeout value to the timer and you can add a timeout statement.

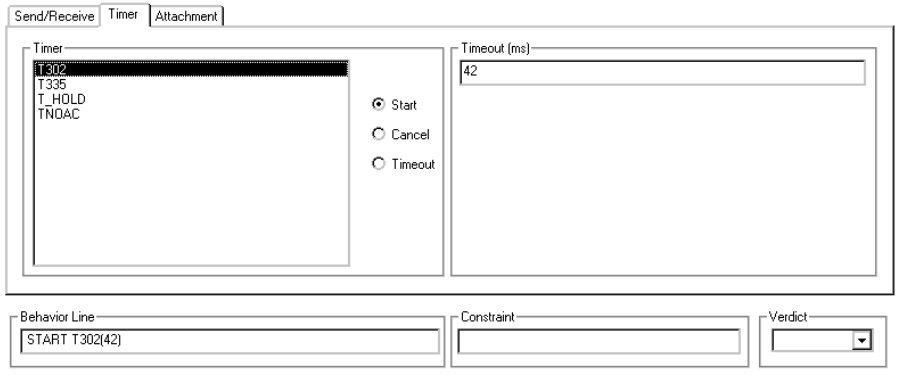

Figure 220: The Timer tab in the Data Dictionary dialog

To add a timer statement:

1. Select the *Timer* tab in the dialog.
2. Select a timer.
3. Select the *Start*, *Cancel* or *Timeout* radio button.
4. If you selected *Start* or *Timeout*, you also have to specify a timer duration in the *Timeout* field.
5. Click *Apply*.

   A new row – containing the contents of the *Behaviour Line*, *Constraint* and *Verdict* fields in the dialog – will be added after the currently selected row and the new row will be selected.

Adding an Attachment Statement

Generate an Attachment statement by selecting a test step and specifying an actual parameter list (if the test step has a formal parameter list).

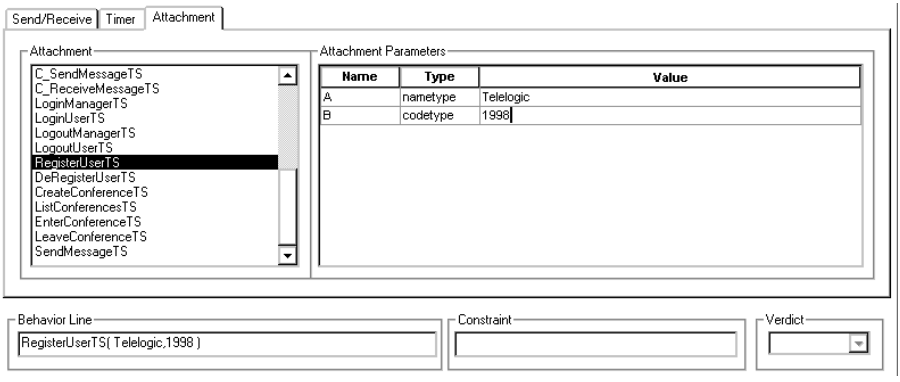

Figure 221: The Attachment tab in the Data Dictionary dialog

To add an attachment statement:

1. Select the *Attachment* tab.
2. Select an attachment.
3. If the selected test step has a formal parameter list, specify the parameter values in the *Attachment Parameters* area.

Comparing TTCN Documents

The Compare tool is used for comparing two TTCN documents with respect to finding *similarities* that exist between them, i.e. two TTCN objects that have the same name. These objects need not necessarily be of the same type.

The Compare tool is accessed from a Browser and is applied to selections of items in that Browser.

Compare will check either only for similar names or for names **and** object type. The comparison can also include the contents of tables if required.

The Compare tool can also check the group structure of TTCN documents for similarities, i.e. it will indicate Test Group, Test Step Group and Default Group paths that are the same in both TTCN documents.

Any similarities that are found may be logged in a log file. There are three levels of log verbosity: *quiet*, *some* and *full*. Execution of the Compare tool may result in a new selection, which can be used to create a separate Browser if so wished.

One of the main uses of this tool will be to help remove conflicts from two TTCN documents prior to performing a merge operation.

Comparing by Using the Compare Tool

To use the Compare tool, you need two TTCN documents to operate on: the *destination* document and the *compare* document.

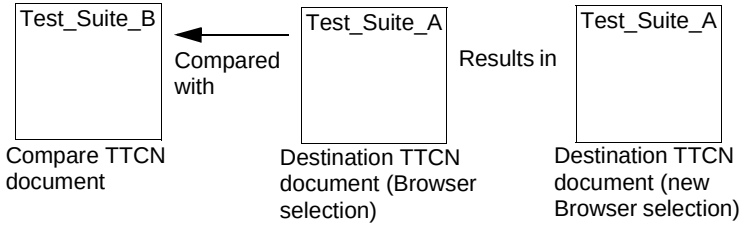

Figure 222: How Compare works

A selection from the *destination* document may be compared with the *compare* document. If any similarities are found between the two TTCN

documents this will result in the modification of the original selection in the *destination* TTCN document.

Open both the *destination* TTCN document and the *compare* TTCN document in browsers. Make the selection in the *destination* TTCN document Browser and call the Compare tool from the menu command ***File -> Compare*** (should this menu item be dimmed, most likely you have currently only one open TTCN document). The following Compare dialog will appear:

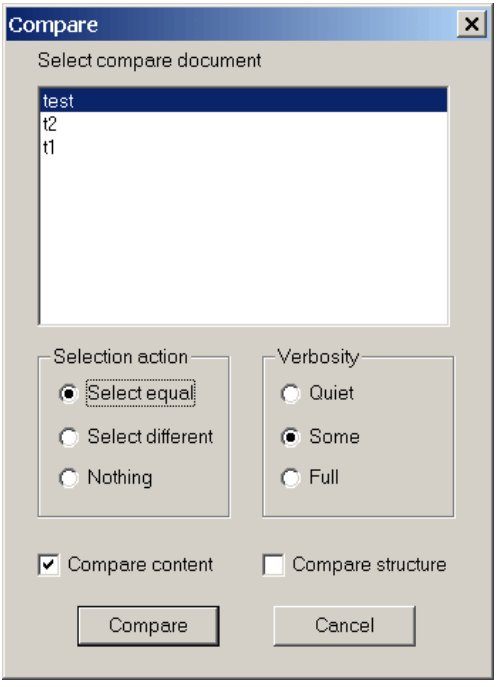

Figure 223: Compare Documents dialog

Select compare document

Presents a list of currently opened TTCN documents except the destination TTCN document, from which the Compare tool was called. Choose in the list the compare TTCN document.

Selection action

Specifies the effect that the Compare operation will have on the original selection in the destination TTCN document.

- *Select equal*

  All items in the original selection that are similar to items in the *compare* TTCN document will **remain selected**, otherwise the items will be deselected.

  In other words, the result of the Compare operation will result in a selection that shows the similarities between the *destination* and the *compare* TTCN documents.

- *Select different*

  All items in the original selection that are similar to items in the *compare* TTCN document will be **deselected**, otherwise the items will remain selected.

  In other words, the result of the Compare operation will result in a selection that shows the differences between the TTCN documents.

- *Nothing*

  Means that the Compare operation will have no effect on the destination selection. However, the results of the Compare operation will still be recorded in the log.

If the *Selection action* is anything except *Nothing*, the TTCN tree is being expanded up till all selected leaf items.

Verbosity

Sets the verbosity level for the log.

- *Quiet*

  Turns the log off. No information will be recorded in the log.

Note:

Using the *Nothing* action together with the *Quiet* option is rather meaningless!

- *Some*

Causes the names of all identically named objects to be printed in the log. If the *Compare content* switch is on, the log will also indicate that a difference has been detected.

- Full

  Causes the names of all identically named objects to be printed in the log. However, if the objects are of different types this will be indicated as well. If the *Compare Content* switch is on, the log will also indicate in detail the differences detected.

Compare Content

Extends the scope of the comparison to include the contents (down to the level of a single character) of the tables as well. Thus, two objects are considered to be identical if their names, object types and entire contents are identical. If the verbosity is full the differences are detailed.

Compare structure

Extends the scope of the comparison to include the Test Group, Test Step Group and Default Group references in the relevant behaviour tables. This option is only available when the Compare content option is chosen.

Merging TTCN Documents

The Merge tool is used for merging one TTCN document (complete or partial) into another TTCN document. There are two ways for merge:

1. Merge the selected tables from the open Test Suite into the another open Test Suite (*Merge to suite*).
2. Merge all tables from any Test Suite into the open Test Suite (*Merge from file*).

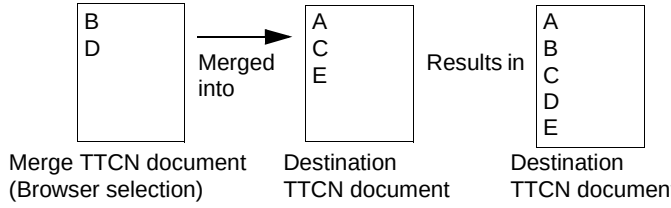

Figure 224: Shows how Merge works

Merge will only work as depicted above if the two TTCN documents do not conflict. A conflict occurs if any TTCN object in the *Merge TTCN document* has the same name as any TTCN object in the *Destination TTCN document*. If such a conflict is detected, the conflicting object will be skipped, information about this will be put in log, and the merge process continued.

Merging of constraint tables are handled separately. For example, the *Merge TTCN document* may contain a TTCN ASP Constraint, *constraint1*, that refers to the type *type1*, where the *type1* Type table is of the incompatible type *TTCN PDU TypeDef*. This will make the merge process insert a copy of constraint1 as a table of type *TTCN PDU Constraint* instead of the original type. There are, however, limitations to this type conversion, the conversion will for example not convert an ASN.1 Constraint to a TTCN Constraint nor vice versa.

Merge to suite

Open the *Merge TTCN document* and the *Destination TTCN document*. Select in *Merge TTCN document* the tables that should be merged into *Destination TTCN document*. From the *File* menu choose *Merge to suite* (should this menu item be dimmed, most likely you have currently

only one open TTCN document). A dialog with names of other open test suites will appear. Select the *Destination TTCN document* and press "Merge" button.

Merge from file

Open *Destination TTCN document*. From the *File* menu choose *Merge from file*. A file selection dialog will appear. Choose the file that contains the *Merge TTCN document*. GR (*.itex) and MP (*.mp) file formats are supported.

It is possible to select several files at same time. In this case they will all be merged one by one into the *Destination TTCN document*.

Merge from command line

`TTCNMerge` is a command-line tool for merging two or more TTCN documents into one.

Usage:

```
TTCNMerge <Destination TTCN Suite file> <Source file 1>
... <Source file n>
```

If `<Destination TTCN Suite file>` doesn't exist, it will be created.

Example 216 ----------

```
TTCNMerge total.itex main.mp decl.mp initial.itex
```

The appearance order of source files in command line is significant such that files are being merged one by one in order of their appearance, and, if the table with the same name exists in several TTCN source documents, only the first appearance will be merged. All others will be skipped with warnings given.

Viewing Log Information

The Log Manager is a collection of log outputs, where each test system component can report information. The Log Manager contains one log per test component, and one common pane that is used for general information.

Examples of actions that can result in log information:

- Analysis of one or more tables: The resulting errors (if any).
- Opening an MP file: Result of the operation.
- Simulation: Simulator traces are reported on both the component log, and the general log.

The Log Manager can be configured to behave in various ways. The default setting is for the Log Manager to be hidden, but appear whenever log output is present. Only one instance of the Log Manager is available.

The contents of each log can be saved as a text file.

You can open tables by clicking and then `<Ctrl>`-right-clicking the name of the table in the log.

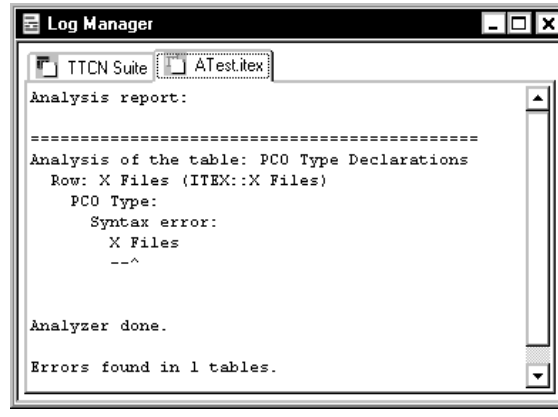

Figure 225: The Log Manager window

Automatic Appearance

The Log Manager can be made to automatically become visible whenever new information is available in a log. This can be handy to reduce the amount of windows open at a given time as the Log Manager can be closed when it is not needed.

To allow the Log Manager to automatically open whenever new information is available:

- Select *Auto-Raise Log* from the *Log* menu.

Changing the Appearance of the Log

The log font can be made smaller or larger, allowing more information to be viewed or increased readability.

To make the log text larger:

- Select *Increase Log Font Size* in the *Log* menu.
  - The shortcut is `<Ctrl+Alt+L>`

To make the log text smaller:

- Select *Decrease Log Font Size* in the *Log* menu.
  - The shortcut is `<Ctrl+Shift+L>`

Exporting Information from the Log

The information contained in a log can be copied to the clipboard, or saved to disk as an ordinary text file. In addition to normal text-selection, all text can also be selected with one operation.

To select all text:

- In the *Log* menu, point to *Select All In Log*.

To copy the selection to the clipboard:

- Select *Copy Log* in the *Log* menu.

To save all text in a log to a file:

- Select *Save Log* in the *Log* menu.

Clearing the Log

To clear the displayed log:

- Select *Clear Log* in the *Log* menu

Finding and Sorting Tables

As an alternative to the Browser, you can use the Finder for displaying TTCN tables in a list, without the ordering restrictions imposed by the TTCN tree structure.

You can search for and display tables in the Finder. The search may for example be based on name, type and content. You can use the entire TTCN document, entire TTCN Suite system, tables selected in TTCN Browser or the Finder Results List as search source, and extend, replace or restrict the number of tables displayed in Finder Results List in any number of steps.

Another way of searching is relationally. This means that you search for tables that reference or are referenced by tables selected in the Finder Results List or in TTCN Browser. The relational search cannot be combined with the ordinary.

The tables that will be displayed in Finder Results List after a search, can be sorted by a number of criteria:

- Name
- Type
- Path in the test tree
- Parse status
- Latest analyze time stamp
- Latest modification time

Reversed sorting is also possible.

In addition, it is possible to for example open, analyze, copy, rename, export to MP file and delete tables from the Finder Results List, but not cut, paste and insert since that require a tree context.

Searching and Replacing

The Search and Replace tool exists in the upper part of the Table Editor, see "Editing Tables" on page 1262 in chapter 30, *Editing TTCN Documents (in Windows)*. Its settings and functionality is absolutely the same as on UNIX, see "Searching and Replacing" on page 1176 in chapter 25, *The TTCN Table Editor (on UNIX)* for information on the TTCN Table Editor on UNIX. The difference is only that there are buttons instead of Search Menu items.

Opening the Finder

To open the Finder:

- Select *Open Finder* from the *View* menu.
  – The shortcut is `<Ctrl+F>`

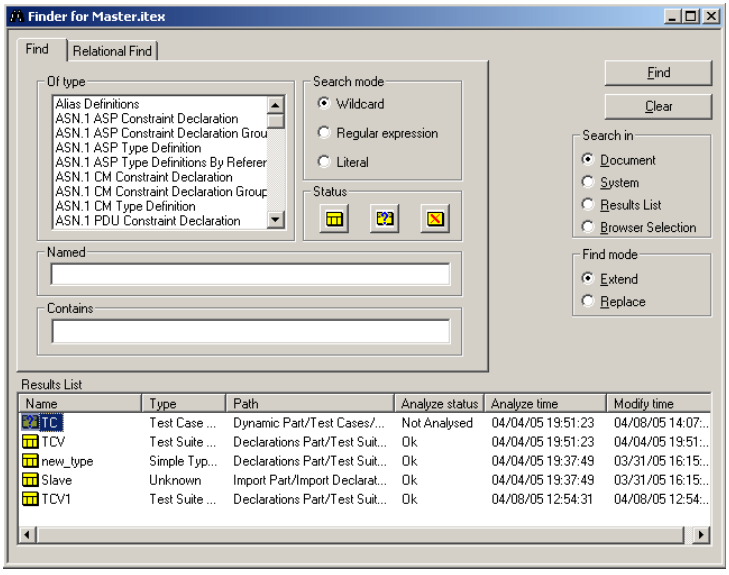

Figure 226: The Finder

The Finder consists of four areas:

- The *Find/Relational Find* area, where you specify criteria for the tables to be found and inserted in the *Results List*.
- The *Search In* area, where you can select to search for tables in the entire document, entire system, tables selected in Browser or only in the *Results List*.
- The *Find mode* area, where you can specify should the *Results List* keep previously found tables or not.
- The *Results List*, where the sorted list of TTCN tables are kept.

About Search Criteria

Search criteria are used for **restricting** a search. This means that if you do not specify any search criteria – all fields are empty and no buttons are clicked – before you click the *Find* button, all dynamic TTCN tables of the test system component will be displayed.

Consequently, if you specify one or more search criteria, TTCN tables that match at least one of the criteria, will be displayed in the Finder. Additionally, this means that specifying all possible search criteria has the same effect as specifying none. This is merely as a convenience for quickly adding all tables of the test system component, as the closed search criteria is not meaningful.

Note:

The search criteria are used for an OR-style search.

Finding Tables

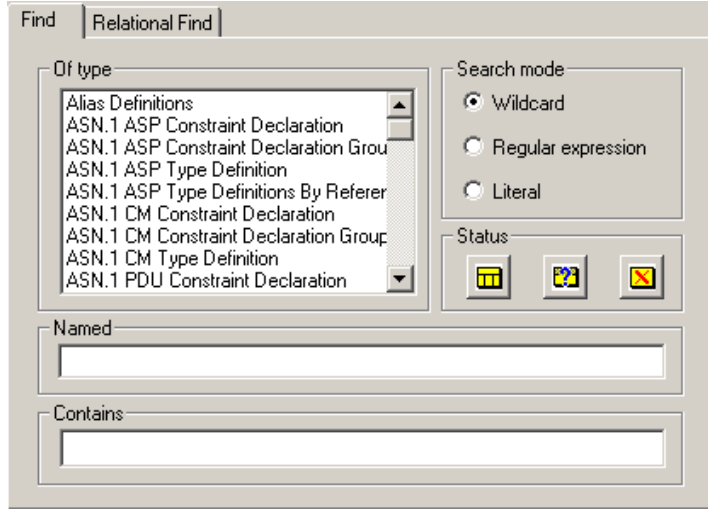

Figure 227: The Find tab in the Finder

To search for tables:

1. Select the *Find* tab.
2. Select Document, System, Results List or Browser Selection in the Search in area to search for tables in:
   - If you select *Document*, the search area will be the entire TTCN document.
   - If you select *System*, the search area will be the entire TTCN system.
   - If you select *Results List*, the search criteria will be used to restrict the set of TTCN tables already present in the *Results List*.
   - If you select *Browser Selection*, the search area will be the tables selected in the TTCN Browser.
3. Select Extend or Replace in the Find mode area to choose should Results List keep previously found tables or not.
4. Optionally, select one or several table types in the *Of type* list. No table types selected means that any table type appropriate.

   This list contains all existing TTCN and ASN.1 table types supported.

5. Click a *Search mode* radio button.

   This selection affects the text you type in the *Name* and *Contains* fields. If you are not going to use those fields in the search, the search mode does not affect the search at all.

   – *Wildcard*

     The *Name* and *Contains* fields can contain wildcards. This means that “a*body” will match “anybody” and “antibody”, while “a??body” only will match “anybody”.

   – *Regular expression*

     The *Name* and *Contains* fields contain regular expression, with its more advanced syntax and matching possibilities. This means that “any[bt]” will match “anybody” and “anything” but not “anyone”.

   – *Literal*

     The *Name* and *Contains* fields contain the exact text. This means that “any?” only will match “any?”.

6. Optionally, type some text in the *Name* field.

   The tables with names that match will be found.

7. Optionally, type some text in the *Contains* field.

   The tables with contents that match will be found.

8. Optionally, click one or several *Status* buttons to sort out tables of a different parse status.

   For example, if you select the error button, only tables with erroneous parse status will be found.

9. Click *Find*.

   Tables that match at least one of the search criteria you have specified will be displayed in the *Results List*.

Finding Tables Relationally

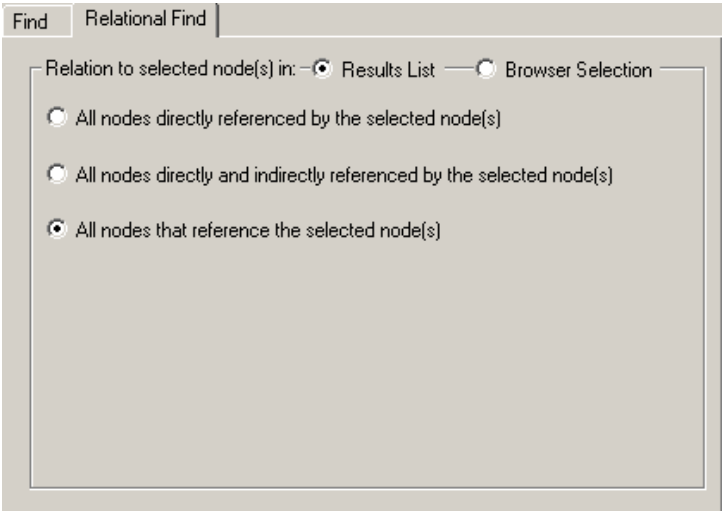

Figure 228: The Relational Find tab in the Finder

You can search for tables that are referenced by, and that reference tables, that are displayed and selected in the *Results list* or selected in TTCN Browser. It is required that the TTCN document is analyzed before start Relational Find. To do this:

1. Select the *Relational Find* tab.
2. Select one or several tables in the *Results List*.or in TTCN Browser and select one of the following radio buttons:
   - Results list
   - TTCN Browser
3. Select one of the following radio buttons:
   - *All nodes directly referenced by the selected node(s)*

     Replaces the contents of the *Results List* with all nodes that are directly referenced by the tables currently selected in the list.
   - *All nodes directly and indirectly referenced by the selected node(s)*

Same as above, but expands the search to include tables that are referenced by the referenced tables, and so forth.

– *All nodes that reference the selected node(s)*

Replaces the contents of the *Results List* with all nodes that reference the tables selected in the list.

4. Select Document, System, Results List or Browser Selection in the Search in area to search for tables in:
   - If you select *Document*, the search area will be the entire TTCN document.
   - If you select *System*, the search area will be the entire TTCN system.
   - If you select *Results List*, the search criteria will be used to restrict the set of TTCN tables already present in the Results List.
   - If you select *Browser Selection*, the search area will be the tables selected in TTCN Browser.
5. Select Extend or Replace in the Find mode area to choose should Results List keep previously found tables or not.
6. Click *Find*.

   The *Results List* will be updated in accordance with your settings.

Results List operations

The *Results List* contains a subset of all dynamic TTCN tables in the TTCN system. You can perform most standard operation (copy, delete, rename, open in Table Editor, export to MP, Analyze, etc) on the tables. However, it is not possible to cut, paste or insert tables, since this requires the structural context of the Browser.

Caution!

Even if the elements of the *Results List* are presented without structural ordering, they still follow the TTCN hierarchy. This means that if you delete a group node, the group and its entire sub tree will be removed.

Sorting the *Results List*

The contents of the *Results List* can be sorted if you click on the header of the information column. The available information is:

- *Name*

  The name of the table.

- *Type*

  The TTCN or ASN.1 type of the table.

- *Path*

  The path of the tree leading to this table on the form root/..../parent/node.

- *Analyze status*

  The parse status of the table.

- *Analyze time*

  The last time the table was analyzed.

- *Modify time*

  The last time the table was modified.

Click a second time on the header to sort the list in reverse order.

Clearing the *Results List*

Click *Clear* to clear the contents of the *Results List*.

When it is necessary to remove some individual tables from *Results List*, select them, right-click and choose *Remove* from *Results List* menu item.

Export to MP file

Tables from *Results List* may be exported to an MP file. To do this select *Tables*, right-click and choose *Export*.

How to isolate a single Test Case

A single Test Case may be isolated from a Test Suite together with all its dependent tables using the Finder.

To do this do the following:

- Analyze the Test Suite. The analysis must complete successfully without any errors.
- Select in the TTCN Browser window the Test Case that should be isolated (it may not be a single Test Case, and in fact even not a Test Case - you can select any table(s) that should be exported together with all their dependent tables).
- Start the Finder, open the "Relational Find" pane. In the section "Relations to selected node(s) in:" you select the "Browser Selections" and "All nodes directly and indirectly referenced by the selected node(s)". In the section "Search In:" you select "System", if the Test Suite is Modular. If the Test Suite is not modular, you can do the search in "Document".
- Press "Find" button. All tables that required by the selected in TTCN Browser window Test Case will appear in Results List.
- Select all these tables (click on the first table and then press Shift key and click on the last one), then right-click and choose "Export" in pop-up menu. Give the file name for the new file, that will contains all these tables.

In the case where you have a Modular Test Suite, the tables that belong to different modules will be exported to different files. Therefore the prompt to give new filenames will appear for each one of the exported

tables. As a result the exported Test Suite will also be Modular and the original structure will be kept. If it is necessary to convert it into a non-modular Test Suite, use the Generate Flat View option from the Analyze TTCN dialog, see "Analyze TTCN" on page 118 in chapter 2, *The Organizer*.

Converting to TTCN-MP

TTCN-GR – the *gr*aphical notation – is the format used when you edit or print a test suite in the TTCN Suite. TTCN-MP – the textual notation (*m*achine *p*rocessable) – can be used when you want to import a TTCN document into a non-TTCN Suite tool or make backups.

To convert a TTCN document to TTCN-MP, either:

- Select *Save As* from the *File* menu.

  This opens a dialog where you can save the current document as TTCN-MP.

- Click the *Export to MP* button.

  This opens a dialog where you can export the current document to TTCN-MP. The MP file will be written to disk, but not opened.

Both TTCN-MP and TTCN-GR can be opened in TTCN Suite.

For a full supported EBNF, see "The TTCN-MP Syntax Productions in BNF" on page 1574 in chapter 38, *Languages Supported in the TTCN Suite*.

The Standard MP Format

When you convert to MP, the TTCN document does not have to be analyzed or correct. TTCN-MP will be generated even for documents that are neither complete nor error-free. This implies that the generated MP file may be, but is not necessarily, conformant to the standardized TTCN-MP format

However, to ensure that the TTCN-MP document can be read by a non-TTCN Suite tool, you should analyze the document and correct any errors.

The IBM Rational MP Format

An optional but non-standard TTCN-MP for compact tables and ASN.1 references is supported. Additional fields in dynamic tables (fields which are transferred to test suite overview tables) are also supported. You are recommended to use this format for transferring TTCN document between the TTCN Suite instances and for making backups of the TTCN documents. Otherwise it works just as the standard MP format.

MP File Format Problem when Opening

When you open certain TTCN-MP documents, a problem with transferring the information (e.g. description) in the overview tables to the tables in Dynamic Part, may occur.

The TTCN standard allow path specifications to optionally include the document name first. This has the unfortunate effect that if the TTCN document contains a top level group with the same name as the TTCN document, there is, in general, no way of knowing if the first part of the paths is a group identifier or the TTCN document identifier.

TTCN Suite assumes that if the first part of the path is equal to the document name, it is the optional document name and, when converting, strips it away. When the document is saved as or exported to MP, the document name is always added to the front of all paths. That way, TTCN Suite is always able to open the MP files it exports.

If the TTCN document contains top level group identifiers equal to the document name, and TTCN Suite is unable to resolve the paths, temporarily change the document name in the MP file and change it back once inside TTCN Suite.

Note that ITEX 2.0 did not add the document name at export, and therefore the problem described may apply when open MP files exported by ITEX 2.0.

Fields Containing the '$' Character

The contents of table fields in a TTCN-MP file are usually ignored. However, to make it possible to open non-bounded free text fields (for example TS_VarValue field) with embedded dollar characters ('$'), those fields will be syntax checked. This means that it is not possible to convert TTCN documents containing unmatched single or double quotes in non-bounded freetext fields, that is, when you open a TTCN-MP file, syntax errors in those fields will not be tolerated.

Revision Control

There is no integrated revision control system in the TTCN Suite. Since normal visible files are used to store the TTCN documents, it is easy to integrate the TTCN Suite in a revision control system. However, since the `.itex` file format is binary, it is better to use the TTCN-MP format.

Converting to HTML

It is possible to export a TTCN document, or only a part of it, to HTML. The result will be one HTML-file containing what you selected to export, and – when applicable – hypertext links as well as information about the structure of the test suite will also be generated.

To convert a TTCN document to HTML:

1. Select the top node in the Browser.
   – You may also select only a part of the test suite, but multiple-selection is not possible.
2. Select *Save As* from the *File* menu.

   A dialog will be opened where you can save the document as HTML.

It is also possible to convert a currently opened table to HTML. To do this:

- Select *Generate HTML* from the pop-up menu in the Table Editor.

Crash Recovery

In the event of a TTCN Suite crash, it is possible to recover up-to-the-minute changes. For a description of the “iconcat” tool see “Crash Recovery” on page 1162 in chapter 24, *The TTCN Browser (on UNIX)*.

Shortcuts

Common Shortcuts

Shortcut	Action
Ctrl+N	Creates a new test suite.
Ctrl+O	Opens an existing test suite.
Ctrl+S	Saves the test suite to file.
Ctrl+P	Prints the test suite.
Ctrl+Z	Undoes latest editing action(s).
Ctrl+Y	Redoes latest undone editing action(s).
Ctrl+L	Shows/Hides Log Manager.
Ctrl+F	Opens a new Finder.
F7	Analyzes the selected node and its sub-tree.
F8	Generates code for the current test suite.
Alt+F8	Displays an options dialog to allow the user to set options for tools working on the Browser.
F5	Runs/continues current simulation.
Pause	Pauses current simulation.
Ctrl+Break	Aborts current simulation.
F11	Steps current simulation.

Browser Shortcuts

Shortcut	Action
<Up arrow>	Sets the focus to the above node in the Browser.
<Down arrow>	Sets the focus to the below node in the Browser.
<Right arrow>	If the selected node is collapsed and has children, it will be expanded. If the selected node is expanded and has children the selection will move to the first child.

Shortcut	Action
<Left arrow>	If the selected node is the root of an expanded sub-tree, the sub-tree will be collapsed. If the selected node is the root of a collapsed sub-tree the selection will move to the parent of the current node (if any).
<Ctrl+X>	Cuts the selected non-static node in the Browser.
<Ctrl+C>	Copies the selected non-static node in the Browser.
<Ctrl+V>	Pastes the contents of the cut/copy buffer after the selected node.
<Ctrl+Shift+V>	Pastes the contents of the cut/copy buffer as a child to the selected node.
<Delete>	Deletes selected node(s).
<Enter>	Opens a Table Editor for each selected node.
<Ctrl+A>	Adds a new table after the selected node.
<Ctrl+Shift+A>	Adds a new table as a child to the selected node.
Click	Sets selection on a node in the Browser.
Right-click	If the mouse pointer is above a node, sets selection on that node and display node specific pop-up menu. If no node is selected, displays background pop-up menu.
Double-click	If the selected node is a static node, the sub-tree will either be collapsed or expanded. If the selected node is a collapsed group, its sub-tree will be expanded. Otherwise the associated group table is opened. Finally, if the node is a non-static table a Table Editor for that node will be opened.
<Shift>-click	Selects/deselects all nodes between this selected node and the previously selected nodes.
<Ctrl>-click	Selects/deselects a node without affecting already selected nodes.

Table Editor Shortcuts

Shortcut	Action
<Tab>	Moves to the next editable field.
<Shift+Tab>	Moves to the previous editable field.
<Ctrl+Up arrow>	Moves to the previous line.
<Ctrl+Left arrow>	Moves to the next editable field.
<Ctrl+Down arrow>	Moves to the next line.
<Ctrl+Right arrow>	Moves to the previous editable field.
<Ctrl+Space>	Toggles selection of current row in a table body.
<Alt+Left arrow>	Moves forward in history.
<Alt+Right arrow>	Move back in history.
<Page Up>/<Page Down>	Scroll stable one page.
<F7>	Analyzes the current table.
<Ctrl+X>	Cuts selected rows.
<Ctrl+V>	Pastes rows after the selected row, or last if no selection exist.
<Ctrl+C>	Copies selected rows.
<F9>	Toggles breakpoint on selected row(s)
Right-click	Context sensitive popup.
<Ctrl>-right-click	Displays the definition of the currently selected identifier.
Click	Sets text selection and clear row selection.
<Ctrl>-click	Toggles row selection.

Log Manager Shortcuts

Shortcut	Action
<Ctrl+Alt+L>	Increases font size.
<Ctrl+Shift+L>	Decreases font size.

Finder Shortcuts

Shortcut	Action
<Up arrow>	Sets the focus to the above node in the *Results List*.
<Down arrow>	Sets the focus to the below node in the *Results List*.
<Ctrl+C>	Copies the selected non-static node in the *Results List*.
<Delete>	Deletes selected node(s).
<Enter>	Opens a Table Editor for each selected node.
Click	Sets selection on a node in the *Results List*.
Right-click	If the mouse pointer is above a node, sets selection on that node and display node specific pop-up menu. If no node is selected, displays background pop-up menu.
Double-click	Opens a Table Editor for the selected node.
<Shift>-click	Selects/deselects all nodes between this selected node and the previously selected nodes.
<Ctrl>-click	Selects/deselects a node without affecting already selected nodes.

Chapter 30 Editing TTCN Documents (in Windows)

Chapter

31

Analyzing TTCN Documents (in Windows)

This chapter contains a reference manual to the Analyzer in the TTCN Suite. You can also find information about how to find erroneous tables displayed in the Analyzer log.

The TTCN Browser and TTCN Table Editor are described in chapter 30, *Editing TTCN Documents (in Windows)*.

See chapter 2, *Introduction to the TTCN Suite (in Windows), in the TTCN Suite 6.2 Getting Started* for an overview of the TTCN Suite tool-set.

> **Note: Windows version**
>
> **This is the Windows version of the chapter. The UNIX version is chapter 26, *Analyzing TTCN Documents (on UNIX)*.**

Analyzing TTCN Documents

The Analyzer in the TTCN Suite does a complete syntax check on both TTCN and ASN.1 (as it is used in TTCN). The Analyzer also performs a number of static semantic checks, mainly the uniqueness and existence of identifiers.

For implementation reasons, the Analyzer does not exactly follow the TTCN standard – some syntax restrictions and relaxations apply. These differences will not affect the vast majority of users, but for reference they are documented together with the standard syntax in chapter 38, *Languages Supported in the TTCN Suite*. This chapter also includes the static semantics supported by the TTCN Suite.

During analysis, the TTCN Suite compiles an extensive symbol table containing all named objects in the TTCN document and the references between them.

Using the Analyzer

In the TTCN Suite, the Analyzer works on the currently active TTCN document. It is also possible to analyze a TTCN document from the Organizer, see "Analyze TTCN" on page 118 in chapter 2, *The Organizer*.

- To analyze a subtree of a TTCN document in the TTCN Suite, select a node in the view and then select *Analyze* from the *Build* menu. The selected node and all nodes in its subtree will be analyzed. If the root node is selected, the entire suite will be analyzed.
  – The shortcut is `<F7>`.

- To analyze the entire test suite, regardless of any selections in the test suite, select *Analyze Suite* from the *Build* menu.
  – The shortcut is `<Ctrl+F7>`.

- To analyze an entire modular TTCN system – containing the currently active suite or module – starting from the root suite, select *Analyze System* from the *Build* menu. This is equivalent to analyzing the root node in the Organizer.

  Note that it may take a while before this operation is completed, depending on the size and complexity of the system.

The Analyzer runs in background. The Progress Bar at the bottom of the TTCN Suite window shows the analysis completion. During the analysis it is possible to browse the already opened TTCN documents. It is not allowed to edit, save, close or open any of the TTCN documents during analysis. The analysis may be canceled by pressing the break button on the toolbar or by the menu choice *Build* > *Break*.

If an item is analyzed incorrectly, this will be recorded as an error message in the log. Items that have been found to be incorrect will be marked in red in all views of the document.

The *Analyzer* Dialog

When you analyze a document for the first time, the *Analyzer* dialog will be opened and you may change the options. Once this has been done, the same options will be used and the dialog will not be opened the next time you start the analysis from a quick-button or a keyboard shortcut. However, the dialog will always be opened when you select an analyzer menu choice. You can also open the dialog by the menu choice *Build* > *Options* or by the shortcut `<Alt+F8>`.

Note that every active TTCN document has its own analysis settings, so in practice, two or more TTCN documents can be edited and/or viewed at the same time in the TTCN Suite, and yet have individual settings. But multiple views of the same TTCN document do of course share the same settings.

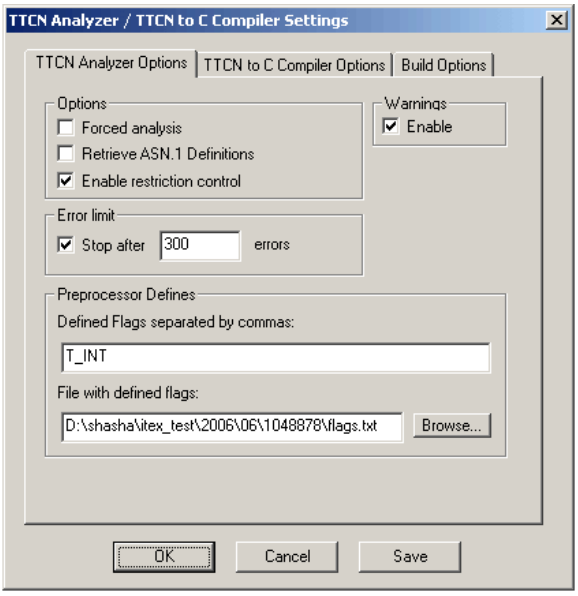

Figure 229: Analyzer dialog

The Analyzer reports all analysis results to the Log Manager. For each different test suite, a new tab will be created to allow the user to easily access the analysis information for different TTCN documents.

Note:

The output of the analysis will not be available if the Log Manager is closed and the option *Auto-Raise Log* is unchecked.

Forced Analysis

Indicates that all selected items are going to be analyzed and no item will be skipped. An item is normally skipped if it is OK.

Retrieve ASN.1 Definitions

Indicates that the definitions of encountered ASN.1 references should be retrieved. An ASN.1 definition is retrieved if this option is set or if the definition has not been fetched before.

Enable Restriction Control

Enables a set of extra controls done on the TTCN code to find even more semantic errors in the analyzed item.

Warnings

Gives more information.

Stop After n Errors

Stops the analysis when the number of errors is reached.

Defined flags

The flags defined for the TTCN Suite preprocessor are separated by commas (see "TTCN Suite Preprocessor" on page 1312).

File with defined flags

This field can be used to point to a file with flags defined for the TTCN Suite preprocessor. Use comma (",") to separate the flags in this file.

Error Messages

Errors detected during analysis are recorded in the log. For the fields in the header of a table, the error messages have the general format:

```
================================
Table name and table type
Field type 1
Error message
Field type 2
Error message
:
:
Field type n
Error message
================================
```

Example 217 ————————————————————————————————

An error found in the default name (identifier) field of the default dynamic behaviour called UT_DEFAULT:

```
========================================
Analysis messages in table: UT_DEFAULT of type:
Default Dynamic Behaviour
 Default Name:
```

```
   The referenced identifier UPPER_PCO is not declared.
   UT_DEFAULT (p : UPPER_PCO)
   ----------------^
   ==========================================
```

In the body of a table (where the field type name does not uniquely define a field) the row number is also included:

- Row number
- Body type
- Error message

Example 218

Errors found in a test step table header (the default field) and in the body (rows 1 and 2 of the behaviour description):

```
   ==========================================
   Analysis messages in table: ESTABLISH_CONNECTION of
   type: Test Step Dynamic Behaviour
    Default:
   Mismatched number of parameters: is 1, should be 0.
      Row: (#1)
         Behaviour Description:
   The referenced identifier CR is of wrong type.
   UPPER_PCO ! CR
   ------------^
      Row: (#2)
         Behaviour Description:
   The referenced identifier CC is of wrong type.
   UPPER_PCO ? CC
   ------------^
   ==========================================
```

Resolving Forward References

During analysis, the TTCN Suite does two main tasks:

- It checks the **syntax** of the abstract TTCN document.
- It checks some of the **static semantics** of the TTCN document.

The syntax of TTCN is defined in ISO/IEC 9646-3 Annex A as a list of BNF productions or rules. See also "The TTCN-MP Syntax Productions in BNF" on page 1574 in chapter 38, *Languages Supported in the TTCN Suite*. The TTCN Suite checks all these rules except for a very few minor deviations; for more information, see "The Restrictions in the TTCN Suite" on page 1570 in chapter 38, *Languages Supported in the TTCN Suite*. If a rule is not followed in the TTCN document then this will be reported as an error by the Analyzer.

The static semantic rules of TTCN are also defined in Annex A of ISO/IEC 9646. These are in the form of text statements which *limit* the use of some of the syntax rules, usually in a specific context. "TTCN Static Semantics" on page 1603 and "ASN.1 Static Semantics" on page 1619 in chapter 38, *Languages Supported in the TTCN Suite* describe the static semantics which are controlled by the Analyzer. The static semantics currently supported are mainly of the following types:

- Identifiers (names) are checked for uniqueness with respect to the scoping rules defined in ISO/IEC 9646-3
- The existence of referenced TTCN objects (e.g. a test step) from another TTCN object (e.g. test case) is verified
- Type control and type restriction control

In order to achieve this, the Analyzer constructs a symbol table of all the named TTCN objects that it finds during analysis, e.g. variable names, type identifiers, tables, etc.

It is important to note that TTCN allows *forward reference*s. For example a test step may attach another test step that is declared **later** on in the TTCN document, that is, the referenced (i.e. attached) test step, appears **after** the test step that has done the attach.

The Analyzer has a feature called *back-pass* designed to resolve forward references. The back-pass is automatically invoked at certain points in the analysis process.

Forward references usually appear in the context of ASP/PDU definitions, constraints and as the result of attachment statements in behaviour trees. The reason for this is that the Analyzer does not traverse the selected items in exactly the listed order. The Analyzer order deviates from the listed order in three places:

- Items in the PDU type definitions sub-tree are analyzed before items in the ASP type definitions sub-tree.
- Items in the PDU constraint declarations sub-tree are analyzed before items in the ASP constraint declarations sub-tree.
- Items in the defaults library sub-tree are analyzed before items in the test step library sub-tree and those are analyzed before items in the test cases sub-tree.

ASN.1 External Type/Value References

References to ASN.1 definitions in external ASN.1 modules can occur in the following four TTCN tables:

- Test suite constant declarations by reference
- ASN.1 type definitions by reference
- ASN.1 ASP type definitions by reference
- ASN.1 PDU type definitions by reference

In these tables there are three important fields to consider:

- *Module Identifier* (set by user)
  The name of the ASN.1 module. This should be the real name of the model, i.e. the name stated inside the module itself.
- *Type Reference/Value Reference* (set by user)
  This is the name of the desired type (or value).
- *Type Definition/Value* (set automatically when fetched)
  This is the field where the fetched type definition/value is copied into.

The term *definition* is used below both to denote an ASN.1 type definition and an ASN.1 value.

When an ASN.1 reference is analyzed, the referred definition must be available to the Analyzer. In the pro formas for this kind of reference in the TTCN Suite, there is an external column where both the definition and the parse tree is stored.

If the Analyzer encounters any reference to a type/value, the definition is fetched, given the type/value name and the module identifier, and copied into the external field before the field is analyzed. The operation of fetching the definition of the reference is controlled by an option in the Analyzer dialog. Important to note is that the fields *Module Identifier* and *Type/Value Reference* are not parsed. This means that if a change is made in either of these two fields, the row will not be analyzed and thus no fetching will be made. The solution to this is to set the *Enable Forced Analysis* in the Analyzer dialog when altering a reference. See "The Analyzer Dialog" on page 1303.

Analyzing ASN.1 References

This is the general algorithm when encountering an ASN.1 in the analysis phase.

1. First of all, an attempted fetch is only made if no current definition exists or the Analyzer fetching-option is selected.
2. The actual fetching is made, see "Retrieving external ASN.1 Definitions" on page 1309.
3. If the definition is successfully fetched, the identifiers in the definition is converted to TTCN compatible syntax, see "Syntactic Conversion" on page 1310.
4. Finally a possible update of the definition is made and the analysis is continued.

Retrieving external ASN.1 Definitions

From the ASN.1 module a simple parse tree is built to access its contents. The parse tree is (re-)built when either it has not been built before or the ASN.1 module has been modified since last access. The parse tree for an ASN.1 module "lives" for the duration of the whole analysis phase.

Syntactic Conversion

The received definition must be manipulated in the following sense. All identifiers must be syntactically checked and altered if they include any characters that is disallowed in TTCN. The rule is that all '-' (dash) characters in an ASN.1 name are replaced by a '_' (underscore).

No special care has to be considered to ASN.1 comments since they are ignored when the parse tree is built from the module.

External type references in the type definition (e.g "... Module.Type...") will only be converted like above and left for the Analyzer to deal with (see also "Restrictions" on page 1310).

Restrictions

The following features are not supported in TTCN:

- External type reference identifiers on the form *ModuleIdentifier.Type/Valuereference* are not supported.
- Type/value references within the same ASN.1 module are not supported.

Furthermore, there are restrictions in the ASN Utilities when it is used to extract the external types and values. These restrictions are introduced in translating ASN.1 to SDL but since the same algorithm is used for extracting types and values, the restrictions are also relevant for the TTCN Suite (see "Translation of ASN.1 to SDL" on page 704 in chapter 13, *The ASN.1 Utilities*).

Error Handling

Any error that occurs while finding, parsing or accessing the ASN.1 module will cause the old definition to remain. Only when a completely successful fetching has been made, the definition will be updated. Possible errors could be:

- The ASN.1 module not found among the dependencies.
- The ASN.1 module file could not be found or was not readable.
- The ASN.1 module file was not syntactically correct.
- The referred type/value could not be found in the module.

See chapter 13, *The ASN.1 Utilities* for a more general view on ASN.1 usage.

TTCN Static Type Restriction Control

The TTCN standard defines a set of semantic rules for type definitions. In particular it defines simple types as types which might contain a true subset of the values which the parent type might contain. The Analyzer now analyzes the TTCN type system and also reports violations of these rules. This analysis is implemented as a post-pass over the related tables, and is only applied when the previous passes have been successful.

Furthermore, restriction control is performed on a number of other constructs in the TTCN language, thus facilitating the task of writing semantically correct TTCN documents. Most of the TTCN types and values are checked and thereby reducing the chance of programming errors slipping through to other tools which depends upon the correctness of the TTCN document.

Application of Static Type Restriction Control

Static type restriction control is applied to at least the following TTCN tables and fields:

- Simple type definitions.
- TTCN structured type / ASP / PDU / CM definitions.
- Test suite constant declarations.
- Test suite variable declarations.
- TTCN structured type / ASP / PDU / CM constraint declarations.
- Actual constraint reference parameter lists.
- Actual parameter lists.

The static type restriction control also evaluates expressions in advance, where possible, and checks that the result does not violate the type restrictions of the field where the value is found. It operates on both types and values, regarding specific values as special cases of types.

TTCN Suite Preprocessor

The TTCN Suite preprocessor is a text processor that manipulates the text of a TTCN table as part of the first phase of Analyzing. TTCN Suite preprocessor allows you to produce different ETS code depending on the flags set. The syntax of TTCN Suite preprocessor directives is similar to directives for a C preprocessor:

```
#if <expr>
....
[#else]
...
#endif

<expr> ::= defined(<flag>) | '!' <expr> | <expr>
'||' <expr> | <expr> '&&' <expr> | (expr)
```

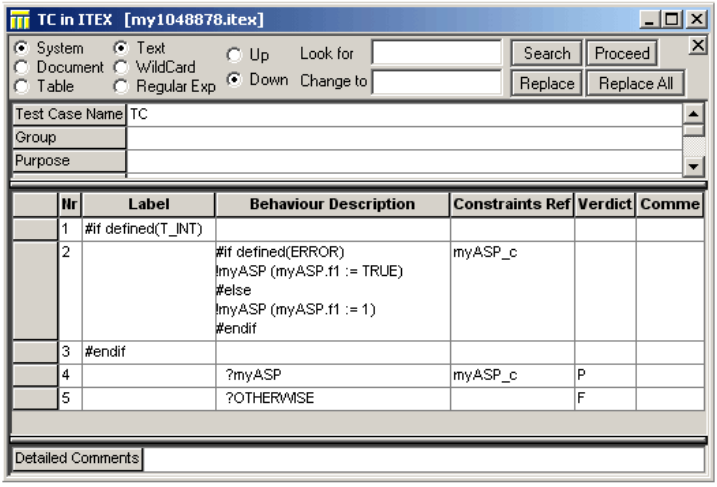

Figure 230: Example of preprocessor directives

These directives can be used in every editable field, not different from TTCN and ASN.1 definitions. The '`#if`' directive and its corresponding '`#endif`' directive must be placed within the same field, except when they are used in the body of a TTCN table that may consist of several rows. In this case it is allowed to use directives '`#if`', '`#else`' and '`#endif`' in separate rows, and only one such directive in the first field is allowed in such a row. The scope of such a directive will be all rows between.

The defined flags for Analysis and Code Generation are set in the Analyzer options (see "The Analyzer Dialog" on page 1303) The flags can also be set via options '-i' and '-I' from a command line session (see "Running the TTCN to C Compiler from the Command Line" on page 1323 in chapter 32, *The TTCN to C Compiler (in Windows)*).

Finding Tables from the Analyzer Log

When you are debugging a TTCN document, it may be useful to search for and display named tables. The search will include the entire current TTCN document – no selections are required.

To find an erroneous table identified in the Analyzer log:

1. Place the cursor on the name of the table in the log and then <Ctrl>-right-click the name of the table.
2. In the popup menu that will be opened, select the table name (at the top of the menu), and the table will be opened.

You can also use the Finder to find a table. See "Finding and Sorting Tables" on page 1282 in chapter 30, *Editing TTCN Documents (in Windows)*.

Chapter

32

The TTCN to C Compiler (in Windows)

This chapter describes what the TTCN to C compiler is used for, how to run it and the structure of the generated code.

When the TTCN to C compiler has translated TTCN into C code, the code must be adapted with the system that is to be tested. The adaption process is described in chapter 36, *Adaptation of Generated Code*.

Note: ASN.1 support

The TTCN to C compiler supports only a limited subset of ASN.1. See "Support for External ASN.1 in the TTCN Suite" on page 733 in chapter 13, *The ASN.1 Utilities, in the User´s Manual* for further details on the restrictions that apply.

Note: Windows version

This is the Windows version of the chapter. The UNIX version is chapter 27, *The TTCN to C Compiler (on UNIX)*.

Introduction to the TTCN to C Compiler

When developing new systems or implementations of any kind, the developing process is divided into well defined phases. Most commonly, the first phases involve some kind of specification and abstract design of the new system. After a while the implementation phase is entered and finally, when all parts are joined together, the test phase is activated.

In any case when a system is tested, we want to make sure that its behavior conforms to a set of well defined rules. TTCN was developed for the specification of test sequences. Unfortunately, as very few systems interpret or compile pure TTCN, we need to translate the TTCN notation into a language which can be compiled and executed. In the case of the TTCN Suite, the TTCN to C compiler translates TTCN to ANSI-C.

Even after the TTCN code has been translated, there are a couple of things that need to be taken care of. In this case, we must *adapt* the generated code with the system it intends to test. This chapter describes how the TTCN to C compiler is used. The adaption process is described in "Adaptation of Generated Code" on page 1487 in chapter 36, *Adaptation of Generated Code*.

Getting Started

Unfortunately, a test sequence description expressed in TTCN cannot easily be executed as it is. This, because the test notation is not executable and only few test environments interpret pure TTCN. A different approach to create an executable test suite (ETS), is to translate the formal test description into a language which can be compiled into an executable format.

The TTCN to C compiler translates TTCN into ANSI-C which can be compiled by an ANSI-C compiler. Figure 231 depicts the first step in the process of creating an ETS using the TTCN to C compiler.

The generated code, called the TTCN runtime behavior, is only one of the two major modules of an ETS.

The second module which is needed includes test support functions which are dependent on the protocol used, the host machine, test equipment, etc. For this reason, it is up to the user to write this second module and in such way adapt the TTCN runtime behavior to the system he/she wants to test.

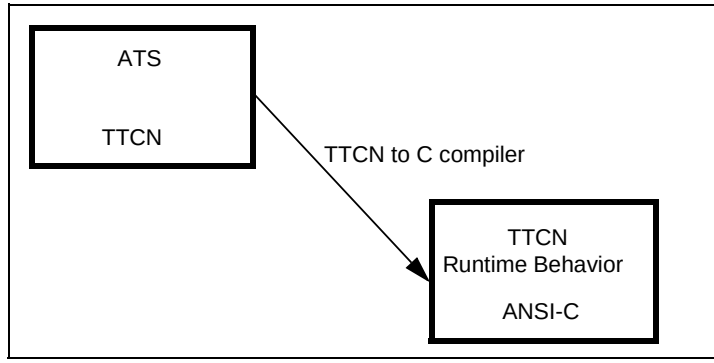

Figure 231: Translating TTCN to ANSI-C

The adaption process is described in "Adaptation of Generated Code" on page 1487 in chapter 36, *Adaptation of Generated Code*. Figure 232 displays the anatomy of the final result.

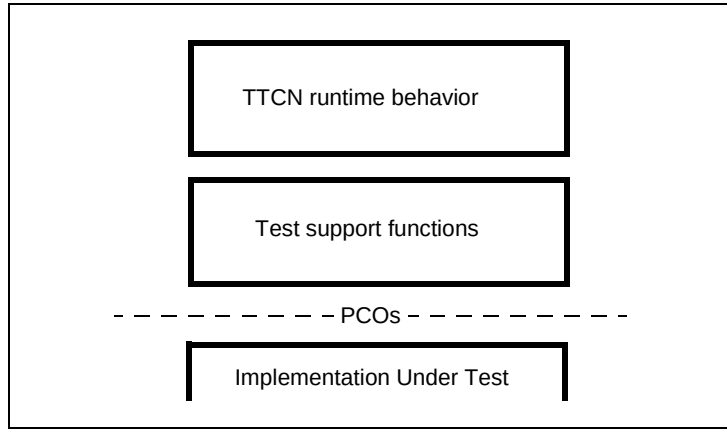

Figure 232: The anatomy of an ETS

Running the TTCN to C Compiler

To generate C code for the currently selected test document:

- Select *Generate Code* from the *Build* menu.
  – The shortcut is `<F8>`.

  This will open a dialog where you may change settings for code generation (see Figure 233).

  You can also open this dialog by the menu choice *Build* > *Options* or by the shortcut `<Alt+F8>`.

> **Note:**
>
> Observe that the TTCN to C compiler is unable to function correctly if the test suite is not fully verified correct. This verification is accomplished by running the Analyzer tool on all the parts of the test suite.

Note that every active TTCN document has its own code generation settings, so in practice, two or more TTCN documents can be edited and/or viewed at the same time in the TTCN Suite, and yet have individual settings. (Multiple views on the same TTCN document does of course share the same settings.)

The TTCN to C compiler runs in background. The Progress Bar at the bottom of the TTCN Suite window shows the TTCN to C compiler completion. During the code generation it is possible browse the already opened TTCN documents. It is not allowed to edit, save, close or open any of the TTCN documents during analysis. The analysis may be canceled by pressing the break button on the toolbar or by the menu choice *Build* > *Break*.

Options

- If the *Ignore bodies of test suite operations* option is checked, the compiler will ignore to generate code for test suite operations. This is useful if you already have a file with your own test suite operations that only need to be linked to the rest of the code. If the option is not checked, the test suite operators will be generated and included in the file `tsop_gen.c`.

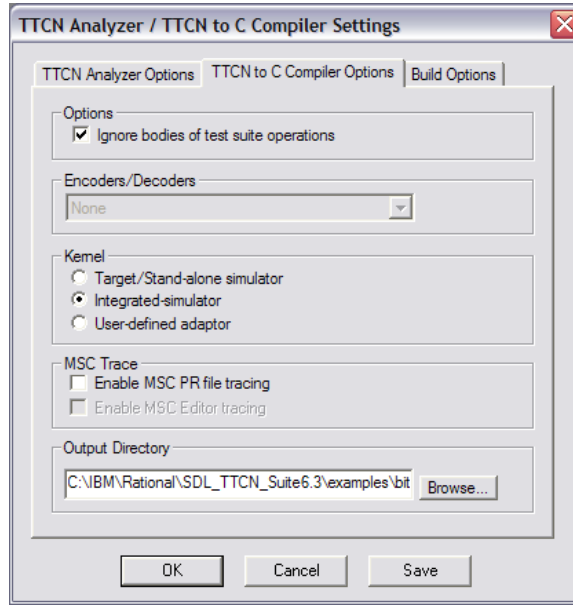

Figure 233: TTCN to C Compiler Options tab

Encoders/Decoders

- By selecting one of the alternatives *None*, *Generate BER encoders/decoders* or *Generate PER encoders/decoders* in the drop down list the compiler will either omit generation of encoders/decoders or generate extra code for BER or PER encoding and decoding support, see chapter 36, *Adaptation of Generated Code*.

Kernel

- To build a TTCN Exerciser, select the option *Target/Stand-alone simulator*. For more information about the TTCN Exerciser, see chapter 34, *The TTCN Exerciser*.
- Select *Integrated-simulator* if you want to execute a test suite together with a simulated SDL system.
- To build a user-defined adaptor, select *User-defined adaptor*.

MSC Trace

- *Enable MSC/PR file tracing*

  Generates MSC/PR format files that are saved in the current working directory. By default, the MSC file names will be on the form `log_<TestCaseId>_<SequenceNo>.mpr`, where `<TestCaseId>` is substituted by the test case name of the logged test case. `<SequenceNo>` is an integer that is started by 0000 and increased by one if there is already a version n in the working directory.

  The preprocessor constant MSC_FILE_MODE should be defined at compile-time of `mscgen.c` to get this mode. The constant GENMSC should be defined for compiling `globalvar.c` to activate appropriate calls.

  If the file cannot be created, a new attempt will be done at the start of the next test case. No file log will be created.

  The function `MscSetPrefix` can be used to change the path and prefix of generated files at runtime.

- *Enable MSC Editor tracing*

  Creates a new diagram in the MSC Editor when a new test case is started and then appends and displays the events as they are executed. This mode assumes that an MSC Editor license is available and that TTCN Suite is running at the host where the ETS is running and provides run-time MSC logging.

  The preprocessor constant MSC_MSCE_MODE should be defined at compile-time of `genmsc.c` to get this mode. The constant GENMSC should be defined for compiling `globalvar.c` for activation of the appropriate calls.

  If the creation of events in the MSC Editor fails, it will be retried at the next event, possibly creating an inconsistent MSC.

  This mode may also require access to the Public Interface libraries and include files that can be found in the installation.

For more information, see "TTCN Test Logs in MSC Format" on page 1328.

Output Directory

The final thing you have to do is to set the output directory.

OK

When you have set the options, click OK to start the generation of code. When the generation phase is started, information about the code generation will be displayed in the Log Manager. You will receive information about what parts that were generated and also some statistics about the amount of tables traversed during the generation phase.

If code is being generated for a large test suite, the status bar will show the progress.

Save

If you would like to store the option settings for future usage, press the *Save* button. The options settings is then saved in a file with the same name as the current test suite's filename (with extension) and with an additional '.ini' extension. For example will the options for 'foo.itex' be saved in a file named 'foo.itex.ini', for a test suite named 'foo.mp' the options will be in the file 'foo.mp.ini'. The options file is placed in the same folder as the test suite file.

The options file is automatically searched and the options settings are loaded when a TTCN Suite browser window is opened (on Windows), or when the TTCN Suite Make dialog is opened (on UNIX).

Build Options

Makefile Type

Choose one of the known make types, corresponding to your compiler, for the generated makefile.

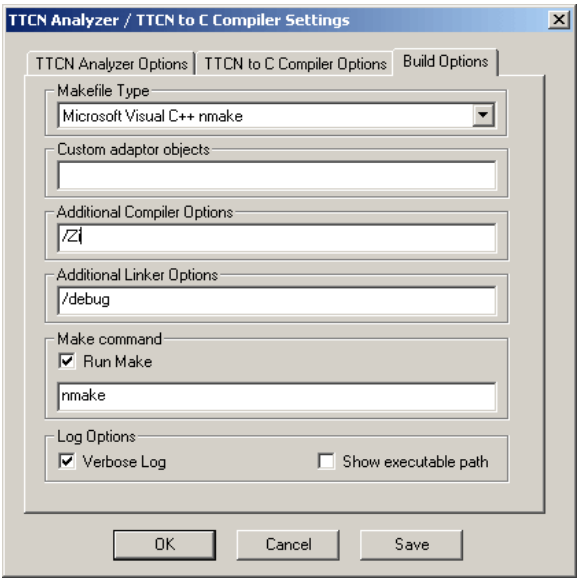

Figure 234: Build Options tab

Custom adaptor objects

This text field allows you to specify additional object files to be linked to ETS.

Make command

The Run Make check box controls if the make command is to be invoked directly after the code generation (provided it has completed successfully). The text field allows a manual change of the invoked make command if this is desired.

Log Options

There are two options in the Build Options tab for log management. These options are also related to a compilation flag, `SHOWSIGNALPARAMETERS`, which is generated in the makefile.

Verbose Log

The *Verbose Log* switches the logging between the default mode, which prints the result of the Make process as it goes along, and the *Verbose* mode, where all possible information is presented. The *Verbose* log is primarily intended for debugging.

The *Verbose* log contains the following information in addition to the default log:

- signal parameters, with an attempt to restore all names (for signal, fields, parameters, choices, etc.), even when these names are lost (which is the case when the user construct the signals directly in the adaptor). The default log can be made to show this if the Compilation flag /DSHOWSIGNALPARAMETERS is set.
- matching processes are presented *Verbose*. Each field shows how it was matched, using the indentation level for nested fields.

Show Executable Path

When *Show Executable Path* is selected, the lines in the ETS log will be prefixed by the path for the executing Test Case and Test Steps, like the following example:

```
Test Case:[line number]  Step_no:[line number] ... Test Step_n
```

Compilation flag /DSHOWSIGNALPARAMETERS

The flag `SHOWSIGNALPARAMETERS` is generated in the Makefile even when the log is not *Verbose*. With this compilation flag the default log will also contain the complete contents of all signals, just like when log is set to *Verbose*. When this is not desired, this flag can easily be removed from the Makefile.

Additional Compiler Options and Additional Linker Options

Here it is possible to specify any compiler and linker options that will be added into the generated Makefile.

Running the TTCN to C Compiler from the Command Line

You can start the TTCN to C compiler by executing `ttcn2c` with command line switches. The usage is `ttcn2c [switches] filename`.

Example 219 ----------

To generate C code for `example.itex` in the current directory, with hard values and in silent mode, use the command:

```
ttcn2c -ms example.itex
```

C Code Generator Parameters

Switch	Explanation
`-a <objs>`	Link with `objs` as adaptor
`-A <ASN1files>`	File containing filenames of ASN.1 module files.
`-b <dir>`	Search in `<dir>` for static files
`-B`	Generate BER encoding/decoding interface
`-C <options>`	Set the additional compiler options
`-d`	Debug information in C code
`-D`	Step through ETS execution
`-e <file>`	Use `file` to be included in the make file
`-f`	Forced mode – always overwrite files
`-F`	Definitions of encountered ASN.1 references should be retrieved. See "Retrieve ASN.1 Definitions" on page 1193 in chapter 26, *Analyzing TTCN Documents (on UNIX)*
`-g`	Ignore bodies of test suite operations See also "Options" on page 1318.
`-h`	Help
`-i <defined flag>`	Set the flag defined for the preprocessor
`-I <flags file>`	Set the file with the flags defined for the preprocessor.
`-j <file>`	User file name for types
`-k <file>`	Use file name for constraints

Switch	Explanation
`-l <file>`	Specify log file
`-L <options>`	Set the additional linker options
`-M file`	Enable MSC/PR file tracing
`-M msce`	Enable MSC Editor tracing
`-o <dir>`	Specify output directory
`-p <file>`	Use file name for behavior
`-P`	Generate PER encoding/decoding interface
`-r <file>`	Use file name to generate a makefile
`-R`	Disable makefile generation
`-s`	Silent mode – do not display messages
`-t`	Generate simulator See also "Kernel" on page 1319.
`-T`	Generate targe/stand-alone kernel
`-u vc`	Generate code for Microsoft Visual compiler
`-w`	No warning mode
`-z <lines>`	Aim at splitting generated file at <lines> number of lines

Generating C Code for Modular Test Suites

Generating C code for modular test suites from the command line, may be a bit tricky. Please see the example below for an explanation of how to proceed.

Example 220 ————————————————————————————

You want to generate C code for the modular test suite `mts.itex`, which depends on `module1.itex`, `module2.itex`, `module3.itex` and `module4.itex`. To do this enter:

```
ttcn2c """mts.itex""""""module1.itex""""""module2.itex""""""module3.itex"
""""""module4.itex"""
```

Note that there are six quotation marks between the file names.

This will generate code for the entire modular test suite.

It is also possible to use MP documents in the same manner.

For a description of file naming, see "Files in the TTCN Suite" on page 24 in chapter 2, *Introduction to the TTCN Suite (in Windows), in the TTCN Suite 6.2 Getting Started*.

What Is Generated?

Figure 231 shows how ANSI-C code is generated from a TTCN test suite. The generated code alone is not executable as it needs the test support functions module (see Figure 232).

In the case of the code generated from the compiler we also need a set of static functions which handle TTCN basics and other internal events. Even if these functions are vital for the successful compilation and execution of the generated code, the user should not have to worry about this part. These functions are gathered in a small set of static files which are compiled by the generated makefile and linked with the rest of the code.

The Code Files

The generated makefile is the file containing a definition of how the code should be compiled and linked. This will not be needed if you are compiling the generated code in a separate development environment.

The `adaptor.h` and `adaptor.c` files are the files that contain the adaptation code. If code is generated for the first time, these files will be generated by the compiler with empty function templates for the user to implement. On the other hand, if these files are present in the target directory the user does not have to worry about getting them overwritten.

The `*_gen.{c,h}` files contains the generated code from the TTCN test suite.

The `asn1ende.h` file contains the encode and decode functions for the ASN.1 Types. See chapter 58, *ASN.1 Encoding and De-coding in the SDL Suite, in the User´s Manual*. (Only if ASN.1 support has been selected)

The Adaptation

We are now ready to deal in greater detail with the adaptation phase which is the final phase to create an executable test suite. The adaptation process is described in "Adaptation of Generated Code" on page 1487 in chapter 36, *Adaptation of Generated Code*.

TTCN Test Logs in MSC Format

The TTCN standard conformance log, though it is a relatively complete logging format, has a few drawbacks for some purposes:

- The conformance log is very detailed.
- The conformance log requires knowledge of TTCN and its semantics.
- The conformance log is not always particularly easy to read.

In order to get a more high-level view, the log must either be filtered or another approach needs to be taken – in this case the MSC log format. The current version of the TTCN Suite has support for an additional logging mode, to generate MSC/PR standard conformant logs – automatically saved in files and also directly to the MSC Editor.

For limitations in the MSC logging, see "MSC Logging" on page 41 in chapter 1, *Compatibility Notes, in the Release Guide*.

MSC Logging Applications

There are several applications of MSC logging. Here are some:

- Test reviews

  The MSC log format is very readable and can be used for reviewing test progress and for evaluating test results with requirements specifications.

- Test result recreation

  If an SDL model has been used to specify the system behavior, a composed MSC log can be used to re-create the test result by using the SDL Explorer's Verify-MSC feature. This will allow a particular test behavior to be handed to system designers who can recreate the result on a workstation level.

- Test re-engineering

  If MSC traces are being used to generate test cases, the tests can be modified at the MSC level. A modified MSC can be used to generate a new tests. For instance – a test written in TTCN generates an MSC. At a review of the MSC logs a new scenario may be identi-

fied. The MSC can be changed to reflect the new scenario, and the MSC can be translated back to TTCN.

MSC Logging Modes

There are three major modes of logging, which can be toggled between the test cases. It is not possible to change the logging mode in a running test case since that would cause an inconsistency in the MSC file. The modes are:

- None

  No MSC logs are generated at all. This mode improves performance somewhat compared to the other modes. For best performance, the MSC generation code can be entirely disabled. For more information see "Compiling an ETS with MSC Generation" on page 1330.

- Composed

  MSC generation of externally visible events of the ETS. This is suitable for test regeneration and for re-viewing test results. The performance is better than Decomposed mode. The generated MSC views the ETS as a set of PCOs that interact with a IUT. The ETS is not visible as one particular instance. Some relative timing information may be lost in this mode.

- Decomposed

  MSC generation of externally visible and internal events of the ETS. This is the most detailed mode and it produces MSC events for almost all actions of the ETS. The purpose of the MSCs that are generated is to visualize the internal events and configuration of the ETS, and for test case debugging purposes.

MSC Instances Generated

Entity	Composed	Decomposed	Comment
SUT	Yes	No	
PCO	Yes	Yes	
MTC	No	Yes	
PTC	No	Yes	Dynamic

Events Logged

Event	Composed	Decomposed	Comment
Final Verdict	Yes	Yes	MSC Text
Preliminary Verdict	No	Yes	MSC Condition
Create	No	Yes	
Done	No	Yes	
Send to PCO	Yes	Yes	
Send to CP	No	Yes	
Receive from PCO	Yes	Yes	
Receive from CP	No	Yes	
Implicit send	No	Yes	
Start Timer	No	Yes	
Cancel Timer	No	Yes	
Timeout Timer	No	Yes	
Implicit Cancel	No	Yes	End of TC
Implicit Receive	No	Yes	End of TC
Message Values	Yes	Yes	

Compiling an ETS with MSC Generation

The ETS Generator can be compiled for a workstation or an embedded environment. Some modifications need to be done for applying it in the embedded environment if it lacks a file system. By default the tool will allow for any of these combinations at code generation time. For more information see "MSC Generation Modifications" on page 1331.

Definitions that may be changed to customize the MSC generation:

Definitions	Explanation
MSC_DEFAULT_SYSTEM_NAME	Name of IUT instance in composed mode.

Definitions	Explanation
MSC_MAX_VALUE_LEN	Maximum length of an encoded message value.
MSC_NO_VALUE_LOGGING	If defined, no message values are displayed – this may make the ETS more efficient and the MSC logs more readable when using complex messages.

MSC Generation Modifications

Modifications to the MSC generation for running on an embedded environment include:

- The MscAppendPREvent function can be modified to transfer the PR events via any type of uni-directional communications device. It is recommended to create another definition similar to the MSC_MSCE_MODE or MSC_FILE_MODE and complement the `mscgen.c` file with these.
- Any place where MSC_FILE_MODE or MSC_MSCE_MODE is used should be having a new definition for the new logging mode.

Chapter 32 The TTCN to C Compiler (in Windows)

Chapter

33

The SDL and TTCN Integrated Simulator (W)

This chapter describes the SDL and TTCN Integrated Simulator in the Windows version of the TTCN Suite. It gives an introduction to the concept of the SDL and TTCN Integrated Simulator, as well as a guide to its functionality.

Note: Windows version

This is the Windows version of the chapter. The UNIX version is chapter 28, *The SDL and TTCN Integrated Simulator (U)*

The SDL and TTCN Integrated Simulator

The SDL and TTCN Integrated Simulator allows you to generate executable test suites (ETS) for testing of simulated SDL systems. This allows the testing of the system design early in the design process.

These ETSs allow you to execute test cases and/or test groups (hereafter referred to as tests) at full speed or by single stepping through the selected tests. There is also the possibility to set breakpoints in the tables of the tests.

It should be noted that there is no separate SDL and TTCN Integrated Simulator GUI. The SDL and TTCN Integrated Simulator will use the Table Editor to present the current line during execution.

More information about the SDL Simulator can be found in *chapter 49, The SDL Simulator*.

Performing an Integrated-Simulation with the SDL Suite

Given a test suite containing a set of tests you want to execute together with a simulated SDL system, the following steps are to be performed:

1. In the TTCN Suite, analyze the test suite and make sure it contains no errors.
2. In the TTCN Suite *TTCN to C Compiler Settings* dialog, generate an executable test suite.

   The following *TTCN to C Compiler Options* should be set:

   – *Integrated-simulator*

   – *Ignore bodies of test suite operations*

   In the *Build Options* tab:

   – You should set *Run Make*.

   – You may have to change the *Makefile Type*.

   For more information about the TTCN to C compiler and the options, see chapter 32, *The TTCN to C Compiler (in Windows)*.

3. Start the SDL and TTCN Integrated Simulator by selecting *Invoke Integrated-Simulatator* from the *Co-Simulate* menu.

   In the file dialog that will be issued, select the simulator ETS – that is, the executable produced in step 2. After that, the TTCN-SDL Integrated Simulator toolbar will appear.

4. Generate and start the SDL Simulator, if not already done. In the SDL Simulator UI, load the SDL Suite generated simulator executable.
5. In the SDL Simulator, give the command **`start-itex`**.
6. In the TTCN Browser, select the tests you wish to execute.
7. Click the *Run/Continue* or *Step* button, to start the actual integrated-simulatation in the TTCN Suite.
8. In the SDL Simulator, give the command **`go-forever`**.

The SDL and TTCN Integrated Simulator Operations

To abort the test in progress:

- Select *Co-Simulate* > *Abort*.
  The SDL Simulator may have to be restarted after this step. A new integrated-simulation can be started now.

To temporarily pause the test simulation:

- Select *Co-Simulate* > *Pause*.
  The integrated-simulation can be continued by doing a “run” or “step” operation.

To step one line of TTCN code:

- Select *Co-Simulate* > *Step*.

To run/continue a test at full speed until it is finished or until a breakpoint is reached:

- Select *Co-Simulate* > *Run/Continue*.

To toggle breakpoint status at currently selected lines in the Table Editor:

- Select *Co-Simulate* > *Toggle Breakpoint*.

Integrated-Simulation from command line

The generated ETS for Integrated-Simulation may be started from command line. Do this without any arguments in command line. In this case ETS has no any graphic interface. It reads commands from stdin and print the results of performed commands, Conformance Log, etc to stdout. Extra debug output will be printed if the environment variable TTCN_SIMULATOR_DEBUG is set.

See "Integrated-Simulation from command line" on page 1232 in chapter 28, *The SDL and TTCN Integrated Simulator (U)*.

Performing "batch mode" Integrated-Simulation

The generated ETS for Integrated-Simulation may be started together with SDL Simulator in "batch mode" (Windows only). It reads the commands from the specified file and executes them one by one. For such execution start the TTCN ETS for Integrated-Simulation and as an argument in the command line you pass the name of the file containing the commands. The SDT Postmaster must be started before the TTCN Integrated-Simulator (the Postmaster is running in the background of the SDL Suite Organizer).

Example 221 ––

```
TTCN_sim.exe simcommand.txt
```

––

The file with commands may contain any of the commands described in chapter above. It should contains 'run-SDL' command for starting the SDL simulator.

Example 222: Contents of “simcommand.txt”––––––––––––––––––

```
run-SDL sim_5918_smc.exe
SDL-command sta-it
SDL-command go
run test
quit
```

––

The Integrated-Simulator prints the result of the performed commands, Conformance Log, etc to stdout, it is also possible to redirect this output. The Final Verdict may be found in output between the `<VERDICT>` tags:

```
<VERDICT>
PASS
</VERDICT>
```

Information Messages

The SDL and TTCN Integrated Simulator can present messages to the user in three forms:

- Informative messages
- Warning messages
- Error messages

Informative Messages

Informative messages are normally presented at the status bar. These might be for instance progress reports or other simple messages, which are only of a temporary interest (such as the tool tips).

Warning Messages

Warnings, also known as “non-critical errors”, are events that indicate a problem during the preparation for a integrated-simulation, or during the actual integrated-simulation run. These are presented in standard warning dialogs.

Error Messages

Critical errors will halt the integrated-simulation. They are presented by an error dialog that appears in front of the application. The error dialog can often appear large and intimidating, but it simply gives a more verbose reason to why the error occurred, and what steps should be taken to avoid it.

Troubleshooting

The Simulators Stop Communicating

The SDL Simulator and the SDL and TTCN Integrated Simulator may stop communicating. This can occur if there are “old” instances of the SDL and TTCN Integrated Simulator ETS process still alive. They will then “steal” messages from the intended recipient. There are some ways to make the Simulators communicate again:

- Exit the SDL and TTCN Integrated Simulator and start it again.
- Exit the SDL and TTCN Integrated Simulator. Restart the SDL Simulator. Start the SDL and TTCN Integrated Simulator again.
- Exit the Simulators and the Organizer. Check that no Postmaster process and no SDL and TTCN Integrated Simulator ETS process remains. If they do, kill them. Start the Organizer, the SDL Simulator and the SDL and TTCN Integrated Simulator.

Test Execution Stops

The execution of tests may stop at a certain point during execution for no reason. If the problem is reproducible, you should check the supported types. There is a possibility that a type has been used in a message between the simulators that is not supported.

The Simulators Get Out of Sync

The simulators may get out of sync. One way of doing this is when an execution in the SDL and TTCN Integrated Simulator has been aborted and the SDL Simulator has not been restarted.

- Press the abort button in the SDL and TTCN Integrated Simulator. Restart the SDL Simulator.

Type Mappings in Integrated-Simulation

The data type mapping used by the integrated-simulation of the SDL simulator and the SDL and TTCN Integrated Simulator in Windows is the same as for the integrated-simulation on UNIX. See “Type Mappings in Integrated-Simulation” on page 1238 in chapter 28, *The SDL and TTCN Integrated Simulator (U)*.

Chapter

34 *The TTCN Exerciser*

A TTCN Exerciser is built from the TTCN to C compiler. For more information, see chapter 27, *The TTCN to C Compiler (on UNIX)* and chapter 32, *The TTCN to C Compiler (in Windows)*.

For information about TTCN Exerciser limitations, see "TTCN Exerciser" on page 44 in chapter 1, *Compatibility Notes, in the Release Guide*.

Introduction

Though the GCI interface is generic and may be used for executing tests in an almost arbitrary environment, there is often a significant effort required to get an adaptation up and running. This has prompted the development of a pre-built kernel which can be used to test executable test suites without requiring them to have complete adaptation layers for some platforms.

The TTCN Exerciser contains functionality for simulation of test suites without the requirement of having an SDL system or IUT to test. Furthermore it allows for one or several PCOs to communicate with a real IUT through a subset of the GCI interface. It is also prepared for adaptation with C++ and object oriented implementations under test by providing an “External C interface”.

Functionality Overview

The TTCN Exerciser provides several features that may come in handy for test development, execution and also adaptor production. The main features of the TTCN Exerciser are as follows:

- Simulated PCO communication

  Allows for a PCO not to be connected to an IUT. A message can be input in a PCO input queue at any time.

- Discrete time simulation

  Test the tester with user-defined timing. An explicit “timeout” command is available to allow for the next pending timer to expire at will. This mechanism has a timer resolution down to individual nanoseconds.

- Realtime simulation

  This mode uses real time as provided by the system clock of the host where the tester is executed. Practical limitations to the time resolution yields an accuracy of approximately 1 millisecond. The theoretical limit of the kernel is 1 nanosecond.

- TTCN test case validation

  Runs “random walks” of test cases in order to detect paths where no verdict is assigned, or where some input causes a deadlock, as well

as several other dynamic error conditions. This can be very useful for getting a degree confidence in the correctness and completeness of the test suites.

- Custom PCO definition

  Provides the ability to define custom PCOs for connection to real IUTs while still having access to all the TTCN Exerciser features.

- Source-level debugging of TTCN

  This includes setting breakpoints, highlighting lines in the TTCN Table Editor as it is running, and more.

- Concurrent TTCN implementation

  The kernel internally implements concurrent TTCN, meaning that there is no extra effort in running concurrent test cases.

- Dynamic MSC generation with the MSC generator

  For more information, see chapter 32, *The TTCN to C Compiler (in Windows)* and chapter 27, *The TTCN to C Compiler (on UNIX)*.

- Command scripting and logging

  Providing repeatability of simulated scenarios, as well as shortcuts for doing common operations.

- Dynamic error detection

  The TTCN Exerciser helps detect a number of dynamic error conditions that a static syntax and semantics analyzer will not detect.

Kernel Operation Modes

In order to appreciate the way the TTCN Exerciser operates, it is important to get an insight in the different global modes it may be in. Each of these modes are outlined in this section. The full global kernel state and behavior is a combination of these modes, and to get the desired behavior, it is good to know how to toggle between the modes at will.

Execution Modes

These are the three major modes of operation of the TTCN Exerciser:

- Simulation mode

  This mode has all PCOs simulated, and input is required from the test operator or user-defined scripts. In essence, there is no IUT and all messages that are sent are only indicated in the various test logs. All messages that are received must be specified by the test operator or a test execution script.

- Target execution mode

  This mode has all the PCOs defined by an adaptor writer (implemented in an adaptation effort). This mode provides source-level debugging of TTCN test suites and an option of discrete time simulation.

- Mixed mode

  This mode is available when some of the PCOs are connected to an actual implementation under test. It enables the features of both the simulation mode and the features of the target execution mode.

Timer Modes

These are the two timer modes:

- Realtime

  This mode uses the system clock to provide timing information. This is the normal mode to run in for target testers. In the case a tester is paused or a breakpoint is reached, the timer mode will be toggled to discrete time simulation. You can resume it by setting the timer mode to `realtime`. See "Realtime" on page 1365 for more information. The realtime mode is recognized by all log messages being prefixed with an asterisk (`*`).

- Discrete time simulation

  This mode only increments time when a `timeout` command is received. It is the default mode for simulations. In effect, the mode keeps track of running timers and their expiration time. This mode is automatically toggled to when the execution is stopped or paused, as well as for many of the kernel commands. See "Discrete" on page 1365 for more information. The discrete time simulation mode is recognized by all log messages being prefixed with a hyphen (`-`).

Control Modes

There are two control modes:

- Simulator UI control

  This mode is for using the SDL and TTCN Integrated Simulator user interface protocol in communications with the operator. The mode appends a set of tags to all messages that are emitted. It is assumed that the tester is started by the SDL and TTCN Integrated Simulator user interface, but the mode is also useful if logs are to be processed by other tools.

- Command line control

  This mode is for running in a command-line environment. An ETS built with the TTCN Exerciser can be run directly from a command-line, thereby providing means for automated, batch style testing.

PCOs

You can operate PCOs by either implicitly enqueueing messages in the PCO by using the receive command, or by customizing the PCO providing your own definition of the PCO behavior.

Customizing the Behavior of PCOs

The behavior of PCOs can be customized for achieving communications with “real” implementations under test. This is similar to the adaptation process. For more information, see chapter 36, *Adaptation of Generated Code*. The difference is that only the GciSend function and a polling/decoding function need to be implemented. Some familiarity with the GCI interface is required in order to successfully add a custom PCO implementation to the TTCN Exerciser – in particular, the use of the GciValue type should be known. Also, knowledge of the protocol and APIs for the implementation of the PCO is required.

Files

The TTCN Exerciser is interfacing to the code generator output in a manner that is conformant to the GCI interface recommendation. The `adaptor.c` file which is supplied with the TTCN Exerciser interface, is pretty much a plain adaptor that calls GCI equivalent functions in the

TTCN Exerciser. It is possible to edit the `adaptor.c` file while still retaining functionality of the TTCN Exerciser.

Custom PCO Registration

PCOs may be registered in the main function, before the IsmMain function is called. The PCO registration is done by calling the IsmRegisterPCOImplementation function. This functions arguments are described in detail in the `ism.h` file. Conceptually, each registered PCO is polled at a maximum interval supplied when the PCO is registered. The PCO has an associated polling function that should be used to check if a message is completely received on the PCO, and in that case decode it and use the GciReceive function to notify the TTCN runtime behavior of the newly arrived message. For sending, the PCO, registration function also requires a Send function argument. This function should send a message to the implementation under test.

It should be noted that these functions should all be possible to call from multiple threads, since the TTCN Exerciser may use multithreading to implement concurrent TTCN.

Timers

For both the realtime and the discrete time simulation, the implementation of the TTCN Exerciser has 64 bit timers. Time is kept as the difference from the timers expiration time and the last time the current time was updated. In realtime mode, the time is updated in the snapshot function. With discrete time simulation, the time is updated at the timeout command. With the 64 bit implementation and the constraint that the resolution is 1 ns, the consequences are that:

- No period of less than 1 ns can be measured.
- The maximum period that can be measured is more than 2 billion seconds, or some 65 years.

Hopefully, this resolution is sufficient for most applications. There are some aspects of discrete simulation that are well worth a special note:

- Discrete time simulation assumes that no processing time is required for executing TTCN and that there is no delay due to messaging and scheduling overhead in concurrent TTCN. This is not en-

tirely true. Apart from this, it is in many cases sufficient for testing a test script in a non-realtime environment.

- Discrete time simulation also expires timers at the exact right time (from the testers aspect, not in a realtime aspect). In many cases, a test process cannot be scheduled at exactly the time when a timer expires, and consequently there is normally a lag in a real-time tester. This lag should normally be accounted for by the test designer in determining timer durations.

Runtime Timer Errors and Warnings

With the timer implementation, there are also some conditions that may be reported in the conformance log:

- READTIMER of a timer that is not currently running. This condition will make the readtimer call return 0 and also produce a message in the conformance log.
- START of a timer with a ps resolution will result in the timer to get an approximate expiration time. This expiration time is the duration of the timer / 1000 ns. In effect this is too early. If the unit of a timer cannot be determined, it is assumed to be seconds. This condition should normally not appear, but will result in a message in the log and possibly also test case termination.

Test Suite Parameters

The test suite parameters are read at startup of the TTCN Exerciser. There are two locations where they are searched for:

- If the test suite parameters pics/pixit reference field contains the literal substring `.ttp`, the whole fields content will be treated as a file name, naming a file in which the parameter should be searched for. The file format is defined below.
- In a file named `pixit.ttp`.

In a pixit-file, the variables declared are to be named according to the following list of predefined type names. The names showed are typed with respect to case and spelling:

```
NULL     INTEGER BOOLEAN
BITSTRING       HEXSTRING       OCTETSTRING
NumericString   PrintableString TeletexString
```

```
T61String       VideotexString  VisibleString
ISO646String    IA5String       GraphicString
GeneralString   RTYPE           SEQUENCE
SEQUENCEOF      SET             SETOF
CHOICE          ENUMERATED      OBJECTIDENTIFIER
UTCTime         GeneralizedTime ObjectDescriptor
```

The file format is defined as:

```
File ::= {Line};
Line ::= Comment | ParameterNameAndValue;
Comment ::= <Non alpha Character> <Any text> | <empty line>;
ParameterNameAndValue ::= ParameterName ISMValueEncoding;
```

The ISMValueEncoding is defined in a separate section. An example would be:

```
#
# This is my parameter file, named pixit.ttp, located in the
# working directory of the ETS with the TTCN Exerciser.
#

TspFoo          3
TspUsePDUPDUA ( INTEGER 1, BOOLEAN TRUE )

# End of this example file.
```

Test Case Validation

The TTCN Exerciser has a rudimentary automatic test validation feature in that it supports running tests with random inputs and timeouts. This feature may be used to attempt to detect missing alternatives and some runtime error conditions without having to manually step through all these alternatives.

Detected conditions include:

- Test incompleteness
- Tests failing to terminate
- Concurrent TTCN dynamic errors:
  - Failure to terminate a PTC
  - Creation of already started PTC
- Tests with paths missing a verdict
- A number of other conditions such as timer errors etc.

The random walk does not provide a guaranteed detection of these conditions, but it will run thousands of test tests in the time it normally takes to run one test.

The random walk has no feature for message generation, and hence requires messages to be imported or defined in the tool. All the messages are stored in a list of eligible messages. This list is referred to as the message list.

The random walk selects random messages from this list, and also timeouts if in a given state, any timers are running. This is repeated until a verdict is reached, an deadlock is detected, or until a defined maximum depth is reached.

Reports are stored in a report list and can be saved or reviewed.

Also, test statistics are stored while running the random walk. These test statistics can be used to determine how many tests were run in total, and which verdicts were reached.

TTCN Exerciser Commands

The TTCN Exerciser operates through a command line interface (which can be encapsulated by for instance the SDL and TTCN Integrated Simulator user interface).

Example 223: General syntax of the command input

```
CommandInput::= {CommandLine} EOF
CommandLine::= Comment|Command
Comment::= <Non Alpha Character> <Free Text>
Command::= <Recognized command or '+'> <Parameters> <NewLine>
```

It is permitted to have any amount of spaces or tabs before the command start. In general, the assembler code modes of some editors works quite well for composing command files.

Example 224: A command file

```
;;;
;;; File Name: example
;;; This is an example command file, uses ; for command delim.
;;;
```

```
;; Initialisation (see command descriptions below)
cl                      ; Set command line log mode
loglevel 2      ; Set log level to 2
nomsc                   ; Disable MSC generation
nopoll                  ; Disable command polling
discrete        ; Use discrete time sim

;; Now run a test case
step TestCase1  ; Will create context
receive Lower ConnectInd { Address 3 }
run                     ; Will actually run till idle
timeout                 ; Do a timeout when idle

;;; End of this file...
```

These are the available commands when a tester built with the TTCN Exerciser is run from the command line or with a batch script. The commands may be abbreviated, as long as the abbreviation yields one unique command name. For instance, the command `cancel` may be abbreviated with `ca` but not with `c`, since that would also match the `cmdlog` command.

The command listing below has the following information:

- Command name

  The formal name of the command, as defined in the ETS/SIMUI protocol document, available on request from IBM Rational.

- Aliases

  Alternative command names that may be handy if running from a command line interface. These are often common names for similar operations in debuggers. A hyphen indicates that the command has no aliases apart from any possible abbreviations. Aliases may also be abbreviated, for instance, the alias `rts` for the `realtime` command can be abbreviated `rt`.

- Synopsis

  The command with “symbolic” parameters. If a parameter is surrounded by square brackets “`[ ]`”, it is optional. If a parameter is surrounded by curly brackets “`{ }`”, it indicates that a list may be accepted. If the parameter is surrounded by angle brackets “`< >`”, it means that the name should be substituted by an identifier of an object of an appropriate type.

- Description

  An informal textual description of the command and some of its possible side-effects.

- Example

  An example of the command used in some context. The examples frequently use other commands than the described one in order to explain the use of the command.

General Commands

Help

- Command name: `help`
- Aliases: `-`
- Synopsis: `help`
- Description:

  List the available commands with a brief note on each commands purpose. The general format is:

  `help [SR *]` Display a brief help on commands

  The printed records are:

  `<command-name> [<states> <debug>] <description>`

`<command-name>`	The unique name of the command.
`<states>`	The set of states where the command is applicable: • `S` – Stopped, no test case is running. • `R` – Running, as test case is in progress.

<debug>	Denotes if the tester needs to be generated with the line information for the command to be running correctly: • D – Requires line-number information. • * – Available with or without line-number information.
<description>	A brief summary of the command functionality.

The help command will automatically transition the tester to a Paused state if it is in running state.

Example 225 ----------

```
-       Command?
help
```

Quit

- Command name: quit
- Aliases: -
- Synopsis: quit
- Description:

Terminate the current test case and also terminate the tester program.

Example 226 ----------

```
-       Command?
quit
```

Include

- Command name: include
- Aliases: -

- Synopsis: `include <filepath>`
  `+filepath`
- Description:

  Enqueue all the commands from the file named by file path. The file path can be relative to the current working directory of the tester, or it may be absolute. Also, the shortcut `+` may be used for simpler access to common scripts. It is recommended but not required that scripts have a file extension of `.ics` (ISM Command Script).

  It is sometimes desirable to use the command `nopoll` in conjunction with script reading, in particular when running test cases from scripts. The `nopoll` command gives a more synchronous behavior.

Example 227 ----------

```
-       Command?
include setup.ics
-       Command?
+setup.ics
```

Test Management Commands

List

- Command name: `list`
- Aliases: `-`
- Synopsis: `list`
- Description:

  List all available test cases. Test cases whose selection expression evaluates to false, get the tag `[N/S]` appended to their name to show that the case is not selected.

Example 228 ----------

```
        Command?
list
MyTest1
MyTest2
```

```
MyTest3[N/S]
```

Glist

- Command name: `glist`
- Aliases: `-`
- Synopsis: `glist`
- Description:

  List all available test case groups.

Example 229 ----------

```
-       Command?
glist
MyGroup1
MyGroup2
```

Run

- Command name: `run`
- Aliases: `go`, `start`
- Synopsis: `run {<TestCaseOrGroupNames>}`
- Description:

  Start the execution of the named test cases or groups. The test cases will run until a breakpoint is reached, the test case terminates, or until another command is entered.

  If a test is already in progress, this command will continue the test execution until one of the above conditions are met.

Example 230 ----------

```
-       Command?
run MyTest1
-
```

```
-       Line: MyTest1 1
-       Line: MyTest1 2
-       Line: MyTest1 3
-       Line: MyTest1 4
-       At breakpoint MyTest1 5
-       Line: MyTest1 5
-       Command?
run
```

Step

- Command name: `step`
- Aliases: `line`
- Synopsis: `step {<TestCaseOrGroupNames>}`
- Description:

  Start the execution of the named test cases or groups. The test cases will run until a breakpoint is reached, the test case terminates, or until another command is entered.

  As opposed to the run command, the test execution will also stop if a line is matched, or if a snapshot (idle) state is reached. This command requires that the tester has been built with line debug information for correct operation.

  If a test is already in progress, this command will continue the test execution until one of the above conditions are met.

  This command will toggle the timer mode to Discrete, since it is not possible to use real-time and line stepping in conjunction.

  Example 231 ––

```
-       Command?
step MyTest1
-
-       Line: MyTest1 1
-       Command?
step
-       Line: MyTest1 2
-       Command?
step
-       Line: MyTest1 3
-       Command?
```

Stop

- Command name: `stop`
- Aliases: `pause`, `break`
- Synopsis: `stop`
- Description:

  Pause the execution. This will toggle the time mode to discrete and halt the test case without discarding any context information. This command requires line debug information to be included when the ETS is built to function correctly.

Example 232

```
-       Command?
run MyTest1
-       Line:   MyTest1 1
-       Line:   MyTest1 2
stop
-       Command?
step
-       Line:   MyTest1 3
-       Command?
```

Cancel

- Command name: `cancel`
- Aliases: `abort`
- Synopsis: `cancel`
- Description:

  Cancel the current test run and reset the tester. This leaves the IUT in an undefined state. It is not recommended to use this command unless a test has lost contact with the IUT or is incomplete.

Example 233 ----------

```
- run test1
```

Loglevel

- Command name: `loglevel`
- Aliases: `ll`
- Synopsis: `loglevel [0-3]`
- Description:

  This command defines how much conformance logging should be performed. The levels are:

`0`	Only verdicts
`1`	Level 0 + PTCs, PCOs and TIMERS (default level)
`2`	Level 1 + matched lines and test trees
`3`	Level 2 + non-matched lines and defaults

If no level is supplied, the default level will be used.

Example 234 ----------

```
-       Command?
loglevel 3
-       Set conformance log level = 3
-       Command?
```

Savestats

- Command name: `savestats`
- Aliases: `ss`
- Synopsis: `savestats [<file path>]`

- Description:

  Save a simple tabulated file with a list of what tests have been executed and what their verdicts were. This is useful for tracking test results over time, typically by loading the result file in some type of information management program. If the file path is omitted, the default file path `results.txt` will be used.

Example 235 ----------

```
-       Command?
savestats testresults.txt
-       Command?
# Just list the contents of the file
system cat testresults.txt
Test                            Verdict
MyTest1                         PASS
MyTest2                         FAIL
MyTest1                         INCONCLUSIVE
```

Liststats

- Command name: `liststats`
- Aliases: `ls`
- Synopsis: `liststats`
- Description:

  List the test results of all test cases that have been run since the TTCN Exerciser was started, or since the last clearstats command.

Example 236 ----------

```
-       Command?
liststats
- Listing test statistics:
- MyTest1                       PASS
- MyTest2                       FAIL
- MyTest1                       INCONCLUSIVE
-       Command?
```

Clearstats

- Command name: `clearstats`
- Aliases: `cs`
- Synopsis: `clearstats`
- Description:

  Clear the list of test results

Example 237 ----------

```
-       Command?
clearstats
-       Clearing test statistics.
-       Command?
```

Test Debugging Commands

Most of these test debugging commands require the tester to be built with line debugging information for correct operation.

Breakpoints

- Command Name: `breakpoints`
- Aliases: `bps`
- Synopsis: `breakpoints`
- Description:

  List all currently set breakpoints.

Example 238 ----------

```
-       Command?
breakpoints
MyTest1                 5
-       Command?
```

Breakpoint

- Command name: `breakpoint`
- Aliases: `bp`
- Synopsis: `breakpoint [table] [line]`
- Description:

  Set a breakpoint at line in table. If either is omitted, the last matched line or table will be used respectively.

Example 239 ----------

```
-       Command?
breakpoints
-       Command?
step MyTest1
-       Line: MyTest1 1
-       Command?
breakpoint
-       Breakpoint set at MyTest1 1
-       Command?
breakpoint 4
-       Breakpoint set at MyTest1 4
-       Command?
breakpoint MyTest2 2
-       Breakpoint set at MyTest2 2
breakpoints
-       MyTest1 1
-       MyTest1 4
-       MyTest2 2
-       Command?
```

Delete

- Command name: `delete`
- Aliases: `-`
- Synopsis: `delete [table] [line]`
- Description:

  Delete the breakpoint at table and line. If either or both is omitted, the last matched line will be used.

Example 240 ----------

```
-       Command?
breakpoint MyTest1 3
-       Breakpoint set at MyTest1 3
-       Command?
breakpoint MyTest1 5
-       Breakpoint set at MyTest1 5
run
-       Line:   MyTest1 1
-       Line:   MyTest1 2
-       Breakpoint reached: MyTest1 3
-       Line:   MyTest1 3
-       Command?
delete
-       Breakpoint deleted: MyTest1 3
-       Command?
delete MyTest1 5
-       Breakpoint deleted: MyTest1 5
-       Command?
breakpoints
-       Command?
```

Disable

- Command name: `disable`
- Aliases: -
- Synopsis: `disable`
- Description:

  Temporarily disable all breakpoints.

Example 241 ----------

```
-       Command?
disable
-       Breakpoints disabled
-       Command?
```

Enable

- Command name: `enable`

- Aliases: -
- Synopsis: `enable`
- Description:

  Re-enable breakpoints after a disable command.

Example 242 ----------

```
-       Command?
disable
-       Breakpoints disabled
-       Command?
enable
-       Breakpoints enabled
-       Command?
```

Timers

- Command name: `timers`
- Aliases: -
- Synopsis: `timers`
- Description:

  List all currently running timers. The output format contains the following information columns:

`PTC`	The PTC to which the timer belongs
`Timer Name`	The TTCN name of the timer
`Id`	The GCI timer identifier
`Remaining (s)`	The remaining time to timeout in seconds

Example 243 ----------

```
-       Command?
timers
-       PTC     Timer Name      Id      Remaining (s)
-       MTC     Tms                     210         0.400000000
-       MTC     TWatchDog       211       59.600000000
```

```
-       PTC1    Tms                         214         0.400000000
-
-       Command?
```

Pcos

- Command name: `pcos`
- Aliases: -
- Synopsis: `pcos`
- Description:

  List all PCOs and the contents of their associated queues.

Example 244

```
-       Command?
step MyTest1
-       Line: MyTest1 1
-       Command?
receive LowerPCO ConnectReq { 6 "Peer1" }
-       Command?
receive LowerPCO ConnectReq { 7 "Peer2" }
-       Command?
pcos
-       PCO UpperPCO
-            <empty input queue>
-       PCO LowerPCO
-            1:  ConnectReq { 6 "Peer1" }
-            2:  ConnectReq { 7 "Peer2" }
-
-       Command?
```

Ptcs

- Command name: `ptcs`
- Aliases: -
- Synopsis: `ptcs`
- Description:

List all the currently active test components. The output columns include the following information:

`Name`	The name of the test component
`Id`	The GCI id of the test component
`Thr`	The host operating system thread id of the component
`Table`	The table name of the last matched TTCN line
`Line`	The last matched line number

Also, the currently active test component will be indicated with an arrow (`->`) in the output of this command.

Example 245 ----------

```
-       Command?
ptcs
-       Name            Id      Thr             Table Line
-       MTC             124     0             MyTest1 5
-    -> PTC1            125     13            MyStep1 3
-
-       Command?
```

Gett

- Command name: `gett`
- Aliases: `print`
- Synopsis: `gett [<ptc>] <variablename>`
- Description:

  Print the value of the named variable in the named test components-context. If the component name is omitted, the current component will be used.

  Example 246 ----------

```
-       Command?
gett MTC TsvFoo
```

```
-       TsvFoo: 4711
-       Command?
gett PTC1 TsvFoo
-       TsvFoo: 1234
-       Command?
```

Test Simulation Commands

Discrete

- Command name: `discrete`
- Aliases: `dts`
- Synopsis: `discrete`
- Description:

  Toggle to discrete time simulation mode. The command has no effect if already in discrete time simulation mode.

  The log prefix will be switched to `'-'`.

Example 247

```
*       Line:   Table1 3
*       Line:   Table1 4
*       Line:   Table1 5
discrete
*       Discrete time simulation is now used.
-       Command?
```

Realtime

- Command name: `realtime`
- Aliases: `rts`
- Synopsis: `realtime`
- Description:

  Toggle to realtime simulation mode. The command has no effect if already in realtime simulation mode.

The log prefix will be switched to `'*'`. A running test will immediately resume execution.

Example 248 ----------

```
-       Line:   Table1 1
-       Command?
step
-       Line:   Table1 2
realtime
-       Realtime simulation is now used
*       Line:   Table1 3
*       MTC             SEND    ASP1
*       MTC             START   Tms(200)
*       Line:   Table1 4
*       MTC             TIMEOUT Tms
*       Line:   Table1 5
*       FINAL VERDICT: PASS
*       Command?
```

Timeout

- Command name: `timeout`
- Aliases: `to`
- Synopsis: `timeout`
- Description:

  Switch to discrete time simulation. Force the shortest pending timer to expire.

Example 249 ----------

```
-       Command?
realtime
*       Command?
run Test1
*       Line:   Test1 1
*       MTC             START TWatchDog(60)
timeout
-       Discrete time simulation is now used
-       Command?
run
-       Line:   Default1 1
-       MTC             TIMEOUT TWatchDog
```

```
-       FINAL VERDICT:  FAIL
-       Command?
```

Receive

- Command name: `receive`
- Aliases: `input`
- Synopsis: `receive <PCOId> <ISMValueEncoding>`
- Description:

  Enqueue the message defined by ISMValueEncoding in the PCO input queue connected to the named PCO.

  It is possible to use input values of types SEQUENCE OF, SET and SET OF. The left/right braces syntax should be:

  – SEQUENCE - '{' and '}'

  – SEQUENCE OF - '[' and ']',

  – SET - '{.' and '.}'

  – SET OF - '[.' and '.]'

  The field's names are mandatory for SET values and optional for SEQUENCE values.

  For an alternative form, see “Messageinput” on page 1376.

Example 250 ----------

```
-       Command?
pcos
-       PCO UpperPCO
-           <empty input queue>
-       PCO LowerPCO
-           <empty input queue>
-
-       Command?
receive UpperPCO AcceptCall { 1, TRUE, { 34, 13, 99, '5'B } }
-       Command?
pcos
-       PCO UpperPCO
-           1:  AcceptCall { 1, TRUE, { 34, 13, 99, '5'B } }
```

```
-       PCO LowerPCO
-           <empty input queue>
-       Command?
```

MSC Generation Commands

Nomsc

- Command name: `nomsc`
- Aliases: -
- Synopsis: `nomsc`
- Description:

  Disable MSC generation.

  The command is only available when the tester is stopped.

Example 251

```
-       Command?
nomsc
-       MSC generation disabled
-       Command?
```

Decomposed

- Command name: `decomposed`
- Aliases: -
- Synopsis: `decomposed`
- Description:

  Enable MSC generation with decomposed MSCs. For more information, see chapter 32, *The TTCN to C Compiler (in Windows)* and chapter 27, *The TTCN to C Compiler (on UNIX)*.

  The command is only available when the tester is stopped.

Example 252 ----------

```
-       Command?
decomposed
-       Decomposed MSC generation enabled
-       Command?
```

Composed

- Command name: `composed`
- Aliases: -
- Synopsis: `composed`
- Description:

  Enable MSC generation with composed MSCs. For more information, see chapter 32, *The TTCN to C Compiler (in Windows)* and chapter 27, *The TTCN to C Compiler (on UNIX)*.

  The command is only available when the tester is stopped.

Example 253 ----------

```
-       Command?
composed
-       Composed MSC generation enabled
-       Command?
```

Mscsystem

- Command name: `mscsystem`
- Aliases: -
- Synopsis: `mscsystem [<system-name>]`
- Description:

  Define the name of the IUT instance in the composed MSC generation. This is for making it easier to generate MSCs which should later be reused in a system verification with an MSC verification tool

such as the SDL Explorer, as well as for test re-generation with a tool such as Autolink.

If the system-name parameter is omitted, a default system name will be used (by default `IUT`).

Example 254 ----------

```
-       Command?
mscsystem env_0
-       IUT Name for composed MSC generation defined.
-       Command?
```

Mscprefix

- Command name: `mscprefix`
- Aliases: `-`
- Synopsis: `mscprefix <path/prefix>`
- Description:

  Set a prefix for file names used when generating MSCs. This prefix is prepended to the file name and can be both a path or a file prefix.

  The default is `log_`.

Example 255 ----------

```
-       Command?
mscprefix /tmp/traces/trace_
-       Path/file prefix defined for MSC generation.
-       Command?
#
#       All test traces will be saved in the named directory
#
```

Test Validation Commands

Clearreports

- Command name: `clearreports`
- Aliases: `cr`
- Synopsis: `clearreports`
- Description:

  Clear the list of reports of dynamic errors encountered so far in test runs.

Example 256 ----------

```
-       Command?
clearreports
-       Reports cleared.
-       Command?
```

Listreports

- Command name: `listreports`
- Aliases: `lr`
- Synopsis: `listreports`
- Description:

  List all the reports of dynamic errors encountered so far in test runs. The reports are in the following general format:

  `Report <index>: [<table>] <line>: <description>`

  The `<table>` field is optional. If it is not present, it implies that the report was not detected in the context of a running test component. If the `<line>` field is 0, there is a context available, but the context is not executing.

  Also, if no line debug information is available, the table and line will be omitted and 0 respectively.

Example 257 ----------

```
-       Command?
listreports
-       Listing reports:
-       Report  1:      TestCase1 7: Missing ?DONE in MTC
-       Report  2:      TestCase2 3: Incomplete test case
-       Command?
```

Savereports

- Command name: `savereports`
- Aliases: `sr`
- Synopsis: `savereports [<filename>]`
- Description:

  Save the reports to named file, or to the file `reports.txt` if no file name is supplied. The file format is the same as for the `listreports` command output.

Example 258 ----------

```
-       Command?
listreports
-       Listing reports:
-       report  1:      TestCase1 7: Missing ?DONE in MTC
-       report  2:      TestCase2 3: Incomplete test case
-       Command?
```

Messagefile

- Command name: `messagefile`
- Aliases: `mf`
- Synopsis: `messagefile <filename>`
- Description:

Append the message definitions in the messagefile to the list of input messages that can be used with the `messageinput` command, and also for selection of messages with the `randomwalk` command.

The syntax of the file named by `filename` is:

```
MessageFile ::= MessageLine | CommentLine;
MessageLine ::= PcoId ISMValueEncoding NL;
CommentLine ::= NonAlphaChar Any NL;
```

Example message file:

```
# This is an example message file named file1.msg

PCO1 ASP1 { 1 2 FALSE '1234'O }
PCO2 ASP3 { 4 2 TRUE '3123'H }

# end of example file
```

Also note that messages can be added with the command `messageadd`. The messagefile is mainly intended for message lists generated by other means than with this tool.

Example 259 ––

```
-       Command?
messagefile file1.msg
-       Adding message definitions:
-       PCO1 ASP1 { 1 2 FALSE '1234'O }
-       PCO2 ASP3 { 4 2 TRUE '3123'H }
-       Command?
```

––

Messageadd

- Command name: `messageadd`
- Aliases: `ma`
- Synopsis: `messageadd <pconame> ISMValueEncoding`
- Description:

  Add the named message on the named PCO to the inputs that can be sent with the `messageinput` command and from which inputs are selected with the random walk.

It is possible to use input values of types SEQUENCE OF, SET and SET OF. The left/right braces syntax should be:

– SEQUENCE - '{' and '}'

– SEQUENCE OF - '[' and ']',

– SET - '{.' and '.}'

– SET OF - '[.' and '.]'

The field's names are mandatory for SET values and optional for SEQUENCE values.

Example 260 ––

```
-       Command?
messagelist
-       Listing message definitions
-       1   : PCO1 ASP1 { 1 2 FALSE '1234'O }
-       2   : PCO2 ASP3 { 4 2 TRUE '3123'H }
-       Command?
messageadd PCO1 ASP2 ( FALSE TRUE )
-       Command?
messagelist
-       Listing message definitions
-       1   : PCO1 ASP1 { 1 2 FALSE '1234'O }
-       2   : PCO2 ASP3 { 4 2 TRUE '3123'H }
-       3   : PCO1 ASP2 ( FALSE TRUE )
-       Command?
```

––

Messagelist

- Command name: `messagelist`
- Aliases: `ml`
- Synopsis: `messagelist`
- Description:

  List all messages defined in the message list.

  Example 261 ––

  ```
  messagelist
  ```

```
-       Listing message definitions
-       1   : PCO1 ASP1 { 1 2 FALSE '1234'O }
-       2   : PCO2 ASP3 { 4 2 TRUE '3123'H }
-       3   : PCO1 ASP2 ( FALSE TRUE )
-       Command?
```

Messageclear

- Command name: `messageclear`
- Aliases: `mc`
- Synopsis: `messageclear [<index>]`
- Description:

  Clear the message at index `<index>` in the message list. If no index is provided, all messages are cleared. The `messagelist` command prints indices for each message definition.

  Also note that the `messageclear` command may change the ordering and indices of messages at higher indices.

Example 262 ----------

```
-       Command?
messagelist
-       Listing message definitions
-       1   : PCO1 ASP1 { 1 2 FALSE '1234'O }
-       2   : PCO2 ASP3 { 4 2 TRUE '3123'H }
-       3   : PCO1 ASP2 ( FALSE TRUE )
-       Command?
messageclear 1
-       Cleared message definition.
-       Command?
messagelist
-       Listing message definitions
-       1   : PCO2 ASP3 { 4 2 TRUE '3123'H }
-       2   : PCO1 ASP2 ( FALSE TRUE )
-       Command?
messageclear
-       Clearing all message definitions
-       Command?
messagelist
messagelist
-       Listing message definitions
-       Command?
```

Messageinput

- Command name: `messageinput`
- Aliases: `mi`
- Synopsis: `messageinput [<index>]`
- Description:

  Provide the message at index `<index>` in the message list as input to the Tester. This is a short form of the `receive` command, appropriate for frequently used messages, and it may also be used to test contents of message files.

  The message is decoded and added at the end of the named PCO queue.

Example 263 ----------

```
-       Command?
messagelist
-       Listing message definitions
-       1  : PCO2 ASP3 { 4 2 TRUE '3123'H }
-       2  : PCO1 ASP2 ( FALSE TRUE )
-       Command?
messageinput 2
-       Command?
step
-       MTC     RECEIVE         PCO1 ? ASP2
-       MTC     STARTTIMERTimer1
```

Randomwalk

- Command name: `randomwalk`
- Aliases: `rw`
- Synopsis: `randomwalk [<repetitions>] {<testcaselist>}`
- Description:

  Will run the test cases of `<testcaselist>` `<repetitions>` times, providing random inputs and timeouts as they go. Reports are collected while running the test cases. Test logging is disabled, but

can be re-enabled if a breakpoint is reached while doing the random walk.

Example 264 ----------

```
-       Command?

# This is a command for running the test case MyTestCase 100
# times while providing random inputs from the message list
# and also timeouts.

randomwalk 100 MyTestCase

-       Starting random walk...

[some logging of verdicts and selected path]

-       Random walk completed
-       Command?
listreports
-       Listing reports:
-       report  1: MyTestCase 4: READTIMER: Timer not running
-       Command?
```

Maxdepth

- Command name: `maxdepth`
- Aliases: -
- Synopsis: `maxdepth <depth>`
- Description:

  Define how many messages and timeouts a test case may receive, until a test case run not producing a verdict should be abandoned. If the maxdepth is exceeded, a report will be produced.

  Example 265 ----------

  ```
  -       Command?
  maxdepth 10
  -       Defined max depth for random walk
  -       Command?
  ```

Kernel Management Commands

Cl

- Command name: `cl`
- Aliases: -
- Synopsis: `cl`
- Description:

  Turn off the SDL and TTCN Integrated Simulator user interface tagging. This makes the outputs of the tester more human-readable. By default, this tagging is enabled, so the first command you enter when running from the command line is typically a `cl` command.

Example 266 ----------

```
<VERDICT>
-       FINAL VERDICT:PASS
</VERDICT>
<MESSAGE UI::READY>
-       Command?
</MESSAGE UI::READY>
cl
-       Output tagging disabled
-       Command?
list
-       TestCase1
-       TestCase2
-       Command?
```

Ui

- Command name: `ui`
- Aliases: -
- Synopsis: `ui`
- Description:

  Enable the SDL and TTCN Integrated Simulator user interface tagging. This makes the output less readable for a human, but easier to

parse by computer programs (such as the SDL and TTCN Integrated Simulator user interface).

Example 267 ----------

```
cl
-       Output tagging disabled
-       Command?
list
-       TestCase1
-       TestCase2
-       Command?
ui
<LOG>
-       Using simulator ui output tagging
</LOG>
<MESSAGE UI::READY>
-       Command?
</MESSAGE UI::READY>
```

Poll

- Command name: `poll`
- Aliases: `-`
- Synopsis: `poll`
- Description:

  Enable command polling and dispatch on each matched TTCN line. This slows down the execution somewhat, but makes it possible to interrupt a tester in other states than an idle state. The command requires that the tester was built with line debugging enabled.

Example 268 ----------

```
-       Command?
poll
-       Command?
```

Nopoll

- Command name: `nopoll`
- Aliases: -
- Synopsis: `nopoll`
- Description:

  Disable command polling in other states than stopped or snapshot (idle). This increases the execution speed, and also facilitates script writing by ensuring that a tester is in one of these two known states before it processes its next command.

Example 269 ----------

```
-       Command?
nopoll
-       Command?
```

Cmdlog

- Command name: `cmdlog`
- Aliases: -
- Synopsis: `cmdlog [<filepath>]`
- Description:

  Start or stop a command log. If the `<filepath>` argument is supplied, the named file will be opened for writing and all commands from the command line or included scripts will be written to the file. If no file name is supplied, the file will be closed and command logging disabled.

Example 270 ----------

```
-       Command?
cmdlog  asp1
-       Command?
receive pco1 asp1 { '10'B FALSE '11'B }
-       Command?
run
```

```
-       Command?
cmdlog
-       Command?
+asp1
-       Command?
+asp1
-       Command?
pcos
-       PCO pco1
-           1: asp1 { '10'B FALSE '11'B }
-           2: asp1 { '10'B FALSE '11'B }
-           3: asp1 { '10'B FALSE '11'B }
```

Status

- Command name: `status`
- Aliases: -
- Synopsis: status
- Description:

  Display current TTCN Exerciser status and mode information overview.

Example 271 ----------

```
-       Command?
status
-       Tester status: STOPPED
-       Time Mode:     Discrete Time Simulation
-       Logging level: 2
-       Breakpoints:   Disabled
-       Command Log:   Disabled
-       Logging Mode:  Command Line
-
-       Command?
```

System

- Command name: `system`
- Aliases: -
- Synopsis: `system <commandline>`

- Description:

  Execute the <commandline> using the command line interpreter of the platform. Uses the C stdlib function system(<commandline>). Use this with care for reviewing, deleting and creating files.

Example 272 ----------

```
-       Command?
system mkdir ./msctraces
-       Command?
mscprefix ./msctraces/trace_
-       Command?
composed
-       Command?
run tc1 tc2 tc3 tc4

        [snip]

-       Command?
system ls ./msctraces
trace_tc1.mprtrace_tc2.mprtrace_tc3.mprtrace_tc4.mpr
-       Command?
```

Log

- Command name: log
- Aliases: -
- Synopsis: log [<filepath>]
- Description:

  Start or stop a total log. If the <filepath> argument is supplied, the named file will be opened for writing. All commands from the command line or included scripts, conformance log and messages from ETS will be written to the file. If no file name is supplied, the file will be closed and logging disabled.

Example 273 ----------

```
-       Command?
log mylog.txt
```

```
-       Command?
receive pco1 asp1 { '10'B FALSE '11'B }
-       Command?
run
-       Command?
log
```

ISM Value Encoding

The ISM Value Encoding defines how values are encoded when sent, or decoded when received. It also defines the format for values when printed or read as test suite parameters. The format is not 100% compatible with the SDL Simulator format, or the MSC generation format, though in most cases it will be able to read those values as well.

The general syntax for the value notation is as follows. Rules named with all capital letters are tokens.

```
ISMValueEncoding ::= OptionalTypeAndValue ;
OptionalTypeAndValue ::= [TYPE] Value ;
TYPE ::= <Name of type defined in TTCN test suite> ;
Value ::= Composite | Atomic | OMIT;
Atomic ::= CSTRING | OSTRING | HSTRING | BSTRING | INTEGER | BOOLEAN ;
Composite ::= LPAR {OptionalTypeAndValue OPTCOMMA } RPAR;
CSTRING  ::= '"' .* '"' ;
OSTRING  ::= ''' ([09afAF][09afAF])* ''O' ;
HSTRING  ::= ''' [09afAF]* ''H' ;
BSTRING  ::= ''' [01]* ''B' ;
INTEGER  ::= '-' [09]* | [09]* ;
BOOLEAN  ::= 'TRUE' | 'FALSE' | 'true' | 'false' ;
LPAR     ::= '{' | '(' ;
RPAR     ::= '}' | ')' ;
OPTCOMMA ::= ',' | ;
OMIT     ::= '-';
```

The CSTRING type is by default IA5String, use TYPE to override with a different character string type. Note also that in TTCN, the character string types are compatible and it may not be necessary to make the distinction.

Examples of this encoding include:

Encoding	Description
`1`	The INTEGER value 1
`FALSE`	The BOOLEAN value FALSE

Encoding	Description
`MyINTEGER 23`	The INTEGER derivate MyINTEGER value 23
`BIT4 '1001'B`	The BITSTRING derivate BIT4 value ‘1001’B
`{ 1 , 2 , 3 }`	A composite type with field values 1, 2 and 3
`ASP1 { 711, TRUE }`	An ASP1 with field 1 = 711 and field 2 = TRUE
`ASP2(BIT4 '1001'B PDU1(12))`	An ASP2 with second field being a PDU1

Chapter

35

TTCN Test Suite Generation

This chapter describes two ways for generating TTCN test suites based on SDL specifications. The first one is to use TTCN Link, which assists you in manual specification of test suites. The other one is to use the Autolink feature of the SDL Explorer, which allows automatic generation of test suites.

For more information about the SDL Explorer, see *chapter 52, The SDL Explorer*.

Tutorials for TTCN Link and Autolink can be found in chapter 8, *Tutorial: The TTCN Link* and chapter 9, *Tutorial: The Autolink Tool, in the TTCN Suite 6.2 Getting Started*.

Introduction

Testing is one of the most important steps in the development of a new product. Often, it is also very time consuming and costly. As part of the Conformance Testing Methodology and Framework, the *Tree and Tabular Combined Notation* (TTCN) has been defined as a formal language for test suite specification. A test suite consists of four basic parts: The test suite overview, the declarations, the constraints and the dynamic behavior description.

In the TTCN Suite, TTCN test suite generation is supported by TTCN Link and Autolink. They both use an SDL specification as the basis for test generation, but they differ in their functionality.

TTCN Link generates the TTCN declarations part automatically and you use it for interactive building of test cases in the dynamic part.

Autolink is embedded in the SDL Explorer. In addition to the SDL specification, it uses MSCs for test purpose descriptions. With this input, Autolink generates the declarations, constraints and dynamic behavior description parts of a TTCN test suite automatically.

In comparison, the test generation features of Autolink are superior to the ones of TTCN Link. If for some reason the test purpose description with MSCs is not applicable, then you should use TTCN Link. In any case, test cases built with TTCN Link can be merged with test cases generated by Autolink.

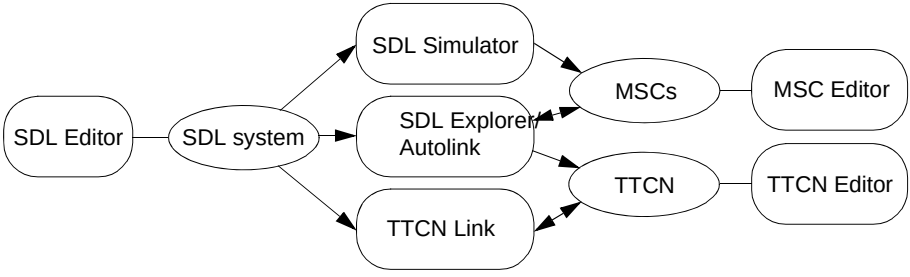

Figure 235: Overview of TTCN Link and Autolink

TTCN Link – Generation of Declarations

TTCN Link automatically generates the TTCN declarations part based on an SDL specification. The default dynamic behavior table is also generated. It contains timeout and otherwise statements for each PCO, which will ensure that any incorrect response from the implementation under test always will give a FAIL verdict as a result from the test case. After the default and constraints tables have been generated, you can interactively build test cases.

When you use TTCN Link, there are four (five) phases involved:

1. In the SDL Editor, you prepare an SDL specification.
2. In the Organizer, you generate a TTCN Link application.
3. In the TTCN Suite, you use TTCN Link for generating the declarations part.
4. In the TTCN Suite, you interactively build test cases.
5. Optionally, you may also merge the test suite with a TTCN-MP file, possibly generated by Autolink.

For more information about TTCN Link, see "Using TTCN Link" on page 1389.

Autolink – Generation of a Test Suite

Autolink can be used for automatic generation of TTCN test suites based on an SDL specification and a number of MSCs. The steps involved when you use Autolink are:

1. In the SDL Editor, you specify the SDL system to be used.
2. In the Organizer, you generate an SDL Explorer.
3. In the SDL Explorer, you define a number of traces through the SDL system for which you want to derive test cases. Each trace is stored as an MSC. Alternatively, you may create the MSCs manually in the MSC Editor or generate them with the help of the SDL Simulator.
4. In a text editor, you define an Autolink configuration. The configuration tells Autolink how to map SDL signals and signal parameters onto TTCN constraint names, and how to group test cases and test steps.

5. In the Explorer, you generate intermediate representations of the test cases and constraints from the MSCs. This can either be done by state space exploration or by direct translation to TTCN.
6. In the Explorer, you may modify the generated constraints. Afterwards, the result is saved in a TTCN-MP file.
7. The TTCN-MP file can be opened in the TTCN Suite, and to complete the test suite, the test suite overview has to be generated. **On UNIX**, you have to generate it explicitly. **In Windows**, the overview is generated automatically, for example before you print.

For more information about Autolink, see "Using Autolink" on page 1431.

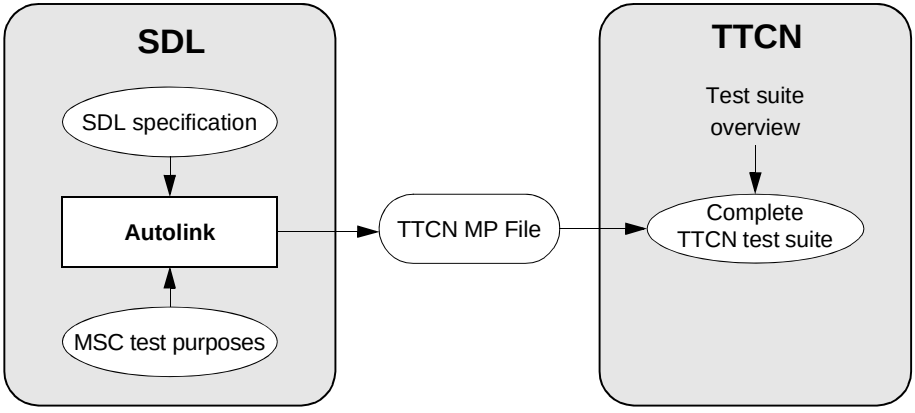

Figure 236: Generation of a TTCN test suite with the TTCN Suite and Autolink

Using TTCN Link

The phases involved when you are using TTCN Link – "Preparing for the Generation of Declarations" on page 1389, "Generating the Declarations" on page 1390 and "Creating Test Cases" on page 1396 – will be described below. You can also read about "Showing SDL System Information" on page 1398 and "Merging TTCN Test Suites in the TTCN Suite" on page 1398.

Preparing for the Generation of Declarations

Before it is possible to generate the declarations, you have to do two things:

1. Adapt the SDL system to the requirements of test generation and TTCN Link.
2. Generate a Link executable for the SDL specification.

Adapting the SDL System

The major adaptation of the SDL system that you have to do, is to modify it to properly describe the test architecture that is to be used. Basically, the requirement is that the channels from/to the environment of the system must correspond to the points of control and observation in the test suite. For example, the SDL system might be a specification of a communication protocol where the lower side of the protocol in practise can only be accessed through a network. To be able to create correct test cases, you also have to include the communication media in the SDL specification. Note however, that the specification of the media does not have to be a detailed specification of the functionality, only a specification of the aspects relevant to the current testing situation.

Generating a Link Executable

Once the SDL specification describing the system to be tested and the test architecture are finished, you can generate a Link executable. (A Link executable is sometimes also referred to as state space generator.) You do this in the same way as when you generate an SDL Simulator or Explorer.

To generate a Link executable:

1. Select *Make* from the *Generate* menu in the Organizer.

   The *Make* dialog will be opened.

2. Select *Analyze & generate code*.
3. Select *Generate Makefile*.
4. Select *Use Standard Kernel* and *TTCN Link*.
5. If necessary, change other options.
6. Click *Full Make*.

   The Link executable will now be generated. It includes the information about the SDL specification that is needed for generation of the TTCN declarations. The name of the executable will be `<sdl system name>_xxx.link`, where `xxx` is depending on the compiler used.

Note:

You should not change the SDL system after you have generated the Link executable. Such changes will not affect the generated Link executable and therefore not affect the generation of declarations.

Generating the Declarations

There are two steps involved in generation of the declarations (and the default table):

1. You select the Link Executable.
2. You start the generation.

Specifying the Link Executable

Before the actual generation of the TTCN declarations, you have to specify the Link executable – and thereby the SDL system – to use. There are two methods for doing this: associating the SDL and TTCN systems in the Organizer and explicitly selecting the Link executable in the TTCN Suite. In case a Link executable has been specified both in the Organizer and in the TTCN Suite, the one selected in the TTCN Suite is the executable that will be used.

Also note that the TTCN test suite that you are going to generate the declarations in, have to be created and added to the Organizer (and the same system file as the SDL system is included in).

Associating the SDL System with the TTCN Test Suite in the Organizer

1. In the Organizer, select the SDL system (the top node).
2. Select *Associate* from the *Edit* menu.

   The *Associate* dialog will be opened.
3. In the dialog, select the TTCN test suite and click *OK*.

   The association will be indicated by a new icon placed under the test suite icon.

Selecting the Link Executable in the TTCN Suite

1. Make sure that the test suite is opened and that the Browser is active.
2. From the *SDT Link* menu point to *Select Link Executable*. **On UNIX**, it is the menu in the Browser.

   The *Select Link Executable* dialog will be opened.
3. In the dialog, select the Link executable and click *OK*.

Note: External synonyms

The SDL system from which the Link executable is generated may contain external synonyms that do not have a corresponding macro definition (see "External Synonyms" on page 2650 in chapter 56, *The Cadvanced/Cbasic SDL to C Compiler*). Such an SDL system cannot be used with TTCN Link and you will get an error message when trying to select the Link executable.

However, if you set the environment variable `SDTEXTSYNFILE` to a synonym definition file before starting SDL Suite or TTCN Suite, this file will automatically be used to define the external synonyms. If `SDTEXTSYNFILE` is set to "[[" all synonyms are given "null" values.
The syntax of a synonym file is described in "Reading Values at Program Start up" on page 2651 in chapter 56, *The Cadvanced/Cbasic SDL to C Compiler*.

Generating the TTCN Declarations

When you have specified the Link executable, you can generate the declarations in the TTCN Suite:

1. Select *Generate Declarations* from the *SDT Link* menu. **On UNIX**, it is the menu in the Browser.

   This will generate the declarations and a default table.

2. Expand the Declarations Part and take a look:

   – One or more PCO type declarations have been generated.

   – For each channel to/from the environment in the SDL system, one PCO declaration has been generated.

   – For each signal on these channels, one ASN.1 ASP/PDU declaration has been generated.

   – For each data type that is used as a parameter on the signals to/from environment, a TTCN/ASN.1 data type definition has been generated if the data type cannot be mapped to a standard TTCN data type.

3. Expand the Dynamic Part. You should see that a default behavior tree called *Otherwise Fail* is generated. This contains otherwise statements with verdict FAIL for all generated PCOs.

PCO Mapping

There are two alternatives available for generation of the PCO types: either one PCO type is generated for each channel in the SDL system or only one PCO type is generated. This is defined by the configuration command `define-pco-type-mapping` (see "PCO Type Generation Strategy" on page 1406). The default is that only one PCO type is generated.

If more than one PCO type is generated, they are named *<Channel-Name>_TypeId*. If only one PCO type is generated it is called *PCO_Type*.

ASP/PDU Mapping

The generated ASPs/PDUs are given the same name as the corresponding SDL signal with one exception: If there are multiple PCO types and there is one signal that can be transported on more than one channel to the environment, this signal is divided into two ASPs, since an ASP may only be associated with one PCO type. The ASPs are then given names like *<SDLSignalName>_<PCOName>*.

By default, ASPs are generated from the SDL signals. However, you can change it to PDUs by using the `define-signal-mapping` command (see "SDL Signal Mapping Strategy" on page 1407).

Data Type Mapping

The data type mapping from SDL to TTCN/ASN.1 is defined in the following table. In most cases a table containing an ASN.1 type definition is generated for each data type. In the table below, this is indicated by a "<TTCN name> -> <ASN.1 definition>" clause. The <TTCN name> is the name used to denote the type in the test suite and the <ASN.1 definition> is the ASN.1 type definition that is the contents of the generated table. If the TTCN name is omitted, the name is given by the name of the corresponding SDL data type.

SDL data type	TTCN/ASN.1 data type
structure	-> SEQUENCE
array (with finite index sort)	-> SEQUENCE OF
string	-> SEQUENCE OF
bag	-> SET OF
enumerated type	-> ENUMERATED
boolean	BOOLEAN
character	Character -> IA5String (SIZE (1))
charstring	CharString -> IA5String
integer	INTEGER
real	Real -> REAL
natural	Natural -> INTEGER (0 .. MAX)

SDL data type	TTCN/ASN.1 data type
syntype	-> subtype
choice	-> CHOICE
bit	Bit -> BIT STRING (SIZE (1))
bit_string	BIT_STRING -> BIT STRING
octet	Octet -> OCTET STRING (SIZE (1))
octet_string	OCTET_STRING -> OCTET STRING
ObjectIdentifier	OBJECT_IDENTIFIER -> OBJECT IDENTIFIER
IA5String	IA5String
NumericString	NumericString
PrintableString	PrintableString
VisibleString	VisibleString
Null	NULL

In addition to the data types above, data types defined in external ASN.1 modules can also be used. These data types are mapped to definitions in the table named “ASN.1 Type Definitions by Reference” in the test suite. For each data type in the external ASN.1 module that is used on signals to/from the environment, one line defining the data type will be generated in this table. Note that the *Generate Declarations* command in the *SDT Link* menu assumes that the external ASN.1 module is setup as a dependency of the TTCN document.

No other data types than the ones mentioned above may occur on signals to/from the environment in the system.

Note that SDL is not case sensitive whereas TTCN is case sensitive. The spelling of the names generated by TTCN Link is given by the defining occurrence of the corresponding SDL name. Also note that no transformation of names is performed during generation of the TTCN names. This may in some cases lead to incorrect TTCN names if for example a reserved word from TTCN is used in the SDL system. To fix this problem, you have to change the name in the SDL system to a legal TTCN name.

Note that the SDL character NUL is mapped to NUL. Unfortunately, NUL is not an IA5String allowed character. So this must manually be changed to a legal character, e.g. ““. The NUL character is especially interesting since un-initialized SDL characters are set to NUL.

Modifying the Generated Declarations

In some cases, you may find it useful to manually modify the declarations that have been generated by TTCN Link before continuing with the development of the test cases. There are in particular two interesting cases:

- ASPs vs. PDUs.

  TTCN Link automatically generates ASPs for all signals visible on the border of the SDL system unless defined otherwise by the define-signal-mapping option (see “SDL Signal Mapping Strategy” on page 1407). If PDU definitions are more suitable for some of the signals, this is the time to change them. The simplest way is to copy the generated ASPs from the section *ASN.1 ASP Type Definitions* and paste them as PDUs in the section *ASN.1 PDU Type Definitions*.

- ASP field names.

  The ASPs are generated based on the SDL signals, and since the signals in SDL have no parameter names (only types), TTCN Link automatically generates names for the ASP fields. The fields are given the name “<type name><no>” where the <type name> is the name of the type of this parameter (but always starting with a non-capital letter to follow ASN.1 rules). It is however possible to change these names in the generated definitions, and if you do it before the test cases are developed, the new manually defined names will also be used in the test cases.

Regeneration of Declarations

It is possible to regenerate the declarations from an SDL system to incorporate new signals, channels and/or data type into the test suite. If you select *Generate Declarations* from the *SDT Link* menu again, only declarations with a name different from the existing test suite declarations will be inserted into the test suite.

Creating Test Cases

To create test cases with TTCN Link, you use the Table Editor in the TTCN Suite. When TTCN Link is used, the test cases are *synchronized*, that is, verified against the SDL specification.

In synchronized mode, the test case is guaranteed to be consistent with the specification. Each action you perform during the development of the test case will be incrementally verified by the state space exploration part of TTCN Link. When a table is in synchronized mode, the *SDT Link* menu of the **UNIX** Table Editor will contain new menu choices for editing of the test case. **In Windows**, you can find the corresponding commands in the *Link* dialog:

- *Send* will add a send statement to the test case. This is a manual step where you define the constraint to be associated with the send statement.
- *Receive* automatically generates all valid responses from the system under test. This implies that you do not need to check with the specification which possible signals the system can send in the state it is driven to by the proceeding lines in the test case.
- *Start timer* and *Cancel timer* are also manual commands where TTCN timers are started and cancelled. However, note that the timeout event corresponding to the timer will be automatically generated as a result of a *Receive* command.
- *Attach test step* will attach a previously defined test step, while still keeping the editor in synchronized mode.

If you modify the contents of the test case by using other menu choices, the editor will leave the synchronized mode.

The verdict for the generated test case lines, will always be either PASS or INCONCLUSIVE since the generated receive lines will always correspond to valid behaviors of the implementation under test.

A default test step, which consists of an otherwise fail for each PCO, will ensure that an incorrect response from the implementation under test always will give a FAIL verdict as a result from the test case.

Constraint Restrictions

The constraints that are used in send and receive statements in the test cases, are subject to certain restrictions:

- They may not use test suite or test case variables or test suite parameters.
- They must be “exactly” defined without any omits, any values, ranges, wildcards, etc.

The following is however allowed in send and receive constraints a test case is resynchronized, even though it is not generated automatically for receive constraints:

- The constraints can be structured/chained, that is, the constraints can reference and use other constraints defined in the test suite.
- The constraints can use test suite constants.
- The constraints can be parametrized.

Creating Test Steps

It is often useful to structure the test case into test steps. To do this by using TTCN Link:

1. Create the TTCN statements that should be in the test step directly in the test case table. This should of course be done in synchronized mode.
2. Cut the lines that should form the test step from the test case.
3. Create a test step table.
4. Paste the lines into the new test step table and adjust the indentation level.
5. Add an attach statement to the test case.

Showing SDL System Information

When you use TTCN Link for creating a test case, it is possible to access the SDL specification from the Table Editor.

To do this you first select a line in the test case. Then you have three alternatives:

- Select *Show SDL* from the *SDT Lin*k menu.

  The SDL Editor will be opened and display the executed SDL symbols that correspond to the selected test case line.

- Select *Show Coverage* from the *SDT Link* menu.

  This will display the Coverage Viewer and coverage information for the current test case.

- Select *Show MSC* from the *SDT Link* menu.

  The MSC Editor will be opened with a generated MSC diagram showing the execution path from the start of the SDL system to the state corresponding to the selected line in the test case. This may be particularly useful if you need to find out how unexpected receive statements are possible.

Merging TTCN Test Suites in the TTCN Suite

By using TTCN Link, you can only generate the declarations and create the dynamic tables. Either you could add the constraints and dynamic tables manually or merge the TTCN Link generated test suite with one generated by Autolink. A test suite generated by Autolink is in TTCN-MP format and contains constraints, declarations and dynamic tables.

To merge the test suites:

1. Make sure that the test suite that you want to merge the MP file into – that is, the *destination document* – is opened and active.

2. **In Windows**, select *Autolink Merge* from the *File* menu.

   On UNIX, select *Autolink Merge* from the *SDT Link* menu in the Browser.

   A dialog will be opened.

3. Find and select the MP file that you want to merge with the currently opened test suite.

4. Click *OK* **(in Windows)** or *Merge* **(on UNIX)**.

   The MP file you selected will be merged into the currently opened test suite.

   To complete the test suite **on UNIX**, you also have to generate the test suite overview. **In Windows**, the overview is generated automatically, for example before you print, and after that it is kept updated.

The merge will only work if the two test suites do not conflict. A conflict occurs if any TTCN object in the MP file has the same name as any TTCN object in the destination document. However, if such a conflict is detected, the merge will continue but the conflicting object in the MP file will be skipped.

Constraints will be merged in a special way. For example, the MP file may contain a TTCN ASP constraint called *constraint1* that refers to the type *type1* which is of the incompatible type TTCN PDU TypeDef. Because of this, a copy of *constraint1* will be inserted as a TTCN PDU constraint instead. However, this “type conversion” is limited. An ASN.1 constraint will not be converted to a TTCN constraint or vice versa.

Summary of TTCN Link

TTCN Link supports test case development and there are two major objectives:

- To help solving the consistency problem that arises as soon as there are two different descriptions of the same system, in this case the SDL specification and the TTCN test suite.
- To supply an environment that, based on the SDL specification, supports test suite development during the TTCN design. Both by directly using the SDL specification, for example to generate the declarations, and by providing access to the SDL specification directly from the TTCN Suite.

Overview of the TTCN Link Algorithm

This section will give a brief introduction to the algorithm used by TTCN Link to synchronize a test case with an SDL system.

The Composed System

The system that TTCN Link analyzes is the composed system that consists of both the SDL specification and the TTCN test case that is interactively created.

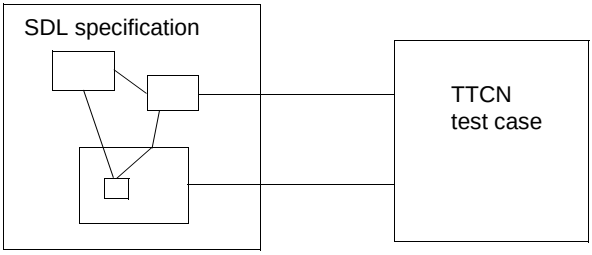

Figure 237: A composed SDL/TTCN system

The connection between the SDL system and the TTCN test case is created by connection of the channels to/from environment in the SDL system to the PCOs in the test suite.

State Space Exploration

The technique used by TTCN Link is based on state space exploration (sometimes referred to as reachability analysis) of the system composed of the SDL system together with the test case that is being created. The state space of this system can be viewed as a graph, where the nodes represent system states and the edges represent actions that can be performed by the system.

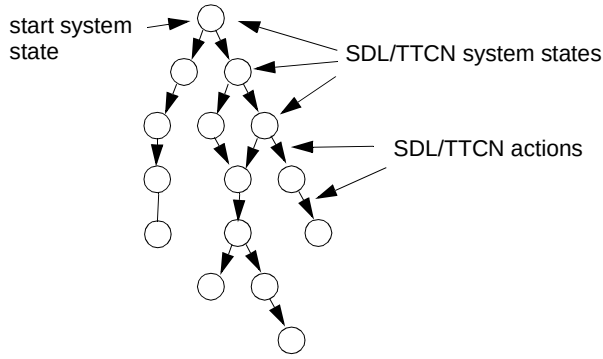

Figure 238: A state space fragment

Each system state represents the combined system in one moment in time. It contains information of for example:

- What SDL process instances exist
- The variable values of all the process instances
- The control flow state of the instances
- Any procedure calls, including local variables in the procedures
- The current line number of the test case
- Any started timers, both SDL and TTCN timers

The actions represented by the edges are either SDL actions like input, output, tasks, etc., or TTCN actions like send, receive or start timer.

Essentially, the algorithm to generate the state space of the combined system is the following, where two *global variables* – StateSpace (a graph that will contain the state space of the system) and TreatList (a list of states that is yet to be treated by the algorithm) – are used:

1. Create the start system state and add it to StateSpace and TreatList.
2. Remove one state (in step 3–4 called the current state) from TreatList.
3. Compute all possible actions that can be performed in the current state and the resulting system state that will be reached when the respective action has been performed.

4. For each action/resulting state:
   - If the resulting state was not already in StateSpace, add it to TreatList.
   - Add the action/resulting state to StateSpace.
5. If TreatList is empty: Terminate algorithm, the state space of the system is now represented by the graph in StateSpace.

   If TreatList is not empty: Go to step 2.

Incremental State Space Exploration

Since you interactively create the test case that describes the TTCN part of the combined SDL/TTCN system, it is not possible for TTCN Link to compute the entire state space at once. Instead, the state space exploration is performed in an incremental fashion in the following way:

1. You compute the state space that can be reached without any action by the test case.
2. When you TTCN Link to add a TTCN statement to a leaf in the test tree, you add the corresponding TTCN action(s)/resulting system state(s) to the state space.
3. Generate the state space that can be reached from the newly created system state(s) without any further action by the test case.
4. Go to step 2.

The consequence of this algorithm is that the state space of the combined SDL/TTCN system is explored in an incremental fashion, where each increment corresponds to a command you have given. Also the structure of the state space is influenced by the incremental way that it is generated. The state space can be visualized as a tree structure, where each node represents one line in the test case and a subpart of the state space, to be more precise, the subpart of the state space where the test case has executed this particular line but not the next one.

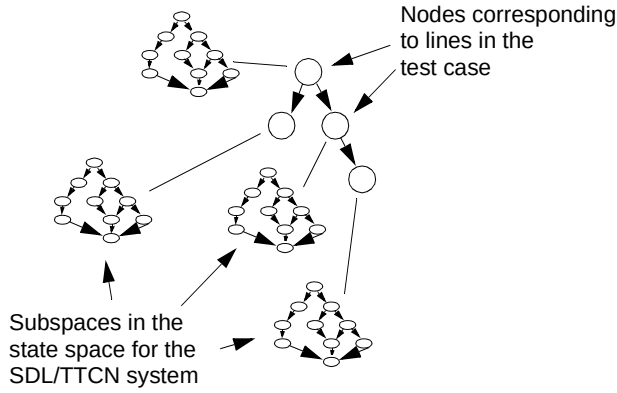

Figure 239: A structured state space

Since each line in the test case is created by a command from you, each node with its associated part of the state space can also be viewed as the state space increment that was created by a specific command.

Random Walk Exploration

The default state space exploration algorithm used by TTCN Link is the algorithm described in the previous sections. This is usually referred to as *exhaustive exploration* since it exhaustively explores the state space until all reachable states has been generated. The benefit of this algorithm is that when the exploration is finished, you can be sure that all possible combinations and alternatives are explored, that is, if TTCN Link generates two alternatives in a receive statement, the algorithm guarantees that there are no more valid alternatives. However, the drawback is that the algorithm requires all states in the state space to be kept in primary memory. For large SDL systems this may not always be possible with the computers available. The response time may also be unacceptable for interactive work with large systems.

To be able to use TTCN Link even in these cases, a second exploration algorithm is also provided. This is the *random walk* algorithm that, instead of exploring the entire state space, explores random paths in the state space using the algorithm described below. The input to the algorithm is a set of start states called StartList and a maximum depth of the exploration (MaxDepth) and the number of repetitions (Rep):

1. Select one state (in step 2–4 called the current state) from StartList.
2. Compute all possible actions that can be performed in the current state and the resulting system states that will be reached when the respective action has been performed.
3. If no actions could be performed from the current state or if the depth of the current random walk is MaxDepth, the current random walk is pruned. If the number of random walks performed so far is less than Rep, go to step 1, otherwise terminate the algorithm.
4. If actions could be performed and the depth is less than MaxDepth, select one of the generated states as a new current state and go to step 2.

The benefit with the random walk algorithm is that not more than a few system states (the current state and its successors) need to be kept in the memory at the time. The drawback is that there is no guarantee that the entire state space is explored, so, for example, even if TTCN Link generates only one receive alternative, it is possible that there are more alternatives.

To accomplish the best, both from exhaustive exploration and random walk, a two-step approach can be used when you use TTCN Link for large SDL systems:

1. Develop the test cases interactively by using the random walk algorithm with a small number of repetitions (1–3).
2. Verify that no more receive alternatives were possible by resynchronizing the test cases and using the exhaustive exploration algorithm. Or, if this is not possible due to lack of memory, use random walk with a high number of repetitions (at least 10, preferably 50–100).

This strategy gives both good performance when you interactively create the test cases and a good verification of the correctness of the test case during the automatic resynchronize. The execution time of the random walk algorithm is proportional to the number of repetitions.

You select which algorithm to use in the `.linkinit` file **(on UNIX)** or the `linkinit.com` file **(in Windows)** by using the `define-algorithm` command as described in section "Configuring the TTCN Link Executable" on page 1405.

Summary of the TTCN Link Algorithm

The algorithm used by TTCN Link to resynchronize a TTCN test case with an SDL system, is based on an incremental state space exploration of the state space of the composed system. The system consists of the SDL specification, together with the test case under construction. In the state space exploration, each command that you give will cause a new part of the state space to be explored, that is, the part that corresponds to the TTCN statement line that is inserted by the command. Two different exploration algorithms are available: exhaustive exploration and random walk. Exhaustive exploration is used for interactive development of test cases for a small SDL system and for verification of test cases for large systems. Random walk is used for interactive development of test cases for large SDL systems.

Configuring the TTCN Link Executable

This section describes the various options that can be used to configure the Link executable. You can change the options by giving the corresponding commands in a file called `.linkinit` **(on UNIX)** or `linkinit.com` **(in Windows)** in the target directory. The options that can be set are:

- Exploration Algorithm
- Random Walk Depth
- Random Walk Repetitions
- PCO Type Generation Strategy
- SDL Signal Mapping Strategy
- Stable State
- Timer Mode
- Transition
- Scheduling
- MSC Trace

These options will be described below.

It is also possible to add user-defined rules to the `.linkinit` file **(on UNIX)** or the `linkinit.com` file **(in Windows)** in order to prune the state space that is explored by Link. The user-defined rules are described in “User-Defined Rules” on page 1414.

Exploration Algorithm

What exploration algorithm is used, is defined by the command

```
define-algorithm [exhaustive|randomwalk]
```

and has the default value `exhaustive`. The differences between the different algorithms are described in section "Overview of the TTCN Link Algorithm" on page 1400.

Random Walk Depth

The maximum depth of each random walk is defined by the command

```
define-randomwalk-depth <integer>
```

and has the default value 500.

Random Walk Repetitions

The number of times a random walk is performed when a state space is explored by using this algorithm is defined by the command

```
define-randomwalk-repetitions <integer>
```

with a default value of 3.

PCO Type Generation Strategy

The PCO Type generation strategy is defined by the command

```
define-pco-type-mapping [system|channel]
```

and has default value `system`.

- If the parameter given is `system` then only one PCO type is generated for the entire system.
- If the parameter is `channel` then one PCO type is generated for each channel to/from the environment.

The choice also has an impact on the ASPs that are generated from SDL signals. Usually the name of the ASP is the same as the name of the SDL signal. However, if one PCO type is generated for each channel to/from the environment and one SDL signal can appear on more than one of these channels, then one ASP is generated for each channel it appears on. This is needed since an ASP can only be associated with one PCO type. The names of the signals are in this case defined as <signal name>_<channel name>.

SDL Signal Mapping Strategy

The SDL signals that appear on channels to/from the environment in the SDL system are either mapped to ASN.1 PDU or ASN.1 ASP definitions in the test suite. The mapping is defined by the command

```
define-signal-mapping [asp|pdu]
```

and has default value `asp`.

Stable State

The stable state option is defined by the command

```
define-stable [on|off]
```

and has the default value `on`.

It works like this:

Consider the situation when an empty test case has been resynchronized. The Link executable will now have computed the state space that can be reached without any input from or output to the tester. Usually, the state space looks something like this:

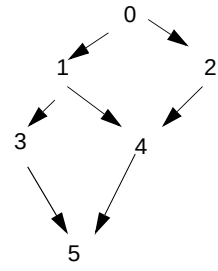

Figure 240: Original state space

where 0 is the start state, 1–4 are intermediate states and 5 is a stable state where all internal queues in the SDL system are empty and nothing more can happen without any input from the tester.

Let us now give a send command. This implies that new states are created as `send transitions` are added to the state space.

If the stable state assumption is `off` then we add one `send transition` to each state in the original state space, the new state space looks something like this:

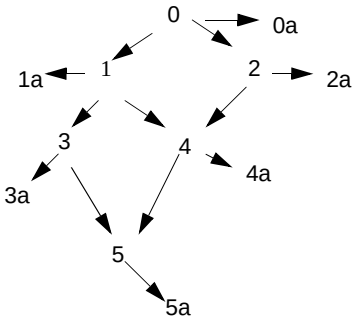

Figure 241: The new state space with stable state assumption "off"

where all states called something with 'a' are new. Now the states space that contains states that can be reached from the 'a' states without any input from or output to the tester is explored.

On the other hand, if the stable state assumption is `on` then we only add a `send transition` to the stable state, giving a new state space looking like:

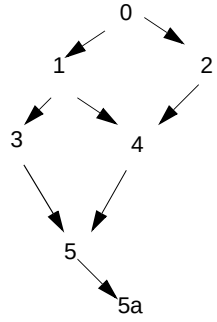

Figure 242: The new state space with stable state assumption "on"

Now, only the states that can be reached from "5a" without any input from or output to the tester are explored. This state space is of course a lot smaller that the one above.

Timer Mode

This is an option that in most cases will not have to be changed. The option defines how to interpret timeout actions compared with all other actions in the system. The option is changed by the command:

```
define-timer-mode [long|short]
```

The default is `long`.

If the timer mode is `long`, timeout actions will never occur if there is an internal event possible in the system. Essentially, the assumption is that the performance of the test system and IUT is good enough to ensure that the execution time for the actions are very small compared to the timeout times. Consider a system with the following state space when the `long` timer mode is used:

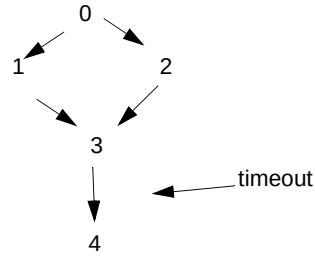

Figure 243: State space with timer mode "long"

In this system, the timeout event does not occur until no other event can happen. The transition leading to states 1–3 are all usual transitions – for example. inputs and outputs – so the timeout will only occur in state 3, where no other event is possible.

If the timer mode would have been `short`, the state space would have looked differently:

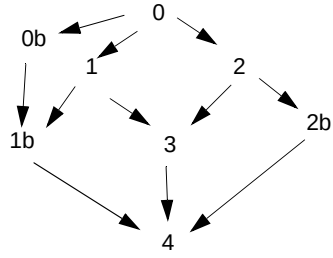

Figure 244: State space with timer mode "short"

The reason is that the timeout event now is possible in all the states 0–3.

Transition

The transition option defines what is considered to be an atomic transition in the state space and is defined by the command:

```
define-transition ['sdl'|'symbol']
```

The default value is `symbol`.

If the transition option is set to `sdl`, then SDL process graph transitions are considered atomic. This means that there will be no states in the state space where SDL processes are in the middle of a process graph transition. In all system states in the state space, the processes will always be in a process graph state.

If the transition option is set to `symbol`, the SDL process graph transitions are **not** considered to be atomic. In theory, this would imply that the processes could be interrupted anywhere during the execution of a transition. However, it turns out that for test generation purposes it is enough if the process graph transitions are divided at the points where one process communicates with another process, for example after an output or a create. A sequence of tasks or decisions is still viewed as atomic.

The consequence of this is that there will be more transitions in the state space if the transition option is `symbol` than if it is `sdl`. Consider a simple system with only one process. Let this process have a transition like:

```
state xx;
  input st1;
    output sig2;
    output sig3;
    output sig4
    nextstate  st2;
```

If the transition option is `sdl`, there will only be one transition in the state space that corresponds to the process graph transition above:

```
X : process is in state st1
|
Y : process is in state st2
```

If the transition option is `symbol`, there will be a sequence of transitions in the state space:

```
X : process is in state st1
| input st1; output sig2;
X1
| output sig2;
X2
| output sig3;
X3
| output sig4; nextstate  st2;
Y : process is in state st2
```

This will of course give a lot bigger state space.

Scheduling

The scheduling option is defined by the command

```
define-scheduling [‘first’|’all’]
```

This option controls how many processes are allowed to execute in a given system state. If the option is set to `first`, only one process (the first in the ready queue) is allowed to execute. If the option is set to `all`, all processes that can execute are allowed to do it. The default value is `all`.

Consider an SDL system with two static processes. If the scheduling option is `all`, the initial part of the state space for this system will probably look like:

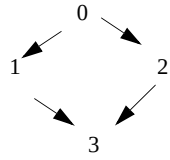

Figure 245: State space with scheduling as "all"

where

- 0 is the initial state (both processes are in the `start symbol`).
- 1 is the state where the first process has executed its start transition while the second process is still in its `start symbol`.
- 2 is the state where the second process has executed its start transition while the first process is still in its `start symbol`.
- 3 is the state where both processes have executed their start transitions.

On the other hand, if the scheduling option is `first`, it will look like:

Figure 246: State space with scheduling as "first"

where

- 0 is the initial state (both processes are in the `start symbol`).
- 1 is the state where the first process has executed its start transition while the second process is still in its `start symbol`.
- 2 is the state where both processes have executed their start transitions.

If there are lots of processes, there will be a significant difference in the size of the state space depending on how the `scheduling` option is set!

MSC Trace

The MSC trace options control what is displayed in the MSCs generated by TTCN Link. There are two different MSC trace options controlling if states and actions in the SDL system are showed as MSC condition symbols and MSC action symbols. The options are set by the following commands:

```
define-MSC-trace-actions [ 'on' | 'off' ]

define-MSC-trace-states [ 'on' | 'off' ]
```

The default value for both options is `'off'`.

An Example of a .linkinit / linkinit.com File

This following `.linkinit` file **(on UNIX)** or `linkinit.com` file **(in Windows)** will change the exploration algorithm to random walk and set the number of repetitions to 2:

```
define-algorithm random
define-random-rep 2
```

This is a useful configuration when you work interactively with TTCN Link, since the random walk algorithm is quicker and requires less memory than the exhaustive algorithm. But, since the random walk in some cases can miss some alternative receive statement, a useful strategy is the following: Use the configuration above when you work interactively with TTCN Link. However, when you have finished with a test case or a number of test cases, check that the assumptions are valid by resynchronizing with the exhaustive algorithm or a larger number of repetitions.

Note that in the commands in the `.linkinit` file **(on UNIX)** and the `linkinit.com` file **(in Windows)** can be abbreviated as long as they are unique.

User-Defined Rules

User-defined rules can be used during state space exploration to prune the search performed by the TTCN Link. Whenever a system state is found that matches the defined rule, the search is pruned at this particular state. This can be useful in order to remove specific exceptional behavior from the test cases that are designed and instead handle these in a special default test step.

Consider an SDL specification that contains a `clock` process that has a timer `intervaltimeout`. Every time the `intervaltimeout` expires, a signal `DisplayTime` is sent to the environment of the SDL system. Since this can happen at any time during the execution, there will be an alternative at all receive statements corresponding to the reception of this signal. To avoid this, it is better to add a receive statement in the default dynamic behaviour that skips this signal.

To achieve this with TTCN Link, you have to do two things:

- Define a rule that prunes the state space at appropriate places.
- Modify the default dynamic behaviour that is generated by TTCN Link.

A rule that prunes the state space whenever the `intervaltimer` expires is the following:

```
def-rule sitype(signal(clock:1))=intervaltimeout;
```

The statements that need to be added to the default behaviour are:

```
PCO?DisplayTime            DisplayTime_Match_All
          RETURN
```

These lines will cause the tester to ignore DisplayTime signals sent from the system.

A rule essentially gives the possibility to define predicates which describe properties of one particular system state. As soon as this predicate matches a system state, TTCN Link will prune the search. A rule consists of a predicate (as described below) followed by a semicolon (';'). In a rule, all identifiers and reserved words can be abbreviated as long as they are unique.

Note:

Only one rule can be used at any moment. If more than one rule is needed, reformulate the rules as one rule, by using the boolean operators described below.

Predicates

The following types of predicates exist:

- Quantifiers over process instances and signals in input ports
- Boolean operator predicates such as “and”, “not” and “or”
- Relational operator predicates such as “=” and “>”

Parenthesis are allowed to group predicates.

Quantifiers

The quantifiers listed below are used to define rule variables denoting process instances or signals. The rule variables can be used in process or signal functions described later in this section.

```
exists <RULE VARIABLE> [: <PROCESS TYPE>]
[ | <PREDICATE>]
```

This predicate is true if there exists a process instance (of the specified type) for which the specified predicate is true. Both the process type and the predicate can be excluded. If the process type is excluded, all process instances are checked. If the predicate is excluded, it is considered to be true.

```
all <RULE VARIABLE> [ : <PROCESS TYPE>]
[ | <PREDICATE>]
```

This predicate is true for all process instances (of the specified type) for which the specified predicate is true. Both the process type and the predicate can be excluded. If the process type is excluded, all process instances are checked. If the predicate is excluded, it is considered to be true.

```
siexists <RULE VARIABLE> [ : <SIGNAL TYPE>]
[ -  <PROCESS INSTANCE>] [ |  <PREDICATE>]
```

This predicate is true if a signal (of the specified type) exists in the input port of the specified process for which the specified predicate is true. If no signal type is specified, all signals are considered. If no process instance is specified, the input ports of all process instances are consid-

ered. If no predicate is specified, it is considered to be true. The specified process can be either a rule variable that has previously been defined in an `exists` or `all` predicate, or a process instance identifier (`<PROCESS TYPE>:<INSTANCE NO>`).

```
siall <RULE VARIABLE> [ :  <SIGNAL TYPE>]
[ - <PROCESS INSTANCE>] [ | <PREDICATE>]
```

This predicate is true for all signals (of the specified type) in the input port of the specified process for which the specified predicate is true. If no signal type is specified, all signals are considered. If no process is specified, the input ports of all process instances are considered. If no predicate is specified, it is considered to be true. The specified process can be either a rule variable that has previously been defined in an `exists` or `all` predicate, or a process instance identifier (`<PROCESS TYPE>:<INSTANCE NO>`).

Boolean Operator Predicates

The following boolean operators are included (with the conventional interpretation):

```
not <PREDICATE>
<PREDICATE> and <PREDICATE>
<PREDICATE> or <PREDICATE>
```

The operators are listed in priority order, but the priority can be changed by parenthesis.

Relational Operator Predicates

The following relational operator predicates exist:

```
<EXPRESSION> = <EXPRESSION>
<EXPRESSION> != <EXPRESSION>
<EXPRESSION> < <EXPRESSION>
<EXPRESSION> > <EXPRESSION>
<EXPRESSION> <= <EXPRESSION>
<EXPRESSION> >= <EXPRESSION>
```

The interpretation of these predicates is conventional. The operators are only applicable to data types for which they are defined.

Expressions

The expressions that are possible to use in relational operator predicates are of the following categories:

- Process functions: Extract values from process instances

- Signal functions: Extract values from signals
- Global functions: Examine global aspects of the system state
- SDL literals: Conventional SDL constant values

Process Functions

Most of the process functions must have a process instance as a parameter. This process instance can be either a rule variable that has previously been defined in an `exists` or `all` predicate, a process instance identifier (`<PROCESS TYPE>:<INSTANCE NO>`) or a function that returns a process instance, e.g. `sender` or `from`.

```
state( <PROCESS INSTANCE> )
```

Returns the current SDL state of the process instance.

```
type( <PROCESS INSTANCE> )
```

Returns the type of the process instance.

```
iplen( <PROCESS INSTANCE> )
```

Returns the length of the input port queue of the process instance.

```
sender( <PROCESS INSTANCE> )
```

Returns the value of the imperative operator sender (a process instance) for the process instance.

```
parent( <PROCESS INSTANCE> )
```

Returns the value of the imperative operator parent (a process instance) for the process instance.

```
offspring( <PROCESS INSTANCE> )
```

Returns the value of the imperative operator offspring (a process instance) for the process instance.

```
self( <PROCESS INSTANCE> )
```

Returns the value of the imperative operator self (a process instance) for the process instance.

```
signal( <PROCESS INSTANCE> )
```

Returns the signal that is to be consumed if the process instance is in an SDL state. Otherwise, if the process instance is in the middle of an SDL process graph transition, it returns the signal that was consumed in the last input statement.

```
<PROCESS INSTANCE> -> <VARIABLE NAME>
```

Returns the value of the specified variable. If `<PROCESS INSTANCE>` is a previously defined rule variable, the `exists` or `all` predicate that defined the rule variable must also include a process type specification.

```
<RULE VARIABLE>
```

Returns the process instance value of `<RULE VARIABLE>`, which must be a rule variable bound to a process instance in an `exists` or `all` predicate.

Signal Functions

Most of the signal functions must have a signal as a parameter. This signal can be either a rule variable that has previously been defined in an `siexists` or `siall` predicate, or a function that returns a signal, e.g. `signal`.

```
sitype( <SIGNAL> )
```

Returns the type of the signal.

```
to( <SIGNAL> )
```

Returns the process instance value of the receiver of the signal.

```
from( <SIGNAL> )
```

Gives the process instance value of the sender of the signal.

```
<RULE VARIABLE> -> <PARAMETER NUMBER>
```

Returns the value of the specified signal parameter. The `siexists` or `siall` predicate that defined the rule variable must also include a signal type specification.

```
<RULE VARIABLE>
```

Returns the signal value of `<RULE VARIABLE>`, which must be a rule variable bound to a signal in a `siexists` or `siall` predicate.

Global Functions

```
maxlen( )
```

Gives the length of the longest input port queue in the system.

```
instno( [<PROCESS TYPE>] )
```

Returns the number of instances of type `<PROCESS TYPE>`. If `<PROCESS TYPE>` is excluded the total number of process instances is returned.

```
depth( )
```

Gives the depth of the current system state in the behavior tree/state space.

SDL Literals

```
<STATE ID>
```

The name of an SDL state.

```
<PROCESS TYPE>
```

The name of a process type.

```
<PROCESS INSTANCE>
```

A process instance identifier of the format `<PROCESS TYPE>:<INSTANCE NO>`, e.g. Initiator:1.

```
<SIGNAL TYPE>
```

The name of a signal type.

```
null
```

SDL null process instance value

```
env
```

Returns the value of the process instance in the environment that is the sender of all signals sent from the environment of the SDL system.

```
<INTEGER LITERAL>
true
false
<REAL LITERAL>
<CHARACTER LITERAL>
<CHARSTRING LITERAL>
```

SDL Restrictions

The restrictions imposed on the SDL specification by TTCN Link are basically of four different kinds:

- General SDL restrictions
- State space exploration restrictions
- Data type mapping restrictions
- TTCN name restrictions

General SDL Restrictions

TTCN Link is based on the SDL to C compiler and has thus the same restrictions as the SDL Simulator and Explorer which are also based on the SDL to C compiler. The major restrictions are:

- No context parameters
- No channel substructures
- No signal refinements
- No axioms, literal mappings, inheritance or name class literals in abstract data types

For more information about the general SDL restrictions see "SDL Restrictions" on page 7 in chapter 1, *Compatibility Notes, in the Release Guide*.

State Space Exploration Restrictions

TTCN Link is based on state space exploration of the combined state space of the SDL system and the TTCN test case. Since there is only a finite amount of memory available in computers, this means that there will be restrictions on the size of the state space that can be handled. It is not possible to give a numeric value on this restriction since it depends both on the SDL system and on the computer, but TTCN Link has been successfully used on SDL systems with more than 10 processes on a SPARCstation 10 computer. Also see "Overview of the TTCN Link Algorithm" on page 1400.

Data Type Mapping Restrictions

Only the data types described in section "Generating the Declarations" on page 1390 are allowed on the channels to/from the system.

TTCN Name Restrictions

The mapping of concepts from SDL to TTCN generates a lot of names in TTCN. For example, the signals in SDL will become ASPs/PDUs in TTCN and SDL data types will become TTCN data types. The names of the generated entities are taken directly from the names on the corresponding SDL entity. This will lead to problems if, for example, the names are reserved words in TTCN. In this case, the names in the SDL system have to be changed.

TTCN Link Commands in the TTCN Suite

TTCN Link Commands in the TTCN Suite on UNIX

This section describes the extra menu choices that are available in the TTCN Suite when TTCN Link is used **on UNIX**.

Browser Commands in the *SDT Link* Menu

The following menu choices are available in the Browser *SDT Link* menu:

- *Select Link Executable*
- *Generate Declarations*

Select Link Executable

Makes a connection between a test suite and the corresponding SDL system. In the file dialog that opens, a Link executable should be selected. If the file is not a legal Link executable, the selection will fail.

When a Link executable is selected, a place holder for it is stored in the test suite. It is possible to change the Link executable if, and only if, there is no test case which uses the current SDL system (i.e. there is no synchronized test case).

It is also possible to select a Link executable by associating the SDL system with the TTCN system in the Organizer. However, a Link executable selected in the TTCN Suite will override an executable selected in the Organizer.

See also "External synonyms" on page 1391.

Generate Declarations

Generates TTCN versions of the relevant type declarations in the SDL system. The menu choice is only available if a Link executable has been selected.

The generated objects use the ASN.1 syntax. They are automatically analyzed after they have been generated. This is necessary for later operations and usage of these types. If there is no other declarations (types) in the test suite (e.g. the test suite is empty), the analysis will not fail. On the contrary if other declarations (types) already exist, the analysis

may fail due to name conflicts and incorrect references. The error messages of this analyzing will not be displayed. To check if the generated declarations are analyzed, use the Selector and the *Show Error Message* command on the incorrect tables.

At the same time that the declarations are generated, a Default table will be generated. It consists of an otherwise statement for each PCO and a timeout statement.

No timer will be generated from the SDL system. If the design of the test suite requires any timers they must be defined manually.

More details about the generated tables etc. can be found in "Generating the Declarations" on page 1390.

Table Editor Commands in the *SDT Link* Menu

To generate a test case (the behaviour description of a test case), the test case table must be in synchronized mode. In synchronized mode, the test case is synchronized (has an established connection) with the selected Link executable.

Once in synchronized mode, the test case editor will stay in this mode as long as only commands from the *SDT Link* menu are used. As soon as any field in the table (besides the comment fields) is edited, the synchronized mode will be terminated. It is however possible to analyze the test case without leaving the synchronized mode.

The following commands are available from a Table Editor for test cases or test steps. They are applied on a behaviour line (they insert a new behaviour line below/after the behaviour line with the input focus) hence it is required that the test case or the test step either is empty or has the input focus on a leaf row.

When each of these commands is performed the input focus is moved to the new generated behaviour line.

- *Send*
- *Receive*
- *Start Timer*
- *Cancel Timer*
- *Attach*
- *Resynchronize*
- *Show SDL*
- *Show MSC*

- *Show Coverage*
- *Show Options*

Send

Adds a send statement below/after the behaviour line with the input focus. The new behaviour line will have an increased indent level compared with the previous one.

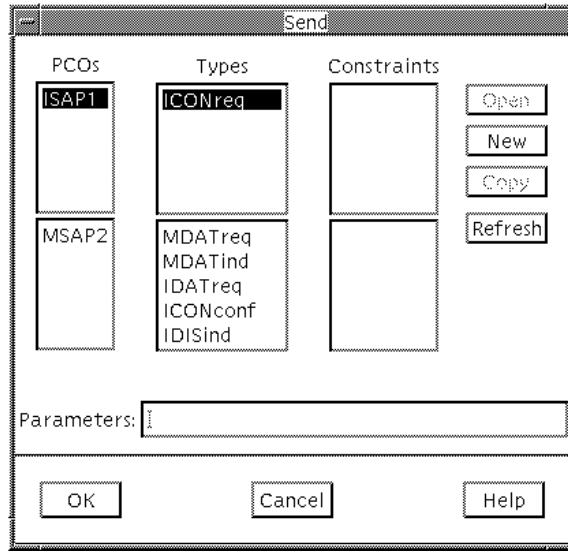

Figure 247: Send dialog

The send statement with the selected PCO, ASP/PDU and constraint will be verified by the selected SDL system. If the verification does not fail, a send statement is generated and inserted below/after the row with the input focus. For a more detailed description of this dialog, see "Add Send Statement" on page 1180 in chapter 25, *The TTCN Table Editor (on UNIX)*.

Receive

Adds appropriated receive and/or timeout statement(s) below/after the behaviour line with the input focus. The new row(s) will have the same

indent level. This indent level will be increased compared with the previous one.

For each retrieved receive statement from the SDL system, a new Constraint is generated if there is no appropriate Constraint (a Constraint with a similar value). The new Constraint will be named with a unique name and will be analyzed. This new name is used in the *Constraints Ref* column.

Start Timer

Adds a start timer statement below/after the behaviour line with the input focus. The new behaviour line will have an increased indent level compared to the previous one.

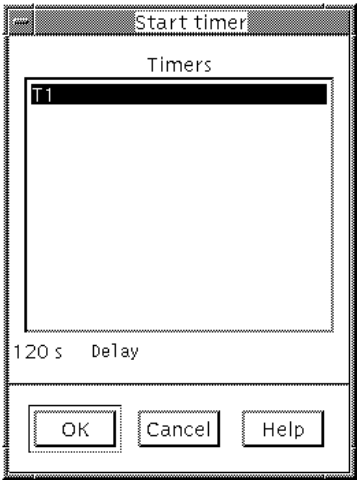

Figure 248: Start Timer dialog

The start timer statement with the selected timer will be verified with the selected SDL system. If the verification does not fail, a start timer statement is generated and inserted below/after the behaviour line with the input focus. For a more detailed description of this dialog see "Add Send Statement" on page 1180 in chapter 25, *The TTCN Table Editor (on UNIX)*.

Cancel Timer

Analogous to *Start Timer*.

Attach

Adds an attachment statement below/after the row with the input focus. The new behaviour line will have an increased indent level compared to the previous one.

The test step dialog used by this command is similar to the dialog in the Table Editor. The selected test step (the behaviour lines in the behaviour description) will be verified with the SDL system. The test step must have passed analysis before this operation.

Resynchronize

Verifies the test case in a Table Editor using the previously chosen Link executable. The table will change mode to the synchronized mode. This command is available from Table Editors for test cases and only if an SDL system is selected.

If the test case does not have any default reference and there is more than one default in the test suite, a selection dialog pops up and a default must be selected. If the test suite contains only one default, it will be selected automatically. If the test case already has a default, no change will be made.

If the test case (or the test step) contains behaviour lines, they will be verified with the current SDL system. If the verification of any line fails, the table will keep the normal mode.

Show SDL

Opens the SDL Editor with the symbols selected which were executed in the SDL system and are associated with the behaviour line which has the input focus. More precisely, the SDL symbols which were executed after the current test case line but before the next test case line, are selected exactly.

Show MSC

Opens the MSC Editor with a process level MSC that illustrates the execution path from the start of the SDL system to the state corresponding to the behaviour line with input focus.

Show Coverage

Opens the Coverage Viewer that displays test coverage information for the current test case. The test coverage displays how many times each symbol in the SDL system has been executed during the generation of the test case. Note that the important information is not the exact number of times a particular symbol has been executed (since this is dependent upon the particular algorithm used by the Link executable). The important information is whether a symbol has been executed or not. If a symbol in the SDL system has not been executed when generating the test case, the requirement defined by this symbol is not tested by the test case.

Show Options

Shows the current settings of the configuration parameters that control the way the Link executable explores the state space of the combined SDL/TTCN system.

TTCN Link Commands in the TTCN Suite in Windows

In Windows, different TTCN Link commands are included in the *SDT Link* menu and the *Link* dialog. The menu choices in the *SDT Link* menu are used for selecting the Link executable, generating declarations and for showing execution information. By using the *Link* dialog, you can generate various statements.

The *SDT Link* menu and the *Link* dialog will be explained below.

The *SDT Link* Menu

The following menu choices are included in the *SDT Link* menu:

- *Select Link Executable*
- *Generate Declarations*
- *Show SDL*
- *Show MSC*
- *Show Coverage*
- *Show Options*

Select Link Executable

Makes a connection between a test suite and the corresponding SDL system. Opens a dialog in which you may select the Link executable.

It is also possible to specify the Link executable in the Organizer by associating the SDL system with the TTCN system. However, a Link executable selected in the TTCN Suite will override an executable selected in the Organizer.

See also "External synonyms" on page 1391.

Generate Declarations

Generates TTCN versions of the relevant type declarations in the SDL system. The menu choice is only available if a Link executable has been selected.

The generated objects use the ASN.1 syntax. They are automatically analyzed after they have been generated. This is necessary for later operations and usage of these types.

At the same time as the declarations are generated, a Default table will be generated. It consists of an otherwise statement for each PCO and a timeout statement.

Timers will not be generated from the SDL system. If the design of the test suite requires any timers, they must be defined manually.

Show SDL

Opens an SDL Editor with the symbols selected which were executed in the SDL system and are associated with the selected behaviour line. More precisely, the SDL symbols which were executed after the current test case line but before the next test case line, are selected exactly.

Show MSC

Opens an MSC Editor with a process level MSC that illustrates the execution path from the start of the SDL system to the state corresponding to selected the behaviour line.

Show Coverage

Opens an SDL Coverage Viewer that displays test coverage information for the current test case. The test coverage displays how many times each symbol in the SDL system has been executed during the generation of the test case. Note that the important information is not the exact number of times a particular symbol has been executed (since this is dependent upon the particular algorithm used by the Link executable). The important information is whether a symbol has been executed or not. If a symbol in the SDL system has not been executed when the test case was generated, the requirement defined by this symbol is not tested by the test case.

Show Options

Shows the current settings of the configuration parameters that control the way the Link executable explores the state space of the combined SDL/TTCN system.

The *Link* Dialog

The *Link* dialog can be opened from the *SDT Link* menu. The *Link* dialog can only be used when a behaviour line is selected in the table or if the table does not yet contain a behaviour line. When the *Link* dialog is opened, the current table automatically becomes synchronized with the Link executable, that is, the table is read-only. The only time synchronization is lost for the current table, is when TTCN Link is activated in another table or when you insert a behaviour line from the *Data Dictionary* dialog in the current table.

The *Link* dialog has almost the same appearance as the *Data Dictionary* dialog. A list in the lower left corner of the dialog makes it possible to switch between the *Link* and *Data Dictionary* dialog. For more information about the Data Dictionary, see "Creating Behaviour Lines" on page 1269 in chapter 30, *Editing TTCN Documents (in Windows)*.

The operations available in the *Link* dialog will be described below. The operations are applied on a selected behaviour line and the result is that a new behaviour line is inserted below/after. The test case or the test step must be empty or a leaf row must be selected.

The *Send/Receive* Tab

Generate a send statement by selecting a PCO, ASP/PDU, constraint, etc. When you press the *Apply* button, the statement will be verified by the selected SDL system. If the verification succeeds, a new send statement will be inserted below the selected behaviour line.

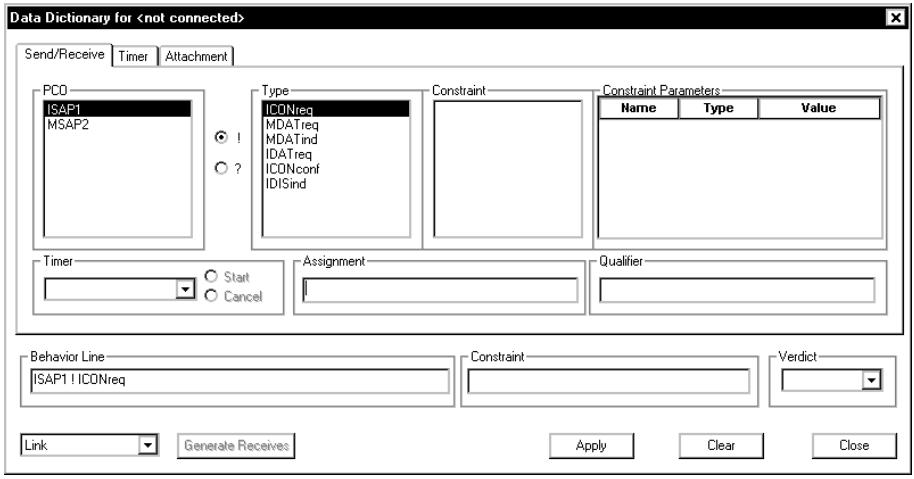

Figure 249: Generating send statements

Generate receives and/or timeout statement(s) below the selected behaviour line by clicking the *Generate Receives* button. The new row(s) will all have the same indent level. This indent level will be increased compared with the previous one.

This operation is only valid when the current selected behaviour line is a leaf row.

For each retrieved receive statement from the SDL system, a new Constraint is generated if there is no appropriate constraint (a constraint with a similar value). The new constraint will be named with a unique name and will be analyzed. This new name is used in the *Constraints Ref* column.

The *Timer* Tab

Generate a timer statement by selecting *Start* or *Cancel* and a timer from the listbox (optional for *Cancel*). When you click the *Apply* button, the timer statement will be verified against the SDL system. If the verification succeeds, a timer statement will be generated and inserted below the selected behaviour line. The new behaviour line will have an increased indent level compared to the previous one.

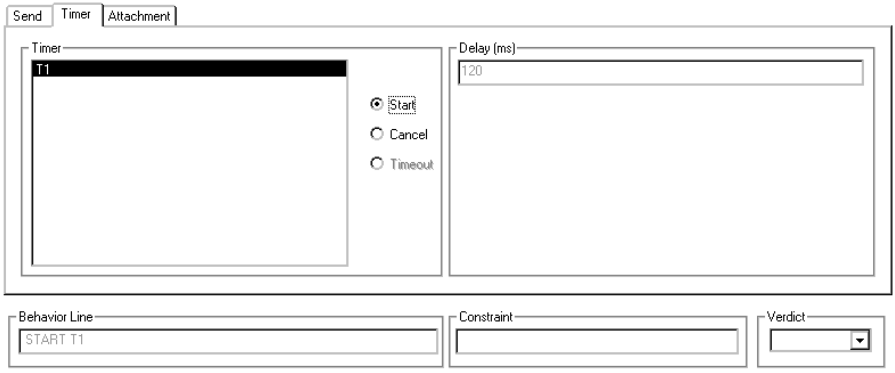

Figure 250: Generating timer statements

The *Attachment* Tab

When you select an attachment and click *Apply*, an attachment statement will be generated below the selected behaviour line. The new line will have an increased indent level compared to the previous one.

The selected test step (the behaviour lines in the behaviour description) will be verified with the SDL system. The test step must have passed analysis before this operation.

Note:

TTCN Link does not support attachment parameters.

Using Autolink

The generation of a TTCN test suite with Autolink proceeds in several steps.

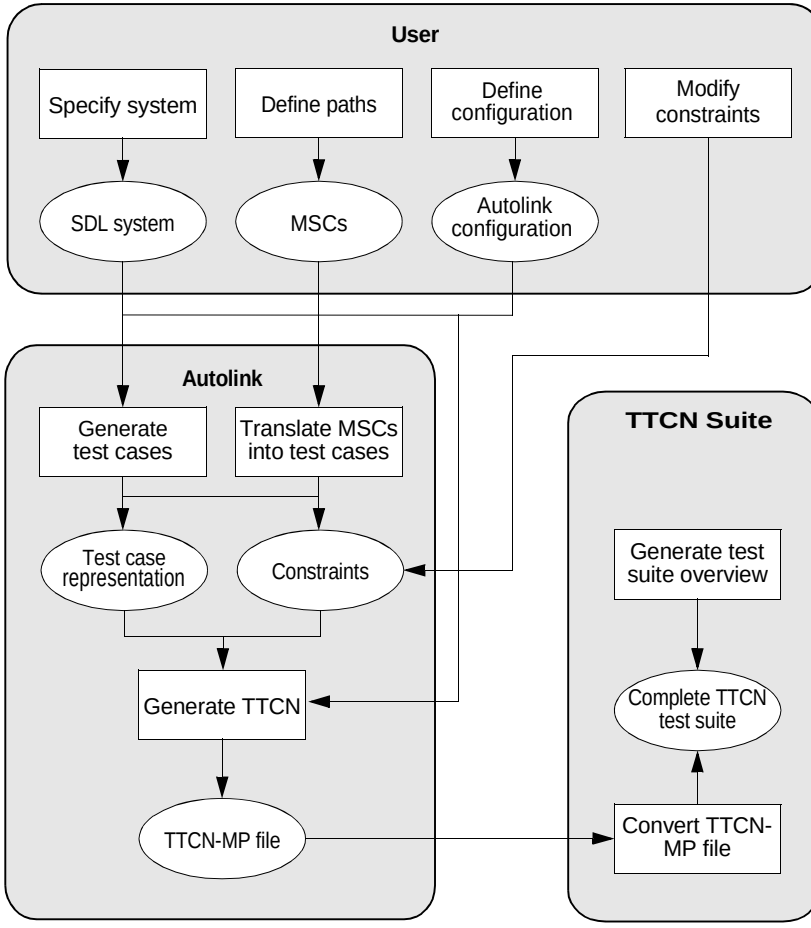

Figure 251: Test suite generation with Autolink

You start by specifying an SDL system, see "Specifying the SDL System and Performing Other Preparations" on page 1432. Based on this SDL specification, you generate an SDL Explorer application which includes Autolink.

Next, you define MSC test cases, see "Defining MSC Test Cases" on page 1434, which describe the purpose of the test cases of your test suite. They are stored on disk as *system level MSCs*, that is, MSCs with only one instance axis for the SDL system and one or more instance axis for the environment. Test cases may contain *test steps* which are stored as separate system level MSCs on disk.

You may also want to define an Autolink configuration, see "Defining an Autolink Configuration" on page 1449, in order to guide the naming and parameterization of constraints. Autolink can also be configured to store test cases into a hierarchy of test groups.

The next step is to generate test cases, see "Translating MSCs into Test Cases" on page 1454. This can be done either by a state space exploration of the SDL system or by directly translating system level MSCs into test cases. In any case, the result is an internal representation for each test case. At the same time, a list of constraints is generated. These constraints can be renamed and merged, see "Modifying Constraints" on page 1455. You can also add new constraints manually.

Finally, you generate a TTCN test suite, see "Generating a TTCN Test Suite" on page 1457, based on the test case representations and the list of constraints. The test suite is stored on disk in TTCN-MP format. **On UNIX**, you can import this file in the TTCN Suite; **in Windows**, you can simply open it in the TTCN Suite. On both platforms, you can convert the TTCN-MP file to the graphical TTCN format in the Organizer.

On the following pages, the steps will be described in more detail.

Specifying the SDL System and Performing Other Preparations

Before you start the SDL Explorer, directories must be created where you will store test case and test step representations. If there are no appropriate directories:

- Create one directory for test cases and one directory for test steps in your working directory.

Specifying the SDL System

You have to specify an SDL system in order to create an SDL Explorer. At minimum, you must specify all channels to the environment of your system and all signals sent via these channels. With such a minimal specification, you can use Autolink to translate MSCs directly into TTCN by using the Translate-MSC-Into-Test-Case command. The advantages and disadvantages of using this command are described in "Translating MSCs into Test Cases" on page 1454.

Generating and Starting an SDL Explorer

When you have specified the SDL system, you can generate and start the Explorer. How to do this is described in "Generating and Starting an SDL Explorer" on page 2393 in chapter 53, *Validating a System*.

Specifying Directories

Before you start defining test cases and test steps, you have to specify where they are to be saved:

1. In the *Explorer*, select *Autolink: Test Cases Directory* from the *Options2* menu.
   - This corresponds to the command Define-MSC-Test-Cases-Directory.
2. In the dialog that will be displayed, select the test case directory that you previously created and click *OK*.
3. Select *Autolink: Test Steps Directory* from the *Options2* menu.
   - This corresponds to the command Define-MSC-Test-Steps-Directory.
4. In the dialog that will be displayed, select the test step directory that you previously created and click *OK*.

When you later leave the Explorer, you can save these values.

Defining MSC Test Cases

In Autolink, an MSC test case is derived from a *path*. A path is a sequence of events that have to be performed in order to go from a start state to an end state. There are two ways to define MSC test cases:

1. Interactive simulation and manual specification
2. Automatic computation by Autolink (see "Defining MSC Test Cases Automatically - Coverage Based Test Generation" on page 1448)

Defining MSC Test Cases Interactively

The creation of MSC test cases by interactive simulation proceeds in several steps:

1. Specify the start state of the test case.

   If this state is identical to the root of the behavior tree, nothing has to be done. Otherwise, you must navigate to the desired state, for example by using the Navigator, selecting a previously defined report or verifying an MSC. Then you set the root to the current state with the `Define-Root Current` command.

> **Note:**
>
> Autolink always considers the current root of the behavior tree to be the start state of a path.
>
> Also note that when a test case is generated, the root has to be the same as it was at the moment of the test case definition. You have to keep track of the start state with Print-Path and Goto-Path, for example if you want to leave the Explorer temporarily.

2. Navigate through the system to the desired end state.
3. Select *MSC: Save Test Case* from the *Autolink1* menu.
   – This corresponds to the Save-MSC-Test-Case command.

An MSC test case consists of one instance axis for the SDL system and a separate instance axis for each channel to/from the environment. In TTCN terms, the single SDL system instance represents the *System Under Test (SUT)*. The environment instances represent the *Points of Control and Observation (PCO)*; PCOs are the interface between the *test system* and the SUT.

The system level MSC that will be saved contains the *observable events* of the path between the start and the end state. Observable events represent the external interaction that takes place between the SDL system and its environment. (During conformance testing, external interaction takes place between the implementation and the test system.)

Figure 252 shows an MSC test case.

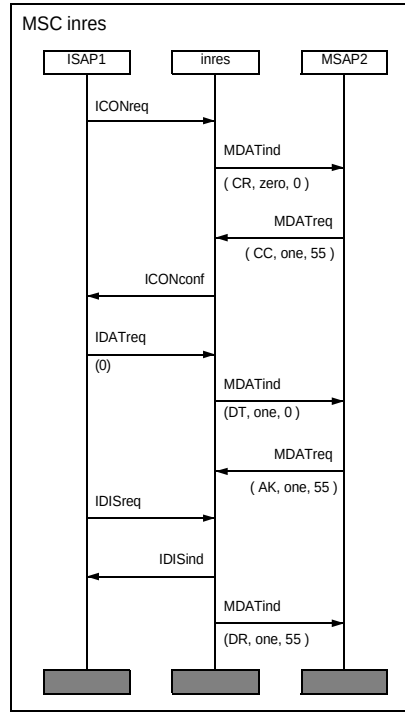

Figure 252: An MSC test case

Incorporating Test Steps in Test Cases

Typically, test cases are structured logically into several parts, for example a preamble, a test body and a postamble. These parts are called test steps. You may incorporate test steps in a test case by using MSC references.

Figure 253 shows an MSC with two MSC references. Each of the referenced MSCs represents a separate test step; they are called *Preamble* and *Postamble*.

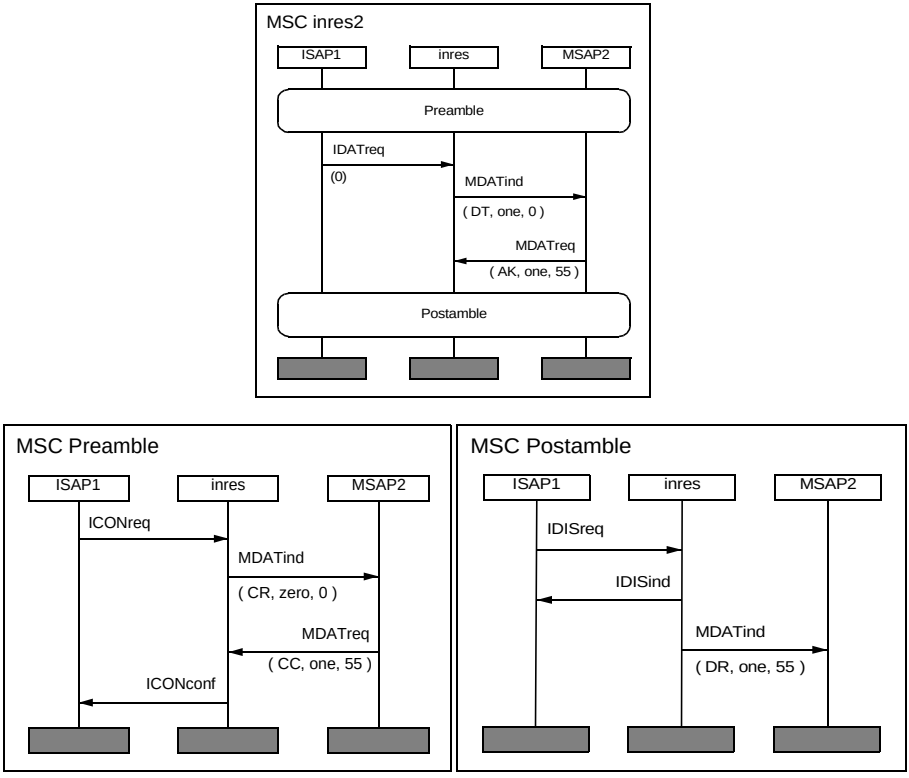

Figure 253: An MSC with a preamble and a postamble

Test steps are stored with the same file extension as test cases (`.mpr`). They are created in analogy to test cases with Save-MSC-Test-Step.

If you want to create a test case with a preamble and a postamble, several steps are necessary:

1. Make sure that you have specified the directories for test cases and test steps as described in "Specifying Directories" on page 1433.

2. Set the root of the state space to the start state of the test case by using the command Define-Root Current.
3. Navigate to the end of the path of the preamble.
4. Use Save-MSC-Test-Step to save the preamble.
5. Set the root of the state space to the current state by using the command Define-Root Current.
6. Navigate to the end of the path of the test body.
7. Use Save-MSC-Test-Case to save the test case/test body.
8. Set the root of the space to the current state.
9. Navigate to the end state of the test case.
10. Use Save-MSC-Test-Step to save the postamble.
11. Add two MSC references manually to the MSC test case with the MSC Editor.

Alternatively, you may create a single MSC test case and split the file into preamble, test body and postamble afterwards.

Test steps may refer to other test steps, but not to test cases. During test case generation, Autolink keeps track of the nested structure of test cases and test steps.

Note:

When Autolink generates test cases (see Generate-Test-Case and Translate-MSC-Into-Test-Case), the semantics of MSC references and MSC reference expressions are different from the semantics given in the ITU-T Recommendation Z.120!

Autolink requires that a test step is completely evaluated before the next test step starts, i.e. it synchronizes among references, whereas Z.120 considers MSC references as macros which do not have to be evaluated as a unit.

With regard to Figure 253, this means that all signals of the test body in `mi_inres2` have to be evaluated before the postamble starts.

Using Timers

Autolink supports test suite timers. There are three types of timers which are commonly needed in test sequences:

1. A global timer is specified to guarantee that test cases end even if they are blocked during execution due to an error. By default, Autolink generates a global timer *T_Global* automatically and starts it at the beginning of each test case. At the end of each test sequence, *T_Global* is cancelled. The automatic generation of timers can be enabled and disabled with the Define-Global-Timer command.

2. A delaying timer is used to delay the sending of a signal from the tester to the SUT. This may be done for several reasons; for example, the sending is delayed on purpose to specify an invalid behavior of the environment.

3. A guarding timer is used to check that the SUT sends a signal within a predefined amount of time.

Delaying and guarding timers have to be specified manually on the environment instances in test case MSCs. As an example, the MSC in Figure 254 contains a guarding timer *T_Guard* on instance *ISAP1* and a delaying timer *T_Wait* on instance *MSAP2*.

T_Guard is set prior to sending a signal to the SUT and reset after the corresponding response from the SUT. If message *ICONconf* is received in time, test execution proceeds normally. Otherwise, a timeout of *T_Guard* will be caught in the Default Dynamic Behavior description and lead to a *fail* verdict.

The setting of timer *T_Wait* is followed immediately by a timeout event, causing the tester to delay the sending of message *MDATreq*.

> **Note:**
>
> Test suite timers are part of the environment of the SUT. Correspondingly, there is no explicit relation between these timers and any timers which might be used within the system. Autolink simply translates timer set events on environment instances into TTCN `START` operations, timer reset events into TTCN `CANCEL` operations and timeout events into TTCN `TIMEOUT` events. However, timer events on any MSC instance belonging to the SUT are not translated into TTCN statements.

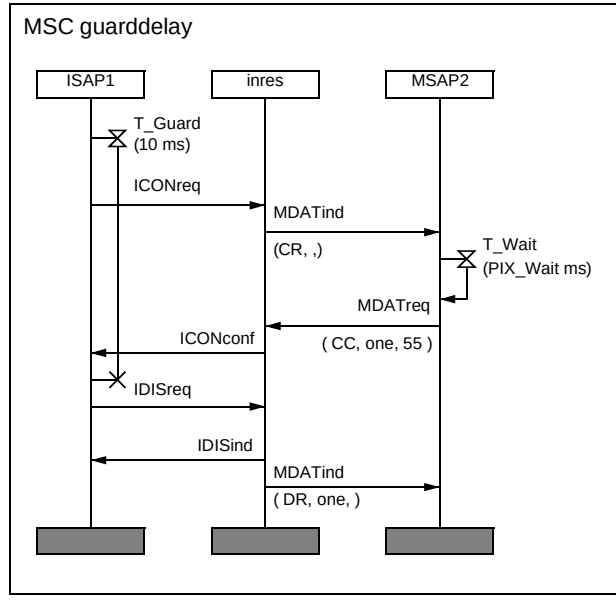

Figure 254: Test case MSC with guarding and delaying timer

Autolink creates timer declarations automatically from the information which it finds in the test case MSCs. From the MSC in Figure 254, Autolink generates a declaration for timer *T_Guard* with the default duration set to *10* and *ms* as unit. Correspondingly, the default duration for *T_Wait* is set to the test suite parameter *PIX_Wait* and its unit is set to *ms* as well. Autolink also generates a declaration for *PIX_Wait*.

This implicit declaration mechanism is convenient if the test suite consists of only one test case. If there are more test cases using timers, declaration conflicts may arise since timers are declared globally for the test suite. In order to solve this problem, Autolink provides the Define-Timer-Declaration command to explicitly declare test suite timers. Explicit timer declarations can not be modified by implicit declarations. It is therefore recommended to define all timer declarations explicate before test case computation starts. In that case, only the timer name must be provided for timer set events in the test case MSCs. The duration is optional (Autolink uses the duration value if it is not empty and different from the default duration specified in the declaration). Finally, the unit can be omitted from the test case MSCs if an explicit declaration exists.

The use of test suite timers and their declaration is explained in more detail in "Test Suite Timers" on page 1483. With respect to timers, the TTCN output generated by Autolink depends on the test architecture. This is also discussed in "Test Suite Timers" on page 1483.

Defining Multiple Test Cases by HMSC Diagrams

HMSC diagrams can be used to illustrate the relationship between various test cases. For example, even though test cases normally have different test purposes, they might share the same preamble and postamble. This commonness can be graphically expressed by the use of an HMSC diagram such as the one in Figure 255.

Note:

HMSCs are not supported by Generate-Test-Case but only by Translate-MSC-Into-Test-Case.

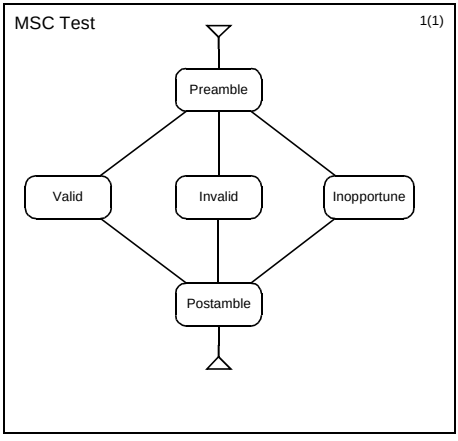

Figure 255: Three test cases described by one HMSC diagram

When the HMSC *Test* is taken as input, Autolink will create three test cases which consist of the test steps *Preamble/Valid/Postamble*, *Preamble/Invalid/Postamble* and *Preamble/Inopportune/Postamble*.

The general interpretation of HMSCs can be described by a simple rule: Autolink generates a separate test case for each possible path through an HMSC. Of course, HMSCs may have more than one node with several outgoing edges, resulting in a potentially large number of test cases.

Note:

Autolink does not translate loops directly into equivalent constructs in TTCN. Instead it handles loops by unrolling. Therefore, you should not introduce loops in HMSC diagrams.

All test cases need to have unique names. With regard to the HMSC *Test* in Figure 255, the resulting test cases will be named *Test_Valid*, *Test_Invalid* and *Test_Inopportune*. Whenever there is a branch in the HMSC, the name of the succeeding MSC reference is postfixed to the name of the top-level MSC (separated by '_').

Describing Indeterministic Behaviour by Inline and Reference Expressions

Sometimes, a system under test may not behave deterministically. For example, there may be unpredictable failures. A tester should be able to handle such situations. By the use of inline expressions and MSC reference expressions, it is possible to describe test cases where the tester reacts flexibly depending on the system behaviour.

If some of your test cases only differ slightly at some point in the test case, you may also use inline and reference expressions to describe different behaviour of the tester. In that case, Autolink generates separate test cases.

Autolink supports the following operators in MSC expressions:

- The *alternative* operator (`alt`) is suitable for the description of situations where the continuation of a test case depends on the former output of the system. If both alternatives start with a signal sent from the system to the tester (i.e. the environment), Autolink will generate two branches within a single test case.

  On the other hand, the operator may also be used to specify two alternative test sequences. If both alternatives start with a signal sent from the tester (environment) to the system, Autolink will generate two distinct test cases.

- The *optional* operator (`opt`) can be used, e.g., to accept signals which may or may not be sent by the system or to react to unexpected signals in a way that the test case can be continued normally afterwards.

- The *exception* operator (`exc`) is intended to be used for error handling. An exception expression may contain signals which prevent the test system from continuing the regular test execution. In MSC *ConnectionRequest* (Figure 256 on page 1442), the reception of signal *IDISind* immediately stops the test case. Optionally, an exception includes a sequence of signals which bring the system under test back into a stable testing state. An exception always results in an “INCONC” verdict.
- The *loop* operator (`loop`) can be used to describe the iterative execution of a (portion of a) test case. As in HMSCs, Autolink does not translate loop expressions directly into equivalent constructs in TTCN. Instead, it handles loops by unrolling. If no upper loop boundary is given, the loop is evaluated up to three times.
- Finally, the *sequence operator* (`seq`) can be used within reference expressions in order to state that one test step follows another.

Note:

Autolink does not support the *parallel* (`par`) and *substitution* (`subst`) operator within inline and reference expressions.

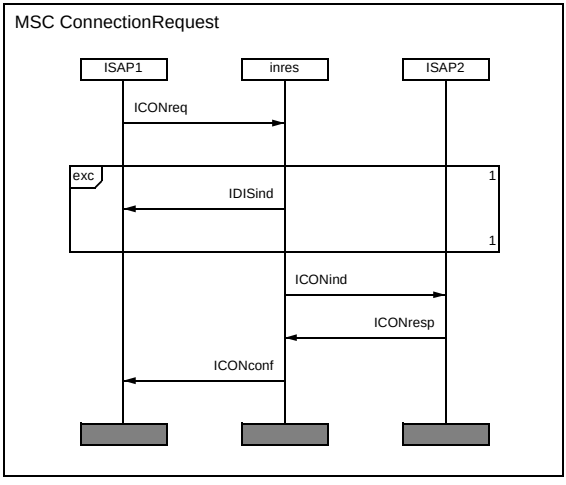

Figure 256: Test case with exception handling

Of course, the usage of the different operators is not restricted to the applications described above. On the other hand, not all MSCs containing inline or reference expressions may describe sensible test cases.

Synchronization among MSC expressions

As mentioned before, Autolink synchronizes at the beginning and the end of MSC references. This modification of the semantics given in the MSC standard is motivated by the ability to consider separate MSCs as different test steps. If we cannot guarantee that all events in one MSC are evaluated before the next MSC is entered, we cannot draw a line between two subsequent test steps.

MSC reference expressions are a generalization of plain MSC references. Autolink generates distinct TTCN test steps for each of the MSCs involved in the expression. For that reason, it makes sense to synchronize at MSC references, too.

When it comes to inline expressions it is not really necessary to synchronize at their beginning and their end. However, for consistency Autolink synchronize at inline expressions, as well.

There are situations where synchronization among inline expressions is preferable, whereas in other cases the TTCN output and Autolink's error messages may be confusing.

In Figure 257, two examples are given. For MSC *Sync1*, Autolink will generate a test case where either *ReceiveB* or *ReceiveC* is anticipated before the test execution proceeds with *SendD*. If Autolink did not synchronize at the end of the alternative expression, *SendD* would be sent before *ReceiveB* (please note that Autolink prioritizes send events). Moreover, since both alternatives are combined in a single behaviour tree, *SendD* would erroneously become an alternative to *ReceiveC*!

Unfortunately, there are also cases where synchronization results in unexpected TTCN test cases. For the second MSC in Figure 257, Autolink will try to generate the following event tree:

```
Env1 ! SendA
  Env2 ? OptReceiveB
    Env1 ! SendC
      Env2 ? ReceiveD
  Env1 ! SendC
    Env2 ? ReceiveD
```

Of course, Autolink detects that there is a conflict among the two alternatives *OptReceiveB* and *SendC* and will print a warning.

Whenever Autolink issues a warning, you should carefully inspect your MSC test case definition. For example, when MSC *Sync2* is interpreted as a test case, it is unclear how long a tester shall wait until it outputs *SendC*. On the other hand, if *OptReceiveB* is not logically caused by *SendA* or may received at any time, a possible solution would be to move *SendC* above the optional expression. In this case, no conflict arises.

Synchronizing Test Events with Conditions

The messages in MSCs are only partially ordered. If a test generation tool would generate all possible test sequences, then send events could appear as alternatives to receive events in TTCN test cases, making them indeterministic. To solve this problem, three solutions are possible:

1. Events received by the tester are prioritized over events sent to the SUT.
2. Events sent to the SUT are prioritized over events received by the tester.
3. All messages in the MSC are evaluated from top to bottom. In that case, only one sequence of test events is generated.

The first alternative may lead to deadlocks and therefore it is not supported by Autolink. Alternative three may be selected with the Define-Autolink-Generation-Mode command.

By default, Autolink uses the second alternative and prioritizes events which are sent from the test system to the SUT over events which are received by the tester from the SUT.

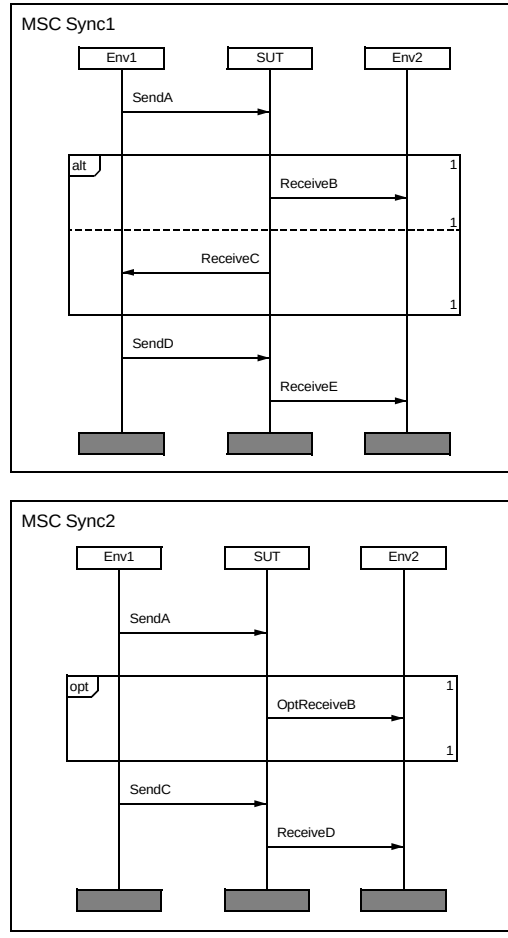

Figure 257: Synchronization among inline expression

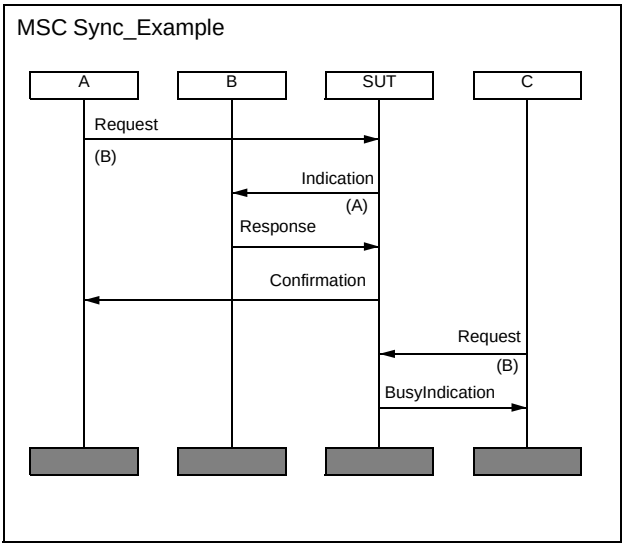

Figure 258: Synchronization example 1

However, there are situations where this “send immediately” strategy leads to incorrect test cases. Consider the following small example: A calls B, B accepts the call, then C tries to call B and gets a busy signal. A corresponding MSC test purpose description would look similar to the one in Figure 258. What test sequence will Autolink generate? First, the tester will send `Request(B)` to the SUT through PCO A. Next, `Request(B)` will be sent to the SUT through PCO C, since this is the next send event on any of the tester instances.

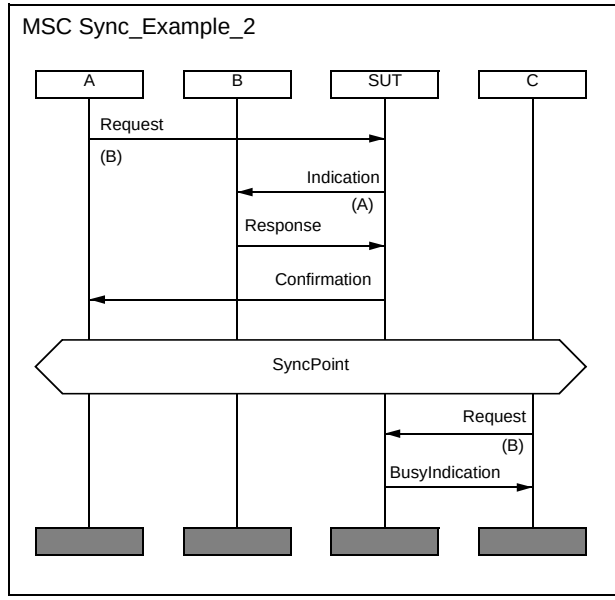

Figure 259: Synchronization example 2

Most likely, this is not what you have anticipated intuitively; the tester should send the second `Request(B)` only after it has received `Confirmation` through PCO A. This is where explicit synchronization with conditions comes in. Figure 259 contains the same MSC as Figure 258, with a global condition added between the reception of `Confirmation` at PCO A and the sending of `Request(B)` through PCO C. If the Autolink synchronization option is turned on (with Define-Condition-Check), then events below the condition can only be executed if all events above the condition have been executed as well. The condition effectively becomes a synchronization point. In the example, the sending of `Request(B)` through C will be delayed until `Confirmation` has been received at PCO A. The name in the condition is required by the ITU Recommendation Z.120, however it is only considered as a comment and does not have any semantics.

Note:

The condition check option also applies to the MSC verification function of the Explorer.

Listing and Clearing Test Cases and Test Steps

- Use List-MSC-Test-Cases-And-Test-Steps for listing all MSC test cases and test steps that are defined in the current test cases and test steps directories.
- Use Clear-MSC-Test-Case to delete an MSC test case.
- Use Clear-MSC-Test-Step to delete an MSC test step.

Note:

Autolink distinguishes between the MSC test case name (which is the name of the system level MSC) and the name of the file on disk that contains the MSC test case. Usually, these names are identical except for the file extension.

When accessing the test cases and the test steps directory, Autolink always refers to the file names, meaning that you also have to specify the file extension (either `.mpr` or `.msc`)

Defining MSC Test Cases Automatically - Coverage Based Test Generation

One common method to generate a test suite is to select a number of test cases which, taken together, obtain a high coverage of the SDL specification. Ideally, this coverage should be 100%. In that case, every SDL symbol in the specification is executed at least once during test generation.

Autolink provides a special state space exploration technique, called *Tree Walk*, which is optimized for finding paths through the state space of the SDL specification that result in a high SDL symbol coverage. Tree Walk combines the advantages of both the depth-first and breadth-first search strategy - it is able to visit states located deep in the reachability graph and to find a short path to a particular state at the same time.

- To use Tree Walk, apply the Tree-Walk command.

The execution of Tree Walk is controlled by two options:

1. The maximum computation time (specified in minutes)
2. The targeted coverage (specified in percent)

When Tree Walk is used, it generates a report for each sequence of transitions in the state space that increases the number of visited SDL symbols. These reports can be converted into system level MSCs with the command Save-Reports-as-MSC-Test-Cases.

Defining an Autolink Configuration

Autolink offers a special language for defining rules for the naming and parameterization of constraints, the introduction of test suite parameters and constants, and the distribution of test cases and test steps into test groups.

- To specify Autolink configuration rules, use the command Define-Autolink-Configuration.

While it is possible to define an Autolink configuration on the fly at the Explorer command prompt, it is better to write a command file which includes the configuration.

- To load this file, use the Include-File command.

  The command corresponds to the menu choice *Configuration: Load* in the *Autolink2* menu.

- To remove a loaded configuration, use the Clear-Autolink-Configuration command.
- To display the current configuration, use the Print-Autolink-Configuration command.
- To save a configuration, use the Save-Autolink-Configuration command.

See also:

- “Translation Rules” on page 1459 for an introduction to translation rules.
- “Test Suite Structure Rules” on page 1465 for the methodology for test suite structure rules.

- "Syntax and Semantics of the Autolink Configuration" on page 1471 for a detailed description of the configuration language.

Computing Test Cases

Once you have defined a set of MSC test cases, you can compute internal test case representations for each MSC test case.

- To compute MSC test cases, use the Generate-Test-Case command.

  A *bit-state exploration* will be started which aims at finding all possible sequences of observable events that conform to the MSC. In addition, Autolink searches for *inconclusive events*. These are events that represent deviations from the behavior specified in the MSC test case, but which are valid alternatives according to the SDL specification.

Either a single test case or a set of test cases in the current test cases directory may be generated at the same time, depending on the parameter of Generate-Test-Case. If an already generated test case is regenerated, its former internal representation and its corresponding constraint definitions are replaced.

> **Note:**
>
> If the SDL specification is not detailed enough in the sense that it does not model the signal flow in a given MSC, the generation of the test case fails. MSCs which cannot be verified can still be converted into test cases with the Translate-MSC-Into-Test-Case command, which is described in "Translating MSCs into Test Cases" on page 1454.
>
> Inline expressions, MSC reference expressions and HMSC diagrams are not supported by Generate-Test-Case. (However, you can use these structural concepts for Translate-MSC-Into-Test-Case.) If you want to generate test cases based on HMSCs, you have to transform your HMSC diagrams into basic MSCs first. You can do this by verifying the HMSCs and saving all *MSC Verification* reports as MSC test cases (command Save-Reports-as-MSC-Test-Cases).

With complex systems, test generation may take a while. To avoid time-consuming test generation failures, you should verify all MSCs first.

- To verify all MSC, use the Verify-MSC command.

In most cases, MSC verification takes only a fraction of the time needed for test generation.

Listing and Clearing Generated Test Cases

- You can list all generated test cases with the List-Generated-Test-Cases command.
- You can clear all generated test cases with the Clear-Generated-Test-Case command.

Displaying and Saving the Internal Representation

- You can display the internal representation of a generated test case – without having to save the test suite and start the TTCN Suite – with the Print-Generated-Test-Case command.
- You can save an internal test case representation with the Save-Generated-Test-Case command.
- You can load an internal test case representation back into memory with the Load-Generated-Test-Cases command.

This makes it possible to distribute the generation of a set of test cases to several computers. When all test cases have been generated and saved in individual files, they can be reloaded on a single machine and saved as a complete test suite.

State Space Exploration Parameters

There are several parameters which influence the state space exploration:

- You can set the maximum search depth with the Define-Autolink-Depth command (default value is 1000).

  If the search depth is set too low, this may result in incomplete pass paths. Since the maximum search depth normally has no impact on the performance of the state space search, it is recommended that you always use a large value (> 1000).

- You can resize the hash table with the Define-Autolink-Hash-Table-Size command (default size is 1,000,000 bytes).

  Increasing the hash table size may be necessary if the SDL system is rather complex.

- Normally, Autolink changes the regular Explorer state space options, because the default values of the Explorer are not sufficient for generating correct test cases.

  For example, for the Inres protocol specification, the following commands are issued:

  ```
  Define-Scheduling All
  Define-Transition Symbol-Sequence
  Define-Symbol-Time Zero
  Define-Priorities 2 1 3 2 2
  Define-Channel-Queue ISAP1 On
  Define-Channel-Queue MSAP2 On
  Define-Max-Input-Port-Length 10
  ```

  Other SDL systems require different Define-Channel-Queue commands.

  Autolink automatically resets the original options when a test case generation is finished. Therefore, previously defined reports are still valid (unless they were generated by verifying an MSC).

  If you do not want to use the default settings for any reason, use the Define-Autolink-State-Space-Options `Off` command. This disables the automatic setting of Autolink's default options.

Test Case Generation Messages

After the generation of a test case, some warnings or error messages may be displayed:

- `Error: Autolink did not find any complete pass paths. No test case is generated.`

  This message appears if no final TTCN *pass* verdict has been assigned to any event in the internal test case representation.

  The most common reason for test generation failure is that the MSC does not describe a valid trace of the SDL system. Hence, before running Autolink, you should check that the MSC test case can indeed be verified using command Verify-MSC.

  The error message above may also appear if the maximum search depth is set too low. Check the state space exploration statistics which are displayed by Autolink at the end of the test case generation. If the number of truncated paths is greater than zero, you should increase the maximum search depth. The required value for

the search depth depends both on the length of the test case and on the selected state space options of the Explorer.

Autolink may also fail if you do not specify the signal parameters in the MSC test cases, but instead use global test values. Make sure that at least all signals sent *into* the system are fully specified in the MSC.

- `Warning: Incomplete pass path found.`
  `The first event X on the incomplete branch`
  `gets an 'INCONC' verdict.`

  This message is displayed if a path in the state space is pruned before a final TTCN *pass* verdict has been assigned to an observable event. (Note that in this context a *pass path* refers to the internal test case representation whereas otherwise, a path refers to the state space of the SDL system.) If this happens, the first event *X* of the incomplete subtree is reassigned as a TTCN *inconc* verdict, and the rest of the subtree is discarded.

  The reasons for a pass path being pruned are numerous. The system level MSC may not be verifiable, for example if the state space is too restricted, or there may be a path in the state space of the SDL system that only partially verifies the MSC. A common problem is the maximum search depth being too low (see above).

- `Warning: Alternative events found for send event.`
  `Inconclusive events are deleted.`

  For test generation, it is assumed that signals which can be sent to the system are sent instantaneously. Therefore, alternatives to send events are not desired.

  With the default options of Autolink, this message should not appear. If you use your own Autolink options, check whether *Input from ENV* has the highest priority. To correct the problem, you should use the Define-Priorities command with parameters `X1 1 X2 X3 X4`, where $X_i > 1$.

- `Warning: No translation rule can be applied to the following signal: <Signal Name>`

  If you define an Autolink configuration containing translation rules, Autolink assumes that you want to map *all* SDL signals onto constraints with the help of user-defined rules. Hence, you will be

warned if there is a signal in a test case to which no translation rule can be applied.

- `Warning: There are events following an event with final 'PASS' verdict.`

  When the MSC test case has been simulated completely, the SDL system was not yet in a stable state. Instead, it sent out one or more additional signals which were not specified in the MSC test case. You should carefully review your test specification, since during a test campaign you may not be able to successfully execute another test case after the execution of the faulty test case.

Translating MSCs into Test Cases

If an SDL system is not fully specified, some or all MSCs may not be converted into test cases if you use the Generate-Test-Case command. Instead, you can use the Translate-MSC-Into-Test-Case command to translate MSCs directly into the same internal test case format which is used for test cases generated by state space exploration. Therefore, you can use all commands related to listing, displaying, removing, saving and loading of test cases (introduced in "Computing Test Cases" on page 1450) with directly translated test cases as well.

Furthermore, all rules for constraint naming (see "Translation Rules" on page 1459) and test grouping (see "Test Suite Structure Rules" on page 1465) apply to translated test cases, too.

> **Note:**
>
> Since the translation of MSCs into test cases does not perform a state space exploration, there is no guarantee that the MSCs and hence the test cases describe valid traces of the specification or the implementation, respectively. Instead, the validity of the test cases has to be assured by the developer. Furthermore, no *inconclusive* events can be computed during MSC translation. Therefore, the resulting test cases return a *fail* verdict for any deviation from the behavior described in the MSC.

Either a set of test cases in the current test cases directory or just a single one may be translated at the same time, depending on the parameter of Translate-MSC-Into-Test-Case. If an already translated test case is retranslated, its former internal representation and its constraint definitions are replaced.

Two different algorithms are available for MSC translation: With the Define-Autolink-Generation-Mode command, you can choose the semantics used to interpret MSCs during translation. By default, Autolink uses the standard semantics of MSC. If the generation mode is set to “total ordering”, then the sequence of input and output events in the MSC is determined straight from top to bottom. If there are two events on different environment instances, Autolink evaluates the event which is closest to the top of the MSC first.

> **Note:**
>
> For test generation with state space exploration (using the Generate-Test-Case command), total ordering is not supported.

MSC into TTCN Translation Messages

After the generation of a test case, some warnings or error messages may be displayed:

- `Error: No test case could be generated. Please check whether the MSC contains separate instance axes for each channel to the environment.`

  The Translate-MSC-Into-Test-Case command does not support the translation of MSCs with only one instance axis for the environment. Use MSCs with a separate instance axis for each channels to the environment (i.e. for each PCO).

- `Warning: No translation rule can be applied to the following signal: <Signal Name>`

  If you define an Autolink configuration containing translation rules, Autolink assumes that you want to map *all* SDL signals onto constraints with the help of user-defined rules. Hence, you will be warned if there is a signal in a test case to which no translation rule can be applied.

Modifying Constraints

It is highly recommended that you specify constraints naming and parameterization rules in an Autolink configuration file. Otherwise, a generic name of the form <Test case name>_<three digit number> is assigned to each constraint during test case generation. However in the latter case, you will probably find it useful to modify the constraints generated by Autolink.

- Use the Rename-Constraint command to change the name of a constraint.

  Besides renaming a constraint, it is also possible to merge two constraints. Do this by giving a constraint the same name as another one. Then you will have to select which of the two signal definitions should be kept (unless they are identical). There is one restriction: Constraints with formal parameters cannot be overwritten by other constraints.

  See also "Translation Rules" on page 1459.

- Use the Merge-Constraints command to merge two constraints by potentially introducing formal parameters.

  If the original constraints are used in test cases, their constraint references will be updated. This means that the concrete signal parameters (which were replaced by formal parameters) will be moved to the constraint references.

Note:

If you rename a constraint or merge two constraints, the internal test case descriptions are updated, too. The links between the events in the test cases and their corresponding constraints remain consistent.

- Use the Define-Constraint command to add new constraints to the current list of constraints.

  If a constraint with the same name but a different signal definition already exists, you will have to choose what to do – rename the new constraint, overwrite the old constraint or remove the new definition.

- Use the Parameterize-Constraint command to replace concrete signal parameter values in a constraint by formal (symbolic) parameters. If the parameterized constraint is used in a test case, the parameter value is not lost, but maintained in the constraint references of the referring test cases instead.

- Use the Clear-Constraint command to delete a constraint.

- Use the List-Constraints command to list all currently defined constraints.

- Use the Save-Constraint command to save one or all constraints.

- Use the Load-Constraints command to reload saved constraints.

Generating a TTCN Test Suite

- Use the Save-Test-Suite command to save a test suite in a TTCN-MP file.

  The internal representations of the test cases will be kept in memory in order to allow you to save test suites in different formats.

- There are two fundamentally different formats to save test suites: "Traditional" TTCN and concurrent TTCN. To switch between these formats, use the ***Define-Concurrent-TTCN*** command. For a detailed description of the concurrent TTCN format, see "Concurrent TTCN" on page 1478.

- By default, constraints are stored as ASN.1 ASP constraints, but before you generate a test suite, you may change an option to have them stored as ASN.1 PDU constraints instead. To do this, use the Define-TTCN-Signal-Mapping command. You are also allowed to select the correct type of constraint for each signal individually by adding rules to an Autolink configuration (see "Defining ASP and PDU Types" on page 1469).

- There are three possible output formats for test steps. Use the Define-TTCN-Test-Steps-Format command to select an output format:
  - One possibility is to store the test steps of a single test case as *local trees*. If a test step is used several times, only one behavior description is generated.
  - Test steps can also be stored globally in the *test step library*. If a test step is used several times in different test cases, only one behavior description is generated.
  - A third alternative is to generate "flat" test cases by including the events of the test steps directly in the test case dynamic behavior descriptions. In this case, no information about test steps is put into the TTCN test suite.

Note:

A test step that is used in several places may lead to trees with different inconclusive events or different verdicts. In this case, they will be given new, unique names.

Preliminary Pass Verdicts

Test cases that are structured into preamble, test body and postamble will automatically be assigned preliminary pass verdicts at the end of the test body. However, test cases can contain an arbitrary number of MSC references (and hence test steps). Therefore, preliminary pass verdicts will be assigned to all events that are directly followed by the last top-level MSC reference in the test case. The preliminary pass verdicts will only be assigned if no event follows the last MSC reference. The event to which a preliminary pass verdict is assigned may appear within the test body as well as within a test step.

Test Suite Generation Messages

During the saving of a test suite, some warnings or error messages may be displayed:

- `Warning: Test step <TS> resulted in different trees. The trees are renamed to '<TS>_1', '<TS>_2', etc. in the test suite.`

  If an MSC test step is reused in several test cases, the resulting TTCN test steps may be different. Typically, this warning appears if a test step is used as a preamble in one test case and then again as a complete test case by itself. In the latter case, a final pass verdict is assigned to the test case, while in the former one it is not.

- `Warning: No test suite structure rule defined for test case/step '<TestCaseName/TestStepName>'.`

  If you define an Autolink configuration containing test suite structure rules, Autolink assumes that you want to place *all* test cases/steps in test groups defined by the test suite structure rules. Hence, you will be warned if there exists a test case/step to which no rule can be applied.

- `Warning: Test suite parameter/constant '<Name>' is not unique.`
  `It is renamed to '<Name>_1', '<Name>_2', etc. in the test suite.`

  By using translation rules (see "Translation Rules" on page 1459) you can introduce test suite parameters and constants. These parameters and constants are checked for consistency in a similar way as test suites. With the warning above, Autolink informs you that it had to rename test suite parameters/constants in order to resolve naming conflicts.

Translation Rules

In "Modifying Constraints" on page 1455, you have learned how to change constraints. However, assigning sensible names to automatically generated constraints is a tedious task. Especially if you have to refine the SDL specification and then to repeat the test generation process, there is a lot of manual work. Moreover, the number of generated constraints may become very large if you do not use constraint parameterization.

In order to address these problems and some additional issues, you can specify so-called *translation rules*. These rules control the look of a test suite with regard to the following items:

1. Naming of constraints
2. Parameterization of constraints
3. Replacement of signal parameter values by wildcards in a constraint declaration table
4. Introduction and naming of test suite parameters and test suite constants

Translation rules build one integral part of an Autolink configuration (see also "Test Suite Structure Rules" on page 1465). Before you start the test generation, you can develop an Autolink configuration file that contains a Define-Autolink-Configuration command. The set of translation rules which tell Autolink how to construct constraints and treat parameters for particular signals, are provided as a kind of long parameter to this command.

For some examples, see "Examples of Translation Rules" on page 1459. More information can be found in "Defining an Autolink Configuration" on page 1449 and "Syntax and Semantics of the Autolink Configuration" on page 1471.

Examples of Translation Rules

A typical translation rule may look like this:

Example 274 ––

```
TRANSLATE MDATind
  CONSTRAINT NAME "C_" + $0
             PARS $1="Type"
```

```
END
-------------------------------------------------------------
```

Example 274 explains how signal `MDATind` is translated into an suitable TTCN constraint. The rule above states that the name of a constraint for signal `MDATind` consists of the concatenation of text `"C_"` and the "nullth" parameter – which is the name of the signal itself. Therefore, signal `MDATind` is translated into a constraint called `C_MDATind`.

Additionally, the first parameter of the signal (referred to by `$1`) becomes a parameter of the constraint. The name of the formal parameter is `Type`. It is printed both in the *Constraint Name* line and the *Constraint Value* section of the constraint declaration table. The actual parameter of the constraint is printed in the dynamic behavior table of each test case that uses this constraint.

A constraint declaration table for signal `MDATind` is shown in Figure 260.

ASN.1 ASP Constraint Declaration

Derivation Path :	
Comments :	
Constraint Value	
{ iPDUType1 Type, sequencenumber2 zero, iSDUType3 0 }	
Detailed Comments :	

Figure 260: A constraint declaration with a formal parameter

It is also possible to define a single translation rule for more than one signal. This is especially useful if similar signals exist which can be treated in the same way.

Example 275 ----------

```
TRANSLATE MDATind | MDATreq
  CONSTRAINT NAME "C_" + $0
             PARS $1="Type"
END
```

If either `MDATind` or `MDATreq` is identical to the signal for which a constraint is to be created during test generation, the rule in Example 275 is applied. The value of `$0` depends on the name of the actual signal investigated at run-time. Since the first signal parameter is always to be replaced by the formal parameter `Type`, the rule is only valid if each of the alternative signals, i.e. `MDATind`, and `MDATreq`, has at least one parameter. When parsing an Autolink configuration, all translation rules are checked automatically for validity.

Constraint names may not only be based on texts and signal names. They can also depend on signal parameters. In a translation rule, a signal parameter is referred to by its number, prefixed with a dollar character (`$`). (Note that Autolink only supports parameters on the top level – it is not possible to refer to a component of a nested parameter.)

In some cases, it is not desirable to use the value of a signal parameter directly as part of a constraint name. For example, a protocol engineer might encode complicated signal information with abbreviations or numbers. But for the TTCN output, parameter values should be mapped onto more meaningful expressions.

Therefore, you may define functions which take an arbitrary number of parameters and map them onto text. In Example 276, the value of the first parameter of signal `MDATind` is passed to function `PDUType`. Depending on the concrete parameter value, which occurs during test case generation, the function returns a text. This text forms the second part of the constraint name.

Example 276 ----------

```
TRANSLATE MDATind
  CONSTRAINT NAME "Medium_" + PDUType($1)
END

FUNCTION PDUType
    $1 == "CR"  : "Ind_Connection_Request"
  | $1 == "AK"  : "Ind_Acknowledge"
  | $1 == "DR"  : "Ind_Disconnection_Request"
  | TRUE        : "Indication"
END
```

Note:

In a translation rule, `$i` refers to the i-th parameter of the signal for which a constraint is created. However in a function, `$i` denotes the i-th parameter which was passed to the function.

You may define complex rules whose evaluation is guarded by conditions. This is illustrated in Example 277.

Example 277 ----------

```
TRANSLATE "MDATind"
  IF $1 == "CR" THEN
    CONSTRAINT NAME "Medium_Connection_Request"
  END
  IF $1 == "AK" AND $2 == "zero" THEN
    CONSTRAINT NAME "Medium_Acknowledge_Zero"
  END
  CONSTRAINT NAME "Medium_Indication"
             PARS $1="Type"
END
```

Conditional translations can be defined by IF-statements. Only if the condition(s) following the `IF` keyword is/are satisfied, the constraint is built according to the subsequent specification. A translation rule can contain several `IF`-clauses. The first clause which condition is satisfied (or which does not have an `IF` statement at all) is chosen for translation.

In the example above, signal `MDATind` is translated into a constraint called `Medium_Connection_Request` if the first signal parameter equals `CR`, and to a constraint called `Medium_Acknowledge` if the first two signal parameters equal `AK` and `zero` respectively. If neither condition is satisfied, the unconditioned section is evaluated. In this case, a constraint with name `Medium_Indication` and formal parameter `Type`

is created. Note that the parameter definition is not taken into account if any of the former IF-conditions is satisfied!

Sometimes, it is useful to indicate that a specific signal parameter is irrelevant. For example, assume that if the first parameter of signal MDATind is CR, the values of the second and third parameter can be ignored. Hence, you can replace them by wildcards in a constraint table. In Example 278, a MATCH statement is added that tells Autolink to replace the values of the signal parameters 2 and 3 by asterisks. The resulting constraint table is displayed in Figure 261.

Example 278 ----------

```
TRANSLATE "MDATind"
  IF $1 == "CR" THEN
    CONSTRAINT NAME "Medium_Connection_Request"
               MATCH $2="*", $3="*"
  END
  CONSTRAINT NAME "Medium_Indication"
             PARS $1="Type"
END
```

> **Note:**
>
> The application of TTCN matching mechanisms is only valid for receive events. Hence, you are not allowed to apply the MATCH statement to signals that become send events in TTCN.

Detailed Comments :	

Figure 261: A constraint table with TTCN matching expressions

Translation rules also allow to introduce test suite parameters and constants. Test suite constants are useful if a concrete parameter value does not give any clues about its meaning and hence should be replaced globally by a more meaningful name. Test suite parameters should be introduced if signal parameter values are implementation dependent. By defining a test suite constant/parameter, a concrete signal parameter

value in a constraint table is replaced by a symbolic constant. The assignment of concrete values to symbolic test suite constants/parameters is made in additional TTCN tables which are created automatically by Autolink.

Example 279 illustrates the use of test suite parameters and constants. If the condition is satisfied, the second signal parameter is replaced globally by `SeqNo` in the TTCN test suite. The third signal parameter is replaced by a test suite parameter called `DataValue`. This parameter refers to PICS/PIXIT proforma entry `PICS_Data`.

If signal MDATreq has not been used for data transfer, the value of the first signal parameter is replaced by a test suite constant which name is based on the concrete signal parameter value. A constraint table and an according constant table for this case is shown in Figure 262 and Figure 263.

Example 279 ----------

```
TRANSLATE "MDATreq"
  IF $1 == "DT" THEN
    CONSTRAINT NAME   "Medium_Req_Data_Transfer"
    TESTSUITE  CONSTS $2="SeqNo"
               PARS   $3="DataValue" / "PICS_Data"
  END
  CONSTRAINT NAME   "Medium_Req_" + PDUType($1)
             MATCH  $3="*"
  TESTSUITE  CONSTS $1=PDUType($1)
END

FUNCTION PDUType
  $1 == "CC" : "ConConf"

Figure 263: A TTCN table for test suite constant declarations

An Autolink configuration typically consists of a large number of translation rules which are evaluated from top to bottom. If a constraint cannot be constructed based on the given rules, a generic name will be assigned to the constraint, in the same way as when no translation rules are defined.

Test Suite Structure Rules

In TTCN, test cases can be combined in test groups. Each test group aims at testing the system under test for one particular aspect. Test groups again can be part of other higher level test groups, resulting in a hierarchy of test groups.

Test steps can be put into test groups as well. In the following, test cases and test steps will not be distinguished, as test structure rules apply to both.

When you start designing a test suite, you should have a clear notion of what the structure of the test suite will be. In fact, for successful test suite development, it is important to first determine what should be tested and how the tests can be classified, before individual test cases are specified.

If you use Autolink for test generation, the test cases are described by MSCs. Ideally, the names of the MSCs should give information about

the structure of the resulting test suite. Because of this, you may specify rules for the automatic placing of test cases in different test groups, depending on the names of the corresponding MSCs. These *test suite structure rules* prevent you from repeating a lot of manual work if you regenerate the test suite due to a modification of the underlying SDL specification. Moreover, test suite structure rules (TSS rules) also save you a lot of work if you create a test suite only once, since a single rule can be applied to several test cases. As will be shown in the example below, one rule may be enough to describe the structure of a complete test suite.

Test suite structure rules are part of an Autolink configuration. Before the test generation starts, you can write an Autolink configuration file which contains a Define-Autolink-Configuration command. The TSS rules are provided as a kind of long parameter to this command.

For details on the Autolink configuration commands see "Defining an Autolink Configuration" on page 1449. A precise description of the Autolink configuration language is given in "Syntax and Semantics of the Autolink Configuration" on page 1471.

Examples of Test Suite Structure Rules

In the following, it is assumed that you want to create a test suite in which test cases can be classified according to three different criteria. On the top level, tests can be distinguished by whether they are related to mandatory or optional capabilities. On the next level, tests may focus on particular protocol phases, for example connection establishment, data transfer and disconnection. Finally, valid, invalid or inopportune behavior may be displayed. A resulting test suite should have the following structure:

```
Mandatory
  Connection
    Valid
    Invalid
    Inopportune
  DataTransfer
    Valid
    ...
  Disconnection
    ...
Optional
    ...
```

It is further assumed that having this structure in mind, you have created MSC test cases with the following names:

```
V_Con_Man_01
V_Dis_Man_01
IV_Data_Man_01
IO_Data_Opt_01
IO_Data_Opt_02
```

MSC test cases that belong to the same test group are numbered sequentially.

Now, a simple TSS rule for the scenario above may look like this:

Example 280 ----------

```
PLACE V_Con_Man_01
  IN    "Mandatory" / "Connection" / "Valid"
END
```

Example 280 states that test case `V_Con_Man_01` is intended to be placed in the test group `Valid`. Since this test group is placed in another test group (`Connection`), you have to specify the complete path, composed of all groups in hierarchical order. The names of the test groups are separated by a slash (‘`/`’) in analogy to the notation of test group references in the TTCN standard.

If you want to place several test cases in the same test group, you can use the alternative operator (‘`|`’) in the header of a TSS rule:

Example 281 ----------

```
PLACE IO_Data_Opt_01 | IO_Data_Opt_02
  IN    "Optional" / "DataTransfer" / "Inopportune"
END
```

Example 281 places both `IO_Data_Opt_01` and `IO_Data_Opt_02` in test group `Optional/DataTransfer/Inopportune`.

Rules like the one shown in Example 280 and Example 281 can be applied to MSC test cases with arbitrary names. In the best case, you have to write one TSS rule for each test group.

However, there is a direct relation between the MSC names and the test groups. For example, the two characters `IO` at the beginning of an MSC name indicate that the corresponding test case has to be placed in a test group called *Inopportune*. Using this information, the number of TSS rules can be further reduced as explained below.

You are allowed to use patterns in the header of a test suite structure rule. The following characters have a special meaning when used in the header:

- '*' matches zero or more arbitrary characters.
- '?' matches exactly one arbitrary character.
- "[...]" matches any single character in the enclosed lists. In order to represent characters ranges, you can type two characters separated by a dash ('-'). For example, "[a-z]" denotes an arbitrary lowercase letter. If the first character is a '!', any character not enclosed is matched.

Note:

Patterns can also be used in a similar way in the header of translation rules. This is useful if signals with similar names are to be treated equally.

Now consider the following complex rule and its auxiliary functions:

Example 282 ----------

```
PLACE "*" + "_" + "*" + "_" + "???" + "_" + "*"
  IN    OptMan( @5 ) / Phase( @3 ) / Behavior( @1 )
END

FUNCTION OptMan
  $1 == "Opt" : "Optional"
| $1 == "Man" : "Manual"
END

FUNCTION Phase
  $1 == "Con"  : "Connection"
| $1 == "Data" : "DataTransfer"
| $1 == "Dis"  : "Disconnection"
END

FUNCTION Behavior
  $1 == "V"  : "Valid"
| $1 == "IV" : "Invalid"
| $1 == "IO" : "Inopportune"
END
```

With the rule in Example 282, *all* test cases can be placed in their appropriate test groups.

When a test suite structure rule is evaluated, it is first checked whether one of the terms following the keyword `PLACE` (which are separated by '|') equals the name of the investigated test case. In the rule above, there is only one term consisting of 7 parts, called atoms. These atoms are concatenated by the '+' operator.

While Autolink simply has to compare strings in Example 280 and Example 281, it has to find out whether a concrete test case name matches the pattern in Example 282. If the test case name matches the pattern, the atoms in the header of the TSS rule are instantiated.

If, for example, the rule is applied to test case `IO_Data_Opt_01` at run-time, the first atom (originally '*') is set to "IO". The value of the third atom becomes "Data", the value of the fifth atom becomes "Opt" and the value of the seventh atom becomes "01". The second, fourth and sixth atom remain unchanged as they do not contain any special characters.

In order to refer to the value of an atom in the rule header, you can use the "at" operator ('@'). For example, "@5" refers to the value of the fifth atom.

Additionally, you may define functions which map parameters onto texts. In Example 282, "@5" is passed to function `OptMan`. Depending on the concrete parameter value which is passed at run-time, the function returns either the text "Optional" or "Manual" (or an error message if the first function parameter is neither "Opt" nor "Man").

An Autolink configuration typically consists of a number of TSS rules which are evaluated from top to bottom. If a test case or a test step cannot be placed in a test group based on the given rules, Autolink places it on top-level and prints an error message. In this case, you can modify your rules, reload them and apply the Save-Test-Suite command again.

Defining ASP and PDU Types

When Autolink produces a TTCN test suite it creates several tables in the declarations part. These tables store information about sorts, ASN.1

data types and signal definitions used in the SDL system. By default, Autolink applies the following rules:

1. SDL sort definitions are mapped onto *ASN.1 type definitions*.
2. ASN.1 data types defined externally in an ASN.1 module are listed as *ASN.1 type definitions by reference* in TTCN.
3. SDL signal definitions become *ASN.1 ASP type definitions*. As a consequence, if a signal is used in a test case, its corresponding TTCN constraint is stored in an *ASN.1 ASP constraint* table.

Very often, this mapping is too strict. For example, during test execution a tester may exchange both Abstract Service Primitives (ASPs) and Protocol Data Units (PDUs) with the system under test. If you want to store constraints as ASN.1 PDU constraints, you may use Define-TTCN-Signal-Mapping with parameter *PDU*. However, in this case *all* signals are considered to be PDUs. Moreover, this command does not apply to SDL sorts and ASN.1 data types.

In order to specify the correct for each different type of information, Autolink provides two commands in its configuration language. These commands start with either the keyword `ASP-TYPES` or `PDU-TYPES`. You can use them to declare single signals and sorts as ASPs and PDUs.

Example 283 ----------

```
ASP-TYPES
  "ICONreq" , "ICONconf", "IDATreq"
END

PDU-TYPES
  "pdu*"
END
```

In Example 282, three SDL signals, namely *ICONreq*, *ICONconf* and *IDATreq* are specified as ASPs. The second rule states that all signals and sorts whose name starts with "pdu" shall be considered to be PDUs. If constraints with corresponding types are used, they are stored as PDU constraints as well.

Stripping signal definitions

When it comes to the automatic generation of TTCN test suites, one of the drawbacks of SDL is that any data which is exchanged between a

system and its environment has to be encapsulated in signals. Especially, if your SDL specification makes use of ASN.1 data types, this restriction imposes a redundant embedding. On the other hand, the concept of signals does not exist in TTCN. Instead, common data values can be sent and received directly. For that reason, Autolink allows to strip signals.

Consider a signal type defined as *MDATreq(PDUType)*. If a signal of this type is used in a test case, say *MDATreq({ CC })*, then Autolink will generate a constraint of type *MDATreq*. However, what you may want to generate is a constraint of type *PDUType*, i.e. the signal should be stripped from its parameter.

Example 284 ––

```
STRIP-SIGNALS
  "MDATreq"
END

PDU-TYPES
  "PDUType"
END
```

––

Example 284 presents a short Autolink configuration statement that tells Autolink to unwrap the signal parameter when generating constraints that are related to signal *MDATreq* in the SDL specification.

Please note that signal stripping can only be applied to signals that have exactly one parameter! Moreover, the embedded parameter must be declared either as PDU or as ASP. If these conditions do not hold, Autolink refuses to strip the signal and issues a warning. If a signal can be stripped successfully, no declaration is generated for it in the TTCN declaration part, since it is not used in the constraints part.

Syntax and Semantics of the Autolink Configuration

Autolink Configuration

The definition of an Autolink configuration is started with the keyword `Define-Autolink-Configuration` and is terminated with `End`. It consists of an arbitrary sequence of five different kinds of statements:

Translation rules, test suite structure rules, ASP/PDU type rules, signal stripping rules and functions.

Example 285: Syntax of Autolink configuration

```
<Start>                ::= "Define-Autolink-Configuration"
                           <Configuration>
                           "End"
<Configuration>        ::= { <TransRule> | <TSStructureRule> |
                             <ASPTypesRule> | <PDUTypesRule> |
                             <StripSignalsRule> | <Function> }*
```

> **Note:**
>
> If you want to define both translation rules and test suite structure rules, you have to place them in the same configuration definition.

Rules and functions can be arbitrarily mixed in a configuration. There is no need to place rules on top of a file, nor do you have to write forward declarations for functions.

> **Note:**
>
> Autolink analyzes translation rules and test suite structure rules in the order they have been defined. As a consequence, the order of the definitions is crucial if several rules can be applied.

Translation Rules

Translation rules are evaluated whenever a constraint is created during test case generation.

A translation rule starts with the specification of the names of the signals to which it shall apply (denoted by `<AlternativeListOf-Terms>`).

Example 286: Syntax of translation rules

```
<TransRule>              ::= "TRANSLATE"
                             [ "SIGNAL" ] <AlternativeListOfTerms>
                               <TransRuleIf>* [ <TransRuleNoIf> ]
                              "END"
<TransRuleIf>            ::= "IF" <Conditions> "THEN"
                             <TransRuleNoIf> "END"
<TransRuleNoIf>          ::= { "CONSTRAINT" <TransRuleConstraint> |
                               "TESTSUITE" <TransRuleTestSuite> }*
<TransRuleConstraint>    ::= { "NAME" <Term> |
                               "PARS" <ParameterList1> |
                               "MATCH" <ParameterList1> }*
<TransRuleTestSuite>     ::= { "CONSTS" <ParameterList1> |
                               "PARS" <ParameterList2> }*
<ParameterList1>         ::= <Parameter1> { "," <Parameter1> }*
<Parameter1>             ::= "$" <Number> [ "=" <Term> ]
<ParameterList2>         ::= <Parameter2> { "," <Parameter2> }*
<Parameter2>             ::= "$" <Number> [ "=" <Term> ]
                                          [ "/" <Term> ]
```

As sketched in the example section, translations can be made dependent on one or more conditions. Hence, the body of a translation rule may consist of one or more statements embedded by `IF` ... `THEN` ... `END` constructs. The first group of statements whose preceding conditions are satisfied (or which do not have an `IF` statement at all) is evaluated. All subsequent definitions are ignored. If no conditions hold for a given signal, Autolink looks for another translation rule which fits the signal.

There are two groups of directives starting with either the keyword `CONSTRAINT` or `TESTSUITE`.

In the `CONSTRAINT` part you can specify the name (keyword `NAME`) and the formal parameters of a constraint (keyword `PARS`) for one or more given signals. Additionally, you can tell Autolink to replace signal parameter values by a TTCN matching mechanism (keyword `MATCH`). Please note that Autolink does not perform any checks concerning matching mechanisms at run-time. It simply handles it as a textual replacement.

In the `TESTSUITE` part, you can specify that parameter values of a signal are replaced by test suite parameters and constants. The declaration of constants is preceded by the keyword `CONSTS`, test suite parameter are introduced with `PARS`.

It is possible to declare a constraint parameter and a test suite constant/parameter for the same signal parameter. However, Autolink en-

sures that a signal parameter is not mapped onto a test suite constant and parameter at the same time.

There exist several default values that are used when an optional parameter is not specified:

- The default name of a constraint is defined by the term `'c' + $0`, i.e. the signal name is prefixed by a `'c'`.
- The default name of a constraint parameter is constructed by “Par” + <SignalNumber> (e.g. `Par3` for the third parameter).
- If a signal parameter is specified after `MATCH`, but no term is given, its values is replaced by ‘*’ in the constraint table.
- The default name of a test suite constant is “TestSuiteConst”.
- The default name of a test suite parameter is “TestSuitePar”.
- By default, there is no PICS/PIXIT reference.

If there are name clashes, test suite constants and parameters are treated similar to constraints and test steps. That means, if there are two constants with the same name but different values, they are distinguished by a sequence number.

Test Suite Structure Rules

Test suite structure rules are similar to translation rules. They share most of the basic concepts, for example terms, functions and conditions. However, while translation rules are applied during test case generation, TSS rules are evaluated when you save a test suite with the Save-Test-Suite command.

A test suite structure rule starts with the specification of the names of the test cases to which it shall apply (denoted by `<AlternativeListOfTerms>`).

Conditions can be used in the same way as in translation rules: The first `IN` statement whose preceding conditions are satisfied (or which is not embedded in an `IF` ... `THEN` ... `END` statement at all), is taken into account. All subsequent statements are ignored. If no conditions hold for a given test case/step, Autolink looks for another TSS rule that fits the test case/step.

Example 287: Syntax of test suite structure rules

```
<TSStructureRule>         ::= "PLACE" <AlternativeListOfTerms>
                              <TSStructureRuleIf>*
                              [ <TSStructureRuleNoIf> ]
                              "END"
<TSStructureRuleIf>       ::= "IF" <Conditions> "THEN"
                              <TSStructureRuleNoIf> "END"
<TSStructureRuleNoIf>     ::= "IN" <Term> { "/" <Term> }*
```

Declaring ASP and PDU Types

The rules to declare ASP and PDU types are evaluated when a TTCN test suite is saved on disk with the Save-Test-Suite command. Please note that each of the rules can only be defined once in an Autolink configuration. However, this is no restriction as you can specify an arbitrary number of signals and sorts in both rules.

Example 288: Syntax for declaring ASP and PDU types

```
<ASPTypesRule>       ::= "ASP-TYPES" <SequentialListOfTerms> "END"
<PDUTypesRule>       ::= "PDU-TYPES" <SequentialListOfTerms> "END"
```

Stripping Signals

Rules for stripping signals are evaluated closely coupled with the rules above for declaring ASP and PDU types. Autolink only strips a signal if its only parameter is declared as ASP or PDU. Autolink only accepts one stripping rule in a configuration.

Example 289: Syntax for stripping signals

```
<StripSignalsRule> ::= "STRIP-SIGNALS" <SequentialListOfTerms>
                       "END"
```

Functions

Functions are identified uniquely by their names. If there are two functions with exactly the same name, the one defined first is always evaluated.

Functions are visible globally, that is, they can be called by any constraint or test suite structure rule and other functions. References to

functions are resolved at run-time. If there is a call to an unknown function, the text `"FunctionXXXNotFound"` is returned.

Example 290: Syntax of functions

```
<Function> ::= "FUNCTION" <Identifier> <Mappings> "END"
<Mappings> ::= <Mapping> { "|" <Mapping> }*
<Mapping>  ::= <Conditions> ":" <Term>
```

A function body consists of a number of mapping rules separated by '|'. Mapping rules specify the possible return values of a function. A mapping is performed if its corresponding condition(s) hold. Mappings are evaluated from top to bottom. If the conditions of all mappings fail, a function returns the text `"NoConditionHoldsInFunctionXXX"`.

Function parameters can be accessed in the same way as signal parameters in a translation rule. For example, `$2` refers to the second parameter. In the context of functions, the reference `$0` denotes the name of the function. Since parameters do not have a name, but are referred to by their position instead, there is no need to declare them in the function header. If you try to access a parameter that has not been passed to the function, the missing parameter is replaced by the text `"ParOutOfRange"`.

> **Note:**
>
> In conditions, the existence of a particular parameter can be checked. For example, condition
>
> ```
> $4 == "ParOutOfRange"
> ```
>
> checks if four parameters have been passed to the function.

Basic Expressions

The only data type defined in the Autolink configuration language is **text**. Whether you refer to a signal parameter or call a function, the result of the operation is always a text.

Example 291: Syntax of basic expressions

```
<Term>                   ::= <Atom> { "+" <Atom> }*
<Atom>                   ::= "$" <Number> | "@" <Number> |
                             <Text> | <Identifier> |
                             <FunctionCall>
<FunctionCall>           ::= <Identifier>
                             "(" <SequentialListOfTerms> ")"
<SequentialListOfTerms>  ::= <Term> { "," <Term> }*
```

```
<AlternativeListOfTerms> ::= <Term> { "|" <Term> }*
<Conditions>             ::= <Condition> { "AND" <Condition> }*
<Condition>              ::= <Term> { "==" | "!=" } <Term> |
                             "TRUE"
```

Texts are constructed by atoms and terms. A single atom can be one of the following expressions, depending on the context in which the atom is used:

- A simple text (e.g. `"Request"`).
- An identifier (e.g. `Request`).
  Identifiers are treated as simple texts.
- A pattern (e.g. `"Sig*"`).
  Patterns can only be used in the header of constraint or test suite structure rules (for details see "Test Suite Structure Rules" on page 1465).
- A function call (e.g. `OpName($3)`).
  Function calls are not allowed in the header of constraint or test suite structure rules.
- A reference to a signal parameter (e.g. `$2`).
  References to signal parameters can only be used in the body of translation rules.
- A reference to a function parameter (e.g. `$2`).
  References to function parameters can only be used in the body of functions.
- A reference to an atom in the header of a constraint or test suite structure rule (e.g. `@2`).
  References to atoms can only be used in the body of constraint and test suite structure rules. Their application in combination with patterns is illustrated in "Test Suite Structure Rules" on page 1465.

Since an atom always evaluates to a text and a term is a concatenation of single atoms, you are allowed to use term expressions for the specification of:

- Constraint names
- Constraint formal parameter names
- Test suite parameter names
- Test suite constant names

- Test case/test step/test group names
- ...

Note:

The text obtained by referring to a signal parameter is identical to the output of the signal parameter value in ASN.1 format.

A condition checks whether two texts are equal (`==`) or unequal (`!=`). There is also a special condition `TRUE` that always evaluates to true.

Conditions can be combined by `AND`. Only if all conditions in a conjunction hold, the expression as a whole is true.

There is no `OR` operator for combination of conditions. However, due to the consecutive evaluation of rules (from top to bottom), this is not a restriction. For example, in a function body, simply place both `OR`-operands in two subsequent mappings.

Concurrent TTCN

In the 1996 version of ISO IS 9646-3, TTCN has been extended with mechanisms to specify test suites for distributed test systems. These extensions are known as *concurrent TTCN*. This section explains what will happen when you save your test suite in the concurrent TTCN format.

Declarations

In a distributed test environment, the test system is composed of a set of *Parallel Test Components (PTC)* which each handle one or more PCOs. The test system also includes one *Main Test Component (MTC)* which starts the PTCs and computes the final test verdict. The MTC may or may not control PCOs. The main and parallel test components exchange *Coordination Messages (CM)* through *Coordination Points (CP)*.

The collection of a number of test components and their connection through coordination points is called a *test configuration*. A test suite may contain more than one test configuration, and each test case has to be associated with a specific test configuration individually.

Coordination messages and corresponding constraints have to be declared similar to messages exchanged with the system under test, but in separate tables.

Dynamic behavior description

In concurrent TTCN, the Test Case Dynamic Behaviour table only describes the behavior of the main test component. The behavior of parallel test components is stored in Test Step Dynamic Behaviour tables. Obviously, the behavior tables of every test component contain only events observed at the PCOs and CPs attached to that test component.

Parallel test components are dynamically created by the main test component. This is done by the inclusion of `CREATE` statements in the test case behavior description. Similarly, the `DONE` event can be used in the test case description to check the termination of parallel test components. The final test case verdict is computed by the MTC from the verdicts returned implicitly by all PTCs before their termination.

Synchronization of test components

With concurrent TTCN, synchronization among test components becomes a necessity. Each test component only gets a partial view of the system under test and has no inherent knowledge of the state of the other test components. Therefore, the correct order of test events can only be established through the use of coordination messages. Consider the example shown in "Synchronizing Test Events with Conditions" on page 1444. If there are separate test components to control A, B and C, then C definitely has to wait for a coordination message before sending its `Request(B)` message to the SUT. If it does not, the test verdict entirely depends on the relative transmission time of the messages and the order of their handling by the SUT.

The Autolink implementation of concurrent TTCN

Autolink generates concurrent TTCN specific information only during the saving of a test suite. Therefore, it does not matter if concurrent TTCN is enabled during the generation or translation of test cases. You may generate your test cases, save the test suite in non-concurrent form, then turn on concurrence and save the test suite again.

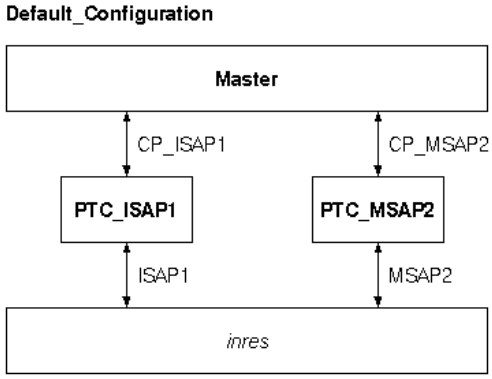

Figure 264: Test configuration for the inres system

Declarations

Autolink supports one kind of test architecture. From this generic architecture and the SDL specification of the system, a concrete test architecture is derived. The following declarations are generated automatically:

- One main test component called `Master`. The MTC does not control any PCOs.
- One parallel test component for each PCO. The name of the test component is `PTC_` + *Name of the PCO*.
- One coordination point between the MTC and each PTC. The name of the coordination point is `CP_` + *Name of the PCO*.
- One test configuration called `Default_Configuration`, which contains all test components and their connections with PCOs and CPs.

Figure 264 shows the test configuration which is generated for the *inres* System. In addition, the following declarations are generated:

- One ASN.1 CM Type Definition. The name of the coordination message is `CM` and its definition is `SEQUENCE {message PrintableString}`.

- Two ASN.1 CM Constraint Declarations, called `Proceed_Indication` and `Ready_Indication`. Both constraints define values for the coordination message `CM`.

`CM`, `Proceed_Indication` and `Ready_Indication` are used for coordination messages between the main and parallel test components. These messages are generated automatically (see Synchronization below).

> **Note:**
> The test architecture and resulting default test configuration can not be changed within Autolink. The coordination message and corresponding constraints are not changeable neither.

Test Case Dynamic Behaviour

Test Case Name : mi_synch2
Group :
Purpose :
Configuration : Default_Configuration
Default : OtherwiseFail
Comments :
Selection Ref :
Description :

Nr	Label	Behaviour Description	Constraints Ref	Verdict	Comments
1		CREATE(PTC_ISAP1:mi_synch2_PTC_ISAP1)		(PASS)	
2		CREATE(PTC_MSAP2:mi_synch2_PTC_MSAP2)			
3		+Synchronization			
4		? DONE(PTC_ISAP1,PTC_MSAP2)		R	

Detailed Comments :

Figure 265: Sample test case description for a main test component

Dynamic behavior description

Autolink splits the internal test case description into separate trees for every test component. The Test Case Dynamic Behaviour table describes the behavior of the main test component; its name is equal to the name of the original MSC test description. Since the MTC does not control any PCOs, it only contains `CREATE` statements for every PTC at the beginning and a `DONE` event at the end. It may also contain attached synchronization test steps in between. Figure 265 shows a sample test case description. The `(PASS)` verdict on line 1 initializes the result variable `R`. At the end of the test case, `R` contains the final test verdict.

Each parallel test component gets a Test Step Dynamic Behaviour table of its own. The name of the test step is *Test case name* + _ + *Test component name*.

Synchronization

Coordination messages are automatically generated by Autolink wherever a condition appears in the MSC test description. As a consequence of the test architecture used by Autolink, synchronization is done via the main test component. Here is a description of the algorithm:

1. For each MSC environment instance connected to a condition: Send a coordination message `CM` with constraint `Ready_Indication` to the MTC.
2. For each MSC environment instance connected to a condition which has a send event immediately following the condition: Receive a coordination message `CM` with constraint `Proceed_Indication` from the MTC.

Test Step Dynamic Behaviour

Test Step Name : Synchronization
Group :
Objective :
Default : OtherwiseFail
Comments :
Description :

Nr	Label	Behaviour Description	Constraints Ref	Verdict	Comments
1		CP_MSAP2 ? CM	Ready_Indication		
2		CP_ISAP1 ? CM	Ready_Indication		
3		CP_ISAP1 ! CM	Proceed_Indication		
4		CP_ISAP1 ? CM	Ready_Indication		
5		CP_MSAP2 ? CM	Ready_Indication		
6		CP_ISAP1 ! CM	Proceed_Indication		

Detailed Comments :

Figure 266: Synchronization test step for a main test component

From the viewpoint of a parallel test component, this means that whenever it reaches a synchronization point, it sends a `Ready_Indication` message to the MTC. If the event immediately following the synchronization point is a send event, then the PTC first waits for a `Proceed_Indication` message, which it receives from the MTC. All coordination events are directly included in the dynamic behavior description of the PTC.

When it reaches a synchronization point, the main test component waits for `Ready_Indication` messages from every PTC involved in the synchronization. Afterwards, it sends `Proceed_Indication` messages to all PTCs which are about to send a message to the system under test. Since the reception of coordination messages from different PTCs can create a lot of alternative paths, all synchronization events for the MTC are put into test steps. Figure 266 shows an example of a synchronization test step for an MTC.

> **Note:**
>
> Coordination messages can not be specified manually in the MSC test description. There are two reasons for this: First, the Explorer and Autolink can not handle messages drawn between environment instances. Second, all instances in the MSC have to relate to a channel in the SDL specification. Since the main test component has no connection with the system under test, it is not possible to add an MTC instance to the MSC.

Caveats

In order to streamline test suites and enhance their readability, Autolink automatically merges test steps which contain identical behavior descriptions. Furthermore, empty test steps are removed.

If your MSC test descriptions contain MSC references and concurrent TTCN is used to save the test suite, then the test step streamlining of Autolink may lead to unexpected results: For example, test steps for parallel test components may be renamed unexpectedly. Within test case and test step behavior descriptions, expected attachments of test steps may be missing. Nevertheless, these test suites are still correct and correspond to the original test descriptions.

Test Suite Timers

In this section, details regarding the declaration and use of test suite timers in test case MSCs is discussed.

Timer declarations

As explained in "Using Timers" on page 1438, the recommended method for using test suite timers with Autolink is to explicitly declare all timers which appear in the test suite with Define-Timer-Declaration before test generation is started. Nevertheless, it is possible to have a mix-

ture of implicit and explicit declaration. Below, the rules are listed which Autolink applies when creating or updating timer declarations. In any case, the syntactical correctness of the timer name is not checked.

Creation of a new explicit timer declaration

- Autolink checks if the duration is an integer value or a syntactically correct test suite parameter. If it is neither, then a warning is displayed and the duration field remains empty. If it is a test suite parameter, a test suite parameter declaration is created in addition to the timer declaration.
- No declaration is created if the unit is not valid.

Note:

The only possibility to specify an empty duration field on purpose is to use an invalid string, e.g. a digit followed by a character.

Creation of a new implicit timer declaration

- Autolink checks if the parameter field of the timer set symbol ends with a valid unit, which means that there must be a whitespace character followed by either *ps*, *ns*, *us*, *ms*, *s* or *min*. If this is the case, then the value of the unit field is set and the rest of the string is considered to be the duration. If no valid unit can be found, then the whole parameter field is considered to be the duration.
- Autolink checks if the duration is an integer value or a syntactically correct test suite parameter. If it is neither, then a warning is displayed and the duration field remains empty. If it is a test suite parameter, a test suite parameter declaration is created in addition to the timer declaration.

Note:

It is the responsibility of the test designer to make sure that either an explicit timer declaration exists or that an implicit declaration is correct. Autolink does not guarantee that a test suite which contains implicit timer declarations passes a TTCN syntax check.

Update of an explicit declaration with an explicit one

An existing explicit declaration can not be updated. A warning is displayed and the new declaration is ignored.

The only way to remove existing timer declarations is to use the Reset command.

Update of an explicit declaration with an implicit one

An existing explicit declaration can not be updated. However, Autolink checks if the unit of the implicit declaration matches the unit of the existing explicit declaration. If it does not match, a warning is displayed.

Update of an implicit declaration with an explicit one

Autolink checks if the unit of the new declaration is valid. If it is not, the existing implicit declaration is kept. If the unit is valid, the implicit declaration is replaced by the explicit one.

Update of an implicit declaration with an implicit one

- Autolink compares the unit of the existing declaration with the unit of the new declaration:
  - if the existing unit is valid and the new one is invalid, then the existing one is kept;
  - if the existing and the new unit are identical, then the unit is not changed;
  - in all other cases, the unit field is cleared; this will result in a syntactically incorrect TTCN test suite.
- If the duration field of the existing declaration is empty or an integer value and the new duration is a test suite parameter, then the test suite parameter replaces the existing value.

Timer pitfalls

Timers in a test suite are declared globally. During test execution, each participating test component receives a complete set of timers which it can use independently. With respect to the readability of a test suite, the number of timer declarations should be minimized. This can be accomplished by declaring a minimal set of timers and reusing them in different test case MSCs.

If concurrent TTCN is enabled, identically named timers may also be used on different instances in the same MSC, because in the resulting TTCN test case, each MSC instance is handled by a different test component. However, if such an MSC is used in a non-concurrent context,

then Autolink may produce unexpected test sequences and care should be taken.

Timer optimization

If concurrent TTCN output is enabled with Define-Concurrent-TTCN, then the dynamic behavior descriptions are optimized with regard to the placement of timer operations. If a timer *START* operation is followed immediately by a send event, then the *START* operation is placed on the same line as the send event. Correspondingly, if a timer *CANCEL* operation follows a receive event, then the *CANCEL* is moved up to the line with the receive event. As an example, if the test sequence according to the test case MSC is

```
START T1
  A ! someSignal
    A ? anotherSignal
      CANCEL T1
```

then Autolink optimizes this and generates the following test sequence:

```
A ! someSignal  START T1
  A ? anotherSignal  CANCEL T1
```

Chapter

36 *Adaptation of Generated Code*

This chapter contains information about making an adaptation of the generated code to make it communicate with the generated code.

The first part of this chapter describes the interface to be used when writing the adaptation, the GCI Interface. The different parts of the interface are explained in detail with recommendations and examples of use.

The second part of this chapter is a C implementation of GCI, this can be used as a reference documentation.

The third part describes the EGci (extended GCI) value construction and functions.

The fourth section introduces the Adaptation Framework that can be used to implement GCI functions in a straightforward way with ready-made low-level protocol implementations such as TCP/IP.

The fifth and final section describes the means and measures to complete the adaptation. It describes the requirements on the adaptation in terms of the necessary functions to implement.

The GCI Interface

The Generic Compiler Interpreter (GCI) interface standardizes the communication between a TTCN component supplied by a vendor and other test system components supplied by the customer, together forming a MOT, Method Of Test.

The GCI interface focuses on what an ATS needs in order to execute in term of functionality, and on what is needed in order to integrate TTCN into a larger system. This chapter contains a natural language description of the interface and a GCI C Reference.

The GCI Interface Model

The main purpose of the GCI interface is to separate TTCN behavior from protocol and test equipment specific code. The GCI interface shall be a standardized set of functions. Communication shall be done by calling functions, passing arguments to the functions and return values from the functions, and in no other way. The interface is bidirectional which means that both parties (the TTCN Runtime Behavior and the Test Adaptation) must provide services to each other. The TTCN Runtime Behavior shall at least provide services for handling values and managing tests (evaluating test cases etc.) and the Test Adaptation shall provide the protocol/test equipment specific parts of an executable (send, snapshot, timer functions etc.). The implementation of the functions in the TTCN Runtime Behavior may only depend on the ATS and 9646-3, no extra information shall be needed to implement them.

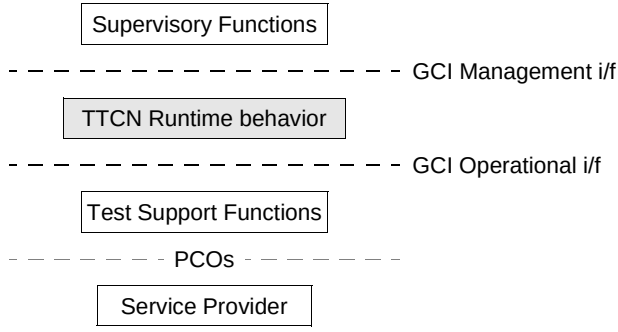

Figure 267: The GCI model

Informal Description of the Test Run Model

This section contains an informal description of how a test run might look like using the GCI interface. A test run is defined as a complete test session, where a selection of test cases are run to ensure a specific behavior of the IUT.

A test run begins when the user decides to run a test case or a collection of test cases. He will then use the Supervisory functions to start test cases and monitor their verdicts. The TTCN Runtime Behavior then executes TTCN, occasionally using the operational interface (send, snapshot, etc.) to gather information or to request some service. The TTCN Runtime Behavior handles verdicts internally during a test case and returns the verdict at the end of a test case.

Before using the TTCN Runtime Behavior, it must be initialized. After that the user chooses which test case to run using the supervisory functions. The test case returns a verdict which the user can use to form reports or stop test runs. The TTCN Runtime Behavior or the GCI interface does not impose any restrictions on this part. Any number of test cases can be run and each is commanded using the Supervisory functions.

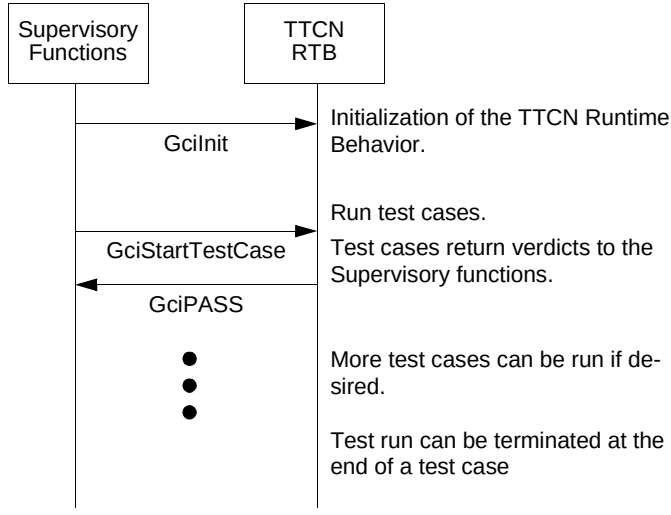

Figure 268: Start of test run

The test case at some point will try to send a message on some PCO. The TTCN Runtime Behavior then passes information to the Test Adaptation about the message to send and on which PCO to send it on. It is the responsibility of the Test Adaptation to properly encode the message and actually send it on some media (e.g. sockets, screen, printer port, pipe). Note that control is in the Test Adaptation until it returns to the TTCN Runtime Behavior. When control returns to the TTCN Runtime Behavior it assumes that the message was sent correctly and continues execution of the test case.

Eventually the test case will have emptied its possibilities to act and needs input from the environment. It therefore passes control to the Test Adaptation in order to take a snapshot of the IUT. Within the snapshot, the Test Adaptation then checks all PCO's for incoming messages and all timers for time-outs. If a message has arrived on a PCO, the Test Adaptation must decode the message and translate it into a proper GCI value. If a timer has timed out, the Test Adaptation must record which timer. The Test Adaptation acts as a filter between the IUT and the TTCN Runtime Behavior. Note that the actual reception of a message or time-out could be handled somewhere else (e.g. in an interrupt routine), only the official communication that the event has taken place must be done in SNAPSHOT.

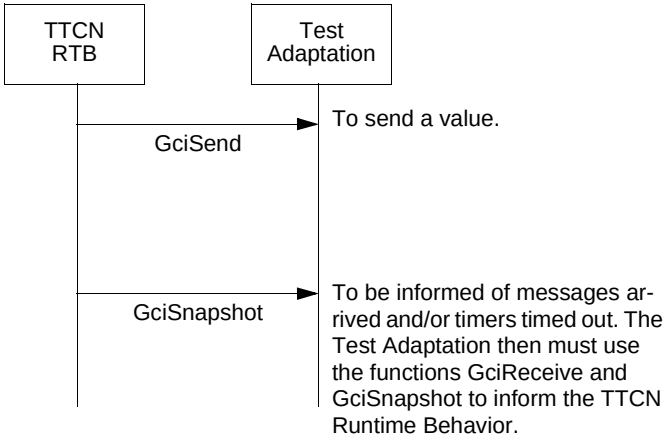

Figure 269: Send and Snapshot

Preliminary verdicts may be set during the test execution and when a final verdict is set, the test case returns to the Test Adaptation immediately. The Test Adaptation then has freedom to decide to continue the test run or not. A final verdict has meaning only in the context of the current test purpose. The meaning of a final verdict is not specified in the context of an entire collection of test cases. For example, when doing regression tests, all test cases should be run regardless of how many failed in order to get a complete picture of the status of the IUT.

Which Does What?

The table below summarizes the responsibilities of the two GCI parties, the TTCN Runtime Behavior and the Test Adaptation. It is meant to describe the model and basic assumptions being made.

TTCN Runtime Behavior	**Test Adaptation**
SEND: Builds the object to be sent and requests the actual sending from the Test Adaptation.	SEND: Receives the object that shall be sent and transfers this to the IUT. This might include encoding in some form.
RECEIVE: When a value is put on a PCO queue by the Test Adaptation, it remains there until a matching receive line is found in TTCN.	RECEIVE: Builds the received object (from the IUT) into a GCI value, which may include some form of decoding, and notifies the TTCN Runtime Behavior that the message has arrived.
Sets the verdict (based on the test case).	Treats the verdict (i.e. decides if the test run should continue or not).
Impl. of value representation.	Encoders/decoders.
Uses the value repr.	Uses the value repr.
Provides test cases. The test cases are sensitive to test case selection references.	Determines which test cases to run and in which order.
Uses send on messages.	Provides the send functionality.

TTCN Runtime Behavior	Test Adaptation
Uses SNAPSHOT to fix a view of the status of the IUT. Expects all changes in system status to be recorded in SNAPSHOT.	Reads system status in SNAPSHOT and records this through GCI interface for the TTCN Runtime Behavior.
Uses the LOG function to log TTCN Runtime Behavior.	Provides the LOG functionality, and also decides on what level logging should be done.

Case Studies

This section contains case studies of a send and a receive. For the case studies, we use an example PDU shown in Figure 270.

TTCN PDU Type Definition		
PDU Name: pdu1		
Field Name	**Field Type**	**Comment**
a	INTEGER	w value 19
b	BOOLEAN	w value FALSE
Comment: Example pdu for GCI case studies		

Figure 270: Example table

Case Study: SEND

Nr	Lbl	Statement Line	Cref	Comment
		`L ! CR`	`CR_c`	

The semantic of the TTCN send statement is as follows:

1. Build the SendObject using the constraint reference.
2. Execute the assignments.
3. Send the SendObject on the PCO.
4. Execute the timer operations.
5. LOG, at least the PCO and the SendObject must be logged.

The SendObject above is a temporary object containing the object to be sent. All steps above are initiated by the TTCN Runtime Behavior.

Steps 3 to 5 require communication with the environment (IUT). The TTCN Runtime Behavior will build a SendObject using the constraint CR_c above. Then it will call the Test Adaptation function Send. By doing this, the TTCN Runtime Behavior has ensured that the message gets sent on whatever PCO was stated. The Test Adaptation function Send then encodes the message using the transfer syntax of the protocol and then sends the message on the medium that represents the PCO. The arguments passed *to* Send is the PCO and the message in the GCI representation, and the *side effect* of Send is to send the message in protocol representation on the PCO in test system representation. Note that the encoding and sending on a PCO might very well be represented as a function call.

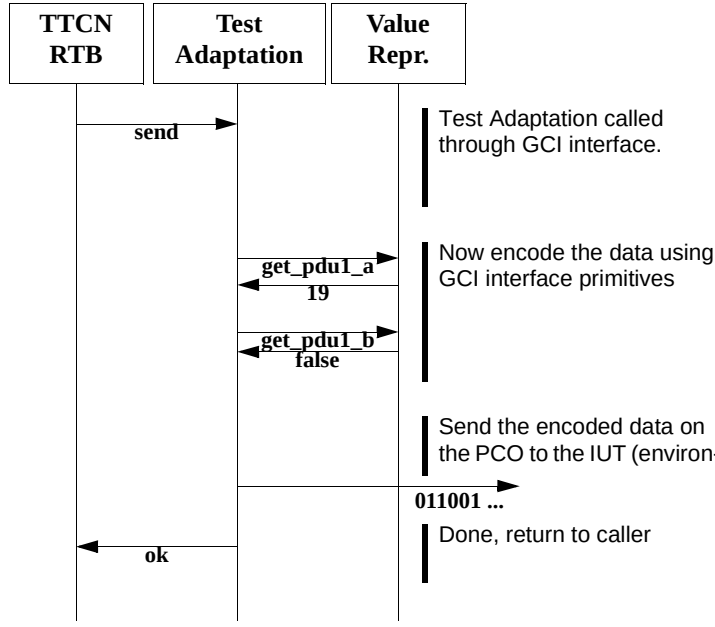

Figure 271: The send event

Case Study: RECEIVE

Nr	Lbl	Statement Line	Cref	Comment
		L ? CC	CC_c	

The receive is a little more complicated than the send. Send is initiated by the TTCN Runtime Behavior while receive is an internal event in the TTCN Runtime Behavior. The actual reception of messages is done in the Test Adaptation and these actions are communicated to the TTCN Runtime Behavior in SNAPSHOT. Note that there may be a difference between the reception of a message and the notification to the TTCN Runtime Behavior that the message has arrived. The TTCN Runtime Behavior calls the function SNAPSHOT and when it returns, the TTCN Runtime Behavior expects all time-outs to have been recorded and all received messages to be put on the correct PCO queues in the correct format. In this case we study the message event only and not the time-out.

> A message has been received from the IUT (not necessarily in SNAPSHOT) and the TTCN Runtime Behavior must be told that the message has been received. This shall be done in SNAPSHOT using the GCI function provided. The message and the PCO must be presented in a representation understood by the TTCN Runtime Behavior. Note that the message probably needs to be translated into the GCI value representation somewhere but again not necessarily in SNAPSHOT.

If SNAPSHOT does what is stated above, the TTCN Runtime Behavior will do the following on the receive line in the test case:

> The PCO queue is checked and if there is a message there, that message is matched against the constraint reference. If the message matches, it is removed from the PCO queue and the receive statement is considered to be TRUE, otherwise, the next alternative is checked.

In Figure 272, we assume that decoding is done in SNAPSHOT. The message is decoded using the value manipulating primitives of the GCI interface. When the message has been decoded into something known to the TTCN Runtime Behavior, it is easy to assign it to a PCO using the GCI function receive.

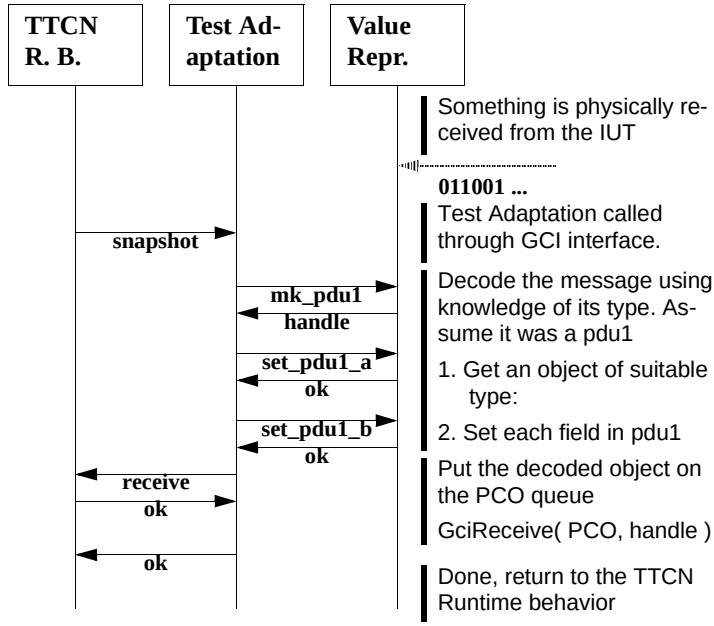

Figure 272: The receive event

Methods Used

This section contains general thoughts on methods used for designing the GCI interface. Choices have been made such as to provide reasonable trade-offs between speed and ease of use. An efficient implementation in C should be possible with the choices made.

Identifying Global Objects in TTCN/ASN.1

One problem is how to identify global objects in TTCN, PCOs, CPs, ASPs etc. There are a number of requirements that should be met:

1. Execution time:

   The TTCN behavior, operational and value interface functions are likely to be called many times in a time sensitive context which requires them to be fast. The management functions does not have this requirement.

2. Compilation time:

   The Test Adaptation and the TTCN Runtime Behavior are likely to be used together with a graphical interface (GUI) or integrated into a larger system. This integration should be possible without re-compiling the GUI or the larger system every time a change has been made in the ATS. This requires that dependencies between the ATS and the management interface implementation must be kept to a minimum.

There are at least three alternative solutions to be considered:

1. Straight name reference using target language semantics, i.e start test case “TC1” by writing the function call “TC1()” in C, and the value of the variable “TCVAR1” is expressed simply as TCVAR1

2. Assign an integer to each object. Symbolic names could then be used. The examples from above would then be:

```
#define TC1 192
#define TCVAR1 1211
Verdict = GciStartTestCase( TC1 );
Display( GciGetValue( TCVAR1 ));
```

3. Use string references.

```
Verdict = GciStartTestCase( TC1 );
Display( GciGetValue( TCVAR1 ));
```

Solution 1 gives the fastest execution but is very unsuitable for integration into a larger application. Solution 2 is at least possible to integrate into a GUI, and almost as fast as solution 1. Solution 3 is excellent for integration but gives slow execution.

In the GCI interface, we choose to use solution 3 (string references) in the management functions and solution 2 in the TTCN behavior functions. It would then be very easy to integrate an ETS into an already existing test system since the interface is string based while we still maintain speed in the execution of test cases.

A similar problem is how to identify fields in structured types. The simplest solution is to address them using integers field 0, field 1, etc., but then the Test Adaptation writer would get very little support from the compiler. From the Test Adaptation writers point of view, he might want to address the fields using names and also get type checking aid from the compiler. The Test Adaptation writer also wants to write generic functions for encode/decode. The GCI interface supports both

views, one view where substructures are identified by numbers, and one which in effect use name addressing.

Test Suite Operation Definitions

The TTCN Runtime Behavior requires that all test suite operations are defined as functions at run-time. Arguments to and return values from the test suite operation functions shall use the GciValue* format. The name of the test suite operation function shall be the same as the name of the test suite operation in TTCN.

Logging

The log will provide a view of a test run. Most things happening in the system will need to be logged. We have identified a number of requirements on the log functionality:

1. It should be possible to only log every event visible to the TTCN Runtime Behavior. I.e. the sending of a message should leave a note in the log while the internal behavior of the TTCN Runtime Behavior should not.
2. For debug purposes, it must be possible to report every event in the system.
3. The granularity of the log must be easy to change by the Test Adaptation writer. It should be possible to be quite specific when logging, i.e. log only sends and receives.

The method that the GCI interface suggests is massive logging. Everything is logged at any time and every type of event (send, receive etc.) is assigned a number. That way it is easy for the Test Adaptation writer to write a log function that only logs interesting log messages.

Value Representation

The GCI interface must provide a stable way of manipulating values. This is most important for the Test Adaptation writer to be able to access and build values in his encode and decode functions. The GCI interface proposes not to specify the value representation but rather the **methods** which can be used on it. The GCI interface specifies what the Test Adaptation writer is able to do with values. The reason for this is that most vendors supporting the GCI interface would like to have their own value representation within their TTCN Runtime Behavior, and the

representation used within TTCN has different requirements than the representation needed for the Test Adaptation.

Introduction to the GCI Interface

This section contains the description of the GCI interface in natural language. The interface functionality is sorted by responsibility. The management, behavior and value interfaces are interfaces to the TTCN Runtime Behavior. The operational interface is the interface to the Test Adaptation.

Management Interface

The management interface consists of those functions necessary for initiating and managing test runs. They provide an API to the ATS. These functions are used by the Supervisory functions to govern test runs.

Initiation of the TTCN Runtime Behavior

Must be called before the TTCN Runtime Behavior is used in any way. It will read test suite variables (using primitives in the operational i/f), set up test case selection references, test suite constants and any other initialization necessary. It should only be called once.

Start Test Case

Shall run a test case according to the dynamic behavior in 9646-3. Input shall be a test case name or test case group name. The test case or all the test cases in the test group shall then be run in the order which they were listed in the ATS. If the selection reference of a test case or test case group is false, that test case or test case group shall not be executed. Verdict shall be set and communicated back to the caller. In case several test cases have been run, the verdict shall be the most negative of the verdicts from each test case (if one test case is FAIL, the verdict would be FAIL, if all are PASS, the verdict would be PASS).

Start Test Component

This function works just line the function to start test cases, but starts test components for example when concurrent TTCN is used.

Test Case List

A list of names of test cases.

Test Case Group List

A list of names of test case groups.

Number of Timers and PCOs

Two functions are needed to return information about the amount of timers and PCOs in the system.

Information About Timers and PCOs

Help functions are needed to get some extra information about timers and PCOs. (For example name and type.)

Configuration Information

A set of functions is needed to retrieve information about configurations when running concurrent TTCN.

Accessing TTCN Values

Values of TTCN (and ASN.1) objects must be accessible from the Test Adaptation. A general access function will be provided. Information passed shall be an object name and the information passed back shall be the value of the object. Valid objects shall be test suite parameters, test case selection expressions, test suite constants, test suite variables and test case variables.

Behavior Interface

The behavior interface consists of functions used to notify the TTCN Runtime Behavior of events in the IUT. The functions are a formalism of what the TTCN Runtime Behavior needs to know about the status of the IUT. The functions are implemented in the TTCN Runtime Behavior and must be used in Snapshot.

Receive

Whenever a message has been received and decoded it must be passed to the TTCN Runtime Behavior in SNAPSHOT in order for it to match it with the constraint. The information passed shall be the PCO descriptor and the value. Note that the value passed in receive must be a GciValue*.

Time Out

Whenever a timer has timed out the TTCN Runtime Behavior must be notified of it in SNAPSHOT. The information passed shall be the timer descriptor.

Done

Whenever a test component has terminated its execution the TTCN Runtime Behavior needs to know about this. The information passed is the descriptor for the given test component.

Operational Interface

The operational interface consists of those primitives necessary for the TTCN Runtime Behavior to implement TTCN, i.e. Send, Snapshot, StartTimer etc. This part of GCI can be compared to POSIX. TTCN Runtime Behavior requires that the functions are defined.

Test Suite Parameters

The TTCN Runtime Behavior shall call the Test Adaptation once for each test suite parameter during the initialization of the TTCN Runtime Behavior. Information passed shall be a handle for the value, the parameter name and the PICS/PIXIT reference.

Test Suite Operations

Each test suite operation must be defined in the Test Adaptation. The name of the test suite operation function shall be the same as in the ATS, and the order of the parameters shall also be the same.

Create

When a test component needs to be created this function will be called from the TTCN Runtime Behavior.

Configuration

When different tests are run, different configurations might be needed. This function is called from the TTCN Runtime behavior to set up a configuration before the test goes on.

Snapshot

The status of the IUT must be read. Events in the IUT must be translated for the TTCN Runtime Behavior to be aware of them. The communicating interface between the TTCN Runtime Behavior and the IUT (environment) is made up of messages that has arrived and timers that have timed out. Therefore there are only two requirements on SNAPSHOT: 1) any received messages shall be recorded and 2) any timers that have timed out shall be recorded. The recording shall be done by using the provided GCI functions described in the Behavior i/f.

Send

This function is used by the TTCN Runtime Behavior to ensure that messages get sent. Send probably involves encoding and physical sending but might as well translate to encoding of some parts of the message and use of a lower layer service. The information passed to the function shall be a PCO descriptor and the value to be sent.

Start Timer

When the TTCN Runtime Behavior needs to start a timer. Information passed shall be the timer descriptor, the integer timeout duration and the timer unit.

Read Timer

Shall pass the current timer value back to the caller. Information passed to the function shall be a timer descriptor.

Cancel Timer

Shall stop a timer identified by a timer descriptor.

Log

Shall log events on an appropriate format. An integer specifying log message type and a log string shall be passed as parameters.

Value Interface

The interface to values is a simple API in which the user is allowed to build and access GciValues in an ordered way. The actual values used are not specified, only the methods that can be used on them are included. This way will allow vendors to have their own value representation within their TTCN Runtime Behavior and still conform to GCI.

Three types of value primitives are needed. Primitives to access structured values:

- Primitives to build and access components of structured values
- Primitives to find and set the type of values
- Primitives to convert base values to and from the value domain of the target language

Value primitives can be further divided in the groups:

- SEQUENCE values, which include SET values and also TTCN ASP, PDU and Struct types
- SEQUENCE OF values, which include SET OF values
- CHOICE values
- OBJECT IDENTIFIER values
- BASE values, integers, booleans, strings and reals

Please note that SET and SET OF values are treated as SEQUENCE and SEQUENCE OF values because there is no semantic difference at this level of abstraction. The unordered behavior of SETs is considered a decoder problem and left to the decoder writer.

GCI C Code Reference

This section is a code description of GCI. It describes what each function does and why it is used. Some of the functions must be implemented by you in your adaptation. See section "Completing the Adaptation" on page 1546.

Predefined Types

These are the GCI value types with their respective value set:

```
GciStatus = { GciNotOk, GciOk }

GciVerdict = { GciFail, GciInConc, GciPass, GciNone}

GciTimeUnit ={ Gcips, Gcins, Gcius, Gcims, Gcis, Gcimin }

GciTimerStatus = { GCIRUNNING, GCISTOPPED, GCIEXPIRED }

GciPCORole = { GciUT, GciLT }

GciPCOID = INTEGER

GciTimerID = INTEGER

GciPosition = <internal position value>

GciSnapshotStatus = { GciSnapshotEvent,
GciSnapshotNoEvent, GciSnapshotNotOk }
```

These are structured GCI value types with their respective members:

The general communication address type

```
typedef struct GciAddress {
  int     type;        /* Address type 0 - 100 is
                          reserved by IBM Rational */
  char*   buffer;      /* The address stored in a
                          buffer */
} GciAddress;
```

The general time value

```
typedef struct GciTime {
  unsigned long time_val;
```

```
  GciTimeUnit   unit;
} GciTime;
```

Management Interface

The management interface consists of the functions necessary for initiating and managing test runs. They provide an API to the TTCN runtime behavior.

`GciStatus GciInit()`

Initiates the TTCN Runtime Behavior. Must be called before any test cases are started.

`GciStatus GciExit()`

Shuts down the TTCN Runtime Behavior system. Usually called last before closing a test session.

`GciVerdict GciStartTestCase( const char* TCorTGName )`

Calling this function with a test case name will start and run the given test case. The verdict returned is the verdict set by the test case.

If the function is called with a test group name, it will start and run the given test group. The verdict returned is the product of the verdicts set in the test cases or test groups contained in the given test group. The individual verdicts from the different test cases or test groups have to be extracted from the log. The verdict algorithm for test groups is defined as follows:

1. The verdict is PASS if the verdict of every test case is PASS.
2. The verdict is INCONC if the verdict of at least one test case is INCONC and all others are PASS.
3. The verdict is FAIL if the verdict of at least one test case is FAIL.

If the given name is not a valid test case nor test group, the function will return `GciNotOk` and log the following message:

```
No such Test Case or Test Group as <name> to run!
```

GciVerdict GciStartTestComponent(char* TSName, GciValue args)**

This function works just like GciStartTestCase but is used to start a parallel test component (PTC) when using concurrent TTCN. TSName is the name of the Test Step to run in the PTC.

GciTCList* GciGetTestCaseList()

This function returns a list of all test case names (including test cases in test groups).

GciTCList GciGetTestCaseGroupList()

This function returns a list of all test group names (including test groups in test groups). List of character strings.

GciValue* GciGetValue(char* TTCNObjectName)

This function returns the TTCN value object given the object's name. If the object name does not exist, the function will return NULL and log the following message:

```
GciGetValue: Could not find <name>! NULL returned
```

If the object name is a TTCN name, but not an object (variable, constant, etc...) the function will return NULL and log the following message:

```
GciGetValue: <name> not an instance! NULL returned
```

int GciGetNoOfTimers( )

Returns the number of timers in the system.

int GciGetTimer(int index)

Returns the identifier of the given timer index.

char* GciGetTimerName(int timer)

Returns the name of the given timer.

int GciGetTimerIndex(int desc)

Returns the index of the given timer descriptor.

int GciGetNoOfPCOs( )

Returns the number of PCOs in the system.

int GciGetPCO(int index)

Returns the descriptor of the given PCO index.

char* GciGetPCOName(int pco)

Returns the name of the given PCO.

int GciGetPCOIndex(int desc)

Returns the index of the given PCO descriptor.

int GciGetPCOType(pco)

Returns the type of a given PCO.

GciStatus GciGetPCORole(int pco, GciPCORole *role)

This function finds the role of PCO from its ID. Returns GciOk and assigns the role value to '`role`' when successful. Returns GciNotOk when the function fails.

GciStatus GciClearAllPCOSAndCPS(void)

This function clear all PCOs and CPs queues. There is no need to call this function before starting a Test Case as the queues are cleared automatically.

int GciGetNoOfComponents(GciConf conf)

Returns the number of components in the given configuration.

GciComponent* GciGetComponent(GciConf conf, int index)

Returns the indexed component in the given configuration.

char* GciGetComponentName(GciComponent* conp)

Returns the name of the given component.

int GciGetComponentType(GciComponent* conp)

Returns the type of the given component (GciMTC or GciPTC).

int GciGetComponentDescriptor(GciComponent* conp)

Returns the descriptor of the given component.

char GciGetComponentCPs(GciComponent* conp)**

Returns the CPs used by the given component.

char GciGetComponentPCOs(GciComponent* conp)**

Returns the PCOs used by the given component.

Behavior Interface

The behavior interface consists of the functions used to notify the TTCN Runtime Behavior of events in the IUT. The functions are a formalism of what the TTCN Runtime Behavior needs to know about the status of the IUT. The functions are implemented in the TTCN Runtime Behavior and must be used in Snapshot.

GciStatus GciTimeout(int timerd)

This function will change the status of the internal timer indexed by the timer descriptor `timerd`. The timer will be marked as timed out.

GciStatus GciReceive(int pcod, GciValue* value)

This function will insert the received object into the internal PCO queue indexed by the PCO descriptor `pcod`.

Operational Interface

The operational interface consists of the functions necessary for the TTCN Runtime Behavior to communicate with the IUT, i.e. the dependencies on the protocol and test environment. It implements functionality for Send, Snapshot, StartTimer, etc. The TTCN Runtime Behavior requires that the functions are defined in the adaptation.

GciValue* GciReadTSPar(char* name, char* pRef)

The user has to implement how to read the test suite parameters. This code will be called one time for each test suite parameter in the system. Here `name` is the name of the test suite parameter and `pRef` is the PICS/PIXIT field (ex. file). The value returned by this function must be a pointer to a valid `GciValue` structure which can be successfully used by the TTCN runtime behavior. If for any reason this could not be done, NULL should be returned.

GciStatus GciConfig(GciConf conf)

When using concurrent TTCN the user is responsible for creating the configurations to be used for a given test. The creation of those configurations is done in this function using a set of help functions in the management interface to traverse the information.

GciStatus GciSnapshot()

This is a very important function that the user has to implement. This function is called from the run-time behavior when it needs input from the test environment (timers and/or PCO's).

- Communication lines (PCOs) must be checked. If something has been received, we must decode the message, build a receive object and insert the object into the correct, internal PCO queue by using the `GciReceive` function with appropriate PCO descriptor. The GCI Value Interface is used to build the object(s).
- Timers must be checked and their status must be reported to the TTCN run-time system. If the user uses the simple adaptation template he/she must self keep track of time and use `GciTimeout` to mark a timer as timed out. If the user uses the timers adaptation template he/she can use the `AdSetTime` function (see below) to have this work done automatically.

GciSnapshotStatus GciPollingSnapshot()

This function is similar to the `GciSnapshot` function.

The main difference is that `GciPollingSnapshot` should poll the PCOs and Timers in the system, check the termination of the different test components, but should not stop and wait for any event above. If no events are done, `GciPollingSnapshot` should return, as opposed to `GciSnapshot`, that can be designed to stop and wait for an event to occur.

There is also a difference in the return value, `GciPollingSnapshot` will show if any event has occured or not, compared to `GciSnapshot`, where the return means that any event occured.

Return Value: `GciSnapshotStatus`

- `GciSnapshotEvent`, if everything in snapshot went fine and any event occured.
- `GciSnapshotNoEvent`, if everything in snapshot went fine and no event occured.
- `GciSnapshotNotOk`, if something catastrophic occured while doing the snapshot.

For backward compatibility with previous versions of adaptation, this function does not have to be implemented. For use with previous versions a dummy implementation exists in the TTCN static library which prevent linker errors.

`GciStatus GciSend(int pcod, GciValue* value)`

The user is responsible for implementing the send functionality. This involves identifying a given PCO and encoding the value before sending the message on that PCO.

`GciStatus GciStartTimer(int timerd, long duration, int unit)`

To start a timer the TTCN runtime behavior will call this function. Note that timer duration value is optional in TTCN but is always present here.

`GciStatus GciCancelTimer(int timerd)`

This function is called to stop the given timer. It should have the effect that the appropriate timer representation in the adaptation is stopped.

`long GciReadTimer(int timerd)`

This function is called when a timer is read. It must return the current timer value.

`GciStatus GciCreate(int ptc, char* tree, GciValue* args)`

This functions is called when a PTC is to be created to run a given dynamic behavior with the given arguments (concurrent TTCN).

`GciValue* <TS_Op>( <Arguments> )`

Every test suite operation must have this function defined. The name shall be the same as in the ATS and arguments must match the parameters in the ATS.

`GciStatus GciImplicitSend( GciValue* value )`

This function is called by the run-time behavior when an Implicit Send Event occurs in the test suite. It is up to the adaptation writer to define its exact implementation.

```
GciStatus GciLog(int logId, char* LogString)
```

The user has to implement parts of the logging facility. As the GCI document describes, all log identifiers are already implemented. User may change the logging for any event like it is desired. The log identifiers (identifies the type of log message) in this function should NOT be changed as they follow the values listed in the GCI document. The TTCN Runtime Behavior uses this function with these identifiers for logging.

logId	Description	logString must contain:
`Msg`	General message	Any information
`StartTC`	Start test case	The name of the test case
`StopTC`	Stop test case	The name of the test case
`Verdict`	Final verdict set	The verdict set
`PVerdict`	Prel. verdict set	The preliminary verdict set
`Match`	Line tried matches	Line number
`NoMatch`	Line tried does not match	Line number
`SendE`	Send Event	Line number The PCO name The type of message sent Constraint name and sent value
`RecE`	Receive Event[a]	Line number The PCO name The type of message received Constraint name and received value
`OtherE`	Otherwise Event	Line number The PCO name The type of message received Received value

logId	Description	logString must contain:
TimeoutE	Timeout Event	Line number The timer name
Assign	Assignment	Line number The left hand side The right hand side (textually)
StartT	Start timer	Line number The timer name The timer duration
CancelT	Cancel timer	Line number The timer name
ReadT	Read timer	Line number The timer name The timer value
Attach	Attachment: enter or exit test step	Line number Name of the attached Test Step Event type: Enter Test Step/Exit Test Step Test Step actual parameters
ImplSend	Implicit send	The sent value
Timeout	Timeout[b]	The timer descriptor number
Error	The error message	Error message text
Create	CREATE construct has been executed	Line number Component name Test Step name Test Step actual parameters
Done	DONE Event	Line number Component name(s)
Activate	Activate Event	Line number List of Defaults

logId	Description	logString must contain:
`MatchFailed`	A received line does not match.	Expected constraint name When logging is verbose, also constraint value and received value
`BeginMatchType`	When logging is verbose: Check that types and names have the constraint and incoming value or their corresponded parts, before trying to match them.	Constraint and incoming value: name, type name, base type name, class and tag.
`SuccMatchType`	When logging is verbose: The constraint and incoming value or their corresponded parts have been matched successfully.	Constraint name and type.
`FailMatchType`	When logging is verbose: The constraint and incoming value or their corresponded parts have not been matched.	Constraint name and type.
`SuccMatchValue`	When logging is verbose: The constraint and incoming value, or their corresponding parts, that were looked upon as simple values (the match process has not looked inside), have been matched successfully.	Constraint and incoming value

logId	Description	logString must contain:
GciLogFailMatchValue	When logging is verbose: The constraint and incoming value, or their corresponding parts, that were looked upon as simple values (the match process has not looked inside), have not been matched	Constraint and incoming value
FailAssignSignal	Generated by the SDL and TTCN Integrated Simulator when impossible to assign the incoming signal to the GCI value. The type on SDL and TTCN side thus has different descriptions	Part of incoming value that was assigned successfully to GCI value.
StartPTC	PTC has started	Test Step name
StopPTC	PTC has finished	Test Step name
CallQueue	When log option “Show executable path” is on, show Test Steps stack when new Test Step is started	Test Steps stack

a. Logging that a receive line matches.

b. Note this is low level logging done when the Test Adaptation writer calls GciTimeout

Value Interface

The interface to values is a simple API in which the user is allowed to build and access GciValues in an ordered way. The actual values used are not specified, only the methods that can be used on them are included. This way will allow vendors to have their own value representation within their TTCN Runtime Behavior and still conform to GCI.

Base Types/Values

These functions are used to transform actual values into the GCI representation. The interface is on base types only, so TTCN simple types are not visible in the interface.

```
GciValue* GciMkINTEGER( long num )
long GciGetINTEGER( GciValue* value )
```

These functions are used for INTEGER values and any simple type values of the base type INTEGER. These functions may be used for INTEGER values in the range of -2^31..2^31-1. Compare these functions with the GciMkBigINTEGER and GciGetBigINTEGER which are more universal and can be used for any unlimited INTEGER value.

Note:

The TTCN Suite RTS supports INTEGER values in the range of:
-2^32-1..2^32-1

```
GciValue* GciMkBigINTEGER(const char *value)
char* GciGetBigINTEGER(GciValue* value, char *buffer)
```

These functions should be used instead of GciMkINTEGER and GciGetINTEGER when the value is unknown or larger than what is allowed for the type long. The buffer should be large enough to store the given value (see the function GciGetBigINTEGERMaxSize).

The GciMkBigINTEGER function returns a new created value. The function will return NULL if there is an error.

A successful call of GciGetBigINTEGER will return a buffer. The function will return NULL if there is an error.

```
int GciGetBigINTEGERMaxSize(GciValue *value)
```

Returns the size of a buffer that is large enough for retrieving the character value of a value of the type INTEGER or ENUMERATED.

```
Bool GciIsBigINTEGERFitsLong(GciValue *value)
```

Returns GcTRUE when a value of the type INTEGER or ENUMERATED can be retrieved in a value of the type long (using the GciGetINTEGER function). The function will otherwise return GcFALSE.

```
GciValue* GciMkBOOLEAN( int bool )
int GciGetBOOLEAN( GciValue* value)
```

Used for Boolean values and for any simple type values with the base type Boolean.

```
GciValue* GciMkREAL(int mantissa, int base, int exponent)
GciReal GciGetREAL( GciValue* value)
```

Used for values of type Real and for any simple type values with the base type Real.

```
GciValue* GciMkBIT_STRING( const char* str )
char* GciGetBIT_STRING( GciValue* value)
```

Used for `bit string` values and for any simple type values with the base type `bit string`.

```
GciValue* GciMkHEXSTRING( const char* str )
char* GciGetHEXSTRING( GciValue* value)
```

Used for hex string values and for any simple type values with the base type hex string.

```
GciValue* GciMkOCTET_STRING( const char* str )
char* GciGetOCTET_STRING( GciValue* value)
```

Used for octet string values and for any simple type values with the base type octet string.

```
GciValue* GciMkNumericString( const char* str )
char* GciGetNumericString( GciValue* value)
```

Used for values numerical strings and for any simple type values with the base type numerical string.

```
GciValue* GciMkPrintableString( const char* str )
char* GciGetPrintableString( GciValue* value)
```

Used for Printable string values and for any simple type values with the base type Printable string.

```
GciValue* GciMkTeletexString( const char* str )
char* GciGetTeletexString( GciValue* value)
```

Used for Teletex string values and for any simple type values with the base type Teletex string.

```
GciValue* GciMkVideotexString( const char* str )
char* GciGetVideotexString( GciValue* value)
```

Used for Videotex string values and for any simple type values with the base type Videotex string.

```
GciValue* GciMkVisibleString( const char* str )
char* GciGetVisibleString( GciValue* value)
```

Used for Visible string values and for any simple type values with the base type Visible string.

```
GciValue* GciMkIA5String( const char* str )
char* GciGetIA5String( GciValue* value)
```

Used for IA5string values and for any simple type values with the base type IA5string.

```
GciValue* GciMkT61String( const char* str )
char* GciGetT61String( GciValue* value)
```

Used for T61string values and for any simple type values with the base type T61string.

```
GciValue* GciMkISO646String( const char* str )
char* GciGetISO646String( GciValue* value)
```

Used for ISO646string values and for any simple type values with the base type ISO646string.

```
GciValue* GciMkGraphicalString( const char* str )
char* GciGetGraphicalString( GciValue* value)
```

Used for Graphical string values and for any simple type values with the base type Graphical string.

```
GciValue* GciMkGeneralString( const char* str )
char* GciGetGeneralString( GciValue* value)
```

Used for General string values and for any simple type values with the base type General string.

```
GciValue* GciMkENUMERATED( int value )
int GciGetENUMERATED( GciValue* value)
```

Used for Enumerated values and for any simple type values of the base type Enumerated. These functions may be used with integer values of ENUMERATED values that are in the range of:

```
-2^31..2^31-1
```

The functions GciMkBigENUMERATED and GciGetBigENUMERATED are more universal and may be used for any unlimited ENUMERATED values.

Note:

The TTCN Suite RTS supports ENUMERATED values in the range of:
-2^32-1..2^32-1

```
GciValue* GciMkBigENUMERATED(const char *enumeration)
char* GciGetBigENUMERATED(GciValue* enumerated_object,
char *buffer)
```

These functions should be used instead of GciMkENUMERATED and GciGetENUMERATED when the value is unknown or larger than what is allowed for the type int. The buffer should be large enough to store the value (see the function GciGetBigINTEGERMaxSize).

The function GciMkBigENUMERATED returns a new created value. The function will return NULL if there is an error.

The function GciGetBigENUMERATED function returns a buffer when successful. The function will return NULL if there is an error.

```
GciValue* GciMkCHOICE(const char* name, GciValue* value)
GciValue* GciGetCHOICE( GciValue* value)
char* GciGetCHOICEName( GciValue* value)
```

Used for Choice values and for any simple type values with base type Choice.

```
GciValue* GciMkOBJECT_IDENTIFIER()
int GciOBJECT_IDENTIFIERSize( GciValue* value)
GciValue* GciAddOBJECT_IDENTIFIERComponent(
   GciValue* value, int comp)
int GciGetOBJECT_IDENTIFIERComponent( GciValue* value,
   int index)
```

Used for Object identifier values and for any simple type values with base type Object identifier.

```
GciValue* GciMkObjectDescriptor( const char* str )
char* GciGetObjectDescriptor( GciValue* value)
```

Used for ObjectDescriptor values and for any simple type values with base type ObjectDescriptor.

```
GciValue* GciMkNULL( )
int GciGetNULL( GciValue* value)
```

Used for Null type values and for any simple type values with base type Null type.

```
GciValue* GciMkANY( GciValue* value )
GciValue* GciGetANY( GciValue* value)
```

Used for ANY values and for any simple type values with base type ANY.

```
GciValue* GciMkR_TYPE( int value )
int GciGetR_TYPE( GciValue* value)
```

Used for R_Type values and for any simple type values with base type R_Type.

```
GciValue* GciMkPDU( GciValue* value )
GciValue* GciGetPDU( GciValue* value)
```

Used for PDU values and for any simple type values with base type PDU.

Base Functions

```
int GciGetType( GciValue* val )
```

Shall return the type of a value. The type is represented as the number used to identify global objects, see "Identifying Global Objects in TTCN/ASN.1" on page 1495. The function is valid for all values, but some values may be untyped in which case the function returns -1. These integer values used to identify all predefined and user-defined types are listed in the "type_gen.h" file generated by the TTCN C Code Generator. There is a function to get the symbolic type name from the integer value ("const char* GciGetTypeNameString(int TypeID)" on page 1519). A reverse function exists to get the integer type value from the symbolic name ("int GciGetTypeDescriptor(const char *type_name)" on page 1519).

```
GciValue* GciSetType( int type, GciValue* val )
```

Shall set the type of a value. The type is represented as the number used to identify global objects, see "Identifying Global Objects in TTCN/ASN.1" on page 1495. Valid for all values. Returns the input value with type set.

int GciGetBaseType (GciValue* val)

Shall return the base type (always one of the predefined types) of a value. The type is represented as the number used to identify global objects, see "Identifying Global Objects in TTCN/ASN.1" on page 1495.

const char* GciGetTypeNameString(int TypeID)

Shall return the symbolic name of a type with integer value `TypeID`.

int GciGetTypeDescriptor(const char *type_name)

Shall return the integer value for the type with the symbolic name `type_name`.

Value Management

The functions are divided into two meta sets derived from ASN.1: The `sequence` and the `sequence of`, corresponding to `struct` and `array` in C. The choice type of ASN.1 is not represented as a meta class because all values in the GCI value representation can be typed and therefore is the choice value implicit in GCI.

The functions only works within their intended set (e.g. GciSetField(GciMkSEQUENCE(2), 1, GciMkINTEGER()) is well defined but GciSetField(GciMkSEQUENCEOF(), 0, GciMkINTEGER()) is not defined and certainly is unpredictable.

Sequence and Set Types/Values

GciValue* GciMkSEQUENCE(int size)

Creates a sequence value with size children.

GciValue* GciSetField(GciValue* seq, int index, GciValue* fld)

Sets the field identified by index to the given value. Indices start at 1. The function is undefined for indices greater than the size of the sequence.

GciValue* GciGetField(GciValue* seq, int index)

Returns the field identified by index. Indices start at 1. The function is undefined for indices greater than the size of the sequence.

`int GciSeqSize( GciValue* seq )`

Returns the number of fields declared in the sequence *seq*.

Sequence of and Set of Types/Values

`GciValue* GciMkSEQUENCEOF()`

Creates a sequence of value.

`GciValue* GciAddElem( GciValue* seqOf, GciValue* elem )`

Adds the element *elem* to the end of sequence of *seqOf*.

`GciValue* GciGetElem( GciValue* seqOf, int index )`

Returns the element number *index* of the sequence of *seqOf*. Indices start at 0. The function is undefined for indices greater than current size.

`int GciSeqOfSize( GciValue* seqOf )`

Returns the current number of elements in *seqOf*.

Examples

This section contains examples of how the mapping between TTCN/ASN.1 and their GCI representation could be done. The examples use a conceptual model for encoding/decoding, no error handling is done and no attention is paid to the fact that some functions would use pointers because of allocation issues.

Global objects (PCOs and types) are identified with an unique number. This number is given a symbolic reference which is its TTCN name with a *D* for Descriptor appended to the end of it. The number for the PCO *L* is therefore referenced as *LD*.

Encoding/Decoding Examples

Each example consists of a table and the corresponding encode (and/or decode) functions. The examples focus on the value representation so the transfer syntax is simple: Each value is preceded by a header. The header contains the type of the value (as a number) and in some cases its length (element count, not size in bytes), in real ASN.1, the header would be built using tags. The header is written/read using primitives

BufWriteType, BufWriteSeqOfSize, etc. They are not encode/decode primitives but rather buffer primitives.

An encode function is a function that translates the GCI value onto a buffer. A decode function is one that reads a value from a buffer and builds a value in the GCI representation. Encoding functions are called from SEND and decoding functions are called from SNAPSHOT. The buffer has type *Buffer* and could be anything behaving as a sequence of bytes. The primitives BufReadInt, BufReadBool are used to read and write GCI basic values.

ASN.1 SEQUENCE Type

ASN.1 PDU Type Definition
PDU Name: T1
Comment: Example PDU for GCI examples
Type Definition
`SEQUENCE {` `  a INTEGER,` `  b BOOLEAN` `}`

Figure 273: Example

Encode

```
void EncodeT1( Buffer buf, GciValue* v)
{
  BufWriteType( buf, GcT1D );
  BufWriteInt( buf, GciGetField( v, 1 ));
  BufWriteBool( buf, GciGetField( v, 2 ));
}
```

Decode

```
void DecodeT1( Buffer buf, GciValue** v)
{
  int i;

  if ( BufReadType( buf ) != GcT1D )
    Error();
  *v = GciMkSEQUENCE( 2 );
  GciSetType( GcT1D, *v );
```

```
  i = BufReadInt( buf );
  GciSetField( *v, 1 , GciMkINTEGER( i ) );

  i = BufReadBool( buf );
  GciSetField( *v, 2 , GciMkBOOLEAN( i ) );
}
```

ASN.1 SEQUENCE OF Type

ASN.1 PDU Type Definition
PDU Name: T2
Comment: Example PDU for GCI examples
Type Definition
`SEQUENCE OF T1`

Figure 274: Example

Encode

```
void EncodeT2( Buffer buf, GciValue* v )
{
  int i;

  BufWriteType( buf, GcT2D );
  BufWriteSeqOfSize( buf, GciSeqOfSize( v ) );
  for (i = 1 ; i <= GciSeqOfSize( v ) ; i++ )
    {
      EncodeT1( buf, GciGetElem( v, i ) );
    }
```

Decode

```
void DecodeT2( Buffer buf, GciValue** v )
{
  int i, seqOfSize;
  GciValue* elem;

  if ( BufReadType( buf ) != GcT2D )
    Error();

  *v = GciMkSEQUENCEOF();
  GciSetType( GcT2D, *v );

  seqOfSize = BufReadSeqOfSize( buf );
```

```
  for ( i = 1 ; i <= seqOfSize ; i++ )
    {
      DecodeT1( buf, &elem );
      GciAddElem( *v, elem );
    }
}
```

ASN.1 CHOICE

ASN.1 PDU Type Definition
PDU Name: T3
Comment: Example PDU for GCI examples
Type Definition
`CHOICE {` `  c1 T1,` `  c2 T2` `}`

Figure 275: Example

Encode

```
void EncodeT3( Buffer buf, GciValue* v )
{
  const char *name = GciGetCHOICEName(v);
  GciValue *member = GciGetCHOICE(v);

  BufWriteType( buf, GcT3D );
  BufWriteString( buf, name );

  if(strcmp(name, "c1") == 0)
      EncodeT1( buf, v );
  else if(strcmp(name, "c2") == 0)
      EncodeT2( buf, v );
  else
      Error();
}
```

Decode

```
void DecodeT3( Buffer buf, GciValue** v )
{
  const char *name;
  GciValue *member;

  if ( BufReadType( buf ) != GcT3D )
    Error();
```

```
  name = BufReadString( buf );

  if(strcmp(name, "c1") == 0)
      DecodeT1( buf, &member );
  else if(strcmp(name, "c2") == 0)
      DecodeT2( buf, &member );
  else
      Error();

  *v = GciMkCHOICE((char *)name, member);
  GciSetType( GcT3D, *v );
  BufFreeString(name);
}
```

In-Line ASN.1 Type

ASN.1 PDU Type Definition
PDU Name: T4
Comment: Example PDU for GCI examples
Type Definition
SEQUENCE {   c1 T1,   c2 SEQUENCE {   c1 INTEGER,   c2 T2   } }

Figure 276: Example

Encode

```
void EncodeT4( Buffer buf, GciValue* v )
{
  GciValue* tmp;

  BufWriteType( buf, GcT4D );
  /* Encode first field */
  EncodeT1( buf, GciGetField( v, 1 ));
  /* Now encode inline type definition */
  tmp = GciGetField( v, 2 );
  BufWriteInt( buf, GciGetField( tmp, 1 ));
  EncodeT2( buf, GciGetField( tmp, 2 ));
}
```

Decode

```
void DecodeT4( Buffer buf, GciValue** v)
{
  int i;
```

```
  GciValue* tmp;
  GciValue* tmpseq;

  if ( BufReadType( buf ) != GcT4D )
    Error();

  *v = GciMkSEQUENCE( 2 );
  GciSetType( GcT4D, *v );

  DecodeT1( buf, &tmp );
  GciSetField( *v, 1, tmp );
  tmpseq = GciMkSEQUENCE( 2 );
  i = BufReadInt( buf );
  GciSetField( tmpseq, 1, GciMkINTEGER( i ) );
  DecodeT2( buf, &tmp );
  GciSetField( tmpseq, 2, tmp );
  GciSetField( *v, 2, tmpseq );
}
```

TTCN Examples

`myQueue` below is the Test Adaptation writers own representation of the PCO queue(s). In this example there is only one PCO, called `L` (`Ld` for its number). Note that the number `Ld` can be any number (most certainly not zero).

Snapshot Example

Snapshot must read the status of the IUT and tell this to the TTCN Runtime Behavior.

```
void GciSnapshot()
{
  GciValue* v;

  /* Check if anything has arrived,  */
  /* This would be a while statement */
  /* in a blocking context           */
  if ( ! myQueue[ 0 ].empty )
    {
      switch ( BufPeekType( myQueue[0].buf ))
        {
        case GcT1D:
          DecodeT1( myQueue[0].buf, &v );
          break;
        case GcT2D:
          DecodeT2( myQueue[0].buf, &v );
          break;
        default:
          Error();
        }
```

```
      GciReceive( GcLD, v );
    }

  /* Nothing has happened. */
}
```

Send Example

For the send example the following ASP table is used to show an API view of encode.

ASN.1 ASP Type Definition
ASP Name: TCONreq
Comment: Example ASP for GCI examples
Type Definition
SEQUENCE {   num INTEGER, -- sequence number   pdu T1 -- Embedded pdu }

Figure 277: Example

```
/* Two examples of send functionality */
GciStatus GciSend( int pcoDescr, GciValue* msg )
{
  if ( pcoDescr == GcPcoToSocketD )
    {
      /* Encode first */
      if ( GciGetType( msg ) == GcT1D )
        {
          EncodeT1( buf, msg );
          BufSocketSend( buf );
        }
    }
  else if ( pcoDescr == GcPcoToAPID )
    {
      if ( GciGetType( msg ) == GcTCONreqD )
        {
          Buffer pdu;
          EncodeT1( pdu, GciGetField( msg, 2 ));
          /* Call to lower layer */
          T_CONreq( GciGetField( msg, 1 ), pdu );
        }
    }
```

EGci Value Construction and Functions

The GCI interface has been defined as a base for executable test suite adaptation. One part of this interface covers values, how to build them, access them, etc. While this interface was not enough, a set of functions has been added with the EGci prefix so that the GCI functions (a set defined by a standard) was not changed. The purpose of this section is to describe this paradigm of value construction and the current EGci functions available.

Value Construction

The major difference in value handling is how values are constructed. Values are either created by the GciMk-prefixed functions, followed by a GciSetType call, or value are created by a call to the EGciMkValue function. The run time system is compatible with both alternatives but the latter is preferred. The difference is that the GciMk-function creates untyped values of a given predefined type (SEQUENCE, SET, INTEGER, etc.) while the EGciMkValue takes the type descriptor of the user-defined type and creates the complete value structure with correct types throughout the whole value structure. Values of type SEQUENCE OF, SET OF and CHOICE cannot be fully instatiated since the size/choice of the value is not known at code generation time. Elements of the SEQUENCE/SET type are appended explicitly and CHOICE values are also selected explicitly.

The procedure is to create the value structure (with uninitialized leaf values) and then extract the proper value (container) through ordinary field access and extraction functions. Then the value is assigned using the EGciAssign function. When available, for simple non-structured values, EGciSet/GciSet-functions can also be used on the extracted values.

Below you will find two alternatives for creating a value given the following type:

```
T ::= SEQUENCE
{
  a SEQUENCE {
     b MyINTEGER
  },
  c MyINTEGER
}

MyINTEGER ::= INTEGER
```

```
v T := { a { b 17 }, c 42 }
```

Alternative 1 – Using GciMkSEQUENCE and GciSetType

The individual values through out the structured value have to be created and the correct type set. It is also impossible to set the correct type for the inlined types since they are unknown.

```
...
value = GciMkSEQUENCE(1);
GciSetType(value, GcTD);

inner_seq = GciMkSEQUENCE(1);
/* GciSetType(inner_seq, ?); This is not possible
since the inlined type is not available to the user.
A generated no-name type exists but is not known. So
the SEQUENCE will be untyped (only a SEQUENCE). This
is not a problem with alternative 2. */

b = GciMkINTEGER(17);
GciSetType(b, GcMyINTEGERD);
GciSetField(inner_sequence, 1, b);
c = GciMkINTEGER(42);
GciSetType(c, GcMyINTEGERD);
GciSetField(value, 1, inner_seq);
GciSetField(value, 2, c);
...
```

Alternative 2 – Using EGciMkValue (Recommended Approach)

Using the EGciMkValue function makes it somewhat more readable, but what is more important is that the final value has the correct type throughout the structure (all done by the generated type information used in the call to EGciMkValue). All field names are also correct.

```
...
value = EGciMkValue(GcTD);
/* With this call the whole structure is created and
the basic leaf values are only extracted and set
("filled in"). */

tmp = GciGetField(value, 1);
tmp = GciGetField(tmp, 1);
EGciSetINTEGER(tmp, 17);

tmp = GciGetField(value, 2);
EGciSetINTEGER(tmp, 42);
...
```

Available Functions

GciValue * EGciMkValue(int)

Takes the generated type identifier constant `Gc<type>D` and creates a proper value using all available type information generated. This function is faster than the `EGciMkValueFromTypeName` but the type identifier constants can potentially change their numeric value if new types are added to the test suite. Any depending encoder/decoders have to be recompiled if the generated type information changes. If generation dependent information is required, the `EGciMkValueFromTypeName` should be used.

Example 292 ----------

Given the type `MyType`, the call for constructing a value would be `EGciMkValue(GcMyTypeD)`.

GciValue * EGciMkValueFromTypeName(const char* tname)

Same as `EGciMkValue` but it takes the (bare) name of the type.

Example 293 ----------

Given the type `MyType` the call for constructing a value would be `EGciMkValueFromTypeName("MyType")`.

----

void EGciRmValue(GciValue *value)

This function deletes a constructed value.

GciStatus EGciAssign(GciValue *destination, GciValue *source)

Given the two values, which must be instantiated values of the same type, the source is assigned to the destination value.

GciValue * EGciGetFieldByName(GciValue *val, const char* name)

This function returns the named member of a SEQUENCE, SET or CHOICE value. If the value given by the parameter `val` has no member with the name given by the parameter `name`, the return val-

ue is NULL. Note that the return value is not a copy of the value member, so if any operations are applied to the return value, this will directly effect the member value.

GciStatus EGciSetMemberByName(GciValue *val, const char* name, GciValue *mem_val)

Sets the named member of a SEQUENCE, SET or CHOICE value to the given value (mem_value). This is the same as doing an extraction followed by an assignment.

GciStatus EGciSetEmptySET_OF(GciValue *value)

Sets the value to the defined state. That is, it is an empty SET OF value.

GciStatus EGciSetEmptySEQUENCE_OF(GciValue *value)

Sets the value to the defined state. That is, it is an empty `SEQUENCE OF` value.

GciStatus EGciSetOMIT(GciValue *value)

Sets the given optional value as omitted.

GciStatus EGciSetBOOLEAN(GciValue *value, Bool v)

Sets a constructed value of the (base) type `BOOLEAN` to the given boolean value.

GciStatus EGciSetSTRING(GciValue *value, const char *)

Sets a constructed value of any string base type (`BITSTRING`, `OCTETSTRING`, `IA5String`, etc.) to the given string value.

GciStatus EGciSetINTEGER(GciValue *value, int number)

This function sets a constructed value of the (base) type `INTEGER` to the value given by the `number` parameter. This function may be used for `INTEGER` values in the range of `-2^31..2^31-1`. The function `EGciSetBigINTEGER` is more universal and is used for unlimited `INTEGER` values.

Note:

In the TTCN Suite RTS there is support for `INTEGER` values in the range of:
`-2^32-1..2^32-1`

GciStatus EGciSetBigINTEGER(GciValue *value, const char *number)

This function sets a constructed value of the (base) type `INTEGER` to the given integer value.

This function should be used instead of `EGciSetINTEGER` when the value is unknown or larger than what is allowed for the type `int`.

GciStatus EGciSetNULL(GciValue *value)

This function sets a constructed value of the (base) type `NULL` to a `NULL` value.

GciValue * EGciSetENUMERATEDByName(GciValue *val, const char* enum_name)

This function sets the actual value of the ENUMERATED value to one of its declared named numbers. For example, EGciSetENUMERATEDByName(gcivalue, “foo”), where “foo” is one of the named numbers in the type.

Example 294 ----------

```
EType ::= ENUMERATED { first, second, third }

GciValue *eval = EGciMkValue(GcETypeD);
EGciSetENUMERATEDByName(eval, "second");
```

----

const char * EGciGetENUMERATEDName(GciValue *value)

Retrieves the name of the current value.

Example 295 ----------

Continuing Example 294, a call to `EGciGetENUMERATEDName(eval)` would return the string `"second"`.

GciValue * EGciGetChoiceMemberByName(GciValue *value, const char *name)

CHOICE values are not constructed all the way down to its leaf value since the information about the selected field is not available in the type information. When this function is called, the value construction is continued and proper value will be constructed for the

selected CHOICE field (name) and the value can then be assigned properly.

GciValue * EGciGetChoiceMemberByTag(GciValue *value, GciTagClass tag_class, int tag)

Equivalent to `EGciGetChoiceMemberByName` but the unique tag of the choice element instead of the name is used.

GciValue * EGciGetSEQUENCE_OFElement(GciValue *value)

Constructs a new value given the underlying/contained type of the SEQUENCE_OF type. The newly constructed value must be appended using the `GciAddElem` function.

GciValue * EGciGetSET_OFElement(GciValue *value)

Constructs a new value given the underlying/contained type of the SET_OF type. The newly constructed value must be appended using the `GciAddElem` function.

Bool EGciGetAnyValue(GciValue *value)

Predicate to check if the value is ANY value attribute. Note that this has nothing to do with the `GciGetANY` function since that function operates on values of the type `ANY`.

Bool EGciGetAnyOrOmit(GciValue *value)

Predicate to check if the value is ANYOROMIT value attribute.

Bool EGciGetIfPresent(GciValue *value)

Predicate to check if the IF_PRESENT value attribute is specified for this value.

Bool EGciGetDefault(GciValue *value)

Predicate to check if the instatiated value comes from the default value of the type or not.

Error Handling

If an error occurs during execution, the error state is propagated up through the call stack and error information is added. An error has occurred when either the EGciGetErrorCount function returns a number greater than zero or a Gci/EGci-function call has returned GciNotOk.

The error message is retrieved by EGciGetLastErrorMessage and reset by EGciClearError.

unsigned int EGciGetErrorCount()

Retrieve the current number of errors detected by the run time system.

const char* EGciGetLastErrorMessage(void)

Retrieve the last error message in text form.

void EGciClearError()

Clear the error state of the run time system.

Miscellaneous

void EGciDumpValue(FILE *stream, const char *prefix, GciValue *value, const char *suffix)

Prints the given value on stream. The prefix and suffix are printed before and after the value dump respectively.

int EGciDumpValueInBuffer(char* buffer, int maxlen, GciValue* value);

Returns 0 when `value` was successfully dumped into `buffer`. If the function fails it returns the required buffer size for a successful dump of `value`.

This function can be used for printing a value from the code, for example a value in a GciValue structure to be printed in a file. Call `EGciDumpValueInBuffer` with a large enough buffer (possibly first check the necessary buffer size), then print the value from `buffer`.

void EGciSetDebugStream(FILE *stream)

Set the debug stream where logging will be made. It is set to `stderr` by default.

Examples

```
MyString         ::= IA5String
EmailAddress     ::= MyString
SnailmailAddress ::= SET { street MyString, number INTEGER }
AddressKind      ::= ENUMERATED { email, snailmail }

-- This represents a contact with name and an address.

Contact ::= SEQUENCE {
  name MyString,
  address_kind AddressKind
  address CHOICE {
    email     EmailAddress,
    snailmail SnailmailAddress
  }
}
```

A value would be constructed in the following way:

```
GciValue *tmp;
GciValue *address;
CciValue *contact;

contact = EGciMkValue( GcContactD);

tmp = EGciGetFieldByName(contact, "name");
EGciSetSTRING(tmp, "Elvis");

tmp = EGciGetFieldByName(contact, "address_kind");
EGciSetENUMERATEDByName(tmp, "snailmail");

 address = EGciGetFieldByName(contact, "address");
 address = EGciGetChoiceMemberByName(address, "snailmail");
 tmp = EGciGetFieldByName(address, "street");
 EGciSetSTRING(tmp, "High road");
 tmp = EGciGetFieldByName(address, "number");
 EGciSetINTEGER(tmp, 42);
```

The Adaptation Framework

Introduction to the Adaptation Framework

The Adaptation Framework, technically referred to as “ACM”, is a collection of the functions that are needed to write a full-fledged adaptation implemented by plug-in libraries that can be used “as is”. Currently, the following plug-in modules are included in the TTCN Suite distribution:

- TCP/IP socket communication implementation.
- Standard system-time timer implementation.

This means that if the target system uses TCP/IP to communicate, the adaptation writer can simply use the Adaptation Framework right from the box to get the IUT connected to generated code with minimal amount of work.

Note that the Adaptation Framework is provided as a standardized way to implement the GCI interface. This means that the Adaptation Framework *does not replace GCI, but rather complements it.* To build the adaptation, simply implement the needed GCI functions by calling the counterpart framework functions that use the compiled-in implementations for the low level code; in this distribution this would be the TCP/IP protocol for communication and a standard system time timer implementation. On the other hand, this means that one can continue to implement adaptations without using the framework altogether, the old way, and old adaptations will continue to work as before.

Examples of usage

The included adaptation residing under the ACM/ subdirectory contains an implementation of the GCI layer by framework functions and is instructive in displaying the way to work with framework functions.

Defined constant values

Defined constant	Meaning
ACM_ADDRESS_TCPIP	The address type specifier used with the TCP/IP implementation of the Adaptation Framework for the `GciAddress` type.

More values will be defined in the file *acm.h* once more plug-in packages are available. The user can also specify new values for his/her own communication modules.

> **Note:**
> Values 0-100 are reserved for use by IBM Rational.

Communication role of the executable test suite

```
typedef enum
{
  ACMClient,
  ACMServer
} ACMConnectionType;
```

The enumerated type *ACMConnectionType* is used when calling `ACMConnect()` to select whether the generated code should act as a server or client to the IUT.

Communication primitives

These functions are used to implement the GCI communication functions.

Initializing the communication and timer package

```
GciStatus ACMInit(const GciTime* max_timeout,
GciTimeUnit time_tick_unit)
```

Must be called after GCIInit() but prior to any use of the ACM communication or timer primitives. The first argument, *max_timeout* defines

the maximum amount of time the system will wait in blocked state for any timer. Setting this to a low value enables the possibility to write a polling snapshot function. A defined constant exists by the name of **ACM_ONE_YEAR_IN_MINUTES** that can be used as a default “big enough” number argument.

The second argument, *time_tick_unit*, depicts the unit of time (in GCI time units) used internally in the run-time system. Since all internal timer data is converted to and from this unit, it is important to set this to a value that encompasses approximately the value range of the time-out values used in the test suite. This parameter also restricts the maximum time that is available for a time-out value, as depicted below.

Internal unit	Maximum length of time before timer wraps
Gcips	4.3 seconds
Gcins	71 minutes
Gcius	49 days
Gcims	136 years
...	...

Resetting the Run-time System

```
GciStatus ACMReset()
```

This function cancels all timers and resets all timer queues and PCO buffers. It is typically called before starting a new test case to ensure that all old data is removed and to put the run-time system into an initial mode.

Registering the GciTimeout Function

```
GciStatus ACMRegisterTimeoutHandler(ACMTimeoutHandler
                                    timeouthandler)
```

This function needs to be supplied with a pointer to the *GciTimeout()* function before using the *ACMSnapshot()* function, since *ACMSnapshot()* calls the timeout function automatically for every timer that has expired.

Registering the GciReceive Function

```
GciStatus ACMRegisterReceiveHandler(GciReceiveHandler
                                    receive_callback)
```

This function needs to be supplied with a pointer to the *GciReceive()* function before using the *ACMSnapshot()* function, since *ACMSnapshot()* calls the receive function automatically for every data packet that has arrived.

Registering the Active Decode Function

```
GciStatus
ACMRegisterDefaultDecodeHandler(ACMDecodeHandler
                                decode_handler)
```

The function *ACMSnapshot()* calls *GciReceive()* automatically for every data packet that are ready to be received. In order to do this, however, a decode function needs to be registered that can decode the incoming data from its transfer syntax to the internal GCI value representation. This is easily done by the above call. Note that this opens the possibility to switch decoding during runtime, since any decode function that fulfills the requirements are eligible to be registered as the default decoder at any time. See "Encoding, and in Particular Decoding within ACM and GCI" on page 1556 in chapter 36, *Adaptation of Generated Code* for details on how to construct the decode function(s).

Registering a Specific Decode Function for a PCO

```
GciStatus ACMRegisterDecodeHandler(ACMDecodeHandler
                                   decode_handler,
                                   GciPCOID pco_id)
```

This function is similar to the previous function, but it enables a certain decode function to be connected with a certain PCO. This means that the function *ACMSnapshot()* will be able to use different decoding mechanisms depending on which PCO the message was received from. See "Encoding, and in Particular Decoding within ACM and GCI" on page 1556 in chapter 36, *Adaptation of Generated Code* for details on how to construct the decode functions.

Connecting to a Communication Port

```
GciStatus ACMConnect(GciPCOID pco_id,
                     GciAddress* address,
                      ACMConnectionType type,
                      unsigned int buffer_size)
```

This function maps the PCO identifier value internally to an external communication port and makes the connection. This makes it possible to use the PCO identifier in all subsequent calls, which makes the code quite clear.

In addition, we need to supply what type of role the ETS will have in the communication with the IUT - as a server (ACMServer) or as a client (ACMClient).

The *buffer_size* argument defines the largest possible buffer (in bytes) that can be received in one chunk. This should usually be set to the largest buffer needed to encode a value in the current value representation.

Disconnecting a Communication Port

```
void ACMDisconnect(GciPCOID pco_id)
```

This function disconnects a previously opened communication link.

Sending a Message

```
GciStatus ACMSend(GciPCOID pco_id, GciBuffer* buffer)
```

This function sends an encoded buffer on the designated PCO. When sending, the function will block until the entire buffer have been sent, or an error has occurred. This is simply because it is preferred to see the send operation as an atomic operation without possible race conditions.

Receiving a Message

```
GciStatus ACMReceive(GciPcoID pco_id, GciBuffer* buffer)
```

This function tries to receive a message from the designated PCO. If successful, the received encoded byte stream is inserted to the provided buffer, which is allocated inside the function.

Retrieving the Position of the First PCO with Received Data

```
GciPosition ACMGetReceivedPCOPos()
```

This function returns the position of the first PCO to have data ready for receiving. The return value is simply meant to be used as an iterator argument to the `ACMGetNextReceivedPCO()` function. If the returned value is zero, there are at this time no PCO that has received data.

Retrieving the position of the next PCO with received data

```
GciPCOID ACMGetNextReceivedPCO(GciPosition* position)
```

This function returns the numeric identifier of the PCO that has data ready to receive and updates the *position* variable to point to the next PCO with data to receive. If the *position* is zero, no further PCO has data to receive.

A simple loop that checks all PCO's for receive can be written in a similar manner to the timer iteration described below in "A Loop That Fetches All Expired Timers and Prints Their ID Numbers" on page 1542 in chapter 36, *Adaptation of Generated Code*.

Timer Primitives

Timer handling can be implemented in various ways. The package makes it easy for the adaptation writer to use timers, by encapsulating functionality that used to be implemented in a fairly standard way in GciSnapshot() implementations over and over again. Instead of using cryptic timer structures the user can now use the GCI identifier for the needed timer in a number of timer access functions. Time itself is fetched from the system clock, normalized to zero at the time of starting the execution.

Starting a Timer

```
GciStatus ACMStartTimer(GciTimerID timer_id,
GciTime timeout)
```

This function starts the designated timer with the given expiration time. If the timer has not yet been created, this call will create it. If the timer was running or expired it is simply restarted.

Cancelling a Timer

```
GciStatus ACMCancelTimer(GciTimerID timer_id)
```

This function transfers the designated timer from the active list to the list of stopped timers. This call needs to be performed once a timer has been noted as expired (via `GciTimeout()` in `GciSnapshot()` for instance)

Cancelling All Timers

```
GciStatus ACMCancelAllTimers()
```

This function cancels all timers, even if they are already expired.

Reading the Value of a Timer

```
GciStatus ACMReadTimer(GciTimerID timer_id,
GciTime* timer_before_timeout)
```

This function places the current time of a given timer in the provided GciTime object.

Checking the Current Status of a Timer

```
GciStatus ACMTimerStatus(GciTimerID timer_id,
GciTimerStatus* timer_status)
```

This function places the current status of the given timer in the status variable. Please refer to the declaration of GciTimerStatus for the various states of a timer.

Retrieving the Key to the First Timer That Has Expired

```
GciPosition ACMGetTimedOutPos()
```

This function retrieves the position to the first timer that has expired from a chronological list of expired timers. The return value is simply meant to be used as an iterator argument to the `ACMGetNextTimed-Out()` function. If the returned value is zero, there are no currently expired timers.

Getting the Next Expired Timer

GciTimerID ACMGetNextTimedOut(GciPosition* position)

Given a position index (the index to the first timer is fetched with the ACMGetTimedOutPos() function), this function returns an expired timer and updates the position variable to point to the next timer in the list of expired timers. If the position value is equal to zero after this call, no more expired timers exist in the list.

Example 296 A Loop That Fetches All Expired Timers and Prints Their ID Numbers

```
. . .
GciPosition pos = ACMGetTimedOutPos()

while (pos != NULL) {
  printf("Timer %d has expired!\n",
         ACMGetNextTimedOut(&pos) );
}
```

Time Left Before the Next Timer Expires

GciStatus ACMTimeLeft(GciTime *time_before_timeout)

This function retrieves the actual time left before the next timer is due to expire. If one or more timers have already expired, the function returns zero as the time left. If no timers exist, or all timers have been stopped, the function returns GciNotOk.

Timer and PCO Handling with a Single Call

GciStatus ACMSnapshot()

For the hardened writer of many adaptations, this function offers a relief. Calling this function will wrap most GciSnapshot functionality into one call. Briefly, what the function performs internally is the following:

1. Check all PCO/CP channels for received data.
2. For each queue that contains fresh data, receive, decode it and call GciReceive() with the result.
3. For each expired timer, call GciTimeout() with the expired timer's ID number and move the timer to the list of stopped timers.
4. Return status of the operations.

In effect, the simplest snapshot implementation can now look like this:

Example 297 The Simplest Snapshot in the World!

```
GciStatus GciSnapshot()
{
  return ACMSnapshot();
}
```

Somewhere in the code, before calling ACMSnapshot() for the first time, it is also necessary to register three functions with ACM:

- GciReceive()
- GciTimeout()
- A decode function.

This is due to the fact that ACMSnapshot() will possibly try to call these functions depending on the internal state. A good place to register these functions is close to the ACMInit() call:

```
.
.
ACMInit(max_timeout, ... );
.
.
ACMRegisterTimeoutHandler(&GciTimeout);
ACMRegisterReceiveHandler(&GciReceive);
ACMRegisterDefaultDecodeHandler(&DecoderFunction);
```

Waiting for the Next Event

`GciStatus ACMWaitForEvent()`

If more functionality is needed in the snapshot function, a mechanism for waiting for the correct amount of time is needed. This function sleeps until the next timer is due, or until data arrives on a PCO, whichever comes first. The function then returns with the status GciOk, at which point the snapshot function can simply poll the input queues for data, and/or take the now arrived timeout. If no timers are running, the function returns after the maximum time to wait as defined in **ACMInit(...)**. If this time is set to a small amount, there is a polling snapshot in effect.

Example 298: The Same Snapshot but with Written Out Code ––––––

```
GciStatus GciSnapshot()
{
  GciPosition expired_pos;
  GciTimerID  expired_timer;
  GciPosition received_pos;
  GciPCOID    received_pco;
  GciBuffer   buffer;
  GciValue*   value;

/* Sleep until either a timer has expired
 * or data is received. For a polling
 * snapshot, remove this. */
  if (ACMWaitForEvent() != GciOk) {
    return GciNotOk;
  }

/* First, check all timers. */
  if (ACMSynchronizeTimers() != GciNotOk) {
    return GciNotOk;
  }
  expired_pos = ACMGetTimedOutPos();

  while(expired_pos != NULL) {
    expired_timer =
       ACMGetNextTimedOut(&expired_pos);
    GciTimeout(expired_timer);
    if (ACMCancelTimer(expired_timer) != GciOk) {
      return GciNotOk;
    }
  }
/* Next, take care of the PCO's */

  buffer.buffer =
   (char *)malloc(sizeof(char) *
                  MAX_ENCODING_BUFFER+1);
  buffer.current_length = 0;
  buffer.max_length = MAX_ENCODING_BUFFER;

  received_pos = ACMGetReceivedPCOPos();

  while(received_pos != NULL) {
    received_pco =
      ACMGetNextReceivedPCO(&received_pos);
    if (ACMReceive(received_pco, &buffer) != GciOk)
    {
      return GciNotOk;
    }
    value = GeneralDecode(&buffer);
    if (value != NULL) {
      if (GciReceive(received_pco, value)!= GciOk) {
        return GciNotOk;
      }
    }
```

```
      else {
        fprintf(stderr,
                "Transfer syntax error on PCO %s\n",
                GciGetPCOName(received_pco) );
        return GciNotOk;
      }
    }
    return GciOk;
  }
```

Retrieving the Current System Time

`GciStatus ACMCurrentTime(GciTime* current_time)`

This function retrieves the time of the system clock in the instance of the function call.

Error Handling

The error handling of the Adaptation Framework will be straightforward to those familiar with the *err_no* paradigm of C. Every time an error occurs, the function sets an internal error code and returns *GciNotOk*. The error code can then be retrieved either as an enumerated value, or as a descriptive string.

The error codes can be found in the file *acm.h*.

Setting the Error Code

`ACMSetLastError(ACM_Error_Number errornumber)`

Sets the error number to the given value.

Retrieving the Error Code of the Last ACM Error

`ACM_Error_Number ACMGetLastError()`

Returns the last error code as an enumerated value.

Retrieving the Error String of the Last ACM Error

`const char* ACMGetLastErrorMessage()`

Returns the last error code as a printable string.

Completing the Adaptation

The generated code has to be extended before it is complete in order to test the intended implementation. This section describes how to make these extensions.

Figure 278 displays in a simple way the anatomy of an executable test suite.

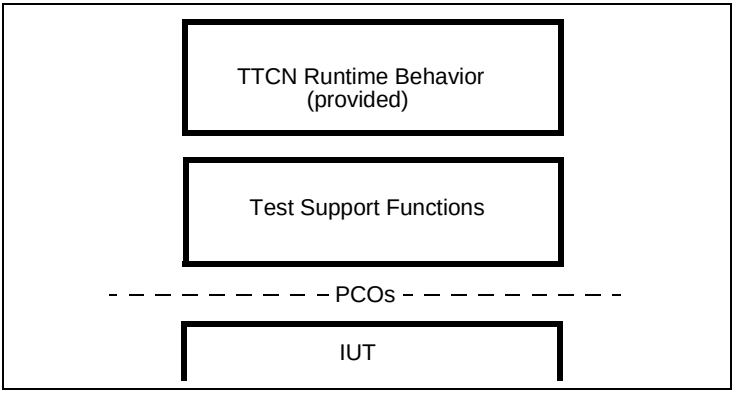

Figure 278: The anatomy of an executable test suite

When code is generated by the code generator, it does not know anything about the system it is about to test. It assumes that it will have access to certain functions, implemented by the user. This is the “Test Support Functions” module in Figure 278.

One important thing to remember is that the previously defined interface called GCI, is a standardized set of functions.See “The GCI Interface” on page 1488 in chapter 36, *Adaptation of Generated Code*. **Adaptation should be made using the functions and data types defined by that interface**.

The Test Support Functions

This is the “glue” between the TTCN Runtime Behavior and the IUT. It is a set of functionality (functions) that is adaptation specific and should be provided by the user.

The following areas have to be covered and they are described in more detail in the sections they refer to.

Implementation and Handling of Timers

The timers defined in the Test Suite must have a real representation in the test environment. The TTCN Runtime Behavior will, when necessary, ask the adaptation about the status of a timer. See "Representation and Handling of PCO and CP Queues" on page 1550 in chapter 36, *Adaptation of Generated Code*.

Representation and Handling of PCOs [and CPs]

Messages are communicated through *Points of Control and Observation* and *Connection Points*. The actual buffering of incoming IUT messages must be supplied by the adaptation. See "Representation and Handling of PCO and CP Queues" on page 1550 in chapter 36, *Adaptation of Generated Code*.

Communication with Test Equipment [and PTCs]

To be able to test the IUT at all, there must be actual communication channels to and from it. The actual communication is of course totally depending on the system environment. See "IUT Communication" on page 1549 in chapter 36, *Adaptation of Generated Code*.

Encoding and Decoding

Values in the test suite (constraints, variables, constants, etc.) must be properly encoded and decoded for sending them to the IUT. The actual protocol for encoding decoding is up to the user. See "Encoding and Decoding" on page 1551 in chapter 36, *Adaptation of Generated Code* and "Encoding and Decoding Using BER" on page 1558 in chapter 36, *Adaptation of Generated Code* for more details.

Implementing the Adaptor the Efficient Way – the Adaptation Framework

The implementation of timer handling and communication primitives can be made by calls to the Adaptation Framework API, which permits the underlying "hard" protocol and timer implementation to change without having to change the high-level adaptation code. See "The Adaptation Framework" on page 1535 in chapter 36, *Adaptation of Generated Code* for a thorough explanation.

Timers

Timers need some special attention. As timers are implemented differently on different systems the implementation of the timers might differ. See the *timers* adaptation template in the installation for ideas.

Timers are simply a number of constructions to keep track of each of the test suite timers. In the generated code a timer is represented by an integer descriptor which uniquely identifies it. The timer implementation supplied with the Adaptation Framework implements the timeout functionality by maintaining an ordered list of the running timers, which means that retrieving the time left to timeout and the next timer to expire are quick operations.

To refresh the current status of timers, the timer lists need to be *synchronized* to the system time. This is made automatically by the snapshot function `ACMWaitForEvent()` (more on this function later) or can be made explicitly by a call to the function `ACMSynchronizeTimers()`. This function simply checks all running timers with the system clock, moving timers that are due to the list of expired timers.

There are four functions to consider regarding timers:

```
GciStartTimer

GciCancelTimer

GciReadTimer

GciSnaphot
```

The interfaces to timers that can (and should) be called in the TTCN Runtime Behavior are:

```
GciTimeout

GciGetNoOfTimers

GetTimer

GciGetTimerName

GetTimerIndex
```

For details concerning these functions, see "GCI C Code Reference" on page 1503 in chapter 36, *Adaptation of Generated Code*.

The Adaptation Framework interfaces to timer functionality that can be used to implement the GCI functions are:

```
ACMStartTimer
ACMCancelTimer
ACMCurrentTime
ACMGetTimedOutPos
ACMGetNextTimedOut
ACMReadTimer
ACMTimeLeft
ACMTimerStatus
ACMWaitForEvent
```

These functions map to a real-time timer implementation that is provided with the installation of TTCN Suite and can be used “as-is”. See Release Notes for details on which platforms are supported by this timer package.

Timer Adaptation Example

The *timers* adaptation template is the simple adaptation template with timers implemented. It demonstrates in general how to use the Adaptation Framework to implement timer functionality, and in particular the use of the call `ACMSynchronizeTimers()` that must be used in snapshot when `ACMWaitForEvent()` cannot be used.

IUT Communication

From an abstract point of view, sending and receiving is done over PCOs (Points of Control and Observation). The physical representation of these PCOs has to be defined by the user. It can be shared memory, serial communication, sockets, etc. This, of course, is only done on the controlling side. The PCOs have to be connected somewhere to the test equipment and the responsibility for this is put upon the user.

The GCI functions that must perform the communication is (at least):

```
GciSend
```

```
GciReceive
```

For details concerning these functions, see "GCI C Code Reference" on page 1503 in chapter 36, *Adaptation of Generated Code*.

Representation and Handling of PCO and CP Queues

PCOs are constructions to handle the PCO queues. Each PCO should have buffers for sending and receiving, a method for retrieving the status of the receive buffer and additional information such as channels and ports must be provided for the physical channels.

If the ETS is to run within the test equipment, i.e. the communication between the ETS and the IUT resides within the test equipment, the ETS has to be moved (cross compiling or if possible compiling within the test equipment).

This queue initialization should of course be made before any test case are run. The function that concerns the PCO's and CPs are:

```
GciSnapshot
```

```
GciSend
```

`GciSnapshot()` can be implemented using for instance `ACMWaitForEvent()`, and `GciSend()` can be implemented using `ACMSend()`. Today, the ACM layer builds upon a TCP/IP socket implementation but other protocol implementations can be easily added.

The interface that should be used when a message has been received (after proper decoding) in the TTCN Runtime Behavior is:

```
GciReceive
```

Note that if the ACM layer function `ACMWaitForEvent()` is used in the snapshot function, the user never has to call `GciReceive()` since this is done automatically from within `ACMWaitForEvent()`!

For details concerning these functions, see "GCI C Code Reference" on page 1503 in chapter 36, *Adaptation of Generated Code*.

Encoding and Decoding

tBuffer is the subsystem of UCF that is used to represent values of ASN.1 types in the transmitted bit pattern. This section describes the interface for tBuffer.

Functions

To invoke functions of tBuffer, the following macros are to be called:

Initialization of buffer

You should initialize tBuffer before using it.

```
void BufInitBuf(tBuffer buf, tDirectionType dirtype,
UCFStatus status)
```

tBuffer buf	Buffer for data storage
tDirectionType dirtype	Data writing order (DIRECT or REVERSE).
UCFStatus status	Status of initialization. Variable “status” is equal to UCF_Ok if no errors were encountered during initialization or an error code otherwise.

Note: Buffer direction mode

`REVERSE` modes is not supported in the buffers anymore, although the prototype of the `BufInitBuf` function still includes the `dirtype` parameter for backwards compatibility. The direction mode parameter is always ignored when calling the `BufInitBuf` function.

Closing of buffer

You should close tBuffer after working with it.

```
void BufCloseBuf(tBuffer buf)
```

tBuffer buf	Buffer

Initialization in write mode

This function initializes tBuffer in write mode. You can write data to the buffer after calling this function.

```
UCFStatus BufInitWriteMode(tBuffer buf)
```

Initialization in read mode

This function initializes tBuffer in read data. You can read data from the buffer after calling this function.

```
UCFStatus BufInitReadMode(tBuffer buf)
```

Closing write mode

This function closes write mode of tBuffer. You should call this function after the 'write to buffer' operation is completed.

```
void BufCloseWriteMode(tBuffer buf)
```

Closing read mode

This function closes read mode of tBuffer. You should call this function after reading from the buffer is finished.

```
void BufCloseReadMode(tBuffer buf)
```

Getting direction type of the buffer

This function returns the direction type of tBuffer.

```
tDirectionType BufGetDirType(tBuffer buf)
```

Note: No REVERSE mode

`REVERSE` mode is not supported in the buffers anymore, although the `BufGetDirType` function is still present in the buffer interface for backwards compatibility. It will always return `DIRECT` mode.

Creating copy of buffer

This function makes a copy of the buffer.

```
UCFStatus  BufCopyBuf(tBuffer dst, tBuffer srs)
```

tBuffer dst	destination buffer
tBuffer src	source buffer

Getting the data byte length

This function returns the buffer's data length in bytes.

```
tLength  BufGetDataLen(tBuffer buf)
```

Getting the data bit length

This function returns the buffer's data length in bits.

```
tLength  BufGetDataBitLen(tBuffer buf)
```

Getting the available length

This function returns the maximal data length you can write into the buffer in one piece (in bytes).

```
tLength  BufGetAvailableLen(tBuffer buf)
```

Getting byte

This function reads one byte from the buffer. The buffer should be initialized in read mode.

```
unsigned char  BufGetByte(tBuffer buf)
```

Getting data segment

This function reads a data segment from the buffer. The buffer should be initialized in read mode.

```
unsigned char*  BufGetSeg(tBuffer buf, tLength
seglen)
```

tBuffer buf	Buffer to read from
tLength seglen	Requested data length

Peeking byte

This function peeks (reads, but does not remove) one byte from the buffer. The buffer should be initialized in read mode.

```
unsigned char  BufPeekByte(tBuffer buf)
```

Peeking data segment

This function peeks (reads, but does not remove) a data segment from the buffer. The buffer should be initialized in read mode.

```
unsigned char*  BufPeekSeg(tBuffer buf, tLength
seglen)
```

tBuffer buf	Buffer to read from
tLength seglen	Requested data length

Putting byte

This function writes one byte into the buffer. The buffer should be initialized in write mode.

```
void  BufPutByte(tBuffer buf, unsigned char byte)
```

tBuffer buf	Buffer to write into
unsigned char byte	Byte to write into buffer

Putting data segment

This function writes a data segment into the buffer. The buffer should be initialized in write mode.

```
void  BufPutSeg(tBuffer buf, unsigned char* data,
tLength seglen)
```

Putting bit

This function writes one bit into the buffer. The buffer should be initialized in write mode.

```
void BufPutBit(tBuffer bud, unsigned char bit)
```

tBuffer buf	Buffer to write into
unsigned char bit	Value of bit (0 or 1)

Getting bit

This function reads one bit from the buffer. The buffer should be initialized in read mode.

```
unsigned char BufGetBit(tBuffer buf)
```

Putting bits

This function writes bits into the buffer. The buffer should be initialized in write mode.

```
void BufPutBits(tBuffer buf, unsigned char bits,
unsigned char num)
```

tBuffer buf	Buffer to write into
unsigned char bits	Sequence of bits

unsigned char num	Number of bits in sequence (num <= 8)

Getting bits

This function reads bits from the buffer. The buffer should be initialized in read mode.

```
unsigned char BufGetBits(tBuffer buf, unsigned char
num)
```

tBuffer buf	Buffer to read from
unsigned char	Number of bits (num <= 8)

Putting padding bits

This function writes padding bits in PER ALIGN variant of encoding. The buffer should be initialized in write mode.

```
void BufPutAlign(tBuffer buf)
```

Getting padding bits

This function reads padding bits in PER ALIGN variant of encoding. The buffer should be initialized in read mode.

```
void BufGetAlign(tBuffer buf)
```

Set encoding variant (PER only)

This function sets the encoding variant.

```
void BufSetEncVar(tBuffer buf, UCFEncVariant encVar)
```

UCFEncVariant encVar	Encoding variant (UCF_Align, UCF_Unalign or UCF_NoEndPad)

Get encoding variant (PER Only)

This function returns the encoding variant.

```
UCFEncVariant  BufGetEncVar(tBuffer buf)
```

Setting up error catcher

This function sets up error catcher. Returns 0 or code of error if any.

```
unsigned int BufSetCatcher(tBuffer buf)
```

Getting error mode

This function gets error mode (bem_Off or bem_On).

```
tBufferErrorMode BufGetErrorMode(tBuffer buf)
```

Supported ASN.1 Types

- BOOLEAN
- INTEGER
- ENUMERATED
- REAL
- OBJECT IDENTIFIER
- NULL
- BIT STRING
- OCTET STRING
- IA5String
- NumericString
- PrintableString
- VisibleString
- UTCTime
- GeneralizedTime
- SEQUENCE
- SET
- SEQUENCE OF
- SET OF
- CHOICE
- Tagged types
- Open types

Encoding, and in Particular Decoding within ACM and GCI

The standard way to implement the encoder and decoder functions are to put at least one function of each in the file *encoder.c* and declare them in the file *encoder.h*. With every adaptation that is provided with the TTCN Suite installation are those files included, often with empty encode/decode functions where the user is supposed to enter the appropriate functionality. The functions should be of the following structure:

The Encoding Function

```
GciStatus Encoder_<name>(const GciValue*,
                         GciBuffer** )
```

If encoding was successful, the GciBuffer should be loaded with the encoded data and *GciOk* returned by the function. Otherwise, the function should return *GciNotOk*.

The Decoding Function

```
GciStatus Decoder_<name>(const GciBuffer*,
                        int*,
                         GciValue**)
```

If decoding was successful, the GciValue should be loaded with the decoded GCI value, the integer should contain the number of bytes that were consumed in the decoding process and the return status *GciOk*. Upon failure, the function should simply return *GciNotOk*.

Note that several encode/decode functions can exist, and the user can switch between them at will, either by calling different functions from *GciSnapshot()* or by registering different functions prior to calling *ACMSnapshot()*. See *"Registering the Active Decode Function" on page 1538 in chapter 36, Adaptation of Generated Code* for details.

General

A test suite has no knowledge of the encoding and decoding rules of the actual application protocol. The definition of signal components and the description of the signal flows are done in an abstract and high-level manner. The physical representation of the signal components and the definition of the actual transfer syntax is not defined within the test suite.

The encoding and decoding rules (functions) simply define a common transfer syntax between the test equipment and the executable test suite.

It is up to the user to write his/her own encoding and decoding rules using the GCI value representation. Even if the TTCN to C Compiler comes with an adaptation template that includes a general encoder and decoder, these rules can not be used at all times.

For test applications that need to send the same type of messages back and forth through a communication channel, the encoding and decoding

functions must be related to each other in such way that the decoding function is the inverse function of the encoding function. This gives the following simple rule:

```
Message = Decode( Encode ( Message ) )
```

This simply states, that if you decode an encoded message, you will get the original message back.

For applications that send and receive messages of different types (for example an application sending commands to an interface one way and receiving command results the other way), the encoding and decoding rules might not be related at all.

It is up to the user to identify how he/she needs to encode and decode messages to successfully be able to communicate with his/her test equipment.

Encoding and Decoding Using BER

TTCN Suite can generate encode/decode function definitions, that give an opportunity for representing values of each ASN.1 type as a string of eight-bits octets and transfer them between the environment and the ETS. TTCN Suite now have support for BER (Basic Encoding Rules) standard, defined in X.690 for the subset of ASN.1 that is defined by TTCN.

BER Encoder/Decoder Support Library

The BER support comes in the form of a static library that supports encoding/decoding functionality of ASN.1. Profiles of all the functions that a user can use are located in the `ucf.h` in the static files directory. This file should be included in the adaptation and the library should be linked together with the adaptation.

The library contains two basic functions that provide functions for encoding/decoding types, computing length of values and buffer handling procedures: `BEREncode(...)` and `BERDecode(...)`.

How to Use BER Support in the TTCN Suite?

First, select *Generate BER encoders/decoders* in the Make options dialog. A file will be generated called `asn1ende.h` in your target directory. This file defines the encoding and decoding functions for the ASN.1 definitions in the test suite.

Second, you should implement the usage of the encoding functions in your `adaptor.c`. This is done in the `GciSend` and `GciSnapshot` functions. Also, you should define buffers and initialize them (this can be done in `main`.

The generated file <ModuleName_of_ASN.1-specification>_asn1icoder.h contains the encoding/decoding function definitions for ASN.1 objects in the Test Suite. For example, if you have ASN.1 ASP Type definition by name of `ASPType1`, two functions will be generated:

```
UCFStatus Encode_ASPType1(tBuffer, GciValue*);

UCFStatus Decode_ASPType1(tBuffer, tLength*, GciValue**);
```

The first parameter of the encode function is the buffer where the encoded data is placed. The decoding is made from the buffer to a GCI value.

The encoding/decoding functions are specific for the ASP/PDU types in question so when calling them in `GciSend` and `GciSnapshot`, you need to make sure that they are called with a value of the correct ASP/PDU type. One way to get around this problem is to define a single ASP/PDU type that is a CHOICE of all types that you are sending or receiving in your test suite.

Example

For example, we have a test suite with ASN.1 ASP Type

```
ASPType1 ::= INTEGER
```

And ASN.1 ASP constraint of ASPType1 named

```
ASPCon1 ::= 5
```

We have PCO named PCO1 and dynamic behavior like this:

```
PCO1 ! ASPType1    | Constraint: ASPCon1
PCO1 ? ASPType1    | Constraint: ASPCon1
```

And we want to use BER for encoding/decoding. After code generation we have a <ModuleName_of_ASN.1-specification>_asn1icoder.h file with the following definitions:

```
tLength Encode_ASPType1(tBuffer, GciValue*);
```

```
tLength Decode_ASPType1(tBuffer, GciValue**);
```

So in our adaptation file we need to declare, initialize and close BER buffers:

```
tBuffer InBuffer;
tBuffer OutBuffer;
.
. (rest of the adaptation)
.
int main(int argc, char* argv[])
{
   BufInitBuf(InBuffer, DIRECT, status);
   BufInitBuf(OutBuffer, DIRECT, status);
   .
   . (ETS control)
   .
  BufCloseBuf(InBuffer);
  BufCloseBuf(OutBuffer);
  return 0;
}
```

In `GciSend()` we should initialize buffer in `WriteMode` and encode value:

```
GciStatus GciSend( int pcod, GciValue* object )
{
    UCFStatus status;
   BufInitWriteMode(OutBuffer);
   .
   .
  Encode_ASPType1(OutBuffer, object);
  status = Encode_ASPType1(OutBuffer, object);
  if(status != UCF_Ok)
  {
   UCFPrintErrorMessage(stderr,status);
   /* warning or exit */
  }
  .
  .
  BufCloseWriteMode(OutBuffer);
  return GciOK;
}
```

In `GciSnapshot()` we should initialize buffer in `ReadMode` and decode value:

```
GciStatus GciSnapshot( )
{
  UCFStatus status;
  tLength DecLength;
```

```
  BufInitReadMode(InBuffer);
  .
  .
  Decode_ASPType1(InBuffer, &result);
 status = Decode_ASPType1(InBuffer, &DecLength,
&result);
 if(status != UCF_Ok)
 {
  UCFPrintErrorMessage(stderr,status);
  /* warning or exit */
 }
  .
  .
  BufCloseReadMode(InBuffer);
  return GciOK;
}
```

How to Use the PER Support in the TTCN Suite

The PER support is used almost exactly like the BER support, so read above first to learn how to use the BER support. The PER Encoding/Decoding functions have been changed and now return a UCFStatus value:

```
 UCFStatus Encode_ASPType1(tBuffer, GciValue*)

 UCFStatus Decode_ASPType1(tBuffer, tLength*,
GciValue**)
```

The primary difference to the BER support is that the PER support includes supporting different variants of PER. The variants supported are Unalign, Align and NoEndPad with the Unalign variant being the default. The Unalign and Align variants are, just like BER, eight-bit octet-oriented, but the NoEndPad variant is bit oriented which necessitates use of the bit-oriented access to the buffer instead of the byte-oriented access.

The mechanism to select PER encoding variants is based on the use of pre-processor symbols. By defining the symbol `UCF_PER_DEFAULT_ENCODING_VARIANT` to the value associated with the selected encoding variant before including the `asn1ende.h` file, all types will get the selected encoding variant unless explicitly overridden.

Overriding the default encoding variant can be done on a per type basis by defining the pre-processor symbol `EncodingVariant_<type name>` to the selected variant value before including the `asn1ende.h` file.

The following example shows a snippet of the `adaptor.c` file in a situation where all types but the type `Type1` is to be encoded/decoded with the Align variant and `Type1` is to use the Unalign variant.

Example 299: Selecting PER encoding variant ––––––––––––––––––

```
#define UCF_PER_DEFAULT_ENCODING_VARIANT UCF_Align
#define EncodingVariant_Type1 UCF_Unalign
#include <asn1ende.h>
```

––

The Adaptation Framework

To make it even easier to connect the generated code to "the real world", the Adaptation Framework (ACM) is introduced, a platform-independent API that encapsulates communication and timer handling provided by *plug-in components.* These components can be communication protocol implementations, simulated timer modules, etc. and can easily be replaced *without having to rewrite the adaptation* – provided the Adaptation Framework has been used to implement the GCI functions in the adaptor.

Currently, the TTCN Suite is delivered with the following plug-in modules for the framework:

- A TCP/IP socket communication implementation.
- A system-time timer package.

This means that if the adaptation is written using the Adaptation Framework, the generated code can instantly be used with TCP/IP communication. As the framework also hides all internal mechanisms of the runtime system, the resulting adaptation will be easier to maintain, more general and much smaller in size.

Example 300: An Implementation of GciSend with ACM ––––––––––

```
GciStatus GciSend (int pcod, GciValue* msg)
{
  GciBuffer  encoded_value;
  GciStatus  status;

  encoded_value.buffer = (char *) malloc(
sizeof(char) * MAX_ENCODING_BUFFER + 1);
  encoded_value.current_length = 0;
  encoded_value.max_length = MAX_ENCODING_BUFFER;
```

```
    status = Encode(&encoded_value, msg);
    if (status != GciOk) {
      fprintf(stderr, "%s\n",
              ACMGetErrorMessage(ACMGetLastError()));
      return GciNotOk;
    }
    status = ACMSend(pcod, &encoded_value);
    free(&encoded_value);

    if (status != GciOk) {
      fprintf(stderr, "%s\n",
              ACMGetErrorMessage(ACMGetLastError()));
      return GciNotOk;
    }
    return status;
  }
```

Adaptation Templates

An empty adaptation is copied to the code directory if the user has no prior adaptation.

It is up to the user to implement the functions in the GCI operational interface. These functions are called from the TTCN runtime behavior and should not be removed even if they are empty.

The function bodies and declarations are found in the empty adaptation files, but the function bodies are empty. They only contain a print statement about the function not being implemented.

The *ACM* adaptor also uses the Adaptation Framework for communication and timer handling and is a good example to study on how to use the Adaptation Framework to implement GCI functions.

Auxiliary Adaptation Functionality

This section describes some extra functionality which is included in the adaptation templates.

`FILE* logStream;`

This is the stream to where log messages are written. The default value is **stdout** and is set in the `main` function, but can be set to whatever stream the user wishes to use.

`extern const int Gc<tablename>D = {int}`

Constant numbers for all tables (test case table, PCO table, timer table, etc...) in TTCN. Used to search in the IcSymTab array (see symbol table below). An example is for **`GcTestCaseD = 517`**.

The simple adaptation template (in the installation) includes all empty functions for the previously described GCI operational functions to be defined by the user.

Chapter

37 *Error Messages in the TTCN Suite*

This chapter contains a general description of how error messages in the TTCN Suite are structured, information about why some error messages are accompanied by a message on the standard output stream and information about how some error messages should be interpreted.

However, this chapter does not provide detailed information about specific error messages.

Error Messages

All user actions can potentially lead to an error, either because the user has made an improper action or because some system imposed limitation has been violated.

Note that all messages are not necessarily **error** messages, there are **query** and **information** messages as well.

The Structure of Error Messages

Error messages are based on information from three separate sources:

1. Tools/commands
2. TTCN Core94
3. System

The first part is always present in an error message but the other two may be inapplicable to some error messages.

Example 301 ----------

```
Open: Operation failure
Can not open the file /home/users/user/suite.itex-lock
Permission denied
```

The example above notifies you about a failed attempt to open a test suite due to you insufficient privileges to create the lock file that should automatically be created when a test suite is opened or created. Observe that as the lock file is created before any attempt is done to open the test suite, the error messages often refer to that file instead of the test suite files.

The following are examples of when the second and third parts are missing and when the third part is missing respectively.

Example 302 ----------

```
Replace: Illegal search pattern: \(foo
```

Example 303 ----------

```
Find table: Can not open foo
No such object
```

Additional Error Messages on Standard Error

The reason for additional messages on standard error in some situations, is that some functionality is accomplished by calling shell commands. If any of those shell commands fail, they write a short message to the standard error output stream. Those messages can sometimes provide additional information about why the error occurred.

Messages When Starting the TTCN Suite

When starting the TTCN Suite some error messages referring to OSF (e.g. osfBeginLine etc.) may be displayed. These messages indicate a problem in the installation related to the file XKeysymDB.

The Meaning of Error Messages

Sometimes the error messages may be a bit difficult to understand. The following list is an attempt to give some additional clues to why some errors occur and what the error messages mean:

- `Unable to display the error message directly`
  `Please check the end of the log`

  This message signifies that the system kernel do not support shared memory. The remedy is to rebuild the kernel with System V IPC support and reboot the machine. Until that is done the work-around is to look in the log for the error message.

- Messages containing `may not` or `can not` usually signifies that something is not allowed by the TTCN language. See the examples below.

Example 304 ––

```
Copy: Operation failure
May not COPY
```

––

Note:

The reason for a failed cut or copy operation may be that the selection contains items that cannot sensibly be pasted together.

Example 305 ----------

```
Rename: Can not rename Declarations Part
```

Example 306 ----------

```
May not edit name
Insert TreeHeader: Can not create tree header
```

Example 307 ----------

```
This table may not contain treeheaders
```

Chapter

38

Languages Supported in the TTCN Suite

The the TTCN Suite editing tools support TTCN and ASN.1 as defined in the TTCN standard. The TTCN to C compiler on the other hand has limitations on its ASN.1 coverage. See "TTCN ASN.1 BER Encoding/Decoding" on page 40 in chapter 1, *Compatibility Notes, in the Release Guide* for further details on the restrictions that apply.

The language supported by the TTCN Suite covers the whole of TTCN and the whole of ASN.1 as it is used in TTCN.

This chapter describes the TTCN and ASN.1 EBNF grammar supported by the TTCN Suite and the additional static semantics supported by the TTCN Suite.

The Restrictions in the TTCN Suite

The TTCN Suite editing tools support TTCN and ASN.1 as defined in the TTCN standard. The TTCN To C compiler on the other hand has limitations on its ASN.1 coverage. See "TTCN ASN.1 BER Encoding/Decoding" on page 40 in chapter 1, *Compatibility Notes, in the Release Guide* for further details on the restrictions that apply. In a few other cases, the TTCN Suite has introduced syntactical restrictions, but in all such cases there are simple work-around solutions.

This section describes the modifications in the TTCN and ASN.1 grammar, e.g. the differences between the TTCN/ASN.1 standards and the language supported by the TTCN Suite. Modifications meaning that some constructs will not be analyzed correctly even though they have legal syntax according to the TTCN/ASN.1 standards.

External ASN.1 Types

The analysis of an ASN.1 Value requires access to its Type. In TTCN it is possible to refer to an external ASN.1 Type and define an ASN.1 Value of that type.

Therefore an extra field is included in the ASN.1 type by reference tables. The user provides the definition of an external ASN.1 type in this field. The allowed syntax/semantic for this field is the same as for regular ASN.1 type definition. ASN.1 values of such a reference type will be analyzed according to the provided type definition.

The extra field is exported if the option IBM Rational MP format is chosen. It is, though, not printed together with the ASN.1 type by reference table.

Another solution to this problem is to open the referred ASN.1 module in the Organizer and define an dependencies link to it (see "Dependencies" on page 138 in chapter 2, *The Organizer* for more information). The type definition is fetched from the referred ASN.1 module before it is analyzed. For more information, see "ASN.1 External Type/Value References" on page 1197 in chapter 26, *Analyzing TTCN Documents (on UNIX)*.

ValueList

The problem is that a ValueList constraint (in MatchingSymbol) with only one element has the same construction as a parenthesized Expression in the top level. In addition, a ConstraintValue and an Expression may appear in the same places (since Expression is allowed in the ConstraintValue).

The Analyzer assumes that a ValueList with only one element is a parenthesized Expression wherever it appears.

Example 308 ––

Assuming the Test Suite Constant C1 (of type integer) with value (2 - X), C2 (also of type integer) with value 3 * (M - K) and C3 (also of type integer) with value (3, X). Both C1 and C2 are correct both syntactically and semantically, but C3 has an illegal value because value lists are not allowed in constants.

Example 309 ––

Assume a TTCN ASP Constraint C with parameters P1 and P2 (both of type integer). The parameter P1 has the value (2 + X) and P2 has the value (2 + Y, X). Both P1 and P2 have a correct value but the value of P1 is considered to be an Expression by the Analyzer.

––

ASN.1 AnyValue

This ASN.1 construct introduces ambiguities into the language. This is because it is hard to find the place where the Type ends and the Value starts.

A restricted form of AnyValue is supported where the Type in the AnyValue must be a reference to a user defined type. This form covers all cases for ASN.1 AnyValue.

Example 310 ––

```
Assume the ASN.1 Type definition T:
SEQUENCE {f1 INTEGER, f2 LT1 DEFAULT {s1 2, s2 LT2
FALSE}}
LT1 ::= SEQUENCE {s1 INTEGER, s2 ANY}
LT2 ::= BOOLEAN
```

––

ASN.1 NamedType & NamedValue

According to the ASN.1 standard (12.5), in some notation within which a type is referenced, the type may be named. In such cases, the ASN.1 standard specifies the use of the notation NamedType which is defined as:

```
NamedType ::= identifier Type | Type | SelectionType
```

The value of a type referenced using the NamedType notation shall be defined by the notation NamedValue which is defined as:

```
NamedValue ::= identifier Value | Value
```

According to the *Information Technology -OSI- ASN.1 (UDC 681.3:621.39)* the identifier in the NamedType definition shall be mandatory. The same modification is suggested for the NamedValue.

The TTCN Analyzer do not allow use of the second alternative of either of these constructs, i.e. the naming identifiers are **not** optional.

Example 311 ----------

```
Assume that the ASN.1 type T is defined as:
SEQUENCE { x INTEGER, y < Element }
Element ::= CHOICE { x BOOLEAN, y INTEGER }
This type definition is legal. The ASN.1 NamedType
in T (x & y) shall be unique (y is considered as a
NamedType in this case).
A legal value for T is: {x 2, y 4}
```

Example 312 ----------

```
Assume another ASN.1 type, T', defined as:
SEQUENCE { x INTEGER, y x < Element }
Element ::= CHOICE { x INTEGER, y BOOLEAN }
This type definition is also legal. The ASN.1
NamedType in T' (x & y) shall be unique (x is not
considered as a NamedType in this case).
The value {x 2, y 4} is not considered to be a legal
value for T' even though it is allowed according to
the ASN.1 standard. A legal value (which will be
accepted by the Analyzer) is {x 2, y x 4}
```

An important point to be noticed is that the TTCN standard does not allow the usage of an ASN.1 NamedValue within arithmetic expressions: (TTCN standard, 10.3.2.2).

Data Object Reference

A consequence of the above described restriction is that the TTCN Suite does not permit the ComponentPosition mechanism for a DataObjectReference.

Another restriction for DataObjectReference is that the TTCN Suite only permits Record referencing via ComponentIdentifiers. The mixed use of ComponentIdentifier, PDU_Identifier, and StructIdentifier for Record Reference is very vaguely described in the Standard. Almost any interpretation of the usage leads to possible ambiguities in the language.

The corresponding grammar for RecordRef (production 311) will in the TTCN Suite be:

```
RecordRef ::= Dot ComponentIdentifier
```

The “path” leading down to the data object must be fully specified, i.e. all the component identifiers from the top to the bottom must be present.

Macro Value

The wildcard values “?”, “*”, or “-” may not in the TTCN Suite be used in a Constraint where the identifier for the ASP Parameter, PDU Field, CM Element, or Structured Type Element is replaced by the macro symbol.

The Standard does not explicitly permit this nor does it allow this. The interpretation of using the wildcards for macros would however be very ambiguous. Rather than imposing one of the possible interpretations the TTCN Suite will not allow the wildcards as macro values at all.

If wildcards are to be used as values for the elements that are inserted via macro expansion they must be written in the elements of a Structured Type Constraint that is referenced as macro value.

The TTCN-MP Syntax Productions in BNF
