# MultiCluster Overview

This section describes the Platform LSF MultiCluster product (“MultiCluster”), its features and benefits.

- Contents
- ◆ Basic Concepts
    - ❖ [“Benefits of MultiCluster”](#) on page 6
    - ❖ [“Two MultiCluster Models”](#) on page 7
  - ◆ Examples and Use Cases
    - ❖ [“Testing the Resource Leasing Model”](#) on page 9
    - ❖ [“Testing the Job Forwarding Model”](#) on page 11

---

## Benefits of MultiCluster

Within an organization, sites may have separate, independently managed LSF clusters. Having multiple LSF clusters could solve problems related to:

- ◆ Ease of administration
- ◆ Different geographic locations
- ◆ Scalability

When you have more than one cluster, it is desirable to allow the clusters to cooperate to reap the following benefits of global load sharing:

- ◆ Access to a diverse collection of computing resources
- ◆ Enterprise grid computing becomes a reality
- ◆ Get better performance and computing capabilities
- ◆ Use idle machines to process jobs
- ◆ Use multiple machines to process a single parallel job
- ◆ Increase user productivity
- ◆ Add resources anywhere and make them available to the entire organization
- ◆ Plan computing resources globally based on total computing demand
- ◆ Increase computing power in an economical way

MultiCluster enables a large organization to form multiple cooperating clusters of computers so that load sharing happens not only within clusters, but also among them. MultiCluster enables:

- ◆ Load sharing across a large numbers of hosts
- ◆ Co-scheduling between different clusters
- ◆ Resource ownership and autonomy to be enforced
- ◆ Non-shared user accounts and file systems to be supported
- ◆ Communication limitations among the clusters to be taken into consideration in job scheduling

---

## Two MultiCluster Models

There are two different ways to share resources between clusters using MultiCluster. These models can be combined, for example, Cluster1 forwards jobs to Cluster2 using the job forwarding model, and Cluster2 borrows resources from Cluster3 using the resource leasing model.

### Job forwarding model

In this model, the cluster that is starving for resources sends jobs over to the cluster that has resources to spare. To work together, two clusters must set up compatible send-jobs and receive-jobs queues.

With this model, scheduling of MultiCluster jobs is a process with two scheduling phases: the submission cluster selects a suitable remote receive-jobs queue, and forwards the job to it; then the execution cluster selects a suitable host and dispatches the job to it. This method automatically favors local hosts; a MultiCluster send-jobs queue always attempts to find a suitable local host before considering a receive-jobs queue in another cluster.

### Resource leasing model

In this model, the cluster that is starving for resources takes resources away from the cluster that has resources to spare. To work together, the provider cluster must “export” resources to the consumer, and the consumer cluster must configure a queue to use those resources.

In this model, each cluster schedules work on a single system image, which includes both borrowed hosts and local hosts.

### Choosing a model

Consider your own goals and priorities when choosing the best resource-sharing model for your site.

- ◆ The job forwarding model can make resources available to jobs from multiple clusters, this flexibility allows maximum throughput when each cluster’s resource usage fluctuates. The resource leasing model can allow one cluster exclusive control of a dedicated resource, this can be more efficient when there is a steady amount of work.
- ◆ The lease model is the most transparent to users and supports the same scheduling features as a single cluster.
- ◆ The job forwarding model has a single point of administration, while the lease model shares administration between provider and consumer clusters.

### Resizable jobs

Resizable jobs across MultiCluster clusters is not supported. This implies following behaviors:

- ◆ For the forwarding model, once job is forwarded to remote cluster, job is not autoresizable.
- ◆ For the lease model, the initial allocation for the job may contain lease hosts. But once the job allocation includes a leased host, LSF does not generate a pending

---

allocation request. LSF does not allocate any leased hosts to pending allocation requests.

- ◆ You cannot run `bresize` commands to grow or shrink allocations from submission clusters in either lease model or job forwarding model

Only `bresize release` is supported in the job forwarding model from execution cluster:

- ◆ The submission cluster does log all events related to `bresize release` in submission cluster `lsb.events` file
- ◆ The submission cluster logs `JOB_RESIZE` events into `lsb.acct` file after the allocation is changed.
- ◆ Users should be able to view allocation changes from submission cluster through `bjobs`, `bhist` and `bacct`, `busers`, `bqueues` etc.

---

## Testing the Resource Leasing Model

The following instructions explain how to configure the lease model on two clusters. `cluster2` will be the resource provider; it will export hosts to `cluster1`.

- 1 In the provider cluster, edit the `LSF_TOP/conf/lsbatch/cluster_name/configdir/lsb.resources` file to specify the hosts to be exported.

For example, in `cluster2`, one job slot each on `hostE` and `hostF` will be exported and can be used by `cluster1`:

```
Begin HostExport
PER_HOST      = hostE hostF
SLOTS         = 1
DISTRIBUTION = ([cluster1, 100])
End HostExport
```

- 2 Reconfigure the cluster:  
`% badmin reconfig`
- 3 Use the `bclusters` command to make sure the cluster is configured correctly.

For example, in `cluster2`:

```
% bclusters
...
[Resource Lease Information]
REMOTE_CLUSTER RESOURCE_FLOW STATUS
cluster1        EXPORT        conn
```

- 4 In the consumer cluster, edit the `LSF_TOP/conf/lsbatch/cluster_name/configdir/lsb.queues` file and add a queue that will use the hosts borrowed from the provider cluster as if they were local resources. For example, in `cluster1`:

```
Begin Queue
QUEUE_NAME = ssimodel
HOSTS      = all@cluster2
DESCRIPTION = Jobs in this queue will use cluster2 hosts
End Queue
```

- 5 Reconfigure the cluster:  
`% badmin reconfig`
  - 6 Use the `bclusters` command to make sure the queue is configured correctly.
- For example, in `cluster1`:

```
% bclusters
...
[Resource Lease Information ]
REMOTE_CLUSTER RESOURCE_FLOW STATUS
cluster2        IMPORT        conn
```

- 7 Submit a job to the queue in `cluster1`. It must run on a host borrowed from `cluster2`.

### Example

Submit a job to the queue named `ssimodel` in `cluster1`:

---

```
% bsub -q ssimodel -R "type==any" sleep 500
Job <204> is submitted to queue <ssimodel>.
```

```
% bjobs
JOBID  USER  STAT  QUEUE      FROM_HOST      EXEC_HOST      JOB_NAME      SUBMI
T_TIME
204    user1  RUN   ssimodel  hostA          hostE@cluster2 sleep 500      Nov
13 12:15
```

```
% bhosts
HOST_NAME      STATUS      JL/U  MAX  NJOBS  RUN  SSUSP  USUSP  RSV
hostE@cluster2 ok          -    1    1      1    0      0      0
hostA          ok          -    -    0      0    0      0      0
```

You can also view this job from `cluster2`, where it has a different job ID:

```
% bjobs
JOBID  USER  STAT  QUEUE                FROM_HOST      EXEC_HOST      JOB_NAME      SUBMI
T_TIME
854    user1  RUN   ssimodel@cluster1  hostA@cluster1 hostE          sleep 500      Nov
13 12:15
```

---

## Testing the Job Forwarding Model

The following instructions explain how to configure the job forwarding model on two clusters. `cluster2` will be the execution cluster; it will run jobs for `cluster1`.

- 1 In the submission cluster, edit the `LSF_TOP/conf/lsbatch/cluster_name/configdir/lsb.queues` file and add a queue to send jobs to the execution cluster.

For example, configure a queue called `sendq` in `cluster1` that will send all jobs to execute in `cluster2`:

```
Begin Queue
QUEUE_NAME = sendq
SNDJOBS_TO = receiveq@cluster2
HOSTS      = none
DESCRIPTION = Jobs submitted to this queue will be run in
cluster2
End Queue
```

`HOSTS = none` specifies that this queue cannot place jobs on any local hosts.

- 2 Reconfigure the cluster:

```
% badmin reconfig
```

- 3 In the execution cluster, edit the

`LSF_TOP/conf/lsbatch/cluster_name/configdir/lsb.queues` file and add a queue to receive jobs sent from the submission cluster.

For example, configure a queue called `receiveq` in `cluster2` that will receive jobs from `cluster1`:

```
Begin Queue
QUEUE_NAME = receiveq
PRIORITY   = 40
RCVJOBS_FROM = cluster1
End Queue
```

- 4 Reconfigure the cluster:

```
% badmin reconfig
```

- 5 Use the `bclusters` command to make sure the queues are configured correctly.

For example, in `cluster1`:

```
% bclusters
LOCAL_QUEUE JOB_FLOW REMOTE CLUSTER STATUS
sendq       send      receiveq cluster2 ok
```

For example, in `cluster2`:

```
% bclusters
LOCAL_QUEUE JOB_FLOW REMOTE CLUSTER STATUS
receiveq    recv      -      cluster1 ok
```

- 6 Submit a job to make sure the queues are configured correctly.

### Example

Submit a job to `cluster1` that will run in `cluster2`:

---

```
% bsub -q sendq -R "type==any" sleep 500
Job <103> is submitted to queue <sendq>.
```

```
% bjobs
```

JOBID	USER	STAT	QUEUE	FROM_HOST	EXEC_HOST	JOB_NAME	SUBMIT_TIME
103	user1	RUN	sendq	hostA	hostE@cluster2	sleep 500	Nov 13 11:44

You can also view this job from `cluster2`, where it has a new job ID:

JOBID	USER	STAT	QUEUE	FROM_HOST	EXEC_HOST	JOB_NAME	SUBMIT_TIME
899	user1	RUN	receiveq	hostA@cluster1	hostE	sleep 500	Nov 13 11:44

## MultiCluster Setup

- Contents
- ◆ Basic Setup (required)
    - ❖ [“Setup Overview”](#) on page 14
  - ◆ Advanced Setup (optional)
    - ❖ [“Non-Uniform Name Spaces”](#) on page 20
    - ❖ [“Restricted Awareness of Remote Clusters”](#) on page 23
    - ❖ [“Security of Daemon Communication”](#) on page 25
    - ❖ [“Authentication Between Clusters”](#) on page 26
  - ◆ Performance Tuning (optional)
    - ❖ [“Resource Use Updating for MultiCluster Jobs”](#) on page 28
    - ❖ [“MultiCluster Information Cache”](#) on page 29

---

## Setup Overview

- ◆ [“System requirements”](#) on page 14
- ◆ [“Installation and configuration procedures”](#) on page 15
- ◆ [“Licensing MultiCluster”](#) on page 17
- ◆ [“Installing MultiCluster products”](#) on page 17
- ◆ [“Setting common ports”](#) on page 18
- ◆ [“Setting common resource definitions”](#) on page 18
- ◆ [“Defining participating clusters and valid master hosts”](#) on page 18

## System requirements

The setup procedures will guide you through configuring your system to meet each requirement. However, you might find it helpful to understand the system requirements before you begin. This section includes:

- ◆ [“Requirements to install MultiCluster”](#)
- ◆ [“Requirements for MultiCluster communication to occur between 2 clusters”](#)
- ◆ [“Requirements for resource sharing to occur between 2 clusters”](#)
- ◆ [“Requirements for jobs to run across clusters”](#)

### Requirements to install MultiCluster

MultiCluster is a licensed product; you will have to obtain a license from Platform Computing in order to run MultiCluster.

You can use MultiCluster to link two or more LSF clusters. Then, the participating clusters can be configured to share resources.

MultiCluster files are automatically installed by LSF’s regular Setup program (`lsfinstall`). Install LSF and make sure each cluster works properly as a standalone cluster before you proceed to configure MultiCluster.

### Requirements for MultiCluster communication to occur between 2 clusters

- ◆ The local master host must be configured to communicate with the remote cluster:
  - ❖ The local cluster can only communicate with other clusters if they are specified in `lsf.shared`. See [“Defining participating clusters and valid master hosts”](#) on page 18.
  - ❖ If the `RemoteClusters` section in `lsf.cluster.cluster_name` is defined, the local cluster has a list of recognized clusters, and is only aware of those clusters. See [“Restricted Awareness of Remote Clusters”](#) on page 23.
- ◆ The local master host must be able to contact the master host of the remote cluster:
  - ❖ The valid master host list for remote clusters is used to locate the current master host on that cluster and ensure that any remote host is a valid master host for its cluster. See [“Defining participating clusters and valid master hosts”](#) on page 18.
  - ❖ Participating clusters must use the same port numbers for the LSF daemons `RES`, `mbatchd`, and `sbatchd`, and the LIM daemon. By default, all clusters have the identical settings. See [“Setting common ports”](#) on page 18.

---

## Requirements for resource sharing to occur between 2 clusters

- ◆ The local cluster must use the same resource definitions as the remote cluster:
  - ❖ Clusters should have common definitions of host types, host models, and resources. Each cluster finds this information in `lsf.shared`. See [“Setting common resource definitions”](#) on page 18.
- ◆ A host cannot belong to more than one cluster.
- ◆ The local cluster and the remote cluster must have compatible configurations, with the resource owner sharing the resource and the resource consumer seeking to use the resource.
  - ❖ For the job forwarding model, See [“Enabling MultiCluster Queues”](#) on page 44.
  - ❖ For the resource leasing model, see [“Creating an Export Policy”](#) on page 62 and [“Borrowing Resources”](#) on page 72.

## Requirements for jobs to run across clusters

- ◆ The user must have a valid user account in each cluster.
  - ❖ By default, LSF expects that the user accounts will have the same name in each cluster. If clusters do not share a file system and common user name space, you can configure account mapping. See [“Account mapping between clusters”](#) on page 20.
- ◆ LSF must be able to transfer job files and data files between clusters.
- ◆ Dynamic IP addressing is not supported across clusters. LSF client hosts require a fixed IP address to communicate with a host that belongs to another cluster.
- ◆ If you use floating client hosts, do not share `lsf.conf` files. You must configure separate `lsf.conf` files for each cluster.
- ◆ If you use static clients (listed in `lsf.cluster.cluster_name`), you may choose to share one `lsf.conf` file across multiple clusters. LSF client hosts can only use servers in their local cluster, so if you do this, you must have at least one host from each cluster listed in the `LSF_SERVER_HOSTS` line. To improve performance, configure separate `lsf.conf` files for each cluster instead of sharing `lsf.conf`.

## Installation and configuration procedures

To install and configure MultiCluster, take these steps:

- 1 [“Plan the cluster”](#)
- 2 [“Required tasks to establish communication between clusters”](#)
- 3 [“Additional tasks that might be required to establish communication between clusters”](#)
- 4 [“Testing communication between clusters”](#)
- 5 [“Required tasks to establish resource sharing”](#)
- 6 [“Optional tasks”](#)

- Plan the cluster 1 Read the overview to learn about how MultiCluster can be useful to you. See [“MultiCluster Overview”](#) on page 5.

- 2 Decide which clusters will participate. Read about setup to learn about the issues that could prevent clusters from working together. See “[MultiCluster Setup](#)” on page 13.
- 3 Decide which resources you want to share.
- 4 Decide how you will share the resources among clusters. To learn about the various configuration options, see “[MultiCluster Job Forwarding Model](#)” on page 31 or “[MultiCluster Resource Leasing Model](#)” on page 55.
- 5 Read about setup to learn about configuration options common to both models. See “[MultiCluster Setup](#)” on page 13.

#### Required tasks to establish communication between clusters

- 1 For each participating cluster, obtain and install a valid MultiCluster license. See “[Licensing MultiCluster](#)” on page 17.
- 2 For each participating cluster, add the MultiCluster product to the LSF cluster configuration file. See “[Installing MultiCluster products](#)” on page 17.
- 3 For resource sharing to work between clusters, the clusters should have common definitions of host types, host models, and resources. Configure this information in `lsf.shared`. See “[Setting common resource definitions](#)” on page 18.
- 4 To establish communication, clusters must be aware of other clusters and know how to contact other clusters. Add each cluster name and its master host name to Cluster section of `lsf.shared`. “[Defining participating clusters and valid master hosts](#)” on page 18.

#### Additional tasks that might be required to establish communication between clusters

- 1 By default, LSF assumes a uniform user name space within a cluster and between clusters.
- 2 With MultiCluster, LSF daemons can use non-privileged ports. By default, LSF daemons in a MultiCluster environment use privileged port authentication. See “[Security of Daemon Communication](#)” on page 25.

#### Testing communication between clusters

- 1 Restart each cluster using the `lsadmin` and `badmin` commands.
 

```
% lsadmin limrestart all
% badmin mbdrestart
```
- 2 To verify that MultiCluster is enabled, run `lsclusters` and `bclusters`.

```
% lsclusters
CLUSTER_NAME  STATUS  MASTER_HOST  ADMIN  HOSTS  SERVERS
cluster1      ok      hostA        admin1  1      1
cluster2      ok      hostD        admin2  3      3
```

```
% bclusters
[Remote Batch Information]
No local queue sending/receiving jobs from remote clusters
```

#### Required tasks to establish resource sharing

- 1 Optional. Run a simple test of resource sharing. See “[Testing the Resource Leasing Model](#)” on page 9 or “[Testing the Job Forwarding Model](#)” on page 11.

- 
- Optional tasks
- 2 Configure resource-sharing policies between clusters. See “[MultiCluster Job Forwarding Model](#)” on page 31 or “[MultiCluster Resource Leasing Model](#)” on page 55.
  - 1 By default, all the clusters in a MultiCluster environment are aware of all the other clusters. This makes it possible for clusters to share resources or information. You can restrict awareness of remote clusters at the cluster level. See “[Restricted Awareness of Remote Clusters](#)” on page 23.
  - 2 With MultiCluster, LSF daemons can use non-privileged ports (by default, LSF daemons in a MultiCluster environment use privileged port authentication). You can also choose the method of daemon authentication. See “[Security of Daemon Communication](#)” on page 25 and “[Authentication Between Clusters](#)” on page 26.
  - 3 When a local cluster requests load or host information from a remote cluster, the information is cached. If the local cluster is required to display the same information again, LSF displays the cached information, unless the cache has expired. The expiry period for cached information is configurable. See “[Cache thresholds](#)” on page 29.
  - 4 The default configuration of LSF is that clusters share information about the resources used by other clusters, and the information is updated every 5 minutes by the execution or provider cluster. You can disable the feature or modify how often MultiCluster resource use is updated. See “[Configuring resource use updating for MultiCluster jobs](#)” on page 28.
  - 5 To learn about optional features related to each configuration model, see “[MultiCluster Job Forwarding Model](#)” on page 31 or “[MultiCluster Resource Leasing Model](#)” on page 55.

## Licensing MultiCluster

To license MultiCluster, do the following:

- 1 Send the license server host IDs for each participating cluster to your LSF vendor, and Platform Computing will generate license keys for you.
- 2 Append the new FEATURE lines to your existing LSF `license.dat` files, so that each participating cluster is appropriately licensed. The feature line required to license MultiCluster is `lsf_multicluster`.
- 3 To make the change take effect, restart each LSF cluster and each license server.

## Installing MultiCluster products

MultiCluster files are automatically installed by LSF’s regular Setup program (`lsfinstall`). Install LSF and make sure each cluster works properly as a standalone cluster before you proceed to configure MultiCluster.

To make each cluster run MultiCluster, add `LSF_MultiCluster` to the products specified in the parameters section of `lsf.cluster.cluster_name`:

```
Begin Parameters
PRODUCTS=LSF_Base LSF_Manager LSF_MultiCluster
End Parameters
```

---

## Setting common ports

Participating clusters must use the same port numbers for the daemons LIM, RES, and MBD.

By default, all clusters have the identical settings, as shown:

```
LSF_LIM_PORT=7869
LSF_RES_PORT=6878
LSB_MBD_PORT=6881
LSB_SBD_PORT=6882
```

**LSF\_LIM\_PORT change** The default for LSF\_LIM\_PORT has changed to accommodate Platform EGO default port configuration. On EGO, default ports start with `lim` at 7869, and are numbered consecutively for the EGO `pem`, `vemkd`, and `egosc` daemons.

This is different from previous LSF releases where the default LSF\_LIM\_PORT was 6879. LSF `res`, `sbatchd`, and `mbatchd` continue to use the default pre-7.0 ports 6878, 6881, and 6882.

Upgrade installation preserves existing port settings for `lim`, `res`, `sbatchd`, and `mbatchd`. EGO `pem`, `vemkd`, and `egosc` use default EGO ports starting at 7870, if they do not conflict with existing `lim`, `res`, `sbatchd`, and `mbatchd` ports.

**YTroubleshooting** To check your port numbers, check the `LSF_TOP/conf/lsf.conf` file in each cluster. (LSF\_TOP is the LSF installation directory. On UNIX, this is defined in the `install.config` file). Make sure you have identical settings in each cluster for the following parameters:

- ◆ LSF\_LIM\_PORT
- ◆ LSF\_RES\_PORT
- ◆ LSB\_MBD\_PORT
- ◆ LSB\_SBD\_PORT

## Setting common resource definitions

For resource sharing to work between clusters, the clusters should have common definitions of host types, host models, and resources. Each cluster finds this information in `lsf.shared`, so the best way to configure MultiCluster is to make sure `lsf.shared` is identical for each cluster. If you do not have a shared file system, replicate `lsf.shared` across all clusters.

## Defining participating clusters and valid master hosts

To enable MultiCluster, define all participating clusters in the Cluster section of the `LSF_TOP/conf/lsf.shared` file.

- 1 For `ClusterName`, specify the name of each participating cluster. On UNIX, each cluster name is defined by `LSF_CLUSTER_NAME` in the `install.config` file.
- 2 For `Servers`, specify one or more candidate master hosts for the cluster (these are the first hosts listed in the `Host` section of `lsf.cluster.cluster_name`). A cluster will not participate in MultiCluster resource sharing unless its current master host is listed here.

---

**Example** Begin Cluster  
ClusterName Servers  
Cluster1 (hostA hostB)  
Cluster2 (hostD)  
End Cluster

In this example, `hostA` should be the master host of `Cluster1` (the first host listed in `lsf.cluster.cluster1` HOST section) with `hostB` as the backup, and `hostD` should be the master host of `Cluster2`. If the master host fails in `Cluster1`, `MultiCluster` will still work because the backup master is also listed here. However, if the master host fails in `Cluster2`, `MultiCluster` will not recognize any other host as the master, so `Cluster2` will no longer participate in `MultiCluster` resource sharing.

## EGO\_PREDEFINED\_RESOURCES in lsf.conf

When Platform EGO is enabled in the LSF cluster (`LSF_ENABLE_EGO=Y`), you also can set the several EGO parameters related to LIM, PIM, and ELIM in either `lsf.conf` or `ego.conf`.

All clusters must have the same value of `EGO_PREDEFINED_RESOURCES` in `lsf.conf` to enable the `nprocs`, `ncores`, and `nthreads` host resources in remote clusters to be usable.

See *Administering Platform LSF* for more information about configuring Platform LSF on EGO.

---

## Non-Uniform Name Spaces

By default, LSF assumes a uniform user name space within a cluster and between clusters.

**User account mapping** To support the execution of batch jobs across non-uniform user name spaces between clusters, LSF allows user account mapping.

See “[Account mapping between clusters](#)” on page 20.

**File transfer** By default, LSF uses `lsrscp` for file transfer (`bsub -f` option),

The `lsrscp` utility depends on a uniform user ID in different clusters.

---

## Account mapping between clusters

By default, LSF assumes a uniform user name space within a cluster and between clusters. To support the execution of batch jobs across non-uniform user name spaces between clusters, LSF allows user account mapping.

For a job submitted by one user account in one cluster to run under a different user account on a host that belongs to a remote cluster, both the local and remote clusters must have the account mapping properly configured. System-level account mapping is configured by the LSF administrator, while user-level account mapping can be configured by LSF users.

## System-level account mapping

You must be an LSF administrator to configure system level account mapping.

System-level account mapping is defined in the `UserMap` section of `lsb.users`. The submission cluster proposes a set of user mappings (defined using the keyword `export`) and the execution cluster accepts a set of user mappings (defined using the keyword `import`). For a user’s job to run, the mapping must be both proposed and accepted.

**Example** `lsb.users` on cluster1:

```
Begin UserMap
LOCAL      REMOTE                                DIRECTION
user1      user2@cluster2                          export
user3      (user4@cluster2 user6@cluster2)         export
End UserMap
```

`lsb.users` on cluster2:

```
Begin UserMap
LOCAL      REMOTE                                DIRECTION
user2      user1@cluster1                          import
(user6 user8) user3@cluster1                        import
End UserMap
```

Cluster1 configures `user1` to run jobs as `user2` in `cluster2`, and `user3` to run jobs as `user4` or `user6` in `cluster2`.

Cluster2 configures `user1` from `cluster1` to run jobs as `user2`, and `user3` from `cluster1` to run jobs as `user6` or `user8`.

---

Only mappings configured in both clusters work. The common account mappings are for `user1` to run jobs as `user2`, and for `user3` to run jobs as `user6`. Therefore, these mappings work, but the mappings of `user3` to users 4 and 8 are only half-done and so do not work.

## User-level account mapping

To set up your own account mapping, set up an `.lsfhosts` file in your home directory with Owner Read-Write permissions only. Do not give other users and groups permissions on this file.

Account mapping can specify cluster names in place of host names.

**Example #1** You have two accounts: `user1` on `cluster1`, and `user2` on `cluster2`. To run jobs in either cluster, configure `.lsfhosts` as shown.

On each host in `cluster1`:

```
% cat ~user1/.lsfhosts
cluster2 user2
```

On each host in `cluster2`:

```
% cat ~user2/.lsfhosts
cluster1 user1
```

**Example #2** You have the account `user1` on `cluster1`, and want to run jobs on `cluster2` under the `lsfguest` account. Configure `.lsfhosts` as shown.

On each host in `cluster1`:

```
% cat ~user1/.lsfhosts
cluster2 lsfguest send
```

On each host in `cluster2`:

```
% cat ~lsfguest/.lsfhosts
cluster1 user1 recv
```

**Example #3** You have a uniform account name (`user2`) on all hosts in `cluster2`, and a uniform account name (`user1`) on all hosts in `cluster1` except `hostX`. On `hostX`, you have the account name `user99`.

To use both clusters transparently, configure `.lsfhosts` in your home directories on different hosts as shown.

On `hostX` in `cluster1`:

```
% cat ~user99/.lsfhosts
cluster1 user1
hostX user99
cluster2 user2
```

On every other host in `cluster1`:

```
% cat ~user1/.lsfhosts
cluster2 user2
hostX user99
```

On each host in `cluster2`:

---

```
% cat ~user2/.lsfhosts
cluster1    user1
hostX      user99
```

---

## Restricted Awareness of Remote Clusters

By default, all the clusters in a MultiCluster environment are aware of all the other clusters. This makes it possible for clusters to share resources or information when you configure MultiCluster links between them.

You can restrict awareness of remote clusters at the cluster level, by listing which of the other clusters in the MultiCluster environment are allowed to interact with the local cluster. In this case, the local cluster cannot display information about unrecognized clusters and does not participate in MultiCluster resource sharing with unrecognized clusters.

### How it works

By default, the local cluster can obtain information about all other clusters specified in `lsf.shared`. The default behavior of RES is to accept requests from all the clusters in `lsf.shared`.

If the `RemoteClusters` section in `lsf.cluster.cluster_name` is defined, the local cluster has a list of recognized clusters, and is only aware of those clusters. The local cluster is not aware of the other clusters in the MultiCluster environment:

- ◆ The cluster does not forward jobs to unrecognized clusters, even if a local queue is configured to do so.
- ◆ The cluster does not borrow resources from unrecognized clusters, even if the remote cluster has exported the resources.
- ◆ The cluster does not export resources to unrecognized clusters, even if the local resource export section is configured to do so.
- ◆ The cluster does not receive jobs from unrecognized clusters, even if a local queue is configured to do so.
- ◆ The cluster cannot view information about unrecognized clusters.

However, remote clusters might still be aware of this cluster:

- ◆ Unrecognized clusters can view information about this cluster.
- ◆ Unrecognized clusters can send MultiCluster jobs to this cluster (they will be rejected, even if a local queue is configured to accept them).
- ◆ Unrecognized clusters can export resources to this cluster (this cluster will not use the resources, even if a local queue is configured to import them).

**Example** This example illustrates how the `RemoteClusters` list works.

The MultiCluster environment consists of 4 clusters with a common `lsf.shared`:

```
CLUSTERS
cluster1
cluster2
cluster3
cluster4
```

In addition, `cluster2` is configured with a `RemoteClusters` list in `lsf.cluster.cluster_name`:

---

```
Begin RemoteClusters
CLUSTERNAME
cluster3
cluster4
End RemoteClusters
```

Because of the `RemoteClusters` list, local applications in `cluster2` are aware of `cluster3` and `cluster4`, but not `cluster1`. For example, if you view information or configure queues using the keyword `all`, LSF will behave as if you specified the list of recognized clusters instead of all clusters in `lsf.shared`.

## Adding or modifying RemoteClusters list

You must have cluster administrator privileges in the local cluster to perform this task.

- 1 Open `lsf.cluster.cluster_name` of the local cluster.
- 2 If it does not already exist, create the `RemoteClusters` section as shown:

```
Begin RemoteClusters
CLUSTERNAME
...
End RemoteClusters
```
- 3 Edit the `RemoteClusters` section. Under the heading `CLUSTERNAME`, specify the names of the remote clusters that you want the local cluster recognize. These clusters must also be listed in `lsf.shared`, so the `RemoteClusters` list is always a subset of the clusters list in `lsf.shared`.

---

## Security of Daemon Communication

With MultiCluster, LSF daemons can be configured to communicate over non-privileged ports (by default, LSF daemons in a MultiCluster environment use privileged port authentication).

If disabling the privileged port authentication makes you concerned about the security of daemon authentication, you can use an `eauth` program to enable any method of authentication for secure communication between clusters. See “[Authentication Between Clusters](#)” on page 26.

- Requirements**
- ◆ Configure all clusters to use non-privileged ports for LSF daemon communication.
  - ◆ If you use a firewall, it must accept incoming communication from non-privileged source ports if the destination ports are the LIM port configured `LSF_LIM_PORT` in `lsf.conf` and `mbatchd` port configured in `LSB_MBD_PORT` in `lsf.conf`.
  - ◆ If you use a firewall, it must allow outgoing communication from non-privileged source ports to non-privileged destination ports.
- Steps**
- 1 To make LSF daemons use non-privileged ports, edit `lsf.conf` in every cluster as shown:  
`LSF_MC_NON_PRIVILEGED_PORTS=Y`
  - 2 To make the changes take effect, restart the master LIM and MBD in every cluster. For example, if a cluster's master host is `hostA`, run the following commands in that cluster:  
`lsadmin limrestart hostA`  
`badmin mbdrestart`

---

## Authentication Between Clusters

For extra security, you can use any method of external authentication between any two clusters in the MultiCluster grid.

Because this is configured for individual clusters, not globally, different cluster pairs can use different systems of authentication. You use a different `eauth` program for each different authentication mechanism.

If no common external authentication method has been configured, two clusters communicate with the default security, which is privileged port authentication.

### eauth executables

Contact Platform Professional Services for more information about the `eauth` programs that Platform distributes to allow LSF to work with different security mechanisms. If you already have an `eauth` that works with LSF for daemon authentication within the cluster, use a copy of it.

If different clusters use different methods of authentication, set up multiple `eauth` programs.

- Steps**
- 1 Copy the corresponding `eauth` program to `LSF_SERVERDIR`.
  - 2 Name the `eauth` program `eauth.method_name`.  
If you happen to use the same `eauth` program for daemon authentication within the cluster, you should have two copies, one named `eauth` (used by LSF) and one named `eauth.method_name` (used by MultiCluster).

### MultiCluster configuration

- Steps**
- 1 Edit the `lsf.cluster.cluster_name RemoteClusters` section.  
If the cluster does not already include a RemoteClusters list, you must add it now. To maintain the existing compatibility, specify all remote clusters in the list, even if the preferred method of authentication is the default method.
  - 2 If necessary, add the AUTH column to the RemoteClusters section.
  - 3 For each remote cluster, specify the preferred authentication method. Set AUTH to `method_name` (using the same method name that identifies the corresponding `eauth` program). For default behavior, specify a dash (-).
  - 4 To make the changes take effect in a working cluster, run the following commands:  

```
lsadmin limrestart master_host  
badmin mbdreconfig
```

Repeat the steps for each cluster that will use external authentication, making sure that the configurations of paired-up clusters match.

### Configuration example

In this example, Cluster1 and Cluster2 use Kerberos authentication with each other, but not with Cluster3. It does not matter how Cluster3 is configured, because there is no extra authentication unless the configurations of both clusters agree.

**Cluster1** `lsf.cluster.cluster1:`

---

```
Begin RemoteClusters
CLUSTERNAME  EQUIV  CACHE_INTERVAL  RECV_FROM  AUTH
cluster2     Y      60              Y          KRB
cluster3     N      30              N          -
End RemoteClusters
```

LSF\_SERVERDIR in Cluster1 includes an eauth executable named eauth.KRB.

**Cluster2** lsf.cluster.cluster2:

```
Begin RemoteClusters
CLUSTERNAME  EQUIV  CACHE_INTERVAL  RECV_FROM  AUTH
cluster1     Y      60              Y          KRB
cluster3     N      30              N          -
End RemoteClusters
```

LSF\_SERVERDIR in Cluster2 includes an eauth executable named eauth.KRB.

---

## Resource Use Updating for MultiCluster Jobs

Upon installation, the default configuration of LSF is that clusters share information about the resources used by other clusters, and the information is updated every 5 minutes by the execution or provider cluster. You can disable the feature or modify how often MultiCluster resource use is updated. Depending on load, updating the information very frequently can affect the performance of LSF.

### Configuring resource use updating for MultiCluster jobs

To change the timing of resource usage updating between clusters, set `MC_RUSAGE_UPDATE_INTERVAL` in `lsb.params` in the execution or provider cluster. Specify how often to update the information in the submission or consumer cluster, in seconds.

To disable LSF resource usage updating between clusters, specify zero:

```
MC_RUSAGE_UPDATE_INTERVAL=0
```

**Restriction** You must configure this parameter manually; you cannot use LSF GUI tools to add or modify this parameter.

---

## MultiCluster Information Cache

When a local cluster requests load or host information from a remote cluster, the information is cached. If the local cluster is required to display the same information again, LSF displays the cached information, unless the cache has expired.

The expiry period for cached information is configurable, so you can view more up-to-date information if you don't mind connecting to the remote cluster more often.

It is more efficient to get information from a local cluster than from a remote cluster. Caching remote cluster information locally minimizes excessive communication between clusters.

### Cache thresholds

The cache threshold is the maximum time that remote cluster information can remain in the local cache.

There are two cache thresholds, one for load information, and one for host information. The threshold for host information is always double the threshold for load information.

By default, cached load information expires after 60 seconds and cached host information expires after 120 seconds.

### How it works

When a local cluster requests load or host information from a remote cluster, the information is cached by the local master LIM.

When the local cluster is required to display the same information again, LSF evaluates the age of the information in the cache.

- ◆ If the information has been stored in the local cluster for longer than the specified time, LSF contacts the remote cluster again, updates the cache, and displays current information.
- ◆ If the age of the cached information is less than the threshold time, LSF displays the cached information.

### Configuring cache threshold

Set `CACHE_INTERVAL` in the `RemoteClusters` section of `lsf.cluster.cluster_name`, and specify the number of seconds to cache load information.

## MultiCluster Job Forwarding Model

This model was developed for the high-throughput computing environment.

## Overview of the Job Forwarding Model

In this model, the cluster that is starving for resources sends jobs over to the cluster that has resources to spare. Job status, pending reason, and resource usage are returned to the submission cluster. When the job is done, the exit code returns to the submission cluster.

---

## Job Scheduling Under the Job Forwarding Model

With this model, scheduling of MultiCluster jobs is a process with two scheduling phases: the submission cluster selects a suitable remote receive-jobs queue, and forwards the job to it; then the execution cluster selects a suitable host and dispatches the job to it. If a suitable host is not found immediately, the job remains pending in the execution cluster, and is evaluated again the next scheduling cycle.

This method automatically favors local hosts; a MultiCluster send-jobs queue always attempts to find a suitable local host before considering an receive-jobs queue in another cluster.

### Phase I, local scheduling phase (all jobs)

- 1 The send-jobs queue receives the job submission request from a user.
- 2 The send-jobs queue parameters affect whether or not the job is accepted. For example, a job that requires 100 MB memory will be rejected if queue-level parameters specify a memory limit of only 50 MB.
- 3 If the job is accepted, it becomes pending in the send-jobs queue with a job ID assigned by the submission cluster.
- 4 During the next scheduling cycle, the send-jobs queue attempts to place the job on a host in the submission cluster. If a suitable host is found, the job is dispatched locally.
- 5 If the job cannot be placed locally (local hosts may not satisfy its resource requirements, or all the local hosts could be busy), the send-jobs queue attempts to forward the job to another cluster.

### Phase II, job forwarding phase (MultiCluster submission queues only)

- 1 The send-jobs queue has a list of remote receive-jobs queues that it can forward jobs to. If a job cannot be placed locally, the send-jobs queue evaluates each receive-jobs queue. All queues that will accept more MultiCluster jobs are candidates. To find out how many additional MultiCluster jobs a queue can accept, subtract the number of MultiCluster jobs already pending in the queue from the queue's pending MultiCluster job threshold (IMPT\_JOBKLG). The order of preference is determined by the capacity; the first queue evaluated is the one that has room to accept the most new MultiCluster jobs.
- 2 If information available to the submission cluster indicates that the first queue is suitable, LSF forwards the job to that queue.
- 3 If the first queue is not suitable, LSF considers the next queue.
- 4 If LSF cannot forward the job to any of the receive-jobs queues, the job remains pending in the send-jobs cluster and is evaluated again during the next scheduling cycle.

---

## Phase III, remote scheduling phase (MultiCluster jobs only)

- 1 The receive-jobs queue receives the MultiCluster job submission.
- 2 The receive-jobs queue parameters affect whether or not the job is accepted. For example, a job that requires 100 MB memory will be rejected if queue-level parameters specify a memory limit of only 50 MB.
- 3 If the job is rejected, it returns to the submission cluster.
- 4 If the job is accepted, it becomes pending in the receive-jobs queue with a new job ID assigned by the execution cluster.
- 5 During the next scheduling cycle, the receive-jobs queue attempts to place the job on a host in the execution cluster. If a suitable host is found, the job is dispatched. If a suitable host is not found, the job remains pending in the receive-jobs cluster, and is evaluated again the next scheduling cycle.
- 6 If the job is dispatched to the execution host but cannot start, it returns to the submission cluster to be rescheduled. However, if the job repeatedly returns to the submission cluster because it could not be started in a remote cluster, LSF suspends the job (PSUSP) in the submission cluster.

---

# Queue Scheduling Parameters Under the Job Forwarding Model

## Forcing consistent scheduling behavior

If the queue policies of the send-jobs queue are the same as the queue policies of the receive-jobs queue, the user should see identical behavior, whether the job is scheduled locally or remotely.

## Queue policies differ

The job-level (user-specified) requirements and queue-level parameters (set by the administrator) are used to schedule and run the job.

If a job runs in the submission cluster, the send-jobs queue parameters apply. If a job becomes a MultiCluster job and runs in another cluster, the receive-jobs queue parameters apply.

Since the receive-jobs queue policies replace the send-jobs queue policies, LSF users might notice that identical jobs are subject to different scheduling policies, depending on whether or not the job becomes a MultiCluster job.

### Send-jobs queue parameters that affect MultiCluster jobs

- ◆ If the job requirements conflict with the send-jobs queue parameters, the job is rejected by the send-jobs queue.
- ◆ In general, queue-level parameters at the submission side don't affect the scheduling of MultiCluster jobs once the jobs have been forwarded to the execution queue.

### Receive-jobs queue parameters that affect MultiCluster jobs

In general, queue-level policies set on the execution side are the only parameters that affect MultiCluster jobs:

- ◆ If the job requirements conflict with the receive-jobs queue parameters, the job is rejected by the receive-jobs queue and returns to the submission cluster.
- ◆ Runtime queue level parameters (terminate when, job starter, load threshold, exclusive, etc): the receive-jobs queue settings are enforced, the send-jobs queue settings are ignored.
- ◆ Resource requirements: the receive-jobs queue settings are enforced, the send-jobs queue settings are ignored.
- ◆ Resource limits: the execution cluster settings are enforced, the submission cluster settings are ignored.
- ◆ Job slot limits (hjob limit, ujob limit, qjob limit): the execution cluster settings are enforced, the submission cluster settings are ignored.

---

## Advance Reservations Across Clusters

Users can create and use advance reservation for the MultiCluster job forwarding model. To enable this feature, you must upgrade all clusters to LSF Version 7 or later.

### Advance reservation

The user from the submission cluster negotiates an advance reservation with the administrator of the execution cluster. The administrator creates the reservation in the execution cluster.

The reservation information is visible from the submission cluster. To submit a job and use the reserved resources, users specify the reservation at the time of job submission.

A job that specifies a reservation can only start on the reserved resources during the time of the reservation, even if other resources are available. Therefore, this type of job does not follow the normal scheduling process. Instead, the job is immediately forwarded to the execution cluster and is held in PENDING until it can start. These jobs are not affected by the remote timeout limit (`MAX_RSCHED_TIME` in `lsb.queues`) since the system cannot automatically reschedule the job to any other cluster.

### Missed reservations

If the execution cluster cannot accept the job because the reservation is expired or deleted, the job will be in the submission cluster in the PSUSP state.

The pending reason is:

```
Specified reservation has expired or has been deleted.
```

The job should be modified or killed by the owner.

If the execution cluster accepts the job and reservation expires or is deleted while job is pending, the job will be in the execution cluster in the PENDING state.

### Broken connections

If cluster connectivity is interrupted, all remote reservation is forgotten.

During this time, submission clusters will not be able to see remote reservations; jobs submitted with remote reservation and not yet forwarded will PENDING; and new jobs will not be able to use the reservation. Reservation information will not be available until cluster connectivity is re-established and the clusters have a chance to synchronize on reservation. At that time (given that reservation is still available), jobs will be forwarded, new jobs can be submitted with specified reservation, and users will be able to see the remote reservation.

### Modifying a reservation

After an advance reservation is made, you can use `brsvmod` modify the reservation.

Advance reservations only can be modified with `brsvmod` in the local cluster. A modified remote reservation is visible from the submission cluster. The jobs attached to the remote reservation are treated as the local jobs when the advance reservation is modified in the remote cluster.

---

## Deleting a reservation

After an advance reservation is made, you can use `brsvdel` to delete the reservation from the execution cluster.

**`brsvdel`** *reservation\_ID*

If you try to delete the reservation from the submission cluster, you will see an error.

---

## Submitting a jobs to use a reservation in a remote cluster

Submit the job and specify the remote advance reservation as shown:

```
bsub -U reservation_name@cluster_name
```

In this example, we assume the default queue is configured to forward jobs to the remote cluster.

## Extending a reservation

`bmod -t` allows the job to keep running after the reservation expires.

The command `bmod` does not apply to pending jobs or jobs that are already forwarded to the remote cluster. However it can be used on the execution cluster. For that, it behaves as if it is a local job.

---

## Special Considerations Under the Job Forwarding Model

- ◆ “[Chunk jobs](#)” on page 39
- ◆ “[Fairshare](#)” on page 39
- ◆ “[Parallel jobs](#)” on page 39
- ◆ “[Job requeue](#)” on page 39
- ◆ “[Job rerun](#)” on page 40
- ◆ “[Job migration](#)” on page 40
- ◆ “[Checkpointing a MultiCluster job](#)” on page 41
- ◆ “[Absolute priority scheduling](#)” on page 42
- ◆

### Chunk jobs

Job chunking is done after a suitable host is found for the job. MultiCluster jobs can be chunked, but they are forwarded to the remote execution cluster one at a time, and chunked in the execution cluster. Therefore, the `CHUNK_JOB_SIZE` parameter in the submission queue is ignored by MultiCluster jobs that are forwarded to a remote cluster for execution.

If MultiCluster jobs are chunked, and one job in the chunk starts to run, both clusters display the `WAIT` status for the remaining jobs. However, the execution cluster behaves as if these jobs are in the `PEND` state, while the submission cluster behaves as if the jobs are in the `RUN` state. This affects the scheduling calculations for fairshare and limits.

### Fairshare

If fairshare scheduling is enabled, resource usage information is a factor used in the calculation of dynamic user priority. MultiCluster jobs count towards a user’s fairshare priority in the execution cluster, and do not affect fairshare calculations in the submission cluster.

There is no requirement that both clusters use fairshare or have the same fairshare policies. However, if you submit a job and specify a local user group for fairshare purposes (`bsub -G`), your job cannot run remotely unless you also belong to a user group of the same name in the execution cluster.

For more information on fairshare, see *Administering Platform LSF*.

### Parallel jobs

A parallel job can be forwarded to another cluster, but the job cannot start unless the execution cluster has enough hosts and resources to run the entire job. A parallel job cannot span clusters.

### Job requeue

If job requeue is enabled, LSF requeues jobs that finish with exit codes that indicate job failure.

For more information on job requeue, see *Administering Platform LSF*.

<b>User-specified job requeue</b>	<p><code>bqueue</code> in the submission cluster causes the job to be requeued in the send-jobs queue.</p> <p><code>bqueue</code> in the execution cluster causes the job to be requeued in the receive-jobs queue.</p>
<b>Automatic job requeue</b>	<ol style="list-style-type: none"> <li>1 If job requeue (<code>REQUEUE_EXIT_VALUES</code> in <code>lsb.queues</code>) is enabled in the receive-jobs queue, and the job's exit code matches, the execution cluster requeues the job (it does not return to the submission cluster). Exclusive job requeue works properly.</li> <li>2 If the execution cluster does not requeue the job, the job returns to the send-jobs cluster, and gets a second chance to be requeued. If job requeue is enabled in the send-jobs queue, and the job's exit code matches, the submission cluster requeues the job.</li> </ol> <p>Exclusive job requeue values configured in the send-jobs queue always cause the job to be requeued, but for MultiCluster jobs the exclusive feature does not work; these jobs could be dispatched to the same remote execution host as before.</p>
<b>Automatic retry limits</b>	<p>The pre-execution command retry limit (<code>MAX_PREEEXEC_RETRY</code>, <code>LOCAL_MAX_PREEEXEC_RETRY</code>, and <code>REMOTE_MAX_PREEEXEC_RETRY</code>), job requeue limit (<code>MAX_JOB_REQUEUE</code>), and job preemption retry limit (<code>MAX_JOB_PREEMPT</code>) configured in <code>lsb.params</code>, <code>lsb.queues</code>, and <code>lsb.applications</code> on the execution cluster are applied.</p> <p>If the forwarded job requeue limit exceeds the limit on the execution cluster, the job exits and returns to the submission cluster and remains pending for rescheduling.</p>

## Job rerun

If job rerun is enabled, LSF automatically restarts running jobs that are interrupted due to failure of the execution host.

If queue-level job rerun (`RERUNNABLE` in `lsb.queues`) is enabled in both send-jobs and receive-jobs queues, only the receive-jobs queue reruns the job.

For more information on job rerun, see *Administering Platform LSF*.

- 1 If job rerun is enabled in the receive-jobs queue, the execution cluster reruns the job. While the job is pending in the execution cluster, the job status is returned to the submission cluster.
- 2 If the receive-jobs queue does not enable job rerun, the job returns to the submission cluster and gets a second chance to be rerun. If job rerun is enabled at the user level, or is enabled in the send-jobs queue, the submission cluster reruns the job.

## Job migration

As long as a MultiCluster job is rerunnable (`bsub -r` or `RERUNNABLE=yes` in the send-jobs queue) and is not checkpointable, you can migrate it to another host, but you cannot specify which host. Migrated jobs return to the submission cluster to be dispatched with a new job ID.

For more information on job migration, see *Administering Platform LSF*.

---

<b>User-specified job migration</b>	To migrate a job manually, run <code>bmig</code> in either the submission or execution cluster, using the appropriate job ID. You cannot use <code>bmig -m</code> to specify a host. Operating in the execution cluster is more efficient than sending the <code>bmig</code> command through the submission cluster.
<b>Automatic job migration</b>	To enable automatic job migration, set the migration threshold (MIG in <code>lsb.queues</code> ) in the receive-jobs queue. You can also set a migration threshold at the host level on the execution host (MIG in <code>lsb.hosts</code> ). The lowest migration threshold applies to the job.  Automatic job migration configured in the send-jobs queue does not affect MultiCluster jobs.
<b>Migration of checkpointable jobs</b>	Checkpointable MultiCluster jobs cannot be migrated to another host. The migration action stops and checkpoints the job, then schedules the job on the same host again.

## Checkpointing a MultiCluster job

Checkpointing of a MultiCluster job is only supported when the send-jobs queue is configured to forward jobs to a single remote receive-jobs queue, without ever using local hosts.

The checkpointable MultiCluster jobs resume on the same host.

For more information on checkpointing, see *Administering Platform LSF*.

### Configuration

#### Checkpointing MultiCluster jobs

To enable checkpointing of MultiCluster jobs, define a checkpoint directory in both the send-jobs and receive-jobs queues (CHKPNT in `lsb.queues`), or in an application profile (CHKPNT\_DIR, CHKPNT\_PERIOD, CHKPNT\_INITPERIOD, CHKPNT\_METHOD in `lsb.applications`) of both submission cluster and execution cluster. LSF uses the directory specified in the execution cluster and ignores the directory specified in the submission cluster.

Checkpointing is not supported if a job runs on a leased host.

LSF writes the checkpoint file in a subdirectory named with the submission cluster name and submission cluster job ID. This allows LSF to checkpoint multiple jobs to the same checkpoint directory. For example, the submission cluster is `ClusterA`, the submission job ID is 789, and the send-jobs queue enables checkpointing. The job is forwarded to `clusterB`, the execution job ID is 123, and the receive-jobs queue specifies a checkpoint directory called `XYZ_dir`. LSF will save the checkpoint file in:

```
XYZ_dir/clusterA/789/
```

You cannot use `bsub -k` to make a MultiCluster job checkpointable.

**Checkpointing a job** To checkpoint and stop a MultiCluster job, run `bmig` in the execution cluster and specify the local job ID. You cannot run `bmig` from the submission cluster. You cannot use `bmig -m` to specify a host.

**Forcing a checkpointed job** Use `brun` to force any pending job to be dispatched immediately to a specific host, regardless of user limits and fairshare priorities. This is the only way to resume a checkpointed job on a different host. By default, these jobs attempt to restart from the last checkpoint.

---

Use `brun -b` if you want to make checkpointable jobs start over from the beginning (for example, this might be necessary if the new host does not have access to the old checkpoint directory).

**Example** In this example, users in a remote cluster submit work to a data center using a `send-jobs` queue that is configured to forward jobs to only one `receive-jobs` queue. You are the administrator of the data center and you need to shut down a host for maintenance. The host is busy running checkpointable MultiCluster jobs.

Before you perform maintenance on a host in the execution cluster, take these steps:

- 1 Run `badmin hclose` to close the host and prevent additional jobs from starting on the host.
- 2 Run `bmig` and specify the execution cluster job IDs of the checkpointable MultiCluster jobs running on the host. For example, if jobs from a remote cluster use job IDs 123 and 456 in the local cluster, type the following command to checkpoint and stop the jobs:

```
bmig 123 456
```

You cannot use `bmig -m` to specify a host.

- 3 Allow the checkpoint process to complete. The jobs are requeued to the submission cluster. From there, they will be forwarded to the same `receive-jobs` queue again, and scheduled on the same host. However, if the host is closed, they will not start.
- 4 Shut down LSF daemons on the host.

After you perform maintenance on a host, take these steps:

- 1 Start LSF daemons on the host.
- 2 Use `badmin hopen` to open the host. The MultiCluster jobs resume automatically.

## Absolute priority scheduling

When absolute priority scheduling (APS) is enabled in the submission queue:

- ◆ The APS value at the submission cluster
  - ❖ The APS value will affect the job forwarding order for new incoming jobs, but not for jobs that have already been forwarded (that is, the job is still pending at the execution cluster)
  - ❖ The APS value does not affect the job order at the remote cluster. Job order is determined by the local policies at the remote cluster.
  - ❖ `bmod -aps` does not apply to the `send-jobs` queue
  - ❖ `bjobs -aps` shows the job order and APS value at the local cluster
- ◆ The APS value at the execution cluster
  - ❖ The APS value at receiving queue will affect remote job execution at the execution cluster
  - ❖ The APS value at the execution cluster will not be sent back to the submission cluster

---

## Strict resource requirement select string syntax

When `LSF_STRICT_RESREQ=y` is configured in `lsf.conf`, resource requirements are checked before jobs are forwarded to the remote cluster. If the selection string is valid, the job is forwarded.

When strict resource requirement checking configuration does not match between the submission and remote clusters, jobs may be rejected by the remote cluster.

## Compute unit requirement strings

When a job is submitted with compute unit resource requirements, any requirements apply only to the execution cluster. Only the syntax of the resource requirement string is checked on the submission side, and if the `cu[]` string is valid, the job is forwarded.

When compute unit requirements cannot be satisfied in the remote cluster (such as a non-existent compute unit type) jobs may be rejected by the remote cluster. Hosts running LSF 7 Update 4 or earlier cannot satisfy compute unit resource requirements.

---

## Enabling MultiCluster Queues

By default, clusters do not share resources, even if MultiCluster has been installed. To enable job forwarding, enable MultiCluster queues in both the submission and execution clusters.

### How it works

- Send-jobs queue** A send-jobs queue can forward jobs to a specified remote queue. By default, LSF attempts to run jobs in the local cluster first. LSF only attempts to place a job remotely if it cannot place the job locally.
- Receive-jobs queue** A receive-jobs queue accepts jobs from queues in a specified remote cluster. Although send-jobs queues only forward jobs to specific queues in the remote cluster, receive-jobs queues that accept jobs from a remote cluster accept work from any and all queues in that cluster.
- Multiple queue pairs**
- ◆ You can configure multiple send-jobs and receive-jobs queues in one cluster.
  - ◆ A queue can forward jobs to as many queues in as many clusters as you want, and can also receive jobs from as many other clusters as you want.
  - ◆ A receive-jobs queue can also borrow resources using the resource leasing method, but a send-jobs queue using the job forwarding method cannot also share resources using the resource leasing method.

### Steps

To set up a pair of MultiCluster queues, do the following:

- 1 In the submission cluster, configure a send-jobs queue that forwards work to the execution queue.
- 2 In the execution cluster, configure a receive-jobs queue that accepts work from the cluster that contains the send-jobs queue.

**Send-jobs queues** To configure a send-jobs queue, define `SNDJOBS_TO` in the `lsb.queues` queue definition. Specify a space-separated list of queue names in the format `queue_name@cluster_name`.

If the send-jobs queue has not got `SNDJOBS_TO` configured, it cannot forward MultiCluster jobs. The job remains pending in the submission cluster and is evaluated again during the next scheduling cycle.

Make sure the `lsb.queues` `HOSTS` parameter specifies only local hosts (or the special keyword `none`). If `HOSTS` specifies any remote hosts, `SNDJOBS_TO` is ignored, and the queue behaves as a receive-jobs queue under the resource leasing method.

**Receive-jobs queues** To configure a receive-jobs queue, define `RCVJOBS_FROM` in the `lsb.queues` queue definition. Specify a space-separated list of cluster names.

---

**Example** Begin Queue  
QUEUE\_NAME=queue1  
SNDJOBS\_TO=queue2@cluster2 queue3@cluster3  
RCVJOBS\_FROM=cluster2 cluster3  
PRIORITY=30  
NICE=20  
End Queue

This queue is both a send-jobs and receive-jobs queue, and links with multiple remote clusters. If queue1 cannot place a job in the local cluster, it can forward the job to queue2 in cluster2, or to queue3 in cluster3. If any queues in clusters 2 or 3 are configured to send MultiCluster jobs to queue1, queue1 accepts them.

---

## Remote-Only Queues

By default, LSF tries to place jobs in the local cluster. If your local cluster is occupied, it may take a long time before your jobs can run locally. You might want to force some jobs to run on a remote cluster instead of the local cluster. Submit these jobs to a remote-only queue. A remote-only queue forwards all jobs to a remote cluster without attempting to schedule the job locally.

### Configuring a remote-only queue

To make a queue that only runs jobs in remote clusters, take the following steps:

- 1 Edit the `lsb.queues` queue definition for the send-jobs queue.
  - ❖ Define `SNDJOBS_TO`. This specifies that the queue can forward jobs to specified remote execution queues.
  - ❖ Set `HOSTS` to `none`. This specifies that the queue uses no local hosts.
- 2 Edit the `lsb.queues` queue definition for each receive-jobs queue.
  - ❖ Define `RCVJOBS_FROM`. This specifies that the receive-jobs queue accepts jobs from the specified submission cluster.

**Example** In `cluster1`:

```
Begin Queue
QUEUE_NAME = queue1
HOSTS = none
SNDJOBS_TO = queue2@cluster2
MAX_RSCHED_TIME = infinit
DESCRIPTION = A remote-only queue that sends jobs to cluster2.
End Queue
```

In `cluster2`:

```
Begin Queue
QUEUE_NAME = queue2
RCVJOBS_FROM = cluster1
DESCRIPTION = A queue that receives jobs from cluster1.
End Queue
```

`Queue1` in `cluster1` forwards all jobs to `queue2` in `cluster2`.

### Disabling timeout in remote-only queues

If you have a remote-only send-jobs queue that sends to only one receive-jobs queue, you should set `MAX_RSCHED_TIME=infinit` to maintain FCFS job order of MultiCluster jobs in the execution queue. Otherwise, jobs that time out are rescheduled to the same execution queue, but they lose priority and position because they are treated as a new job submission.

In general, the timeout is helpful because it allows LSF to automatically shift a pending MultiCluster job to a better queue.

---

## Forcing a job to run in a remote cluster

You can use `bsub -q` and specify a remote-only MultiCluster queue if you want to prevent your job from running in the local cluster.

This is not compatible with `bsub -m`; when your job is forwarded to a remote queue, you cannot specify the execution host by name.

**Example** `queue1` is a remote-only MultiCluster queue.

```
% bsub -q queue1 myjob
```

```
Job <101> is submitted to queue <queue1>.
```

This job will be dispatched to a remote cluster.

---

## Remote Cluster Equivalency

By default, if no cluster name is specified, LSF utilities such as `lsload` return information about the local cluster.

If you configure a remote cluster to be equivalent to the local cluster, LSF displays information about the remote cluster as well. For example, `lsload` with no options lists hosts in the local cluster and hosts in the equivalent remote clusters.

The following commands automatically display information about hosts in a remote cluster if equivalency is configured:

- ◆ `lshosts`
- ◆ `lsload`
- ◆ `lsplace`
- ◆ `lsrun`

### Performance limitation

Expect performance in a cluster to decrease as the number of equivalent clusters increases, because you must wait while LSF retrieves information from each remote cluster in turn. Defining all clusters in a large MultiCluster system as equivalent can cause a performance bottleneck as the master LIM polls all clusters synchronously.

## Transparency for users

To make resources in remote clusters as transparent as possible to the user, configure a remote cluster to be equivalent to the local cluster. The users see information about the local and equivalent clusters without having to supply a cluster name to the command.

Hosts in equivalent clusters are all identified by the keyword `remoteHost` instead of the actual host name. For example, `bjobs -p -l` will show `remoteHost@cluster_name` instead of `host_name@cluster_name`.

## Simplifying MultiCluster administration

If you have many clusters configured to use MultiCluster, create one cluster for administrative purposes, and configure every other cluster to be equivalent to it. This allows you to view the status of all clusters at once, and makes administration of LSF easier.

## Configuration

To specify equivalent clusters, set `EQUIV` in the `RemoteClusters` section of `lsf.cluster.cluster_name` to `Y` for the equivalent clusters.

---

## Remote Resources

If you have no concerns about running only local jobs on your submission cluster, you can allow the submission forward policy to consider remote resource availability before forwarding jobs. This allows more jobs to be forwarded because more resources are available.

### Configuring remote resource availability

To enable the submission forward policy to consider remote resource availability, define `MC_PLUGIN_REMOTE_RESOURCE=y` in `lsf.conf`.

**Note** When `MC_PLUGIN_REMOTE_RESOURCE` is defined, only the following resource requirements are supported: `-R "type==type_name"`, `-R "same[type]"` and `-R "defined(resource_name)"`

---

## Pre-Exec Retry Threshold

When a job has a pre-execution command, LSF runs the job's pre-execution command first. By default, LSF retries the pre-execution command five times.

With a threshold configured, LSF returns the entire job to the submission cluster if the pre-execution command fails to run after a certain number of attempts. The submission cluster can then reschedule the job.

### Configuring pre-exec retries

To limit the number of times the *local* cluster attempts to run the pre-execution command, set `LOCAL_MAX_PREEEXEC_RETRY` in `lsb.params` and specify the maximum number of attempts. Configure `MAX_PREEEXEC_RETRY` or `REMOTE_MAX_PREEEXEC_RETRY` to limit pre-execution retry attempts on the the *remote* cluster.

The pre-execution command retry limit configured in `lsb.params`, `lsb.queues`, and `lsb.applications` on the execution cluster is applied.

---

## Retry Threshold and Suspend Notification

If a job is forwarded to a remote cluster and then fails to start, it returns to the submission queue and LSF retries the job. After a certain number of failed retry attempts, LSF suspends the job (PSUSP). The job remains in that state until the job owner or administrator takes action to resume, modify, or remove the job.

By default, LSF tries to start a job up to 6 times (the threshold is 5 retry attempts). The retry threshold is configurable.

You can also configure LSF to send email to the job owner when the job is suspended. This allows the job owner to investigate the problem promptly. By default, LSF does not alert users when a job has reached its retry threshold.

### Configuring retries

Set `LSB_MC_INITFAIL_RETRY` in `lsf.conf` and specify the maximum number of retry attempts. For example, to attempt to start a job no more than 3 times in total, specify 2 retry attempts:

```
LSB_MC_INITFAIL_RETRY = 2
```

### Configuring mail notification

To make LSF email the user when a job is suspended after reaching the retry threshold, set `LSB_MC_INITFAIL_MAIL` in `lsf.conf` to `y`:

```
LSB_MC_INITFAIL_MAIL = y
```

By default, LSF does not notify the user.

---

## Pending MultiCluster Job Limit

The pending MultiCluster job limit determines the maximum number of MultiCluster jobs that can be pending in the queue. The queue rejects jobs from remote clusters when this limit is reached. It does not matter how many MultiCluster jobs are running in the queue, or how many local jobs are running or pending.

By default, the limit is 50 pending MultiCluster jobs.

### Configuring a pending MultiCluster job limit

Edit `IMPT_JOBKLG` in `lsb.queues`, and specify the maximum number of MultiCluster jobs from remote clusters that can be pending in the queue. This prevents jobs from being over-committed to an execution cluster with limited resources.

If you specify the keyword `infinite`, the queue will accept an infinite number of jobs.

**Considerations** When you set the limit, consider the following:

- ◆ Make sure there are enough pending jobs in the queue for LSF to dispatch, in order to make full use of the execution servers. If you use advance reservation, set the limit higher to allow for the pending jobs that are waiting to use a reservation.
- ◆ Make sure the queue does not fill up with so many MultiCluster jobs that LSF cannot dispatch them all in the near future.

Therefore, estimate your expected job flow and set the limit 50% or 100% higher than the estimate.

**Example** Assume that locally submitted jobs do not occupy all the available resources, so you estimate that each processor can schedule and execute 2 MultiCluster jobs per scheduling session. To make full use of the job slots, and make sure the queue never runs out of jobs to dispatch, set the limit at 3 or 4 jobs per processor: if this queue has 20 processors, set the limit to allow 60 or 80 MultiCluster jobs pending. You expect to run about 40 of them immediately, and the remainder only wait for one scheduling cycle.

---

## Updating the Pending Reason for MultiCluster Jobs

By default, the pending reasons for MultiCluster jobs are updated every 5 minutes by the execution cluster, but the maximum amount of data transferred between clusters is 512 KB. If LSF cannot update the pending reasons for all jobs at once, it will update the additional jobs during the next cycles.

You can disable the feature or modify how often the pending reasons are updated and how much data can be transferred at one time. Depending on load, updating the information very frequently or sending an unlimited amount of information can affect the performance of LSF.

### Configuring the pending reason updating interval

To change the timing of pending reason updating between clusters, set `MC_PENDING_REASON_UPDATE_INTERVAL` in `lsb.params` in the execution cluster. Specify how often to update the information in the submission cluster, in seconds.

To disable pending reason updating between clusters, specify zero:

```
MC_PENDING_REASON_UPDATE_INTERVAL=0
```

**Restriction** You must configure this parameter manually; you cannot use LSF GUI tools to add or modify this parameter.

### Configuring the pending reason update package size

To change the package size of each pending reason update, set `MC_PENDING_REASON_PKG_SIZE` in `lsb.params` in the execution cluster. Specify the maximum package size, in KB.

To disable the limit and allow any amount of data in one package, specify zero:

```
MC_PENDING_REASON_PKG_SIZE=0
```

This parameter has no effect if pending reason updating is disabled (`MC_PENDING_REASON_UPDATE_INTERVAL=0`).

**Restriction** You must configure this parameter manually; you cannot use LSF GUI tools to add or modify this parameter.

---

## Remote Timeout Limit

### Remote timeout limit

The remote timeout limit is set in the submission cluster and determines how long a MultiCluster job stays pending in the execution cluster. After the allowed time, the job returns to the submission cluster to be rescheduled.

The remote timeout limit in seconds is:

```
MAX_RSCHED_TIME(lsb.queues) * MBD_SLEEP_TIME(lsb.params)
```

By default, `MBD_SLEEP_TIME` is one minute and the multiplying factor for MultiCluster is 20, so the timeout limit is normally 20 minutes.

### Problem with remote-only queues

By default, LSF queues dispatch jobs in FCFS order. However, there is one case in which the default behavior can be a problem. This is when a send-jobs queue sends to only one remote queue, and never uses local hosts.

In this case, jobs that time out in the receive-jobs cluster can only be re-dispatched to the same receive-jobs queue. When this happens, the receive-jobs queue takes the re-dispatched job as a new submission, gives it a new job ID, and gives it lowest priority in FCFS ordering. In this way, the highest-priority MultiCluster job times out and then becomes the lowest-priority job. Also, since local jobs don't time out, the MultiCluster jobs get a lower priority than local jobs that have been pending for less time.

To make sure that jobs are always dispatched in the original order, you can disable remote timeout for the send-jobs queue.

### Disabling timeout

To disable remote timeout, edit `MAX_RSCHED_TIME` in `lsb.queues` in the submission cluster, and specify the keyword `INFINITE`. This increases the remote timeout limit to infinity.

Even if the limit is set to infinity, jobs time out if a remote execution cluster gets reconfigured. However, all the pending jobs time out at once, so when the queue attempts to send them again, the original priority is maintained.

## MultiCluster Resource Leasing Model

The resource leasing model was developed to be transparent to the user.

- In this section
- ◆ [“Overview of Lease Model”](#) on page 56
  - ◆ [“Using the Lease Model”](#) on page 58

Configuring the Provider Cluster:

- ❖ [“Resource Exporting”](#) on page 61
- ❖ [“Creating an Export Policy”](#) on page 62
  - ❖ [“Exporting Workstations”](#) on page 64
  - ❖ [“Exporting Special Hosts”](#) on page 66

Configuring of the Consumer Cluster:

- ❖ [“Borrowing Resources”](#) on page 72

Special Considerations under the Lease Model

- ❖ [“Running Parallel Jobs with the Lease Model”](#) on page 74

---

## Overview of Lease Model

Two clusters agree that one cluster will borrow resources from the other, taking control of the resources. Both clusters must change their configuration to make this possible, and the arrangement, called a “lease”, does not expire, although it might change due to changes in the cluster configuration.

With this model, scheduling of jobs is always done by a single cluster. When a queue is configured to run jobs on borrowed hosts, LSF schedules jobs as if the borrowed hosts actually belonged to the cluster.

### How the lease model works

#### 1 Setup:

- ❖ A resource provider cluster “exports” hosts, and specifies the clusters that will use the resources on these hosts.
- ❖ A resource consumer cluster configures a queue with a host list that includes the borrowed hosts.

#### 2 Establishing a lease:

- ❖ To establish a lease,
  - i Configure two clusters properly (the provider cluster must export the resources, and the consumer cluster must have a queue that requests remote resources).
  - ii Start up the clusters.
  - iii In the consumer cluster, submit jobs to the queue that requests remote resources.

At this point, a lease is established that gives the consumer cluster control of the remote resources.

- ❖ If the provider did not export the resources requested by the consumer, there is no lease. The provider continues to use its own resources as usual, and the consumer cannot use any resources from the provider.
- ❖ If the consumer did not request the resources exported to it, there is no lease. However, when entire hosts are exported the provider cannot use resources that it has exported, so neither cluster can use the resources; they will be wasted.

#### 3 Changes to the lease:

- ❖ The lease does not expire. To modify or cancel the lease, you should change the export policy in the provider cluster.
- ❖ If you export a group of workstations allowing LSF to automatically select the hosts for you, these hosts do not change until the lease is modified. However, if the original lease could not include the requested number of hosts, LSF can automatically update the lease to add hosts that become available later on.
- ❖ If the configuration changes and some resources are no longer exported, jobs from the consumer cluster that have already started to run using those resources will be killed and requeued automatically.

If LSF selects the hosts to export, and the new export policy allows some of the same hosts to be exported again, then LSF tries to re-export the hosts that already have jobs from the consumer cluster running on them (in this case, the

---

jobs continue running without interruption). If LSF has to kill some jobs from the consumer cluster to remove some hosts from the lease, it selects the hosts according to job run time, so it kills the most recently started jobs.

---

## Using the Lease Model

### Submit jobs

LSF will automatically schedule jobs on the available resources, so jobs submitted to a queue that uses borrowed hosts can automatically use the borrowed resources.

**bsub** To submit a job and request a particular host borrowed from another cluster, use the format *host\_name@cluster\_name* to specify the host. For example, to run a job on *hostA* in *cluster4*:

```
bsub -q myqueue -m hostA@cluster4 myjob
```

This will not work when you first start up the MultiCluster grid; the remote host names are not recognized until the lease has been established.

**bmod** The **bmod** syntax also allows you to specify borrowed hosts in the same format *host\_name@cluster\_name*.

### Administration

**badmin** The administrator of the consumer cluster can open and close borrowed hosts using **badmin**. Use the format *host\_name@cluster\_name* to specify the borrowed host. This action only affects scheduling on the job slots that belong to that consumer cluster. For example, if slots on a host are shared among multiple consumers, one consumer can close the host, but the others will not be affected or be aware of any change.

You must be the administrator of the provider cluster to shut down or start up a host. This action will affect the consumer cluster as well.

**Host groups or host partitions** When you define a host group in *lsb.hosts*, or a host partition, you can use the keyword **allremote** to indicate all borrowed hosts available to the cluster. You cannot define a host group that includes borrowed hosts specified by host name or cluster name.

**Compute units** Compute units defined in *lsb.hosts* can use wild cards to include the names of borrowed hosts available to the cluster. You cannot define a host group that includes borrowed hosts specified by host name or cluster name directly.

Hosts running LSF 7 Update 4 or earlier cannot satisfy compute unit resource requirements, and thus cannot be included in compute units.

**Automatic retry limits** The pre-execution command retry limit (**MAX\_PREEEXEC\_RETRY** and **REMOTE\_MAX\_PREEEXEC\_RETRY**), job requeue limit (**MAX\_JOB\_REQUEUE**), and job preemption retry limit (**MAX\_JOB\_PREEMPT**) configured in *lsb.params*, *lsb.queues*, and *lsb.applications* apply to jobs running on remote leased hosts as if they are running on local hosts

### Tracking

**bhosts** By default, **bhosts** only shows information about hosts and resources that are available to the local cluster and information about jobs that are scheduled by the local cluster. Therefore, borrowed resources are included in the summary, but exported resources are not normally included (the exception is reclaimed resources, which are shown during the times that they are available to the local cluster).

---

For borrowed resources, the host name is displayed in the format *host\_name@cluster\_name*. The number of job slots shown is the number available to the consumer cluster, the JL/U and host status shown is determined by the consumer cluster, and the status shown is relative to the consumer cluster. For example, the consumer might see `closed` or `closed_Full` status, while the provider sees `ok` status.

- ◆ Cluster1 has borrowed one job slot on hostA. It shows the borrowed host is closed because that job slot is in use by a running job.

```
bhosts
HOST_NAME          STATUS  JL/U  MAX  NJOBS  RUN  SSUSP  USUSP
RSV
hostA@cluster2    closed   -
   1   1   1   0   0   0
```

- ◆ Cluster2 has kept 3 job slots on hostA for its own use. It shows the host is open, because all the available slots are free.

```
bhosts
HOST_NAME          STATUS  JL/U  MAX  NJOBS  RUN  SSUSP  USUSP
RSV
hostA              ok     -
   3   0   0   0   0   0
```

**bhosts -e** This option displays information about the exported resources. The provider cluster does not display JL/U or host status; this status information is determined by the consumer cluster and does not affect the provider.

**bhosts -e -s** This option displays information about exported shared resources.

**bjobs** The `bjobs` command shows all jobs associated with hosts in the cluster, including MultiCluster jobs. Jobs from remote clusters can be identified by the `FROM_HOST` column, which shows the remote cluster name and the submission or consumer cluster job ID in the format *host\_name@remote\_cluster\_name:remote\_job\_ID*.

If the MultiCluster job is running under the job forwarding model, the `QUEUE` column shows a local queue, but if the MultiCluster job is running under the resource leasing model, the name of the remote queue is shown in the format *queue\_name@remote\_cluster\_name*.

Use `-w` or `-l` to prevent the MultiCluster information from being truncated.

**bclusters** For the resource leasing model, `bclusters` shows information about each lease.

- ◆ Status

- ❖ `ok` means that the resources are leased and the resources that belong to the provider are being used by the consumer.
- ❖ `conn` indicates that a connection has been established but the lease has not yet started; probably because the consumer has not yet attempted to use the shared resources. If this status persists in a production environment, it could mean that the consumer cluster is not properly configured.
- ❖ `disc` indicates that there is no connection between the two clusters.

- ◆ Resource flow

- ❖ For resources exported to another cluster, the resource flow direction is “EXPORT”, and the remote cluster specified is the consumer of the resources.
- ❖ For resources borrowed from another cluster, the resource flow direction is IMPORT, and the remote cluster specified is the resource provider.

---

# Resource Exporting

## lsb.resources file

The `lsb.resources` file contains MultiCluster configuration information for the lease model, including the export policies which describe the hosts and resources that are exported, and the clusters that can use them.

You must reconfigure the cluster to make the configuration take effect.

## Resources that can be exported

- Job slots** To export resources, you must always export job slots on hosts, so that the consumer cluster can start jobs on the borrowed hosts.
- Additional host-based resources** By default, all the jobs on a host compete for its resources. To help share resources fairly when a host's job slots are divided among multiple clusters, you can export quantities of memory and swap space, also for the use of the consumer cluster.
- Shared resources** By default, shared resources such as software licenses are not exported. You can create a separate policy to export these resources.

## Who can use exported resources

The export policy defines the consumers of exported resources. By default, resources that are exported can be used by the provider; this applies to job slots on a host and also to resources like memory.

With resource reclaim, exported job slots can be reclaimed by the provider if the consumer is not using them to run jobs. In this way, the provider can share in the use of the exported job slots. For more information, see [“Shared Lease”](#) on page 70.

---

## Creating an Export Policy

An export policy defined in `lsb.resources` is enclosed by the lines:

```
Begin HostExport
...
End HostExport
```

In each policy, you must specify which hosts to export, how many job slots, and distribution of resources. Optionally, you can specify quantities of memory and swap space.

To export hosts of HostExport Type==DLINUX, specifying swap space is mandatory. See [“Exporting Other Resources”](#) on page 68.

Configure as many different export policies as you need.

Each export policy corresponds to a separate lease agreement.

### Export policy examples

This simple export policy exports a single job slot on a single host to a single consumer cluster:

```
Begin HostExport
PER_HOST=HostA
SLOTS=1
DISTRIBUTION=( [Cluster5, 1] )
End HostExport
```

This simple policy exports all the resources on a single Linux host to a single consumer cluster:

```
Begin HostExport
RES_SELECT=type==LINUX
NHOSTS=1
DISTRIBUTION=( [Cluster5, 1] )
End HostExport
```

### Exporting hosts

To export resources such as job slots or other resources, you must specify which hosts the resources are located on. There are two ways to specify which hosts you want to export: you can list host names, or you can specify resource requirements and let LSF find hosts that match those resource requirements. The method you use to specify the exported hosts determines the method that LSF uses to share the hosts among competing consumer clusters.

#### Exporting a large number of hosts

If you have a group of similar hosts, you can share a portion of these hosts with other clusters. To choose this method, let LSF automatically select the hosts to export. The group of hosts can be shared among multiple consumer clusters, but each host is leased to only one consumer cluster, and all the job slots on the host are exported to the consumer.

See [“Exporting Workstations”](#) on page 64.

---

**Sharing a large computer** You can share a powerful multiprocessor host among multiple clusters. To choose this method, export one or more hosts by name and specify the number of job slots to export. The exported job slots on each host are divided among multiple consumer clusters.

See “[Exporting Special Hosts](#)” on page 66.

## Distributing exported resources

An export policy exports specific resources. The distribution statement in `lsb.resources` partitions these resources, assigning a certain amount exclusively to each consumer cluster. Clusters that are not named in the distribution list do not get to use any of the resources exported by the policy.

The simplest distribution policy assigns all of the exported resources to a single consumer cluster:

```
DISTRIBUTION= ([Cluster5, 1])
```

**Distribution list syntax** The syntax for the distribution list is a series of share assignments. Enclose each share assignment in square brackets, as shown, and use a space to separate multiple share assignments. Enclose the full list in parentheses:

```
DISTRIBUTION= ([share_assignment] ...)
```

**Share assignment syntax** The share assignment determines what fraction of the total resources is assigned to each cluster.

The syntax of each share assignment is the cluster name, a comma, and the number of shares.

```
[cluster_name, number_shares]
```

- ◆ *cluster\_name*  
Specify the name of a cluster allowed to use the exported resources.
- ◆ *number\_shares*  
Specify a positive integer representing the number of shares of exported resources assigned to the cluster.

The number of shares assigned to a cluster is only meaningful when you compare it to the number assigned to other clusters, or to the total number. The total number of shares is just the sum of all the shares assigned in each share assignment.

**Examples** ◆ In this example, resources are leased to 3 clusters in an even 1:1:1 ratio. Each cluster gets 1/3 of the resources.

```
DISTRIBUTION= ([C1, 1] [C2, 1] [C3, 1])
```

- ◆ In this example, resources are leased to 3 clusters in an uneven ratio. There are 5 shares assigned in total, so C1 gets 2/5 of the resources, C2 gets the same, and C3 gets 1/5 of the resources.

```
DISTRIBUTION= ([C1, 2] [C2, 2] [C3, 1])
```

---

## Exporting Workstations

These steps describe the way to share part of a large farm of identical hosts. This is most useful for reallocating resources among different departments, to meet a temporary need for more processing power.

- 1 Create the new policy.
- 2 Specify the hosts that are affected by the policy. Each host is entirely exported; the provider cluster does not save any job slots on the exported hosts for its own use. See [“Allowing LSF to select the hosts you want to export”](#) on page 64.
- 3 Specify the distribution policy. This determines which clusters share in the use of the exported job slots. See [“Distribution policy for automatically selected hosts”](#) on page 65.
- 4 Optional. Share additional resources (any combination of memory, swap space, or shared resources). See
  - ❖ [“Exporting Other Resources”](#) on page 68
  - ❖ [“Exporting Shared Resources”](#) on page 69

### Allowing LSF to select the hosts you want to export

To export a set of hosts that meet certain resource requirements, specify both `RES_SELECT` and `NHOSTS` in `lsb.resources`.

For `RES_SELECT`, specify the selection criteria using the same syntax as the “select” part of the resource requirement string (normally used in the LSF `bsub` command). For details about resource selection syntax, see *Administering Platform LSF*. For this parameter, if you do not specify the required host type, the default is “`type==any`”.

For `NHOSTS`, specify a maximum number of hosts to export.

```
Begin HostExport
RES_SELECT=type==LINUX
NHOSTS=4
```

In this example, we want to export 4 Linux hosts. If the cluster has 5 Linux hosts available, 4 are exported, and the last one is not exported. If the cluster has only 3 Linux hosts available at this time, then only 3 hosts are exported, but LSF can update the lease automatically if another host becomes available to export later on.

Use `lshosts` to view the host types that are available in your cluster.

---

## Distribution policy for automatically selected hosts

For syntax of the distribution policy, see “[Distributing exported resources](#)” on page 63.

When you export hosts by specifying the resource selection statement, multiple hosts are divided among multiple consumer clusters, but each host is entirely exported to a single consumer cluster. All the job slots on a host are exported to the consumer cluster, along with all its other host-based resources including swap space and memory.

**Example**

```
Begin HostExport
RES_SELECT=type==LINUX
NHOSTS=2
DISTRIBUTION=( [C1, 1] [C2, 1] )
End HostExport
```

In this example, 2 hosts that match the resource requirements are selected, suppose they are `HostA` and `HostB`, and each has 2 job slots. All job slots on each host are exported. Resources are shared evenly among 2 clusters, each cluster gets 1/2 of the resources.

Since the hosts are automatically selected, the hosts are distributed to only one consumer cluster, so the first host, `HostA`, goes to `Cluster1`, and the second host, `HostB`, goes to `Cluster2`. Assume each host has 2 job slots for use by the consumer cluster. `Cluster1` gets 2 job slots on `HostA`, and `Cluster2` gets 2 job slots on `HostB`.

In this example there is an even distribution policy, but it is still possible for one consumer cluster to get more resources than the other, if the exported hosts are not all identical.

---

## Exporting Special Hosts

These steps describe the way to share a large multiprocessor host among multiple clusters. This is most useful for allowing separate departments to share the cost and use of a very powerful host. It might also be used to allow multiple clusters occasional access to a host that has some unique feature.

- 1 Create the new policy.
- 2 Specify the hosts that are affected by the policy. See [“Naming the hosts you want to export”](#) on page 66.
- 3 Specify how many job slots you want to export from each host. Optionally, reduce the number of job slots available to the local cluster by the same amount. See [“Controlling job slots”](#) on page 66.
- 4 Specify the distribution policy. This determines which clusters share in the use of the exported job slots. See [“Distribution policy for named hosts”](#) on page 67.
- 5 Optional. Share additional resources (any combination of memory, swap space, or shared resources). See
  - ❖ [“Exporting Other Resources”](#) on page 68
  - ❖ [“Exporting Shared Resources”](#) on page 69

### Naming the hosts you want to export

Specify the name of a host in the PER\_HOST parameter in `lsb.resources`:

```
Begin HostExport
PER_HOST=HostA
```

If you specify multiple hosts, this policy will apply to all the hosts you specify:

```
Begin HostExport
PER_HOST=HostA HostB HostC
```

### Controlling job slots

Use the SLOTS parameter to specify the number of job slots to export from each host. By default, the provider can still run the usual number of jobs at all times. The additional jobs that the consumer clusters are allowed to start might overload the host. If you are concerned with keeping the host’s performance consistent, reduce the job slot configuration in the local cluster to compensate for the number of slots exported to remote clusters.

For example, this policy exports 4 job slots on each host:

```
Begin HostExport
PER_HOST=HostA HostB
SLOTS=4
```

- ◆ Default configuration of `lsb.hosts` in the provider cluster:

```
HOST_NAME  MXJ
HostA      6
HostB      8
```

- ◆ How you can update `lsb.hosts` to compensate for the exported job slots:

---

HOST_NAME	MXJ
HostA	2
HostB	4

## Distribution policy for named hosts

For syntax of the distribution policy, see “[Distributing exported resources](#)” on page 63.

When you export hosts by specifying host names, the job slots on each host are divided among multiple consumer clusters, so each cluster gets a part of each host.

**Example**

```
Begin HostExport
PER_HOST=HostA HostB
SLOTS=2
DISTRIBUTION=( [C1, 1] [C2, 1] )
End HostExport
```

In this example, 2 job slots are exported from `HostA` and `HostB`. Resources are shared evenly among 2 clusters, so each cluster is entitled to 1/2 of the resources.

Because the hosts are specified by name, the distribution policy is applied at the job slot level. The first job slot on `HostA` goes to `Cluster1`, and the second job slot on `HostA` goes to `Cluster2`. Similarly, one job slot on `HostB` goes to `Cluster1`, and the other job slot on `HostB` goes to `Cluster2`. Each consumer cluster can start 2 jobs, one on `HostA`, and one on `HostB`.

The provider cluster can always use the number of job slots that are configured in the provider cluster (no matter how many slots are exported). You might want to adjust the configuration of the provider cluster after exporting hosts and reduce the number of job slots (`MXJ` in `lsb.hosts`); otherwise, you might notice a difference in performance because of the extra jobs that can be started by the consumer clusters.

---

## Exporting Other Resources

Once you have exported a host, you can export memory and swap space in addition to job slots.

By default, the consumer cluster borrows a job slot but is not guaranteed that there will be free memory or swap space, because all jobs on the host compete for the host's resources. If these resources are exported, each consumer cluster schedules work as if only the exported amount is available (the exported amount acts a limit for the consumer cluster), and the provider cluster can no longer use the amount that has been exported.

- ◆ The distribution policies that apply to job slots also apply to other resources.
- ◆ If the provider cluster doesn't have the amount that is specified in the export policy, it will export as much as it has.

---

To export hosts of `HostExport Type==DLINUX`, exporting swap space is mandatory. If you do not specify swap space, the hosts of this host type are filtered because the resource is seen as unavailable

---

### Exporting memory

To export memory, set `MEM` in `lsb.resources` host export policy, and specify the number of MB per host:

- ◆ exporting 100 MB on each host:  

```
RES_SELECT=type==LINUX
NHOSTS=3
MEM=100
```

### Exporting swap space

To export swap space, set `SWP` in `lsb.resources` host export policy, and specify the number of MB per host:

- ◆ exporting 100 MB on each host:  

```
PER_HOST=HostA HostB HostC
SWP=100
```

---

## Exporting Shared Resources

In addition to job slots and some other built-in resources, it is possible to export numeric shared resources (for example, representing software application licenses). The resource definitions in `lsf.shared` must be the same in both clusters.

Export policies for shared resources are defined in `lsb.resources`, after export policies for hosts. The configuration is different—shared resources are not exported per host.

When you export a shared resource to a consumer cluster, you must already have a host export policy that exports hosts to the same consumer cluster, and the shared resource must be available on one or more of those exported hosts. Otherwise, the export policy does not have any effect.

### Configure shared resource export

In `lsb.resources`, configure a resource export policy for each resource as shown:

```
Begin SharedResourceExport
NAME          = AppX
NINSTANCES   = 10
DISTRIBUTION = ([C1, 30] [C2, 70])
End SharedResourceExport
```

In each policy, you specify one shared numeric resource (here, a license for ApplicationX), the maximum number of these you want to export, and distribution, using the same syntax as a host export policy. See “[Distributing exported resources](#)” on page 63.

If some quantity of the resource is available, but not the full amount you configured, LSF exports as many instances of the resource as are available to the exported hosts.

---

## Shared Lease

Optional.

You can export resources from a cluster and enable shared lease, which allows the provider cluster to share in the use of the exported resources. This type of lease dynamically balances the job slots according to the load in each cluster.

Only job slots will be shared. If you export memory, swap space, and shared resources, they become available to the consumer cluster exclusively.

### About shared lease

By default, exported resources are for the exclusive use of the consumer, they cannot be used by the provider. If they are not being used by the consumer, they are wasted.

There is a way to lease job slots to a cluster part-time. With shared lease, both provider and consumer clusters can have the opportunity to take any idle job slots. The benefit of the shared lease is that the provider cluster has a chance to share in the use of its exported resources, so the average resource usage is increased.

Shared lease is not compatible with advance reservation.

If you enable shared leasing, each host can only be exported to a single consumer cluster. Therefore, when shared leasing is enabled, you can export a group of workstations to multiple consumers using RES\_SELECT syntax, but you cannot share a powerful multiprocessor host among multiple consumer clusters using PER\_HOST syntax unless the distribution policy specifies just one cluster.

### How it works

By default, a lease is exclusive, which means a fixed amount of exported resources is always dedicated exclusively to a consumer cluster. However, if you configure leases to be shared, the job slots exported by each export policy can also become available to the provider cluster.

Reclaimable resources are job slots that are exported with shared leasing enabled. The reclaim process is managed separately for each lease, so the set of job slots exported by one resource export policy to one consumer cluster is managed as a group.

When the provider cluster is started, the job slots are allocated to the provider cluster, except for one that is reserved for the consumer cluster, to allow a lease to be made. Therefore, all but one slot is initially available to the provider cluster, and one slot could be available to the consumer. The lease is made when the consumer schedules a job to run on the single job slot that is initially available to it.

To make job slots available to a different cluster, LSF automatically modifies the lease contract. The lease will go through a temporary “inactive” phase each time. When a lease is updated, the slots controlled by the corresponding export policy are distributed as follows: the slots that are being used to run jobs remain under the control of the cluster that is using them, but the slots that are idle are all made available to just one cluster.

To determine which cluster will reclaim the idle slots each time, LSF considers the number of idle job slots in each cluster:

```
idle_slots_provider = available_slots_provider -  
used_slots_provider
```

---

```
idle_slots_consumer = available_slots_consumer -
used_slots_consumer
```

The action depends on the relative quantity of idle slots in each cluster.

- ◆ If the consumer has more idle slots:  

```
idle_slots_consumer > idle_slots_provider
```

then the provider reclaims idle slots from the consumer, and all the idle slots go to the provider cluster.
- ◆ If the provider has more idle slots:  

```
idle_slots_provider > idle_slots_consumer
```

then the reverse happens, and all the idle slots go to the consumer cluster.
- ◆ However, if each cluster has an equal number of idle slots:  

```
idle_slots_consumer = idle_slots_provider
```

then the lease does not get updated.

LSF evaluates the status at regular intervals, specified by `MC_RECLAIM_DELAY` in `lsb.params`.

The calculations are performed separately for each set of reclaimable resources, so if a provider cluster has multiple resource export policies, some leases could be reconfigured in favor of the provider while others get reconfigured in favor of the consumer.

## Configure shared leasing

**Enable shared leasing** To make a shared lease, set `TYPE=shared` in the resource export policy (`lsb.resources HostExport` section). Remember that each resource export policy using `PER_HOST` syntax must specify just one cluster in the distribution policy, if the lease is shared.

```
Begin HostExport
PER_HOST=HostA
SLOTS=4
TYPE=shared
DISTRIBUTION=( [C1, 1] )
End HostExport
```

In this example, `HostA` is exported with shared leasing enabled, so the lease can be reconfigured at regular intervals, allowing LSF to give any idle job slots to the cluster that needs them the most.

**Configure reclaim interval** Optional. To set the reclaim interval, set `MC_RECLAIM_DELAY` in `lsb.params` and specify how often to reconfigure a shared lease, in minutes. The interval is the same for every lease in the cluster.

The default interval is 10 minutes.

---

## Borrowing Resources

**Default queues** When you add new hosts to a single LSF cluster, you might need to update your queues to start sending work to the new hosts. This is often not necessary, because queues with the default configuration can use all hosts in the local cluster.

However, when a MultiCluster provider cluster exports resources to a consumer cluster, the default queue configuration does not allow the consumer cluster to use those resources. You must update your queue configuration to start using the borrowed resources.

**Queues that use borrowed hosts** By default, LSF queues only use hosts that belong to the submission cluster. Queues can use borrowed resources when they are configured to use borrowed hosts (and the provider cluster's export policy must be compatible).

**Queues for parallel jobs** If your clusters do not have a shared file system, then parallel jobs that require a common file space could fail if they span multiple clusters. One way to prevent this is to submit these jobs to a queue that uses hosts all from one cluster (for example, configure the queue to use local hosts or borrowed hosts, but not both).

### Configure a queue to use borrowed resources

To configure a queue to use borrowed resources, edit `lsb.queues HOSTS` parameter and specify the hosts you want to borrow from one or more other clusters.

- ◆ The keyword `all` does not include borrowed hosts, only hosts that belong to the consumer cluster.
- ◆ The keyword `allremote` specifies the group of borrowed hosts belonging to all provider clusters.
- ◆ The keyword `others` does not include borrowed hosts, only hosts that belong to the consumer cluster.
- ◆ The keyword `none` is not compatible with the resource leasing model.
- ◆ You can specify a borrowed host in the format `host_name@cluster_name`. Make sure you configure this correctly, LSF does not validate names of borrowed hosts when you reconfigure the cluster.
- ◆ You can specify a host group that includes borrowed resources; see “[Host groups or host partitions](#)” on page 58.
- ◆ You can specify all the hosts borrowed from another cluster in the format `all@cluster_name`.

**all and allremote** ◆ Queues configured with the keyword `all` can use all available resources that belong to the consumer cluster. You can specify additional clusters or hosts to use selected borrowed resources also.

```
HOSTS = all all@cluster2 hostB@cluster4
```

- ◆ Queues configured with the keyword `allremote` can use all available borrowed resources, from all other clusters. You can also specify additional host names to use selected resources that belong to the consumer cluster.

```
HOSTS = hostB hostC allremote
```

- ◆ Queues configured with both keywords can use all available resources whether the hosts are borrowed or belong to the consumer cluster.

---

```
HOSTS = all allremote
```

**Preference** You can specify preference levels for borrowed resources, as well as for local resources. If your clusters do not have a common file system, the extra overhead of file transfer between clusters can affect performance, if a job involves large files. In this case, you should give preference to local hosts.

```
HOSTS = all+1 allremote
```

---

## Running Parallel Jobs with the Lease Model

To run parallel jobs (specifying multiple processors with `bsub -n`) across clusters, you must configure the `RemoteClusters` list in each cluster. By default, this list is not configured. For more information on running parallel jobs, see *Administering Platform LSF*.

- 1 If you do not already have a `RemoteClusters` list, create the `RemoteClusters` list and include the names of all remote clusters (the same list as `lsf.shared`). This enables proper communication among all clusters, and enables cross-cluster parallel jobs for all clusters.
- 2 If you have a `RemoteClusters` list, and you do not want to run parallel jobs on resources from all provider clusters, configure the `RECV_FROM` column in `lsf.cluster.cluster_name`.
  - ❖ Specify “N” to exclude a remote cluster (LSF will not start parallel jobs on resources that belong to the remote cluster).
  - ❖ Specify “Y” to enable resource-sharing for parallel jobs. This is the default.

- scheduling policies 35
- send-jobs

  - configuring 44
  - description 44

- setting up 44
- using borrowed hosts 72
- using remote hosts 46

## R

RCVJOBS\_FROM parameter in Isb.queues

- accepting jobs from local cluster 46
- adding a receive-jobs queue 11
- configuring a receive-jobs queue 44
- configuring a remote-only queue 46
- configuring multiple queue pairs 45

receive-jobs queues

- configuring 44
- description 44

reclaim interval 71

RECV\_FROM column in Isf.cluster 74

remote resource availability 49

remote timeout limit 54

REMOTE\_MAX\_PREEXEC\_RETRY parameter in

- lsb.applications, lsb.params, lsb.queues 40, 50, 58
- RemoteClusters list in lsf.cluster
  - adding 24
  - AUTH column 26
  - modifying 24
  - specifying equivalent clusters 48
- RemoteClusters list in lsf.shared 74
- remote-only queues
  - configuring 46
  - description 46
  - disabling timeout 46
  - problems 54
- QUEUE\_EXIT\_VALUES parameter in lsb.queues 40
- RERUNNABLE parameter in lsb.queues 40
- RES parameter in lsf.shared 23
- RES\_SELECT parameter in lsb.resources
  - allowing LSF to select hosts for export 64
  - distributing exported resources 65
  - export policies 62
  - exporting memory 68
- resource availability
  - remote resources 49
- resource leasing model 56
- resource leasing model. *See* lease model
- resources

- retry threshold 51

## S

- security 25, 26
- send-jobs queues
  - configuring 44
  - description 44
- share assignment 63
- shared lease
  - description 70
- SLOTS parameter in lsb.resources
  - configuring resource reclaim 71
  - distributing exported resources 67
  - export policies 62
  - exporting hosts 9
  - specifying the number of job slots to export 66
- SNDJOB\_TO parameter in lsb.queues
  - accepting jobs from local cluster 46
  - adding a send-jobs queue 11
  - configuring a remote-only queue 46
  - configuring a send-jobs queue 44
  - configuring multiple queue pairs 45
  - local scheduling 44
- swap space, exporting 61, 68
- SWP parameter in lsb.resources 68
- system-level accounts, mapping 20

## T

- thresholds
  - pre-exec retry 50, 51
- timeout
  - disabling 46, 54
  - limit 54
- TYPE parameter in lsb.resources
  - configuring resource reclaim 71

## U

- update interval
  - resource usage 28
- user accounts, mapping 20
- user-level accounts, mapping 21
- user-specified job migration 41

## W

- workstations, exporting 64
