[8.13: Problem Determination Hints and Tips](#)

[8.14: How to Report a Problem to IBM](#)

## 8: Problem determination

This section provides information about resources and techniques to help you identify and respond to problems. You can perform problem determination at different levels within your system. Several resources are available for identifying problems:

- Logs
- Trace files
- Messages
- Tools

In order to identify a problem, it is important to understand both the topology of the system and how your application fits into this topology. See WebSphere Structure in this section. Consider the following questions:

- Are all the components installed successfully?
- What is your application attempting to do?
- How is your application deployed?
- What technology is used to connect to back-end systems?
- Can you re-create the problem?
- What resources best identify the problem?

Next, choose the diagnostic tasks that can help you identify the component within WebSphere Application Server or within your application that is causing the problem. Diagnostic tasks include:

- Determining what tuning parameters to specify
- Identifying error messages
- Locating logs and trace files
- Determining whether system and server classpath settings are set correctly
- Identifying failing product components
- Identifying appropriate tools for a problem
- Understanding how to invoke and use available tools

### WebSphere Structure topology

This section describes the basic elements of WebSphere Application Server. Becoming familiar with this information is useful preparation for using the process, resources and diagnostics for problem determination.

## 8.1: Problem determination vs. tuning

This section describes a summary of the difference between problem determination and tuning. Problem determination and tuning are closely related topics, each having the same outcome: a better performing product. You might perceive tuning as a subset of problem determination.

Understanding the difference between problem determination and tuning is important. Knowing when to use tuning and when to use problem determination will save you time.

### Problem determination

Problem determination is the process of determining the source of a problem; for example, a program component, machine failure, telecommunication facilities, user or contractor-installed programs or equipment, environmental failure such as a power loss, or user error.

### Tuning

Tuning is the process of adjusting an application or a system to operate in a more efficient manner in the work environment of a particular installation.

In other words, problem determination fixes functional problems, while tuning alleviates slow processes.

The [WebSphere Performance and Tuning Guide](#) describes the parameters that should be modified to create an optimum product environment.

- [9.1: WebSphere Application Server Tuning Guide](#)

## 8.2: How to view messages

There are three ways to view messages:

- [Console Messages area](#) - located on the administrative GUI
- [Administrative and application server logs](#)
- [Activity log](#)

### Console messages area

The console messages area, located at the bottom of the WebSphere Administrative Console GUI, provides tracing information. The console messages area shows all messages for a given domain. The console messages can be disabled as to not use the facility.

The `com.ibm.ws.ras.SeriousEventEnable` property allows you to specify whether or not serious events (audit, warning, error, fatal, terminate) are written to the administrative Database. If writing of serious events to the administrative database is disabled, the corresponding messages will not be available for display in the administrative console.

This property is located in the `<install_dir>/properties/logging.properties` file. A process must be restarted for the change to take effect.

See the InfoCenter article [6.6.0.1: Using the Java administrative console](#) to learn more information about the messages area.

### Event viewer

The event viewer maintains a collection of the most recent message events. You can configure the event viewer to show any combination of audit, fatal, terminate, and warning message events. See the InfoCenter article [6.6.0.1: Using the Java administrative console](#) to learn more information about the event viewer.

The property `com.ibm.ws.ras.UnitOfWork` allows you to specify whether or not a correlation ID should be generated and included in message events and diagnostic trace entries. If set to true, each application client request is assigned a unique identifier that is propagated to all servers touched as part of servicing that request. This allows correlation of events across multiple server processes.

This property is located in the `<install_dir>/properties/logging.properties` file. A process must be restarted for the change to take effect.

### Administrative and application server logs

These logs will show the messages for a given server process. Use your favorite text editor to view these logs. See the [Logs](#) section for more information.

### Activity log

The activity log will show messages for a given server process. Use the Log Analyzer or the showlog facility to view the messages. See the [Logs](#) section for more information.

## 8.2.a: How to View Messages

You can view messages in the console messages area and with the events viewer.

### Console Messages area

The Console Messages area, located at the bottom of the WebSphere Administrative Console, provides the highest level of tracing information. When a message event occurs, it is displayed in the Messages area.

When you require more information than the Messages area provides, review the messages recorded in the Event Viewer.

### Event Viewer

The Event Viewer maintains a collection of the most recent message events. You can configure the Event Viewer to show any combination of audit, fatal, terminate, and warning message events.

The Event Viewer "Log Limit" property specifies how many event records to keep. They are stored in the administrative repository (database). If your database is becoming too full, set the Log Limit to the minimum value that is reasonable for your environment.

Access the Event Viewer from the Console menu on the menu bar of the administrative console.

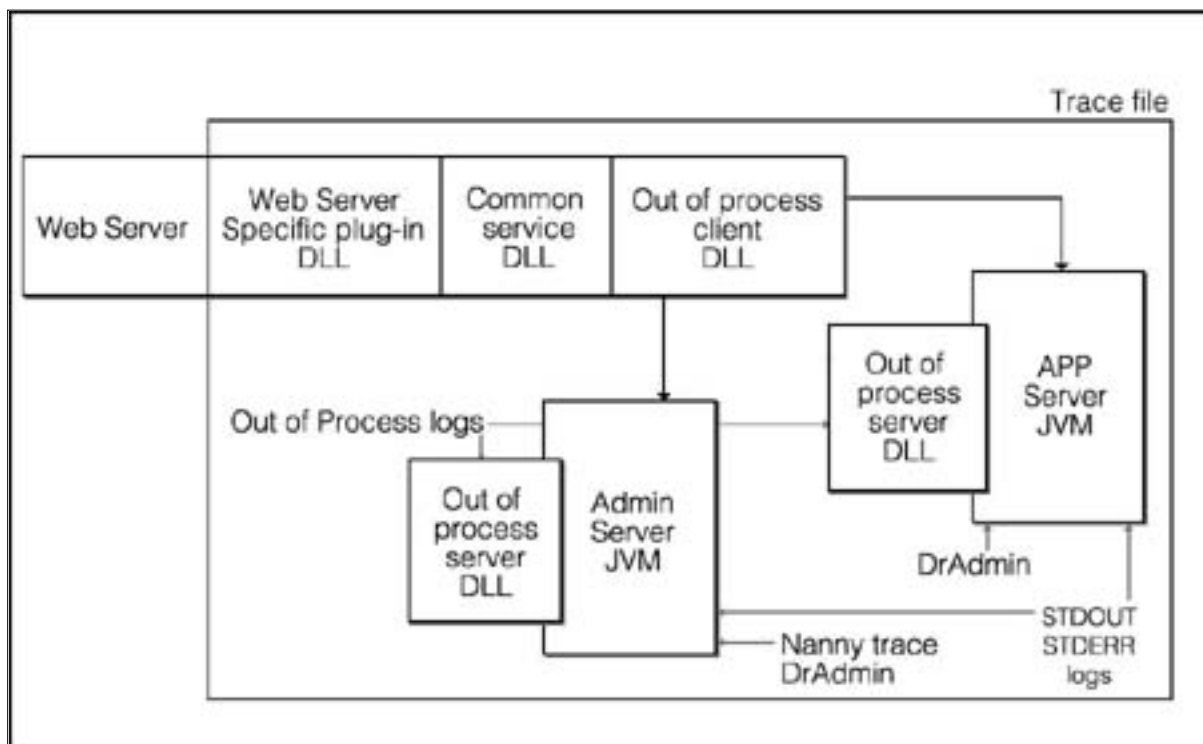

## 8.3: Logs

WebSphere Application Server provides many error logs to help you diagnose run-time problems. This section describes these error logs telling you where to find and how to format the files. The logs are:

- [activity.log](#)
- [stderr.log](#)
- [stdout.log](#)
- [oop logs for the application server](#)
- [oop logs for the administrative server](#)
- **NT** [wasdb2.log](#)
- **NT** [wssetup.log](#)
- **UNIX** [WebSphere.instl](#)

The tools required to process some of these logs (as well as some of the trace logs) are described in [Using Internal Tools](#). You can also refer to [Problem determination hints and tips](#) for additional tips on the use and processing of some of these error logs. If you need to report a problem to IBM, you might need to gather some of these error logs and send them to IBM for diagnosis; for more information, refer to [How to report a problem to IBM](#).

View the following graphic for a description of the log and trace points in WebSphere Application Server:

[InfoCenter Home](#) >

[8: Problem determination](#) >

8.3: Logs <- **you are here**

# Activity log for problem determination

The activity log captures events that show a history of WebSphere Application Server's activities. Some of the entries in the log are informational, while others report on system exceptions, such as returned CORBA exceptions.

When you encounter WebSphere Application Server run-time errors, you will often find it useful to use [Log Analyzer](#) to read the activity log and try to diagnose the problem yourself. When you need assistance from IBM to help you diagnose problems, you will be asked to provide the formatted activity log output to IBM.

## Location of the activity log

There is one activity log for each host machine. The activity.log file resides in the logs directory of where the product is installed. All application servers, including the administrative server, write error records to this file. The activity.log file is a binary file and cannot be viewed with an ASCII editor. You can view the activity.log file in one of two ways:

- [Log Analyzer](#)
- [showlog](#)

## How to view the activity.log file with Log Analyzer

1. Change the directory to:  
product\_installation\_root/bin
2. Run the waslogbr script file, which is called:
  - waslogbr.bat on Windows NT
  - waslogbr.sh on Unix systems

It needs to be run from the bin directory cited above.  
This will start the Log Analyzer graphical interface.

3. In the interface:
  1. Select File>Open.
  2. Navigate to the directory containing the activity.log file.
  3. Select the activity.log file.
  4. Select Open.

## How to view the activity.log file on a remote machine using showlog

The Log Analyzer cannot be used to view remote files. An alternate tool named showlog can be used instead of Log Analyzer to format the activity.log file for viewing when no GUI display capabilities are available.

showlog.bat or showlog.sh is a script/batch file that can be found in the bin directory of the WebSphere Application Server installation. Follow these instructions to use showlog:

1. Change directory to:  
product\_installation\_root/bin
2. Run the showlog tool with no parameters to display the usage instructions:

- On Windows NT, run showlog.bat
- On Unix systems, run showlog.sh

Examples:

- To direct the activity log contents to stdout, use the invocation:  
showlog activity.log
- To dump the activity.log to a text file that can be viewed using a text editor, use the invocation:  
showlog activity.log textFileName

## Changing activity.log file size

In the course of using Log Analyzer, you might have to set the maximum activity.log file size. The activity.log file grows to a predetermined size and then wraps. The default size is 1MB. Follow these steps to change the log size:

1. Open the properties file in a text editor:  
product\_installation\_root/properties/logging.properties
2. For the SHARED\_LOG\_LENGTH property, specify the value you would like in Kilobytes (KB). If an individual size is entered, the default size is used.
  - Example: To change the log size to 2MB, enter in the line:  
SHARED\_LOG\_LENGTH=2048 (do not use spaces)

The size change will take effect at the next server startup.

See other related tasks, including changing the port of the logging service, diagnosing port conflicts and confirming the creation of the activity.log file in the [Log Analyzer](#) section.

[InfoCenter Home](#) >

[8: Problem determination](#) >

8.3: Logs <- **you are here**

## stderr and stdout logs for problem determination

The stderr and stdout logs capture events presented through two of the three standard I/O streams, or:

- stdin - arguments entered with a command or program
- stdout - output displayed to the user
- stderr - errors thrown by the code

In WebSphere Application Server, the stdout and stderr logs are created for:

- Application servers
- Servlet redirectors

The application server stderr and stdout logs contain application server communication. Output from `System.err.println` and `System.out.println` statements in the servlet code also appear in the application server stdout and stderr logs.

[InfoCenter Home](#) >

[8: Problem determination](#) >

8.3: Logs <- **you are here**

# Out-of-process(oop) logs for problem determination

There are two types of out-of-process logs: those created for administrative servers and those created for application servers. These logs contain error and informational messages generated from the native code portion of the out-of-process engine. This information reflects server startup and server status change requests (start/stop/restart).

The default log file mask setting for the oop logs is **error**. If these logs have a file length of zero, no error messages were generated during the server status change requests.

To change the default log file mask setting:

1. Select the process to trace, for example **Servlet Engine**.
2. Click the Advanced tab for the Servlet Engine.
3. Click the Settings button.
4. Choose the log file mask from one of four options.
5. Click the Restart Plug-in button

The oop log files are now dated so the file format is consistent with that of the HTTP Server trace logs. For example, an administrative server oop log file name is: `adminserver_native.log.was.oop.Thu_May_26_23.26.20.2000`

[InfoCenter Home](#) >

[8: Problem determination](#) >

8.3: Logs <- **you are here**

## wasdb2 log

This log is created when the DB2 database, *was*, is configured. Review this log to determine if the *was* database was created correctly and if WebSphere Application Server can connect to it. Errors creating the system management repository tables will be logged in this file.

[InfoCenter Home](#) >

[8: Problem determination](#) >

8.3: Logs <- **you are here**

## wssetup log

This log is created during the install process. Review this log to ensure the install process was successful. The install process consists of:

- Verifying prerequisites
- Downloading files
- Updating the configuration files for both WebSphere Application Server and the Web server

[InfoCenter Home](#) >

[8: Problem determination](#) >

8.3: Logs <- **you are here**

# UNIX WebSphere.instl

On AIX and Solaris, a native install of WebSphere Application Server generates the WebSphere.instl log that is located in the `/tmp` directory.

Information on the WebSphere Application Server install process on HP is placed in the HP system log, `swagent.log`, that is located in the `/opt/WebSphere/AppServer/var/adm/sw` directory.

See the file, [Sample Logs](#), for examples of WebSphere.instl and swagent.log logs.

See the file, [WebSphere Application Server Directories](#), for a listing of files and directories in Version 3.5. This listing may help with problem determination.

The Related information links to instructions and additional detail about enabling and interpreting logs.

## 8.4: Traces

Traces are just [logs](#). Traces and logs differ in that you must turn traces on to see output in a trace file. Logs are always enabled and log entries are automatically generated.

Tracing occurs at two levels:

- On administrative servers (usually one per node)
- On application servers

You can enable trace for each Java™ class in the system.

The trace subsystem does not trace user code (such as servlets or EJB components) unless `System.err.println` or `System.out.println` statements are added to the code. Output from the `println` statements appears either in the application server stdout or stderr logs.

See the [stdout and stderr logs](#) description for more information on stdout and stderr logs.

Beginning with WebSphere Application Server Version 3.0, an object level debugger is provided with the product to trace and debug user code. See the [Object Level Tracing and Debugging \(OLT and OLD\)](#) section for information on object level tracing.

### Trace and log entry format

Since trace is just another log, both a WebSphere Application Server log entry and a trace entry will have the same format. The following example of a log entry illustrates the format:

Log entry example: **[00.07.11 22:47:12:191 EDT] 53ccc3c5 ActiveEJBCont W Could not create bean table xxx**

The following table includes a description of each of part of the log entry:

<b>[00.07.11 22:47:12:191 EDT]</b>	<b>53ccc3c5</b>	<b>ActiveEJBCont</b>	<b>W</b>	<b>Could not create bean table</b>	<b>xxx</b>
<b>TS:</b> The timestamp in fully qualified date (YYMMDD), Time (Millisecond precision), and Time zone format.	<b>TID:</b> The thread ID or the hash code of the thread issuing this message.	<b>COMPONENT:</b> The short name of component issuing this message.	<b>LEVEL:</b> The level of the message or trace. Possible levels are: <ul style="list-style-type: none"><li>● &gt; Entry to a method (debug)</li><li>● &lt; Exit a method (debug)</li><li>● A Audit</li><li>● W Warning</li><li>● X Error</li><li>● E Event (debug)</li><li>● D Debug (debug)</li></ul>	<b>MESSAGE:</b> The text of the message.	<b>ARGUMENTS:</b> Optional message arguments.

			<ul style="list-style-type: none"> <li>● <b>T</b>Terminate (exits process)</li> <li>● <b>F</b> Fatal (exits process)</li> </ul>	
--	--	--	---	--

## Types of traces

The following are the traces you will find in WebSphere Application Server:

- [Trace file](#)
- **UNIX** Nanny trace
- [DrAdmin](#)

View the following graphic for a description of the log and trace points in WebSphere Application Server:

## Trace file

The trace file provides trace entries on the interaction of various WebSphere ApplicationServer components with the administrative server. Use the trace file to identify a problem and to review events preceding the error situation.

**Note:** Always review trace entries prior to the error. Trace entries recorded after the error has occurred represent program recovery and will not help with problem determination.

Review the [Collecting traces](#) section for additional trace documentation.

[Trace file samples](#)

## UNIX Nanny trace

On UNIX platforms, the nanny process starts the administrative server. The `nanny.maxtries` parameter in the `admin.config` file tells the nanny process how many times it should attempt to restart the administrative server.

On Windows NT, the `nannyservice` is part of the IBM WebSphere Administrative Server service that is registered with the operating system. Starting the IBM WebSphere Administrative Server service invokes `adminservice.exe`. If this service does not start, verify that:

- The service was installed and is available from Start > Settings > Control Panel > Services
- The userID under which WebSphere Application Server was installed has service privileges

If the nanny process fails to start the administrative server on UNIX or if the IBM WebSphere Administrative Server service does not start on Windows NT, you can bypass the nanny function and just start the administrative server. Follow these steps to start the administrative server:

1. Go to the `<WAS_root>bin/debug` directory
2. Invoke `adminserver.sh` on UNIX or `adminserver.bat` on Windows NT

**Note:** Starting the administrative server without using the `nanny` function means that nothing is monitoring the administrative server. If it fails in this state, nothing will restart it.

A nanny trace is only available on UNIX platforms.

On Windows NT, use the Event Viewer to view entries related to the WebSphere nanny service. Follow these steps to view the Event Viewer :

1. Select Start > Programs > Administrative Tools
2. Select Event Viewer
3. View events related to WebSphere Application Server

### [Nancy trace samples](#)

## DrAdmin trace function

The DrAdmin function generates thread dumps.

On UNIX platforms, the IBM JDK allows users to send signals to force `javacore.txt` files to be created in the application server's working directory. The application server continues to run and a sequence of `javacore` files are created. These files can help in debugging "loop" or "system hang" problems.

To generate thread dumps similar to the `javacore` files, especially on a Windows NT platform, use the DrAdmin function.

A unique DrAdmin port is generated each time an application server starts. To generate a thread dump for that port:

1. View the [console messages area](#) or the [trace file](#) for message SMTL0018I "DrAdmin available on port."
2. Enter the following command:  
`DrAdmin <port number> -dumpThreads`
3. Review the [stderr](#) log for the thread dump.

After installing and starting WebSphere Application Server, you will see DrAdmin entries in the [console messages area](#). These entries appear regardless of the options specified during installation, and have the

following format:

DrAdmin available on port 1,055

DrAdmin entries are also recorded in the trace file. To locate the DrAdmin entry in the trace file:

1. In the <WAS\_ROOT>**logs** directory, open the trace file.
2. Go to the bottom of the trace file and then scroll up until you locate the following entry: DrAdmin available on port xxxx

## What is DrAdmin?

DrAdmin is a service, provided by each of the servers, to enable and disable tracing. Each time a server starts, DrAdmin registers itself on a different (next available) port number. There are no output messages associated with DrAdmin. The DrAdmin entries in the console messages area are generated to tell users the port number where DrAdmin is listening.

## When to use DrAdmin?

You should always use the administrative console [trace](#) facilities to debug a problem. DrAdmin is a diagnostic tool to be used when you have no other choices. It was designed to provide IBM support personnel with another way of obtaining traces. Use DrAdmin in these situations only:

- When input to the administrative console is not accepted
- When the administrative server is in a wait state
- When the administrative server is not responding (e.g., in an infinite loop or hung state)
- When you have to dump the thread stacks in a server
- When the administrative client topology tree disappears

**Note:** DrAdmin is an internal interface that is used to assist users with problem determination. As an internal interface, it is subject to change at any time, and there is no national language support for it.

## How to use DrAdmin?

The DrAdmin interface is the same on all platforms. Since DrAdmin is another way of turning on a trace, the tracing mechanism is the same as the one used by the administrative console [trace](#) facilities. Therefore, whether you are looking at the trace file or a DrAdmin output file, the trace entries will have the same format.

See the DrAdmin samples to learn how to invoke DrAdmin.

To specify the DrAdmin trace output in the admin.config file:

- In the admin.config file located in the <WAS\_ROOT>bin directory, append the following property where the file name consists of an absolute path and the file that you want to create: `com.ibm.ejs.sm.adminServer.traceOutput=<filename>`
- Restart the administrative server. The trace file specified in the admin.config file should be created during startup of the administrative server. The administrative server might not start if the path specified for file name does not exist, or if the directory permissions where the trace file is to be created, are incorrect or insufficient.
- If the administrative server starts but the trace file is not created, ensure the traceOutput parameter in the admin.config file is correct, and the path to the file exists.

[DrAdmin samples](#)

For more information on traces, see file [What are messages, logs and traces?](#)

# 8.4.1: Trace samples

Select one of the following traces to view sample output:

- [Trace file](#)
- **UNIX** [Nanny trace](#) (available on UNIX platforms only)
- [DrAdmin](#)

## Trace file

The following trace fragment is an example of a trace file. Use this trace to debug server startup or shutdown problems:

```

## UNIX Nanny trace

The following trace fragment is an example of a nanny trace. Use the nanny trace to monitor administrative server events:

```
[00.07.17 17:05:00:032 EDT] 1fa4cc16 Nanny > main"admin.config"[00.07.17 17:05:00:032 EDT] 1fa4cc16 Nanny >
Initial admin server startup..[00.07.17 17:05:06:231 EDT] 1fa4cc16 Nanny < Initial adminserver startup
successful..[00.07.17 17:05:06:321 EDT] 1fa50b45 Nanny > run : AdminServerMonitorThread[00.07.17 17:05:06:321 EDT]
1fa50b45 Nanny E AdminServerMonitorThread: Waiting for process 1719 to terminate.
```

## DrAdmin

**NT** To invoke DrAdmin:

1. Go to the <WebSphere\AppServer\bin\debug> directory.
2. Copy adminserver.bat to DrAdmin.bat

**UNIX** **Note:** On Unix platforms, the adminserver.bat file is adminserver.sh. Copy adminserver.sh to DrAdmin.sh.

3. Replace the following line in the DrAdmin.bat file:  
%JAVA\_HOME%\bin\java -mx128m com.ibm.ejs.sm.server.AdminServer -bootFile %WAS\_HOME%\bin\admin.config %restart% %1 %2 %3 %4

with

%JAVA\_HOME%\bin\java com.ibm.ejs.sm.util.debug.DrAdmin %1 %2 %3 %4 %5 %6 %7 %8 %9

4. Save and close the DrAdmin.bat file
  5. From a command prompt in the <WebSphere\AppServer\bin\debug> directory, type DrAdmin [options] where options are:
    - o -help [shows the help message]
    - o -serverHost <Server host name> [Specify the host name of the server... defaults to local host]
    - o -serverPort <Server port number> [Required... enter the port number where DrAdmin is listening]
    - o -setTrace <Trace specification> [Specify any valid traceString, for example, "com.ibm.ejs.sm.\*=all=enabled"]
    - o -setRingBufferSize <Number of ring buffer entries in k> [Specify the number of trace entries to store in the main memory buffer... the default is 8k]
    - o -dumpRingBuffer <Name of file to dump the ring buffer> [Defaults to file name JMONDump.xxxxxxxx where xxxxxxxx is a combination time of day and unique PID identifier extension]
- NT Note:** On Windows NT, if the administrative server is started as a service, the default DrAdmin dump file will be located in the <Winnt\system32> directory.
- o -dumpState <dumpString> [Specify a unique identifier for this dump]
  - o -stopServer [Stops the administrative server]
  - o -stopNode [Does not apply unless the node is connected to the administrative server]
  - o -dumpThreads [Dumps the threads in the server]

### Another example of implementing a DrAdmin trace:

#### NT On Windows NT:

1. Create a DrAdminRun.bat file that contains the following information:
 

```
set CLASSPATH=C:/jdk1.1.7/lib/classes.zip;C:/WebSphere/AppServer/lib/ujc.jar;C:/WebSphere/AppServer/lib/ejs.jar;C:/WebSphere/AppServer/lib/admin.jar
echo %CLASSPATH%
java -classpath %CLASSPATH% com.ibm.ejs.sm.util.debug.DrAdmin -serverPort %1 -setTrace %2=%3=%4
```
2. Invoke DrAdminRun.bat with the port number and the trace string. Use the port number from DrAdmin entry in the trace file, xxxx. Your input from a command prompt will be:
 

```
DrAdminRun xxxx com.ibm.ejs.* all enabled
```
3. Start administrative client with the debug option by invoking adminclient.bat from the WAS\_ROOT bin directory:
 

```
adminclient debug
```

#### UNIX On UNIX platforms:

1. Create a shell script file DrAdminRun that contains the following information:
 

```
# modify classpath as appropriate for platform/environment
# run as follows: sh DrAdminRun <server port> <trace spec>
export CLASSPATH=/usr/jdk_base/lib/classes.zip:/usr/WebSphere/AppServer/lib/ujc.jar:/usr/WebSphere/AppServer/lib/ejs.jar:/usr/WebSphere/AppServer/lib/admin.jar
echo %CLASSPATH%
java -classpath $CLASSPATH com.ibm.ejs.sm.util.debug.DrAdmin -serverPort $1 -setTrace $2
```

**Note:** Verify the CLASSPATH is correct for your environment. The script example was written for AIX. You must change the CLASSPATH for Solaris.
2. Invoke DrAdminRun with the port number and the trace string. Use the port number from DrAdmin entry in the trace file, xxxx. Your input from a command prompt will be:
 

```
sh DrAdminRun xxxx com.ibm.ejs.*=all=enabled
```
3. Start the administrative client with the debug option by invoking adminclient.sh from the WAS\_ROOT bin directory:
 

```
adminclient.sh debug
```

## 8.4.1.1: Plugin Problems

HTTP Servers are legacy Web products, created at a time when they were the only conduit between Browsers and HTML or CGI files. With the evolution of Web technology, users now require servers to handle servlets, JSP files and EJBs. WebSphere Application Server supports this technology but to provide these functions, it must intercept requests sent to the HTTP Server.

The *plugin* component extends the function of the HTTP Server. It intercepts requests and passes them to either WebSphere Application Server or the HTTP Server. The following three files in the `<WAS_root>temp` directory allow the plugin to determine the request's destination:

- `<WAS_root>/temp/rules.props`  
(Provides a snapshot of the existing topology and lists available Web resources and paths to handle service requests.)
- `<WAS_root>/temp/vhosts.props`  
(Provides virtual hosting information that is transferred to the WebSphere Application Server runtime environment.)
- `<WAS_root>/temp/queues.props`  
(Provides names of links to different servlet engines. The number of links listed in this file vary according to the number of AppServers, clones, and other servlet engine resources that are defined in the product.)

This is the high level view of the plugin process flow:

Browser --> WebSphere plugin --> HTTP Server or WebSphere Application Server

### Typical plugin problems

Generally plugin failures are caused by missing files or an incorrectly configured HTTP Server.

To diagnose plugin problems, verify the data in the files is consistent with both the HTTP request and the active configuration in the Servlet Engine. The plugin configuration files are regenerated periodically so a delay can occur between the time a change is made in the system and the time the change is reflected in the configuration files.

The following error descriptions are symptomatic of plugin problems:

1. ***Servlet requests are not fulfilled.*** Verify the following to determine the cause of the problem:
  - Web server can serve HTML pages.
  - Admin console can connect to Web server.
  - Default Server is started.
  - Ensure the Web server hostname and port number are identical to the ones defined in the virtual host's alias table.
  - Ensure the appropriate **.DLL** file for the Web server is present in directory:  
`<WebSphere-root>bin`
2. ***Pipe broken messages appear.*** Verify the following to determine the cause of the problem:
  - TCP/IP connection exists between Web server and WebSphere Application Server.
  - No process or thread failures occurred.
  - No access violations occurred.

### How to debug plugin problems

Check for errors in the following logs, and in the *tracefile*:

- `trace.log.<http server>.<date>`

- <AppServer>\_stderr.log
- <AppServer>\_stdout.log
- <AppServer>\_native.log.<date>

See files [8.3: Logs](#) and [8.4: Identifying the Problem](#) for trace and log information.

If there are no entries in the logs or tracefile, comment out the WebSphere ApplicationServer plugin in the *httpd.conf* file. This will help you determine if the failure originates with WebSphere Application Server or the HTTP Server.

The WebSphere plugin property in *httpd.conf* is:

***Load Module ibm\_app\_server\_module***

Restart the HTTP Server. If the Web Server initializes and runs, then WebSphere Application Server has a problem.

## 8.4.1.2: Servlet Redirector Problems

Servlet redirectors are used to separate the HTTP server from the WebSphere Application Server. There are different types of redirectors:

- Thick - servlet redirector resides on the same machine as WebSphere Administrative Server.
- Thin - servlet redirector runs on a separate machine from the WebSphere Administrative Server. A *thin* servlet redirector is useful in network configurations where the HTTP server is outside a firewall but WebSphere Application Server is behind a firewall, or where WebSphere Application Server is located in the DMZ, a machine located between two firewalls.

**Note:** If Web Server, App server and the Server handling servlet requests all reside on the same machine, use OSE - Open Servlet Engine, instead of a servlet redirector

### Key features

The key features of servlet redirectors are:

1. Use IIOP (Internet Inter-Orb Protocol) for communication
2. Are initialized by copying the *queues.properties*, *rules.properties*, and *vhosts.properties* files from the WebSphere Application Server machine to the servlet redirector machine.
3. Use the following ports to transfer the properties files:
  - port 900 - bootstrap port
  - port 9000 - name services port
  - redirector listener port
4. Require the receiving RemoteSRP bean to be running on the WebSphere Application Server
5. When servlet redirectors are running, beside the ports previously listed, they also require the following, additional ports:
  - Application Server listener port
  - Admin server nanny listener port
  - *Thick* servlet redirectors also require repository database connection ports

### Typical Problems

Typical problems with servlet redirectors are:

1. **Error 404 - URL not found** appears on browser when accessing a servlet.  
The trace log for the HTTP server contains entry:  
*Failure while locating a vhost for <server>*  
This error may occur if:
  - The short (myserver) and fully qualified (myserver.mydomain.com) hostnames of the HTTP server are not in the **virtual host alias list**.
  - A port other than the standard port 80 is used and that port is not in the **virtual host alias list**.
2. **CORBA.COMM\_FAILURE** appears when running the *thin* servlet redirector. This error may occur if:
  - Syntax error exists in batch file
  - Hostname/port number is not in DNS or *hosts.properties* file on servlet redirector machine
  - Hostname/port number is not in DNS or *hosts.properties* file on WebSphere Application Server machine

- -ListenerPort parameter value is not unique
  - Syntax error in -ListenerPort parameter
3. **Unable to initialize threads: (null)** error when running the batch/script file to configure the plugin files. This error may occur if:
- Some JDK other than the IBM supported JDK is in the CLASSPATH ahead of the supported JDK. To resolve this problem, install the supported IBM JDK, and change the PATH and CLASSPATH to point to it first.
  - PATH does not point to *java.exe*.
4. When starting servlet redirector with batch/script file, get error message ***Error locating Remote SRP Home - Attribute Not Set***. This error occurs because:
- RemoteSRP bean was **not** added and started on WebSphere Application Server
5. Do **not** use servlet redirectors if you must:
- enable security on your *thin* servlet redirector machine
  - provide the real Web browser on your *thin* servlet redirector machine
  - use the *Network Address Translation* feature of firewalls so that the internal address of WebSphere Application Server is not available outside the firewall

**Reminder:** Generally errors occur configuring the *thin* servlet redirector function because required configuration files are missing. A *thin* servlet redirector machine requires the following shell script files (on UNIX platforms), or bat files on Windows NT as well as the *iiopredirector.xml* file to enable the servlet redirector function.

**Unix and NT:**

*iiopredirector.xml*  
in directory:  
<AppServer root> properties

**NT:**

*redirectorConfig.bat*  
*redirectorStart.bat*  
in directory:  
<AppServer root>\binkdebug

**Unix:**

*redirectorConfig.sh*  
*redirectorStart.sh*  
in directory:  
<AppServer root>/bin/debug

**Unix and NT:**

*iiopredirector.xml*  
in directory:  
<AppServer root> properties

## 8.4.1.3: Workload Management/Cloning/Remote Administration Problems

Unlike WebSphere Application Server Advanced Edition, the Standard Edition does not support the Workload Management function. WebSphere Application Server Standard Edition is limited to a single physical server. However, Standard Edition provides multiple JVMs that can be mapped to multiple virtual hosts on a single HTTP Server. Therefore multiple Web sites can still be hosted using one Standard Edition Application Server.

### Description of the Workload Management function and cloning

Like the Standard Edition, WebSphere Application Server Advanced Edition provides multiple JVMs, but it also supports distributed system management for networks and clusters of Advanced Edition Application Servers. Distributed system management is an outcome of the the Workload Management function. This function enables cloning, or creating instances of a model. Clones can be created on a single machine or across multiple machines in a cluster. Modifying a model automatically propagates the changes to all of its clones. By administering a model, you can simultaneously administer several copies of a server (the clones).

Scalability in a workload management environment occurs in two forms:

- **Horizontal scaling** - the number of concurrent connected users.
- **Vertical scaling** - the number of concurrent requests.

With Workload Management, requests can be routed to any server on any node with the same results. Workload Management provides for **Failover** where requests are routed to other nodes (servers) when one node fails. Failover occurs without affecting throughput or reliability.

### Workload Management and Cloning problem descriptions

The following resources can be cloned. Select a specific type of resource to view typical problem scenarios.

- [Application Servers](#)
- [EJB Containers](#)
- [Enterprise Beans](#)
- [Servlet Engines](#)
- [Web Applications](#)
- [Servlets](#)

### Application Server issues

There may be some performance impacts using cloning:

1. Make small, incremental changes to your model to minimize performance hit on the client.
2. Change your model when few clients and servers are running.
3. You do not need to reconfigure server groups to reflect an unavailable server unless that server will be unavailable for an extended period of time. In that case, reconfigure the model to optimize performance.

### EJB Containers and Enterprise Beans

Homes of session beans have special information to indicate that these "homes" are workload management

(WLM) enabled; that is, deployed on one or more servers. When a client accesses the home of a session bean, the client is referred to the homeOfHomes on the Admin Server. The client then creates proxies for each clone using a specific workload management policy as for example, round robin.

Problems occur when:

- Client stubs are generated that are not WLM enabled. All stubs generated by VisualAge for Java are WLM enabled. For those stubs not created through VisualAge for Java, you must use the wlmjar file.
- Client stubs are WLM enabled but should not be. To create non-WLM stubs, use "rmic -iiop" and jar the output files.
- You WLM enable a stateful session bean instead of its container.
- If all your requests are sent to the same server, verify that your client jar file is WLM enabled. Use `jar -tvf` on the jar file, and verify the jar file contains both `x_Stub` and `x_BaseStub`, not just `x_Stub`.

## Servlet Engines, Web applications and Servlets

If requests are going to one server, verify that your model has more than one clone. Also verify that each clone has xBean deployed. This particularly applies to a *Thin Servlet Redirector* configuration since the ThinRedirector is an EJB client to the RemoteSRP bean. Also verify that the first server in the model is running. The first server must be running for the lookup phase to work correctly.

## Remote Administration

You can remotely administer WebSphere Application Server using:

- [remote admin console](#)
- [X Windows clients on UNIX machines](#)
- [Web based WebSphere admin console](#)

### Remote admin console

Use can run admin console remotely using the ***adminclient.bat*** file on Windows NT, or ***adminclient.sh*** file on UNIX. See article [Administrative models](#) for more information on implementing a remote admin client.

Typical remote admin console problems are:

- ***com.ibm.ejs.util.cache.FaultException*** error occurs in the stack trace because the JDK running on the client machine cannot communicate with the JDK running on the Admin Server machine. The resolution is to upgrade the backlevel JDK.
- The NAT (Network Address Translation) function in firewalls cannot be used with a remote admin client. The internal address of the Admin Server is not recognized by the admin client outside the firewall. **No** circumvention exists for this problem.

### X Windows clients on UNIX machines

X windows client software can run on any platform but requires a UNIX X Windows Server. (Currently the X Windows Server is only available on AIX and Solaris platforms.)

Typical X window client problems are:

- You cannot run an admin console remotely through the X windows client using an unauthorized, ***non-root*** account with global security enabled. Error message, ***FATAL Could not bind to the Admin Server on {0}{1}***, appears on the screen when the adminclient .sh or .bat file is executed. **No** circumvention exists

for this problem.

## **Web based WebSphere admin console**

See article [Web administrative console overview](#) for informationon configuring and implementing a Web based admin console.

## 8.5: Identifying the problem

Please select a related topic.

## 8.5.1: Plug-in problems

HTTP servers are legacy Web products, created at a time when they were the only conduit between browsers and HTML or CGI files. With the evolution of Web technology, users now require servers to handle servlets, JSP files and EJBs. WebSphere Application Server supports this technology, but to provide these functions it must intercept requests sent to the HTTP Server.

The plug-in component extends the function of the HTTP Server by intercepting requests and passing them to either WebSphere Application Server or the HTTP Server. The following three files in the `<WAS_root>temp` directory allow the plug-in to determine the request's destination:

- `<WAS_root>/temp/rules.props`
  - Provides a snapshot of the existing topology and lists available Web resources and paths to handle service requests
- `<WAS_root>/temp/vhosts.props`
  - Provides virtual hosting information that is transferred to the WebSphere Application Server runtime environment
- `<WAS_root>/temp/queues.props`
  - Provides names of links to different servlet engines. The number of links listed in this file vary according to the number of application servers, clones and other servlet engine resources that are defined in the product.

This is the high level view of the plug-in process flow:

Browser --> WebSphere plugin --> HTTP Server or WebSphere Application Server

### Typical plug-in problems

Generally, plug-in failures are caused by missing files or an incorrectly configured HTTP Server.

To diagnose plug-in problems, verify the data in the files are consistent with both the HTTP request and the active configuration in the servlet engine. The plug-in configuration files are regenerated periodically so a delay can occur between the time a change is made in the system and the time the change is reflected in the configuration files.

The following error descriptions are symptoms of plug-in problems:

1. Servlet requests are not fulfilled. Verify the following to determine the cause of the problem:
  - The Web server can serve HTML pages
  - The administrative console can connect to the Web server
  - The Default server is started
  - Ensure the Web server hostname and port number are identical to the ones defined in the virtual host's alias table.
  - Ensure the appropriate .DLL file for the Web server is present in the `<WebSphere-root>bin`
2. Pipe broken messages appear. Verify the following to determine the cause of the problem:
  - TCP/IP connection exists between Web server and WebSphere Application Server.
  - No process or thread failures occurred.
  - No access violations occurred.

### How to debug plug-in problems

Check for errors in the following logs, and in the trace file:

- `trace.log.<http server>.<date>`
- `<AppServer>_stderr.log`
- `<AppServer>_stdout.log`
- `<AppServer>_native.log.<date>`

See files [8.3: Logs](#) and [8.4: Trace](#) for more information on logs and trace file.

If there are no entries in the logs or trace file, comment out the WebSphere ApplicationServer plugin in the httpd.conf file. This will help you determine if the failure originates with WebSphere Application Server or the HTTP Server.

The WebSphere plugin property in the httpd.conf file is:

```
Load Module ibm_app_server_module
```

Restart the HTTP Server. If the Web Server initializes and runs, then WebSphere Application Server has a problem.

## 8.5.2: Servlet redirector problems

Servlet redirectors are used to separate the HTTP server from the WebSphere Application Server. There are different types of redirectors:

- Thick - servlet redirector resides on the same machine as WebSphere Administrative Server.
  - Thin - servlet redirector runs on a separate machine from the WebSphere Administrative Server. A *thin* servlet redirector is useful in network configurations where the HTTP server is outside a firewall but WebSphere Application Server is behind a firewall, or where WebSphere Application Server is located in the DMZ, a machine located between two firewalls.
- Note:** If the Web server, application server and the server handling servlet requests all reside on the same machine, use Open Servlet Engine (OSE), instead of a servlet redirector

### Key features

The key features of servlet redirectors are:

1. Use Internet Inter-Orb Protocol (IIOP) for communication
2. Are initialized by copying the queues.properties, rules.properties, and vhosts.properties files from the WebSphere Application Server machine to the servlet redirector machine.
3. Use the following ports to transfer the properties files:
  - port 900 - bootstrap port
  - port 9000 - name services port
  - redirector listener port
4. Require the receiving RemoteSRP bean to be running on the WebSphere Application Server
5. When servlet redirectors are running, beside the ports previously listed, they also require the following, additional ports:
  - Application Server listener port
  - Admin server nanny listener port
  - *Thick* servlet redirectors also require repository database connection ports

### Typical problems

Typical problems with servlet redirectors are:

1. **Error 404** - URL not found appears on browser when accessing a servlet.  
The trace log for the HTTP server contains entry:  
*Failure while locating a vhost for <server>*  
This error may occur if:
  - The short (myserver) and fully qualified (myserver.mydomain.com) host names of the HTTP server are not in the virtual host alias list.
  - A port other than the standard port 80 is used and that port is not in the virtual host alias list.
2. CORBA.COMM\_FAILURE appears when running the thin servlet redirector. This error may occur if:
  - Syntax error exists in batch file
  - Host name/port number is not in DNS or hosts.properties file on servlet redirector machine
  - Host name/port number is not in DNS or hosts.properties file on WebSphere Application Server machine

- -ListenerPort parameter value is not unique
  - Syntax error in -ListenerPort parameter
3. Unable to initialize threads: (null) error when running the batch/script file to configure the plug-in files. This error may occur if:
- Some JDK other than the IBM supported JDK is in the classpath ahead of the supported JDK. To resolve this problem, install the supported IBM JDK, and change the path and classpath to point to it first.
  - Path does not point to java.exe.
4. When starting servlet redirector with batch/script file, get error message "Error locating Remote SRP Home - Attribute Not Set." This error occurs because:
- RemoteSRP bean was not added and started on WebSphere Application Server
5. Do not use servlet redirectors if you must:
- Enable security on your thin servlet redirector machine
  - Provide the real Web browser on your thin servlet redirector machine
  - Use the Network Address Translation feature of firewalls so that the internal address of WebSphere Application Server is not available outside the firewall

**Reminder:** Generally errors occur configuring the thin servlet redirector function because required configuration files are missing. A thin servlet redirector machine requires the following shell script files (on UNIX platforms), or bat files on Windows NT as well as the iioptredirector.xml file to enable the servlet redirector function.

**Unix and NT:**

*iiopredirector.xml*  
in directory:  
<AppServer root> properties

**NT:**

*redirectorConfig.bat*  
*redirectorStart.bat*  
in directory:  
<AppServer root>\bin\debug

**Unix:**

*redirectorConfig.sh*  
*redirectorStart.sh*  
in directory:  
<AppServer root>/bin/debug

**Unix and NT:**

*iiopredirector.xml*  
in directory:  
<AppServer root> properties

## 8.5.3: Workload management/cloning/remote administration problems

Unlike WebSphere Application Server Advanced Edition, the Standard Edition does not support the workload management function. WebSphere Application Server Standard Edition is limited to a single physical server. However, Standard Edition provides multiple JVMs that can be mapped to multiple virtual hosts on a single HTTP Server. Therefore multiple Web sites can still be hosted using one Standard Edition Application Server.

### Description of the workload management function and cloning

Like the Standard Edition, WebSphere Application Server Advanced Edition provides multiple JVMs, but it also supports distributed system management for networks and clusters of Advanced Edition Application Servers. Distributed system management is an outcome of the Workload Management function. This function enables cloning, or creating instances of a model. Clones can be created on a single machine or across multiple machines in a cluster. Modifying a model automatically propagates the changes to all of its clones. By administering a model, you can simultaneously administer several copies of a server (the clones).

Scalability in a workload management environment occurs in two forms:

- Horizontal scaling - the number of concurrent connected users
- Vertical scaling - the number of concurrent requests

With workload management, requests can be routed to any server on any node with the same results. Workload management provides for failover where requests are routed to other nodes (servers) when one node fails. Failover occurs without affecting throughput or reliability.

### Workload management and cloning problem descriptions

The following resources can be cloned. Select a specific type of resource to view typical problem scenarios.

- [Application servers](#)
- [EJB containers](#)
- [Enterprise beans](#)
- [Servlet engines](#)
- [Web applications](#)
- [Servlets](#)

### Application server issues

There may be some performance impacts using cloning:

1. Make small, incremental changes to your model to minimize performance hits on the client.
2. Change your model when few clients and servers are running.
3. You do not need to reconfigure server groups to reflect an unavailable server unless that server will be unavailable for an extended period of time. In that case, reconfigure the model to optimize performance.

### EJB containers and enterprise beans

Homes of session beans have special information to indicate that these "homes" are workload management

(WLM) enabled; that is, deployed on one or more servers. When a client accesses the home of a session bean, the client is referred to the homeOfHomes on the Admin Server. The client then creates proxies for each clone using a specific workload management policy as for example, round robin.

Problems occur when:

- Client stubs are generated that are not WLM enabled. All stubs generated by VisualAge for Java are WLM enabled. For those stubs not created through VisualAge for Java, you must use the wlmjar file.
- Client stubs are WLM enabled but should not be. To create non-WLM stubs, use "rmic -iiop" and jar the output files.
- You WLM enable a stateful session bean instead of its container.
- If all your requests are sent to the same server, verify that your client jar file is WLM enabled. Use `jar -tvf` on the jar file, and verify the jar file contains both `x_Stub` and `x_BaseStub`, not just `x_Stub`.

## Servlet engines, Web applications and servlets

If requests are going to one server, verify that your model has more than one clone. Also verify that each clone has xBean deployed. This particularly applies to a *Thin Servlet Redirector* configuration since the ThinRedirector is an EJB client to the RemoteSRP bean. Also verify that the first server in the model is running. The first server must be running for the lookup phase to work correctly.

## Remote administration

You can remotely administer WebSphere Application Server using:

- [Remote administrative console](#)
- [X Windows clients on UNIX machines](#)
- [Web based WebSphere administrative console](#)

## Remote administrative console

Use can run admin console remotely using the adminclient.bat file on Windows NT, or adminclient.sh file on UNIX. See article [Administrative models](#) for more information on implementing a remote admin client.

Typical remote admin console problems are:

- The `com.ibm.ejs.util.cache.FaultException` error occurs in the stack trace because the JDK running on the client machine cannot communicate with the JDK running on the administrative server machine. The resolution is to upgrade the backlevel JDK.
- The Network Address Translation (NAT) function in firewalls cannot be used with a remote administrative client. The internal address of the administrative server is not recognized by the administrative client outside the firewall. No circumvention exists for this problem.

## X Windows clients on UNIX machines

X windows client software can run on any platform but requires a UNIX X Windows server. (Currently the X Windows server is only available on AIX and Solaris platforms.)

Typical X Windows client problems are:

- You cannot run an administrative console remotely through the X Windows client using an unauthorized, non-root account with global security enabled. The error message, FATAL Could not bind to the Administrative Server on {0}{1}, appears on the screen when the adminclient.sh or .bat file is

executed.No circumvention exists for this problem.

## **Web-based administrative console**

See article [Web administrative console overview](#) for informationon configuring and implementing a Web-based administrative console.

## 8.5.4: Installation problems

Successful installation means that no errors occur during the install process and, more importantly, that the product runs correctly the first time you start it.

Installation and start-up problems occur for one of the following reasons:

- [Database is not configured properly](#)
- [Classpath is incorrect](#)
- [Administrative server fails to start](#)

### Install options

WebSphere Application Server provides a Java™ Graphical User Interface (GUI) install that is available on all platforms, and a native install that is available on the UNIX platforms (AIX, Solaris, HP).

**Note:** If you used the native install option to install WebSphere Application Server on a UNIX platform, you **must** also **uninstall** using the native uninstall option. In other words, you cannot do a native install and a Java GUI uninstall.

Follow the steps in one of the "platform specific" install guides to install the product. These install guides are available from the InfoCenter, in the [Selecting installation steps](#) section.

### Database configuration problems

If the database is not configured properly, installation of WebSphere Application Server will fail. If specific WebSphere components did install but the database is misconfigured, the product will not run properly.

Starting WebSphere Application Server with an improperly configured database will generate the following error messages and exceptions:

```
Establishing connection please wait ... Error - could not get attributescom.ibm.ejs.util.cache.FaultException at
java.lang.Throwable<init>com.ibm.ejs.sm.client.ClientException getAttributeFailure Attributes may be
involvedcom.ibm.ejs.sm.client.RpositoryOpException could not get attributes
```

### Classpath problems

The classpath provides the Java™ runtime environment for the following WebSphere Application Server processes:

- Administrative service - the backend process for system management
- Administrative console - the Graphical User Interface (GUI) used for system management
- One or more application servers - each application server consists of multiple containers for deployment of Enterprise Java Beans (EJBs) and one servlet engine for deployment of Web applications
- Nanny service (on UNIX platforms only) - a daemon that monitors the administrative service. The nanny service starts the administrative service initially and restarts it if it fails.

Each of these processes runs in its own Java Virtual Machine (JVM). The classpath for each process tells that process where to search for classes. The classpath can be set:

- In an administrative service startup script
- In an admin.config file
- With application server command line arguments
- By Web applications

### Classpath properties

Each process has an associated set of properties ("Java-speak" for environment variables). These properties are defined in the admin.config file that is located in directory:

<WebSphere root> bin

The applicable properties in admin.config are:

- com.ibm.ejs.sm.util.process.Nanny.maxtries
- com.ibm.ejs.sm.adminserver.classpath
- com.ibm.ejs.sm.util.process.Nanny.path
- com.ibm.ws.jdk.path

The classpath settings in the admin.config file apply to the administrative service, and they are also inherited by all other WebSphere Application Server processes.

For more information on these and other WebSphere Application Server properties, see file, [6: Administer applications](#).

## Classpath failures

Typical classpath failures are:

1. When a servlet class is missing from a Web application classpath, the following errors occur:
  - In a browser window, the browser displays error **Error 500** with message, "Failed to load target servlet [snoop]."
  - Browser stack trace and <AppServerName>\_stderr.log show  
java.lang.ClassNotFoundException
  - <AppServerName>\_stdout.log shows  
javax.servlet.ServletException
2. When utility classes, such as dates.class or time.class, are in a Web application's classpath, the following errors occur:
  - Browser shows error message java.lang.VerifyError
  - Verbose JVM output written to the <AppServerName>\_stderr.log shows  
java.lang.VerifyError: com/bcs/jsftest/test

**Note:** A WebSphere Application Server problem exists on the Windows NT platform which prevents the stderr buffer from being flushed until the application server is stopped. No circumvention for this problem is available at this time.
3. When classes use Java Native Interface (JNI), the following errors occur:
  - <AppServerName>\_stdout.log shows  
java.lang.UnsatisfiedLinkError

To resolve the problem, do the following:

- Ensure the shared libraries are available in the path statement on Windows NT. On UNIX, make sure the LD\_LIBRARY\_PATH is defined in file startupServer.sh.
- Ensure that the property defined in com.ibm.ejs.sm.adminserver.classpath, in the admin.config file, includes classes that make JNI calls into shared libraries.

## Administrative server problems

Successfully starting the administrative server not only indicates a successful install of WebSphere Application Server, but it also means the following tasks were completed:

- System management repository tables were created in the database.
- Nodes and host aliases were created in the repository tables with xml.
- Default repository tables were created with xml.

Therefore, when the administrative server fails to start, it also means the installation of WebSphere Application Server is incomplete.

## Administrative server start failures

The administrative server fails to start for the following reasons:

1. The port is in use. See the [port problems](#) section for more information.
2. Another administrative server is running. The administrative server service in the Windows NT control panel or the startupServer.sh script on UNIX, is the same service/process as the one started through WebSphere\Appserver\bin\debug\adminserver.bat file on Windows NT or adminserver.sh on UNIX.
3. The WebSphere Application Server database repository, (WAS on DB2 or ORCL on Oracle), is not created. The first time you start the administrative server process, it attempts to create the default configuration in the WAS or ORCL database. You will see a 2140 error message if the database is not created.
4. Connection to DB2 or Oracle fails. This also shows up as a 2140 error message. Ensure DB2 is running. Verify the connection to the WAS database is successful.  
To test the DB2 connection, from a DB2 command window, type:

```
DB2 connect to was
```

If you cannot connect to DB2, verify the following:

- Ensure the right level of code is installed on the WebSphere Application Server machine
- For a remote repository, ensure the DB2 client is configured properly to point to DB2 server for the WAS database.

Perform the same tests for Oracle.

5. User ID does not have proper authority or access:

- To ensure proper authority, follow the database configuration steps in the [install guides](#).
- In the UNIX environment, log on as **root** to start AdminServer.
- In the Windows NT environment, verify the following conditions are true:
  - User is logged in as an administrative user
  - User name in security panel is correct
  - User is part of the administrator's group.
  - The Administrative server is registered as a service to NT. To manually add the administrative server as a service, from a command prompt, enter:  
<WebSphere\AppServer>\bin\adminservice.exe install <WebSphere\AppServer>\bin\admin.config  
<HostName>\<User> <Password>
  - User ID has proper rights to start the administrative server. If using a domain ID, start the administrative server with a local ID to see if the domain is the problem. To check a user's rights:
    1. From **Start** > Programs > Administrative Tools > User Manager
    2. Select **Policies** > **User Rights**
    3. Check **Show Advanced User Rights** checkbox in lower left corner
    4. Add the following rights to the user ID:
      - Log on as a service
      - Act as part of the operating system
  - If you change the Windows NT user ID/password but WebSphere Application Server is not updated, then the administrative server startup will fail.  
Update the user ID/password in the following areas:
    - In Windows NT services for the IBM WebSphere Administrative Server service:
      1. From **Start** > Settings > Control Panel, double click **Services**
      2. Select **IBM WebSphere Administrative Server**
      3. Click **Startup**
      4. Change the user ID/password under this account
    - in admin.config (if the DB2 userid/password also changed)

## Port problems

WebSphere Application Server will fail to start if certain ports are in use. Typical port problem descriptions follow:

1. When the bootstrap port is in use, you may see the following error when starting WebSphere:

```
009.765.6005c5b F Nameserver Failed to start the Bootstrap server
org.omg.CORBA.INTERNAL: minor code: 8 completed: No
```

This error is similar to the [Port 9000 in use](#) error when starting WebSphere Application Server.

To fix the problem, change the bootstrap port (the default is 900) in file, **admin.config**, using property name:

```
com.ibm.ejs.sm.adminServer.bootstrapPort
```

If this property does not exist in file **admin.config**, add it.

2. Port 9000 is the default port of the Admin Server location service daemon. Port 9000 is also used by many system resources including AIX X-windows manager. If you see error message,

```
Port 9000 in use-select another port
```

when executing the `./startupServer.sh` command on AIX, the Admin Server process cannot start because port 9000 is in use. You can change the port the location service daemon listens on by:

- specifying **-lsdPort** option on the admin server command line
- setting **com.ibm.ejs.sm.adminServer.lsdPort** property in the **admin.config** file located in directory **<WAS\_ROOT>\bin** on

Windows NT and<WAS\_ROOT>/bin on UNIX.

## 8.6: Diagnosing configuration and installation problems

WebSphere Application Server uses a database to store and share configuration information across nodes. Problems configuring the database are described in the installation problems section.

Generally, if the database is not configured properly, the WebSphere Application Server installation process will fail. Configuration problems occur after the product is installed.

The following table describes common configuration problems. Select an entry for more information.

Problem description	Cause of problem
Cannot retrieve data for a specific session	Incorrect use of the database as a session store: <ul style="list-style-type: none"><li>• <a href="#">Datasource incorrectly created or configured</a></li><li>• <a href="#">EJSPersistenceException</a> occurs</li></ul>
Servlet requests are not satisfied	Web server problems: <ul style="list-style-type: none"><li>• <a href="#">Plug-in failure</a></li><li>• <a href="#">Virtual host configuration incorrect</a></li></ul>
Error 404 - URL not found occurs when accessing a servlet	<a href="#">HTTP Server hostname or port problem</a>
<a href="#">CORBA.COMM_FAILURE</a> appears when running thin servlet redirector	<a href="#">Servlet redirector configuration problem</a>
Error message - Error locating RemoteSRP Home - Attribute Not Set	<a href="#">Receiving RemoteSRP bean is not running</a>
Error 500 - Failed to load target servlet	<a href="#">Servlet missing from Web application classpath</a>
FATAL - Could not bind to the administrative server error	<a href="#">Remote administration failure</a>
Changes to clones not visible	<a href="#">Workload management/cloning failures</a>
Nanny process fails to start administrative server	<a href="#">Verify all installation steps were successful</a>
Administrative server fails to start	<a href="#">Generally an installation setup problem</a>

## 8.6.1: ORB-related Minor Codes

This document provides explanations of the minor error codes used by the WebSphere Application Server Advanced Edition Java ORB. These minor codes are not CORBA-compliant. CORBA-compliant minor codes usually begin with an OMG-assigned identification code, which consists of the vendor ID followed and digits that identify the minor code. However, the Java ORB minor codes do not contain the vendor ID.

Minor codes are associated with CORBA exceptions and provide greater detail about the errors that can occur. There is not a one-to-one mapping of exception names to minor codes. Instead, a minor code can be associated with several exception names. A minor code message can have different meanings depending on the exception that was thrown.

Minor codes are scoped to System Exceptions in the range 0 to 4095. A minor code ID must be a unique number within the scope for each System Exception, but there is no restriction that minor codes be unique across all System Exceptions.

The following table lists the System Exceptions and the corresponding minor error codes, where:

- Minor code: The minor error code
- Static variable: The name of the static variable for the minor error code
- Explanation: A description of the problem that caused the error
- User response: Actions to resolve the problem

### **org.omg.CORBA.BAD\_PARAM**

- Minor code: 1
- Static variable: `com.sun.rmi.util.MinorCodes.NULL_PARAM`
- Explanation: A parameter with a value of NULL was received. The parameter is not valid.
- User response: Ensure that parameters are initialized correctly.

### **org.omg.CORBA.COMM\_FAILURE**

- Minor code: 1
- Static variable: `com.sun.rmi.util.MinorCodes.CONNECT_FAILURE`
- Explanation: The ORB could not establish a connection to the server on the host and port that was identified by the object reference.
- User response: Ensure that the server is running and listening on the designated host and port.
- Minor code: 2
- Static variable: `com.sun.rmi.util.MinorCodes.CONN_CLOSE_REBIND`
- Explanation: A client request could not be processed, because the server had notified the client to close the connection and a new connection could not be established.
- User response: Ensure that the server is running and try the request again.
- Minor code: 3
- Static variable: `com.sun.rmi.util.MinorCodes.WRITE_ERROR_SEND`
- Explanation: An error was encountered while writing the request to the output stream.
- Minor code: 4
- Static variable: `com.sun.rmi.util.MinorCodes.GET_PROPERTIES_ERROR`
- Explanation: An exception was encountered while reading the initial services from a URL.
- User response: Ensure that the initial services URL is valid.

- Minor code: 6
- Static variable: com.sun.rmi.util.MinorCodes.INVOKE\_ERROR
- Explanation: The ORB was unable to successfully connect to the server after several attempts.
- User response: Ensure that the server is running.

#### **org.omg.CORBA.DATA\_CONVERSION**

- Minor code: 1
- Static variable: com.sun.rmi.util.MinorCodes.BAD\_HEX\_DIGIT
- Explanation: The object reference in string format contains at least one hexadecimal character that is not valid.
- User response: Obtain the original object reference and reformat it as a string using the object\_to\_string method on the ORB.
- Minor code: 2
- Static variable: com.sun.rmi.util.MinorCodes.BAD\_STRINGIFIED\_IOR\_LEN
- Explanation: The length of the string-formatted object reference is not valid.
- User response: Obtain the original object reference and reformat it as a string using the object\_to\_string method on the ORB.
- Minor code: 3
- Static variable: com.sun.rmi.util.MinorCodes.BAD\_STRINGIFIED\_IOR
- Explanation: The string-formatted object reference is not valid.
- User response: Obtain the original object reference and reformat it as a string using the object\_to\_string method on the ORB.
- Minor code: 4
- Static variable: com.sun.rmi.util.MinorCodes.BAD\_MODIFIER
- Explanation: The initial reference could not be resolved, because the host or the port is not valid or was not specified.
- User response: Specify the correct host and port.
- Minor code: 5
- Static variable: com.sun.rmi.util.MinorCodes.CODESET\_INCOMPATIBLE
- Explanation: While processing the service context code sets for a request, an incompatible code set was encountered.

#### **org.omg.CORBA.INTERNAL**

- Minor code: 8
- Static variable: com.sun.rmi.util.MinorCodes.CREATE\_LISTENER\_FAILED
- Explanation: The ORB could not establish a listener thread on the port identified by the object reference. The port was already in use or there was an error in creating the daemon thread.
- Minor code: 9
- Static variable: com.sun.rmi.util.MinorCodes.BAD\_LOCATE\_REQUEST\_STATUS
- Explanation: The locator performed a locate request for an object reference and returned a locate reply with a status that is not valid.
- Minor code: 10
- Static variable: com.sun.rmi.util.MinorCodes.STRINGIFY\_WRITE\_ERROR
- Explanation: An exception was encountered while attempting to create a string-formatted object

reference.

#### **org.omg.CORBA.INV\_OBJREF**

- Minor code: 1
- Static variable: com.sun.rmi.util.MinorCodes.NO\_PROFILE\_PRESENT
- Explanation: The object reference does not contain a profile.
- User response: The current object reference is not valid. Obtain a valid object reference from the object supplier.
- Minor code: 2
- Static variable: com.sun.rmi.util.MinorCodes.BAD\_CODE\_SET
- Explanation: An unsupported code set or a code set that is not valid was used to write the data to the input stream.
- User response: Use a Unicode or ASCII code set.

#### **org.omg.CORBA.MARSHAL**

- Minor code: 4
- Static variable: com.sun.rmi.util.MinorCodes.READ\_OBJECT\_EXCEPTION
- Explanation: An error was encountered while trying to read and convert a marshalled object reference into an in-memory object.
- User response: Ensure that the object (passed as a parameter) is in one of the locations identified by the system CLASSPATH environment variable.
- Minor code: 6
- Static variable: com.sun.rmi.util.MinorCodes.CHARACTER\_OUTOFRANGE
- Explanation: While marshalling or unmarshalling an object, a character that is not compliant with ISO Latin-1 (8859.1) was encountered. The character is not in the range 0 to 255.

#### **org.omg.CORBA.NO\_IMPLEMENT**

- Minor code: 2
- Static variable: com.sun.rmi.util.MinorCodes.GETINTERFACE\_NOT\_IMPLEMENTED
- Explanation: The get\_interface method is not implemented on the server.
- Minor code: 3
- Static variable: com.sun.rmi.util.MinorCodes.SEND\_DEFERRED\_NOTIMPLEMENTED
- Explanation: Deferred sends are not supported by the ORB.

#### **org.omg.CORBA.OBJ\_ADAPTER**

- Minor code: 1
- Static variable: com.sun.rmi.util.MinorCodes.NO\_SERVER\_SC\_IN\_DISPATCH
- Explanation: The object reference could not be dispatched to the server, because an object adapter that matches the object key could not be found.
- User response: Ensure that the object server still services the requested object.
- Minor code: 2
- Static variable: com.sun.rmi.util.MinorCodes.NO\_SERVER\_SC\_IN\_LOOKUP
- Explanation: The requested object could not be located, because an object adapter that matches the adapter that matches the object key could not be found.
- User response: Ensure the object server that processes the locate requests still services the requested object.

- Minor code: 3
- Static variable: com.sun.rmi.util.MinorCodes.NO\_SERVER\_SC\_IN\_CREATE\_DEFAULT\_SERVER
- Explanation: The ORB was unable to create the default object adapter for an object in the server that processes the actual method call.
- Minor code: 4
- Static variable: com.sun.rmi.util.MinorCodes.ORB\_CONNECT\_ERROR
- Explanation: An error was encountered while trying to connect to an object in the server that processes the actual method call.
- User response:

#### **org.omg.CORBA.OBJECT\_NOT\_EXIST**

- Minor code: 1
- Static variable: com.sun.rmi.util.MinorCodes.LOCATE\_UNKNOWN\_OBJECT
- Explanation: A locate request was performed and the response indicated that the object is not known to the locator.
- User response: Ensure that the locator that processes the locate requests still services the requested object.
- Minor code: 2
- Static variable: com.sun.rmi.util.MinorCodes.BAD\_SERVER\_ID
- Explanation: The server ID of the server that received the request does not match the server ID of the request object reference. The server that originally served the object is no longer identified by that server ID.
- User response: Obtain a new object reference for the object from the server that is now servicing that object.
- Minor code: 3
- Static variable: com.sun.rmi.util.MinorCodes.BAD\_IMPLID
- Explanation: The implementation ID (identified by the object reference) does not match any implementation on the server.
- User response: Obtain a new object reference for the object from the server that is now servicing that object.
- Minor code: 4
- Static variable: com.sun.rmi.util.MinorCodes.BAD\_SKELETON
- Explanation: A skeleton that matches the object reference (identified by the object key) could not be found on the server.
- User response:
- Minor code: 5
- Static variable: com.sun.rmi.util.MinorCodes.SERVANT\_NOT\_FOUND
- Explanation: The object adapter identified by the object key within the object reference could not locate the servant (an object on the server) to process the object request.
- User response: Ensure that the servant is known to the object adapter.

## **org.omg.CORBA.UNKNOWN**

- Minor code: 1
- Static variable: `com.sun.rmi.util.MinorCodes.UNKNOWN_CORBA_EXC`
- Explanation: The server threw an unknown user exception.
- User response: Ensure that all user exceptions that can be thrown are declared on the throws clause of the method.
- Minor code: 3
- Static variable: `com.sun.rmi.util.MinorCodes.RUNTIMEEXCEPTION`
- Explanation: The server encountered an unknown application error.
- Minor code: 4
- Static variable: `com.sun.rmi.util.MinorCodes.UNKNOWN_SERVER_ERROR`
- Explanation: The server threw an unknown exception.

## 8.7: Using application level facilities

WebSphere Application Server Standard Edition only supports Web applications, not enterprise beans. WebSphere Application Server Advanced Edition supports both Web applications and enterprise beans.

For more information on enterprise beans and Web applications, see the file on [developing applications](#).

Tools that are specifically designed to debug application, servlet and EJB problems include OLT and Distributed Debugger.

Typical application and EJB problems are:

- Invoking a servlet from a browser window
- A modified servlet is not reloaded
- Incorrectly using of databases as a session store
- Various exceptions running enterprise beans

### Invoking a servlet by its URL

The following example describes what you should enter in a browser window to invoke a servlet. Errors occur when you fail to include the webapp directory in the path.

`http://server_machine/webapp/examples/showCfg`

The components of the URL are:

server_machine	webapp	examples	showCfg
Name of the application server computer	<p>Virtual directory of the Web application loader.</p> <hr/> <p>Do not create a webapp directory. This directory is defined for you by WebSphere Application Server. For more information on <i>webapp</i>, see the file on the <a href="#">programming model and environment</a>.</p>	<p>Application Web path</p> <hr/> <p>This is a default WebSphere servlet Web path. You can create a directory by any name as long as it is defined in the Web application's category.</p>	<p>Servlet URL, not the name of the code.</p> <hr/> <p>In this example, the actual Servlet class name is <code>ServletEngineConfigDumper</code>.</p>

The URL illustrated above is the URL for showCfg, one of the default servlets shipped with WebSphere Application Server.

### Reloading servlets

In earlier versions of WebSphere Application Server, specific reload directories in the reload process had to be defined. Currently, the only reload requirement is to store servlet classes in the Web application category. That is, ensure all your servlets are handled in the context of the Web application loader. After you update your servlets, the Web application loader will automatically reload them for you.

If your servlet classes are installed in the context of the Web application loader, but are not being reloaded, ensure the Auto Reload property is set to true. Follow these steps to check the setting of the Auto Reload property:

1. From the WebSphere Administration Console, select your application (or default\_app if you stored your servlets in the default directory structure).
2. From the Web Application:default\_app panel, select the **Advanced** tab.
3. Verify that the Auto Reload is set to true.

## Incorrect use of a database as a session store

WebSphere Application Server makes JDBC calls, using a predefined JDBC driver, to communicate with a database. Both the JDBC driver and data sources must be configured using the administrative console.

The following errors occur if a data source is misconfigured or does not exist:

- The browser window displays Error 500 with the message: `java.lang.NullPointerException`
- The `<App_Server>.stderr.log` displays the message: `javax.naming.NameNotFoundException: jdbc/xxx`
- The `<App_Server>.stdout.log` displays the message: `Failure while creating connection COM.ibm.db2.jdbc.app.DB2Exception: [IBM] [CLI Driver] SQL1013N The database alias name or database name "SAMPLE" could not be found. SQLSTATE=42705`

Database connectivity problems cause persistence exceptions. An `EJSPersistenceException` error may indicate JDBC or connection problems:

1. An invalid JDBC driver will prevent access to jar and class files
2. Review the `SQLSTATE:COM.ibm.db2.jdbc.app.DB2Exception: [IBM][CLI Driver]SQL1224N A database agent could not be started...SQLSTATE=55032...` The SQLSTATE code of 55032 indicates the system is out of connections.

**Note:** Not using connection pooling causes most problems for BMP type EJBs. Common symptoms include:

- Performance problems connecting to the database
- Running out of connections

To resolve the problem:

1. Increase the number of connections permitted by DB2 or Oracle.
  2. On AIX, catalog the database as if it were remote.
  3. Ensure you close connections when programming exceptions occur.
  4. Verify that connections obtained in one method, are returned to the pool via `close()`.
  5. Verify that your application does not try to access pre-empted connections (idle connections that are now used by other resources).
3. A database init failure could indicate the database does not

exist:com.ibm.ejs.persistence.EJSPersistenceException: Database init failure:Nested exception is:COM.ibm.db2.jdbc.app.DB2Exception: [IBM][CLI Driver]SQL1013N The database alias name or database name "YYY" could not be found...SQLSTATE=42705...The SQLSTATE code of 42705 indicates the database does not exist or the server cannot connect to it.

## 8.7.1: ORB-related minor codes

This document provides explanations of the minor error codes used by the WebSphere Application Server Advanced Edition Java ORB. These minor codes are not CORBA-compliant. CORBA-compliant minor codes usually begin with an OMG-assigned identification code, which consists of the vendor ID and digits that identify the minor code. However, the Java ORB minor codes do not contain the vendor ID.

Minor codes are associated with CORBA exceptions and provide greater detail about the errors that can occur. There is not a one-to-one mapping of exception names to minor codes. Instead, a minor code can be associated with several exception names. A minor code message can have different meanings depending on the exception that was thrown.

Minor codes are scoped to system exceptions in the range 0 to 4095. A minor code ID must be a unique number within the scope for each system exception, but there is no restriction that minor codes be unique across all system exceptions.

The following table lists the system exceptions and the corresponding minor error codes, where:

- Minor code: The minor error code
- Static variable: The name of the static variable for the minor error code
- Explanation: A description of the problem that caused the error
- User response: Actions to resolve the problem

### org.omg.CORBA.BAD\_PARAM

- Minor code: 1
- Static variable: com.sun.rmi.util.MinorCodes.NULL\_PARAM
- Explanation: A parameter with a value of NULL was received. The parameter is not valid.
- User response: Ensure that parameters are initialized correctly.

### org.omg.CORBA.COMM\_FAILURE

- Minor code: 1
- Static variable: com.sun.rmi.util.MinorCodes.CONNECT\_FAILURE
- Explanation: The ORB could not establish a connection to the server on the host and port that was identified by the object reference.
- User response: Ensure that the server is running and listening on the designated host and port.
- Minor code: 2
- Static variable: com.sun.rmi.util.MinorCodes.CONN\_CLOSE\_REBIND
- Explanation: A client request could not be processed, because the server had notified the client to close the connection and a new connection could not be established.
- User response: Ensure that the server is running and try the request again.
- Minor code: 3
- Static variable: com.sun.rmi.util.MinorCodes.WRITE\_ERROR\_SEND
- Explanation: An error was encountered while writing the request to the output stream.
- Minor code: 4
- Static variable: com.sun.rmi.util.MinorCodes.GET\_PROPERTIES\_ERROR
- Explanation: An exception was encountered while reading the initial services from a URL.
- User response: Ensure that the initial services URL is valid.

- Minor code: 6
- Static variable: com.sun.rmi.util.MinorCodes.INVOKE\_ERROR
- Explanation: The ORB was unable to successfully connect to the server after several attempts.
- User response: Ensure that the server is running.

#### **org.omg.CORBA.DATA\_CONVERSION**

- Minor code: 1
- Static variable: com.sun.rmi.util.MinorCodes.BAD\_HEX\_DIGIT
- Explanation: The object reference in string format contains at least one hexadecimal character that is not valid.
- User response: Obtain the original object reference and reformat it as a string using the object\_to\_string method on the ORB.
- Minor code: 2
- Static variable: com.sun.rmi.util.MinorCodes.BAD\_STRINGIFIED\_IOR\_LEN
- Explanation: The length of the string-formatted object reference is not valid.
- User response: Obtain the original object reference and reformat it as a string using the object\_to\_string method on the ORB.
- Minor code: 3
- Static variable: com.sun.rmi.util.MinorCodes.BAD\_STRINGIFIED\_IOR
- Explanation: The string-formatted object reference is not valid.
- User response: Obtain the original object reference and reformat it as a string using the object\_to\_string method on the ORB.
- Minor code: 4
- Static variable: com.sun.rmi.util.MinorCodes.BAD\_MODIFIER
- Explanation: The initial reference could not be resolved, because the host or the port is not valid or was not specified.
- User response: Specify the correct host and port.
- Minor code: 5
- Static variable: com.sun.rmi.util.MinorCodes.CODESET\_INCOMPATIBLE
- Explanation: While processing the service context code sets for a request, an incompatible code set was encountered.

#### **org.omg.CORBA.INTERNAL**

- Minor code: 8
- Static variable: com.sun.rmi.util.MinorCodes.CREATE\_LISTENER\_FAILED
- Explanation: The ORB could not establish a listener thread on the port identified by the object reference. The port was already in use or there was an error in creating the daemon thread.
- Minor code: 9
- Static variable: com.sun.rmi.util.MinorCodes.BAD\_LOCATE\_REQUEST\_STATUS
- Explanation: The locator performed a locate request for an object reference and returned a locate reply with a status that is not valid.
- Minor code: 10
- Static variable: com.sun.rmi.util.MinorCodes.STRINGIFY\_WRITE\_ERROR
- Explanation: An exception was encountered while attempting to create a string-formatted object

reference.

#### **org.omg.CORBA.INV\_OBJREF**

- Minor code: 1
- Static variable: com.sun.rmi.util.MinorCodes.NO\_PROFILE\_PRESENT
- Explanation: The object reference does not contain a profile.
- User response: The current object reference is not valid. Obtain a valid object reference from the object supplier.
- Minor code: 2
- Static variable: com.sun.rmi.util.MinorCodes.BAD\_CODE\_SET
- Explanation: An unsupported code set or a code set that is not valid was used to write the data to the input stream.
- User response: Use a Unicode or ASCII code set.

#### **org.omg.CORBA.MARSHAL**

- Minor code: 4
- Static variable: com.sun.rmi.util.MinorCodes.READ\_OBJECT\_EXCEPTION
- Explanation: An error was encountered while trying to read and convert a marshalled object reference into an in-memory object.
- User response: Ensure that the object (passed as a parameter) is in one of the locations identified by the system CLASSPATH environment variable.
- Minor code: 6
- Static variable: com.sun.rmi.util.MinorCodes.CHARACTER\_OUTOFRANGE
- Explanation: While marshalling or unmarshalling an object, a character that is not compliant with ISO Latin-1 (8859.1) was encountered. The character is not in the range 0 to 255.

#### **org.omg.CORBA.NO\_IMPLEMENT**

- Minor code: 2
- Static variable: com.sun.rmi.util.MinorCodes.GETINTERFACE\_NOT\_IMPLEMENTED
- Explanation: The get\_interface method is not implemented on the server.
- Minor code: 3
- Static variable: com.sun.rmi.util.MinorCodes.SEND\_DEFERRED\_NOTIMPLEMENTED
- Explanation: Deferred sends are not supported by the ORB.

#### **org.omg.CORBA.OBJ\_ADAPTER**

- Minor code: 1
- Static variable: com.sun.rmi.util.MinorCodes.NO\_SERVER\_SC\_IN\_DISPATCH
- Explanation: The object reference could not be dispatched to the server, because an object adapter that matches the object key could not be found.
- User response: Ensure that the object server still services the requested object.
- Minor code: 2
- Static variable: com.sun.rmi.util.MinorCodes.NO\_SERVER\_SC\_IN\_LOOKUP
- Explanation: The requested object could not be located, because an object adapter that matches the adapter that matches the object key could not be found.
- User response: Ensure that the object server that processes the locate requests still services the requested object.

- Minor code: 3
- Static variable: com.sun.rmi.util.MinorCodes.NO\_SERVER\_SC\_IN\_CREATE\_DEFAULT\_SERVER
- Explanation: The ORB was unable to create the default object adapter for an object in the server that processes the actual method call.
- Minor code: 4
- Static variable: com.sun.rmi.util.MinorCodes.ORB\_CONNECT\_ERROR
- Explanation: An error was encountered while trying to connect to an object in the server that processes the actual method call.
- User response:

#### **org.omg.CORBA.OBJECT\_NOT\_EXIST**

- Minor code: 1
- Static variable: com.sun.rmi.util.MinorCodes.LOCATE\_UNKNOWN\_OBJECT
- Explanation: A locate request was performed and the response indicated that the object is not known to the locator.
- User response: Ensure that the locator that processes the locate requests still services the requested object.
- Minor code: 2
- Static variable: com.sun.rmi.util.MinorCodes.BAD\_SERVER\_ID
- Explanation: The server ID of the server that received the request does not match the server ID of the request objectreference. The server that originally served the object is no longer identified by that server ID.
- User response: Obtain a new object reference for the object from the server that is now servicing that object.
- Minor code: 3
- Static variable: com.sun.rmi.util.MinorCodes.BAD\_IMPLID
- Explanation: The implementation ID (identified by the object reference) does not match any implementation on the server.
- User response: Obtain a new object reference for the object from the server that is now servicing that object.
- Minor code: 4
- Static variable: com.sun.rmi.util.MinorCodes.BAD\_SKELETON
- Explanation: A skeleton that matches the object reference (identified by the object key) could not be found on the server.
- User response:
- Minor code: 5
- Static variable: com.sun.rmi.util.MinorCodes.SERVANT\_NOT\_FOUND
- Explanation: The object adapter identified by the object key within the object reference could not locate the servant (an object on the server) to process the object request.
- User response: Ensure that the servant is known to the object adapter.

## **org.omg.CORBA.UNKNOWN**

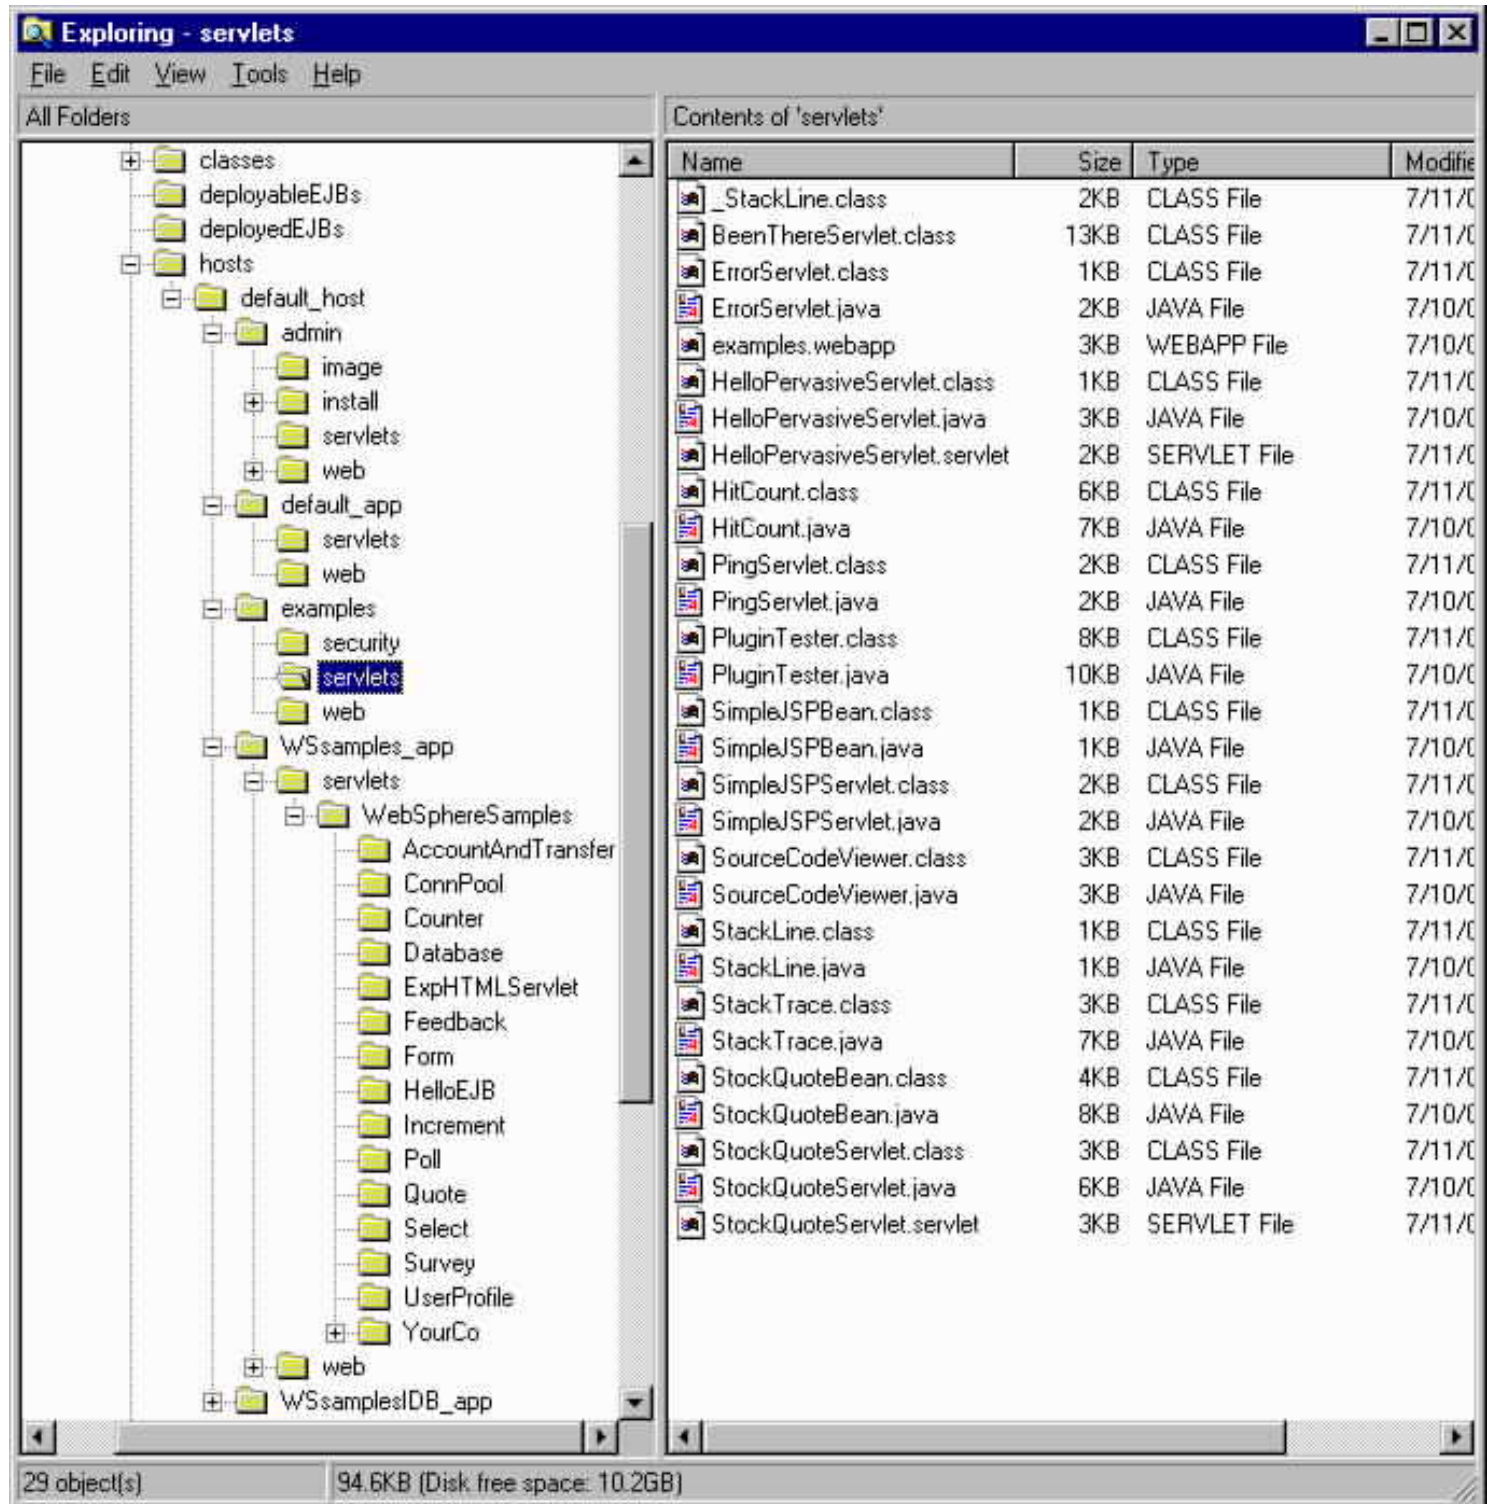

- Minor code: 1
- Static variable: `com.sun.rmi.util.MinorCodes.UNKNOWN_CORBA_EXC`
- Explanation: The server threw an unknown user exception.
- User response: Ensure that all user exceptions that can be thrown are declared on the throws clause of the method.
- Minor code: 3
- Static variable: `com.sun.rmi.util.MinorCodes.RUNTIMEEXCEPTION`
- Explanation: The server encountered an unknown application error.
- Minor code: 4
- Static variable: `com.sun.rmi.util.MinorCodes.UNKNOWN_SERVER_ERROR`
- Explanation: The server threw an unknown exception.

## 8.8: Using internal tools

You can use WebSphere Application Server servlets and internal tools to help diagnose problems.

### Servlets

View file [samples.html](#) for information on sample servlets shipped with the product. Most WebSphere Application Server servlets are located in the examples directory:

The screenshot shows a window titled "Exploring - servlets" with a menu bar (File, Edit, View, Tools, Help). The left pane, "All Folders", shows a tree structure with folders like classes, deployableEJBs, deployedEJBs, hosts, default\_host, admin, image, install, servlets, web, default\_app, security, web, examples, WSsamples\_app, and WSsamples!DB\_app. The right pane, "Contents of 'servlets'", displays a table of files.

Name	Size	Type	Modified
_StackLine.class	2KB	CLASS File	7/11/0
BeenThereServlet.class	13KB	CLASS File	7/11/0
ErrorServlet.class	1KB	CLASS File	7/11/0
ErrorServlet.java	2KB	JAVA File	7/10/0
examples.webapp	3KB	WEBAPP File	7/10/0
HelloPervasiveServlet.class	1KB	CLASS File	7/11/0
HelloPervasiveServlet.java	3KB	JAVA File	7/10/0
HelloPervasiveServlet.servlet	2KB	SERVLET File	7/11/0
HitCount.class	6KB	CLASS File	7/11/0
HitCount.java	7KB	JAVA File	7/10/0
PingServlet.class	2KB	CLASS File	7/11/0
PingServlet.java	2KB	JAVA File	7/10/0
PluginTester.class	8KB	CLASS File	7/11/0
PluginTester.java	10KB	JAVA File	7/10/0
SimpleJSPBean.class	1KB	CLASS File	7/11/0
SimpleJSPBean.java	1KB	JAVA File	7/10/0
SimpleJSPServlet.class	2KB	CLASS File	7/11/0
SimpleJSPServlet.java	2KB	JAVA File	7/10/0
SourceCodeViewer.class	3KB	CLASS File	7/11/0
SourceCodeViewer.java	3KB	JAVA File	7/10/0
StackLine.class	1KB	CLASS File	7/11/0
StackLine.java	1KB	JAVA File	7/10/0
StackTrace.class	3KB	CLASS File	7/11/0
StackTrace.java	7KB	JAVA File	7/10/0
StockQuoteBean.class	4KB	CLASS File	7/11/0
StockQuoteBean.java	8KB	JAVA File	7/10/0
StockQuoteServlet.class	3KB	CLASS File	7/11/0
StockQuoteServlet.java	6KB	JAVA File	7/10/0
StockQuoteServlet.servlet	3KB	SERVLET File	7/11/0

At the bottom, it shows "29 object(s)" and "94.6KB (Disk free space: 10.2GB)".

The following table describes servlets that can be used as debug tools:

<b>servlet</b>	<b>location</b>	<b>description</b>
Hit Count	<WebSphere\AppServer>\hosts\default_host\examples\	Verifies correct implementation of Servlets, JSPs, EJBs, and HTTP Session.
Snoop Servlet	<WebSphere\AppServer>\hosts\default_host\default_app\servlets\Snoop.class	Useful for examining request parameters coming from the client and for verifying the operation of the servlet engine.
ShowCfg	<WebSphere\AppServer>\hosts\default_host\examples\	Useful for validating the configuration of the system.
BeenThere	<WebSphere\AppServer>\hosts\default_host\examples\web\beenthere.html	Useful for demonstrating and testing session persistence.

## Internal tools

The available internal tools apply to specific operations. For example, the `jdbctest.java`™ tool tests JDK™ settings and database access.

See the [WebSphere ProblemDetermination Tools](#) website for detailed information about these tools. The website also offers you the opportunity to add ideas about tools and add a new tool. Check the website periodically for updates.

<b>tool</b>	<b>description</b>
<a href="#">Jdbctest.java</a> >	Tests JDK™ settings and database connectivity
<a href="#">Java™ Name Tree Browser</a>	Displays elements in WebSphere Application Server name space
<a href="#">Java™ Socket Level Trace</a>	Describes ORB communication problems over heterogeneous networks via IIOP
<a href="#">DrAdmin trace function</a>	Dumps the thread stacks in a server
<a href="#">OLT</a>	Object level trace
<a href="#">Distributed Debugger</a>	Debugs application level problems

## 8.8.1: Using the Log Analyzer for Advanced Edition

The Log Analyzer takes one or more activity logs, merges all of the data, and displays the entries. Based on its "symptom database," it analyzes and interprets the error conditions in the log entries to help you debug problems. The Advanced Edition Log Analyzer has a special feature enabling it to download the latest symptom database from the IBM Web site. See "About the Log Analyzer" for details.

- [About the Log Analyzer](#)
- [Obtaining the Log Analyzer](#)
- [About the activity log](#)
- [Using the Log Analyzer](#)
- [Related tasks:](#)
  - [Set the maximum activity.log size](#)
  - [Changing the port of the logging service](#)
  - [View an activity.log on a remote machine](#)

### About the Log Analyzer

A Log Analyzer quite similar to the one available for use with IBM WebSphere Application Server is available with IBM Component Broker, part of the Enterprise Edition of IBM WebSphere Application Server.

To learn about the Component Broker Log Analyzer, see the Component Broker problem determination guide (currently, Chapter 11). You can view the document on the IBM Web site without having to obtain Enterprise Edition:

<ftp://ftp.software.ibm.com/software/websphere/info/appserv/v35/ee/cbprbdet.pdf>

The main differences between the Log Analyzer available with WebSphere Application Server and the Component Broker Log Analyzer are the following:

- The Log Analyzer for Advanced Edition is capable of downloading the latest symptom database (bin/symptomdb.xml) from the IBM support site. Use the file -> Update Database -> Adv Symptom Database option in the Log Analyzer interface to take advantage of this feature.
- The functions for ORB trace formatting, minor codes, message IDs and GPFAre **not** supported for Advanced Edition
- The script for starting the Log Analyzer is in a different location ([see below for instructions](#))
- The default directory for opening logs for Advanced Edition is the logs directory. For Enterprise Edition, it is the service directory.

### Obtaining the Log Analyzer

The Log Analyzer is available separately from IBM WebSphere Application Server, starting on or shortly after the release of Fix Pack 2 (Version 3.5.2) for IBM WebSphere Application Server.

To obtain the Log Analyzer, including its installation instructions, visit the IBM WebSphere Application Server Tools site:

<http://www.ibm.com/software/web servers/appserv/tools.html>

### About the activity log

Recall, the Log Analyzer collects messages from various product components and places them in a shared file. The file is a binary file located at:

[product\\_installation\\_root](#)/logs/activity.log

The activity.log cannot be easily viewed using a text editor. The Log Analyzer is the tool for viewing the file.

### Using the Log Analyzer

To view the activity.log using the Log Analyzer:

1. Change directory to:  
[product\\_installation\\_root](#)/bin
2. Run the waslogbr script file, which is called:
  - waslogbr.bat on Windows NT
  - waslogbr.sh on UNIX systems

It needs to be run from the bin directory cited above.

This will start the Log Analyzer graphical interface.

3. In the interface:
  1. Select File-> Open.
  2. Navigate to the directory containing the activity.log file.
  3. Select the activity.log file.
  4. Select Open.

### Related tasks

In the course of using the Log Analyzer, you might need to perform the following tasks.

## Setting the maximum activity.log file size

The activity.log file grows to a predetermined size, then wraps. The default size is 1 Megabyte (MB).

To change the log size:

1. Open the properties file in a text editor:  
[product\\_installation\\_root](#)/properties/logging.properties
2. For the SHARED\_LOG\_LENGTH property, specify the value you would like, in Kilobytes (KB).

If an invalid size is entered, the default size is used.

The size change will take effect at the next server startup.

Syntax example:

- To change the log size to 2MB, enter in the line:  
SHARED\_LOG\_LENGTH=2048  
without any spaces in it.

## Changing the port of the logging service

The logging service starts automatically at server startup. It requires the use of a dedicated port. The default port is 1707.

To change the port value:

1. Stop all application servers and the WebSphere administrative server. (If you do not stop a server, it will not pick up the property change until it is stopped and started again).
2. Open the properties file in a text editor:  
[product\\_installation\\_root](#)/properties/logging.properties
3. For the SHARED\_LOG\_LOCK\_PORT property, specify the value you would like.
4. Start the application and administrative servers that you stopped.

Syntax example:

- To change the port to 1708, specify:  
SHARED\_LOG\_LOCK\_PORT=1708

If the port is in use by another application, the logging service might not be able to start or might not function correctly. The activity.log file will not be created or updated correctly. See [the information about how to tell whether a port is currently allocated to another application](#).

To diagnose a port conflict, perform these heuristic checks:

- Check to see if the activity.log file has been created, and check the timestamp of the file.
- Check these files:

[product\\_installation\\_root](#)/`<server_name>_stderr.log product\_installation\_root/logs/adminserver_stderr.log`

**Note:** The above paths are the default locations of the files. The administrator might have configured different locations.

Look for a stack trace such as the following:

```
java.lang.Exception: Unable to obtain Shared Log Lock on port 1707 at
com.ibm.ejs.ras.SharedLogBase.acquireHostLock(SharedLogBase.java:187) at
com.ibm.ejs.ras.SharedLogWriter.<init>(SharedLogWriter.java:130) at
com.ibm.ejs.ras.SharedLogWriter.getInstance(SharedLogWriter.java:100) at
com.ibm.ejs.ras.Tr.initialize(Tr.java:241) at
com.ibm.ejs.sm.server.ManagedServer.main(ManagedServer.java:121)
```

## Viewing an activity.log file in the absence of a GUI.

The Log Analyzer cannot be used to view remote files. If the operating system on which you are running WebSphere Application Server does not support the use of a graphical interface, then transfer the file in binary to the system on which you are running the WebSphere Java administrative console. Use the Log Analyzer tool there.

In cases in which transferring the file is impractical or inconvenient, an alternate tool named "showlog" is provided for viewing the activity.log file:

1. Change directory to:  
[product\\_installation\\_root](#)/bin
2. Run the showlog tool with no parameters to display the usage instructions:
  - On Windows NT, run showlog.bat
  - On UNIX systems, run showlog.sh

Syntax examples:

- To direct the activity log contents to stdout, use the invocation:

```
showlog activity.log
```

- To dump the activity.log to a text file that can be viewed using a text editor, use the invocation:

```
showlog activity.log textFileName
```

## 8.9: Thread dumps

This section introduces the concept of thread dumps in WebSphere Application Server.

A thread represents a work item or task, such as a servlet request. Java processes are usually multi-threaded. This means there can be many tasks occurring simultaneously (i.e. multi-threading) within one JVM (Java Virtual Machine) process. Therefore, understanding what is occurring within a JVM process means obtaining information about all the different threads that are defined within the process.

## What is a thread dump?

There are two types of thread dumps that could appear when running Java programs:

- [System dump](#)
- [Java dump](#)

## System thread dumps

System thread dumps provide a system view of a failing JVM (Java Virtual Machine) process. On Unix systems, they usually appear as core files. On Windows systems they appear as `drwtsn32.log` files.

System dumps do not understand Java classes. Everything in a system dump is C library oriented. The system dump information provided for JVM processes refers to Java's C libraries and not the reference class files.

System dumps should only be interrogated when a Java thread dump is unavailable. Pertinent information can be obtained from system dumps. However, mapping this information back into Java source code is very difficult. The following sections explain how to interrogate the core and `drwtsn32.log` files. When they are generated by the system, they need to be interrogated.

## Unix platforms

### Core files

Core files on Unix systems can be interrogated by `dbx` and `gdb`. `Dbx` is a tool that is part of the AIX install. On Sun, `dbx` can be installed for an additional expense. The [gdb \(GNU debugger\)](#) is freeware that can be downloaded.

Core file tips:

1. Ensure that the system core file size specification is unlimited.
2. Ensure that the file system containing the core file has enough space.

The following is a sample of how to use `ulimit` to verify and set the core dump size. If it is too small, a unusable core file will be generated.

**Ulimit** sample:

```
[pwh501]:root> ulimit -a
time(seconds) unlimited
file(blocks) unlimited
data(kbytes) unlimited
stack(kbytes) unlimited
memory(kbytes) unlimited
coredump(blocks) unlimited
nofiles(descriptors) 2000
```

The following commands will change the `coredump (-c)` and `file (-f)` to unlimited:

```
ulimit -f unlimited
ulimit -c unlimited
```

The following is an example of using the `df` command to verify that there is enough room in the file system for the core. The core file is placed in the `./bin` directory. On AIX this is in the `/usr` filesystem. A core file can be 200MB.

**Df** sample:

```
[pwh501]:root> df
Filesystem 512-blocks Free %Used Iused %Iused Mounted on
/dev/hd4 131072 80416 39% 2480 8% /
/dev/hd2 8306688 2835096 66% 76320 8% /usr
/dev/hd9var 606208 55176 91% 390 1% /var
/dev/hd3 475136 459808 4% 32 1% /tmp
```

```
/dev/hd1 1310720 426120 68% 12453 8% /home
/dev/lv00 65536 47048 29% 96 2% /usr/lpp/netviewdm
/dev/lv01 606208 296504 52% 915 2% /db2
/dev/lv02 4014080 2806320 31% 3328 1% /Projects
```

**Note:** These samples were taken from the AIX 4.3.3 system.

## DBX command

The purpose of the dbx command is to provide an environment to debug and run programs under the operating system. The dbx command provides a symbolic debug program for C, C++, Pascal, and Fortran programs, allowing you to carry out operations including:

- Examine object and core files
- Provide a controlled environment for running a program
- Set breakpoints at selected statements or run the program one line at a time
- Debug using symbolic variables and display them in their correct format

## DBX syntax

```
dbx [ -a ProcessID ] [ -c CommandFile ] [ -d NestingDepth ] [ -I Directory ]
[-E DebugEnvironment ] [ -k ] [ -u ] [ -F ] [ -r ] [ -x ] [ ObjectFile
[ CoreFile ] ]
```

The ObjectFile parameter is an object (executable) file produced by a compiler. Use the -g (generate symbol table) flag when compiling your program to produce the information the dbx command needs.

**Note:** The -g flag of the cc command should be used when the object file is compiled. If the -g flag is not used or if symbol references are removed from the xcoff file with the strip command, the symbolic capabilities of the dbx command are limited.

If the -c flag is not specified, the dbx command checks for a .dbxinit file in the user's \$HOME directory. It then checks for a .dbxinit file in the user's current directory. If a .dbxinit file exists in the current directory, that file overrides the .dbxinit file in the user's \$HOME directory. If a .dbxinit file exists in the user's \$HOME directory or current directory, that file's subcommands run at the beginning of the debug session. Use an editor to create a .dbxinit file.

If ObjectFile is not specified, then dbx asks for the name of the object file to be examined. The default is a.out. If the core file exists in the current directory or a core file parameter is specified, then dbx reports the location where the program failed. Variables, registers and memory held in the core image may be examined until execution of ObjectFile begins. At that point the dbx debug program prompts for commands.

**Note:** The commands are referenced in the AIX Version 4.3 Commands Reference, Volume 2.

## DBX tips

The common procedure of interrogating a core file is to change the directory to where the core file resides. You can then issue the command with the binary executable file as the parameter. It is important that the binary executable is used. Usually the java command is a shell script that calls the executable. If you enter the shell script, java, as the parameter a "cannot find" error message is returned.

The following commands show you how to find the binary executable and invoke the dbx command. It also shows an illegal instruction was executed (i.e. Invalid opcode):

```
-----
[pwh501]:root> cd /usr/jdk_base
[pwh501]:root> find . -name java -print
./bin/aix/native_threads/java
./bin/java
[pwh501]:root> cd /usr/WebSphere/AppServer/bin
[pwh501]:root> ls -l core
-rw-r--r-- 1 root system 191495883 Aug 07 15:08 core
[pwh501]:root> dbx /usr/jdk_base/bin/aix/native_threads/java

Type 'help' for help.

Warning: The core file is truncated. You may need to increase the ulimit for file and core dump, or free some space on the file system.

Reading symbolic information ...Warning: no source compiled with -g [using memory image in core]

Illegal instruction (reserved addressing fault) in . at 0x0 ($t29)

0x00000000 00000001 Invalid opcode.
-----
```

If you don't know where the java binary is located, the following command will display the true java executable name of the core:

**strings core | more**

After you enter dbx, the where command provides a stack trace of where the error occurred. The following example shows a:

- [Stack trace](#)
- [Output of the help command](#)
- [How to exit dbx](#)

### Stack trace

```
(dbx) where
```

```
warning: could not locate trace table from starting address 0x0
```

```

```
up use whatis where whereis which
```

```
Topics:
```

```
startup execution breakpoints files data
```

```
machine environment threads expressions scope
```

```
set_variables usage
```

```
Type "help" for help on a command or topic.
```

### How to exit dbx

```
(dbx) quit
```

```
[pwh501]:root>
```

Another useful purpose of the dbx command is to monitor a running process. The -a parameter allows the user to attach to a process. The catch and run commands can be used to walk through the processing of the JVM process and see all signals that are caught. Use of the help xxx command will provide additional information on each of the above commands.

## DBXTRACE.SH

There are shell scripts that call the dbx command and format the thread information from the core file. The name of the script is usually dbxtrace.sh. There is an AIX version and a Solaris version.

Here's a description on how to run the shell script:

```
[pwh501]:root> ./dbxtrace -a
```

Usage: Automate getting dbx trace information

For core files:

Usage: dbxtrace [executable] [core]

or : dbxtrace -c corefile

Example: dbxtrace /usr/jdk\_base/bin/aix/native\_threads/java core

(Please make sure you use the java executable and not the java script)

To attach to a running or hung process

Usage: dbxtrace -a PID

Example: dbxtrace -a 1234

The following information describes the beginning of the output when using dbxtrace on AIX:

```
[pwh501]:root> ./dbxtrace.sh | more
*****
* Failure of this script or dbx may *
* overwrite your existing core file. *
* It is recommended that you rename your *
* existing core file and use the -c flag *
* Do you wish to continue (y/n): *****
Creating subcommand file....
Running dbx...
Type 'help' for help.
warning: The core file is truncated. You may need to increase the ulimit for file and core dump, or free some space on the
filesystem.
Reading symbolic information ...warning: no source compiled with -g
```

**Note:** The user is prompted for (y/n). Therefore, if the user redirects the output to a file [pwh501]:root> ./dbxtrace.sh > myfile 2>&1 a standalone "y" must be entered before the output is generated.

The output of the dbxtrace.sh provides information about each defined thread. The output has the following sections:

- [Error condition](#)
- [One line description of each thread](#)
- [Detail thread information](#)
- [Stack trace of each thread](#)

#### Error condition:

## Windows platform

The drwtsn32.log files are similar to core files on Unix. On Windows 2000, these files are found in the following directory C:\Documents and Settings\All Users\Documents\DrWatson.

After entering `drwtsn32` ?, the "Dr. Watson for Windows 2000" box appears. The DrWatson logfile overview option will display a screen which explains the format of the `drwtsn32.log` files. The output of the `dbxtrace.sh` provides information about each defined thread. The output has the same section as a Unix platform:

- [Error condition](#)
- [One line description of each thread](#)
- [Detail thread information](#)
- [Stack trace of each thread](#)

## Java thread dumps

Java thread dumps provide a Java view of a failing JVM process. Depending on the platform, Java dumps can appear with different names and at different locations.

A Java dump provides information about the executing Java classes and allows the problem determination process to reference the Java source code.

### How to obtain a JAVA Thread Dump

There are two ways to obtain a Java thread dump:

- DrAdmin function
- `kill -3` command

DrAdmin works on all platforms. On Unix, the `kill -3` command serves the same function and is easier to use. Therefore, DrAdmin is discussed in the Windows platform section and `kill -3` is discussed in the Unix platforms section.

### Unix platforms

Sometimes Java thread dumps will occur due to an error in the JVM. At other times, the user might need to understand what is occurring within a JVM that is currently active. In either case, the Java thread dump is placed at the location described in [locations table](#). Information on how to manually obtain a thread dump is available in the remainder of this section.

When a process hangs or is working hard (i.e. looping), it might be helpful to understand what the individual threads of a JVM process are doing. Obtaining a stack trace of the individual threads will provide this information. The `kill -3 processid` command provides this stack trace information. This command should not impact the running process.

### Identifying process IDs

WebSphere supports four processes:

- Nanny - started with `startupServer.sh`
- Administrative server - started by the nanny process
- Administrative client - started with `adminclient.sh`
- Managed server - started by the administrative server either automatically or manually via the administration client console.

These processes are usually started in the sequence that they are listed. Therefore, their process IDs increase in value. The `ps -ef | grep java` command will display all the processes that are associated with java.

The process IDs are listed under the second column in the command's output. The user can not use the administration client interface if managed servers are automatically started by the administrative server.

Unfortunately, the `ps -ef | grep java` command does not always allow the user to identify the different processes. The command string to start the processes can be very long and the length of the command string saved by the system may not be adequate for the `ps -ef | grep java` command.

On AIX, the complete command line is listed in the above `ps -ef | grep` command output. The user can also enter the following commands to focus on an individual process ID:

- `ps -ef | grep Nanny`
- `ps -ef | grep AdminServer`
- `ps -ef | grep AdminClient`
- `ps -ef | grep ManagedServer`

There could be multiple managed servers running simultaneously. The managed server process ID(s) are also displayed within the `./bin/tracefile` with:

Starting Server: "Default Server" (pid "116032")

Default server is the name of the managed server. On the administration client window, the **General** tab information for the managed server also displays the process ID.

As the root user, the `kill -3 xxxx` can now be entered where `xxxx` is the process ID of the WebSphere JVM in which you need to see a thread dump.

### Location of thread dump

The location of the thread dump depends on the operating system.

Process	AIX 4.3.3	Sun OS 5.7	HP-UX B.11.0.0
Administrative server	<code>./bin/javacore....txt</code>	Appended to <code>./logs/tracefile</code>	Appended to <code>./logs/tracefile</code>
Managed server	<code>./bin/javacore...txt</code>	<code>./Appended to stderr.file</code> for managed server (Note 1)	Appended to <code>stdout</code> file for managed server (Note 1)
Administrative client	<code>./bin/javacore...txt</code>	Prompted at window used to enter <code>adminclient.sh</code>	Window used to enter <code>adminclient.sh</code>
Nanny	<code>./bin/javacore...txt</code>	Prompted at window used to enter <code>startupServer.sh</code>	Window used to enter <code>startupServer.sh</code>

**Note 1:** The stderr and stdout files are defined within the managed server configuration. The configuration can be viewed with the administrative console. Click on the managed server (for example default server). The standard output file and standard error file are defined within fields on the **General** Tab.

If the user starts a server in the background, the kill command may not dump the thread information. The workaround for this situation is to do the following:

```
startupServer.sh &
```

```
Ctrl-Z
```

```
fg
```

```
kill -3 xxxx
```

## Windows platform

### Create DrAdmin.bat

There is no DrAdmin.bat file shipped with WebSphere Application Server that will execute the DrAdmin function. One needs to be created. The following procedure is an example on how to create a DrAdmin.bat file. The procedure assumes that the WebSphere install is located at D:\WebSphere\AppServer. Follow these steps to create a DrAdmin.bat file:

1. Change the current directory to the directory containing adminserver.bat (cd D:\WebSphere\AppServer\bin\debug)
2. Copy the adminserver.bat file to DrAdmin.bat in the same directory of adminserver.bat
3. Modify the newly created file, DrAdmin.bat, to execute the DrAdmin function. When changing the java commandline, the command needs to be on one continuous line. Modify the following line:

```
%JAVA_HOME%\bin -DDER_DRIVER_PATH=%DER_DRIVER_PATH% -Xmx128m -Xminf0.15 -Xmaxf0.25 com.ibm.ejs.sm.server.AdminServer-bootFile  
%WAS_HOME%\bin\admin.config %restart% %1 %2 %3 %4
```

*with*

```
%JAVA_HOME%\bin\java com.ibm.ejs.sm.util.debug.DrAdmin %1 %2 %3 %4 %5 %6 %7 %8 %9
```

### Find the port number of interest

The next step is to identify the port number for either the administrative server or a managed server. The port number is different for the administrative server and each of the managed server(s). The port number values are contained in the standard out files for each of these processes. Information on how to find these files and the port number are described below.

After starting the administrative server, you should obtain the DrAdmin port number within the .\logs\tracefile file inside the message:

```
DrAdmin available on port xxxx
```

After starting the managed server (for example, default server), you should obtain the DrAdmin port number provided in the standard output file for the managed server. The location of the file can be found with the administrative console interface in the managed server configuration via the **General** tab to standard output field. The message within the file containing the port number is:

```
DrAdmin available on port xxxx
```

### Execute DrAdmin

The DrAdmin.bat file can now be executed providing the port number obtained above. The format of the command to use is:

```
DrAdmin -serverPort xxxx -dumpThreads
```

where xxxx is the port number from the above message (without the comma).

### Locate the thread dump

The administrative server thread information is placed in .\logs\adminserver\_stderr.log file. Because this file is not closed, its length of 0 will not change. The application server thread information is placed in the standard error file which can be found with the administrative console interface in the application server configuration via the **General** tab to standard error field. The thread information is dumped immediately into this file.

In order to view the thread information, copy the above files into a new file. Edit the new file with an HTML editor, which will display the thread information. Some editors (i.e. emacs and vi) will allow you to view the thread information directly from the .\logs\adminserver\_stderr.log file or the standard error file.

## How to interrupt a Java thread dump

A thread dump can be forced or can occur when a Java process error occurs. When a thread dump is not forced, it usually means that an error within a Java process has occurred and it should be investigated. A thread dump of a Java process needs to be forced when the process has a thread deadlock condition. A **thread deadlock condition** is defined as:

```
Thread A currently owns Lock X.
```

```
Thread B owns Lock Y.
```

```
Thread A is waiting for the release of Lock Y in order to continue processing.
```

```
Thread B is waiting for the release of Lock X in order to continue processing.
```

Because of this stalemate condition, neither thread is able to complete its processing.

The referenced Java thread dump information is taken from a sample AIX dump. Java thread dumps on other platforms have similar information, but they may be formatted differently.

## Monitors

In order to have a thread safe application, the application may have to ensure that two threads don't execute the same code simultaneously. This can be accomplished with

the use of a `synchronized()` statement or a `synchronized` modifier of a class method.

Each of the above will create a monitor/lock that will prevent other threads from executing the same code. It is important to understand that threads can be holding multiple monitors/locks while processing a request. Therefore two threads could find themselves in a deadlock condition defined by the following situation:

Thread A owns Lock X.

Thread B owns Lock Y.

Thread A is waiting for the release of Lock Y.

Thread B is waiting for the release of Lock X.

Because of this stalemate condition, neither thread is able to complete its processing.

## Example of a deadlock condition

You can recognize a deadlock when looking within the native stack information. For example, when looking at the native stack information of Thread A you can easily recognize that it is blocked by a monitor/lock held by Thread B. This information does not appear in the native stack information of the Thread B. Thread B is currently deleting a connection, (`deleteConn`), from the `ConnectionTable`. The `deleteConn()` is a `synchronized` method which causes a monitor/lock to occur for the `ConnectionTable` class. There is only one **ConnectionTable** instance. Therefore the monitor/lock held by **Thread-9** is preventing the **JavaIDL Listener** from completing.

The above diagnosis requires an understanding of the involved source code (i.e. which methods are `synchronized`). However, the Java thread dump does provide the pointers to do this additional investigation.

A summary of the object monitors will provide additional information that identifies Thread A as blocked. Thread B with:  
`com.ibm.CORBA.iiop.IIOPConnection@4fe89740: owner: "Thread B" "Thread A" (0x36951ba8) blocked`

Unfortunately, this information does not appear in the summary for the monitor being held by Thread A.

## Stack traces

Stack traces represent the current call path of a thread. Call path information explains what functional calls were made to get to the thread's current location.

### System dump stack trace

Note that the `sysAcceptFD()` call is the last function called on the stack. It is a system call that was invoked by `java_net_PlainSocketImpl_socketAccept()` call. The call indicates that a Java thread did an accept operation on a socket. Question marks appear as parameters. This is because the Java process was not run in debug mode. For Java 1.1 installations (i.e. before WebSphere 3.5), debug mode is started by using the `java_g` command. For Java 1.2 installations (i.e. WebSphere 3.5), the `-Xdebug` options should be used with the Java command. For either type of installation, the administration console screen for a managed server configuration has a Debug tab. Debug mode can be set within this tab. As stated above, no class file information appears in the stack trace. Only the functions with C libraries are referenced.

### Java dump stack trace

The reader is able to follow the sequence of calls from the `run()` method through the `read()` method of the `SocketInputStream` class. The package names of the classes are also present. The "Compiled Code" characters appear as parameters in the call because the Java dump occurred for a JVM that was not running in debug mode. When running in debug mode, the line number of the call within the source replaces the "Compiled Code" characters. For Java 1.1 installations (i.e. before WebSphere 3.5), debug mode is started by using the `java_g` command. For Java 1.2 installations (i.e. WebSphere 3.5), the `-Xdebug` options should be used with the Java command. For either type of installation, the administration console screen for a managed server configuration has a Debug tab. Debug mode can be set with this tab. Another way of obtaining the source line numbers is to turn off the JIT (Just In Time) compiler. This can be done by starting the JVM with the `-Djava.compiler=NONE` parameter. This parameter can also be placed on the managed server command line. The command line information can be displayed with the administration console interface on the **General** tab of the managed server configuration.

## WebSphere Application Server thread information

### Object Request Broker information

During startup of the different WebSphere Application Server processes, the processes are initialized and placed in a state to accept additional network activity. One of the first steps in initializing a process is to create an ORB instance. This step will create threads that will be used to complete the initialization step and later accept network activity to be processed.

These activities are described within each of the two diagrams of the next two sections. The diagrams describe:

- o Administrative server startup and immediate administrative server takedown
- o Managed server startup with servlet traffic

The administrative server has two ORBs defined within it. For each ORB there is at least one ORB server listener thread that continually waits for input on a port. When input is received, it is dispatched to a ORB server reader thread so the ORB server listener thread can again wait for input on the port. The ORB server reader thread again dispatches the request to a third thread that completes the work activity. The reply to the work activity is sent from the third thread to a ORB client reader thread that receives replies from the ORB reader thread. An ORB request has four steps/threads involved:

1. ORB Server Listener thread receives input on port X.
2. ORB Server Reader thread is given a request.
3. Pooled/instantiated thread handles the request and sends a reply.
4. ORB Client Reader thread handles the reply.

The managed server has one ORB defined within it. There are two ORB server listener threads and multiple ORB client threads. The servlet traffic does not use the ORB for communications. It is done with the plug-in interface. This interface supports a pool of worker threads (`Worker#_`) that complete the HTTP requests.

The following port numbers are preset:

- 9000 is used for obtaining naming services (i.e. data source names, EJB names)
- 900 is used by the administrative server to listen for administrative client requests

Other port numbers are randomly chosen for ORB communications.

## Thread names

### ORB threads

The ORB instance creates reader and listener threads. The names of these threads get changed after they begin processing (i.e. during run() method processing). The name is constructed with the following parameters separated by a colon (:):

- ORB information
  - P = unique for this process and algorithmically constructed from a time stamp
  - O = number of ORB's within this process
- Thread type
  - StandardRT = identifies which reader thread is within the ORB
  - CT = client thread
  - LT = listener thread
- Connection values
  - LocalPort = Local port that thread is dealing with
  - RemoteHost = Hostname for ORB server reader thread, or IP address for ORB client reader thread
  - RemotePort = Port number on the remote host for the connection

### Worker#\_\_ (SERVLET ENGINE THREADS)

These thread names begin with Worker# and process HTTP requests.

### Thread-x

These thread names are the default thread name for Windows 2000 and AIX. Because no thread name is provided this name is used. X is incremented as each new thread is created.

### Pooled ORB request dispatch WorkerThread

These threads are created by the main thread (i.e. P=479481:O=0:CT) and handle the request/replies that are sent across IIOP connections.

### Web server plug-in configuration thread

Thread used for setting the Web server configuration.

### Alarm manager

This thread manages the creation of alarm thread x's.

### Alarm thread 1

The alarm thread 1 reclaims unused connections.

### BackgroundLruEvictionStrategy

This thread sweeps a cache, reclaiming the least recently used objects.

### Refresh

This thread insures that any changes to a model get propagated to clones.

## Thread stack traces

When a thread is created, the start() method is used to invoke the run() method. The start() method is executed on one thread and the run() method is executed on the newly created thread. Depending on when the stack trace is obtained, an activity (i.e. piece of work) could have different stack traces. Therefore, thread names have two base method calls. The following text describes these base method calls for the common thread names used for both the administrative server and the managed server. Two stacktrace examples of base method calls are also provided:

#### Base method calls

1. Main or P=xx:O=0:CT
  - run ---> com.ibm.ejs.sm.server.AdminServer.main()
2. ORB server listener thread (JavaIDL Listener or P=xx:O=0:LT=0:port=9000)
  - start ---> com.ibm.ejs.sm.server.AdminServer.main()
  - run ---> com.ibm.CORBA.iiop.ListenerThread.run()

3. ORB server reader thread (JavaIDL Reader for hostname:port# or P=xx:O=0:StandardRT=0:LocalPort=port#:RemoteHost=hostname:RemotePort=port#:)
  - start ---> com.ibm.CORBA.iiop.ListenerThread.run()
  - run ---> com.ibm.CORBA.iiop.StandardReaderThread.run()
4. ORB client reader thread (JavaIDL Reader for ipaddr:port# or P=xx:O=1:StandardRT=1:LocalPort=port#:RemoteHost=ipaddr:RemotePort=port#:)
  - start ---> com.ibm.ejs.sm.server.AdminServer.main()
  - run ---> com.ibm.CORBA.iiop.StandardReaderThread.run()
5. Pooled ORB request dispatch WorkerThread
  - start ---> com.ibm.CORBA.iiop.StandardReaderThread.run()
  - run ---> com.ibm.ejs.oa.pool.ThreadPool\$PooledThread.run()
6. Worker#\_\_
  - start ---> com.ibm.ejs.sm.server.AdminServer.main()
  - run ---> com.ibm.servlet.engine.oselister.outofproc.OutOfProcThread\$CtlRunnable.run() java.lang.Thread.run()
7. Web server plug-in configuration thread
  - start ---> com.ibm.ejs.sm.server.AdminServer.main()
  - run ---> com.ibm.servlet.engine.oselister.outofproc.OutOfProcThread\$CtlRunnable.run() java.lang.Thread.run()
8. Alarm manager
  - start ---> com.ibm.ejs.sm.server.AdminServer.main() <--AdminServer
  - com.ibm.ejs.oa.pool.ThreadPool\$PooledThread.run() <--AppServer
  - run ---> com.ibm.ejs.util.am.AlarmManagerThread.run() java.lang.Thread.run()
9. Alarm thread 1
  - start ---> com.ibm.ejs.util.am.AlarmManagerThread.run() java.lang.Thread.run() <--AdminServer
  - com.ibm.ejs.oa.pool.ThreadPool\$PooledThread.run() <--AppServer
  - run ---> com.ibm.ejs.oa.pool.ThreadPool\$PooledThread.run() <--AdminServer
  - com.ibm.ejs.util.am.AlarmThread.run() <--AppServer
10. BackgroundLruEvictionStrategy
  - start ---> com.ibm.ejs.sm.server.AdminServer.main()
  - run ---> com.ibm.ejs.util.cache.BackgroundLruEvictionStrategy.run()
11. RefreshThread
  - start ---> com.ibm.ejs.sm.server.AdminServer.main()
  - run ---> com.ibm.ejs.wlm.server.config.ServerGroupRefresh\$RefreshThread.run()

## Examples

Thread dump of a standard reader thread:

```
"P=863240:O=1:StandardRT=16:LocalPort=10502:RemoteHost=gofast:RemotePort=2619:"
(TID:0x11ccef0, sys_thread_t:0xcdd81d0, state:R, native ID:0x128) prio=5
>at java.net.SocketInputStream.socketRead(Native Method)
at java.net.SocketInputStream.read(SocketInputStream.java:Compiled Code))
at com.ibm.rmi.iiop.Message.readFully(Message.java:Compiled Code))
at com.ibm.rmi.iiop.Message.createFromStream(Message.java:173)
at com.ibm.CORBA.iiop.IIOPConnection.createInputStream(Unknown Source)
at com.ibm.CORBA.iiop.StandardReaderThread.run(Unknown Source)
```

The base method, com.ibm.CORBA.iiop.StandardReaderThread.run(), is identified as the run base method for JavaIDL Reader for hostname:port# threads. Also, the thread is waiting for input because it is in the java.net.SocketInputStream.socketRead() method.

Thread dump of a worker thread:

```
"Worker#49" (TID:0x10793660, sys_thread_t:0xab25b0, state:R, native ID:0x19a) prio=5
at com.ibm.servlet.engine.oselister.outofproc.NativeServerQueueImp.nativeGetSeviceMessageId( )
at com.ibm.servlet.engine.oselister.outofproc.NativeServerQueueImp.getSeviceMessageId( )
at
com.ibm.servlet.engine.oselister.serverqueue.SQWrapperEventSource$SelectRunnable.getNewConnectionFromQueue( )
at com.ibm.servlet.engine.oselister.serverqueue.SQWrapperEventSource$SelectRunnable.run( )
at com.ibm.servlet.engine.oselister.outofproc.OutOfProcThread$CtlRunnable.run( )
at java.lang.Thread.run( )
```

The base method, java.lang.Thread.run(), is identified as the run base method for Worker#\_\_ threads. Also, the thread is waiting for input from the Web server plug-in (native code) because it is in the com.ibm.servlet.engine.oselister.outofproc.NativeServerQueueImp.nativeGetSeviceMessageId() method.

## Administrative Server Startup with Immediate Takedown Diagram

The following diagram has highlighted request flows that start with a SendReqXXX where XXX is the portnumber of the send request. The steps in the flow changes between different threads. The sequence of the steps are identified with, for example, 1A, 1B, 1C and 1D. It also shows how the port that the request is sent to determines which thread the processing has completed.

## Diagram Legend

In each diagram, every continuous line (-----) is a thread. The name of the thread always appears between (...). The letters in the diagram have the following meanings:

C = Thread name changed to (....)

S = Start method called on this thread

R = Run method called on this thread  
W = Thread is in wait state waiting for notify  
WM = Thread is waiting for message from plugin (Worker# threads only)  
SendReq\_\_\_\_ = Request sent to port number (\_\_\_\_)  
SendReply\_\_\_\_ = Reply sent to port number (\_\_\_\_)

For example:

C(P=479481:O=0:CT) = thread name is changed to P=479481:O=0:CT  
R = thread is placed in a running state

**Note:** Thread-x are default names of threads. The above numbers may be different. depending on the system the managed server runs on.

## Summary

In multi-processing and multi-thread environments, problem determination can require analysis of actively running threads. This thread information can be obtained with system thread dumps and Java thread dumps. When doing problem determination in a WebSphere Application Server environment, Java thread dumps provide much more information and are recommended. However, sometimes system thread dumps are the only information obtained and should be interrogated.

When dealing with thread deadlock problems, Java thread dumps can be forced using kill -3 on Unix platforms and DrAdmin on all platforms.

The output of these commands provides thread information necessary to diagnose the problem.

## 8.10: Applying e-fixes

E-fixes are individual fixes for critical problems. They have been individually tested, but not integration tested and should only be applied if you have a critical problem without a valid workaround. They may be applied to both versions of WebSphere, except where specifically noted. All e-fixes are rolled into the next scheduled FixPack. Each fix has a readme file with installation instructions.

To learn about the fixes made available since the last FixPack, see the [FixPacks and E-fixes](#) website.

## 8.11: Resource reference

Use these links to learn about other performance tools and techniques.

- [9.1: Tuning the Product](#)

## 8.13: Problem determination hints and tips

When you encounter an error or problem with WebSphere Application Server, you can follow the [Hints and Tips](#) to help you quickly gather relevant data to diagnose the problem.

## 8.14: How to report a problem to IBM

Use the information in this section to help you report a problem to IBM.

Before reporting problems to IBM, please review the known problems in the Release Notes, Hints and Tips, FAQ's, and other resources on the [support website](#). If you find that the problem is not a known defect, then report the problem to IBM.

There are a variety of ways to report your problem to IBM:

- [Phone](#)
- [Fax](#)
- [Internet](#)

If you need assistance with problems, you are required to purchase technical support. You can select the exact mix of services to fit your specific business needs. IBM Software Support is delivered in a consistent manner for all IBM software products based upon the way in which a product is charged (one time charge or monthly license charge basis).

You can report suspected defects via fax, mail or electronically until the product's service expiration date. This free service is called Warranty/Defect Support. For information on reporting suspected defects, call 1-800-237-5511 in the United States and Puerto Rico. In Canada, call 1-800-465-9600. Telephone numbers for [countries outside North America](#) are also available. The service expiration date is defined in your License Information booklet under Program Services.

### What to provide when reporting problems

You will need the following information available when reporting a problem to IBM:

- The product name and version number
- The kind of hardware and software you are using
- What happened and what you were doing when the problem occurred
- Whether you tried to solve the problem and how
- The exact wording of any messages displayed

After you have reported a problem to IBM support using any of the methods above, especially by phone, you might want to provide relevant logs, traces or files. You can also send an ASCII text description of the problem in your own words. Send logs and text files together in a zip file for ease of transfer.

Follow these steps to send files to IBM:

1. Note the problem record number assigned to you by IBM support.
2. FTP `testcase.software.ibm.com`
3. Login: anonymous
4. Password: [your email id]
5. Change directory: `cd /ps/toibm/internet`
6. Make a directory: `mkdir pmrnumber` [use your problem number, for example, `pmr89401`]
7. Put [filename]
8. Call IBM Support back and ask that it be noted in your problem record that files are available on the testcase ftp server. Give the path to the files. Files will remain available on the testcase ftp server for 72 hours and will then be deleted.

## Technical support by phone

If you are a licensed customer in the U.S. or Puerto Rico who has a support contract and you need support, please call IBM Support at 1-800-237-5511. In Canada, call 1-800-IBM-SERV (1-800-426-7378). Telephone numbers for countries [outside North America](#) are also available.

If you are a licensed customer and wish to purchase support, you may contact IBM or your IBM authorized business partner.

If you have an IBM customer number, call 1-888-426-4343 Monday - Friday 8:00 a.m. to 7:00 p.m. Eastern Standard Time.

In Canada, call 1-800-465-9600 Monday - Friday 8:00 a.m. to 5:00 p.m. Central Standard Time.

If you do not have an IBM customer number, call 1-800-237-5511 Monday - Friday 8:00 a.m. to 5:00 p.m. Central Standard Time.

In Canada, call 1-800-465-9600 Monday - Friday 8:00 a.m. to 5:00 p.m. Central Standard Time.

## Technical support by fax

Contact us via the Faxback System: 1-800-426-4329.

Telephone numbers for countries [outside North America](#) are also available.

## Technical support on the Internet

Online help is available through the [IBM Support Line](#). Support Line is the service offering through which IBM delivers electronic support for installation, usage, and code-related questions. Electronic support is also available through Passport Advantage's online [incident report](#) page. Solution developers can also receive online help through the [PartnerWorld for Developers](#).

Information on IBM SupportLine and IBM Services is available on the Internet at the URL listed above. For IBM Lotus Passport Advantage customers, support information is also available at this Internet site.

**Note:** Information may not apply to all products. Support information is subject to change without notice.
