  The JNLP specification requires all the resource (JAR or EAR) files used in a JNLP file to be signed.

  You can specify the –CC arguments defined in the launchClient tool for a J2EE Application client application in application arguments section of the JNLP descriptor files. However, only –CCD is supported for a Thin Application client application to define system properties and the JNLP <property> tag can also be used to define system properties. See the following example for details:

  ```
  <property name="java.naming.provider.url" value="corbaloc:iiop:myserver.com:9089"/>
  ```

  For a J2EE Application client application, specify the following application arguments as defined in the JNLP.

  1. Specify your target server provider URL, as shown in the following example:

     ```
     <argument> >-CCDjava.naming.provider.url =corbaloc:iiop:myserver.mydomain.com:9080</argument>
     ```

  2. Specify the SSL Key File and SSL Trust File location. These files are expected to be available in the client machine. To use the ones in the Application Clients run-time dependency installed in JWS cache, specify these application arguments:

```
<argument> -CCDcom.ibm.ssl.keyStore=${WAS_ROOT}/etc/DummyClientKeyFile.jks </argument>
<argument>-CCDcom.ibm.ssl.trustStore=${WAS_ROOT}/etc/DummyClientTrustFile.jks </argument>
```

3. Specify the initial naming context factor, as shown in the following example:

   ```
   <argument>-CCDjava.naming.factory.initial=
    com.ibm.websphere.naming.WsnInitialContextFactory </argument>
   ```

   For a Thin Application client application, you also need to specify the actual location of the `sas.client.props` file located in the Application Clients run-time dependency that is installed in the JWS cache.

   ```
   <argument>-CCDcom.ibm.CORBA.ConfigURL=file:${WAS_ROOT}/properties/sas.client.props</argument>
   ```

   If any of the default settings in the `sas.client.props` file need modifying, use the –CCD to change the settings through the system properties, as shown in the following example:

   ```
   <argument>-CCDjavacom.ibm.CORBA.securityEnabled=false </argument>
   ```

   Note: The ${*install_root*} token used in the JNLP file is replaced by the launcher class, com.ibm.websphere.client.launcher.ClientLauncher, to the actual location of the Application Clients run-time dependency installation in the JWS cache. If you are using JSP to dynamically create this JNLP description file, you must escape this token because it has a different meaning in JSP 2.0. See the following example for details:

   ```
   <argument>-CCDcom.ibm.ssl.keyStore=\${WAS_ROOT}/etc/DummyClientKeyFile.jks </argument>
   <argument>-CCDcom.ibm.ssl.trustStore=\${WAS_ROOT}/etc/DummyClientTrustFile.jks </argument>
   ```

Here is an example of the client application JNLP descriptor file for a J2EE Application client application.

```
<%--    This is a generic jnlp for a client app.  It will specify the WAS JRE
    as a dependency as well as the client launcher
-->
<%! private final String description="J2EE Client Example";    private final
String earName="J2EEWebStart.ear";
%>
<%  // locally declared variable

String urlSt = request.getRequestURL().toString();
String jnlpCodeBase=urlSt.substring(0,urlSt.lastIndexOf('/'));
String jnlpRefURL=urlSt.substring(urlSt.lastIndexOf('/')+1,urlSt.length());
// The client application descriptor noted a resource reference to be resolved
// at deploy time as following
%>
<%--
 Need to set a JNLP mime type - if Web Start is installed on the client,
 this header will induce the browser to drive the Web Start Client

--%><%
 response.setContentType("application/x-java-jnlp-file");   1
 response.setHeader("Cache-Control", null);
 response.setHeader("Set-Cookie", null);
 response.setHeader("Vary", null);
%>

</application-desc>
</jnlp>
```

- **1**--Specifies the mime type of the file must be JNLP so that the browser will know what to do with the file.
- **2**--Specifies that the application is depending on the `WASclient6.0` Java Runtime Environment and specifies the URL of the JNLP for the Application Clients run-time dependency.
- **3**--Specifies the JAR file containing the launcher class. This should be the first jar specified and must contain the URL of the JAR file.
- **4**--Specifies the EAR file to be downloaded, which is similar to the one you run on an Application Client for WebSphere Application Server installation.
- **5**--Specifies the value of the EAR file name of the J2EE application.
- **6**--Specifies an application descriptor.
- **7**--Specifies the arguments for the J2EE Application client application as they are specified on the launchClient call.
- **8, 9**--Overrides the values in the `sas.client.props` file. They are needed because the installation location of the Application Clients run-time dependency component is unknown before it is actually installed. By default, security is turned on for the client application, and these values are required. The ${*install_root*} directory name is substituted with the Application Clients run-time dependency component installation location at run time.

ClientLauncher class: The class, com.ibm.websphere.client.installer.ClientLauncher, contains a main() method that is called by Java Web Start (JWS) to launch the client application. It is packaged in the `WebSphereClientLauncher.jar` file that is located in a WebSphere Application Server clients installation under the <*install_root*>/ JWS directory.

This launcher class configures the run-time environment for J2EE application clients and thin client applications (not J2EE application clients).

The launcher class requires that the following properties are defined. These properties are not defined in a separate properties file. Instead, they are defined as part of the Java Network Launching Protocol (JNLP) files.

com.ibm.websphere.client.launcher.main
If the client application is a Thin Application client, then this property should be specified. It specifies the class where the main entry point of the client application resides.

com.ibm.websphere.client.launcher.ear
If the client application is a J2EE Application client, then this property should be specified. It specifies the name of the EAR file to be executed. This property takes precedence over com.ibm.websphere.client.launcher.main. However, only one of the two properties should be specified.

com.ibm.websphere.client.launcher.classpath.* (required for J2EE client applications only)
There can be a set of properties that are prefixed with com.ibm.websphere.client.launcher.classpath. Each property specifies a JAR file that is to be added to the class path of the client application. This JAR file is a JAR file that is already defined as a resource for the client application. This file is needed so that the correct elements of the class path of the Java Virtual Machine (JVM) starting the client launcher can be retrieved and added to the class path of the (JVM) that is to be spawned for the client application.

Preparing the Application Client run-time dependency component for Java Web Start:

For a J2EE application client application and or Thin application client application to be launched using Java Web Start (JWS), an Java Runtime Environment that IBM provides, the library JAR files and properties files bundled in Application Client for WebSphere Application Server must be installed in the JWS. This article provides the steps to build the Application Client run-time dependency component from an Application Client installation. It is packaged as a Web Archive Resource (WAR) file that can be installed in an Application Server.

Install the Application Client for WebSphere Application Server for the platform to which the client application deploys. If there is a requirement to deploy the client application to multiple platforms, the Application Client run-time dependency component must be built separately for each platform that client application supports.

For example, if the client application deploys to both the Windows platform and Linux platform, follows the steps for this task to build the Application Client run-time dependency component for Windows on a Windows platform machine with the Application Client for WebSphere Application Server for Windows installed. Now, repeat the steps for this task to build the Application Client run-time dependency component for Linux on a Linux platform machine with the Application Client for WebSphere Application Server for Linux installed.

1. Install the Application Client for WebSphere Application Server for the client application supported operating systems. Install Application Client in the `C:\Program Files\IBM\WebSphere\AppClient` directory.
2. Change the directory to the installation bin directory. See the following example for help:
   ```
   CD C:\Program files\IBM\WebSphere\AppClient\bin
   ```
3. Run the buildClientRuntime tool to generate the Application Client run-time JAR file in a temporary directory which contains the Java 2 Runtime Environment, Application Client run-time properties, the SSL KeyStore and TrustStore file, and the Application Client run-time library JAR files. See the following example for help:
   ```
   buildClientRuntime C:\WebApp1\runtime\WASClient6.0_windows.jar
   ```
   If you are building an Application Client run-time JAR file only for serving Thin application client applications and not for J2EE application client applications, you can reduce the size of the generated JAR file by not including the Application Client run-time library JAR files. An extra parameter is passed to the buildClientRuntime tool, as the following example shows:

```
buildClientRuntime C:\WebApp1\runtime\WASClient6.0_windows.jar
                   buildThin
```

4. Copy the `WebSphereClientRuntimeInstaller.jar` file to the same location of the JAR file generated in the previous step. This JAR file is located in the JWS directory of the WebSphere Application Server clients installation. See the following example for help:

   ```
   copy ..\JWS\WebSphereClientRuntimeInstaller.jar   C:\WebApp1\runtime
   ```

5. Sign the JAR files created from the previous steps, using the Java 2 SDK jarsigner utility, as the following example shows:

   ```
   cd C:\WebApp1\runtime

   jarsigner -keystore myKeystore -storepass myPassword
                   WASClient6.0_windows.jar myKeyAliasName

   jarsigner -keystore myKeystore -storepass myPassword
                   WebSphereClientRuntimeInstaller.jar myKeyAliasName
   ```

   a. This step also requires you to create a keystore file, such as `myKeystore`.
   b. You must also create a self-signed certificate for the `myKeystore` file. For more information, see the topic, ″Creating self-signed personal certificates″ in the *Securing applications and their environment* PDF.

6. Create an Application Client run-time installer JNLP descriptor file or a JavaServer Pages (JSP) file if it is generated dynamically in the same temporary directory as previous step. See the sample JNLP file shown in the Example section of this topic.
7. Package the two signed JAR files and the Application Client run-time installer JNLP descriptor file into a WAR file. This WAR file is packaged into an EAR file that can be deployed to an Application Server.

Your Web application is ready to serve the Application Client run time and the JRE environment.

```
<%--
     This is an Installer JNLP
     It will download two .jars:
     WebSphereClientRuntimeInstaller.jar - includes the installer utility
     WASClient6.0_<platform>.jar - the client runtime JRE image

  The installer will unzip the client runtime jar on the client machine, and register
     it with Java Web Start

  --%>
<%! private final String description=″WebSphere Client 6.0 Runtime JRE″;
    // The version here is (WAS based) JRE version - as to be managed on the client
    private final String JREversion=″WASclient6.0″;%>
<%
      // locally declared variable
      String url=request.getRequestURL().toString();
      String jnlpCodeBase=url.substring(0,url.lastIndexOf('/'));
      String jnlpRefURL=url.substring(url.lastIndexOf('/')+1,url.length());

      // Need to set a JNLP mime type - if Web Start is installed on the client,
      // this header will induce the browser to drive the Web Start Client
      response.setContentType(″application/x-java-jnlp-file″);    1
      response.setHeader(″Cache-Control″, null);
      response.setHeader(″Set-Cookie″, null);
      response.setHeader(″Vary″, null);

      // An installer must reply with the version number for a given install
      if (response.containsHeader(″x-java-jnlp-version-id″))
```

```
        response.setHeader("x-java-jnlp-version-id", JREversion);     2
      else
        response.addHeader("x-java-jnlp-version-id", JREversion);

%>
<?xml version="1.0" encoding="utf-8"?>
<!-- JNLP File for <%=description %> -->

  <property name="com.ibm.websphere.client.jre.launch.java" value="java/jre/bin/java"/>
 </resources>
 <installer-desc />
</jnlp>
```

1. Specifies that the file is a JNLP mime type so that the browser can process the JNLP file.
2. Specifies the exact version of this Application Client run-time dependency component in the response by setting the HTTP header field: `x-java-jnlp-version-id`.
3. Specifies the required JRE version to run the installer program.
4. Specifies the installer `WebSphereClientRuntimeInstaller.jar` file, which contains the ClientRuntimeInstaller class.
5. Specifies a system property that defines the version of Application Client run-time dependency component. This version is registered to the JNLP client.

6. Specifies resources for a particular platform. Each supported client application platform needs its own separate JAR file.
7. Specifies the Application Client run-time dependency component JAR file.
8. Specifies the program to call that starts a JVM for the client application.

Preparing Application Client run-time library component for Java Web Start.

buildClientRuntime tool: The buildClientRuntime tool builds the required components from the WebSphere Application Server clients installation into the JAR file specified on the command. This JAR file contains:

- License files
- Java 2 Runtime Environment (JRE) that IBM provides
- Application Clients run-time properties and configuration
- SSL KeyStore and TrustStore files
- Run-time library JAR files

In the case of building an Application Clients run-time JAR file only for serving Thin Application client applications and not for J2EE Application client applications, the run-time library JAR files and the Application Clients run-time properties files are not included, except the two configuration files, `sas.client.props` and `soap.client.props`.

The command-line invocation syntax for the buildClientRuntime tool is shown in the following example:

```
Windows Usage:  buildClientRuntime .bat  jar_file  [type]
Unix Usage:          buildClientRuntime.sh    jar_file  [type]
Where:
      jar_file    Specifies the target jar file name.
      type             Range:
                                   buildJ2EE - Default value that builds a Application Clients
                                                       run-time library for J2EE application.
                                   buildThin  - Builds a Application Clients run-time library
                                                       for Thin application.
```

ClientRuntimeInstaller class: This class, com.ibm.websphere.client.installer.ClientRuntimeInstaller, contains a main() method that Java Web Start (JWS) calls to install the Application Client for WebSphere Application Server run-time dependency component in JWS cache. It is packaged in `WebSphereClientRuntimeInstaller.jar` file located in the Application Client for WebSphere Application Server installation in the `<`*`install_root`*`>/JWS` directory.

Specify the `WebSphereClientRuntimeInstaller.jar` file and the Application Client run-time dependency component JAR file as JAR resources in the Application Client run-time installer Java Network Launcher Protocol (JNLP) descriptor file. See the following example for details:

```
<jar href="Launcher/WebSphereClientRuntimeInstall.jar" main="true"/>
<jar href="Launcher/WASClient6.0_windows.jarRuntimeInstall.jar" main="true"/>
```

The ClientRuntimeInstaller class main method requires the following properties to be set in the JNLP file:

com.ibm.websphere.client.jre.version
Specifies a Java Runtime Environment (JRE) version name that is to be used when referring to the Application Client run-time dependency component.

com.ibm.websphere.client.jre.launch.java
Specifies the relative location of the javaw.exe program in the Application Client run-time dependency component JAR file.

The previously mentioned properties, JRE version name and the location of the javaw.exe program are registered to the Java Web Start Application Manager, as shown in the following example:

```
<property name="com.ibm.websphere.client.jre.version" value="java\jre\bin\javaw.exe"/>
<property name="com.ibm.websphere.client.jre.launch.java" value="WASclient6.0"/>
```

Preparing Application Clients run-time library component for Java Web Start:

For a Thin Application client application to be launched using Java Web Start (JWS), you also need to create a Java Network Launching Protocol (JNLP) component to serve the Application Clients run-time library JAR files from the Application server. This JNLP component is referenced in the client application JNLP file with the <extension> tag. This article provides the steps to build the Application Clients run-time library component from an Application Clients installation. It is packaged as its own Web Archive Resource (WAR) file or to the same WAR file that contains the Application Clients run-time dependency component, and can be installed in an Application server.

Install the Application Client for WebSphere Application Server for the platform to which client applications deploy.

1. Install the Application Clients on the client application supported operating system. For example, install Application Clients in the `C:\Program Files\IBM\WebSphere\AppClient` directory.
2. Change directory to the installation bin directory. See the following example for help:
   ```
   CD C:\Program files\IBM\WebSphere\AppClient\bin
   ```
3. Run `buildClientLibJars` to copy the Application Clients run-time library JAR files from the Application Clients installation to a temporary directory. All the JAR files in the temporary directory are signed, as shown in the following example.
   ```
   buildClientLibJars C:\WebApp1\runtime\WebSphereJars
                      myKeystore myPassword myKeyAliasName
   ```
   a. This step also requires you to create a keystore file, such as `myKeystore`.
   b. You must also create a self-signed certificate for the `myKeystore` file. For more information, see the topic, ″Creating self-signed personal certificates″ in the *Securing applications and their environment* PDF.
4. Create an Application Clients run-time installer JNLP descriptor file or a JavaServer Pages (JSP) file, if it is generated dynamically in the same temporary directory as previous step. See the sample JNLP file shown in the Example section of this topic.
5. Package these JAR files and the Application Clients run-time library component JNLP descriptor file into a WAR file. You can also package both Application Clients run-time library component and Application Clients run-time dependency component in the same WAR file. This WAR file is packaged into an EAR file that can deployed to an Application server.

```

```

- **1**--Specifies that the file is a JNLP mime type so that the browser can process the JNLP file.
- **2**--Specifies the Last-Modified header so that any changes to this JSP file are downloaded to the JNLP client.
- **3**--Specifies all the JAR files in the Application Clients run-time library component that are generated by the buildClientLibJars tool.

buildClientLibJars tool: The buildClientLibJars tool copies the JAR files from the Application Client for WebSphere Application Server installation and creates a `properties.jar` file, which contains the properties files from the Application Clients installation properties directory to a specified location. When this property is created, the tool uses the value of `keystore`, `storepass` and `alias` to sign all the JAR files in the specified location.

```
Windows Usage: buildClientLibJars.bat  target_dir keystore  storepass  alias
Unix Usage:        buildClientLibJars.sh  target_dir keystore  storepass  alias
Where:
     target_dir       Specifies the target directory where the Application
                           Clients library JAR files copied to.
    keystore         Specifies a keystore file.
    storepass       Specifies the keystore password.
    alias                Specifies an alias for the key object in the key file.
```

Using the Java Web Start sample:

The EAR file, `WebSphereClientRuntime.ear`, is provided in the JWS directory of the Client Application for WebSphere Application Server installation. This EAR file provides a sample Application Clients run-time installer JNLP descriptor file and a sample Application Clients run-time library component JNLP descriptor file. Follow the steps in this task to build the Application Clients run-time dependency component and the Application Clients run-time library component. Add these components to the `WebSphereClientRuntime.ear` file, and then install the EAR file in an Application Server to be used by the client application.

Install the Application Client for WebSphere Application Server for the platform to which the client application deploys. If there is a requirement to deploy the client application to multiple platforms, the Application Clients run-time dependency component must be built separately for each platform that the client application supports.

1. Install the Application Clients on the client application supported operating system. For example, install Application Clients in the `C:\Program Files\IBM\WebSphere\AppClient` directory.
2. Create the following temporary working directories:
   ```
   MKDIR C:\WebApp1
   MKDIR C:\WebApp1\runtime
   MKDIR C:\WebApp1\runtime\Widnows
   MKDIR C:\WebApp1\runtime\WebSphereJars
   ```
3. Change directory to the installation bin directory. See the following example for help:
   ```
   CD C:\Program files\IBM\WebSphere\AppClient\bin
   ```
4. Run the buildClientRuntime tool to generate the Application Clients run-time JAR file in a temporary directory that contains the Java 2 Runtime Environment that IBM provides, Application Clients run-time properties, the SSL KeyStore and TrustStore files, and the Application Clients run-time library JAR files. See the following example for details:
   ```
   buildClientRuntime C:\WebApp1\runtime\windows\WASClient6.0_windows.jar
   ```
5. Copy the `WebSphereClientRuntimeInstaller.jar` file to the same location of the JAR file generated in the previous step. This JAR file is located in the `JWS` directory of the Application Client for WebSphere Application Server installation. For example, copy the `..\JWS\WebSphereClientRuntimeInstaller.jar` file to the `C:\WebApp1\runtime` directory.
6. Sign the JAR files created from the previous steps, using the Java 2 SDK jarsigner utility. See the following example for details:
   ```
   cd C:\WebApp1\runtime

   jarsigner -keystore myKeystore -storepass myPassword
                   WASClient6.0_windows.jar myKeyAliasName

   jarsigner -keystore myKeystore -storepass myPassword
                   WebSphereClientRuntimeInstaller.jar myKeyAliasName
   ```
   a. This step also requires you to create a keystore file, such as `myKeystore`.
   b. You must also create a self-signed certificate for the `myKeystore` file. For more information, see the topic, ″Creating self-signed personal certificates″ in the *Securing applications and their environment* PDF.
7. Run buildClientLibJars to copy the Application Clients run-time library JAR files from the Application Client for WebSphere Application Server installation to a temporary directory. All the JAR files in the temporary directory are signed. See the following example for details:

```
buildClientLibJars C:\WebApp1\runtime\WebSphereJars
                   myKeystore myPassword myKeyAliasName
```

   a. This step also requires you to create a keystore file, such as `myKeystore`.
   b. You must also create a self-signed certificate for the `myKeystore` file. For more information, see the topic, ″Creating self-signed personal certificates″ in the *Securing applications and their environment* PDF.

8. Add all the JAR files created in the previous steps in the `C:\WebApp1` directory to the WAR file within the `WebSphereClientRuntime.ear` file. The contents of the WAR file are shown in the following example:

```
The root of the WAR
├───META-INF
│                 MANIFEST.MF
│
├───Runtime
│   │          jnlp.jsp
│   │          WebSphereClientRuntimeInstaller.jar
│   ├───windows │
│   │                WASClient6.0_windows.jar
│   │
│   └───WebSphereJars
│                      jnlp.jsp
│                      activities.jar
│                            :
│                      (all the jars created in step 7 under
│                        c:\WebApp1\Runtime\WebSphereJars)
│
├───theme
│                Master.css

                   ibm-web-bnd.xmi
                   ibm-web-ext.xmi
                    web.xml
```

9. Install the `WebSphereClientRuntime.ear` file to an Application Server. You have just created an Application Clients run-time dependency component and Application Clients run-time libraries for serving J2EE Application client applications and Thin Application client applications using Java Network Launching Protocol (JNLP) or Java Web Start (JWS).

Installing Application Client for WebSphere Application Server

Running J2EE and Thin application clients that communicate with WebSphere Application Server requires that elements of the Application Server are installed on the machine on which the client runs. However, if the system does not have the Application Server installed, you can install Application Clients, which provide a stand-alone client run-time environment for your client applications. See the Supported Prerequisites page for more information on supported product platforms.

This article describes how to install the Application Client for WebSphere Application Server using the installation image on the product CD-ROM. The steps that follow provide enough detail to guide you through preparing for, choosing, and installing the variety of options and features provided. To prepare for installation and to make yourself familiar with installation options, complete the steps in this article and read the related topics, before you start to use the installation tools. Specifically, read these topics before installing the product:

- Installing silently
- Best practices for installing

As a general rule, if you launch an installation and there is a problem such as not having enough temporary space or not having the right packages on your Linux or UNIX systems, then cancel the installation, and make the required changes. Restart the installation to initiate your changes.

Although it is not supported or recommended, you can install this product as a non-root user on a UNIX operating system. However, you must use a user ID that is part of the administrator group on Windows platforms.

In Version 6, the Application Server for WebSphere Application Server is installable on a machine with a previous version of Application Clients. However, you cannot install a Version 6 Application Client on top of a previous version of the Application Client. For example, if a Version 5 Application Clients install under the `C:\WebSphere\AppClient` directory, you can not choose the same install location for your V6 Application Clients installation.

Note: For Application Client coexisting, there is a limitation on Applet client and ActiveX client on Windows that can not be coexisted with V5.0.x and V4.x of the clients. For example, the Applet client feature in Version 6 cannot coexist with the Applet client feature in any previous release. This coexistence is not available because the installation of Applet client feature in Version 6 sets the browser default Java Virtual Machine (JVM) using the Java Runtime Environment (JRE) from the Version 6 installation, which is Java Runtime Environment Version 1.4.2. Similarly, the ActiveX to EJB Bridge feature in Version 6 sets the Windows system path to use the JRE from the Version 6 installation.

1. Install Application Client for WebSphere Application Server using the launchpad. The launchpad program is available on the root directory of the product CD in the program, `launchpad.sh`, on Linux and UNIX platforms and `launchpad.bat` on Windows platforms.

   Note: The free download Application Client installation is not packaged with the launchPad program.

   a. Click **Launch the installation wizard for Application Client for WebSphere Application Server** from the launchpad tool to launch the InstallShield for MultiPlatforms installation wizard. This action launches the installation wizard.

      The Readme documentation to which the launchpad links is the `readme.html` file in the CD root directory. The readme directory off the root of the CD has more detailed Readme files. The Installation Guide is in the `/docs` directory of the CD root directory.

      Note: Readme file names are based on product offerings.

      When you install application clients, the current working directory must be the directory where the installer binary program is located. This placement is important because the resolution of the class files location is done in the current working directory. For example:

      ```
      cd /install_root/AppClient

      ./install
      ```

      or

      ```
       cd <CD mount point>/AppClient

           ./install
      ```

      Failing to use the correct working directory can cause ISMP errors that abort the installation.

      The installation wizard does not upgrade or remove previous Application Clients installation automatically. However, you must change the directory of any previously installed versions of the Application Client because you cannot install Version 6 on top of previously existing Application Client.

   b. As indicated in the previous example, you can start the installation wizard from the product CD-ROM, using the command line.

      On other Linux platforms and UNIX-based platforms, run the `./install` command.

      On Windows platforms, run the `Install.exe` command.

   c. You can also perform a silent installation using the `-options responsefile` parameter, which causes the installation wizard to read your responses from the options response file, instead of from the interactive graphical user interface. Customize the response file before installing silently. After customizing the file, issue the command to silently install. Silent installation is particularly useful if you install the product often.

The rest of this procedure assumes that you are using the installation wizard. There are corresponding entries in the response file for every prompt that is described as part of the wizard. Review the description of the response file for more information. Comments in the file describe how to customize its options.

2. Click **Next** to continue when the Welcome panel is displayed.
   a. Click the radio button beside the **I accept the terms in the license agreement** message if you agree to the license agreement, and click **Next** to continue.
3. Specify a destination directory. Click **Next** to continue.
   a. Ensure that there is adequate space available in the target directory.
   b. Specify a target directory for the Application Client product.
   c. Enter the required target directory to proceed to the next panel. Deleting the default target location and leaving an installation directory field empty prevents you from continuing the installation process.
4. Choose a type of installation, and click **Next**.

   If you use the GUI, you can choose a Typical installation type, which installs J2EE and Thin application client, Samples and IBM Developer Kit, Java 2 Technology Edition or a Custom installation type.

   The Custom installation type lets you select which features to install. However you can not install the J2EE and Java Thin application client feature and the Pluggable application client feature together.

   (Windows Only) If you select the **ActiveX to EJB Bridge** feature, then the following is displayed in a dialog box: `Do you want to add Java runtime to the system path and make it the default JRE?` If you answer **Yes**, then the Java run time is added to the beginning of the system path. If you answer **No**, then the ActiveX to EJB Bridge does not function from the Active Server Pages (ASP), unless you add the Java run time to the path. To add the Java run time later, see the topic ActiveX application clients or reinstall the Application Client.(Windows Only) If you select the **Applet client** feature, then the following message might be displayed: `An existing JDK or JRE has been detected on your computer. You chose to install the Applet Client, which will overwrite the registry entries for this JDK or JRE. Do you want to continue and install the Applet Client?` If you select **Yes**, the installation overrides the registry on your machine. If you select **No**, the Applet client feature is not installed, and you are directed back feature dialog box.
5. Install the Software Developer Kit, if you need to use any of the utilities that it provides, such as the javaccompiler, the jarutility or the jarsinger utility. The Java 2 Development Kit that IBM provides has two components, Java Runtime Environment (JRE) and a complete Software Developer Kit (SDK). The JRE sub feature is selected by default when the J2EE or Thin application client feature is selected. The SDK component is optional; however, you must install the SDK component to compile the sample.
6. Enter the host name of the WebSphere Application Server machine. Click **Next** to continue. The default port number for product Version 6 server is 2809.
7. Review the summary information, and click **Next** to install the product code or you might also click **Back** to change your specifications.
8. Click **Finish** to exit the wizard, after the Application Client installs.
9. Verify the success of the installer program by examining the Completion panel and the `<`*`install_root`*`>/logs/WAS.Client.isntall.log` file for installation status. The installer program records the following indicators of success in the logs:
   - `INSTCONFSUCCESS` indicates that the installation is successful and that no further log analysis is required.
   - `INSTCONFFAILED` indicates an installation failure that you cannot retry or recover from without reinstalling.

You successfully installed the Application Client for WebSphere Application Server and the features you selected.

If the installation is not successful, fix the error as indicated in the installation error message. For example, if you do not have enough disk space, add more space, and reinstall the Application Client.

Best practices for installing application clients

The following table offers tips for installing application clients on multiple platforms.

Operating environment	Tip
Linux and UNIX systems	Spaces are not supported in the name of the installation directory on Linux and UNIX platforms.
UNIX systems	When the application client installations are successful, the return code `1` is issued from the UNIX shell where you issued the `/install` command. Any other return code indicates an unsuccessful installation.
Solaris systems	Double-byte character set (DBCS) characters are not supported in the name of the installation directory on Solaris systems.
All platforms	Reserve at least 4 to 5MB free space in the target platform temporary directory.

All platforms	When specifying a different temporary directory while installing application clients, the following message is displayed if the target platform default temporary directory does not have enough free space to install application clients:
	`Error writing file =  There may not be enough`
	`temporary disk space.`
	`Try using -is:tempdir to use a temporary`
	`directory on a partition with more disk`
	`space.`
	Use the `-is:tempdir` installation option to specify a different temporary directory. For example, the following command uses `/swap` as a temporary directory during installation:
	`./install -is:tempdir /swap`

All platforms	After the installation, when changing the installation settings for the WebSphere Application Server host name and the port number, edit the `setupClient.bat` for Windows or `setupClient.sh` for UNIX. Change the `DEFAULTSERVERNAME` and `SERVERPORTNUMBER` to the new WebSphere Application Server host name and port number, respectively. If the `SERVERPORTNUMBER` is not set, then the default is 2809. Review the following example:
	`set DEFAULTSERVERNAME=NDServerName`
	`set SERVERPORTNUMBER=9810`
	The `setupClient.bat` file or `setupClient.sh` file is located in the `bin` sub-directory under the application clients installation destination.

Installing application clients silently

Use these steps to perform a silent installation, which uses the installation wizard to install the product. Instead of displaying a user interface, the silent installation provides interaction between you and the wizard by reading all of your responses from a file that you must customize.

1. Verify that the user ID that you are using to run the silent installation has sufficient authority to perform the task.
2. Customize the option response file.
   a. Locate the sample options response file. The file name is `setup.response` in the operating system platform directory on the product CD-ROM.
   b. Make a copy to preserve the original response file. For example, copy the file as `myoptionsfile`.
   c. Edit the copy in your flat file editor of choice, on the target operating system. Read the directions within the response file to choose appropriate values.

   Note: To prepare the file for a silent installation on AIX, use UNIX line-end characters (0x0D0A) to terminate each line of the options response file.

   d. Make a non-commented option to have a silent install.
   e. Include custom option responses that reflect parameters for your system.
   f. Follow the instructions in the response file to choose appropriate values.
   g. Save the file.

3. Issue a command to use your custom response file: `Install.exe -options myoptionsfile` for Windows platforms and `install -options ./myoptionsfile` for Linux and UNIX platforms.

   The sample options response file is located in the `operating-system platform` directory on the product CD-ROM.

   a. Issue the following command from a command prompt to update your response file: `-W silentInstallLicenseAcceptance.value=″true’`.

      Issuing this command changes the value for `silentInstallLicenseAcceptance.value` from `false` to `true`, which is necessary for installing application clients.

4. **Optional:** Restart your machine in response to the prompt that appears on Windows platforms when the installation is complete.

You installed application clients silently by using the response file.

To verify the silent install, look for the string `RC=INSTCONFSUCCESS` in the log file for successful installation and `RC=INSTCONFFAILED` for a failed install installation.

For UNIX platforms, the install command returns a return code of **1** to indicate a successful installation. Any other return code means that the installation failed.

Uninstalling Application Client for WebSphere Application Server

This task describes using the uninstaller program to uninstall the Application Client for WebSphere Application Server.

Before uninstalling, verify that you have no open Web browsers that are accessing the administrative console.

If you want to uninstall Application Clients manually, see the topic, ″Manually uninstalling on a Windows system″ in the information center.

1. Stop any browsers and any Java processes related to WebSphere Application Server products as described in ″Uninstalling the product″ in the information center.

2. Change directories to the `_uninst` directory before issuing the uninstall command. The command file is located in the *install_root*`/product/_uninst` directory on a Linux or UNIX platform, and in the *install_root*`\product\_uninst` directory on a Windows system.

   For example, to change directories before uninstalling the product from a Linux platform, issue this command if your installation root is `/opt/IBM/WebSphere/AppServer`:

   ```
   cd /opt/IBM/WebSphere/AppServer/product/_uninst
   ```

3. Issue the **uninstaller** command. The command file is named `uninstaller.bin` for Linux and UNIX platforms and `uninstaller.exe` on Windows platforms.

   Linux UNIX On Linux and UNIX platforms, issue the **uninstaller.bin** command from the *install_root*`/product/_uninst` directory:

   ```
   ./uninstaller.bin
   ```

   Windows On Windows platforms, call the **uninstaller.exe** command:

   ```
   install_root\product\_uninst\uninstaller.exe
   ```

Windows Call the program directly from the *install_root*\product_uninst directory. For example, if the installation root is C:\IBM\WebSphere\AppServer, issue the following command:

```
C:\IBM\WebSphere\AppServer\product\_uninst> uninstaller.exe
```

The Uninstaller wizard begins and displays the Welcome panel.

4. Click **Next** to begin uninstalling the product. The Uninstaller wizard displays a Confirmation panel that lists the product and features that you are uninstalling.
5. Click **Next** to continue uninstalling the product. The Uninstaller wizard deletes existing profiles first.

   After deleting profiles, the Uninstaller wizard deletes core product files by component.
6. Click **Finish** to close the wizard after the wizard removes the product.

Application Client for WebSphere Application Server is uninstalled.

Verify the uninstall procedure by viewing the *install_root*/product/logs/uninstlog.txt log file for errors. Look for the INSTCONFSUCCESS, indicating a successful uninstall in the log file:

```
Uninstall, com.ibm.ws.install.ni.ismp.actions.ISMPLogSuccessMessageAction, msg1,
   INSTCONFSUCCESS
```

Deploying J2EE application clients on workstation platforms

After developing an application client, deploy this application on client machines. *Deployment* consists of pulling together the various artifacts that the application client requires.

The *Application Client Resource Configuration Tool* (ACRCT) defines resources for the application client. These configurations are stored in the client .jar file within the application .ear file. The application client run time uses these configurations for resolving and creating an instance of the resources for the application client.

Note: This task only applies to J2EE application clients. Only perform this task if you configured your J2EE application client to use resource references.

1. Start the ACRCT and open an EAR file.
2. Configure new data source providers.
3. Configure mail providers and sessions.
4. Configure URL providers and sessions.
5. Configure Java messaging resources.
6. Configure new environment entries.
7. (Optional) Remove application client resources.
8. Save the EAR file.

Resource Adapters for the client

A resource adapter is a system-level software driver that a Java application uses to connect to an enterprise information system (EIS). A resource adapter plugs into an application client and provides connectivity between the EIS and the enterprise application.

The resource adapter support for the J2EE client applications is a subset of the support for the server. For any resource adapter installed using the clientRAR tool, the client resource adapter is used in a non-managed environment and must conform to the J2EE Connector Architecture Specification Version 1.5 or higher. Only outbound connections to the EIS are supported through the ManagedConnectionFactory interfaces. The inbound messaging support (from the EIS), life cycle management, and work management aspects of the specification are not supported on the client.

For a client application to use a resource adapter, it must be installed in the directory specified by the environment variable, CLIENT_CONNECTOR_INSTALL_ROOT, defined when the setupCmdLine.bat command (on Windows systems) or setupCmdLine.sh (on UNIX platforms) command runs. The launchClient tool, Application Client Resource Configuration Tool (ACRCT) and clientRAR tool all use this variable to find the default location of all installed resource adapters. To install a resource adapter in the client, use the clientRAR tool. Once the resource adapter is installed, it must be configured using the ACRCT. The client configuration tool adds the resource adapter configuration to the EAR file. Then, connection factories and administered objects are defined.

When running J2EE application clients, the `launchClient` script specifies a system property called `com.ibm.ws.client.installedConnector`, which is set to the same value as the `CLIENT_CONNECTOR_INSTALL_ROOT` variable. This is the default location for installed resource adapters and can be overridden for each `launchClient` call by specifying the `-CCD` parameter. When the client container is activated, all resource adapter subdirectories under the specified default location for the resource adapters directory are added to the classpath. This action allows the client application to use the resource adapters without using the ACRCT to specify any of the client resources.

Using resource adapters is a new mechanism for easily extending client applications.

Configuring resource adapters

1. Start the Application Client Resource Configuration Tool (ACRCT).
2. Open the EAR file for which you want to configure new resource adapters. The EAR file contents display in a tree view.
3. Select the JAR file in which you want to configure the new resource adapters from the tree.
4. Expand the JAR file to view its contents.
5. Right-click the **Resource Adapters** folder, and click **New**.
6. Configure the resource adapter settings in the resulting property dialog.
7. Click **OK**.
8. Click **File** > **Save** on the menu bar to save your changes.

Resource adapter settings:

Use this panel to view or change the configuration properties of the resource adapter. These configuration properties control how resource adapters are created.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Resource Adapter**. Right-click **Resource Adapter** and click **New**. The following fields appear on the **General** tab.

Name:

The name by which this Resource Adapter is known for administrative purposes within IBM WebSphere Application Server. The name must be unique within the Resource Adapters across the product administrative domain.

Data type	String

Description:

A description of this resource adapter for administrative purposes within IBM WebSphere Application Server.

Data type	String

Class Path:

Any additional class path. The path to the resource adapter directory is automatically added.

Data type	String
Default	The path to your Resource Adapter directory.

Native Path:

The native path where the Resource Adapter is located. Enter any additional native class path here.

Data type	String

Resource Adapter Name:

A mandatory field that points to an installed resource adapter subdirectory. The entry does not represent the full directory name for the resource adapter. The full directory name is the installed resource adapter path, plus the resource adapter name.

Data type	String

Installed Resource Adapter Path:

The directory where resource adapters are installed. If you do not complete this field, then the default takes effect.

If you specify the value, `${CONNECTOR_INSTALL_ROOT}`, then this value replaces the value of the `CLIENT_CONNECTOR_INSTALL_ROOT` variable on the machine on which the client application runs. This action allows the application to run easily on different machines, where the client installation might be in different locations.

Data type	String
Default	${CONNECTOR_INSTALL_ROOT}

clientRAR tool:

This section describes the command line syntax for the client resource adapter installation tool. If this tool is used to add or delete resource adapters on the server, then only the client can use the resource adapter. If the resource adapter is installed on the server using the wsadmin tool or the administrative console, then do not use the clientRAR tool remove it. Only resource adapters that are installed using the clientRAR tool should be removed using the clientRAR tool.

The command line invocation syntax for the `clientRAR` tool follows:

```
clientRAR [-help | -?] [-CRDcom.ibm.ws.client.installedConnectors=<dir>] <task> <archive>

where
-help, -?
Print the usage information.
-CRDcom.ibm.ws.client.installedConnectors
The directory where resource adapters are installed.
This will override the system property of the same name (com.ibm.ws.client.installedConnectors).

<task>
The task to perform: add - install, delete - uninstall.
```

```
<archive>
if task=add then this is the fully qualified name of the resource adapter archive file.
If task=delete then this is the filename of the resource adapter archive to be uninstalled.
```

The following examples demonstrate correct syntax.

On the Windows operating systems:

- clientRAR add c:\rars\myrar.rar
- clientRAR delete myrar.rar

On the UNIX operating systems:

- ./clientRAR add /usr/rars/myrar.rar
- ./clientRAR delete myrar.rar

Configuring new connection factories for resource adapters:

Complete this task to configure new connection factories for resource adapters.

1. Start the Application Client Resource Configuration Tool (ACRCT).
2. Open the EAR file for which you want to configure new connection factories. The EAR file contents display in a tree view.
3. Select the JAR file in which you want to configure the new connection factories from the tree.
4. Expand the JAR file to view its contents.
5. Click the **Resource Adapters** folder.
6. Expand the resource adapter for which you want to create connection factories.
7. Right-click the **Connection Factories** folder and click **New**.
8. Configure the connection factory properties in the resulting property dialog.
9. Click **OK**.
10. Click **File** > **Save** on the menu bar to save your changes.

Resource adapter connection factory settings:

Use this panel to view or change the configuration properties of the selected resource adapter connection factory.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Resource Adapters**. Right-click the **Connection Factories** folder, and click **New**. The following fields appear on the **General** tab.

Name:

The name by which this connection factory is known for administrative purposes within WebSphere Application Server. The name must be unique within the resource adapter connection factories across the product administrative domain.

Data type	String

Description:

An optional description of this connection factory for administrative purposes within IBM WebSphere Application Server.

Data type	String

JNDI Name:

The JNDI name that is used to match this resource adapter connection factory definition to the deployment descriptor. This entry should be a `resource-ref` name.

Data type	String

User Name:

The **User Name** used, with the **Password** property, for authentication if the calling application does not provide a `userid` and `password` explicitly when getting a connection. If this field is used, then the Properties field `UserName` is ignored.

If you specify a value for the **User Name** property, you must also specify a value for the **Password** property.

The connection factory **User Name** and **Password** properties are used if the calling application does not provide a `userid` and `password` explicitly when getting a connection.

Data type	String

Password:

Specifies an encrypted password. If you complete this field, then the **Password** field in the Properties box is ignored.

If you specify a value for the **UserName** property, you must also specify a value for the **Password** property.

Data type	String

Re-Enter Password:

Confirms the password.

Type:

A drop-down list of all the `connectionFactoryInterfaces` as defined for the factories in the Resource Adapter Archive.

For each **Type**, there is a set of properties specified in the Properties box. This set of properties is constructed by retrieving the properties from each connection definition object. For any existing connection factories that are displayed for updating, this list of properties is overlaid with the properties specified for the objects. When the **Type** field is changed, the properties also change to reflect the correct properties for that type.

Data type	String

Configuring administered objects:

Before you configure new administered objects, you must complete the following prerequisites:

1. Install the Resource Adapter Archive file (RAR) using the clientRAR tool.
2. Configure the resource adapter for the `.ear` file, using the Application Client Resource Configuration Tool (ACRCT) tool.

Complete this task to configure new administered objects for installed resource adapters.

1. Start the Application Client Resource Configuration Tool (ACRCT).
2. Open the EAR file for which you want to configure new administered objects. The EAR file contents display in a tree view.
3. Select the JAR file in which you want to configure the new administered objects from the tree.
4. Expand the JAR file to view its contents.
5. Click the **Resource Adapters** folder.
6. Expand the resource adapter for which you want to create administered objects.
7. Right-click the **Administered Objects** folder and click **New**.
8. Configure the administered object properties in the resulting property dialog.
9. Click **OK**.
10. Click **File** > **Save** on the menu bar to save your changes.

Administered objects settings:

Use this panel to view or change the configuration properties of the selected administered objects.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Resource Adapters** > *resource_adapter_instance*. Right-click **Administered Objects** and click **New**. The following fields appear on the **General** tab.

The settings for administered objects are handled similarly to connection factories. When updating administered objects, use the same panels that you used to create administered objects.

Name:

The name by which this administered object is known for administrative purposes within IBM WebSphere Application Server. The name must be unique within the resource adapter administered objects across the product administrative domain.

Data type	String

Description:

An optional description of this connection factory for administrative purposes within IBM WebSphere Application Server.

Data type	String

JNDI Name:

This entry is a `resource-env-ref` name, a `message-destination-ref` name (if the `message-destination-ref` has no link), or a `message-destination` link.

Data type	String

Type:

A drop-down list of all the administered object class-interface pairs as defined for the admin objects in the Resource Adapter Archive (RAR) file.

For each **Type**, there is a set of properties specified in the Properties box. This set of properties is constructed by retrieving the properties from each administered object definition. For any existing administered objects that are displayed for updating, this list of properties is overlaid with the properties specified for the objects. When the **Type** field is changed, the properties also change to reflect the correct properties for that type.

Data type	String

Starting the Application Client Resource Configuration Tool and opening an EAR file

Note: This task only applies to J2EE application clients.

Use these steps to start the Application Client Resource Configuration Tool. When you start the tool, one of the most common tasks that you perform is opening and modifying the components of EAR files.

1. Open a command prompt and change to the `install_root\bin` directory.
2. Run the `clientConfig.bat` file for a Windows system or the `clientConfig.sh` file for a UNIX system.
3. Open an EAR file within the Application Client Resource Configuration Tool (ACRCT):
   - Click **File** > **Open**.
   - Select the file and click **Open**.
4. Save your changes to the file and close the tool:
   - Click **File** > **Save**.
   - Click **File** > **Exit**.

Data sources for the Application Client

WebSphere Application Server and the Application Client for WebSphere Application Server do not provide client database drivers to be used directly from a J2EE application client. If your application client accesses a database directly, you must provide the database drivers on the client machine. You might contact your database vendor to acquire client database driver code and licenses. In addition, data sources configured on the server and looked up on the client do not participate in global transactions. Instead of accessing the database directly, it is recommended that your client application use an enterprise bean. Accessing a database through an enterprise bean eliminates the need to have database drivers on the client machine, since the database access is handled by the enterprise bean running on WebSphere Application Server. For a current list of providers that are supported on WebSphere Application Server visit the Supported hardware, software, and APIs Web site:

Configuring new data source providers (JDBC providers) for application clients

During this task, you create new data source providers, also known as JDBC providers, for your application client. In a separate administrative task, install the Java code for the required data source provider on the client machine on which the application client resides.

Use this task to connect application clients to relational databases.

1. Start the Application Client Resource Configuration Tool (ACRCT) and open the EAR file for which you want to configure the new data source provider. The EAR file contents display in a tree view.
2. Select the JAR file in which you want to configure the new data source provider from the tree.
3. Expand the JAR file to view its contents.
4. Click the **Data Source Providers** folder. Do one of the following:
   - Right-click the folder and click **New Provider**.
   - Click **Edit > New** on the menu bar.
5. Configure the data source provider properties in the resulting property dialog.
6. Click **OK** when you finish.
7. Click **File > Save** on the menu bar to save your changes.

Example: Configuring data source provider and data source settings: The purpose of this article is to help you to configure data source provider and data source settings.

- Required fields:
  - Data Source Provider Properties page: name
  - Data Source Properties page: name, jndiName
- Special cases:
  - The user name and password fields have no equivalent XMI tags. You must specify these fields in the custom properties.
  - The password is encrypted when you use the Application Client Resource Configuration Tool (ACRCT). If you do not use the ACRCT the field cannot be encrypted.
- Example:

```
<resources.jdbc:JDBCProvider xmi:id="JDBCProvider_1" name="jdbcProvider:name"
description="jdbcProvider:description" implementationClassName="jdbcProvider:
ImplementationClass">
<classpath>jdbcProvider:classPath</classpath>
<factories xmi:type="resources.jdbc:WAS40DataSource" xmi:id="WAS40DataSource_1"
name="jdbcFactory:name" jndiName="jdbcFactory:jndiName"
description="jdbcFactory:description" databaseName="jdbcFactory:databasename">
<propertySet xmi:id="J2EEResourcePropertySet_13">
<resourceProperties xmi:id="J2EEResourceProperty_13" name="jdbcFactory:customName"
value="jdbcFactory:customValue"/>
<resourceProperties xmi:id="J2EEResourceProperty_14" name="user"
value="jdbcFactory:user"/>
<resourceProperties xmi:id="J2EEResourceProperty_15" name="password"
value="{xor}NTs9PBk+PCswLSZlMT4yOg=="/>
</propertySet>
</factories>
<propertySet xmi:id="J2EEResourcePropertySet_14">
<resourceProperties xmi:id="J2EEResourceProperty_16" name="jdbcProvider:customName"
value="jdbcProvider:customeValue"/>
</propertySet>
</resources.jdbc:JDBCProvider>
```

Data source provider settings for application clients:

Use this page to create a data source under a JDBC provider which provides the specific JDBC driver implementation class.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file. Right-click **Data Source Providers** > and click **New**. The following fields appear on the **General** tab:

Name:

Specifies the display name for the data source.

For example you can set this field to *Test Data Source*.

Data type	String

Description:

Specifies a text description for the resource.

Data type	String

Class Path:

A list of paths or `.jar` file names which together form the location for the resource provider classes.

Implementation class:

Use this setting to perform database specific functions.

Data type	String
Default	Dependent on JDBC driver implementation class

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Data source properties for application clients:

Use this page to create or modify the data sources.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Data Source Providers** > *Data source provider instance*. Right-click **Data Sources** and click **New**. The following fields are displayed on the **General** tab:

Name:

Specifies the display name of this data source.

Data type	String

Description:

Specifies a text description of the data source.

Data type	String

JNDI Name:

The application client run time uses this field to retrieve configuration information.

Database Name:

The name of the database to which you want to connect.

User:

Use the user ID with the Password property, for authentication if the calling application does not provide a user ID and password explicitly.

If you specify a value for the User ID property, then you must also specify a value for the Password property. The connection factory User ID and Password properties are used if the calling application does not provide a user ID and password explicitly.

Password:

Use the password with the User ID property, for authentication if the calling application does not provide a user ID and password explicitly.

If you specify a value for the Password property, then you must also specify a value for the User ID property.

Re-Enter Password:

Confirms the password.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Configuring new data sources for application clients

During this task, you create new data sources for your application client.

1. Click the data source provider for which you want to create a data source in the tree. Take one of the following actions as needed:
   - Configure a new data source provider.
   - Click an existing data source provider.
2. Expand the data source provider to view its **Data Sources** folder.
3. Click the data source folder. Take one of the following actions as needed:
   - Right click the data source folder and click **New Factory**.
   - Click **Edit > New** on the menu bar.
4. Configure the data source properties in the displayed fields.
5. Click **OK** when you finish.
6. Click **File > Save** on the menu bar to save your changes.

Configuring mail providers and sessions for application clients

Use the Application Client Resource Configuration Tool (ACRCT) to edit the configurations of JavaMail sessions and providers for your application clients to use.

1. Start the ACRCT.
2. Open an EAR file.
3. Locate the JavaMail objects in the tree that displays. For example, if your file contains JavaMail sessions, expand **Resources** > ***application*.jar** > **JavaMail Providers** > ***java_mail_provider_instance*** > **JavaMail Sessions**.

   In this example, ***java_mail_provider_instance*** is a particular JavaMail provider.

The JavaMail session instances are located in the **JavaMail Sessions** folder.

Mail provider settings for application clients:

Use this page to implement the JavaMail API and create mail sessions.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file. Right-click **Mail Providers** > and click **New**. The following fields appear on the **General** tab:

Name:

The name of the JavaMail resource provider.

Description:

An optional description for the resource provider.

Class Path:

Specifies a list of paths or JAR file names which together form the location for the resource provider classes.

Protocol:

Specifies the name of the protocol.

Classname:

Specifies the name of the class implementing the protocol. Leave this field blank if you want to use the default implementation.

Type:

This menu contains the following two values: `TRANSPORT` or `STORE`.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Mail session settings for application clients:

Use this page to configure mail session properties.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Mail Providers** > *mail provider instance*. Right-click **Mail Sessions** and click **New**. The following fields appear on the **General** tab:

Name:

Represents the administrative name of the JavaMail session object.

Description:

Provides an optional description for your administrative records.

JNDI Name:

The application client run time uses this field to retrieve configuration information.

Mail Transport Host:

Specifies the server to connect to when sending mail.

Mail Transport Protocol:

Specifies the transport protocol to use when sending mail.

Mail Transport User:

Specifies the user ID to use when the mail transport host requires authentication.

Mail Transport Password:

Specifies the password to use when the mail transport host requires authentication.

Enable strict Internet address parsing:

Specifies whether the recipient addresses must be parsed strictly in compliance with RFC 822, which is a specifications document issued by the Internet Architecture Board.

This setting is not generally used for most mail applications. RFC 822 syntax for parsing addresses effectively enforces a strict definition of a valid e-mail address. If you select this setting, JavaMail will adhere to RFC 822 syntax and reject recipient addresses that do not parse into valid e-mail addresses (as defined by the specification). If you do not select this setting, JavaMail will not adhere to RFC 822 syntax and will accept recipient addresses that do not comply with the specification. By default, this setting is deselected. You can view the RFC 822 specification at the following URL for the World Wide Web Consortium (W3C): http://www.w3.org/Protocols/rfc822/.

Re-Enter Password:

Confirms the password.

Mail From:

Specifies the mail originator.

Mail Store Host:

Specifies the mail account host (or ″domain″) name.

Mail Store User:

Specifies the user ID of the mail account.

Mail Store Password:

Specifies the password of the mail account.

Re-Enter Password:

Confirms the password.

Mail Store Protocol:

Specifies the protocol to be used when receiving mail.

Mail Debug:

When `true`, JavaMail interaction with mail servers, along with these mail session properties are printed to the `stdout` file.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Example: Configuring JavaMail provider and JavaMail session settings for application clients: The purpose of this article is to help you configure JavaMail provider and JavaMail session settings.

- Required fields:
  - JavaMail Provider Properties page: name, and at least one protocol provider
  - JavaMail Session Properties page: name, jndiName, mail transport protocol, mail store protocol
- Special cases:
  - The password is encrypted when using the ACRCT tool. Without the tool, you cannot encrypt this field.
- Example:

```
<resources.mail:MailProvider xmi:id="MailProvider_1" name="Default Mail Provider"
description="IBM JavaMail Implementation">
<classpath>mailProvider:classpath</classpath>
<factories xmi:type="resources.mail:MailSession" xmi:id="MailSession_1"
name="mailSession:name" jndiName="mailSession:jndiName"
description="mailSession:description" mailTransportHost="mailSession:mailTransportHost"
mailTransportUser="mailSession:mailTransportUser"
mailTransportPassword="{xor}Mj42Mww6LCw2MDFlMT4yOg=="
mailFrom="mailSession:mailFrom" mailStoreHost="mailSession:mailStoreHost"
mailStoreUser="mailSession:mailStoreUser"
mailStorePassword="{xor}Mj42Mww6LCw2MDFlMT4yOg==" debug="true"
mailTransportProtocol="ProtocolProvider_1" mailStoreProvider="ProtocolProvider_1">
<propertySet xmi:id="J2EEResourcePropertySet_1">
<resourceProperties xmi:id="J2EEResourceProperty_1"
name="mailSession:customName" value="mailSession:customValue"/>
</propertySet>
</factories>
<propertySet xmi:id="J2EEResourcePropertySet_2">
<resourceProperties xmi:id="J2EEResourceProperty_2" name="mailProvider:customName"
value="mailProvider:customValue"/>
</propertySet>
<protocolProviders xmi:id="ProtocolProvider_1" protocol="smtp"
classname="smtp:className"/>
<protocolProviders xmi:id="ProtocolProvider_2" protocol="pop3"
classname="pop3:className"/>
<protocolProviders xmi:id="ProtocolProvider_3" protocol="imap"
classname="imap:className"/>
</resources.mail:MailProvider>
```

Configuring new mail sessions for application clients

During this task, you configure new mail sessions for your application client. The mail sessions are associated with the pre-configured default mail provider supplied by the product.

1. Start the Application Client Resource Configuration Tool (ACRCT) and open the EAR file. The EAR file contents are displayed in a tree view.

2. Select the JAR file in which you want to configure the new JavaMail session.
3. Expand the JAR file to view its contents.
4. Click **JavaMail Providers** > **MailProvider** > **JavaMail Sessions**. Complete one of the following actions:
   - Right click the **JavaMail Sessions** folder and select **New Factory**.
   - Click **Edit** > **New** on the menu bar.
5. Configure the JavaMail session properties in the displayed fields.
6. Click **OK**.
7. Click **File** > **Save** on the menu bar to save your changes.

URLs for application clients

A *Uniform Resource Locator* (URL) is an identifier that points to an electronically accessible resource, such as a directory file on a machine in a network, or a document stored in a database.

URLs appear in the format *scheme*:*scheme_information*.

You can represent a *scheme* as `http`, `ftp`, `file`, or another term that identifies the type of resource and the mechanism by which you can access the resource.

In a World Wide Web browser location or address box, a URL for a file available using HyperText Transfer Protocol (HTTP) starts with `http:`. An example is `http://www.ibm.com`. Files available using File Transfer Protocol (FTP) start with `ftp:`. Files available locally start with `file:`.

The *scheme_information* commonly identifies the Internet machine making a resource available, the path to that resource, and the resource name. The scheme_information for HTTP, FTP and File generally starts with two slashes (//), then provides the Internet address separated from the resource path name with one slash (/). For example,

`http://www-4.ibm.com/software/webservers/appserv/library.html`.

For HTTP and FTP, the path name ends in a slash when the URL points to a directory. In such cases, the server generally returns the default index for the directory.

URL providers for the Application Client Resource Configuration Tool

A URL provider implements the function for a particular URL protocol, such as Hyper Text Transfer Protocol (HTTP). This provider, comprised of a pair of classes, extends the `java.net.URLStreamHandler` and `java.net.URLConnection` classes.

Configuring new URL providers for application clients

During this task, you create URL providers and URLs for your client application. In a separate administrative task, you must install the Java code for the required URL provider on the client machine on which the client application resides.

1. Start the Application Client Resource Configuration Tool (ACRCT).
2. Open the EAR file for which you want to configure the new URL provider. The EAR file contents display in a tree view.
3. Select the JAR file in which you want to configure the new URL provider from the tree.
4. Expand the JAR file to view the contents.
5. Click the folder called **URL Providers**. Complete one of the following actions:
   - Right click the folder and select **New Provider**.
   - Click **Edit** > **New** on the menu bar.
6. Configure the URL provider properties in the resulting property dialog.
7. Click **OK**.

8. Click **File** > **Save** on the menu bar to save your changes.

Configuring URL providers and sessions using the Application Client Resource Configuration Tool:

Use the Application Client Resource Configuration Tool (ACRCT) to edit the configurations of URL providers and URLs to be used by your application clients.

1. Start the ACRCT.
2. Open an EAR file.
3. Locate the URL objects in the tree that displays. For example, if your file contains URL providers and URLs, expand **Resources** -> ***application*.jar** -> **URL Providers** -> ***url_provider_instance***

   where ***url_provider_instance*** is a particular URL provider.
4. If you expand the tree further, you will also see the **URLs** folders containing the URL instances for each URL provider instance.

URL settings for application clients:

Use this page to implement the function for a particular URL protocol, such as Hyper Text Transfer Protocol (HTTP).

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **URL Providers** > *URL provider instance*. Right-click **URLs** and click **New**. The following fields appear on the **General** tab.

This provider, comprised of classes, extends the `java.net.URLStreamHandler` and `java.net.URLConnection` classes.

Name:

The administrative name for the URL.

Description:

This is an optional description of the URL for your administrative records.

JNDI Name:

The application client run time uses this field to retrieve configuration information.

URL:

A Uniform Resource Locator (URL) name that points to an Internet or intranet resource. For example: `http://www.ibm.com`.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

URL provider settings for application clients:

Use this page create new URL providers.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file. Right click **URL Providers**, and click **New**. The following fields appear on the **General** tab.

A URL provider implements the function for a particular URL protocol, such as Hyper Text Transfer Protocol (HTTP). This provider, comprised of classes, extends the `java.net.URLStreamHandler` and `java.net.URLConnection` classes.

Name:

Administrative name for the URL.

Description:

Optional description of the URL, for your administrative records.

Class Path:

A list of paths or JAR file names which together form the location for the resource provider classes.

Protocol:

Protocol supported by this stream handler. For example, `nntp`, `smtp`, `ftp`, and so on.

To use the default protocol, leave this field blank.

Stream handler class:

Fully qualified name of a User-defined Java class that extends the `java.net.URLStreamHandler` for a particular URL protocol, such as FTP.

To use the default stream handler, leave this field blank.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Example: Configuring URL and URL provider settings for application clients: The purpose of this article is to help you to configure URL and URL provider settings.

- Required fields:
  - URL Properties page: name, jndiName, url
  - URL Provider Properties page: name
- Example:

```
<resources.url:URLProvider xmi:id="URLProvider_1" name="urlProvider:name"
description="urlProvider:description"
streamHandlerClassName="urlProvider:streamHandlerClass"
protocol="urlProvider:protocol">
<classpath>urlProvider:classpath</classpath>
<factories xmi:type="resources.url:URL" xmi:id="URL_1" name="urlFactory:name"
jndiName="urlFactory:jndiName" description="urlFactory:description"
spec="urlFactory:url">
```

```
<propertySet xmi:id="J2EEResourcePropertySet_18">
<resourceProperties xmi:id="J2EEResourceProperty_20" name="urlFactory:customName"
value="urlFactory:customValue"/>
</propertySet>
</factories>
<propertySet xmi:id="J2EEResourcePropertySet_19">
<resourceProperties xmi:id="J2EEResourceProperty_21" name="urlProvider:customName"
value="urlProvider:customValue"/>
</propertySet>
</resources.url:URLProvider>
```

Configuring new URLs with the Application Client Resource Configuration Tool

During this task, you create URLs for your client application.

1. Click the URL provider for which you want to create a URL in the tree. Do one of the following:
   - Configure a new URL provider.
   - Click an existing URL provider.
2. Expand the URL provider to view the **URLs** folder.
3. Click the URL folder. Complete one of the following actions:
   - Right click the folder and click **New Factory**.
   - Click **Edit -> New** on the menu bar.
4. Configure the URL properties in the displayed fields.
5. Click **OK** when you finish.
6. Click **File** > **Save** in the menu bar to save your changes.

WebSphere asynchronous messaging using the Java Message Service API for the Application Client Resource Configuration Tool

WebSphere Application Server supports asynchronous messaging as a method of communication based on the Java Message Service (JMS) programming interface. The JMS interface provides a common way for Java programs (clients and J2EE applications) to create, send, receive, and read asynchronous requests as JMS messages.

This topic provides an overview of asynchronous messaging using JMS support provided by the WebSphere Application Server.

The base support for asynchronous messaging using the JMS API provides the common set of JMS interfaces and associated semantics that define how a JMS client can access the facilities of a JMS provider. This support enables WebSphere product J2EE applications, as JMS clients, to exchange messages asynchronously with other JMS clients, by using JMS destinations (queues or topics). A J2EE application can use JMS queue destinations for point-to-point messaging and JMS topic destinations for Publisher and Subscriber messaging. A J2EE application can explicitly poll for messages on a destination, and then retrieve messages for processing by business logic beans (enterprise beans).

With the base JMS and XA support, the J2EE application uses standard JMS calls to process messages, including any responses or outbound messaging. An enterprise bean can handle responses acting as a sender bean, or within the enterprise bean that receives the incoming messages. Optionally, this process can use two-phase commit within the scope of a transaction. This level of function for asynchronous messaging is called *bean-managed messaging*, and gives an enterprise bean complete control over the messaging infrastructure, for example, connection and session pool management. The common container has no role in bean-managed messaging.

WebSphere Application Server also supports automatic asynchronous messaging using message-driven beans (a type of enterprise bean defined in the EJB 2.0 specification) and JMS listeners (part of the JMS application server facilities). Messages are automatically retrieved from JMS destinations, optionally within a transaction, then sent to the message-driven bean in a J2EE application, without the application having to explicitly poll JMS destinations.

Java Message Service (JMS) providers for clients

This topic describes the different ways that client applications can use JMS providers with WebSphere Application Server. A JMS provider enables use of the Java Message Service (JMS) and other message resources in WebSphere Application Server.

IBM WebSphere Application Server supports asynchronous messaging through the use of a JMS provider and its related messaging system. JMS providers must conform to the JMS specification version 1.1. To use message-driven beans the JMS provider must support the optional Application Server Facility (ASF) function defined within that specification, or support an inbound resource adapter as defined in the JCA specification version 1.5.

The service integration technologies of IBM WebSphere Application Server can act as a messaging system when you have configured a service integration bus that is accessed through the default messaging provider. This support is installed as part of WebSphere Application Server, administered through the administrative console, and is fully integrated with the WebSphere Application Server runtime.

WebSphere Application Server also includes support for the following JMS providers:

WebSphere MQ
Provided for use with supported versions of WebSphere MQ.

Generic
Provided for use with any 3rd party messaging system which supports ASF.

For backwards compatibility with earlier releases, WebSphere Application Server also includes support for the V5 default messaging provider which enables you to configure resources for use with the WebSphere Application Server version 5 Embedded Messaging system. The V5 default messaging provider can also be used with a service integration bus.

WebSphere applications can use messaging resources provided by any of these JMS providers. However the choice of provider is most often dictated by requirements to use or integrate with an existing messaging system. For example, you may already have a messaging infrastructure based on WebSphere MQ. In this case you may either connect directly using the included support for WebSphere MQ as a JMS provider, or configure a service integration bus with links to a WebSphere MQ network and then access the bus through the default messaging provider.

Configuring Java messaging client resources

In a separate administrative task, install the Java Message Service (JMS) client on the client machine where the application client resides. The messaging product vendor must provide an implementation of the JMS client. For more information, see your messaging product documentation.

During this task, you create new JMS provider configurations for your application client. The application client can use a messaging service through the Java Message Service APIs. A JMS provider provides two kinds of J2EE factories. One is a *JMS connection factory*, and the other is a *JMS destination factory*.

1. Start the Application Client Resource Configuration Tool (ACRCT).
2. Open the EAR file for which you want to configure the new JMS provider. The EAR file contents are in the displayed tree view.
3. Select the JAR file in which you want to configure the new JMS provider from the tree.
4. Expand the JAR file to view its contents.
5. Right-click **Messaging Providers** and select **New**.
6. Configure the JMS provider properties in the resulting property dialog.
7. Click **OK**.
8. Click **File** > **Save**.

Configuring new JMS providers with the Application Client Resource Configuration Tool:

During this task, you create new Java Message Service (JMS) provider configurations for the Application Client. The Application Client makes use of a messaging service through the JMS interfaces. A JMS provider provides two kinds of J2EE resources. One is a JMS connection factory, and the other is a JMS destination.

In a separate administrative task, you must install the JMS client on the client machine where your particular application client resides. The messaging product vendor must provide an implementation of the JMS client. For more information, see your messaging product documentation.

1. Start the Application Client Resource Configuration Tool and open the EAR file for which you want to configure the new JMS provider. The EAR file contents are displayed in a tree view.
2. From the tree, select the JAR file in which you want to configure the new JMS provider.
3. Expand the JAR file to view its contents.
4. Right-click **Messaging Providers**. Complete one of the following actions:
   - Right click the folder and select **New**.
   - On the menu bar, click **Edit > New**.
5. In the resulting property dialog, configure the JMS provider properties.
6. Click **OK** when finished.
7. Click **File -> Save** on the menu bar to save your changes.

JMS provider settings for application clients:

Use this page to configure properties of the Java Message Service (JMS) provider, if you want to use a JMS provider other than the default messaging provider or the WebSphere MQ as a JMS provider.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file. Right click **Messaging Providers**, and click **New**. The following fields appear on the **General** tab.

Name:

The name by which the JMS provider is known for administrative purposes.

Data type	String

Description:

A description of the JMS provider, for administrative purposes.

Data type	String

Class Path:

A list of paths or `.jar` file names which together form the location for the resource provider classes.

Context factory class:

The Java class name of the initial context factory for the JMS provider.

For example, for an LDAP service provider the value has the form: `com.sun.jndi.ldap.LdapCtxFactory`.

Data type	String

Provider URL:

The JMS provider URL for external JNDI lookups.

For example, an LDAP URL for a JMS provider has the form: `ldap://hostname.company.com/contextName`.

Data type	String

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Default Provider connection factory settings:

Use this panel to view or change the configuration properties of the selected JMS connection factory for use with the internal product Java Message Service (JMS) provider that is installed with WebSphere Application Server. These configuration properties control how connections are created between the JMS provider and the service integration bus that it uses

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **Default Provider**. Right-click **Connection Factories** and click **New**. The following fields appear on the **General** tab.

Settings that have a default value display the appropriate value. Any settings that have fixed values have a drop down menu.

Name:

The name of the connection factory.

Data type	String

Description:

A description of this connection factory for administrative purposes within IBM WebSphere Application Server.

Data type	String

JNDI Name:

The JNDI name that is used to match this Resource Adapter connection factory definition to the deployment descriptor. This entry is a `resource-ref` name.

Data type	String

User Name:

The **User Name** used with the **Password** property for connecting to an application.

If you specify a value for the **User Name** property, you must also specify a value for the **Password** property.

The connection factory **User ID** and **Password** properties are used if the calling application does not provide a `userid` and `password` explicitly. If a user name and password are specified, then an authentication alias is created for the factory where the password is encrypted.

Data type	String

Password:

The password used to authenticate connection to an application.

If you specify a value for the **User Name** property, you must also specify a value for the **Password** property.

Data type	String

Re-Enter Password:

Confirms the password.

Bus Name:

The name of the bus to which the connection factory connects.

Data type	String

Client Identifier:

The name of the client. Required for durable topic subscriptions.

Data type	String

Nonpersistent Messaging Reliability:

The reliability applied to nonpersistent JMS messages sent using this connection factory.

If you want different reliability delivery options for individual JMS destinations, you can set this property to **As bus** destination. The reliability is then defined by the Reliability property of the bus destination to which the JMS destination is assigned.

Default	ReliablePersistent

Range

None There is no message reliability for nonpersistent messages. If a nonpersistent message cannot be delivered, it is discarded.

Best effort nonpersistent
Messages are never written to disk, and are thrown away if memory cache overruns.

Express nonpersistent
Messages are written asynchronously to persistent storage if memory cache overruns, but are not kept over server restarts.

Reliable nonpersistent
Messages can be lost if a messaging engine fails, and can be lost under normal operating conditions.

Reliable persistent
Messages can be lost if a messaging engine fails, but are not lost under normal operating conditions.

Assured persistent
Highest degree of reliability where assured message delivery is supported.

As Bus destination
Use the delivery option configured for the bus destination.

Persistent Message Reliability:

The reliability applied to persistent JMS messages sent using this connection factory.

If you want different reliability delivery options for individual JMS destinations, you can set this property to **As bus destination**. The reliability is then defined by the Reliability property of the bus destination to which the JMS destination is assigned.

Default	ReliablePersistent

Range

None There is no message reliability for nonpersistent messages. If a nonpersistent message cannot be delivered, it is discarded.

Best effort nonpersistent
Messages are never written to disk, and are thrown away if memory cache overruns.

Express nonpersistent
Messages are written asynchronously to persistent storage if memory cache overruns, but are not kept over server restarts.

Reliable nonpersistent
Messages can be lost if a messaging engine fails, and can be lost under normal operating conditions.

Reliable persistent
Messages can be lost if a messaging engine fails, but are not lost under normal operating conditions.

Assured persistent
Highest degree of reliability where assured message delivery is supported.

As Bus destination
Use the delivery option configured for the bus destination.

Durable Subscription Home:

The name of the durable subscription home.

Data type String

Share durable subscriptions:

Controls whether or not durable subscriptions are shared across connections with members of a server cluster.

Normally, only one session at a time can have a TopicSubscriber for a particular durable subscription. This property enables you to override this behavior, to enable a durable subscription to have multiple simultaneous consumers.

Data type Selection list

Default In cluster

Range

In cluster
Allows sharing of durable subscriptions when connections are made from within a server cluster.

Always shared
Durable subscriptions can be shared across connections.

Never shared
Durable subscriptions are never shared across connections.

Read Ahead:

Controls the read-ahead optimization during message delivery.

Default	Default
Range	Default, AlwaysOn and AlwaysOff

Related concepts

"Resource Adapters for the client" on page 874

Target:

The name of the Workload Manager target group containing the messaging engine.

Data type	String

Target Type:

The type of Workload Manager target group that contains the messaging engine.

Default	BusMember
Range	BusMember, Custom, ME

Target Significance:

The priority of significance for the target specified.

Default	Preferred
Range	Preferred, Required

Target Inbound Transport Chain:

The name of the protocol that resolves to a group of messaging engines.

Data type	String

Provider Endpoints:

The list of comma separated endpoints used to connect to a bootstrap server.

Type a comma-separated list of endpoint triplets with the syntax: host:port:protocol.

Example

`merlin:7276:BootstrapBasicMessaging,Gandalf:5557:BootstrapSecureMessaging`

where

`BootstrapBasicMessaging` corresponds to the remote protocol InboundBasicMessaging (JFAP-TCP/IP).

Default

- If the host name is not specified, then the default `localhost` is used as a default value.
- If the port number is not specified, then `7276` is used as a default value.
- If the chain name is not specified, a predefined chain, such as `BootstrapBasicMessaging`, is used as a default value.

Connection Proximity:

The proximity that the messaging engine should have to the requester.

Default	Bus
Range	Bus, Host, Cluster, Server

Temporary Queue Name Prefix:

The prefix to apply to the names of temporary queues. This name is a maximum of 12 characters.

Data type	String

Temporary Topic Name Prefix:

The prefix to apply to the names of temporary topics. This name is a maximum of 12 characters.

Data type	String

Default Provider queue connection factory settings:

Use this panel to view or change the configuration properties of the selected JMS queue connection factory for use with the internal product Java Message Service (JMS) provider that is installed with WebSphere Application Server. These configuration properties control how connections are created between the JMS provider and the service integration bus that it uses

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **Default Provider**. Right-click **Queue Connection Factories** and click **New**. The following fields appear on the **General** tab.

Settings that have a default value display the appropriate value. Any settings that have fixed values have a drop down menu.

Name:

The name of the queue connection factory.

Data type	String

Description:

A description of this queue connection factory for administrative purposes within IBM WebSphere Application Server.

Data type	String

JNDI Name:

The JNDI name that is used to match this queue connection factory definition to the deployment descriptor. This entry is a `resource-ref` name.

Data type	String

User Name:

The **User Name** used, with the **Password** property, for authentication if the calling application does not provide a `userid` and `password` explicitly. If this field is used, then the Properties field `UserName` is ignored.

If you specify a value for the **User Name** property, you must also specify a value for the **Password** property.

The connection factory **User Name** and **Password** properties are used if the calling application does not provide a `userid` and `password` explicitly. If a user name and password are specified, then an authentication alias is created for the factory where the password is encrypted.

Data type	String

Password:

The password used to create an encrypted. If you complete this field, then the Password field in the Properties box is ignored.

If you specify a value for the **User Name** property, you must also specify a value for the **Password** property.

Data type	String

Re-Enter Password:

Confirms the password.

Bus Name:

The name of the bus to which the queue connection factory connects.

Data type	String

Client Identifier:

The client identifier. Required for durable topic subscriptions.

Data type	String

Nonpersistent Messaging Reliability:

The reliability applied to nonpersistent JMS messages sent using this connection factory.

If you want different reliability delivery options for individual JMS destinations, you can set this property to **As bus** destination. The reliability is then defined by the Reliability property of the bus destination to which the JMS destination is assigned.

Default	ReliablePersistent

Range

None There is no message reliability for nonpersistent messages. If a nonpersistent message cannot be delivered, it is discarded.

Best effort nonpersistent
Messages are never written to disk, and are thrown away if memory cache overruns.

Express nonpersistent
Messages are written asynchronously to persistent storage if memory cache overruns, but are not kept over server restarts.

Reliable nonpersistent
Messages can be lost if a messaging engine fails, and can be lost under normal operating conditions.

Reliable persistent
Messages can be lost if a messaging engine fails, but are not lost under normal operating conditions.

Assured persistent
Highest degree of reliability where assured message delivery is supported.

As Bus destination
Use the delivery option configured for the bus destination.

Persistent Message Reliability:

The reliability applied to persistent JMS messages sent using this connection factory.

If you want different reliability delivery options for individual JMS destinations, you can set this property to **As bus destination**. The reliability is then defined by the Reliability property of the bus destination to which the JMS destination is assigned.

Default ReliablePersistent

Reliable persistent
Messages can be lost if a messaging engine fails, but are not lost under normal operating conditions.

Assured persistent
Highest degree of reliability where assured message delivery is supported.

As Bus destination
Use the delivery option configured for the bus destination.

Persistent Message Reliability:

The reliability applied to persistent JMS messages sent using this connection factory.

If you want different reliability delivery options for individual JMS destinations, you can set this property to **As bus destination**. The reliability is then defined by the Reliability property of the bus destination to which the JMS destination is assigned.

Default ReliablePersistent

Range

None There is no message reliability for nonpersistent messages. If a nonpersistent message cannot be delivered, it is discarded.

Best effort nonpersistent
Messages are never written to disk, and are thrown away if memory cache overruns.

Express nonpersistent
Messages are written asynchronously to persistent storage if memory cache overruns, but are not kept over server restarts.

Reliable nonpersistent
Messages can be lost if a messaging engine fails, and can be lost under normal operating conditions.

Reliable persistent
Messages can be lost if a messaging engine fails, but are not lost under normal operating conditions.

Assured persistent
Highest degree of reliability where assured message delivery is supported.

As Bus destination
Use the delivery option configured for the bus destination.

Durable Subscription Home:

The name of the durable subscription home.

Data type	String

Share durable subscriptions:

Controls whether or not durable subscriptions are shared across connections with members of a server cluster.

Normally, only one session at a time can have a TopicSubscriber for a particular durable subscription. This property enables you to override this behavior, to enable a durable subscription to have multiple simultaneous consumers.

Data type	Selection list
Default	In cluster

Range

In cluster
Allows sharing of durable subscriptions when connections are made from within a server cluster.

Always shared
Durable subscriptions can be shared across connections.

Never shared
Durable subscriptions are never shared across connections.

Read Ahead:

Controls the read-ahead optimization during message delivery.

Default	Default
Range	Default, AlwaysOn and AlwaysOff

Target:

The name of the Workload Manager target group containing the messaging engine.

Data type	String

Target Type:

The type of Workload Manager target group that contains the messaging engine.

Default	BusMember
Range	BusMember, Custom, ME

Target Significance:

The priority of significance for the target specified.

Default	Preferred
Range	Preferred, Required

Target Inbound Transport Chain:

The name of the protocol that resolves to a group of messaging engines.

Data type	String

Provider Endpoints:

The list of comma separated endpoints used to connect to a bootstrap server.

Type a comma-separated list of endpoint triplets with the syntax: host:port:protocol.

Example	`localhost:7777:BootstrapBasicMessaging` where `BootstrapBasicMessaging` corresponds to the remote protocol InboundBasicMessaging (JFAP-TCP/IP).
Default	• If the host name is not specified, then the default `localhost` is used as a default value. • If the port number is not specified, then `7276` is used as a default value. • If the chain name is not specified, a predefined chain, such as `BootstrapBasicMessaging`, is used as a default value.

Connection Proximity:

The proximity that the messaging engine should have to the requester.

Default	Bus
Range	Bus, Host, Cluster, Server

Temporary Topic Name Prefix:

The prefix to apply to the names of temporary topics. This name is a maximum of 12 characters.

Data type	String

Default Provider queue destination settings:

Use this panel to view or change the configuration properties of the selected JMS queue destination for use with the internal product Java Message Service (JMS) provider that is installed with WebSphere Application Server.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **Default Provider**. Right-click **Queue Destinations**. Click **New**. The following fields appear on the **General** tab.

Name:

The name of the queue destination factory. You must complete this field.

Data type	String

Description:

A description of this queue destination for administrative purposes within WebSphere Application Server.

Data type	String

JNDI Name:

The JNDI name used to match this definition to a deployment descriptor `resource-env-ref` name.

Data type	String

Queue Name:

The name of the queue.

Data type	String

Delivery Mode:

The delivery mode for messages sent to this destination.

Data type	String
Range	Application, Persistent or NonPersistent

Default	Application

Time to Live:

The default length of time from its dispatch time that a message sent to this destination should be retained by the system, where **0** indicates that time to live value does not expire. Value from the producer is used if the Time to Live field is not completed.

Data type	Integer
Units	Milliseconds

Priority:

The priority for messages sent to this destination. The value from the producer is used if not completed.

Data type	Integer
Range	0 to 9 with **0** as the lowest priority and **9** as the highest priority

Read Ahead:

Used to control read-ahead optimization during message delivery.

Data type	String
Range	AsConnection, AlwaysOn and AlwaysOff
Default	AsConnection

Default Provider topic destination settings:

Use this panel to view or change the configuration properties of the selected JMS topic destination for use with the internal product Java Message Service (JMS) provider that is installed with WebSphere Application Server.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **Default Provider**. Right-click **Topic Destinations**, and click **New**. The following fields appear on the **General** tab.

Name:

The name of the topic destination entry.

Data type	String

Description:

A description of the entry.

Data type	String

JNDI Name:

The JNDI name used to match this definition to a deployment descriptor `resource-env-ref` name.

Data type	String

Topic Space:

The name of the topic space. This field is required.

Data type	String
Default	DEFAULT_TOPIC_SPACE

Topic Name:

The name of the topic. This field is required.

Data type	String

Delivery Mode:

The default mode for messages sent to this destination.

Data type	String
Range	Application, Persistent or NonPersistent
Default	Application

Time to Live:

The default length of time from its dispatch time that a message sent to this destination should be retained by the system, where **0** indicates that time to live value does not expire. Value from the producer is used if not completed.

Data type	Long
Units	Milliseconds

Priority:

The priority for messages sent to this destination. Value from producer is used if not completed.

Data type	Integer
Range	0 to 9 with **0** as the lowest priority and **9** as the highest priority

Read Ahead:

Used to control read-ahead optimization during message delivery.

Data type	String
Range	AsConnection, AlwaysOn and AlwaysOff
Default	AsConnection

Version 5 Default Provider queue connection factory settings for application clients:

Use this panel to browse or change the configuration properties of the selected JMS queue connection factory for point-to-point messaging for use by WebSphere Application Server version 5 applications. These configuration properties control how connections are created between the JMS provider and the default messaging system that it uses.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Provider** > **Version 5 Default Provider**. Right-click **Queue Connection Factories** and click **New**. The following fields appear on the **General** tab.

A queue connection factory is used to create JMS connections to queue destinations. The queue connection factory is created by the internal WebSphere Application Server product JMS provider. A Version 5 Default Provider queue connection factory has the following properties:

Name:

The name by which this queue connection factory is known for administrative purposes within IBM WebSphere Application Server. The name must be unique within the JMS connection factories across the WebSphere administrative domain.

Data type	String

Description:

A description of this connection factory for administrative purposes within IBM WebSphere Application Server.

Data type	String
Default	Null

JNDI Name:

The application client run time uses this field to retrieve configuration information.

User ID:

The User ID used, with the **Password** property, for authentication if the calling application does not provide a `userid` and `password` explicitly.

If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.

The connection factory **User ID** and **Password** properties are used if the calling application does not provide a User ID and password explicitly, for example, if the calling application uses the method createQueueConnection(). The JMS client flows the `userid` and `password` to the JMS server.

Data type	String

Password:

The password used, with the **User ID** property, for authentication if the calling application does not provide a `userid` and `password` explicitly.

If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.

Re-Enter Password:

Confirms the password.

Node:

The WebSphere node name of the administrative node where the JMS server runs for this connection factory. Connections created by this factory connect to that JMS server.

Data type	String

Application Server:

Enter the name of the application server. This name is not the host name of the machine, but the name of the configured application server.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Version 5 Default Provider topic connection factory settings for application clients:

Use this panel to view or change the configuration properties of the selected topic connection factory for use with the internal product Java Message Service (JMS) provider. These configuration properties control how connections are created between the JMS provider and the messaging system that it uses.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **Version 5 Default Provider**. Right click **Topic Connection Factories** and click **New**. The following fields appear on the **General** tab.

A Version 5 Default Provider topic connection factory has the following properties.

Name:

The name by which this queue connection factory is known for administrative purposes within WebSphere Application Server. The name must be unique within the JMS connection factories across the WebSphere Application Server administrative domain.

Data type	String

Description:

A description of this topic connection factory for administrative purposes within WebSphere Application Server.

Data type	String

JNDI Name:

The application client run time uses this field to retrieve configuration information.

User ID:

The user ID used, with the **Password** property, for authentication if the calling application does not provide a `userid` and `password` explicitly.

If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.

The connection factory **User ID** and **Password** properties are used if the calling application does not provide a `userid` and `password` explicitly, for example, if the calling application uses the method createTopicConnection(). The JMS client flows the `userid` and `password` to the JMS server.

Data type	String

Password:

The password used, with the **User ID** property, for authentication if the calling application does not provide a `userid` and `password` explicitly.

If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.

Data type	String

Re-Enter Password:

Confirms the password.

Node:

The WebSphere Application Server node name of the administrative node where the JMS server runs for this connection factory. Connections created by this factory connect to that JMS server.

Data type	Enum
Range	Pull-down list of nodes in the WebSphere Application Server administrative domain.

Application Server:

Enter the name of the application server. This name is not the host name of the machine, but the name of the configured application server.

Port:

Which of the two ports that connections use to connect to the JMS Server. The QUEUED port is for full-function JMS publish/subscribe support, the DIRECT port is for nonpersistent, nontransactional, nondurable subscriptions only.

Note: Message-driven beans cannot use the direct listener port for publish or subscribe support. Therefore, any topic connection factory configured with the Port set to `Direct` cannot be used with message-driven beans.

Data type	Enum
Default	QUEUED

Range	**QUEUED** The listener port used for full-function JMS compliant, publish or subscribe support. **DIRECT** The listener port used for direct TCP/IP connection (nontransactional, nonpersistent, and nondurable subscriptions only) for publish or subscribe support. The TCP/IP port numbers for these ports are defined on the product internal JMS server.

Client ID:

The JMS client identifier used for connections to the MQSeries queue manager.

Data type	String

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Version 5 Default Provider queue destination settings for application clients:

Use this panel to view or change the configuration properties of the selected queue destination for use with product Java Message Service (JMS) provider.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **Version 5 Default Provider**. Right click **Queue Destinations** and click **New**. The following fields are displayed on the **General** tab.

A queue destination is used to configure the properties of a JMS queue. A Version 5 Default Provider queue destination has the following properties.

Name:

The name by which the queue is known for administrative purposes within WebSphere Application Server.

Data type	String

Description:

A description of the queue, for administrative purposes.

Data type	String

JNDI Name:

The application client run time uses this field to retrieve configuration information.

Persistence:

Whether all messages sent to the destination are persistent, nonpersistent, or have their persistence defined by the application.

Data type
Enum

Default
APPLICATION_DEFINED

Range

Application defined
Messages on the destination have their persistence defined by the application that put them onto the queue.

Queue defined
[WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.

Persistent
Messages on the destination are persistent.

Nonpersistent
Messages on the destination are not persistent.

Priority:

Whether the message priority for this destination is defined by the application or the **Specified priority** property.

Data type
Enum

Default
APPLICATION_DEFINED

Range

Application defined
The priority of messages on this destination is defined by the application that put them onto the destination.

Queue defined
[WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.

Specified
The priority of messages on this destination is defined by the **Specified priority** property. *If you select this option, you must define a priority on the **Specified priority** property.*

Specified Priority:

If the **Priority** property is set to `Specified`, type here the message priority for this queue, in the range 0 (lowest) through 9 (highest).

If the **Priority** property is set to `Specified`, messages sent to this queue have the priority value specified by this property.

Data type
Integer

Units
Message priority level

Range
0 (lowest priority) through 9 (highest priority)

Expiry:

Whether the expiry timeout for this queue is defined by the application or the **Specified expiry** property, or whether messages on the queue expire (have an unlimited expiry timeout).

Data type	Enum
Default	APPLICATION_DEFINED
Range	**Application defined** The expiry timeout for messages in this queue is defined by the application that put them onto the queue. **Specified** The expiry timeout for messages in this queue is defined by the **Specified expiry** property.If you select this option, you must define a time out on the **Specified expiry** property. **Unlimited** Messages in this queue have no expiry timeout, and those messages never expire.

Specified Expiry:

If the **Expiry timeout** property is set to `Specified`, specify the number of milliseconds (greater than 0) after which messages on this queue expire.

Data type	Integer
Units	Milliseconds
Range	Greater than or equal to 0 • 0 indicates that messages never timeout. • Other values are an integer number of milliseconds.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Version 5 Default Provider topic destination settings for application clients:

Use this panel to view or change the configuration properties of the selected topic destination for use with the internal product Java Message Service (JMS) provider.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **Version 5 Default Provider**. Right click **Topic Destinations** and click **New**. The following fields appear on the **General** tab.

A topic destination is used to configure the properties of a JMS topic for the associated JMS provider. A Version 5 Default Provider topic has the following properties.

Name:

The name by which the topic is known for administrative purposes.

Data type	String

Description:

A description of the topic, for administrative purposes within WebSphere Application Server.

Data type	String

JNDI Name:

The application client run-time environment uses this field to retrieve configuration information.

Topic Name: The name of the topic as defined to the JMS provider.

Data type	String

Persistence:

Whether all messages sent to the destination are persistent, nonpersistent, or have their persistence defined by the application.

Data type	Enum
Default	APPLICATION_DEFINED
Range	**Application defined** Messages on the destination have their persistence defined by the application that put them onto the queue. **Queue defined** [WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties. **Persistent** Messages on the destination are persistent. **Nonpersistent** Messages on the destination are not persistent.

Priority:

Whether the message priority for this destination is defined by the application or the **Specified priority** property.

Data type	Enum
Default	APPLICATION_DEFINED
Range	**Application defined** The priority of messages on this destination is defined by the application that put them onto the destination. **Queue defined** [WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties. **Specified** The priority of messages on this destination is defined by the **Specified priority** property.*If you select this option, you must define a priority on the **Specified priority** property.*

Specified Priority:

If the **Priority** property is set to `Specified`, specify the message priority for this queue, in the range 0 (lowest) through 9 (highest).

If the **Priority** property is set to `Specified`, messages sent to this queue have the priority value specified by this property.

Data type	Integer
Units	Message priority level
Range	0 (lowest priority) through 9 (highest priority)

Expiry:

Whether the expiry timeout for this queue is defined by the application or the **Specified expiry** property, or messages on the queue never expire (have an unlimited expiry timeout).

Data type
Enum

Default
APPLICATION_DEFINED

Range

Application defined
The expiry timeout for messages on this queue is defined by the application that put them onto the queue.

Specified
The expiry timeout for messages on this queue is defined by the **Specified expiry** property. *If you select this option, you must define a timeout on the **Specified expiry** property.*

Unlimited
Messages on this queue have no expiry timeout, so those messages never expire.

Specified Expiry:

If the **Expiry timeout** property is set to `Specified`, type here the number of milliseconds (greater than 0) after which messages on this queue expire.

Data type
Integer

Units
Milliseconds

Range
Greater than or equal to 0
- 0 indicates that messages never time out.
- Other values are an integer number of milliseconds.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

WebSphere MQ Provider queue connection factory settings for application clients:

Use this panel to view or change the configuration properties of the selected queue connection factory for use with the MQSeries product Java Message Service (JMS) provider. These configuration properties control how connections are created between the JMS provider and WebSphere MQ.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **WebSphere MQ Provider**. Right click **Queue Connection Factories**, and click **New**. The following fields are displayed on the **General** tab.

Note:

- The property values that you specify must match the values that you specified when configuring WebSphere MQ for JMS resources. For more information about configuring WebSphere MQ for JMS resources, see the WebSphere MQ *Using Java* book, located in the WebSphere MQ Family library.
- In WebSphere MQ, names can have a maximum of 48 characters, with the exception of channels which have a maximum of 20 characters.

A queue connection factory for the JMS provider has the following properties.

Name:

The name by which this queue connection factory is known for administrative purposes within IBM WebSphere Application Server. The name must be unique within the JMS connection factories across the WebSphere administrative domain.

Data type	String

Description:

A description of this connection factory for administrative purposes within IBM WebSphere Application Server.

Data type	String
Default	Null

JNDI Name:

The application client run time uses this field to retrieve configuration information.

User ID:

The user ID used, with the **Password** property, for authentication if the calling application does not provide a userid and password explicitly.

If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.

The connection factory **User ID** and **Password** properties are used if the calling application does not provide a `userid` and `password` explicitly; for example, if the calling application uses the method createQueueConnection(). The JMS client flows the `userid` and `password` to the JMS server.

Data type	String

Password:

The password used, with the **User ID** property, for authentication if the calling application does not provide a `userid` and `password` explicitly.

If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.

Data type	String
Default	Null

Re-Enter Password:

Confirms the password.

Queue Manager:

The name of the MQSeries queue manager for this connection factory.

Connections created by this factory connect to that queue manager.

Data type	String

Host:

The name of the host on which the WebSphere MQ queue manager runs for client connection only.

Data type	String
Default	Null
Range	A valid TCP/IP host name

Port:

The TCP/IP port number used for connection to the WebSphere MQ queue manager, for client connection only.

This port must be configured on the WebSphere MQ queue manager.

Data type	Integer
Default	Null
Range	A valid TCP/IP port number, configured on the WebSphere MQ queue manager.

Channel:

The name of the channel used for connection to the WebSphere MQ queue manager, for client connection only.

Data type	String
Default	Null
Range	1 through 20 ASCII characters

Transport type:

Specifies whether the WebSphere MQ client connection or JNDI bindings are used for connection to the WebSphere MQ queue manager. The external JMS provider controls the communication protocols between JMS clients and JMS servers. Tune the transport type when you are using non-ASF nonpersistent, nondurable, nontransactional messaging or when you want to satisfy security issues and the client is local to the queue manager node.

Data type Enum

Units Not applicable

Default BINDINGS

Range

BINDINGS
JNDI bindings are used to connect to the queue manager. BINDINGS is a shared memory protocol and can only be used when the queue manager is on the same node as the JMS client and poses security risks that should be addressed through the use of EJB roles.

CLIENT
WebSphere MQ client connection is used to connect to the queue manager. CLIENT is a typical TCP-based protocol.

DIRECT
For WebSphere MQ Event Broker using DIRECT mode. DIRECT is a lightweight sockets protocol used in nontransactional, nondurable and nonpersistent Publish/Subscribe messaging. DIRECT only works for clients and message-driven beans using the non-ASF protocol.

QUEUED
QUEUED is a standard TCP protocol.

Recommended

Queue connection factory transport type
BINDINGS is faster by 30% or more, but it lacks security. When you have security concerns, BINDINGS is more desirable than CLIENT.

Topic connection factory transport type
DIRECT is the fastest type and should be used where possible. Use BINDINGS when you want to satisfy additional security tasks and the queue manager is local to the JMS client. QUEUED is the fallback for all other cases. WebSphere MQ 5.3 before CSD2 with the DIRECT setting can lose messages when used with message-driven beans and under load. This loss also happens with client-side applications unless the broker maxClientQueueSize is set to 0. You can set this to `0` with the command (shown here on 2 lines for publication):

```
#wempschangeproperties WAS_nodeName_server1 -e default -o
  DynamicSubscriptionEngine -n
  maxClientQueueSize -v 0 -x executionGroupUUID
```

where `executionGroupUUID` can be found by starting the broker and looking in the Event Log/Applications for event 2201. This value is usually `ffffffff-0000-0000-000000000000`.

Client ID:

The JMS client identifier used for connections to the MQSeries queue manager.

Data type String

CCSID:

The coded character set identifier for use with the WebSphere MQ queue manager.

This coded character set identifier (CCSID) must be one of the CCSIDs supported by WebSphere MQ.

Data type String

For more information about supported CCSIDs, and about converting between message data from one coded character set to another, see the *WebSphere MQ System Administration* and the *WebSphere MQ Application Programming Reference* books. These references are available from the WebSphere MQ messaging multiplatform and platform-specific books Web pages; for example, at http://www-3.ibm.com/software/ts/mqseries/library/manualsa/manuals/platspecific.html, the IBM Publications Center, or from the WebSphere MQ collection kit, SK2T-0730.

Message Retention:

Select this check box to specify that unwanted messages are to be left on the queue. Otherwise, unwanted messages are handled according to their disposition options.

Data type	Enum
Units	Not applicable
Default	Cleared
Range	**Selected** Unwanted messages are left on the queue. **Cleared** Unwanted messages are handled according to their disposition options.

Temporary model:

The name of the model definition used to create temporary connection factories if a connection factory does not already exist.

Data type	String
Range	1 through 48 ASCII characters

Temporary queue prefix:

The prefix used for dynamic queue naming.

Data type	String

Fail if quiesce:

Specifies whether applications return from a method call if the queue manager has entered a controlled failure.

Data type	Check box
Default	Selected

Local Server Address:

Specifies the local server address.

Data type	String

Polling Interval:

Specifies the interval, in milliseconds, between scans of all receivers during asynchronous message delivery

Data type	Integer
Units	Milliseconds
Default	5000

Rescan interval:

Specifies the interval in milliseconds between which a topic is scanned to look for messages that have been added to a topic out of order.

This interval controls the scanning for messages that have been added to a topic out of order with respect to a WebSphere MQ browse cursor.

Data type	Integer
Units	Milliseconds
Default	5000

SSL cipher suite:

Specifies the cipher suite to use for SSL connection to WebSphere MQ.

Set this property to a valid cipher suite provided by your JSSE provider. The value must match the CipherSpec specified on the SVRCONN channel as the Channel property.

You must set this property, if you set the SSL Peer Name property.

SSL certificate store:

Specifies a list of zero or more Certificate Revocation List (CRL) servers used to check for SSL certificate revocation. If you specify a value for this property, you must use WebSphere MQ JVM at Java 2 version 1.4.

The value is a space-delimited list of entries of the form:

```
ldap://hostname:[port]
```

A single slash (/) follows this value. If *port* is omitted, the default LDAP port of 389 is assumed. At connect-time, the SSL certificate presented by the server is checked against the specified CRL servers. For more information about CRL security, see the section “Working with Certificate Revocation Lists” in the *WebSphere MQ Security book*; for example at: http://publibfp.boulder.ibm.com/epubs/html/csqzas01/csqzas012w.htm#IDX2254.

SSL peer name:

For SSL, a distinguished name skeleton that must match the name provided by the WebSphere MQ queue manager. The distinguished name is used to check the identifying certificate presented by the server at connection time.

If this property is not set, such certificate checking is performed.

The SSL peer name property is ignored if SSL Cipher Suite property is not specified.

This property is a list of attribute name and value pairs separated by commas or semicolons. For example:

```
CN=QMGR.*, OU=IBM, OU=WEBSPHERE
```

The example given checks the identifying certificate presented by the server at connect-time. For the connection to succeed, the certificate must have a Common Name beginning QMGR., and must have at least two Organizational Unit names, the first of which is IBM and the second WEBSPHERE. Checking is not case-sensitive.

For more details about distinguished names and their use with WebSphere MQ, see the section "Distinguished Names" in the WebSphere MQ Security book.

Connection pool:

Specifies an optional set of connection pool settings.

Connection pool properties are common to all J2C connectors.

The application server pools connections and sessions with the JMS provider to improve performance. This is independent from any WebSphere MQ connection pooling. You need to configure the connection and session pool properties appropriately for your applications, otherwise you may not get the connection and session behavior that you want.

Change the size of the connection pool if concurrent server-side access to the JMS resource exceeds the default value. The size of the connection pool is set on a per queue or topic basis.

Data type	Check box
Default	Selected

WebSphere MQ Provider topic connection factory settings for application clients:

Use this panel to view or change the configuration properties of the selected topic connection factory for use with the WebSphere MQ product Java Message Service (JMS) provider. These configuration properties control how connections are created between the JMS provider and WebSphere MQ.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **WebSphere MQ Provider**. Right-click **Topic Connection Factories** and click **New**.

Note:

- The property values that you specify must match the values that you specified when configuring WebSphere MQ product JMS resources. For more information about configuring WebSphere MQ product JMS resources, see the WebSphere MQ *Using Java* book.
- In WebSphere MQ, names can have a maximum of 48 characters, with the exception of channels which have a maximum of 20 characters.

A topic connection factory for the WebSphere MQ product JMS provider has the following properties.

Name:

The name by which this topic connection factory is known for administrative purposes within IBM WebSphere Application Server. The name must be unique within the JMS provider.

Data type	String

Description:

A description of this topic connection factory for administrative purposes within IBM WebSphere Application Server.

Data type	String

JNDI Name:

The Java Naming and Directory Interface (JNDI) name that is used to bind the topic connection factory into the application server name space.

As a convention, use the fully qualified JNDI name; for example, in the form jms/*Name*, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type	String
Units	En_US ASCII characters
Range	1 through 45 ASCII characters

User ID:

The user ID used, with the **Password** property, for authentication if the calling application does not provide a `userid` and `password` explicitly.

If you specify a value for the **User** property, you must also specify a value for the **Password** property.

The connection factory **User** and **Password** properties are used if the calling application does not provide a `userid` and `password` explicitly, for example, if the calling application uses the method createTopicConnection(). The JMS client flows the `userid` and `password` to the JMS server.

Data type	String

Password:

The password used, with the **User ID** property, for authentication if the calling application does not provide a `userid` and `password` explicitly.

If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.

Data type	String

Re-Enter Password:

Confirms the password.

Queue Manager:

The name of the WebSphere MQ queue manager for this connection factory. Connections created by this factory connect to that queue manager.

Data type	String

Host:

The name of the host on which the WebSphere MQ queue manager runs for client connections only.

Data type	String
Range	A valid TCP/IP host name

Port:

The TCP/IP port number used for connection to the WebSphere MQ queue manager, for client connection only.

This port must be configured on the WebSphere MQ queue manager.

Data type	Integer
Range	A valid TCP/IP port number, configured on the WebSphere MQ queue manager.

Channel:

The name of the channel used for client connections to the WebSphere MQ queue manager for client connection only.

Data type	String
Range	1 through 20 ASCII characters

Transport Type:

Whether WebSphere MQ client connection or JNDI bindings are used for connection to the WebSphere MQ queue manager.

Data type	Enum
Default	BINDINGS
Range	**CLIENT** WebSphere MQ client connection is used to connect to the WebSphere MQ queue manager. **BINDINGS** JNDI bindings are used to connect to the WebSphere MQ queue manager.

Client ID:

The JMS client identifier used for connections to the WebSphere MQ queue manager.

Data type	String

CCSID:

The coded character set identifier to be used with the WebSphere MQ queue manager.

This coded character set identifier (CCSID) must be one of the CCSIDs supported by WebSphere MQ.

Data type	String

Broker Control Queue:

The name of the broker control queue to which all command messages (except publications and requests to delete publications) are sent.

Data type	String
Units	En_US ASCII characters

Range	1 through 48 ASCII characters

Broker Queue Manager:

The name of the WebSphere MQ queue manager that provides the Publisher and Subscriber message broker.

Data type	String
Units	En_US ASCII characters
Range	1 through 48 ASCII characters

Broker Publish Queue:

The name of the broker input queue that receives all publication messages for the default stream.

The name of the broker's input queue (stream queue) that receives all publication messages for the default stream. Applications can also send requests to delete publications on the default stream to this queue.

Data type	String
Units	En_US ASCII characters
Range	1 through 48 ASCII characters

Broker Subscribe Queue:

The name of the broker queue from which nondurable subscription messages are retrieved.

The name of the broker queue from which nondurable subscription messages are retrieved. The subscriber specifies the name of the queue when it registers a subscription.

Data type	String
Units	En_US ASCII characters
Range	1 through 48 ASCII characters

Broker CCSubQ:

The name of the broker queue from which nondurable subscription messages are retrieved for a ConnectionConsumer request. This property applies only for use of the Web container.

Data type	String
Units	En_US ASCII characters
Range	1 through 48 ASCII characters

Broker Version:

Specifies whether the message broker is provided by the WebSphere MQ MA0C SupportPac or newer versions of WebSphere family message broker products.

Data type	Enum
Default	Advanced

Range	**Advanced** The message broker is provided by newer versions of WebSphere family message broker products (MQ Integrator and MQ Publish and Subscribe). **Basic** The message broker is provided by the WebSphere MQ MA0C SupportPac (WebSphere MQ - Publish and Subscribe).

Cleanup level:

Specifies the level of clean up provided by the publish or subscribe cleanup utility.

Data type	Enum
Default	SAFE
Range	**ASPROP** **NONE** **STRONG**

Cleanup interval:

Specifies the interval, in milliseconds, between background executions of the publish/subscribe cleanup utility.

Data type	Integer
Units	Milliseconds
Default	6000

Message selection:

Specifies where broker message selection is performed.

Data type	Enum
Default	BROKER
Range	**BROKER** Message selection is done at the broker location. **Message CLIENT** Message selection is done at the client location.

Publish acknowledge interval:

The interval, in number of messages, between publish requests that require acknowledgement from the broker.

Data type	Integer
Default	25

Sparse subscriptions:

Enables sparse subscriptions.

Data type	Check box
Default	Cleared

Status refresh interval:

The interval, in milliseconds, between transactions to refresh publish or subscribe status.

Data type	Integer
Default	6000

Subscription store:

Specifies where WebSphere MQ stores data relating to active JMS subscriptions.

Data type	Enum
Default	MIGRATE
Range	**MIGRATE** **QUEUE** **BROKER**

Multicast:

Specifies whether this connection factory uses multicast transport.

Data type	Enum
Default	NOT USED
Range	**NOT USED** This connection factory does not use multicast transport. **ENABLED** This connection factory always uses multicast transport. **ENABLED_IF_AVAILABLE** This connection factory uses multicast transport. **ENABLED_RELIABLE** This connection factory uses reliable multicast transport. **ENABLED_RELIABLE_IF_AVAILABLE** This connection factory uses reliable multicast transport if available.

Direct authentication:

Specifies whether to use direct broker authorization.

Data type	Enum
Default	NONE

Range

NONE Direct broker authorization is not used.

PASSWORD
Direct broker authorization is authenticated with a password.

CERTIFICATE
Direct broker authorization is authenticated with a certificates.

Proxy Host Name:

Specifies the host name of a proxy to be used for communication with WebSphere MQ.

Data type	String

Proxy Port:

Specifies the port number of a proxy to be used for communication with WebSphere MQ.

Data type	Integer
Default	0

Fail if quiesce:

Specifies whether applications return from a method call if the queue manager has entered a controlled failure.

Data type	Check box
Default	Selected

Local Server Address:

Specifies the local server address.

Data type	String

Polling Interval:

Specifies the interval, in milliseconds, between scans of all receivers during asynchronous message delivery.

Data type	Integer
Units	Milliseconds
Default	5000

Rescan interval:

Specifies the interval in milliseconds between which a topic is scanned to look for messages that have been added to a topic out of order.

This interval controls the scanning for messages that have been added to a topic out of order with respect to a WebSphere MQ browse cursor.

Data type	Integer
Units	Milliseconds
Default	5000

SSL cipher suite:

Specifies the cipher suite to use for SSL connection to WebSphere MQ.

Set this property to a valid cipher suite provided by your JSSE provider. The value must match the CipherSpec specified on the SVRCONN channel as the **Channel** property.

You must set this property, if you set the **SSL Peer Name** property.

SSL certificate store:

Specifies a list of zero or more Certificate Revocation List (CRL) servers used to check for SSL certificate revocation. If you specify a value for this property, you must use WebSphere MQ JVM at Java 2 version 1.4.

The value is a space-delimited list of entries of the form:

```
ldap://hostname:[port]
```

A single slash (/) follows this value. If *port* is omitted, the default LDAP port of 389 is assumed. At connect-time, the SSL certificate presented by the server is checked against the specified CRL servers. For more information about CRL security, see the section “Working with Certificate Revocation Lists” in the *WebSphere MQ Security book*; for example at: http://publibfp.boulder.ibm.com/epubs/html/csqzas01/csqzas012w.htm#IDX2254.

SSL peer name:

For SSL, a distinguished name skeleton that must match the name provided by the WebSphere MQ queue manager. The distinguished name is used to check the identifying certificate presented by the server at connection time.

If this property is not set, such certificate checking is performed.

The SSL peer name property is ignored if **SSL Cipher Suite** property is not specified.

This property is a list of attribute name and value pairs separated by commas or semicolons. For example:

```
CN=QMGR.*, OU=IBM, OU=WEBSPHERE
```

The example given checks the identifying certificate presented by the server at connect-time. For the connection to succeed, the certificate must have a Common Name beginning QMGR., and must have at least two Organizational Unit names, the first of which is IBM and the second WEBSPHERE. Checking is not case-sensitive.

For more details about distinguished names and their use with WebSphere MQ, see the section “Distinguished Names” in the WebSphere MQ Security book.

Connection pool:

Specifies an optional set of connection pool settings.

Connection pool properties are common to all J2C connectors.

The application server pools connections and sessions with the JMS provider to improve performance. This is independent from any WebSphere MQ connection pooling. You need to configure the connection and session pool properties appropriately for your applications, otherwise you may not get the connection and session behavior that you want.

Change the size of the connection pool if concurrent server-side access to the JMS resource exceeds the default value. The size of the connection pool is set on a per queue or topic basis.

Data type	Check box
Default	Selected

"Configuring new JMS providers with the Application Client Resource Configuration Tool" on page 892

WebSphere MQ Provider queue destination settings for application clients:

Use this panel to view or change the configuration properties of the selected queue destination for use with the WebSphere MQ product Java Message Service (JMS) provider.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **WebSphere MQ Provider**. Right-click **Queue Destinations** and click **New**. The following fields are displayed on the **General** tab.

Note:

- The property values that you specify must match the values that you specified when configuring WebSphere MQ product for JMS resources. For more information about configuring WebSphere MQ product for JMS resources, see the WebSphere MQ *Using Java* book.
- In WebSphere MQ, names can have a maximum of 48 characters.

A queue for use with the WebSphere MQ product JMS provider has the following properties.

Name:

The name by which the queue is known for administrative purposes within IBM WebSphere Application Server.

Data type	String

Description:

A description of the queue, for administrative purposes.

Data type	String

JNDI Name:

The application client run-time environment uses this field to retrieve configuration information.

Persistence:

Whether all messages sent to the destination are persistent, nonpersistent or have their persistence defined by the application.

Data type	Enum

Default	APPLICATION_DEFINED
Range	**Application defined** Messages on the destination have their persistence defined by the application that put them onto the queue. **Queue defined** [WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties. **Persistent** Messages on the destination are persistent. **Nonpersistent** Messages on the destination are not persistent.

Priority:

Whether the message priority for this destination is defined by the application or the **Specified priority** property.

Data type	Enum
Units	Not applicable
Default	APPLICATION_DEFINED
Range	**Application defined** The priority of messages on this destination is defined by the application that put them onto the destination. **Queue defined** [WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties. **Specified** The priority of messages on this destination is defined by the **Specified priority** property. *If you select this option, you must define a priority on the **Specified priority** property.*

Specified Priority:

If the **Priority** property is set to `Specified`, specify the message priority for this queue, in the range 0 (lowest) through 9 (highest).

Data type	Integer
Units	Message priority level
Range	0 (lowest priority) through 9 (highest priority)

Expiry:

Whether the expiry timeout value for this queue is defined by the application or the by **Specified expiry** property or whether messages on the queue never expire (have an unlimited expiry time out).

Data type	Enum
Units	Not applicable
Default	APPLICATION_DEFINED

Range	**Application defined** The expiry timeout for messages on this queue is defined by the application that put them onto the queue. **Specified** The expiry timeout for messages on this queue is defined by the **Specified expiry** property. If you select this option, you must define a timeout on the **Specified expiry** property. **Unlimited** Messages on this queue have no expiry timeout and those messages never expire.

Specified Expiry:

If the **Expiry timeout** property is set to `Specified`, type here the number of milliseconds (greater than 0) after which messages on this queue expire.

Data type	Integer
Units	Milliseconds
Range	Greater than or equal to 0 • 0 indicates that messages never time out • Other values are an integer number of milliseconds

Base Queue Name:

The name of the queue to which messages are sent, on the queue manager specified by the **Base queue manager name** property.

Data type	String

Base Queue Manager Name:

The name of the WebSphere MQ queue manager to which messages are sent.

This queue manager provides the queue specified by the **Base queue name** property.

Data type	String
Units	En_US ASCII characters
Range	A valid WebSphere MQ Queue Manager name, as 1 through 48 ASCII characters

CCSID:

The coded character set identifier to use with the WebSphere MQ queue manager.

This coded character set identifier (CCSID) must be one of the CCSID identifier supported by WebSphere MQ queue manager.

Data type	String

Integer encoding:

If native encoding is not enabled, select whether integer encoding is normal or reversed.

Data type Enum
Default NORMAL
Range

NORMAL
Normal integer encoding is used.

REVERSED
Reversed integer encoding is used.

For more information about encoding properties, see the WebSphere MQ *Using Java* document.

Decimal encoding:

Indicates that if native encoding is not enabled to select whether decimal encoding is normal or reversed.

Data type Enum
Default NORMAL
Range

NORMAL
Normal decimal encoding is used.

REVERSED
Reversed decimal encoding is used.

For more information about encoding properties, see the WebSphere MQ *Using Java* document.

Floating point encoding:

Indicates that if native encoding is not enabled to select the type of floating point encoding.

Data type Enum
Default IEEENORMAL
Range

IEEENORMAL
IEEE normal floating point encoding is used.

IEEEREVERSED
IEEE reversed floating point encoding is used.

S390 S390 floating point encoding is used.

For more information about encoding properties, see the WebSphere MQ *Using Java* document.

Native encoding:

Indicates that the queue destination use native encoding (appropriate encoding values for the Java platform) when you select this check box.

Data type Enum
Default Cleared
Range

Cleared
Native encoding is not used, so specify the following properties for integer, decimal and floating point encoding.

Selected
Native encoding is used (to provide appropriate encoding values for the Java platform).

For more information about encoding properties, see the WebSphere MQ *Using Java* document.

Target client:

Whether the receiving application is JMS-compliant or is a traditional WebSphere MQ application.

Data type	Enum
Default	WebSphere MQ
Range	**WebSphere MQ** The target is a traditional WebSphere MQ application that does not support JMS. **JMS** The target application supports JMS.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

WebSphere MQ Provider topic destination settings for application clients:

Use this panel to view or change the configuration properties of the selected topic destination for use with the WebSphere MQ product Java Message Service (JMS) provider.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **WebSphere MQ Provider**. Right click **Topic Destinations**, and click **New**. The following fields are displayed on the **General** tab.

Note:

- The property values that you specify must match the values that you specified when configuring WebSphere MQ product JMS resources. For more information about configuring WebSphere MQ product JMS resources, see the WebSphere MQ *Using Java* book.
- In WebSphere MQ, names can have a maximum of 48 characters.

A topic destination is used to configure the properties of a JMS topic for the associated JMS provider. A topic for use with the WebSphere MQ product JMS provider has the following properties.

Name:

The name by which the topic is known for administrative purposes.

Data type	String

Description:

A description of the topic for administrative purposes within IBM WebSphere Application Server.

JNDI Name:

The application client run time uses this field to retrieve configuration information.

Persistence:

Specifies whether all messages sent to the destination are persistent, nonpersistent, or have their persistence defined by the application.

Data type	Enum
Default	APPLICATION_DEFINED
Range	**Application defined** Messages on the destination have their persistence defined by the application that put them in the queue. **Queue defined** [WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties. **Persistent** Messages on the destination are persistent. **Nonpersistent** Messages on the destination are not persistent.

Priority:

Specifies whether the message priority for this destination is defined by the application or the **Specified priority** property.

Data type	Enum
Default	APPLICATION_DEFINED
Range	**Application defined** The priority of messages on this destination is defined by the application that put them in the destination. **Queue defined** [WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties. **Specified** The priority of messages on this destination is defined by the **Specified priority** property. If you select this option, you must define a priority for the **Specified priority** property.

Specified Priority:

If the **Priority** property is set to `Specified`, type the message priority for this queue, in the range 0 (lowest) through 9 (highest).

If the **Priority** property is set to `Specified`, messages sent to this queue have the priority value specified by this property.

Data type	Integer
Units	Message priority level
Range	0 (lowest priority) through 9 (highest priority)

Expiry:

Whether the expiry timeout for this queue is defined by the application or by the **Specified expiry** property or by messages on the queue never expire (have an unlimited expiry timeout).

Data type	Enum
Default	APPLICATION_DEFINED
Range	**Application defined** The expiry timeout for messages on this queue is defined by the application that put them in the queue. **Specified** The expiry timeout for messages in this queue is defined by the **Specified expiry** property. If you select this option, you must define a timeout value for the **Specified expiry** property. **Unlimited** Messages on this queue have no expiry timeout, and these messages never expire.

Specified Expiry:

If the **Expiry timeout** property is set to `Specified`, type the number of milliseconds (greater than 0) after which messages on this queue expire.

Data type	Integer
Units	Milliseconds
Range	Greater than or equal to 0 • 0 indicates that messages never time out. • Other values are an integer number of milliseconds.

Base Topic Name:

The name of the topic to which messages are sent.

Data type	String

CCSID:

The coded character set identifier to use with the WebSphere MQ queue manager.

This coded character set identifier (CCSID) must be one of the CCSID identifiers that WebSphere MQ supports.

Data type	String

Integer encoding:

Indicates whether integer encoding is normal or reversed when native encoding is not enabled.

Data type	Enum
Default	NORMAL
Range	**NORMAL** Normal integer encoding is used. **REVERSED** Reversed integer encoding is used. For more information about encoding properties, see the WebSphere MQ *Using Java* document.

Decimal encoding:

If native encoding is not enabled, select whether decimal encoding is normal or reversed.

Data type
Enum

Default
NORMAL

Range

NORMAL
Normal decimal encoding is used.

REVERSED
Reversed decimal encoding is used.

For more information about encoding properties, see the WebSphere MQ *Using Java* document.

Floating point encoding:

Indicates the type of floating point encoding when native encoding is not enabled.

Data type
Enum

Default
IEEENORMAL

Range

IEEENORMAL
IEEE normal floating point encoding is used.

IEEEREVERSED
IEEE reversed floating point encoding is used.

S390 S/390 floating point encoding is used.

For more information about encoding properties, see the WebSphere MQ *Using Java* document.

Native encoding:

Indicates that the queue destination uses native encoding (appropriate encoding values for the Java platform) when you select this check box.

Data type
Enum

Default
Cleared

Range

Cleared
Native encoding is not used, so specify the previous properties for integer, decimal and floating point encoding.

Selected
Native encoding is used (to provide appropriate encoding values for the Java platform).

For more information about encoding properties, see the WebSphere MQ *Using Java* document.

BrokerDurSubQueue:

The name of the broker queue from which durable subscription messages are retrieved.

The subscriber specifies the name of the queue when it registers a subscription.

Data type
String

Units
En_US ASCII characters

Range
1 through 48 ASCII characters

BrokerCCDurSubQueue:

The name of the broker queue from which durable subscription messages are retrieved for a ConnectionConsumer. This property applies only for use of the Web container.

Data type	String
Units	En_US ASCII characters
Range	1 through 48 ASCII characters

Target Client:

Specifies whether the receiving application is JMS compliant or is a traditional WebSphere MQ application.

Data type	Enum
Default	WebSphere MQ
Range	**WebSphere MQ** The target is a traditional WebSphere MQ application that does not support JMS. **JMS** The target is a JMS compliant application.

Multicast:

Specifies whether this connection factory uses multicast transport.

Data type	Enum
Default	AS_CF
Range	**AS_CF** This connection factory uses multicast transport. **DISABLED** This connection factory does not use multicast transport. **NOT_RELIABLE** This connection factory always uses multicast transport. **RELIABLE** This connection factory uses multicast transport when the topic destination is not reliable. **ENABLED** This connection factory uses reliable multicast transport.

Generic JMS connection factory settings for application clients:

Use this panel to view or change the configuration properties of the selected Java Message Service (JMS) connection factory for use with the associated JMS provider. These configuration properties control how connections are created between the JMS provider and the messaging system that it uses.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > *new_JMS_Provider_instance*. Right-click **Connection Factories**, and click **New**. The following fields are displayed on the **General** tab.

A Java Message Service (JMS) connection factory creates connections to JMS destinations. The JMS connection factory is created by the associated JMS provider. A JMS connection factory for a generic JMS provider (other than the internal default messaging provider or WebSphere MQ as a JMS provider) has the following properties:

Name:

The name by which this JMS connection factory is known for administrative purposes within IBM WebSphere Application Server. The name must be unique within the associated JMS provider.

Data type	String

Description:

A description of this connection factory for administrative purposes within IBM WebSphere Application Server.

Data type	String
Default	Null

JNDI Name:

The application client run time uses this field to retrieve configuration information.

User ID:

Indicates the user ID used with the **Password** property, for authentication if the calling application does not provide a `userid` and `password` explicitly.

If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.

The connection factory **User ID** and **Password** properties are used if the calling application does not provide a userid and password explicitly; for example, if the calling application uses the method createQueueConnection(). The JMS client flows the `userid` and `password` to the JMS server.

Data type	String

Password:

The password used with the **User ID** property for authentication if the calling application does not provide a `userid` and `password` explicitly.

If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.

Data type	String
Default	Null

Re-Enter Password:

Confirms the password entered in the **Password** field.

External JNDI Name:

The JNDI name that is used to bind the queue into the application server name space.

As a convention, use the fully qualified JNDI name, for example, `jms/Name`, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI API by the platform.

Data type	String

Connection Type:

Whether this JMS destination is a queue (for point-to-point) or topic (for publication or subscription).

Select one of the following options:

Queue
A JMS queue destination for point-to-point messaging.

Topic A JMS topic destination for publish subscribe messaging.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Generic JMS destination settings for application clients:

Use this panel to view or change the configuration properties of the selected JMS destination for use with the associated JMS provider.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > *new JMS Provider instance*. Right-click **Destinations**, and click **New**. The following fields are displayed on the **General** tab.

A JMS destination is used to configure the properties of a JMS destination for the associated generic JMS provider. Connections to the JMS destination are created by the associated JMS connection factory. A JMS destination for use with a generic JMS provider (not the default messaging provider or WebSphere MQ as a JMS provider) has the following properties.

Name:

The name by which the queue is known for administrative purposes within WebSphere Application Server.

Data type	String

Description:

A description of the queue, for administrative purposes.

JNDI Name:

The JNDI name of the actual (physical) name of the JMS destination bound into JNDI.

External JNDI Name:

The JNDI name that is used to bind the queue into the application server name space.

As a convention, use the fully qualified JNDI name; for example, in the form jms/*Name*, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type	String

Destination Type:

Whether this JMS destination is a queue (for point-to-point) or topic (for publishing or subscribing).

Select one of the following options:

Queue
A JMS queue destination for point-to-point messaging.

Topic A JMS topic destination for pub/sub messaging.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Example: Configuring JMS provider, JMS connection factory and JMS destination settings for application clients: The purpose of this article is to help you to configure JMS Provider, JMS Connection Factory and JMS Destination settings.

- Required fields include:
  - JMS Provider Properties page: name, and at least one protocol provider
  - JMS Connection Factory Properties page: name, jndiName, destination type
  - JMS Destination Properties page: name, jndiName, destination type
- Special cases:
  - The destination type must be `QUEUE`, or `TOPIC`.
- Example:

```
<resources.jms:JMSProvider xmi:id="JMSProvider_3" name="genericJMSProvider:name"
description="genericJMSProvider:description"
externalInitialContextFactory="genericJMSProvider:contextFactoryClass"
externalProviderURL="genericJMSProvider:providerUrl">
<classpath>genericJMSProvider:classpath</classpath>
<factories xmi:type="resources.jms:GenericJMSDestination"
xmi:id="GenericJMSDestination_1" name="jmsDestination:name"
jndiName="jmsDestination:jndiName" description="jmsDestination:description"
externalJNDIName="jmsDestination:externalJndiName" type="QUEUE">
<propertySet xmi:id="J2EEResourcePropertySet_15">
<resourceProperties xmi:id="J2EEResourceProperty_17" name="jmsDestination:customName"
value="jmsDestination:customValue"/>
</propertySet>
</factories>
<factories xmi:type="resources.jms:GenericJMSConnectionFactory"
xmi:id="GenericJMSConnectionFactory_1" name="jmsCF:name" jndiName="jmsCF:jndiName"
description="jmsCF:description" userID="jmsCF:user" password="{xor}NTIsHBllMT4yOg=="
```

```
externalJNDIName="jmsCF:externalJndiName" type="QUEUE">
<propertySet xmi:id="J2EEResourcePropertySet_16">
<resourceProperties xmi:id="J2EEResourceProperty_18" name="jmsCF:customName"
value="jmsCF:customValue"/>
</propertySet>
</factories>
<propertySet xmi:id="J2EEResourcePropertySet_17">
<resourceProperties xmi:id="J2EEResourceProperty_19"
name="genericJMSProvider:customName" value="genericJMSProvider:customValue"/>
</propertySet>
</resources.jms:JMSProvider>
```

Configuring new JMS connection factories for application clients

Use this task to create a new Java Message Service (JMS) connection factory configuration for your application client.

1. Click the JMS provider for which you want to create a connection factory in the tree. Complete one of the following actions:
   - Configure a new JMS provider.
   - Click an existing JMS provider.
2. Expand the JMS provider to view its **JMS Connection Factories** folder.
3. Click the connection factory folder, and complete one of the following actions:
   - Right-click the folder and select**New Factory**.
   - Click **Edit > New** on the menu bar.
4. Configure the JMS connection factory properties in the displayed fields.
5. Click **OK** when you finish.
6. Click **File > Save** on the menu bar to save your changes.

Configuring new Java Message Service destinations for application clients

Use this task to create a new Java Message Service (JMS) destination configuration for your application client.

1. Click the JMS provider in the tree for which you want to create a destination. Complete one of the following actions:
   - Configure a new JMS provider.
   - Click an existing JMS provider.
2. Expand the JMS provider to view its **JMS Destinations** folder.
3. Click the provider folder, and complete one of the following actions:
   - Right-click the folder and select **New**.
   - Click **Edit > New** on the menu bar.
4. Configure the JMS destination properties in the displayed fields.
5. Click **OK** when you finish.
6. Click **File > Save** on the menu bar to save your changes.

Example: Configuring MQ Queue and Topic connection factories and destination factories for application clients

The purpose of this article is to help you configure MQ Queue connection factory, MQ Topic connection factory, MQ Queue destination factory, and MQ Topic destination factory settings.

- Required fields:
  - MQ Queue Connection Factory Properties page: name, jndiName and transport type
  - MQ Topic Connection Factory Properties page: name, jndiName and broker Version
  - MQ Queue Factory Properties page: name, jndiName, persistence, priority, expiry, baseQueueName and targetClient
  - MQ Topic Factory Properties page: name, jndiName, persistence, priority, expiry, baseQueueName and targetClient
- Special cases:
  - The transport type must be `CLIENT`, or `BINDINGS`.

- The Broker Version must be MA0C, or MQSI.
  - The port must be a numerical value between -2417483648 and 2417483647.
  - The CCSID must be a numerical value between -2417483648 and 2417483647.
  - The persistence value must be APPLICATION_DEFINED, QUEUE_DEFINED, PERSISTENT or, NONPERSISTENT.
  - The priority must be APPLICATION_DEFINED, QUEUE_DEFINED, or SPECIFIED.
  - The expiry must be APPLICATION_DEFINED, UNLIMITED, or SPECIFIED.
  - The integer encoding must be Normal, or Reversed.
  - The decimal encoding must be Normal, or Reversed.
  - The floating encoding must be IEEENormal, IEEEReversed or S390.
  - The target client must be JMS or MQ.
  - On the MQ Queue Connection Factory Properties page, only set the queueManager, host, and port values. These are required fields if the transport type is CLIENT.
  - On the MQ Topic Connection Factory Properties page, only set the queueManager, host, and port (required) fields if the transport type is CLIENT.
  - On the MQ Topic Factory Properties, and the MQ Queue Factory Properties pages, only set the Integer encoding, decimal encoding, and floating point encoding (required) fields if you do not set the nativeEncoding value.
  - On the MQ Topic Factory Properties and the MQ Queue Factory Properties pages, the specified priority entry field must be an integer between 0 and 9 if priority is set to SPECIFIED .
  - On the MQ Topic Factory Properties and the MQ Queue Factory Properties pages, the specified expiry entry field must be a value greater than 0 if the expiry value is set to SPECIFIED.
- Example:

```
<resources.jms:JMSProvider xmi:id="JMSProvider_1" name="MQ JMS Provider"
description="mqJMSProvider:description"
externalInitialContextFactory="mqJMSProvider:contextFactoryClass"
externalProviderURL="mqJMSProvider:providerUrl">
<classpath>mqJMSProvider:classpath</classpath>
<factories xmi:type="resources.jms.mqseries:MQQueueConnectionFactory"
xmi:id="MQQueueConnectionFactory_1" name="mqQCF:name" jndiName="mqQCF:jndiName"
description="mqQCF:description" userID="mqQCF:user" password="{xor}Mi4OHBllMT4yOg=="
queueManager="mqQCF:queueManager" host="mqQCF:host" port="1" channel="mqQCF:channel"
transportType="CLIENT" clientID="mqQCF:clientId" CCSID="2">
<propertySet xmi:id="J2EEResourcePropertySet_3">
<resourceProperties xmi:id="J2EEResourceProperty_3" name="mqQCF:customName"
value="mqQCF:customValue"/>
</propertySet>
</factories>
<factories xmi:type="resources.jms.mqseries:MQTopicConnectionFactory"
xmi:id="MQTopicConnectionFactory_1" name="mqTCF:name" jndiName="mqTCF:jndiName"
description="mqTCF:description" userID="mqTCF:user"
password="{xor}Mi4LHBllNTE7NhE+Mjo=" host="mqTCF:host" port="1"
transportType="CLIENT" channel="mqTCF:channel" queueManager="mqTCF:queueManager"
brokerControlQueue="mqTCF:brokerControlQueue"
brokerQueueManager="mqTCF:brokerQueueManager" brokerPubQueue="mqTCF:brokerPubQueue"
brokerSubQueue="mqTCF:brokerSubQueue" brokerCCSubQ="mqTCF:brokerCCSubQ"
brokerVersion="MA0C" clientID="mqTCF:clientId" CCSID="2">
<propertySet xmi:id="J2EEResourcePropertySet_4">
<resourceProperties xmi:id="J2EEResourceProperty_4" name="mqTCF:customName"
value="mqTCF:customValue"/>
</propertySet>
</factories>
<factories xmi:type="resources.jms.mqseries:MQQueue" xmi:id="MQQueue_1" name="mqQ:name"
jndiName="mqQ:jndiName" description="mqQ:description" persistence="APPLICATION_DEFINED"
priority="SPECIFIED" specifiedPriority="1" expiry="SPECIFIED" specifiedExpiry="1"
baseQueueName="mqQ:baseQueueName" baseQueueManagerName="mqQ:baseQueueManagerName"
CCSID="1" integerEncoding="Normal" decimalEncoding="Normal"
floatingPointEncoding="IEEENormal" targetClient="JMS">
<propertySet xmi:id="J2EEResourcePropertySet_5">
<resourceProperties xmi:id="J2EEResourceProperty_5" name="mqQ:customName"
value="mqQ:customValue"/>
</propertySet>
</factories>
```

```
<factories xmi:type="resources.jms.mqseries:MQTopic" xmi:id="MQTopic_1"
name="mqT:name" jndiName="mqT:jndiName" description="mqT:description"
persistence="APPLICATION_DEFINED" priority="SPECIFIED" specifiedPriority="1"
expiry="SPECIFIED" specifiedExpiry="2" baseTopicName="mqT:baseTopicName" CCSID="3"
integerEncoding="Normal" decimalEncoding="Normal" floatingPointEncoding="IEEENormal"
targetClient="JMS" brokerDurSubQueue="mqT:brokerDurSubQueue"
brokerCCDurSubQueue="mqT:brokerCCDurSubQueue">
<propertySet xmi:id="J2EEResourcePropertySet_6">
<resourceProperties xmi:id="J2EEResourceProperty_6" name="mqT:customName"
value="mqT:customValue"/>
</propertySet>
</factories>
<propertySet xmi:id="J2EEResourcePropertySet_7">
<resourceProperties xmi:id="J2EEResourceProperty_7" name="mqJMSProvider:customName"
value="mqJMSProvider:customValue"/>
</propertySet>
</resources.jms:JMSProvider>
```

Example: Configuring WAS Queue and Topic connection factories and destination factories for application clients

The purpose of this article is to help you configure Queue connection factory, Topic connection factory, Queue destination factory, and Topic destination factory settings.

- Required fields include:
  - Java Message Service (JMS) Provider Properties page: name
  - WebSphere Application Server Queue Connection Factory Properties page: name, jndiName and node
  - WebSphere Application Server Topic Connection Factory Properties page: name, jndiName, node and port
  - WebSphere Application Server Queue Factory Properties page: name, jndiName, node, persistence, priority and expiry
  - WebSphere Application Server Topic Factory Properties page: name, jndiName, topic name, persistence, priority and expiry
- Special cases:
  - The port value must be `QUEUED` or `DIRECT`.
  - The CCSID must be a numerical value between -2417483648 and 2417483647.
  - The persistence value must be `APPLICATION_DEFINED`, `PERSISTENT`, or `NONPERSISTENT`.
  - The priority value must be `APPLICATION_DEFINED`, or `SPECIFIED`.
  - The expiry value must be `APPLICATION_DEFINED`, `UNLIMITED`, or `SPECIFIED`.
  - On the WAS Topic Factory Properties, and the WAS Queue Factory Properties pages, the specified priority entry field must be an integer between 0 and 9, if the priority value is set to `SPECIFIED` .
  - On the WAS Topic Factory Properties, and the WAS Queue Factory Properties pages, the specified expiry entry field must be a value greater than 0 if expiry is set to `SPECIFIED`.
- Example:

```
<resources.jms:JMSProvider xmi:id="JMSProvider_2" name="WebSphere JMS Provider"
description="wasJMSProvider:description"
externalInitialContextFactory="wasJMSProvider:contextfactoryclass"
externalProviderURL="wasJMSProvider:providerURL">
<classpath>wasJMSProvider:classpath</classpath>
<factories xmi:type="resources.jms.internalmessaging:WASQueueConnectionFactory"
xmi:id="WASQueueConnectionFactory_1" name="wasQCF:name" jndiName="wasQCF:jndiName"
description="wasQCF:description" userID="wasQCF:user" password="{xor}KD4sDhwZZSosOi0="
node="wasQCF:Node">
<propertySet xmi:id="J2EEResourcePropertySet_8">
<resourceProperties xmi:id="J2EEResourceProperty_8" name="wasQCF:customName"
value="wasQCF:customValue"/>
</propertySet>
</factories>
<factories xmi:type="resources.jms.internalmessaging:WASTopicConnectionFactory"
xmi:id="WASTopicConnectionFactory_1" name="wasTCF:name" jndiName="wasTCF:jndiName"
description="wasTCF:description" userID="wasTCF:user" password="{xor}KD4sCxwZZTE+Mjo="
node="wasTCF:node" port="QUEUED" clientID="wasTCF:clientId">
<propertySet xmi:id="J2EEResourcePropertySet_9">
```

```
<resourceProperties xmi:id="J2EEResourceProperty_9" name="wasTCF:customName"
value="wasTCF:customValue"/>
</propertySet>
</factories>
<factories xmi:type="resources.jms.internalmessaging:WASQueue" xmi:id="WASQueue_1"
name="wasQ:name" jndiName="wasQ:jndiName" description="wasQ:description"
node="wasQ:node" persistence="APPLICATION_DEFINED" priority="SPECIFIED"
specifiedPriority="1" expiry="SPECIFIED" specifiedExpiry="1">
<propertySet xmi:id="J2EEResourcePropertySet_10">
<resourceProperties xmi:id="J2EEResourceProperty_10" name="wasQ:customName"
value="wasQ:customValue"/>
</propertySet>
</factories>
<factories xmi:type="resources.jms.internalmessaging:WASTopic" xmi:id="WASTopic_1"
name="wasT:name" jndiName="wasT:jndiName" description="wasT:description"
topic="wasT:topicName" persistence="APPLICATION_DEFINED" priority="SPECIFIED"
specifiedPriority="1" expiry="SPECIFIED" specifiedExpiry="1">
<propertySet xmi:id="J2EEResourcePropertySet_11">
<resourceProperties xmi:id="J2EEResourceProperty_11" name="wasT:customName"
value="wasT:customValue"/>
</propertySet>
</factories>
<propertySet xmi:id="J2EEResourcePropertySet_12">
<resourceProperties xmi:id="J2EEResourceProperty_12" name="wasJMSProvider:customName"
value="wasJMSProvider:customValue"/>
</propertySet>
</resources.jms:JMSProvider>
```

Configuring new resource environment providers for application clients

During this task, you create new resource environment provider configurations for your application client.

To configure a new resource environment provider, perform the following steps:

1. Start the Application Configuration Resource Tool and open the EAR file for which you want to configure the new Java Message Service (JMS) provider. The EAR file contents display in a tree view.
2. Select from the tree the JAR file in which you want to configure the new JMS provider.
3. Expand the JAR file to view its contents.
4. Click the **Resource Environment Providers** folder. Take one of the following actions:
   - Right-click the provider folder, and click **New Provider**.
   - Click **Edit > New** on the menu bar.
5. Configure the JMS provider properties in the displayed fields.
6. Click **OK** when you finish.
7. Click **File > Save** on the menu bar to save your changes.

Resource environment provider settings for application clients:

Use this page to specify resource environment entry properties.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected Java Archive (JAR) file. Right-click **Resource Environment Providers**, and click **New**. The following fields are displayed on the **General** tab:

Name:

Specifies the administrative name for the resource environment provider.

Description:

Specifies a description of the resource environment provider for your administrative records.

Class Path:

Specifies the path to the JAR file that contains the implementation classes for the resource environment provider.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Configuring new resource environment entries for application clients

During this task, you create new resource environment entries for your client application.

1. Start the Application Client Resource Configuration Tool (ACRCT).
2. Open the EAR file for which you want to configure the new resource environment entry. The EAR file contents are in the displayed tree view.
3. Click the desired resource environment provider, and complete the following action to configure new providers:
   - Configure a new resource environment provider.
4. Expand the resource environment provider to view the **Resource Environment Entries** folder.
5. Click the resource environment entries folder, and complete one of the following actions:
   - Right-click the folder and select **New**.
   - Click **Edit > New** on the menu bar.
6. Configure the resource environment entry properties in the displayed fields.
7. Click **OK**.
8. Click **File > Save** on the menu bar to save your changes.

Resource environment entry settings for application clients:

Use this page to specify resource environment entry properties.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Resource Environment Providers** > *resource environment instance*. Right-click **Resource environment entry**, and click **New**. The following fields appear on the **General** tab:

Name:

Specifies the administrative name for the resource environment entry.

Description:

Specifies a description of the URL for your administrative records.

JNDI Name:

Specifies the Java Naming and Directory Interface (JNDI) name for the resource, including any naming subcontexts.

Use this name to link to the binding information of the platform. The binding associates the resources defined in the deployment descriptor of the module to the actual (or physical) resources bound into JNDI by the platform.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Creating locally defined objects for message destination references and message destinations

After developing an application client, deploy this application on client machines. *Deployment* consists of pulling together the various artifacts that the application client requires.

The *Application Client Resource Configuration Tool* (ACRCT) defines resources for the application client. These configurations are stored in the application client `.ear` file. The application client run time uses these configurations for resolving and creating an instance of the resources for the application client.

Note: This task only applies to J2EE application clients. Only perform this task if you configured your J2EE application client to use resource references.

When a local object definition is created using the ACRCT, the JNDI name of the local object definition points to the reference for which the local object definition applies. The object might be a `resource-ref`, `resource-env-ref` or `message-destination-ref`. If the `message-destination-ref` has a `message-destination-link`, then point the local object definition to the message-destination. Local object definitions either point to the `message-destination-ref` (if the `message-destination-ref` has no link) or to the `message-destination` (if the message-destination-ref has a link). Any local object definitions pointing to `message-destination-refs` that have a link are ignored.

1. Start an assembly tool such as Application Server Toolkit (AST) or Rational Web Developer, and open an EAR file. See ″Starting an assembly tool″ in the information center for additional information.
2. Create a locally defined object.
3. Point the object to the appropriate message destination.
4. Save the EAR file.

Managing application clients

Perform the following tasks after deploying application clients. This task only applies to J2EE application clients.

1. Update data source and data source provider configurations.
2. Update URLs and URL provider configurations.
3. Update mail session configurations.
4. Update JMS provider, connection factories, and destination configurations.
5. Update MQ JMS provider, MQ connection factories and MQ destination configurations.
6. Update Resource Environment Entry and Resource Environment Provider configurations.
7. (Optional) Remove application client resources.

Updating data source and data source provider configurations with the Application Client Resource Configuration Tool:

During this task, you update the configuration of an existing data source or data source provider. Perform this task when your database configuration changes.

1. Start the Application Client Resource Configuration Tool (ACRCT), and open the Enterprise Archive (EAR) file containing the data source or data source provider. The EAR file contents display in a tree view.
2. Select Java Archive (JAR) file from the navigation tree containing the data source or data source provider to update.
3. Expand the JAR file to view its contents until you locate the particular data source or data source provider to update. Take one of the following actions:
   - Right-click the data source object and click **Properties**.
   - Click **Edit > Properties** on the menu bar.
4. Update the properties in the displayed fields. For detailed field help, see:
   - Data source provider properties
   - Data source properties
5. Click **OK** when you finish.
6. Click **File > Save** on the menu bar to save your changes.

Updating URLs and URL provider configurations for application clients:

1. Start the tool and open the Enterprise Archive (EAR) file containing the URL or URL provider. The EAR file contents are displayed in a tree view.
2. Select from the tree the Java Archive (JAR) file containing the URL or URL provider to update.
3. Expand the JAR file to view its contents.
4. Keep expanding the JAR file contents until you locate the particular URL or URL provider to update. Take one of the following actions:
   a. Right-click the URL object and click **Properties**.
   b. Click **Edit** > **Properties** on the menu bar.
5. Update the properties in the displayed fields.
6. Click **OK** when you finish.
7. Click **File** > **Save** on the menu bar to save your changes.

Updating mail session configurations for application clients:

During this task, you update the configuration of an existing JavaMail session. You cannot update the name of the default JavaMail provider, and you cannot delete the default JavaMail provider from the navigation tree.

1. Start the tool and open the Enterprise Archive (EAR) file containing the JavaMail session. The EAR file contents are displayed in the navigation tree view.
2. Select the Java Archive (JAR) file containing the JavaMail session to update from the navigation tree.
3. Expand the JAR file to view its contents.
4. Keep expanding the JAR file contents until you locate the particular JavaMail session to update. Take one of the following actions:
   a. Right-click the object and click **Properties**
   b. Click **Edit** > **Properties** from the menu bar.
5. Update the properties in the displayed fields.
6. Click **OK** when you finish.
7. Select **File** > **Save** from the menu bar to save your changes.

Updating Java Message Service provider, connection factories, and destination configurations for application clients:

During this task, you update the configuration of an existing Java Message Service (JMS) provider, connection factory or destination.

1. Start the tool and open the Enterprise Archive (EAR) file containing the Java Message Service (JMS) provider, connection factory, or destination. The EAR file contents display in a tree view.
2. Select the Java Archive (JAR) file containing the JMS provider, connection factory, or destination to update from the navigation tree.
3. Expand the JAR file to view its contents until you locate the particular JMS provider, connection factory, or destination to update. When you find it, do one of the following actions:
   - Right-click the provider, and click **Properties**.
   - Click **Edit > Properties** on the menu bar.
4. Update the properties in the displayed fields. For detailed field help, see:
   - JMS provider properties
   - WebSphere Application Server Queue connection factory properties
   - WebSphere Application Server Topic connection factory properties
   - WebSphere Application Server Queue destination properties
   - WebSphere Application Server Topic destination properties
5. Click **OK**.
6. Click **File > Save** to save your changes.

Updating WebSphere MQ as a Java Message Service provider, and its JMS resource configurations, for application clients:

Use this task to update an existing configuration of WebSphere MQ as a Java Message Service (JMS) provider, and to update the configuration of WebSphere MQ connection factories or WebSphere MQ destinations.

1. Start the Application Client Resource Configuration Tool (ACRCT).
2. Open the Enterprise Archive (EAR) file containing the WebSphere MQ JMS provider, WebSphere MQ connection factory, or WebSphere MQ destination. The EAR file contents are displayed in the navigation tree view.
3. Select the Java Archive (JAR) file containing the JMS provider, connection factory, or destination to update.
4. Expand the JAR file to view its contents until you locate the particular JMS provider, connection factory, or destination that you want to update. Complete one of the following actions:
   - Right-click the appropriate object and click **Properties**.
   - Click **Edit > Properties** on the menu bar.
5. Update the properties in the displayed fields. For detailed field help, see:
   - JMS provider properties
   - MQ Queue connection factory properties
   - MQ Topic connection factory properties
   - MQ Queue destination properties
   - MQ Topic destination properties
6. Click **OK**.
7. Click **File > Save** to save your changes.

Updating resource environment entry and resource environment provider configurations for application clients:

During this task, you update the configuration of an existing resource environment entry or resource environment provider.

1. Start the tool and open the Enterprise Archive (EAR) file containing the resource environment entry or resource environment provider. The EAR file contents display in a navigation tree view.

2. Select from the tree the Java Archive (JAR) file containing the resource environment entry or resource environment provider to update.
3. Expand the JAR file to view its contents until you locate the resource environment entry or resource environment provider to update. Take one of the following actions:
   - Right-click the resource environment object, and click **Properties**.
   - Click **Edit > Properties** on the menu bar.
4. Update the properties in the displayed fields. For detailed field help, see:
   - Resource environment provider properties
   - Resource environment entry properties
5. Click **OK** when you finish.
6. Click **File > Save** on the menu bar to save your changes.

Example: Configuring Resource Environment settings: The purpose of this topic is to help you configure Resource Environment settings.

- Required fields:
  - Resource Environment Provider page: **Name**
  - Resource Environment Entry page: **Name, JNDI Name**
- Example:

```
<resources.env:ResourceEnvironmentProvider xmi:id="ResourceEnvironmentProvider_1"
name="resourceEnvProvider:name" description="resourceEnvProvider:description">
<classpath>resourceEnvProvider:classpath</classpath>
<factories xmi:type="resources.env:ResourceEnvEntry" xmi:id="ResourceEnvEntry_1"
name="resourceEnvEntry:name" jndiName="resourceEnvEntry:jndiName"
description="resourceEnvEntry:description">
<propertySet xmi:id="J2EEResourcePropertySet_20">
<resourceProperties xmi:id="J2EEResourceProperty_22"
name="resourceEnvEntry:customName" value="resourceEnvEntry:customValue"/>
</propertySet>
</factories>
<propertySet xmi:id="J2EEResourcePropertySet_21">
<resourceProperties xmi:id="J2EEResourceProperty_23"
name="resourceEnvProvider:customName" value="resourceEnvProvider:customValue"/>
</propertySet>
</resources.env:ResourceEnvironmentProvider>
```

Example: Configuring resource environment custom settings for application clients: The purpose of this topic is to help you configure resource environment custom settings.

- The custom page applies to every resource type. You can specify as many custom names and values as you need.
- Example:

```
<propertySet xmi:id="J2EEResourcePropertySet_20">
<resourceProperties xmi:id="J2EEResourceProperty_22"
name="resourceEnvEntry:customName" value="resourceEnvEntry:customValue"/>
</propertySet>
```

Removing application client resources:

The option to delete an item does not offer a confirmation dialog. As a safeguard, consider saving your work right before you begin this task. If you change your mind after removing an item, you can close the EAR file without saving your changes, canceling your deletion. Remember to close the EAR file immediately after the deletion, or you also lose any unsaved work that you performed since the deletion.

This task only applies to J2EE application clients.

1. Start the Application Client Resource Configuration Tool (ACRCT) and open the Enterprise Archive (EAR) file from which you want to remove an object. The EAR file contents display in the navigation tree view. If you already have an EAR file open and have made some changes, click **File** > **Save** to save your work before preceding to delete an object.

2. Locate the object that you want to remove in the tree.
3. Right-click the object, and click **Delete**.
4. Click **File** > **Save**.

Web services

Implementing Web services applications

This topic introduces you to using Web services that are based on the Web Services for Java 2 Platform, Enterprise Edition (J2EE) specification. WebSphere Application Server supports Web services that are developed and implemented based on Web Services for J2EE. Use Web services when operating across a variety of platforms, including the J2EE 1.4 and non-J2EE platforms.

Using Web services makes most sense if your application clients are non-J2EE applications, unless you have J2EE applications spread across the Web. It is recommended that you use J2EE technologies if all your clients are J2EE applications because performance can decrease when you use a Web service in a J2EE exclusive environment.

Decide if a Web service implementation benefits your business process.

Implementing Web services applications is an easy way to integrate application systems together within or outside your company's infrastructure that otherwise function as a standalone systems. For example, your customer information database is a standalone application, but you want your accounting application to be able to access the customer data. You can create a web service for the customer database and then enable the accounting application as Web service client. Now, the accounting application can access the customer information. By implementing a Web service, these two applications can share information in an efficient manner.

Because Web services are easily applied to existing applications and information technology assets, new solutions can be deployed quickly and recomposed to address new opportunities. As Web services become more popular, the pool of services grows, promoting development of more robust models of just-in-time application and business integration over the Internet.

Use Web services applications with WebSphere Application Server by following the steps provided:

1. Plan to use Web services.
2. (Optional) Migrate existing Web services.

   If you have used Web services based on Apache SOAP and now want to develop and implement Web services based on the Web Services for J2EE specification, you need to migrate client applications developed with all versions of 4.0, and versions of 5.0 prior to 5.0.2.
3. Deploying Web services

   This topic is a good starting point in learning about how to develop a J2EE Web service.
4. Configure Web services deployment descriptors

   You need to configure the deployment descriptors so that WebSphere Application Server can process the incoming Web services requests.
5. Assemble Web services.

   This topic presents what you need to assemble a Web service and in what order you should assemble the parts, for example an enterprise archive (EAR) file.
6. Deploy Web services.

   This topic presents the steps necessary to deploy the EAR file that has been configured and enabled for Web services.

7. Configure Web service client bindings. This topic explains how to edit bindings for a Web service after these bindings are deployed on a server. When one Web service communicates with another Web service, you must configure the client bindings to access the downstream Web service.
8. Publish the WSDL file. Refer to ″Publishing the WSDL file″ in the information center or in the *Administering applications and their environment* PDF.

   After installing a Web services application, and optionally modifying the endpoint information, you might need WSDL files containing the updated endpoint information. This topic presents the steps necessary to publish the WSDL files so that this information is available.
9. Develop Web services clients.

   This topic explains how to develop a Web services client based on the Web Services for J2EE specification.
10. Secure Web services.

    This topic presents the methods used to integrate message-level security into a WebSphere Application Server environment.
11. Tune Web services.

    This topic includes information to help you use the Performance Monitoring Infrastructure (PMI) to measure the time required to process Web services requests.
12. Troubleshoot Web services.

    You can use this topic to learn more about troubleshooting different processes used to develop, implement and use Web services, including command-line tools, Java compiling errors, client runtime errors and exceptions, serialization and deserialization errors, and authentication challenges and authorization failures with Web services security.

The following example illustrates how a business might use Web services.

The owner of a flower shop wants to start receiving orders from customers through the Web. This owner starts the process by finding wholesale flower suppliers, pricing the product, and completing contracts for future flower orders.

Using Web services, the flower shop owner can find wholesale flower suppliers.

The flower shop owner can request price lists from each of the suppliers by obtaining a Web Services Description Language (WSDL) file for each potential supplier. The WSDL can be downloaded from the supplier’s Web page, received through e-mail, or retrieved from the supplier’s UDDI registry entry.

The WSDL describes the procedure call. When using WebSphere Application Server, the procedure call is a Java API for XML-based remote procedure call (JAX-RPC), which retrieves price lists. The WSDL file also specifies the Universal Resource Locator (URL) where the request is sent.

The flower shop owner now has to compare the prices received back from each supplier, decide which suppliers to do business with, and make arrangements for future orders to fill. The flower shop can now sell merchandise through the Web by using Web services to communicate with suppliers for the best prices and complete the ordering processes. The merchandise price lists need publishing to the Web site and a mechanism is needed for customers to order flowers.

The Web services clients of the flower supplier are deployed on the flower shop server. When a customer makes a transaction to purchase flowers through the Web, the order is sent to the supplier through JAX-RPC. The supplier responds by sending a confirmation with the order number and shipping date. The suppliers maintain the inventory and the flower shop owner handles billing and customer order management.

Similarly, the flower shop catalog can be composed automatically from the catalogs of all the suppliers. If the supplier ships directly to the customer, the order tracking inquiries can pass directly to the supplier’s order tracking system. The supplier can also use Web services to send invoices for orders and by the flower shop to pay the supplier's invoices. Processes that previously required forms to fill manually, and fax or mail, can now be done automatically, saving labor costs for both the flower shop and the supplier.

Using Web services is beneficial because a much larger inventory is made available to the flower shop. No merchandise maintenance overhead exists, but the flower shop can offer their customers products that they otherwise might not have. Selling flowers through the Web increases capital for the flower shop without overhead of another store or money invested into additional product.

For a more detailed scenario, see ″Web services scenario: Overview″ in the information center which tells the story of a fictional online garden supply retailer named Plants by WebSphere and how they incorporated the Web services concept.

Web services

Web services are self-contained, modular applications that you can describe, publish, locate, and invoke over a network.

WebSphere Application Server supports Web services that are developed and implemented based on the Web Services for Java 2 Platform, Enterprise Edition (J2EE) specification.

A typical Web services scenario is a business application requesting a service from another existing application. The request is processed through a given Web address using SOAP messages over a HTTP, Java Message Service (JMS) transport or invoked directly as Enterprise JavaBeans (EJB). The service receives the request, processes it, and returns a response. Examples of a simple Web service include weather reports or getting stock quotes. The method call is synchronous, that is, it waits until the result is available. Transaction Web services, supporting quotes, business-to-business (B2B) or business-to-client (B2C) operations include airline reservations and purchase orders.

Web services can include the actual service or the client that accesses the service.

Web services are Web applications that help you be more flexible in your business processes by integrating with applications that otherwise do not communicate. The inner-library loan program at your local library is a good example of the Web services concept and its evolution. The Web service concept existed even before the term; the concept became widely accepted with the creation of the Internet. Before the Internet was created, you visited your library, searched the collections and checked out your books. If you did not find the book that you wanted, the librarian did a search for you by computer or phone and located the book at a nearby library. The librarian ordered the book for you and you picked it up after it was delivered to your local library. By incorporating Web services applications, you can streamline your library visit.

Now, you can search the local library collection and other local libraries at the same time. When other libraries provide your library with a Web service to search their collection (the service might have been provided through UDDI), your results yield their resources. Another Web service application might enable you to check the book out and get it sent to your home. Using Web services applications saves time and provides a convenience for you, as well as freeing the librarian to do other business tasks.

Web services reflect the service-oriented architecture (SOA) approach to programming. This approach is based on the idea of building applications by discovering and implementing network-available services, or by invoking the available applications to accomplish a task. Web services deliver interoperability, for example, Web services applications provide components created in different programming languages to work together as if they were created using the same language. Web services rely on existing transport technologies, such as HTTP, and standard data encoding techniques, such as Extensible Markup Language (XML), for invoking the implementation.

The key components of Web services include:

- Web Services Description Language (WSDL)

WSDL is the XML-based file that describes the Web service. The Web service request uses this file to bind to the service.

- SOAP

  SOAP is the XML-based protocol that the Web service request uses to invoke the service.

For a more detailed scenario, see ″Web services scenario: Overview″ in the information center, which tells the story of a fictional online garden supply retailer named Plants by WebSphere, and how this retailer incorporated the Web services concept.

Web Services for J2EE specification

The *Web services for Java 2 Platform, Enterprise Edition (J2EE)* specification defines the programming model and run-time architecture for implementing Web services based on the Java language. Another name for the Web Services for J2EE specification is the Java Specification Requirements (JSR) 109. The specification includes open standards for developing and implementing Web services.

Version 6.0 uses Web Services for J2EE 1.1 as the standard for developing and implementing Web services. Web Services for J2EE 1.1 is one of the Web service APIs available in J2EE 1.4.

The Web Services for J2EE specification focuses on Extensible Markup Language (XML) remote procedure call (RPC) and the Java language, including representing XML-based interface definitions in the Java language; Java language definitions in XML-based definition languages, such as SOAP, and assembling.

The J2EE technology can be integrated with Web services in a variety of ways. J2EE components, for example, JavaBeans and enterprise beans, can be exposed as Web services. These services can be accessed by clients written in Java code or by existing Web service clients that are not written in Java code. J2EE components can also act as Web service clients.

The Web Services for J2EE specification is the preferred platform for Web-based programming because it provides open standards allowing different types of languages, operating systems and software to communicate seamlessly through the Internet.

For a Java application to act as Web service client, a mapping between the Web Services Description Language (WSDL) file and the Java application must exist. The mapping is defined by the Java API for XML-based RPC (JAX-RPC) specification.

You can use a Java component to implement a Web service by specifying the component interface and binding information in the WSDL file and designing the application server infrastructure to accept the service request.

This entire process encompassed is based on the Web Services for J2EE specification.

The specification brings with it the `webservices.xml` deployment descriptor specifically for Web services. You are responsible for providing various elements to the deployment descriptor, including:

- Port name
- Port service implementation
- Port service endpoint interface
- Port WSDL definition
- Port QName
- JAX-RPC mapping
- Handlers (optional)
- Servlet mapping (optional)

The Enterprise JavaBeans (EJB) 2.1 specification also states that for a Web service developed from a session bean, the EJB deployment descriptor, `ejb-jar.xml`, must contain the service-endpoint element. The service-endpoint value must be the same as that stated in the webservices.xml deployment descriptor. To learn more about the EJB 2.1 specification see Enterprise beans: Resources for learning.

To review the entire Web Services for J2EE specification, see Web services: Resources for learning.

JAX-RPC

The *Java API for XML-based RPC (JAX-RPC)* specification enables you to develop SOAP-based interoperable and portable Web services and Web service clients. JAX-RPC 1.1 provides core APIs for developing and deploying Web services on a Java platform and is a required part of the J2EE 1.4 platform. The J2EE 1.4 platform allows you to develop portable Web services. Web services can also be developed and deployed on J2EE 1.3 containers.

WebSphere Application Server implements JAX-RPC 1.1 standards.

The JAX-RPC standard covers the programming model and bindings for using Web Services Description Language (WSDL) for Web services in the Java language. JAX-RPC simplifies development of Web services by shielding you from the underlying complexity of SOAP communication.

On the surface, JAX-RPC looks like another instantiation of remote method invocation (RMI). Essentially, JAX-RPC allows clients to access a Web service as if the Web service was a local object mapped into the client's address space even though the Web service provider is located in another part of the world. The JAX-RPC is done by using the XML-based protocol SOAP, which typically rides on top of HTTP.

JAX-RPC defines the mappings between the WSDL port types and the Java interfaces, as well as between Java language and Extensible Markup Language (XML) schema types.

A JAX-RPC Web service can be created from a JavaBean or a enterprise bean implementation. You can specify the remote procedures by defining remote methods in a Java interface. You only need to code one or more classes that implement the methods. The remaining classes and other artifacts are generated by the Web service vendor's tools. The following is an example of a Web service interface:

```
package com.ibm.mybank.ejb;
import java.rmi.RemoteException;
import com.ibm.mybank.exception.InsufficientFundsException;
/**
 * Remote interface for Enterprise Bean: Transfer
 */
public interface Transfer_SEI extends java.rmi.Remote {
   public void transferFunds(int fromAcctId, int toAcctId, float amount)
      throws java.rmi.RemoteException;

}
```

The interface definition in JAX-RPC must follow specific rules; most of these rules are from RMI with some additions for JAX-RPC. The following are the rules for defining a JAX-RPC interface:

- The interface must extend `java.rmi.Remote` just like RMI.
- Methods must throw `java.rmi.RemoteException`.
- Method parameters cannot be remote references.
- Method parameter must be one of the parameters supported by the JAX-RPC specification. The following list are examples of method parameters that are supported. For a complete list of method parameters see the JAX-RPC specification.
  - Primitive types: `boolean`, `byte`, `double`, `float`, `short`, `int` and `long`
  - Object wrappers of primitive types: `java.lang.Boolean`, `java.lang.Byte`, `java.lang.Double`, `java.lang.Float`, `java.lang.Integer`, `java.lang.Long`, `java.lang.Short`
  - `java.lang.String`

  - `java.lang.BigDecimal`
  - `java.lang.BigInteger`
  - `java.lang.Calendar`
  - `java.lang.Date`
- Methods can take value objects which consist of a composite of the types previously listed, in addition to aggregate value objects.

A client creates a stub and invokes methods on it. The stub acts like a proxy for the Web service. From the client code perspective, it seems like a local method invocation. However, each method invocation gets marshaled to the remote server. Marshaling includes encoding the method invocation in XML as prescribed by the SOAP protocol.

The following are key classes and interfaces needed to write Web services and Web service clients:

- **Service interface**: A factory for stubs or dynamic invocation and proxy objects used to invoke methods
- **ServiceFactory class**: A factory for Services.
- **`loadService`**

  The `loadService` method is provided in WebSphere Application Server Version 6.0 to generate the service locator which is required by a JAX-RPC implementation. If you recall, in previous versions there was no specific way to acquire a generated service locator. For managed clients you used a JNDI method to get the service locator and for non-managed clients, you were required to instantiate IBM's specific service locator `ServiceLocator service=new ServiceLocator(...);` which does not offer portability. The `loadService` parameters include:
  - **`wsdlDocumentLocation:`** A URL for the WSDL document location for the service or null.
  - **`serviceName`**: A qualified name for the service
  - **`properties`**: A set of implementation-specific properties to help locate the generated service implementation class.
- **`isUserInRole`**

  The `isUserInRole` method returns a boolean indicating whether the authenticated user for the current method invocation on the endpoint instance is included in the specified logical role.
  - **`role`**: The role parameter is a String specifying the name of the role.
- **Service**
- **Call interface**: Used for dynamic invocation
- **Stub interface**: Base interface for stubs

If you are using a stub to access the Web service provider, most of the JAX-RPC API details are hidden from you. The client creates a ServiceFactory (`java.xml.rpc.ServiceFactory`). The client instantiates a Service (`java.xml.rpc.Service`) from the ServiceFactory. The service is a factory object that creates the port. The port is the remote service endpoint interface to the Web service. In the case of DII, the Service object is used to create Call objects, which you can configure to call methods on the Web service's port.

To learn more about JAX-RPC see Web services: Resources for learning.

SOAP

Simple Object Access Protocol (SOAP) is a specification for the exchange of structured information in a decentralized, distributed environment. As such, it represents the main way of communication between the three key actors in a service oriented architecture (SOA): service provider, service requestor and service broker. The main goal of its design is to be simple and extensible. A SOAP message is used to request a Web service.

WebSphere Application Server follows the standards outlined in SOAP 1.1.

SOAP was submitted to the World Wide Web Consortium (W3C) as the basis of the Extensible Markup Language (XML) Protocol Working Group by several companies, including IBM and Lotus. This protocol consists of three parts:

- An *envelope* that defines a framework for describing message content and processing instructions.
- A set of *encoding rules* for expressing instances of application-defined data types.
- A *convention* for representing remote procedure calls and responses.

SOAP is a protocol-independent transport and can be used in combination with a variety of protocols. In Web services that are developed and implemented with WebSphere Application Server, SOAP is used in combination with HTTP, HTTP extension framework, and Java Message Service (JMS). SOAP is also operating-system independent and not tied to any programming language or component technology.

As long as the client can issue XML messages, it does not matter what technology is used to implement the client. Similarly, the service can be implemented in any language, as long as the service can process SOAP messages. Also, both server and client sides can reside on any suitable platform.

For more information about SOAP, see Web services: Resources for learning.

SOAP with Attachments API for Java

SOAP with Attachments API for Java (SAAJ) is used for SOAP messaging that works behind the scenes in the Java API for XML-based RPC (JAX-RPC) implementation.

Web services uses SOAP messages to represent remote procedure calls between the client and the server. In normal JAX-RPC flows, the SOAP message is deserialized into a series of Java value type business objects that represent the parameters and return values. In addition, JAX-RPC provides APIs that support applications and handlers to manipulate the SOAP message directly. The SOAP message is manipulated using the SAAJ data model. The primary interface in the SAAJ model is javax.xml.soap.SOAPElement.

WebSphere Application Server uses SAAJ Version 1.2. The main benefit of SAAJ Version 1.2 is that the model extends the Document Object Model (DOM) model. The DOM model is used by applications that manipulate XML. Using this model applications are able to process an SAAJ model that uses pre-existing DOM code. It is also easier to convert pre-existing DOM objects to SAAJ objects.

Messages created using SAAJ follow SOAP standards. A SOAP message is represented in the SAAJ model as a javax.xml.soap.SOAPMessage object. The XML content of the message is represented by a javax.xml.soap.SOAPPart object. Each SOAP part has a SOAP envelope. This envelope is represented by the SAAJ javax.xml.SOAPEnvelope object. The SOAP specification defines various elements that reside in the SOAP envelope; SAAJ defines objects for the various elements in the SOAP envelope.

The SOAP message can also contain non-XML data that is called attachments. These attachments are represented by SAAJ AttachmentPart objects that are accessible from the SOAPMessage object.

A number of reasons exist as to why handlers and applications use the generic SOAPElement API instead of a tightly bound mapping:

- The Web service might be a conduit to another Web service. In this case, the SOAP message is only forwarded.
- The Web service might manipulate the message using a different data model, for example a Service Data Object (SDO). It is easier to convert the message from a SAAJ Document Object Model (DOM) to a different data model.
- A handler, for example, a digital signature validation handler, might want to manipulate the message generically.

To review the entire SAAJ API, see Web services: Resources for learning.

Web Services-Interoperability Basic Profile

The *Web Services-Interoperability (WS-I) Basic Profile* is a set of non-proprietary Web services specifications that promote interoperability.

WebSphere Application Server conforms to the WS-I Basic Profile 1.1.

The WS-I Basic Profile is governed by a consortium of industry-leading corporations, including IBM, under direction of the WS-I Organization. The profile consists of a set of principles that relate to bringing about open standards for Web services technology. All organizations that are interested in promoting interoperability among Web services are encouraged to become members of the Web Services Interoperability Organization.

Several technology components are used in the composition and implementation of Web services, including messaging, description, discovery, and security. Each of these components are supported by specifications and standards, including SOAP 1.1, Extensible Markup Language (XML) 1.0, HTTP 1.1, Web Services Description Language (WSDL) 1.1, and Universal Description, Discovery and Integration (UDDI). The WS-I Basic Profile specifies how these technology components are used together to achieve interoperability, and mandates specific use of each of the technologies when appropriate. You can read more about the WS-I Basic Profile at the WS-I Organization Web site. A link to this Web site is listed in Web services: Resources for learning.

Each of the technology components have requirements that you can read about in more detail at the WS-I Organization Web site. For example, support for Universal Transformation Format (UTF)-16 encoding is required by WS-I Basic Profile. UTF-16 is a kind of Unicode encoding scheme using 16-bit values to store Universal Character Set (UCS) characters. UTF-8 is the most common encoding that is used on the Internet; UTF-16 encoding is typically used for Java and Windows product applications; and UTF-32 is used by various Linux and Unix systems. Unlike UTF-8, UTF-16 has issues with big-endian and little-endian, and often involves Byte Order Mark (BOM) to indicate the endian. BOM is mandatory for UTF-16 encoding and it can be used in UTF-8.

See how to modify your encoding from UTF-8 to UTF-16 if you need to change from UTF-8 to UTF-16.

The following table summarizes some of the properties of each UTF:

Bytes	Encoding form
EF BB BF	UTF-8
FF FE	UTF-16, little-endian
FE FF	UTF-16, big-endian
00 00 FE FF	UTF-32, big-endian
FF FE 00 00	UTF-32, little-endian

BOM is written prior to the XML text, and it indicates to the parser how the XML is encoded. The XML declaration contains the encoding, for example: `<?xml version=`*`xxx`*` encoding=″utf-`*`xxx`*`″?>`. BOM is used with the encoding to determine how to interpret the XML. Here is an example of a SOAP message and how BOM and UTF encoding are used:

```
POST http://www.whitemesa.net/soap12/add-test-rpc HTTP/1.1
Content-Type: application/soap+xml; charset=utf-16; action=""
SOAPAction:
Host: localhost: 8080
Content-Length: 562

0xFF0xFE<?xml version="1.0" encoding="utf-16"?>
<soap:Envelope xmlns:soap="http://www.w3.org/2002/12/soap-envelope"
 xmlns:soapenc="http://www.w3.org/2002/12/soap-encoding
 xmlns:tns="http://whitemesa.net/wsdl/soap12-test"
 xmlns:types="http://whitemesa.net/wsdl/soap12-test/encodedTypes"
 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
 <soap:Body>
  <q1:echoString xmlns:q1="http://soapinterop.org/">
   <inputString soap:encodingStyle="http://example.org/unknownEncoding"
   xsi:type="xsd:string">
    Hello SOAP 1.2
   </inputString>
  </q1:echoString>
 </soap:Body>
</soap:Envelope>
```

In the example code, 0xFF0xFE represents the byte codes, while the *<?xml>* declaration is the textual representation.

To learn more about the WS-Basic profile, including scenarios, UTF and BOM, see Web services: Resources for learning.

RMI-IIOP using JAX-RPC

Java API for XML-based Remote Procedure Call (JAX-RPC) is the Java standard API for invoking Web services through remote procedure calls. A transport is used by a programming language to communicate over the Internet. You can use protocols with the transport such as SOAP and Remote Method Invocation (RMI). You can use Remote Method Invocation over Internet Inter-ORB Protocol (RMI-IIOP) with JAX-RPC to support non-SOAP bindings.

Using RMI-IIOP with JAX-RPC, enables WebSphere Java clients to invoke enterprise beans using a WSDL file and the JAX-RPC programming model instead of using the standard J2EE programming model. When a enterprise JavaBeans implementation is used to invoke a Web service, multiprotocol JAX-RPC permits the Web service invocation path to be optimized for WebSphere Java clients. Learn more about this by reviewing ″Using WSDL EJB bindings to invoke an EJB from a Web services client ″ in the information center.

Benefits of using the RMI/IIOP protocol instead of a SOAP- based protocol are:

- XML processing is not required to send and receive messages; Java serialization is used instead.
- The client JAX-RPC call can participate in a user transaction, which is not the case when SOAP is used.

WS-I Attachments Profile

The *Web Services-Interoperability (WS-I) Attachments Profile* is a set of non-proprietary Web services specifications that promote interoperability. This profile compliments the WS-I Basic Profile 1.1 to add support for interoperable SOAP messages with attachments-based Web services.

WebSphere Application Server conforms to the WS-I Attachments Profile 1.0.

Attachments are typically used to send binary data, for example, data that is mapped in Java code to java.awt.Image and javax.activation.DataHandler. The raw data can be sent in the SOAP message, however, this approach is inefficient because an XML parser has to scan the data as it parses the message.

The WS-I Attachments Profile provides a solution to the limitations that are presented by Web Services Description Language (WSDL) 1.1. Because WSDL 1.1 attachments are not part of the XML schema type space, they can be message parts only. As message parts, the attachments cannot be arrays or properties of Java beans. The profile defines the wsi:swaRef XML schema type.Use the wsi:swaRef XML schema type to overcome the limitations of WSDL 1.1 attachments.

The wsi:swaRef type is an extension of the xsd:anyURI type, where its value contains the content-ID of the attachment.

Web services: Resources for learning

This topic provides relevant supplemental information about the following Web services-related topics:

- Web services overview
- Developing Web services:

  Includes developing Web services based on the Java 2 Platform, Enterprise Edition (J2EE) and Java API for XML-based remote procedure call (JAX-RPC) specifications.
- Universal Description Discovery and Integration (UDDI)

  Includes an overview about UDDI and information about the UDDI Java API.
- The Web Services Invocation Framework (WSIF)

  Includes a look into the Apache Software Foundation and its maintenance of WSIF.
- Web Services-Interoperability (WS-I) Basic Profile

  Includes an overview about the WS-I Basic Profile.
- SOAP

  Includes an overview about SOAP, information about the SOAP syntax and processing rules.
- Security

  Includes a roadmap to security, the WS-Security specification, best practices, a profile of the OASIS Security Assertion Markup Language (SAML) and more.
- Samples

  Includes the Samples Gallery for WebSphere Application Server and Samples Central for UDDI and WSIF.

The information resides on IBM and non-IBM Internet sites, whose sponsors control the technical accuracy of the information.

These links are provided for convenience. Often, the information is not specific to an IBM WebSphere Application Server product, but is useful all or in part for understanding the product. When possible, links are provided to technical papers and Redbooks that supplement the broad coverage of the release documentation with in-depth examinations of particular product areas.

Web services overview

- WebSphere Version 5.1.1 Web Services Handbook

  This IBM Redbook describes the new concept of Web services from various perspectives. It presents the major building blocks on which Web services rely. Well-defined standards and new concepts are presented and discussed.
- Web services (r)evolution, Part 1

  This article focuses on the benefits and challenges of building Web services applications. Web services might be an evolutionary step in designing distributed applications, however, the technology is not without problems. Outlined are the difficulties developers face in creating a truly workable distributed system of Web services. This article also outlines author Graham Glass's plan for building peer-to-peer Web applications.

Developing Web services

- Java Web Services: SOAP with Attachments API for Java (SAAJ)

  This document describes the SOAP with Attachments API for Java (SAAJ) and how this API provides a standard way to send XML documents over the Internet from the Java platform.
- JSR 109: Implementing Enterprise Web services

  This document describes the Java 2 Platform, Enterprise Edition (J2EE) specification.
- JAX-RPC: Core Web services API in the Java platform

  This document reviews the JAX-RPC specification which enables Java technology developers to develop SOAP-based interoperable and portable Web services.
- A developer introduction to the JAX-RPC specification, Part 1: Learn the ins and outs of the JAX-RPC type-mapping system. The JAX-RPC specification is an important step forward in the quest for Web services interoperability. This DeveloperWorks WebSphere article explains the mapping between WSDL

and XML types and Java types. It explains how the JAX-RPC standard defines this feature and some of the important points on designing an interoperable type system.

- A developer introduction to JAX-RPC, Part 2: Mine the JAX-RPC specification to improve Web service interoperability. This DeveloperWorks WebSphere article explains how you can achieve the next level of Web service interoperability using the JAX-RPC standard client and server side interface definitions and message processing model. It includes information on developing JAX-RPC handlers and handler chains.
- Getting Started with JAX-RPC. This article explains some of the basic JAX-RPC programming concepts. It describes the JAX-RPC client and server programming models and provides some simple examples for illustration. The article is intended to give developers a good grasp of how to use the JAX-RPC specification to develop or use Web services.
- Web Services Description Language

  This article is a detailed overview of Web Services Description Language (WSDL), which includes programming specifications.

UDDI

- Universal Description, Discovery and Integration

  This article is a detailed overview of Universal Description, Discovery, and Integration (UDDI).
- A new approach to UDDI and WSDL: Introduction to the new OASIS UDDI WSDL Technical Note

  This article is about using WSDL with UDDI. Although it is based on the UDDI Registry in WebSphere Application Server Version 5, it remains a useful description of the recommended approach for use of WSDL with UDDI.
- UDDI Version 3 Features List

  This article is an introduction to the new features in UDDI Version 3.

WSIF

- The Apache Software Foundation. The Apache Software Foundation provides support for the Apache community of open-source software projects. Of particular interest is the Apache Web services project. The WSIF source code is donated by IBM to the Apache Software Foundation, and is maintained here as an Apache project.

WS-I Basic Profile

- Web Services Interoperability Organization This Web site offers resources and guidelines for Web services interoperability. You can also view the latest specification documents for WS-I Basic Profile from the documentation link on the home page.
- UTF and BOM Frequently Asked Questions. This Web site offers general information about UTF-8, UTF-16, UTF-32, along with Byte Order Mark (BOM) in a question and answer format.

SOAP

- SOAP

  This article is a detailed overview of SOAP, which includes programming specifications.
- SOAP Security Extensions: Digital Signature

  This document specifies the syntax and processing rules of a SOAP header entry to carry digital signature information within a SOAP 1.1 Envelope

Security

- Security in a Web Services World: A Proposed Architecture and Roadmap

  This document describes a proposed model for addressing security within a Web service environment. It defines a comprehensive Web Services Security model that supports, integrates, and unifies several popular security models, mechanisms, and technologies, including both symmetric and public key technologies. Enable a variety of systems to securely interoperate in a platform and language-neutral manner. It also describes a set of specifications and scenarios that show how these specifications can be used together.

- Web Services Security (WS-Security)

  The Web Services security specifications describe enhancements to SOAP messaging to provide the quality of protection through message integrity, message confidentiality, and single message authentication. Use these mechanisms to accommodate a wide variety of security models and encryption technologies. Web Services security also provides a general-purpose mechanism for associating security tokens with messages. Additionally, Web Services Security describes how to encode binary security tokens. Specifically, the specification describes how to encode X.509 certificates and Kerberos tickets, as well as how to include opaque encrypted keys. It also includes extensibility mechanisms that can be used to further describe the characteristics of the credentials that are included with a message.
- SOAP Security Extensions: Digital Signature

  This document specifies the syntax and processing rules of a SOAP header entry to carry digital signature information within a SOAP 1.1 envelope
- Web Services Security Addendum

  This document describes clarifications, enhancements, best practices, and errata of the Web Services Security specification.
- WS-Security Profile of the OASIS Security Assertion Markup Language (SAML) Working Draft 04, 10 September 2002

  This document proposes a set of standards for SOAP extensions used to increase message confidentiality.
- Web Services Security: SOAP Message Security Working Draft 12, Monday 21 April 2003

  This document describes the support for multiple token formats, trust domains, signature formats, and encyrption technologies.
- JSR 55:Certification Path API

  This document provides a short description of the certification path API.
- XML-Signature Syntax and Processing

  This document specifies XML digital signature processing rules and syntax. XML signatures provide integrity, message authentication, or signer authentication services for data of any type, whether located within the XML that includes the signature or elsewhere.
- Canonical XML Version 1.0

  This specification describes a method for generating a physical representation, the canonical form, of an XML document that accounts for the permissible changes.
- Exclusive XML Canonicalization Version 1.0

  Canonical XML [XML-C14N] specifies a standard serialization of XML that, when applied to a subdocument, includes the subdocument ancestor context including all of the namespace declarations and attributes in the ″xml:″namespace.
- XML Encryption Syntax and Processing

  This document specifies a process for encrypting data and representing the result in XML.
- Decryption Transform for XML Signature

  This document specifies an XML Signature decryption transform that enables XML Signature applications to distinguish between those XML encryption structures that are encrypted before signing, and must not be decrypted, and those that are encrypted after signing, and must be decrypted, for the signature to validate.
- WS-Security

  This document specifies resources for the April 2002 Web Services Security Specification. The following addenda and drafts are available:
  - http://schemas.xmlsoap.org/ws/2002/07/secext/
  - http://schemas.xmlsoap.org/ws/2002/07/utility/
  - OASIS draft 12 for secext
  - OASIS draft 12 for utility

- Specification: Web Services Security (WS-Security) Version 1.0 05 April 2002
- XML Encryption Syntax and Processing W3C Recommendation 10 December 2002
- XML-Signature Syntax and Processing W3C Recommendation 12 February 2002
- Web Services Security Addendum
- Web Services Security Core Specification Working Draft 01, 20 September 2002
- Web Services Security: SOAP Message Security Working Draft 13, Thursday, 01 May 2003
- Internet X.509 Public Key Infrastructure Certificate and Certificate Revocation List (CRL) Profile, RFC3280, April 2002
- OASIS Web Services Security Technical Committee

Samples

- Samples Gallery
- Samples Central. Samples and associated documentation for the following Web services components are available through the Samples Central page of the DeveloperWorks WebSphere Web site:
  - The IBM WebSphere UDDI Registry.
  - The Web Services Invocation Framework (WSIF).

Deploying Web services

This task explains how to deploy a Web service into WebSphere Application Server.

To deploy Web services that are based on the Web Services for Java 2 Platform, Enterprise Edition (J2EE) specification, you need an enterprise application, also known as an enterprise archive (EAR) file that is configured and enabled for Web services.

If you have a Web service that was deployed on a previous version of WebSphere Application Server, you might want to run the **wsdeploy** command so that you can benefit from performance features that have been added to this release.

This task is one of the steps in developing and implementing Web services.

You can use either the administrative console or the **wsadmin** scripting tool to deploy an EAR file. If you are installing an application containing Web services by using the **wsadmin** command, specify the -deployws option. If you are installing an application containing Web services by using the administrative console, select **Deploy WebServices** in the Install New Application wizard. For more information about installing applications using the administrative console see Installing a new application.

If the Web services application is previously deployed with the **wsdeploy** command, it is not necessary to specify Web services deployment during installation.

The following actions deploy the EAR file with the **wsadmin** command:

1. Start `*install_root*\bin\wsadmin` from a command prompt. If you are using Linux or Unix platforms, start `*install_root*/bin/wsadmin.sh`.
2. Enter the **$AdminApp install *EARfile* "-usedefaultbindings -deployws"** command at the **wsadmin** prompt.

You have a Web service installed into the Application Server.

Protect your Web services applications by adding security to the applications.

wsdeploy command

This topic explains how to use the **wsdeploy** command-line tool with Web services that are based on the Web Services for Java 2 Platform, Enterprise Edition (J2EE) specification. The **wsdeploy** command adds WebSphere product-specific deployment classes to a Web services-compatible enterprise application enterprise archive (EAR) file or an application client Java archive (JAR) file. These classes include:

- Stubs

- Serializers and deserializers
- Implementations of service interfaces

This deployment step must be performed at least once, and can be performed more often. Deployment can be performed separately using the **wsdeploy** command, assembly tools, or when the application is installed. When using the **wsadmin** command for installation, specify the **-deployws** option.

The **wsdeploy** command operates as noted in the following list:
- Each module in the enterprise application or JAR file is examined
- If the module contains Web services implementations, indicated by the presence of the `webservices.xml` deployment descriptor, the associated Web Services Description Language (WSDL) files are located and the **WSDL2Java** command is run with the role deploy-server option.
- If the module contains Web services clients, indicated by the presence of the client deployment descriptor, the associated WSDL files are located and the **WSDL2Java** command is run with the role deploy-client option.
- The files generated by the **WSDL2Java** command are compiled and repackaged.

See **WSDL2Java** command for more information about the files that are generated for deployment.

When the generated files are compiled, they can reference application-specific classes outside the EAR or JAR file, if the EAR or JAR file is not self-contained. In this case, use either the -jardir or -cp option to specify additional JAR or zip files to be added to CLASSPATH variable when the generated files are compiled.

wsdeploy command syntax

The command syntax is noted in the following example:

```
wsdeploy Input_filename Output_filename [options]
```

Required options:
- ***Input_filename***

  Specifies the path to the EAR or JAR file to deploy.
- ***Output_filename***

  Specifies the path of the deployed EAR or JAR file. If *output_filename* already exists, it is silently overwritten. The *output_filename* can be the same as the*input_filename*.

Other options:
- **-jardir** *directory*

  Specifies a directory that contains JAR or zip files. All JAR and zip files in this directory are added to the CLASSPATH used to compile the generated files. This option can be specified zero or more times.
- -**cp** *entries*

  Specifies entries to add to the CLASSPATH when the generated classes are compiled. Multiple entries are separated the same as they are in the CLASSPATH environment variable, with a semicolon on Windows platforms and a colon for Linux and Unix platforms.
- **-codegen**

  Specifies to generate but not compile deployment code. This option implicitly specifies the -keep option.
- **-debug**

  Includes debugging information when compiling, that is, use javac -g to compile.
- **-help**

  Displays a help message and exit.
- **-ignoreerrors**

  Do not stop deployment if validation or compilation errors are encountered.
- **-keep**

Do not delete working directories containing generated classes. A message is displayed indicating the name of the working directory that is retained.

- **-novalidate**

  Do not validate the Web services deployment descriptors in the input file.
- **-trace**

  Displays processing information, including the names of the generated files.

Example The following example illustrates how the options are used with the **wsdeploy** command:

```
wsdeploy x.ear x_deployed.ear -trace -keep
Processing web service module x_client.jar.
Keeping directory: f:\temp\Base53383.tmp for module: x_client.jar.
Parsing XML file:f:\temp\Base53383.tmp\WarDeploy.wsdl
Generating f:\temp\Base53383.tmp\generatedSource\com\test\WarDeploy.java
Generating f:\temp\Base53383.tmp\generatedSource\com\test\WarDeployLocator.java
Generating f:\temp\Base53383.tmp\generatedSource\com\test\HelloWsBindingStub.java
Compiling f:\temp\Base53383.tmp\generatedSource\com\test\WarDeploy.java.
Compiling f:\temp\Base53383.tmp\generatedSource\com\test\WarDeployLocator.java.
Compiling f:\temp\Base53383.tmp\generatedSource\com\test\HelloWsBindingStub.java.
Done processing module x_client.jar.
```

Messages

- Flag *-f*is not valid.

  Option *f* was not recognized as a valid option.
- Flag *-c* is ambiguous.

  Options can be abbreviated, but the abbreviation must be unique. In this case, the **wsdeploy** command cannot determine which option was intended.
- Flag *-c* is missing parameter *-p*.

  A required parameter for an option is omitted.
- Missing *p* parameter.

  A required option is omitted.

Configuring Web service client bindings

When a Web service application is deployed into WebSphere Application Server, an instance is created for each application or module. The instance contains deployment information for the Web module or enterprise JavaBean (EJB) module, including client bindings.

Deploy the Web service into WebSphere Application Server.

To complete this task, you need to know the topology of the URL endpoint address of the Web services servers and which Web service the client depends upon. You can view the deployment descriptors in the administrative console to find topology information. See the article ″View Web services server deployment descriptors″ in the information center for more information.

The client bindings define the Web Services Description Language (WSDL) file name and preferred ports. The relative path of a Web service in a module is specified within a compatible WSDL file that contains the actual URL to be used for requests. The address is only needed if the original WSDL file did not contain a URL, or when a different address is needed. For a service endpoint with multiple ports, you need to define an alternative WSDL file name.

The following steps describe how to edit bindings for a Web service after these bindings are deployed on a server. When one Web service communicates with another Web service, you must configure the client bindings to access the downstream Web service.

You can also configure client bindings with **wsadmin**.

To configure client bindings through the administrative console:

1. Open the administrative console.
2. Click **Applications** > **Enterprise Applications** > *application_instance* > **Web modules** > *module_instance* > **Web services client bindings**.

   For EJB modules, click **Applications** >**Enterprise Applications** > *application_instance* > **EJB modules** > *module_instance* > **Web services client bindings**.
3. Find the Web service you want to update.

   The Web services are listed in the **Web Service** field.
4. Select the WSDL file name from the drop down box in the WSDL file name field.
5. Click **Edit** in the Preferred port mappings field to configure the default port to use.
   1. Specify the port type and the preferred ports in the Port type and Preferred ports fields.

      Configuring the preferred port enables you to select an optimal port implementation use non-SOAP protocols. See RMI-IIOP Web services using JAX-RPC for more information about using non-SOAP protocols.
   2. Click **Apply** and **OK**.
6. Click **Edit** in the Port information field to configure the request timeout, the overridden endpoint, and the overridden binding namespace for a port.

   Configuring the request timeout accommodates complex topologies that can have multiple cascaded Web services that involve multiple hops or long-running services.

   Timeout values can be configured based on observed behavior of the overall system as integration proceeds. For example, a Web service client might time out because of changing network conditions or the performance of an external Web service. When you have applications containing Web services clients that timeout, you can change the request time out values for the clients.
   1. Click **Apply** and **OK**.

Your Web service client bindings are configured.

Now you can finish any other configurations, start or restart the application, and verify the expected behavior of the Web service.

Web services client bindings

The client bindings define the Web Service Description Language (WSDL) file name, preferred ports and other port information. Use this page to specify the client bindings and the port mappings for the Web services in a module.

A Web service can specify the relative path within the module of a compatible WSDL file containing the actual URL to be used for requests. The relative path only needs to be specified if the original WSDL file does not contain a URL or when a different URL is needed. For a service endpoint with multiple ports defined, a preferred mapping specifies the default port to use for a port type.

To view this page, click **Applications** >**Enterprise Applications** > *application_instance* > **Web modules** > *module_instance*>**Web services client bindings**.

For EJB modules, click **Applications** >**Enterprise Applications** > *application_instance* > **EJB modules** > *module_instance*>**Web services client bindings**.

Web service:

Identifies the name of this Web service. A module can contain one or more Web services.

EJB:

Identifies the name of the EJB for the EJB modules.

WSDL file name:

Specifies the WSDL file name, which is relative to the module. Locate the WSDL file name in the drop down menu.

Preferred port mappings:

Specifies and manages the preferred port type mapping for a Web service when a particular port type is requested.

Click **Edit** to edit the preferred port mapping information on the **Preferred port mappings** panel.

Port information:

Specifies additional configuration information for the ports of this Web service.

Click **Edit** to edit the port information on the **Port information** panel. You can set a request timeout, override an endpoint and override a binding namespace for each client port.

Preferred port mappings:

Use this page to view and manage a preferred portType mapping for a Web service.

When you have multiple ports that reference the same portType (service endpoint interface), a preferred port specifies the port to use when the `Service.getPort(Class SEI)` method is called with only the service endpoint interface.

To view this administrative console page, click **Applications** >**Enterprise Application** > *application_instance* > **Web modules** > *module_instance*>**Web services client bindings** > **Edit**> *preferred_port_instance*.

For EJB modules, click **Applications** >**Enterprise Application** > *application_instance* > **EJB modules** > *module_instance*>**Web services client bindings** > **Edit**> *preferred_port_instance*.

portType:

Specifies the portType.

The preferred port and the portType values are both of the type `java.xml.namespace.QName`.

Preferred port:

Specifies the preferred port to be associated with a particular portType. The `Service.getPort(Class)` method returns the preferred port associated with the specified service endpoint interface class (portType).

The preferred ports available are listed, as well as a value of `None`, which indicates no preferred port is selected.

Web services client port information:

Use this page to specify a request timeout, override an endpoint, and override a binding namespace for a Web services client port.

A Web service can have multiple ports. You can view and configure the port attributes for each defined Web service port. The Web services are listed on the Web services client bindings panel.

To view this page, click **Applications** >**Enterprise Applications** > *application_instance* > **Web modules** > *module_instance*>**Web services client bindings** > **Edit**.

For EJB modules, click **Applications** >**Enterprise Applications** > *application_instance* > **EJB modules** > *module_instance*>**Web services client bindings** > **Edit**.

Port:

Identifies the name of a port.

Request timeout:

Specifies the time, in milliseconds, that the Web service client waits for a request to complete on this port. If a timeout is not specified, the default request timeout for the client to wait is `360` seconds. If the value is set at `0` (zero), the client's request does not timeout.

A typical use for this setting is to customize the client's behavior when it is configured to use a JMS transport to access a Web service to make it wait longer for an expected completion. Depending upon network conditions, or the nature of a Web service implementation, it might be necessary to tune the timeout.

Overridden endpoint:

Specifies the name of an endpoint that is used to override the current endpoint. A client invoking a request on this port uses this endpoint instead of the endpoint specified in the WSDL file.

If an assembled application contains a Web service client that is statically bound, the client is locked into using the implementation (service end point) identified in the WSDL file used during development. Overriding the endpoint is an alternative to configuring the deployed WSDL attribute.

The overridden endpoint URI attribute is specified on a per port basis. It does not require an alternative WSDL file within the module. The overridden endpoint URI takes precedence over the deployed WSDL attribute. The client uses this value for the service end point URI or SOAP address, instead of the value in the static client bindings.

Overridden binding:

Specifies the WSDL file binding namespace URI to use with this port, instead of the namespace in the WSDL file. This binding does not need to exist in the WSDL file. A client invoking a request on this port uses this binding instead of the binding specified in the WSDL file. An overridden binding namespace cannot be specified unless an overridden endpoint is specified.

Configuring the scope of a Web service port

When a Web service application is deployed into WebSphere Application Server, an instance is created for each application or module. The instance contains deployment information for the Web module or enterprise bean module, including implementation scope, client bindings and deployment descriptor information. There are three levels of scope that can be set: application, session and request.

Deploy the Web service into WebSphere Application Server.

Web Services for Java 2 platform Enterprise Edition (J2EE) specifies that Web services implementations must be stateless. Therefore, to maintain specification compliance, the scope can remain at the application level because the state relevant to the individual sessions level or the requests level is not supposed to be maintained in the implementation. If you want to deviate from the specification and want to access a different JavaBean instance, because you are looking for information that is located in another JavaBean implementation, the scope settings need to change.

The setting that you configure for the scope determines how frequently a new instance of a service implementation class is created for the Web service ports in a module. Use this task to configure the scope of a Web service port.

You can also configure the scope with the wsadmin tool.

To change the scope setting through the administrative console:

1. Open the administrative console.
2. Click **Applications** >**Enterprise Applications** > *application_instance* > **Web Modules** > *module_instance*>**Web Services Implementation Scope**. If you are using an EJB module click **EJB Modules** instead of **Web Modules**.
3. Set the scope to application, session or request. The application scope causes the same instance of the implementation to be used for all requests on the application. The session scope causes the same instance to be used for all requests in each session. The request scope causes a new instance to be used for every request. For example, with the scope set to application, every message that comes to the server accesses the same JavaBean instance because that is the way the scope settings are configured.
4. Click **Apply**.
5. Click **OK**.

The scope for a Web service port is configured.

Now you can finish any other configurations, start or stop the application, and verify the expected behavior of the Web service.

Web services implementation scope

The scope determines when a new implementation instance is created for Web service ports. For example, setting the scope to `application` causes the same instance of the implementation to be used for each request. Setting the scope to `session` causes the same instance of the implementation to be used for each requests of a session. Setting the scope to `request` causes a new instance to be created for each request.

Use this page to view and manage the scope of the ports of a Web service application.

To view this administrative console page, click **Applications** >**Enterprise Applications** > *application_instance* > **Web modules** > *module_instance*>**Web services implementation scope**.

Port:

Specifies a port name for a Web service. A module can contain one or more Web services, each of which can contain one or more ports.

Web service:

Specifies the name of the Web service. A module can contain one or more Web services.

URI:

Specifies the Uniform Resource Identifier (URI) of the binding file that defines the scope. The URI is relative to the Web module.

Scope:

Specifies the scope of a port. The valid values for scope are `request`, `session` and `application`.

Web Services Invocation Framework (WSIF): Enabling Web services

The Web Services Invocation Framework (WSIF) provides a Java API for invoking Web services, independent of the format of the service or the transport protocol through which it is invoked. This framework includes an EJB provider for EJB invocation using Remote Method Invocation over Internet Inter-ORB Protocol (RMI-IIOP). However, for EJB(IIOP)-based Web service invocation you should instead invoke RMI-IIOP Web services using JAX-RPC.

The Web Services Invocation Framework (WSIF) is a WSDL-oriented Java API. You use this API to invoke Web services dynamically, regardless of the service implementation format (for example enterprise bean (EJB)) or the service access mechanism (for example Java Message Service (JMS)).

Using WSIF, you can move away from the usual Web services programming model of working directly with the SOAP APIs, towards a model where you interact with representations of the services. You can therefore work with the same programming model regardless of how the service is implemented and accessed.

If you want to know more about the issues that WSIF addresses, see Goals of WSIF.

If you want to know how WSIF addresses these issues, see An overview of WSIF.

To use WSIF, see the following topics in the information center:
- Using WSIF to invoke Web services.
- WSIF system management and administration.
- WSIF API.

For more information about working with WSIF, visit the Web sites listed in Web services: Resources for Learning.

Goals of WSIF

SOAP bindings for Web services are part of the WSDL specification, therefore when most developers think of using a Web service, they immediately think of assembling a SOAP message and sending it across the network to the service endpoint, using a SOAP client API. For example: using Apache SOAP the client creates and populates a Call object that encapsulates the service endpoint, the identification of the SOAP operation to invoke, the parameters to send, and so on.

While this process works for SOAP, it is limited in its use as a general model for invoking Web services for the following reasons:
- Web services are more than just SOAP services.
- Tying client code to a particular protocol implementation is restricting.
- Incorporating new bindings into client code is hard.
- Multiple bindings can be used in flexible ways.
- A freer Web services environment enables intermediaries.

The goals of the Web Services Invocation Framework (WSIF) are therefore:
- To give a binding-independent mechanism for Web service invocation.
- To free client code from the complexities of any particular protocol used to access a Web service.
- To enable dynamic selection between multiple bindings to a Web service.
- To help the development of Web service intermediaries.

WSIF - Web services are more than just SOAP services: You can deploy as a Web service any application that has a WSDL-based description of its functional aspects and access protocols. If you are using the Java 2 platform, Enterprise Edition (J2EE) environment, then the application is available over multiple transports and protocols.

For example, you can take a database-stored procedure, expose it as a stateless session bean, then deploy it into a SOAP router as a SOAP service. At each stage, the fundamental service is the same. All that changes is the access mechanism: from Java DataBase Connectivity (JDBC) to Remote Method Invocation over Internet Inter-ORB Protocol (RMI-IIOP) and then to SOAP.

The WSDL specification defines a SOAP binding for Web services, but you can add binding extensions to the WSDL so that, for example, you can offer an enterprise bean as a Web service using RMI-IIOP as the access protocol. You can even treat a single Java class as a Web service, with in-thread Java method invocations as the access protocol. With this broader definition of a Web service, you need a binding-independent mechanism for service invocation.

WSIF - Tying client code to a particular protocol implementation is restricting:

If your client code is tightly bound to a client library for a particular protocol implementation, it can become hard to maintain.

For example, if you move from Apache SOAP to Java Message Service (JMS) or enterprise bean, the process can take a lot of time and effort. To avoid these problems, you need a protocol implementation-independent mechanism for service invocation.

WSIF - Incorporating new bindings into client code is hard: As is explained in Web services are not just SOAP services, if you want to make an application that uses a custom protocol work as a Web service, you can add extensibility elements to WSDL to define the new bindings. But in practice, achieving this capability is hard. For example you have to design the client APIs to use this protocol. If your application uses just the abstract interface of the Web service, you have to write tools to generate the stubs that enable an abstraction layer. These tasks can take a lot of time and effort. What you need is a service invocation mechanism that allows you to update existing bindings, and to add new bindings.

WSIF - Multiple bindings can be used in flexible ways: Imagine that you have successfully deployed an application that uses a Web service which offers multiple bindings. For example, imagine that you have a SOAP binding for the service and a local Java binding that lets you treat the local service implementation (a Java class) as a Web service.

The local Java binding for the service can only be used if the client is deployed in the same environment as the service. In this case, it is more efficient to communicate with the service by making direct Java calls than by using the SOAP binding.

If your clients could switch the actual binding used based on run-time information, they could choose the most efficient available binding for each situation. To take advantage of Web services that offer multiple bindings, you need a service invocation mechanism that can switch between the available service bindings at run-time, without having to generate or recompile a stub.

WSIF - Enabling a freer Web services environment promotes intermediaries:

Web services offer application integrators a loosely-coupled paradigm. In such environments, intermediaries can be very powerful.

Intermediaries are applications that intercept the messages that flow between a service requester and a target Web service, and perform some mediating task (for example logging, high-availability or transformation) before passing on the message. The Web Services Invocation Framework (WSIF) is designed to make building intermediaries both possible and simple. Using WSIF, intermediaries can add value to the service invocation without needing transport-specific programming.

An overview of WSIF

The Web Services Invocation Framework (WSIF) provides a Java API for invoking Web services, independent of the format of the service or the transport protocol through which it is invoked. This framework addresses all of the issues identified in the goals of WSIF.

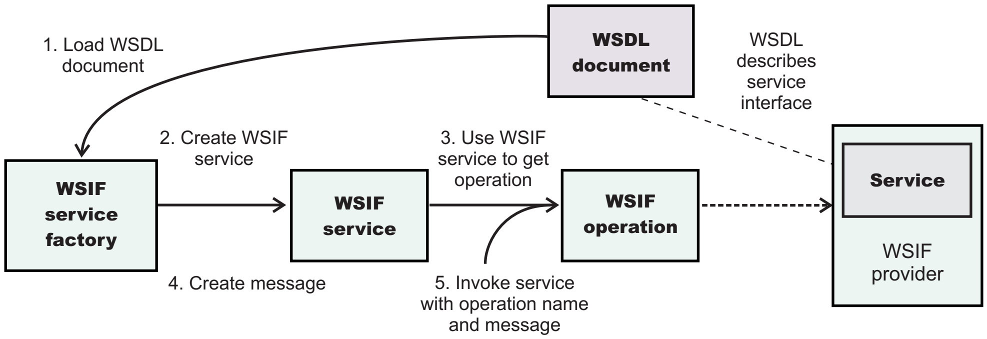
WSIF provides the following features:
- An API that provides binding-independent access to any Web service.
- A close relationship with WSDL, so it can invoke any service that you can describe in WSDL.
- A stubless and completely dynamic invocation of a Web service.
- The capability to plug a new or updated implementation of a binding into WSIF at run-time.
- The option to defer the choice of a binding until run-time.

WSIF is designed to work both in an unmanaged environment (stand-alone) and inside a managed container. You can use the Java Naming and Directory Interface (JNDI) to find the WSIF service, or you can use the location described in the WSDL.

For more conceptual information about WSIF and WSDL, see the following topics:
- WSIF and WSDL
- WSIF architecture
- Using WSIF with Web services that offer multiple bindings
- WSIF usage scenarios
- Dynamic invocation

WSIF supports Internet Protocol Version 6, and Java API for XML-based Remote Procedure Calls (JAX-RPC) Version 1.1 for SOAP.

WSIF architecture: The Web Services Invocation Framework (WSIF) architecture is shown in the figure.



The components of this architecture include:

WSDL document
The Web service WSDL document contains the location of the Web service. The binding document defines the protocol and format for operations and messages defined by a particular portType.

WSIF service
The WSIFService interface is responsible for generating an instance of the WSIFOperation interface to use for a particular invocation of a service operation. For more information, see ″Finding a port factory or service″ in the information center.

WSIF operation
The run-time representation of an operation, called WSIFOperation is responsible for invoking a service based on a particular binding. For more information, see ″WSIF API reference: Using ports″ in the information center.

WSIF provider
A WSIF provider is an implementation of a WSDL binding that can run a WSDL operation through

a binding-specific protocol. WSIF includes SOAP providers, JMS providers, Java providers and EJB providers. For more information, see ″Using the WSIF providers″ in the information center.

Using WSIF with Web services that offer multiple bindings:

Using WSIF, a client application can choose dynamically the optimal binding to use for invoking Web service operations.

For example, a Web service might offer a SOAP binding, and also a local Java binding so that you can treat the local service implementation (a Java class) as a Web service. If a client application is deployed in the same environment as the service, then this client can use the local Java binding for the service. This provides more efficient communication between the client and the service by making direct Java calls rather than indirect calls using the SOAP binding.

For more information on how to configure a client to dynamically select between multiple bindings, see ″Developing a WSIF service″ in the information center.

WSIF and WSDL: WSDL is the acronym for Web Services Description Language.

In WSDL a service is defined in three distinct sections:
- The **portType**. This section defines the abstract interface offered by the service. A portType defines a set of *operations*. Each operation can be In-Out (request-response), In-Only, Out-Only and Out-In (Solicit-Response). Each operation defines the input and/or output *messages*. A message is defined as a set of *parts*, and each part has a schema-defined type.
- The **binding**. This section defines how to map between the abstract portType and a real service format and protocol. For example the SOAP binding defines the encoding style, the SOAPAction header, the namespace of the body (the targetURI), and so on.
- The **port**. This section defines the actual location (endpoint) of the available service. For example, the HTTP Web address at which a SOAP service is available.

Currently in WSDL, each port has one and only one binding, and each binding has a single portType. But (more importantly) each service (portType) can have multiple ports, each of which represents an alternative location and binding for accessing that service.

The Web Services Invocation Framework (WSIF) follows the semantics of WSDL as much as possible:
- The WSIF dynamic invocation API directly exposes run-time equivalents of the model from WSDL. For example, invocation of an operation involves executing an operation with an input message.
- WSDL has extension points that support the addition of new ports and bindings. This enables WSDL to describe new systems. The equivalent concept in WSIF is a provider, that enables WSIF to understand a class of extensions and thereby to support a new service implementation type.

As a metadata-based invocation framework, WSIF follows the design of the metadata. As WSDL is extended, WSIF is updated to follow.

The implicit and primary type system of WSIF is XML schema. WSIF supports invocation using dynamic proxies, which in turn support Java type systems, but when you use the WSIFMessage interface it is your responsibility to populate WSIFMessage objects with data based on the XML schema types as defined in the WSDL document. You should define your object types by a canonical and fixed mapping from schema types into the run-time.

For more information on WSDL, see Web services: Resources for learning.

WSIF usage scenarios:

This topic describes two brief scenarios that illustrate the role WSIF plays in the emerging Web services environment.

Scenario: Redevelopment and redeployment

When you first implement a Web service, you create a simple prototype. When you want to move a prototype Web service into production, you often need to redevelop and redeploy it.

The Web Services Invocation Framework (WSIF) uses the same API calls irrespective of the underlying technologies, therefore if you use WSIF:

- You can reimplement and redeploy your services without changing the client code.
- You can use existing reliable and high-performance infrastructures like Remote Method Invocation over Internet Inter-ORB Protocol (RMI-IIOP) and Java Message Service (JMS) without sacrificing the location-independence that the Web service model offers.

Scenario: Service Flow composition

A service flow typically invokes a Web service, then passes the response from one Web service to the next Web service, perhaps performing some transformation in the middle.

There are two key aspects to this flow that WSIF provides:

- A representation of the service invocation based on the metadata in WSDL.
- The ability to build invocations based solely on the portType, which can therefore be used in any implementation.

For example, imagine that you build a meta-service that uses a number of services to build a process. Initially, several of those services are simple Java bean prototypes that are written and exposed through SOAP, but you plan to reimplement some of them as EJB components, and to out-source others.

If you use SOAP, it ties up multiple threads for every onward invocation, because they pass through the Web server and servlet engine and on to the SOAP router. If you use WSIF to call the beans directly, you get much better performance compared to SOAP and you do not lose access or location transparency. Using WSIF, you can replace the Java bean implementations with EJB implementations without changing the client code. To move some of the Web services from local implementations to external SOAP services, you just update the WSDL.

Dynamic invocation: For the Web Services Invocation Framework (WSIF), dynamic invocation means providing the following levels of support when invoking Web services:

1. Support for WSDL extensions and bindings that were not known at build time.
2. Support for Web services that were not known at build time.

WSIF supports (1) through the use of providers.

The providers support (2) by using the WSDL description to access the target service.

Getting started with UDDI Registry

This section covers the basic knowledge you need to get started either as an administrator of a UDDI Registry or as a user of a UDDI Registry that has already been set up.

- Getting started for UDDI Administrators
- Getting started for UDDI users

Getting started for UDDI Administrators

Use this topic if you are involved in installing (setting up and deploying), customizing, or managing a UDDI Registry.

This section contains a list of some of the topics that you will need to refer to as an administrator of a UDDI Registry:

- ″UDDI Registry Terminology″ in the information center introduces some terms with which you will need to be familiar in order to administer a UDDI Registry
- Setting up and deploying a new UDDI Registry explains how to install a UDDI Registry node by setting up the resources that it will use, and deploying the UDDI Registry application.
- ″Managing the UDDI Registry″ in the information center explains how to use the UDDI pages in the WebSphere Administrative Console, or the UDDI Registry Administrative interface, to administer a UDDI Registry node. It also covers how to back up and restore your UDDI Registry data.
- ″UDDI node settings″ in the information center explains how to view and set UDDI properties and policies, and how to manage UDDI publishers, tiers and user entitlements.
- ″UDDI Registry Management Interfaces″ covers details of programmatic interfaces that you can use to administer a UDDI Registry node (UDDI Registry Administrative (JMX) Interface), to add custom Value Set data to a UDDI Registry (User Defined Value Set Support), and to export and import UDDI version 2 entities (UDDI Utility Tools).

″UDDI Registry troubleshooting″ in the information center might be useful if you encounter any problems or unexpected behaviour while using the UDDI Registry, and ″UDDI Registry messages″ explains any UDDI messages which you might see.

Getting started for UDDI users

Use this topic if you use a UDDI Registry to publish or find UDDI entities either through a user interface or by writing UDDI client applications.

This section contains a list of some of the topics that you might want to refer to as a user of a UDDI Registry:

″UDDI Registry Terminology″ in the information center introduces some terms with which you might need to be familiar with to use a UDDI Registry.

″UDDI Registry user interface″ in the information center tells you how to access the UDDI User Console, which is a user interface that allows you to find UDDI entities and carry out simple UDDI publish operations.

See ″Displaying the user interface″ in the information center for the URL for the UDDI User Interface.

UDDI Registry SOAP Service End Points contains details for accessing the UDDI version 3 Inquiry, Publish, Security, and custody transfer APIs, as well as the UDDI version 1 and version 2 APIs.

UDDI Registry Client Programmingexplains how to write UDDI client application programs. The recommended client programming interface is the IBM UDDI version 3 Client for Java.

″IBM JAXR Provider for the UDDI Registry″ in the information center is for users who want to use the Java API for XML Registries to access UDDI.

″User Defined Value Set Support in the UDDI Registry″ explains how to add custom value set data to a UDDI Registry.

″UDDI Registry troubleshooting″ in the information center might be useful if you encounter any problems or unexpected behaviour while using the UDDI Registry, and ″UDDI Registry messages″ in the information center explains any UDDI messages which you might see.

Planning to use Web services

This topic discusses how to plan your use of Web services that are developed and implemented based on the Web Services for Java 2 Platform, Enterprise Edition (J2EE) specification.

Read the ″Web services scenario: Overview″ in the information center which tells the story of a fictional online garden supply retailer named Plants by WebSphere and how this retailer incorporated the Web services concept.

Web services are Web applications that help you be more flexible in your business processes by integrating with applications that otherwise do not communicate.

Web services reflect the service-oriented architecture approach to programming. This approach is based on the idea of building applications by discovering and implementing network-available services, or by invoking the available applications to accomplish a task. Web services deliver interoperability, for example, Web services applications provide a way for components created in different programming languages to work together as if they were created using the same language. Web services rely on existing transport technologies, such as HTTP, and standard data encoding techniques, such as Extensible Markup Language (XML), for invoking the implementation.

To plan to use Web services:

1. Identify your goals and design Web services to fit your e-business solution. Consider what you want to accomplish by using Web services. Decide how Web services fit into your current topology, applications and programming model. Determine how the Web services process requests on the server and how the clients manage and use the Web service.
2. Design your Web services for reliability, availability, manageability and security. For example, you want your Web services to process a transaction in a reasonable time at all hours of the day and provide users with good security characteristics, such as authentication for buyers. Planning to use Web services to work with WebSphere Application Server helps to meet these requirements.
3. To support Web services, extend WebSphere Application Server to support Web services standards. For interoperable Web services running on platforms supplied by multiple vendors, standards are essential.
4. Decide what development and implementation tools to use. You can use a variety of manual development and implementation tasks. Whether you have an existing Web service to implement or you want to develop your own from a Java bean or from Enterprise JavaBeans (EJB), you can choose different tasks respective to your resources. You can also use Rational Application Developer (RAD) to complete development and implementation tasks.

   See Developing Web services for information about developing Web services based on the Java language through the WebSphere Application Server. To read more about RAD see the information center for the product.
5. Install WebSphere Application Server.
6. Review Web services Samples.

You have a design plan for implementing Web services applications into your business architecture.

Develop a Web service.

This topic explains how to develop a Web service using the Web Services for J2EE specification.

Service-oriented architecture

A *service-oriented architecture (SOA)* is a collection of services that communicate with each other, for example, passing data from one service to another or coordinating an activity between one or more services.

Companies want to integrate existing systems to implement Information Technology (IT) support for business processes that cover the entire business value chain. A variety of designs are used, ranging from rigid point-to-point electronic data interchange (EDI) to Web auctions. By using the Internet, companies make their IT systems available to internal departments or external customers, but the interactions are not flexible and are without standardized architecture.

Because of this increasing demand for technologies that support connecting and sharing resources and data, a need exists for a flexible, standardized architecture. SOA is a flexible architecture that unifies business processes by structuring large applications into building blocks, or small modular functional units or services, for different groups of people to use inside and outside the company. The building blocks can be one of three roles: service provider, service broker, or service requestor. See Web services approach to a service-oriented architecture to learn more about these roles.

Requirements for an SOA

To efficiently use an SOA, follow these requirements:

- **Interoperability between different systems and programming languages**.

  The most important basis for a simple integration between applications on different platforms is to provide a communication protocol. This protocol is available for most systems and programming languages.
- **Clear and unambiguous description language**.

  To use a service offered by a provider, it is not only necessary to be able to access the provider system, but the syntax of the service interface must also be clearly defined in a platform-independent fashion.
- **Retrieval of the service**.

  To support a convenient integration at design time or even system run time, a search mechanism is required to retrieve suitable services. Classify these services as *computer-accessible*, *hierarchical* or *taxonomies* based on what the services in each category do and how they can be invoked.

Web services approach to a service-oriented architecture

The Web services approach implements a service-oriented architecture (SOA). A major focus of Web services is to make functional building blocks accessible over standard Internet protocols that are independent from platforms and programming languages. These services can be new applications or just wrapped around existing legacy systems to make them network-enabled. A service can rely on another service to achieve its goals.

Each SOA building block can assume one or more of three roles:

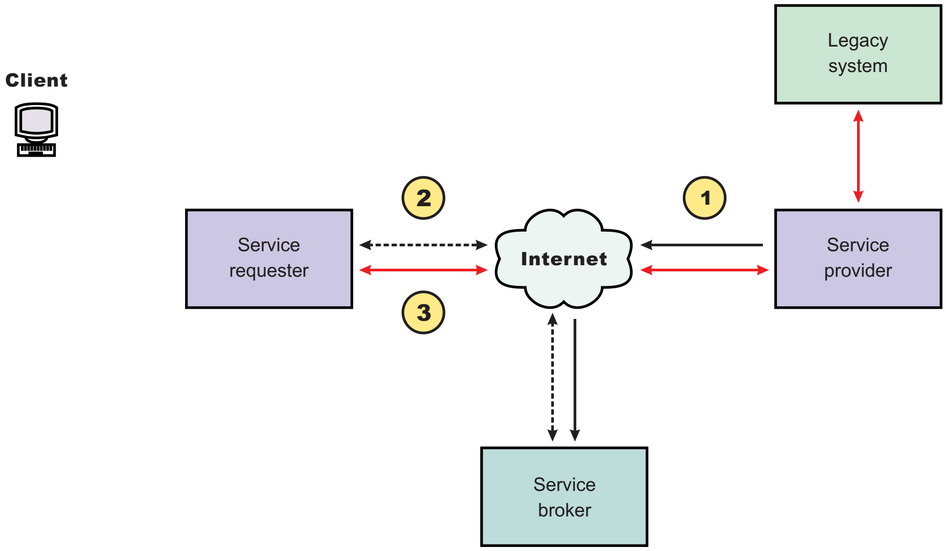
- **Service provider**

  The service provider creates a Web service and possibly publishes its interface and access information to the service registry. Each provider must decide which services to expose, how to make trade-offs between security and easy availability, how to price the services, or how to exploit free services for other value. The provider also has to decide which category to list the service in for a given broker service and what sort of trading partner agreements are required to use the service.
- **Service broker**

  The service broker, also known as *service registry*, is responsible for making the Web service interface and implementation access information available to any potential service requestor. The implementer of the broker decides the scope of the broker. Public brokers are available through the Internet, while private brokers are only accessible to a limited audience, for example, users of a company intranet. Furthermore, some decisions need to be made about the amount of the offered information. Some brokers specialize in many listings. Others offer high levels of trust in the listed services. Some cover a broad landscape of services and others focus within an industry. Some brokers catalog other brokers. Depending on the business model, brokers can attempt to maximize look-up requests, the number of listings or the accuracy of the listings. The Universal Description, Discovery and Integration (UDDI) specification defines a way to publish and discover information about Web services.

- **Service requester**

  The service requestor or Web service client locates entries in the broker registry using various find operations and then binds to the service provider to invoke one of its Web services.



Characteristics of the SOA

The presented SOA illustrates a loose coupling between the participants, which provides greater flexibility in the following ways:

- A client is coupled to a service. Therefore, the integration of the server takes place outside the scope of the client application programs.
- Old and new functional blocks or applications and systems, are encapsulated into components that work as services.
- Functional components and their interfaces are separate, so that new interfaces can be plugged in more easily.
- Within complex applications, the control of business processes can be isolated. A business rule engine can be incorporated to control the workflow of a defined business process. Depending on the state of the workflow, the engine calls the respective services.
- Services can be incorporated dynamically during run time.
- Bindings are specified using configuration files and can be easily adapted to new needs.

Properties of a service-oriented architecture

The service-oriented architecture offers the following properties:

- **Web services are self-contained.**

  On the client side, no additional software is required. A programming language with Extensible Markup Language (XML) and HTTP client support is enough to get you started. On the server side, a Web server and a SOAP server are required. It is possible to enable an existing application for Web services without writing a single line of code.
- **Web services are self-describing.**

  Neither the client nor the server knows or cares about anything besides the format and content of the request and response messages (loosely coupled application integration). The definition of the message format travels with the message; no external metadata repositories or code generation tool are required.
- **Web services can be published, located, and invoked across the Internet.**

This technology uses established lightweight Internet standards such as HTTP and it leverages the existing infrastructure. Some other standards that are required include, SOAP, Web Services Description Language (WSDL), and UDDI.

- **Web services are language-independent and interoperable.**

  Client and server can be implemented in different environments. Existing code does not have to change in order to be Web services enabled.
- **Web services are inherently open and standard-based.**

  XML and HTTP are the major technical foundation for Web services. A large part of the Web service technology has been built using open-source projects.
- **Web services are dynamic.**

  Dynamic e-business can become reality using Web services because with UDDI and WSDL you can automate the Web service description and discovery.
- **Web services are composable.**

  Simple Web services can be aggregated to more complex ones, either using workflow techniques or by calling lower-layer Web services from a Web service implementation. Web services can be chained together to perform higher-level business functions. This chaining shortens development time and enables best-of-breed implementations.
- **Web services are loosely coupled.**

  Traditionally, application design has depended on tight interconnections at both ends. Web services require a simpler level of coordination that supports a more flexible reconfiguration for an integration of the services.
- **Web services provide programmatic access.**

  The approach provides no graphical user interface; it operates at the code level. Service consumers need to know the interfaces to Web services, but do not need to know the implementation details of services.
- **Web services provide the ability to wrap existing applications.**

  Already existing stand-alone applications can easily integrate into the service-oriented architecture by implementing a Web service as an interface.

Web services business models supported

The properties and benefits of using a service-oriented architecture (SOA) such as Web services is well suited for binding small modules that perform independent tasks within a highly heterogeneous e-business model. Web services can be easily wrapped around existing applications in your business model and plugged into different business processes.

For connecting to a large monolithic system that does not support the implementation of different flexible business processes, other approaches might be better suited, for example, to satisfy specialized features, such as performance or security.

The following business models are easily implemented by using an architecture including Web services:

- **Business information**

  Sharing of information with consumers or other businesses. Web services can be used to expand the reach through such services as news streams, local weather reports, integrated travel planning, and intelligent agents.
- **Business integration**

  Providing transactional, fee-based services for customers. A global network of suppliers can be easily created. Web services can be implemented in auctions, e-marketplaces, and reservation systems.
- **Business process externalization**

Web services can be used to model value chains by dynamically integrating processes to a new solution within an organizational unit or even with those of other e-businesses. This modeling can be achieved by dynamically linking internal applications to new partners and suppliers, to offer their services to complement internal services.

Setting up and deploying a new UDDI Registry

Start the installation of WebSphere Application Server Version 6 and create the profile for your application server (for example, server1) to be used to host UDDI.

You have a choice of deploying either a default UDDI node, or a user customized UDDI node.

A default UDDI node would be a suitable option for initial evaluation of UDDI and for development and test purposes. With a customized UDDI node, you have more control over the database management system used for the UDDI database, and the properties used to set up the UDDI database. With a user customized UDDI node, you create the UDDI database and datasource to your own specifications, and then use the uddiDeploy.jacl script to deploy the UDDI application.

The main difference between *default* and *user customized*, in the context of these set up tasks, refers to a number of vital UDDI properties. For a default set up these vital properties are automatically set to default values and are not changeable by the user. For a user customizable set up, the user is given an opportunity to set these vital properties, but once set they can not be changed for this configuration.

Important: Important Note for DB2 users - Starting the WebSphere Application Server in which the UDDI Registry is deployed

On Unix and Linux platforms, before you start the WebSphere server that is hosting your UDDI DB2 application, you must run the db2profile script which is found in the home directory for you db2 userid, for example /home/db2inst1/sqllib/db2profile

Similarly when in an ND configuration and starting the server via the Deployment Manager, you must ensure the db2profile is run before starting the relevant nodeagent.

The information above is true during initial set up and deployment of UDDI and also every time you start the application server or node agent. For this reason it is strongly recommended that you update the user profile for the user that will start the nodeagent and server to also execute the db2profile.

If running the profile manually type:

```
. /home/db2inst1/sqllib/db2profile
```

In the above example, notice that the ’.’ is followed by a single space character.

Deploying into a Network Deployment cell (but not a cluster)

It is important to note that the uddiDeploy.jacl script must be run with the Deployment Manager as the target.

If you are deploying into a network deployment cell you cannot create a default Cloudscape node using uddiDeploy.jacl. You may, however, manually create the default Cloudscape database (with a default profile) by following the instructions in Creating a Cloudscape database and adding the parameter ’DEFAULT’ as the last argument.

You will not be able to use the default option on uddiRemove for a UDDI node that is deployed into an application server which is part of a Network Deployment cell. See ″Removing a UDDI Registry node″ for more information.

If you have a non default UDDI setup in a base application server, you can issue an *addNode -includeapps* command which will add the necessary definitions into the deployment manager.

Deploying into a cluster within a Network Deployment cell

It is important to note that uddiDeploy.jacl and uddiRemove.jacl can not be used in a cluster environment.

It is assumed a single database will be used for all members of the cluster.

You can follow the same guidelines for a non cluster set up in general for the resources such as the JDBC provider and datasource as described in this Information Center, but they may need updating on individual cluster members to correctly access the shared database for example.

The options that are available are:

- Deploy UDDI into a standalone server , as described in this Information Center (using uddiDeploy), and then create a cluster using that server as a template for the other members.
- If using an cluster that already exists, you can use the admin console or wsadmin for example (and not uddiDeploy.jacl), to deploy the uddi.ear across the cluster members, but follow the additional advice in the main instructions.

Changing from a base application server to a Network Deployment cell.

It is possible to move from a base application server to a network deployment cell using the standard *addNode* command. During the move, any applications may be lost unless you use the *-includeapps* option. This applies to all applications and not just UDDI applications. See the addNode command for details. This applies to a default or a user customized UDDI node.

Moving from a default UDDI node to a user customized UDDI node.

After testing the UDDI deployment in a default UDDI node, you can move to a user customized node by recreating the database using the instructions in Setting up a customized UDDI node, but you must be aware that any data saved in the default node (both policies, properties and user data) will be lost in the move.

Moving between Cloudscape, DB2 and Oracle databases.

If you decide to move between one type of database to another, the datasource of the old database will still have a JNDI name of datasources/uddids. You must either rename this JNDI name to something different, or delete the datasource before you define the new database, create the new datasource and initialize the database.

You now have the choice of a default UDDI node, or a user customized UDDI node.

Setting up a customized UDDI node

You can set up a customized UDDI node by completing the following steps:

1. Create a database schema to hold the UDDI registry by executing one of the following:
   - Creating a DB2 database
   - Creating an Oracle database
   - Creating a Cloudscape database

Note: You must not run the final step to set the default node indicator in the database.

2. Create a J2C Authentication Data Entry (not required for Cloudscape):
   a. Expand **Global Security** and **JAAS Configuration** (on the right), then click on **J2C Authentication Data**
   b. Select **New** to create a new J2C authentication data entry
   c. Fill in the details as follows:

      Alias a suitable (short) name, such as ″UDDIAlias″

      Userid
      the database userid, which is used to read and write to the UDDI registry database.

      Password
      The password associated with the userid specified above.

      Description
      a suitable description to describe the chosen userid.

      Click 'Apply' and then Save the changes to the master configuration
3. Create a JDBC Provider (if a suitable one does not already exist):
   - For DB2, select the options **DB2 Legacy CLI-based Type 2 JDBC Driver** and **Connection Pool datasource**.
   - For Oracle, select the options **Oracle JDBC Driver** and **Connection Pool datasource**.
   - For Cloudscape, select the **Cloudscape JDBC Driver** and **Connection Pool datasource**.

   For details on how to create a JDBC provider, see Creating and configuring a JDBC provider using the administrative console.
4. Create a datasource for the UDDI Registry by following these steps:
   a. Expand **Resource** and **JDBC Providers**
   b. Select the desired 'scope' of the JDBC provider you selected or created earlier. For example, select:

      ```
      Server: yourservername
      ```

      This displays the JDBC providers at the server level.
   c. Select the JDBC provider created earlier.
   d. Under **Additional Properties**, select **Data Sources** (*not* the Data Sources Version 4 option)
   e. Select 'New' to create a new datasource
   f. Fill in the details for the datasource as follows:

      Name a suitable name, such as UDDI Datasource

      JNDI name
      set to **datasources/uddids** - this value is obligatory.

      Note: You must not have any other datasources using this JNDI name. If you have another datasource using this JNDI name, then you must either remove it or change its JNDI name. For example, if you have previously created a default UDDI node using Cloudscape, you should use the uddiRemove.jacl script with the default option to remove the datasource and the UDDI application instance, before continuing.

      Description
      a suitable description

      Category
      set to uddi

      Data store helper class name
      filled in for you as:

- for **DB2** - com.ibm.websphere.rsadapter.DB2DataStoreHelper
- for **Oracle 9i** - com.ibm.websphere.rsadapter.OracleDataStoreHelper
- for **Oracle 10g** - com.ibm.websphere.rsadapter.Oracle10gDataStoreHelper
- for **Cloudscape** - com.ibm.websphere.rsadapter.CloudscapeDataStoreHelper

Relational Database Management System **data source properties**

- for **DB2** - **Database name** - for example:

  ```
  UDDI30
  ```

- for **Oracle** - **URL** - for example:

  ```
   jdbc:oracle:oci8:@<Oracle database name>
  ```

- for **Cloudscape** - **Database name** - for example:

  ```
  ${USER_INSTALL_ROOT}/databases/com.ibm.uddi/UDDI30
  ```

Component-managed authentication alias

- for **DB2**, select the alias that you created in step 3 from the pulldown. It will have the node name appended in front of it, for example MyNode/UDDIAlias.
- for **Oracle**, select the alias that you created in step 3 from the pulldown. It will have the node name appended in front of it, for example MyNode/UDDIAlias.
- for **Cloudscape** leave this set to (none).

Container-managed authentication alias
Set to DefaultPrincipalMapping

Mapping-configuration alias
Set to (none)

g. Use this Data Source in container-managed persistence (CMP), and ensure it is unchecked.

5. Test the connection to your UDDI database by clicking on the ″Test Connection″ button for the datasource. You will see a message similar to ″Test Connection for datasource UDDI Datasource on server server1 at node MyNode was successful″. If you do not see this message investigate the problem with the help of the error message.
6. Deploy the UDDI Registry into the server by running the uddiDeploy.jacl command from a command prompt as shown.

   This file is located in

   ```
   WAS_HOME/bin
   ```

   The syntax of the command is:

   ```
   wsadmin [-conntype none] -f uddiDeploy.jacl <node> <server>
   ```

   where:

   -conntype none
   is optional, and is only needed if the application server is not running.

   <node>
   the name of the WebSphere node on which the target server runs. Note that the node name is case sensitive.

   <server>
   is the name of the target server on which you wish to deploy the UDDI Registry, such as server1. Note the server name entered is case sensitive.

   You are recommended to deploy the UDDI application using the uddiDeploy.jacl, but note that you can also use the administrative console to deploy the application in the normal way. If you use the administrative console you must ensure that the Classloader Mode for the application is set to PARENT_LAST, and that the WAR class loader Policy is set to Application. The uddiDeploy.jacl command in a command prompt will do this for you.

For example, to deploy UDDI on node ’MyNode’ and server ’server1’ on a Windows system you might enter the following (assuming that server1 is already started):

```
wsadmin -f uddiDeploy.jacl MyNode server1
```

You should now start the UDDI application, or start the application server if it is not already running.

As you have chosen a user customized UDDI node, you will need to set up the properties for the UDDI node using UDDI administration, and initialize the node before it is ready to accept UDDI requests (see ″Configuring the UDDI Registry Application″ in the information center for details).

Setting up a default UDDI node

There are two ways to setup a default UDDI node:

- Either by executing the `uddiDeploy.jacl` script and specifying the **default** option. This creates a running default UDDI node within a Cloudscape database, or
- Executing an additional step after you have created your database.

Run one of the following

1. **Optional: For a default Cloudscape UDDI node:**

   For a default Cloudscape configuration Network Deployment read the section ’Installing into a Network Deployment Cell’ first.

   Deploy the UDDI Registry by running the uddiDeploy.jacl script from a command prompt as shown.

   This file is located in

   ```
   WAS_HOME/bin
   ```

   The syntax of the command is (shown here on 2 lines for publication):

```
wsadmin [-conntype none] -wsadmin_classpath WAS_HOME/cloudscape/lib -f
   uddiDeploy.jacl <node> <server> default
```

   where:

   -conntype none
   is optional, and is only needed if the application server is not running.

   WAS_HOME
   is the directory name of the WebSphere Application Server install location

   <node>
   is the name of the WebSphere node on which the target server runs. Note that the node name is case sensitive.

   <server>
   is the name of the target server on which you wish to deploy the UDDI Registry, such as server1. Note the server name entered is case sensitive.

   default
   using the ’default’ option causes the command to create a UDDI node, with default policies within a Cloudscape database and datasource. This is a special case only for Cloudscape and creates everything required to run a UDDI node, in a standalone application server.

   For example, to create a UDDI node called ’MyNode’ on server ’server1’ on a Windows system, you might enter the following (this assumes server1 is started). The command is shown on 2 lines for publication.

```
wsadmin -wsadmin_classpath C:\Progra~1\IBM\WebSphere\AppServer\cloudscape\lib
   -f uddiDeploy.jacl MyNode server1 default
```

   If the server is not started the command is (shown here on 2 lines for publication):

```
wsadmin -conntype none -wsadmin_classpath C:\Progra~1\IBM\WebSphere\AppServer\cloudscape\lib
  -f uddiDeploy.jacl MyNode server1 default
```

   (Note that these should be entered as one command on a single line)

You should now start the UDDI application, or start the application server if it is not already running.

2. **Optional: For a default DB2, default Cloudscape or default Oracle UDDI node:**

   DB2, Cloudscape or Oracle may be used for a single application server installation or a Network Deployment installation.

   a. Initially you need to define some resources and run some scripts to set up the database. Go to Creating the DB2 database, Creating the Cloudscape databaseor Creating the Oracle database to create and load the database, ensuring you have run the final step to set the default node indicator in the database, and return to this point. You must create a JDBC Provider if a suitable one does not already exist or select one, and a Datasource to reference the UDDI database.

      - For DB2, select the 'DB2 Legacy CLI-based Type 2 JDBC Driver' option and Connection Pool datasource option.
      - When using Oracle ensure you select 'Oracle JDBC Driver' and the Connection Pool datasource option.
      - For Cloudscape, select the supplied **Cloudscape JDBC Driver**
      - Refer to Creating and configuring a JDBC provider using the administrative console for details on how to create a JDBC Provider.

   b. Create a J2C Authentication Data Entry for DB2 or Oracle access (not required for Cloudscape) using the WebSphere Application Server administrative console by following these steps:

      1) Expand 'Global Security' and 'JAAS Configuration' and click on 'J2C Authentication Data Entries'
      2) Select 'New' to create a new J2C authentication data entry
      3) Fill in the details as follows:

         Alias a suitable (short) name, such as UDDIAlias

         Userid
         your DB2 userid, such as db2admin, or your Oracle userid, such as SYSTEM.

         Password
         The password associated with your userid.

         Description
         a suitable description

      Click 'Apply' and then Save the changes to the master configuration

   c. Create a datasource for the UDDI Registry by following these steps:

      1) Expand 'Resource' and 'JDBC Providers'
      2) Select the desired 'scope' of the JDBC provider created earlier. For example, select:

         ```
         Server: yourservername
         ```

         to show the JDBC providers at the server level.
      3) Select your DB2 or Oracle JDBC provider as selected or created earlier
      4) Under 'Additional Properties', select 'Data Sources' (**not** the Data Sources Version 4 option)
      5) Select 'New' to create a new datasource
      6) Fill in the details for the datasource as follows:

         Name a suitable name, such as UDDI Datasource

         JNDI name
         set to **datasources/uddids** - this value is obligatory.

         Note: Note that you must not have any other datasources using this JNDI name. If you have another datasource using this JNDI name, then you must either remove it or change its JNDI name. For example, if you have previously created a default

UDDI node using Cloudscape, you should use the uddiRemove.jacl script with the default option to remove the datasource and the UDDI application instance before continuing.

Description
a suitable description

Category
set to uddi

Data store helper class name
filled in for you as:

- for **DB2** - com.ibm.websphere.rsadapter.DB2DataStoreHelper
- for **Oracle 9i** - com.ibm.websphere.rsadapter.OracleDataStoreHelper
- for **Oracle 10g** - com.ibm.websphere.rsadapter.Oracle10gDataStoreHelper
- for **Cloudscape** - com.ibm.websphere.rsadapter.CloudscapeDataStoreHelper

Relational Database Management System **data source properties**

- for **DB2** - **Database name** - for example:
  ```
  UDDI30
  ```
- for **Oracle** - **URL** - for example:
  ```
   jdbc:oracle:oci8:@<Oracle database name>
  ```
- for **Cloudscape** - **Database name** - for example:
  ```
  ${USER_INSTALL_ROOT}/databases/com.ibm.uddi/UDDI30
  ```

Component-managed authentication alias

- for **DB2**, select the alias that you created in step 3 from the pulldown. It will have the node name appended in front of it, for example MyNode/UDDIAlias.
- for **Oracle**, select the alias that you created in step 3 from the pulldown. It will have the node name appended in front of it, for example MyNode/UDDIAlias.
- for **Cloudscape** leave this set to (none).

Container-managed authentication alias
select the alias that you created earlier from the pulldown. It will have the node name appended in front of it, for example MyNode/UDDIAlias.

Mapping-configuration alias
set to DefaultPrincipleMapping from the pulldown (this might already be filled in).

Leave all other fields unchanged.

Click ’Apply’ and Save the changes to the master configuration.

d. Test the connection to your UDDI database by clicking on the ″Test Connection″ button for the datasource. You will see a message similar to ″Test Connection for datasource UDDI Datasource on server server1 at node MyNode was successful″. If you do not see this message investigate the problem with the help of the error message.

e. Deploy the UDDI Registry into the server by running the uddiDeploy.jacl script from a command prompt as shown.

This file is located in

```
WAS_HOME/bin
```

The syntax of the command is:

```
wsadmin [-conntype none] -f uddiDeploy.jacl <node> <server>
```

where:

-conntype none
is optional, and is only needed if the application server is not running.

<node>
the name of the WebSphere node on which the target server runs. Note that the node name is case sensitive.

<server>
is the name of the target server on which you wish to deploy the UDDI Registry, such as server1. Note the server name entered is case sensitive.

You are recommended to deploy the UDDI application using the uddiDeploy.jacl, but note that you can also use the administrative console to deploy the application in the normal way. If you use the administrative console you must ensure that the Classloader Mode for the application is set to PARENT_LAST, and that the WAR class loader Policy is set to Application. The uddiDeploy.jacl command in a command prompt will do this for you.

For example, to deploy UDDI on node 'MyNode' and server 'server1' on a Windows system you might enter the following (assuming that server1 is already started):

```
wsadmin -f uddiDeploy.jacl MyNode server1
```

You should now start the UDDI application, or start the application server if it is not already running.

As you have chosen to use a default UDDI node, it will be initialized when the UDDI application is started for the first time.

Creating a DB2 database

Perform this task if you want to use DB2 as the database store for your UDDI Registry data. You only need do this once for each UDDI Registry, as part of Setting up and deploying a UDDI Registry.

Before you begin

The steps below use a number of variables for which you need to enter appropriate values. You should decide the values that you will use before you start. The variables used, and suggested values are:

<DataBaseName>
is the name of the UDDI Registry database. A recommended value is UDDI30, and this name is assumed throughout the UDDI documentation. If you use some other name, then you should substitute that name whenever you see 'UDDI30' in other sections of the documentation.

<DB2UserID>
is a DB2 userid with administrative privileges.

<DB2Password>
is the password for the DB2 userid.

<BufferPoolName>
is the name of a buffer pool to be used by the UDDI Registry database. A suggested name is uddibp, but any name can be used, as the buffer pool is created as part of this task.

<TableSpaceName>
is the name of a table space. A suggested value is uddits, but any name can be used.

<TempTableSpaceName>
is the name of a temporary table space. A suggested value is udditstemp, but any name can be used, as the temporary table space is created as part of this task.

To create the DB2 database follow the steps shown below:

1. Run the following commands to setup the DB2 environment variables from the DB2 Command Line Processor (that is, at a prompt which requires db2 to be entered before each command):
   a. Not required for DB2 Vesion 8 and onwards: `db2set DB2_INDEX_2BYTEVARLEN=YES`
   b. `db2set DB2CODEPAGE=1208`
2. Create the DB2 database by entering the following command from the DB2 Command Line Processor:

a. `db2 create database <DataBaseName> using codeset UTF-8 territory en` where <DataBaseName> is the name of the database being created.

3. Configure the DB2 database by entering the following commands from the DB2 Command Line Processor:
   a. `db2 connect to <DataBaseName> user <DB2UserID> using <DB2Password>`
   b. `db2 update db cfg for <DataBaseName> using applheapsz 2048`
   c. `db2 update db cfg for <DataBaseName> using logfilsiz 8192`
   d. `db2 connect reset`
   e. `db2 terminate`
4. Create additional database structures by entering the following commands from the DB2 Command Line Processor:
   a. `db2 connect to <DataBaseName> user <DB2UserID> using <DB2Password>`
   b. `db2 create bufferpool <BufferPoolName> size 250 pagesize 32K`
   c. `db2 connect reset`
   d. `db2 terminate`
   e. `db2 force application all`
   f. `db2 terminate`
   g. `db2stop`
   h. `db2start`
5. Create further database structures by entering the following commands from the DB2 Command Line Processor:
   a. `db2 connect to <DataBaseName> user <DB2UserID> using <DB2Password>`
   b. `db2 create regular tablespace uddits pagesize 32K managed by system using ('<TableSpaceName>') extentsize 64 prefetchsize 32 bufferpool <BufferPoolName>`
   c. `db2 create system temporary tablespace <TempTableSpacename> pagesize 32K managed by system using ('<TempTableSpacename>') extentsize 32 overhead 14.06 prefetchsize 32 transferrate 0.33 bufferpool <BufferPoolName>`
6. Enter the following commands exactly as shown (noting in particular one step uses -vf rather than -tvf) into a DB2 Command Window to define the database structures needed to store the UDDI data (before running these commands change dirstory to WAS_HOME/UDDIReg/databaseScripts):
   a. `db2 -tvf uddi30crt_10_prereq_db2.sql`
   b. `db2 -tvf uddi30crt_20_tables_generic.sql`
   c. `db2 -tvf uddi30crt_25_tables_db2udb.sql`
   d. `db2 -tvf uddi30crt_30_constraints_generic.sql`
   e. `db2 -tvf uddi30crt_35_constraints_db2udb.sql`
   f. `db2 -tvf uddi30crt_40_views_generic.sql`
   g. `db2 -tvf uddi30crt_45_views_db2udb.sql`
   h. `db2 -vf uddi30crt_50_triggers_db2udb.sql`
   i. `db2 -tvf uddi30crt_60_insert_initial_static_data.sql`
7. This last step should only be run if you want your database to be used as a default UDDI node.
   a. Enter the following command from the DB2 Command Line Window: `db2 -tvf uddi30crt_70_insert_default_database_indicator.sql`

Continue with setting up and deploying your UDDI Registry node.

Creating an Oracle database

Perform this task if you want to use Oracle as the database store for your UDDI Registry data. You need only do this once for each UDDI registry, as part of Setting up and deploying a UDDI Registry.

Note: Only Version 9i[1] and Oracle 10g[2]

Before you begin

Note that this task will create two new schemas, ibmudi30 and ibmuds30. You will be unable to complete this task if you already have existing schemas of those names.

The steps below use a number of variables for which you need to enter appropriate values. You should decide the values that you will use before you start. The variables used, and suggested values are:

<OracleUserID>
is the Oracle userid to be used to create the database.

<OraclePassword>
is the password for the Oracle userid.

1. Run the following commands:
   a. `sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_10_prereq_oracle.sql`
   b. `sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_20_tables_generic.sql`
   c. Complete one of the two following actions depending on your level of Oracle:
      - For Version 10g and later:
        ```
        sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_25_tables_oracle.sql
        ```
      - For Oracle 9i:
        ```
        sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_25_tables_oracle_pre10g.sql
        ```
   d. `sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_30_contraints_generic.sql`
   e. `sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_35_constraints_oracle.sql`
   f. `sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_40_views_generic.sql`
   g. `sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_45_views_oracle.sql`
   h. `sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_50_triggers_oracle.sql`
   i. `sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_60_insert_initial_static_data.sql`
2. This last command should only be run if you want the database to be used as a default UDDI node.
   ```
   sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_70_insert_default_database_indicator.sql
   ```

Continue with setting up and deploying your UDDI Registry node.

Creating a Cloudscape database

Perform this task if you want to use Cloudscape as the database store for your UDDI Registry, and you do not want to use the default option on uddiDeploy.jacl (see 'Setting up a default UDDI node'). The most likely reasons for not using the default option on uddiDeploy.jacl are that you want to set up a customized

[1]

Restrictions:
discoveryURL (Business) maximum 4000 bytes, UDDI specification 4096 characters; accessPoint (bindingTemplate) maximum 4000 bytes), UDDI Specification 4096 characters; instacneParms (tModelInstanceInfo) maximum 4000 bytes, UDDI specification 8192 characters; overviewURL (tModelInstanceInfo) maximum 4000 bytes, UDDI specification 4096 characters; Digital Signature maximum 4000 bytes.

[2]

Restrictions:
discoveryURL (business) maximum 4000 bytes, UDDI specification 4096 characters.

UDDI node, or that you are deploying UDDI into a Network Deployment cell. You need only perform this task once for each UDDI Registry, as part of the Setting up and deploying a UDDI Registry.

The commands below use a number of arguments for which you need to enter appropriate values. You should decide the values that you will use before you start. The arguments used, and suggested values, are:

arg1 is the path of the SQL files, which on a standard install will be WAS_HOME/UDDIReg/databasescripts

arg2 is the path to the location where you want to install the Cloudscape database, such as WAS_HOME/databases/com.ibm.uddi

arg3 is the name of the Cloudscape database. A recommended value is UDDI30, and this name is assumed throughout the UDDI documentation. If you use some other name, you should substitute that name whenever you see 'UDDI30' in other sections of the UDDI documentation.

arg4 is an optional argument, and must either be omitted or be the string 'DEFAULT'. DEFAULT should only be specified if you want your database to be used as a default UDDI node. Note that this argument is case sensitive.

Run the following java -jar command to create a UDDI Cloudscape database using UDDICloudscapeCreate.jar, which is created in WAS_HOME/Lib directory.

1. On Solaris and HP-UX platforms:

   ```
   java -Djava.ext.dirs=WAS_HOME/cloudscape/lib:WAS_HOME/java/lib/ext -jar
             UDDICloudscapeCreate.jar arg1 arg2 arg3 arg4
   ```

2. On all other platforms:

   ```
   java -cp WAS_HOME/cloudscape/lib/db2j.jar -jar UDDICloudscapeCreate.jar arg1 arg2 arg3 arg4
   ```

Continue with setting up and deploying your UDDI Registry node.

Using a remote database for the UDDI Registry

It is possible for the UDDI Registry database to be hosted on a separate system (remote system) from the system on which the UDDI Registry application is deployed.

This is achieved using standard database capabilities of the database product used for the UDDI Registry database. You should refer to documentation for the database product if you are not familiar with these capabilities. Some considerations specific to each database product are:

Remote DB2

Create a DB2 UDDI database on the remote system, and use the DB2 Client to create an alias to reference it. Use the alias name as the Database name in the UDDI datasource.

Remote Oracle

Create the Oracle tables used for an Oracle UDDI database on the remote system, and use the URL property of the UDDI datasource to reference the remote Oracle instance.

Networked Cloudscape

Create a Cloudscape UDDI database on the remote system, and use the Cloudscape Network Server using Universal data source properties (Database name, Server name and Port number) of the UDDI datasource to reference the remote Cloudscape database.

UDDI Registry Installation Verification Program (IVP)

This topic describes a simple test that you can carry out as an Installation Verification Program (IVP) to verify that you have deployed a UDDI Registry successfully. You should perform this task *after* you have followed the instructions in Setting up and Deploying a new UDDI Registry.

Open a browser window and enter the URL to access the UDDI Registry User Interface. Under the ’Quick Find’ heading on the Find tab, select the ’Business’ radio button and enter ’%’ in the box. Click the ’Find’ button, and you should see the business displayed in the detail frame which will be this UDDI node’s business entity. You can click on the listed business in order to see its detail.

If you see a business listed in the detail frame, your UDDI Registry has been deployed successfully.

As a further IVP, you can publish and find more UDDI entities by using the UDDI Registry User Interface, or you can compile and run one or more of the UDDI Registry Samples.

Publishing WSDL files

To publish a Web Services Description Language (WSDL) file you need an enterprise application, also known as an enterprise archive (EAR) file, that contains a Web services-enabled module and has been deployed into WebSphere Application Server. See Deploying Web services based on Web Services for Java 2 platform, Enterprise Edition (J2EE).

The purpose of publishing the WSDL file is to provide clients with a description of the Web service, including the URL identifying the location of the service.

After installing a Web services application, and optionally modifying the endpoint information, you might need WSDL files containing the updated endpoint information. You can obtain the updated WSDL files by publishing them to the file system. If you are a client developer or a system administrator, you can use WSDL files to enable clients to connect to a Web service.

Before you publish a WSDL file, you can configure Web services to specify endpoint information in the form of URL fragments to enable full URL specification of WSDL ports. Refer to the tasks describing configuring endpoint URL information.

The WSDL files for each Web services-enabled module are published to the file system location you specify. You can provide these WSDL files to clients that want to invoke your Web services.

You can specify endpoint information for HTTP ports, Java Message Service (JMS) ports or directly access enterprise JavaBeans (EJBs) that are acting as Web services.

To publish a WSDL file:

1. Configure the URL endpoint information. Do one of the following depending on what kind of bindings you are using:
   - Configure the URL endpoint information for HTTP bindings.
   - Configure the URL endpoint information for JMS bindings.
   - Configure the URL endpoint information to directly access enterprise beans.
2. Externalize or publish the WSDL file out of the application. You can complete this task in one of three ways:
   - Publish a WSDL file with the administrative console
   - Publish a WSDL file through a URL.
   - Publish a WSDL file with the **wsadmin** command tool.

Apply security to the Web service.

WSDL

Web Services Description Language (WSDL) is an Extensible Markup Language (XML)-based description language. This language was submitted to the World-Wide Web Consortium (W3C) as the industry standard for describing Web services. The power of WSDL is derived from two main architectural principles: the ability to describe a set of business operations and the ability to separate the description into two basic units. These units are a description of the operations and the details of how the operation and the information associated with it are packaged.

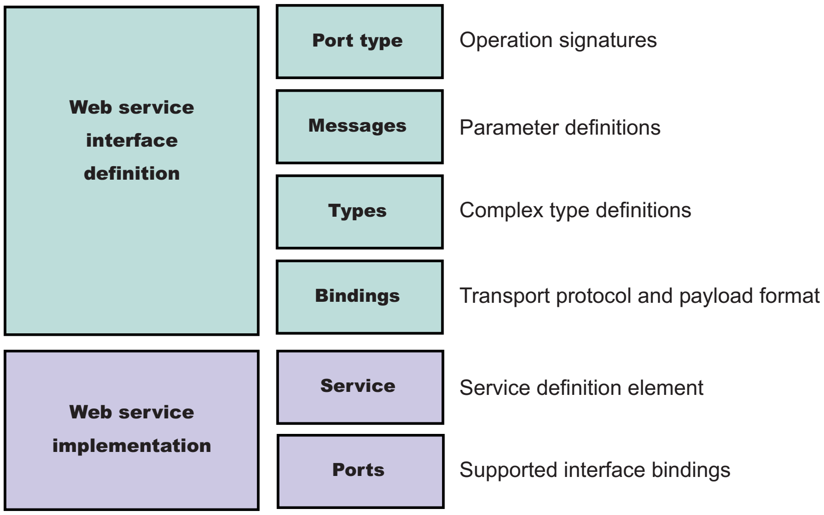
A WSDL document defines services as collections of network endpoints, or ports. In WSDL, the abstract definition of endpoints and messages is separated from their concrete network deployment or data format bindings. This separation supports the reuse of abstract definitions: messages, which are abstract descriptions of exchanged data, and port types, which are abstract collections of operations. The concrete protocol and data format specifications for a particular port type constitutes a reusable binding. A port is defined by associating a network address with a reusable binding, and a collection of ports define a service. Therefore, a WSDL document is composed of several elements. See WSDL architecture for more information and examples of the WSDL elements.

When creating Web services for WebSphere Application Server, you must first have an implementation bean that includes a service endpoint interface. Then, you use the **Java2WSDL** command-line tool to create a WSDL file that defines the Web services. To learn more about how the WSDL file is used in the development process, see Developing Web services.

WSDL architecture

Web Services Description Language (WSDL) files are written in Extensible Markup Language (XML). To learn more about XML, see Web services: Resources for learning.

The following is the structure of the information in a WSDL file:



Web service interface definition
Port type
Operation signatures
Messages
Parameter definitions
Types
Complex type definitions
Bindings
Transport protocol and payload format
Web service implementation
Service
Service definition element
Ports
Supported interface bindings

A WSDL file contains the following parts:

- **Web service interface definition**

  This is part contains the elements, as well as the namespaces.
- **Web service implementation**

  This part contains the definition of the service and ports.

A WSDL file describes a Web service with the following elements:

portType

The description of the operations and associated messages. The portType element defines abstract operations.

```
<portType name="EightBall">
 <operation name="getAnswer">
  <input message="ebs:IngetAnswerRequest"/>
  <output message="ebs:OutgetAnswerResponse"/>
 </operation>
</portType>
```

message

The description of input and output parameters and return values.

```
<message name="IngetAnswerRequest">
 <part name="meth1_inType" type="ebs:questionType"/>
</message>
<message name="OutgetAnswerResponse">
 <part name="meth1_outType" type="ebs:answerType"/>
</message>
```

types

The schema for describing XML types used in the messages.

```
<types>
 <xsd:schema targetNamespace="...">
  <xsd:complexType name="questionType">
   <xsd:element name="question" type="string"/>
  </xsd:complexType>
  <xsd:complexType name="answerType">
  ...
</types>
```

binding

The bindings describe the protocol that is used to access a portType, as well as the data formats for the messages that are defined by a particular portType element.

```
<binding name="EightBallBinding" type="ebs:EightBall">
 <soap:binding style="rpc" transport="schemas.xmlsoap.org/soap/http">
 <operation name="ebs:getAnswer">
 <soap:operation soapAction="urn:EightBall"/>
  <input>
   <soap:body namespace="urn:EightBall" ... />
  ...
```

The services and ports define the location of the Web service.

Service

The service contains the Web service name and a list of ports.

Ports

The ports contain the location of the Web service and the binding used for service access.

```
<service name="EightBall">
 <port binding="ebs:EightBallBinding" name="EightBallPort">
  <soap:address location="localhost:8080/axis/EightBall"/>
 </port>
</service>
```

Multipart WSDL best practices

WebSphere Application Server supports deployment of Web services using a multipart Web Services Description Language (WSDL) file. In multipart WSDL files, an implementation WSDL file contains the wsdl:service. This implementation WSDL flie imports an interface WSDL file, which contains the other WSDL constructs. This supports multiple Web services using the same WSDL interface definition.

The <wsdl:import> element indicates a reference to another WSDL file. If the <wsdl:import> element location attribute does not contain a URL, that is, it contains only a file name, and does not begin with `http://`, `https://` or `file://`, the imported file must be located in the same directory and must not contain a relative path component. For example, if `META-INF/wsdl/A_Impl.wsdl` is in your module and contains the `<wsdl:import="A.wsdl" namespace="..."/>` import statement, the `A.wsdl` file must also be located in the module `META-INF/wsdl` directory.

It is recommended that you place all WSDL files in either the `META-INF/wsdl` directory, if you are using Enterprise JavaBeans (EJB), or the `WEB-INF/wsdl` directory, if you are using JavaBeans components, even if relative imports are located within the WSDL files. Otherwise, implications exist with the WSDL publication when you use a path like `<location="../interfaces/A_Interface.wsdl"namespace="..."/>`. Using a path like this example fails because the presence of the relative path, regardless of whether the file is located at that path or not. If the location is a Web address, it must be readable at both deployment and server startup.

WSDL publication

You can publish the files located in the `META-INF/wsdl` or the `WEB-INF/wsdl` directory through either a URL address or file, including WSDL or XSD files. For example, if the file referenced in the <wsdl-file> element of the `webservices.xml` deployment descriptor is located in the `META-INF/wsdl` or the `WEB-INF/wsdl` directory, it is publishable. If the files imported by the <wsdl-file> are located in the `wsdl/` directory or its subdirectory, they are publishable.

If the WSDL file referenced by the <wsdl-file> element is located in a directory other than `wsdl`, or its subdirectories, the file and its imported files, either WSDL or XSD files, which are in the same directory, are copied to the `wsdl` directory without modification when the application is installed. These types of files can also be published.

If the <wsdl-file> imports a file located in a different directory (a directory that is not `-INF/wsdl` or a subdirectory), the file is not copied to the `wsdl` directory and not available for publishing.

Configuring endpoint URL information for JMS bindings

WebSphere Application Server supports the use of the Java Message Service (JMS) API to transport Web services requests, as an alternative to using HTTP.

Review the topic Using the Java Message Service to transport Web services requests.

Configuring a service endpoint is necessary to connect Web service clients to any Web services among the components being assembled or to any external Web services. You can configure the endpoint URL information for JMS during application installation

In this task, enter the JMS endpoint URL prefix to use for each Web service-enabled enterprise JavaBean (EJB) Java archive (JAR) file that belong to the application. The JMS endpoint URLs are included in the Web Service Description Language (WSDL) files published for clients to use.

You can specify HTTP URL prefixes for Web services that are accessed through HTTP by using the Provide HTTP endpoint URL information panel in the administrative console. These prefixes are used to form complete endpoint addresses that are included in WSDL files when published.

You can specify JMS URL prefixes by using the Provide JMS and EJB endpoint URL information panel in the administrative console during or after application installation.

To configure JMS URL prefixes:

1. Open the administrative console.
2. Click **Applications** > **Enterprise Applications** > *application_instance* > **Provide JMS and EJB endpoint URL information**.
3. Locate the list of Web services modules that are accessible through JMS transport.
4. Type the JMS URL fragment in the **URL fragment** field. Enter a URL fragment that is a prefix to the initial URL part that is obtained by examining the deployment information of the Web service. See the usage scenario following this task for more information.

   The value that you enter is used to define the location attribute of the port soap:address element within the WSDL file that is published using the `*application_name*_ExtendedWSDLFiles.zip` or the `*application_name*_WSDLFiles.zip` file on the Publish WSDL zip files panel.

You have a Web service that is accessible through the JMS transport and configured with JMS bindings.

Suppose an application called StockQuoteService contains an EJB JAR file that is named StockQuoteEJB, which contains one or more Web services that are accessible through the JMS transport. In Using the Java Message Service to transport Web services requests you defined a queue with the Java Naming and Directory Interface (JNDI) name of `jms/StockQuote_Q`, and a connection factory with the JNDI name of `jms/StockQuote_CF`, for your application. In this example, you specify the following string as the JMS URL prefix within the Provide JMS and EJB endpoint URL information panel:

```
jms:/queue?destination=jms/StockQuote_Q&connectionFactory=jms/StockQuote_CF
```

The WSDL publisher uses this partial URL string to produce the actual JMS URL for each port component that is defined in the module. The `targetService=<*port_name*>` string is added to the end of the JMS URL, for example:

```
jms:/queue?destination=jms/StockQuote_Q&connectionFactory=jms/
     StockQuote_CF&targetService=getQuote
```

The published WSDL file is used by clients to invoke the Web service.

Publish WSDL files.

Provide JMS and EJB endpoint URL information

Use this page to specify endpoint URL fragments for Web services accessed through SOAP and Java Message Service (JMS) or directly as enterprise JavaBean (EJBs). Fragments are used to form complete endpoint addresses included in published Web Services Description Language (WSDL) files.

To view this administrative console page, click **Applications** >**Enterprise Applications** > *application_instance* > **Provide JMS and EJB endpoint URL information**.

You can specify a fragment of the endpoint URL to be used in each Web service module. In a published WSDL file, the URL defining the target endpoint address is found in the location attribute of the port's `soap:address` element.

If you are using Web services modules that are configured to use JMS or configured to access EJBs directly, these modules are listed on this panel.

URL fragment for JMS:

Specifies a URL fragment for Web services accessed through a JMS transport. You can enter a value that is used to define the `soap:address` of a Web service. When WSDL files are published, a URL is formed using this fragment and is contained in the WSDL files.

The URL fragment that is entered as a value is a prefix to which the targetService=property is appended to form a complete JMS URL endpoint. The default value is obtained by examining the installed service's deployment information, for example, `jms:/queue?destination=jms/MyQueue&connectionFactory=jms/MyCF`.

This information is obtained from the Web service's configured JMS endpoint, which is a Message Driven Bean (MDB) defined by the **endpointEnabler** command-line tool. You can modify the URL fragment, for example, by adding properties. The URL fragment is combined with the targetService property to form the complete URL, for example, `jms:/queue?destination=jms/MyQueue&connectionFactory=jms/MyCF&priority=5&targetService=GetQuote`.

URL fragment for EJB:

Specifies a URL fragment for Web services accessed through an EJB binding. You can enter a value used to define the location attribute of the port's `generic:address` element of a Web service. This port address is contained in the WSDL zip file when the zip file is published using the ***application_name_ExtendedWSDLFiles*.zip** field on the **Publish WSDL zip file** panel.

The URL fragment value entered is a suffix, which is appended to the initial part of the URL obtained by examining the Web service's deployment information. For example, the following URL fragment can be obtained from the EJB's deployment information: `wsejb:/com.acme.sample.MyStockQuoteHome?jndiName=ejb/MyStockQuoteHome`.

In this case, you can enter the following information in the URL fragment field, `jndiProviderURL=corbaloc:iiop:myhost.mycompany.com:2809`, which results in this endpoint URL, `wsejb:/com.acme.sample.MyStockQuoteHome?jndiName=ejb/MyStockQuoteHome&jndiProviderURL=`

`corbaloc:iiop:myhost.mycompany.com:2809`.

Configuring Web services applications with the wsadmin tool

You can use the wsadmin scripting tool to complete the several tasks for a Web services application.

Develop a Web services application.

The WebSphere Application Server wsadmin tool provides the ability to run scripts. You can use the wsadmin tool to manage a WebSphere Application Server installation, as well as configuration, application deployment, and server run-time operations. The WebSphere Application Server only supports the Jacl and Jython scripting languages.

To use the wsadmin tool to configure a Web services application or publish a Web Services Description Language (WSDL) file:

1. Launch a scripting command.
2. Follow the steps in one of the following topics, depending on what task you want to complete:
   - Configure Web service client bindings.
   - Configure Web service client preferred port mappings .
   - Configure Web service client port information .
   - Configure the scope of a Web service port .

You have configured Web services applications with the wsadmin tool.

WSIF system management and administration

The Web Services Invocation Framework (WSIF) is provided as a stand-alone JAR file named `wsif.jar`. The JAR file contains the core WSIF classes, and the Java, EJB, SOAP over HTTP and SOAP over JMS providers. Additional providers are packaged as separate JAR files.

When you install WebSphere Application Server, the wsif.jar file is put on the WebSphere or Java Virtual Machine (JVM) class path.

WSIF requires no further configuration. WSIF is a thin abstraction layer between application code and the relevant invocation infrastructure.

For specific information on other aspects of managing your WSIF system, see the following topics:
- Maintaining the WSIF properties file
- Enabling security for WSIF
- Trace and logging for WSIF
- Troubleshooting the Web Services Invocation Framework
- WSIF (Web Services Invocation Framework) messages
- WSIF - Known restrictions.

Maintaining the WSIF properties file

The Web Services Invocation Framework (WSIF) properties are stored in the wsif.jar file, in a properties file named wsif.properties.

The wsif.jar file is located in the *install_root*/lib directory, where *install_root* is the root directory for your installation of IBM WebSphere Application Server.

You must keep the “as shipped” wsif.properties file on the class path, so that WSIF can find it and the client administrator can use it to configure WSIF. However if you make any changes to the file, you do not replace the original copy in the wsif.jar file. Instead, you save the modified version in the *install_root*/lib/properties directory.

Here is a copy of the initial contents of the wsif.properties file. All the possible properties are listed and described.

```
# Two properties are used to override which WSIFProvider is selected when there
# exists multiple providers supporting the same namespace URI. These properties are:
#
#    wsif.provider.default.CLASSNAME=N
#    wsif.provider.uri.M.CLASSNAME=URI
#
# CLASSNAME is the WSIFProvider class name
# N is the number of following default wsif.provider.uri.M.CLASSNAME properties
# M is a number from 1 to N to uniquely identify each wsif.provider.uri.M.CLASSNAME
#   property key.
# For example the following two properties would override the default SOAP provider
# to be the Apache SOAP provider:
#
# wsif.provider.default.org.apache.wsif.providers.soap.ApacheSOAP.WSIFDynamicProvider_ApacheSOAP=1
# wsif.provider.uri.1.org.apache.wsif.providers.soap.ApacheSOAP.WSIFDynamicProvider_ApacheSOAP=\
# http://schemas.xmlsoap.org/wsdl/soap/
#

# maximum number of milliseconds to wait for a response to a synchronous request.
# Default value if not defined is to wait forever.
wsif.syncrequest.timeout=10000

# maximum number of seconds to wait for a response to an async request.
# if not defined on invalid defaults to no timeout
wsif.asyncrequest.timeout=60
```

To enable your legacy Web services to continue to work with WSIF, you might need to change the default WSIF SOAP provider back to the former Apache SOAP provider.

Enabling security for WSIF

The Web Services Invocation Framework (WSIF) interacts with a security manager in the following ways:
- WSIF runs in the Java 2 platform, Enterprise Edition (J2EE) security context without modification.
- When WSIF is run under a J2EE container, port implementations can use the security context to pass on security tokens or credentials as necessary.
- WSIF implementations can automatically convert J2EE security context into appropriate context for onward services.

For WSIF to interact effectively with the WebSphere Application Server security manager, enable the following permission in the `was.policy` file: **FilePermission** to load the WSDL. This permission is required when a WSDL file is referred to using the `file://` protocol.

Troubleshooting the Web Services Invocation Framework

For information on resolving WebSphere-level problems, see the *Troubleshooting and support* PDF.

To identify and resolve Web Services Invocation Framework (WSIF)-related problems, you can use the standard WebSphere Application Server trace and logging facilities. If you encounter a problem that you think might be related to WSIF, you can check for error messages in the WebSphere Application Server administrative console, and in the application server `stdout.log` file. You can also enable the application server debug trace to provide a detailed exception dump.

A list of the WSIF run-time system messages, with details of what each message means, is provided in Message reference for WSIF.

A list of the main known restrictions that apply when using WSIF is provided in WSIF - Known restrictions.

Here is a checklist of major WSIF activities, with advice on common problems associated with each activity:

Create service
Handcrafted WSDL can cause numerous problems. To help ensure that your WSDL is valid, use a tool such as Rational Application Developer to create your service.

Define transport mechanism
For the Java Message Service (JMS), check that you have set up the Java Naming and Directory Interface (JNDI) correctly, and created the necessary connection factories and queues.

For SOAP, make sure that the deployment descriptor file `dds.xml` is correct - preferably by creating it using Rational Application Developer or similar tooling.

Create client - Java code
Follow the correct format for creating a WSIF service, port, operation and message. For examples of correct code, see the Address Book Sample.

Compile code (client and service)
Check that the build path against code is correct, and that it contains the correct levels of JAR files.

Create a valid EAR file for your service in preparation for deployment to a Web server.

Deploy service
When you install and deploy the service EAR file, check carefully any messages given when the service is deployed.

Server setup and start
Make sure that the WebSphere Application Server `server.policy` file (in the `/properties` directory) has the correct security settings. For more information, see Enabling security for WSIF.

WSIF setup
Check that the `wsif.properties` file is correctly set up. For more information, see Maintaining the WSIF properties file.

Run client

Either check that you have defined the class path correctly to include references to your client classes, WSIF JAR files and any other necessary JAR files, or (preferably) run your client using the WebSphere Application Server launchClient tool.

Here is a list of common errors, and information on their probable causes:

- **“No class definition” errors received when running client code.**

  This problem usually indicates an error in the class path setup. Check that the relevant JAR files are included.

- **“Cannot find WSDL” error.**

  Some likely causes are:
  - The application server is not running.
  - The server location and port number in the WSDL are not correct.
  - The WSDL is badly formed (check the error messages in the application server `stdout.log` file).
  - The application server has not been restarted since the service was installed.

  You might also try the following checks:
  - Can you load the WSDL into your Web browser from the location specified in the error message?
  - Can you load the corresponding WSDL binding files into your Web browser?

- **Your Web service EAR file does not install correctly onto the application server.**

  It is likely that the EAR file is badly formed. Verify the installation by completing the following steps:
  - For an EJB binding, run the WebSphere Application Server tool `\bin\dumpnamespace`. This tool lists the current contents of the JNDI directory.
  - For a SOAP over HTTP binding, open the `http://pathToServer/WebServiceName/admin/list.jsp` page (if you have the SOAP administration pages installed). This page lists all currently installed Web services.
  - For a SOAP over JMS binding, complete the following checks:
    - Check that the queue manager is running.
    - Check that the necessary queues are defined.
    - Check the JNDI setup.
    - Use the “display context” option in the `jmsadmin` tool to list the current JNDI definitions.
    - Check that the Remote Procedure Call (RPC) router is running.

- **There is a permissions problem or security error.**

  Check that the WebSphere Application Server `server.policy` file (in the `/properties` directory) has the correct security settings. For more information, see Enabling security for WSIF.

- **Using WSIF with multiple clients causes a SOAP parsing error.**

  Before you deploy a Web service to WebSphere Application Server, you must decide on the scope of the Web service. The deployment descriptor file `dds.xml` for the Web service includes the following line:

  ```
  <isd:provider type="java" scope="Application" ......
  ```

  You can set the `Scope` attribute to `Application` or `Session`. The default setting is `Application`, and this value is correct if each request to the Web service does not require objects to be maintained for longer than a single instance. If `Scope` is set to `Application` the objects are not available to another request during the execution of the single instance, and they are released on completion. If your Web service needs objects to be maintained for multiple requests, and to be unique within each request, you must set the scope to `Session`. If `Scope` is set to `Session`, the objects are not available to another request during the life of the session, and they are released on completion of the session. If scope is set to `Application` instead of `Session`, you might get the following SOAP error:

```
SOAPException: SOAP-ENV:ClientParsing error, response was:
FWK005 parse may not be called while parsing.;
nested exception is:

[SOAPException: faultCode=SOAP-ENV:Client; msg=Parsing error, response was:
```

```
FWK005 parse may not be called while parsing.;
       targetException=org.xml.sax.SAXException:
FWK005 parse may not be called while parsing.]
```

- **Using the same names for JMS messaging queues and queue connection factories that run on application servers on different machines can cause JNDI lookup errors.** You should not use the same names for messaging queues and queue connection factories that run on application servers on different machines, because WSIF always looks first for JMS destinations locally, and only uses the full JNDI reference if it cannot find the destination locally. For example, if you run a Web service on a remote machine, and have an application server running locally that uses the same names for the messaging queues and queue connection factories, then WSIF will find and use the local queues even if the remote JNDI destination is provided in full in the WSDL service definition.
- **The current WSIF default SOAP provider (the IBM Web Service SOAP provider) does not fully interoperate with services that are running on the former (Apache SOAP) provider.** This restriction is due to the fact that the IBM Web Service SOAP provider is designed to interoperate fully with a JAX-RPC compliant Web service, and Apache SOAP cannot provide such a service. To enable interoperation, modify either your Web service or the WSIF default SOAP provider as described in WSIF SOAP provider: working with legacy applications.

Trace and logging for WSIF:

If you want to enable trace for the Web Services Invocation Framework (WSIF) API within WebSphere Application Server, and have trace, stdout and stderr for the application server written to a well-known location, see ″Enabling trace″ and ″Setting up component trace (CTRACE)″ in the *Troubleshooting and support* PDF.

WSIF offers trace points at the opening and closing of ports, the invocation of services, and the responses from services.

To trace the WSIF API, you need to specify the following trace string:

```
wsif=all=enabled
```

WSIF also includes a `SimpleLog` utility through which you can run trace when using WSIF outside of WebSphere Application Server. To enable this utility, complete the following steps:

1. Create a file named `commons-logging.properties` with the following contents:

```
org.apache.commons.logging.LogFactory=org.apache.commons.logging.impl.LogFactoryImpl
org.apache.commons.logging.Log=org.apache.commons.logging.impl.SimpleLog
```

2. Create a file named `simplelog.properties` with the following contents:

```
org.apache.commons.logging.simplelog.defaultlog=trace
org.apache.commons.logging.simplelog.showShortLogname=true
org.apache.commons.logging.simplelog.showdatetime=true
```

3. Put both these files, and the `commons-logging.jar` file, on the class path.

The `SimpleLog` uitility writes trace to the `System.err` file.

WSIF (Web Services Invocation Framework) messages:

This topic contains a list of the WSIF run-time system messages, with details of what each message means.

WebSphere system messages are logged from a variety of sources, including application server components and applications. Messages logged by application server components and associated IBM products start with a unique message identifier that indicates the component or application that issued the message.

For more information about the message identifier format, see the topic Message reference.

WSIF0001E: An extension registry was not found for the element type “{0}”

Explanation: Parameters: {0} element type. No extension registry was found for the element type specified.

User Response: Add the appropriate extension registry to the port factory in your code.

WSIF0002E: A failure occurred in loading WSDL from “{0}”

Explanation: Parameters: {0} location of the WSDL file. The WSDL file could not be found at the location specified or did not parse correctly

User Response: Check that the location of the WSDL file is correct. Check that any network connections required are available. Check that the WSDL file contains valid WSDL.

WSIF0003W: An error occurred finding pluggable providers: {0}

Explanation: Parameters: {0} specific details about the error. There was a problem locating a WSIF pluggable provider using the J2SE 1.3 JAR file extensions to support service providers architecture. The WSIF trace file will contain the full exception details.

User Response: Verify that a META-INF/services/org.apache.wsif.spi.WSIFProvider file exists in a provider jar, that each class referenced in the META-INF file exists in the class path, and that each class implements org.apache.wsif.spi.WSIFProvider. The class in error will be ignored and WSIF will continue locating other pluggable providers.

WSIF0004E: WSDL contains an operation type “{0}” which is not supported for “{1}”

Explanation: Parameters: {0} name of the operation type specified. {1} name of the portType for the operation. An operation type which is not supported has been specified in the WSDL.

User Response: Remove any operations of the unsupported type from the WSDL. If the operation is required then make sure all messages have been correctly specified for the operation.

WSIF0005E: An error occurred when invoking the method “{1}” . (“{0}”)

Explanation: Parameters: {0} name of communication type. For example EJB or Apache SOAP. {1} name of the method that failed. An error was encountered when invoking a method on the Web service using the communication shown in brackets.

User Response: Check that the method exists on the Web service and that the correct parts have been added to the operation as described in the WSDL. Network problems might be a cause if the method is remote and so check any required connections.

WSIF0006W: Multiple WSIFProvider found supporting the same namespace URI “{0}” . Found (“{1}”)

Explanation: Parameters: {0} the namespace URI. {1} a list of the WSIFProvider found.. There are multiple org.apache.wsif.spi.WSIFProvider classes in the service provider path that support the same namespace URI.

User Response: A following WSIF0007I message will be issued notifying which WSIPFProvider will be used. Which WSIFProvider is chosen is based on settings in the wsif.properties file, or if not defined in the properties, the last WSIFProvider found will be used. See the wsif.properties file for more details on how to define which provider should be used to support a namespace URI.

WSIF0007I: Using WSIFProvider “{0}” for namespaceURI “{1}”

Explanation: Parameters: {0} the classname of the WSIFProvider being used. {1} the namespaceURI the provider will be used to support.. Either a previous WSIF0006W message has been issued or the SetDynamicWSIFProvider method has been used to override the provider used to support a namespaceURI.

User Response: None. See also WSIF0006W.

WSIF0008W: WSIFDefaultCorrelationService removing correlator due to timeout. ID:“{0}”

Explanation: Parameters: {0} the ID of the correlator being removed from the correlation service. A stored correlator is being removed from the correlation service due to its timeout expiring.

User Response: Determine why no response has been received for the asynchronous request within the timeout period. The wsif.asyncrequest.timeout property of the wsif.properties file defines the length of the timeout period.

WSIF0009I: Using correlation service - “{0}”

Explanation: Parameters: {0} the name of the correlation service being used. This identifies the name of the correlation service that will be used to process asynchronous requests.

User Response: None. If a correlation service other than the default WSIF supplied one is required, ensure that it is correctly registered in the JNDI java:comp/wsif/WSIFCorrelationService namespace.

WSIF0010E: Exception thrown while processing asynchronous response - “{0}”

Explanation: Parameters: {0} the error message string of the exception. While processing the response from an executeRequestResponseAsync call an exception was thrown.

User Response: Use the exception error message string to determine the cause of the error. The WSIF trace will have more details on the error including the exception stack trace.

WSIF0011I: Preferred port “{0}” was not available

Explanation: Parameters: {0} the user’s preferred port. The preferred port set by the user on org.apache.wsif.WSIFService is not available

User Response: None unless this message appears for long periods of time in which case the user might want to pick a different port as their preferred port.

WSIF - Known restrictions:

This topic lists the main known restrictions that apply when using WSIF.

Threading

WSIF is not thread-safe.

External Standards

WSIF supports:

- SOAP Version 1.1 (not 1.2 or later).
- WSDL Version 1.1 (not 1.2 or later).

WSIF does not provide WS-I compliance, and it does not support the Java API for XML-based Remote Procedure Calls (JAX-RPC) Version 1.1 (or later).

Full schema parsing

WSIF does not support full schema parsing. For example, WSDL references in complex types in the schema are not handled, and attributes are not handled.

SOAP WSIF does not support:

- SOAP headers that are passed as `<parts>`.
- Unreferenced attachments in SOAP responses.
- Document Encoded style SOAP messages.

Note: This is not primarily a WSIF restriction. Although you can specify Document Encoded style in WSDL, it is not generally considered to be a valid option and is not supported by the Web Services Interoperability Organization (WS-I).

SOAP provider interoperability

The current WSIF default SOAP provider (the IBM Web Service SOAP provider) does not fully interoperate with services that are running on the former (Apache SOAP) provider. This restriction is due to the fact that the IBM Web Service SOAP provider is designed to interoperate fully with a JAX-RPC compliant Web service, and Apache SOAP cannot provide such a service. For information on how to overcome this restriction, see WSIF SOAP provider: working with legacy applications

Type mappings

The current WSIF default SOAP provider (the IBM Web Service SOAP provider) conforms to the JAX-RPC type mapping rules that were finalized after the former (Apache SOAP) provider was created. The majority of types are mapped the same way by both providers. The exceptions are:

xsd:date, xsd:dateTime, xsd:hexBinary and xsd:QName. Both client and service need to use the same mapping rules if any of these four types are used. Below is a table detailing the mapping rules for these four types:

XML Data Type	Apache SOAP Java Mapping	JAX-RPC Java Mapping
xsd:date	java.util.Date	Not supported
xsd:dateTime	Not supported	java.util.Calendar
xsd:hexBinary	Hexadecimal string	byte [ ]
xsd:QName	org.apache.soap.util.xml.QName	javax.xml.namespace.QName

Arrays and complex types

WSIF does not support general complex types, it only handles complex types that map to Java Beans. To use schema complex types, you must write your own custom serializers. The specific complex type and array support for WSIF outbound invocation of Web services is as follows:

- WSIF supports Java classes generated by WebSphere Studio Application Developer - Integration Edition (WSAD-IE) message generators (the normal case when WSDL files are downloaded from somewhere else). The WSAD-IE-based generation happens automatically when you use the BPEL editor, or the generation actions available on the Enterprise Services context menu, or the Business Integration toolbar.
- WSIF does not support Java beans generated by other tools, including the base WSAD tool.
- For WSAD-IE generated Java beans, attributes defined in the WSDL do not work. That is to say that these attributes, although they appear in the Java beans generated to represent the complex type, do not appear in the SOAP request created by WSIF.
- WSIF does not support arrays when they are a field of a Java bean. That is to say, WSIF only supports an array that is passed in as a named <part>. If an array is wrappered inside a Java bean, the array is not serialized in the same way.

Object Serialization

WSIF does not support serialization of objects across different releases.

Asynchronous invocation

WSIF supports synchronous invocation for all providers. For the JMS and the SOAP over JMS providers, WSIF also supports asynchronous invocation. You should call the supportsAsync() method before trying to execute an asynchronous operation.

The EJB provider

The target service of the WSIF EJB provider must be a remote-home interface, it cannot be an EJB local-home interface. In addition, the EJB stub classes must be available on the client class path.

Running outside WebSphere Application Server

WSIF is not supported for use outside WebSphere Application Server.

Using the UDDI Registry

Welcome to the IBM WebSphere UDDI Registry.

Use the table of contents (on the left and below) to view the various topics for a specific product or technology. Select the topic you are interested in to either open documentation locally or find information about how to locate documentation.
- An Overview of the IBM Version 3 UDDI Registry

An overview of the IBM Version 3 UDDI Registry

The Universal Description, Discovery and Integration (UDDI) specifications define a way to publish and discover information about Web services. The term 'Web service' describes specific business functionality exposed by a company, usually through an Internet connection, to allow another company, or its subsidiaries, or software program to use the service.

The UDDI specifications define a standard for the visibility, reusability and manageability essential for a Service Oriented Architecture (SOA) registry service.

IBM WebSphere UDDI Registry

The IBM WebSphere UDDI Registry is a directory for Web services that is implemented using the UDDI specifications. It is a component of WebSphere Application Server Version 6.

A critical component of IBM's on-demand Service Oriented Architecture, IBM WebSphere UDDI Registry solves the problem of discovery of technical components for an enterprise and its partners by:

- Providing control, flexibility and confidentiality so that an enterprise can protect its e-business investments
- Increasing efficiency by making it easier to identify technical assets
- Leveraging existing infrastructures

For example, the IBM WebSphere UDDI Registry could be used in the following way within a larger enterprise:

A company has a legacy application that provides telephone numbers and Human Resources (HR) information about employees. This is turned into a Web service and published to the registry. A developer in the same company needs to write an application for a procurement function that also needs to provide HR information to the supplier. The application should allow the supplier to have access to the employee account codes once the employee provides his name or serial number. Before Web services, the developer had there choices:

1. Would not have known about the similar application
2. Knew about it but could not reuse due to technical barriers
3. Knew about it and reused only after significant time and negotiation

With UDDI, the developer can search for the ″web service″ and reuse the existing technical component in their new application for the supplier in a matter of minutes. The developer saves time and gets the application up and running sooner than they would have otherwise, thereby increasing efficiency and saving the company time and money. The IBM WebSphere UDDI Registry was the first version 2 standard-compliant UDDI registry for private enterprise work. The IBM WebSphere UDDI Registry in WebSphere Application Server Version 6.0:

- Supports the UDDI Version 3.0 specifications and also supports the Version 2.0 standard API.
- Leverages the proven, reliable WebSphere Application Server technology
- Uses a relational database, such as DB2, for its persistent store

What’s new in UDDI Version 3

The main aspects of UDDI Version 3 specification that are provided within WebSphere Application Server Version 6 are as follows: (There are also some additional capabilities provided by the IBM WebSphere UDDI Registry in WebSphere Application Server Version 6.0 which are described in a section below).

Improved recognition of the importance of Private UDDI Registries

These are registries that are installed, owned, managed and controlled by a department, company, consortium and so on.

Publisher-assigned keys

This allows the publisher of a UDDI entity to specify its key, rather than having a unique key assigned by the registry. As well as allowing more human-friendly, URI-based keys, this also makes it easier to manage multiple registries.

UDDI Information Model improvements

The UDDI data structures have been extended in a number of ways which improve the ability of UDDI to represent businesses and services via metadata.

Security Enhancements

The introduction of digital signatures provides additional security. Each of the main UDDI entities can be digitally signed, thus improving the integrity and trustworthiness of UDDI data.

Ownership transfer APIs

These allow the ownership of a UDDI entity to be transferred from one publisher to another.

UDDI Policy

Allows the behavior of a UDDI Registry (or a node within a multi-node registry) to be defined by setting policy, thus recognizing the various different environments in which a UDDI Registry will be used.

HTTP GET support for UDDI entities

The HTTP GET service is extended beyond the scope for discovery URLs that is a part of the UDDI Version 2 specification. The service allows HTTP GET to be used to access XML representations of each of the UDDI data structures.

Additional Capabilities provided by the UDDI Registry

The Version 3 UDDI Registry provided in WebSphere Application Server Version 6.0 provides the following capabilities in addition to support for the UDDI Version 3 specification:

Version 2 UDDI Inquiry and Publish SOAP API compatibility

Backward compatibility is maintained for the Version 1 and Version 2 SOAP Inquiry and Publish APIs.

UDDI Admin Console extension

The WebSphere Application Server Version 6 Administrative Console includes a section which will allow administrators to manage UDDI-specific aspects of their WebSphere environment. This includes the ability to set defaults for initialization of the UDDI node (such as its node ID), and to set the UDDI Version 3 Policy values.

UDDI Registry Administrative Interface

A JMX administrative interface allows administrators to programmatically manage UDDI-specific aspects of the WebSphere environment.

Multi-database support

The UDDI data is persisted to a registry database. In WebSphere Application Server Version 6 the databases that are supported are DB2, Cloudscape, and Oracle. Support is provided for remote databases.

User-defined Value Set support

This allows users to create their own categorization schemes or value sets, in addition to the standard schemes, such as NAICS, that are provided with the product.

UDDI Utility Tools

UDDI Utility Tools allows importing and exporting of entities using the UDDI Version 2 API.

UDDI user interface

The UDDI user console supports the Inquiry and Publish APIs providing a similar level of support for the Version 3 APIs as was offered for UDDI Version 2 in WebSphere Application Server Version 5.

UDDI Version 3 Client

The IBM Java Client for UDDI Version 3 is a Java client for UDDI which handles the construction of raw SOAP requests for the client application. It is a JAX-RPC client and uses Version 3 datatypes generated from the UDDI Version 3 WSDL and schema. These datatypes are serialized/deserialized to the XML which constitutes the raw UDDI requests.

UDDI Version 2 Clients

The following clients for UDDI Version 2 requests are provided:

- UDDI4J - a Java class library for issuing UDDI requests. This was provided in WebSphere Application Server Version 5 for both UDDI Version 1 requests (uddi4j.jar) and Version 2 requests (uddi4jv2.jar). These class libraries continue to be supported but are now both deprecated.
- JAXR - the Java API for XML Registries is a Java client API for accessing UDDI and ebXML registries. WebSphere Application Server 6.0 provides a JAXR Provider for accessing the IBM WebSphere UDDI Registry. It conforms to the JAXR 1.0 specification.
- EJB - an EJB interface for issuing UDDI version 2 requests. This continues to be supported but is now deprecated.

UDDI Registry terminology

Throughout the UDDI documentation in this Information Center the directory location of the WebSphere Application Server is referred to as **WAS_HOME**. The default locations are:

Windows

WAS_HOME
C:\Program Files\IBM\WebSphere\AppServer\

Linux/Solaris/HP Platforms

WAS_HOME
/opt/IBM/WebSphere/AppServer/

AIX Platform

WAS_HOME
/usr/IBM/WebSphere/AppServer/

z/OS Platform

WAS_HOME
/WebSphere/V6R0M0/AppServer/

UDDI Definitions

bindingTemplate
Technical information about a service entry point and construction specifications.

businessEntity
Information about the party who publishes information about a family of services.

businessService
Descriptive information about a particular service.

Customized UDDI node
This is a UDDI node that is initialized with customized settings for the UDDI properties and UDDI policies, in particular with non-default values for those properties that are read-only after initialization. A customized UDDI node is recommended for anything other than simple testing purposes (for which a default UDDI node is sufficient). You can set up a customized UDDI node by following the instructions in Setting up a customized UDDI node. When a customized UDDI node is first started, you have to set values for certain properties and to initialize the node (using the Administrative Console or UDDI Administrative Interface), before the node is ready to accept UDDI requests. The properties that need to be set control characteristics of the UDDI node that cannot be changed after initialization. An advantage of using a customized UDDI node is that it allows you to set these properties to values that are suitable for your environment and usage of UDDI. After a customized UDDI node has been initialized, it differs from a default UDDI node only in that it uses customized UDDI property and policy values.

Default UDDI node
This is a UDDI node which has been initialized with default settings for the UDDI properties and UDDI policies, including the properties that are read-only after initialization. A default UDDI node is intended for test purposes and as a simple way to become familiar with the behavior of the UDDI Registry. You can set up a default UDDI node in two ways. The first is to specify the 'default' option when you run uddiDeploy.jacl, in which case the UDDI database will be a Cloudscape database. The second is to run the supplied SQL script insert_default_database_indicator against the UDDI database, in which case the UDDI database can be Cloudscape, DB2 or Oracle. After a default UDDI node has been initialized, it differs from a customized UDDI node only in that it uses default UDDI property and policy values.

Policy profile
A set of UDDI policies. The default policy profile is the profile created when the default UDDI node is created. In this instance, the nodeID and root key generator are set to read only and are unchangeable after installation.

publisherAssertion
Information about a relationship between two parties, asserted by one or both.

tModel

Short for technical model.

A tModel is a data structure representing a reusable concept, such as a Web service type, a protocol used by Web services, or a category system.

tModel keys within a service description are a technical ″fingerprint″ that you can use to trace the compatibility origins of a given service. They provide a common point of reference that allows you to identify compatible services.

tModels are used to establish the existence of a variety of concepts and to point to their technical definitions. tModels that represent value sets such as category, identifier, and relationship systems are used to provide additional data to the UDDI core entities to facilitate discovery along a number of dimensions. This additional data is captured in keyedReferences that reside in category Bags, identifierBags, or publisherAssertions. The tModelKey attributes in these keyedReferences refer to the value set that relates to the concept or namespace being represented. The keyValues contain the actual values from that value set. In some cases keyNames are significant, such as for describing relationships and when using the general keywords value set. In all other cases, however, keyNames are used to provide a human readable version of what is in the keyValue.

UDDI Application

The IBM WebSphere UDDI Registry J2EE application.

UDDI entitlement

An entitlement that a UDDI user or publisher has within a UDDI registry, such as the capability to publish keyGenerators, or the tier to which the publisher is assigned (in other words, the number of entities that the publisher is entitled to published). Each UDDI publisher will have a set of settings for the various UDDI entitlements. A UDDI entitlement is sometimes referred to as a ’user entitlement’, or as the UDDI publisher’s set of ’user entitlements’.

UDDI Node

A set of Web Services supporting at least one of the UDDI API sets, which supports interaction with UDDI data through the UDDI APIs. There is no direct mapping between a UDDI node and a WebSphere Application Server (WAS) node. A UDDI node consists of an instance of the UDDI application running in an application server (or a cluster of UDDI application instances running in a cluster of application servers) together with an instance of the UDDI database containing UDDI data.

UDDI node initialization

The process of node initialization sets up values in the UDDI database, and establishes the ″personality″ of the UDDI node. A UDDI node cannot accept UDDI API requests until it has been initialized.

UDDI node state

Describes the current state of the UDDI node, as opposed to the state of the UDDI application (which is either stopped or started). The state of a UDDI node can be one of not initialized, initialization pending, initialization in progress, activated or deactivated.

UDDI NodeId

A unique identifier of a UDDI node.

UDDI Policy

A UDDI policy is a statement of required and expected behavior of a UDDI Registry, specified via policy values for the various policies defined in the UDDI Version Specification.

UDDI property

A value for a property which controls the personality or behavior of a UDDI node.

UDDI publisher

A WebSphere user who is entitled to publish UDDI entities to a specified UDDI Registry. A UDDI publisher is sometimes referred to as a ’UDDI user’, or simply as a ’publisher’ when used in a UDDI context.

UDDI Registry

A UDDI Registry comprises one or more UDDI nodes. The IBM WebSphere UDDI Registry in WebSphere Application Server Version 6.0 only supports single-node UDDI registries.

UDDI Tier

Determines the number of UDDI entities of each type (business, services per business, bindings per service, tModel, publisher assertion) that a UDDI publisher is entitled to publish. Each UDDI publisher will be assigned (either by default or explicitly by a UDDI administrator) to a particular tier, and will not be able to publish more entities than are allowed for that tier. There are some predefined tiers supplied with the UDDI Registry, and a UDDI administrator can create additional tiers. A UDDI tier is often referred to simply as a 'tier' when used in a UDDI context.

Version 2 UDDI Registry

A shorthand term used to refer to an IBM WebSphere UDDI Registry implementation which supports Version 2 of the UDDI specification (and also Version 1). A Version 2 UDDI Registry is included in WebSphere Application Server Network Deployment Version 5.x.

Version 3 UDDI Registry

A shorthand term used to refer to an IBM WebSphere UDDI Registry implementation which supports Version 3 of the UDDI specification (and also Versions 1 and 2). A Version 3 UDDI Registry is included in WebSphere Application Server Version 6.0. It should be noted that the term 'Version 3 UDDI Registry' does not indicate a registry which only supports UDDI version 3 requests.

The following table shows how the various versions of the IBM UDDI Registry relate to the relevant OASIS specification and WebSphere Application Server level:

IBM UDDI Registry Version	OASIS UDDI specification levels supported	Supported on WebSphere Application Server version
1.1	• UDDI Version 1 • UDDI Version 2	4.0.2
1.1.1	• UDDI Version 1 • UDDI Version 2	4.0.3 and later
2.0.x	• UDDI Version 1 • UDDI Version 2	5.0.x
2.1.x	• UDDI Version 1 • UDDI Version 2	5.1.x
3.0.2	• UDDI Version 1 • UDDI Version 2.0.4 (APIs), Version 2.0.3 (data structures) • UDDI Version 3.0.2	6.0

UDDI Registry Security

The IBM UDDI V3 Registry is designed to exploit the advantages of WebSphere security, and it supports the UDDI v1,v2 security features and UDDI V3 Security API.

For production use, it is recommended that the IBM UDDI V3 Registry is configured to use WebSphere security and avoid use of UDDI V1,V2 security features and the V3 Security API.

But, for solutions with a strong preference for UDDI security, the IBM UDDI V3 Registry can be configured to enable its use, both when WAS security is enabled and when it is disabled.

Configuring UDDI to use WAS security

To exploit WebSphere security features WebSphere Application Server (WAS) security must be enabled. When security is enabled, the default settings in UDDI v3 Application and Web deployment descriptors result in the following features:

Authentication

UDDI exploits WAS security Role Mapping by mapping users of UDDI Publish services to the special AllAuthenticatedUsers role to ensure that only valid WebSphere registered users can access these services. This is the default setting for:

- V1,2 SOAP Publish service (SOAP_Publish _User)
- EJB Publish service (EJB_Publish_Role)
- V3 GUI Publish service (GUI_Publish_User)
- V3 Publish service (V3SOAP_Publish_User_Role)
- V3 Custody Transfer service (V3SOAP_CustodyTransfer_User_Role)
- V3 Security service (V3SOAP_Security_User_Role)

The following services are mapped to the special role Everyone and are not protected:

- V1,2 SOAP Inquiry service (SOAP_Inquiry_User)
- EJB Inquiry service (EJB_Inquiry_Role)
- V3 GUI Inquiry service (GUI_Inquiry_User)
- V3 SOAP Inquiry service (V3SOAP_Inquiry_User_Role)

This restriction can be managed using WebSphere Administrative Console features:**Applications > Enterprise Applications> UDDI V3 Registry > Additional Properties > Map security roles to users/groups**.

Further information is also available in: Configuring UDDI Security Roles.

Data Confidentiality

UDDI also exploits the advantages of the WAS security feature enforcing service data confidentiality (’security constraint‘,’user-data-constraint‘, ’transport-guarantee‘ = ’CONFIDENTIAL‘ requiring the use of HTTPS) for the following services:

- V1,2 SOAP Publish service (SOAP_Publish _User)
- EJB Publish service (EJB_Publish_Role)
- V3 GUI Publish service (GUI_Publish_User)
- V3 Publish service (V3SOAP_Publish_User_Role)
- V3 Custody Transfer service (V3SOAP_CustodyTransfer_User_Role)
- V3 Security service (V3SOAP_Security_User_Role)

By default the following services are do not enforce data confidentiality (’security constraint‘, ’user-data-constraint‘, ’transport-guarantee‘ = ’NONE‘ not requiring the use of HTTPS, HTTP is OK):

- V1,2 SOAP Inquiry service (SOAP_Inquiry_User)
- EJB Inquiry service (EJB_Inquiry_Role)
- V3 GUI Inquiry service (GUI_Inquiry_User)
- V3 SOAP Inquiry service (V3SOAP_Inquiry_User_Role)

For information on how to manage the data confidentiality restriction, please refer to ’Configuring SOAP API and GUI services‘ section on user data constraint transport guarantee.

Configuring UDDI to use UDDI security

It is possible to exploit UDDI security features when WebSphere Application Server (WAS) security is enabled or disabled. Depending on the WAS security enabled/disabled setting, different configuration is required and different behavior achieved. While useful for test, it is not anticipated that WAS security is disabled for production configurations.

UDDI security with WAS Security enabled

When WAS security is enabled, to use the UDDI v1//2 (publish) security features (get_AuthToken,discard_AuthToken) or the UDDI v3 security API (get_AuthToken, discard_AuthToken) it is necessary to do the following:

- • set the WAS security Role Mappings to Everyone for:
  - V1,2 SOAP Publish service (SOAP_Publish _User)
  - V3 Publish service (V3SOAP_Publish_User_Role)
  - V3 Custody Transfer service (V3SOAP_CustodyTransfer_User_Role)
  - V3 Security service (V3SOAP_Security_User_Role)

  As identified above this can be managed using the WebSphere Administrative Console: **Applications > Enterprise Applications> UDDI V3 Registry > Additional Properties > Map security roles to users/groups**
- • ensure that UDDI Policy is set to require the use of AuthTokens for the Publish and CustodyTransfer API services (it is implicit for V1/2 Publish).

  This can be managed using the WebSphere Administrative Console: **UDDI>UDDI Nodes>uddinodename>Policy Groups>APIs>‘authorization for publish‘, ’authorization for custody transfer‘**

With this configuration, no Security Role authentication restriction is imposed, but the credentials associated with the authToken are authenticated by WebSphere. Further information is also available in: Configuring UDDI Security Roles.

Note, that when WAS security is enabled, WAS data confidentiality management is independent of UDDI security and is managed as described above.

UDDI security with WAS Security disabled

With WAS Security disabled, neither WAS Security Roles nor data confidentiality constraints apply. This mode may be useful for test UDDI Registry configurations.

In this mode, UDDI V1/2 security features are active, and UDDI V1/2 authTokens should be used on UDDI V1/2 publish requests. Publisher requesting an authToken or using an authToken do have to be a registered WAS users.

With respect to UDDI V3, the use of the UDDI V3 Security API, and the use of authTokens with V3 Publish and Custody Transfer APIs is optional. If required, the following configuration steps are necessary:

- use the WebSphere Administrative Console to identify that use of authInfo is required: **UDDI>UDDI Nodes>uddinodename >General Properties>** check ’Use authInfo credentials if provided‘
- ensure that UDDI Policy is set to require the use of AuthTokens for the Publish and CustodyTransfer using the WebSphere Administrative Console: **UDDI>UDDI Nodes>uddinodename>Policy Groups>APIs>check ‘authorization for publish‘ and ’authorization for custody transfer**

Additional security considerations

The UDDI Registry also supports use of XML Digital Signatures to sign UDDI entities. This is described in Use of digital signatures with the UDDI Registry.

Additional Policy considerations

A number of the UDDI property and policy settings also determine the behavior of a UDDI Registry with respect to security:

- Default user name -used when WAS Security is disabled and no authToken data is supplied (see WebSphere Administrative Console **> UDDI>UDDI Nodes>uddiNodeName >General Properties> Default user**).
- Authorization for Inquiry, Authorization for Publish, Authorization for Custody Transfer – as described above, checked to require use of authTokens when not 'overridden' by WAS Security Role AllAuthenticatedUsers (see WebSphere Administrative Console**> UDDI>UDDI Nodes>uddiNodeName > Policy Groups>APIs>'authorization for Inquiry', 'authorization for publish' and 'authorization for custody transfer'**).
- Use authInfo credential if provided – as described above, applicable when WAS security is disabled (**UDDI>UDDI Nodes>uddinodename >General Properties> 'Use authInfo credentials if provided'**).
- Authentication token expiry period – to determine the length of idle time allowed before an authToken becomes invalid (see WebSphere Administrative Console > **UDDI>UDDI Nodes>uddiNodeName >General Properties> Authentication token expiry period**).
- Key space requests require digital signature – determines whether all tModel:keyGenerator requests for key space must be signed. To understand key space refer to the Entity Keys Section, to manage this setting (see WebSphere Administrative Console **> UDDI>UDDI Nodes>uddiNodeName > General Properties> Key space requests require digital signature**).

In addition to Security specific policies and properties, awareness of some Keying Policy and User Policies also influences publish behavior:

- Keying Policy – Registry key generation. If this is set, publishers may request key space and if successful publish with publisher assigned keys (see WebSphere Administrative Console **> UDDI>UDDI Nodes>uddiNodeName >Policy Groups> UDDI Keying**).
- Automatically register UDDI publishers – UDDI requires publisher entitlements to be set, before allowing any publish request. This option automatically registers Users with default entitlements (see WebSphere Administrative Console **> UDDI>UDDI Nodes>uddiNodeName >General Properties> Automatically register UDDI Publishers**).
- UDDI Publishers – if the 'Automatically register UDDI publishers' option is not selected, then Users (and their entitlements) can be registered (see WebSphere Administrative Console **> UDDI>UDDI Nodes>Additional properties> UDDI Publishers**).See also the topics on Create UDDI Publishers and UDDI Publisher settings.
- UDDI tier limits – UDDI V3 publish tier limits management (enforcing publisher tier limit) can be activated (see WebSphere Administrative Console **> UDDI>UDDI Nodes> uddiNodeName>General Properties>Use TierLimits**). Also refer to the 'Use tier limits' UDDI property.
- If the above option is checked, then it relevant to configure Tiers (see WebSphere Administrative Console **> UDDI>UDDI Nodes> uddiNodeName>Addition Properties>Tiers**) also to set any registered UDDI Publishers Tier entitlement (see WebSphere Administrative Console**> UDDI>UDDI Nodes> uddiNodeName>Addition Properties>UDDI Publishers**).

UDDI Registry user interface

This topic describes the UDDI user interface (also referred to as the UDDI User Console), which you can use to explore the IBM WebSphere UDDI Registry.

For information about how to display the UDDI user console, see Displaying the user interface.

If you will be using the UDDI console, you must configure the application server into which you have installed the UDDI Registry for UTF-8 encoding support: To do this, refer to ″Configuring application servers for UTF-8 encoding″ elsewhere in this Information Center.

- The user console provides a graphical user interface to the majority of the UDDI Version 3 API. It is not intended to support the full API set: there is some focus on inquiry operations, as the main purpose of the UDDI user console is to allow users to issue inquiry requests and to familiarize themselves with general UDDI concepts. This section documents those areas for which support through the user console is not provided, together with other known restrictions to the user console.
  - General
    - Help is provided in the form of explanatory text on the screens.
    - Maximum rows cannot be specified on finds. The single maximum rows value for the registry can be set through the *Maximum inquiry result set size* general property on the WebSphere Administrative console.
  - Find business
    - The business identifier feature is not supported.
  - Find technical model (tModel)
    - The business identifier feature is not supported.
  - Add business
    - You must supply the business contact as a name and role (no other information is supported).
  - Add technical model (tModel)
    - You can enter the overview URL, but only with one description in English.
  - Business Relationships
    - There is no support for Business Relationships
- **Note:** The UDDI Version 3 specification states that when a tModel is deleted, it should not be physically deleted. This allows the tModel to be reinstated. One effect of this is that, if you delete a tModel using the UDDI user console, the tModel is still visible through the Show Owned Entities display.

The UDDI user console is split into three distinct areas. At the top of the screen are buttons that activate various functions in the areas below this bar. These buttons are:

Home Returns you to the IBM WebSphere UDDI Registry welcome page

Find Activates the Find tab on the frame below to the left

Publish
Similarly activates the Publish tab on the frame below to the left

Below the WebSphere UDDI Registry banner the screen is split into two parts. On the left are the two tabs mentioned above, the Find and Publish tabs.

Find tab

The Find tab is in two parts. At the top, a **Quick Find** service is provided. There are three radio buttons to enable a choice of ’service’, ’business’ and ’technical model’ finds. Below these radio buttons is a text entry box for entering the name to search for and, beneath this, a ’Find’ link to start the search. Comments are provided to show the user the wildcard character. The results of clicking the ’Find’ link are shown in the detail frame to the right.

Beneath the Quick Find is a section for **Advanced Find** functions which enables the user to choose which entity they want to perform an advanced search on. There are three links: **Find services**, **Find businesses** and **Find technical models**. Clicking one of these links displays the corresponding advanced search form in the frame to the right, where the user can specify search criteria. To initiate a Find, the user must first enter a search path (the % wildcard may be used) and then click the Add Name link to enter the search. Then click the ’Find Services’ (or ’Find Businesses/Find technical models) link below to initiate the Find operation. The **Locator** section has a link (marked in blue with the words ″**Show category tree**″) which displays the tree from which the user can select categories (or taxonomies). This is shown in the left-hand frame. In the advanced search form there are two links to start the search (mid-way down and at the bottom).

The results of the search are displayed in the same detail frame.

Publish tab

The *Publish* link on the top banner activates the Publish tab in the navigation frame to the left. The Publish tab is split into three distinct sections.

1. **Quick Publish Function**

   The top part is a **Quick Publish** section to allow the user to publish a business or technical model by name only. There are two radio buttons to enable a choice of 'business' or 'technical model'. Below these radio buttons is a text entry box for entering the name to assign to the selected entity and, beneath this, a blue **Publish** link to publish the entity. The results of clicking the **Publish** link are shown in the detail frame to the right.
2. **Advanced Publish Functions**

   To publish an entity with more detail, such as with multiple names, descriptions and categories, use the **Advanced Publish** section below this. The comments below each link ('Add a business' and 'Add a technical model') describe individual functions. Clicking one of these links displays the corresponding advanced publish form in the detail frame where the user may enter details about the entity they want to publish. Similarly the **Locator** section allows taxonomies to be shown in the left frame from which the user can select categories.

   Following entry of the relevant details on the **Advanced Publish** section, the user must click the **Publish Business** bar in order for the business to be published to the UDDI Registry.
3. **Registered Information**

   Below the Advanced Publish section is a **Registered Information** section which has a link to **Show Owned Entities** in order to show the businesses, services and technical models registered to the individual user. Clicking the **Show Owned Entities** link displays the **Show Owned Entities** page in the detail frame at the right. The **Show Owned Entities** page is organized in two sections: **Registered Businesses** and **Registered Technical Models**. Each section shows the number of registered items.

   Edit and Delete Businesses

   Users can **Edit** or **Delete** businesses owned by them by clicking the appropriate links in the **Actions** column.

   After an **Edit** or **Delete** function has been completed, the user *must* click the **Update Business** bar to publish the service to the UDDI Registry.

   To delete a Business select the **Show Owner Entities** link and click the **Delete** link shown next to the business.

   Adding a Service to a Business

   Services are added to a business by clicking the **Add a Service** link in the **Services** column of the **Registered Businesses** section.

   Click the **Add Service** button to publish the service to the UDDI Registry.

   Technical Models

   Technical Models owned by the user are shown in the bottom **Registered Technical Models** section. As for businesses, users can Edit or Delete technical models owned by them by clicking the appropriate links in the **Actions** column.

   Note: Users should take note that deletion of Technical Models (tModels) does **not** cause them to be physically deleted, but hidden. This is in accordance with the UDDI Registry Version 3.0 specifications. After deletion Technical Models are shown under the ″**Shown Owned Entities**″ link on the publish page but not via the Find links on the Find page. ALL other entities are deleted from the UDDI Registry in the normal way.

Example of publishing a Business, Service and tModel with the User Console

For the example, here, we will assume a business called Modern Cars that sells used cars

1. **Add the Business**

Click the Publish tab in the left hand navigation frame. Then click ’Add a business’ in the Advanced Publish in the left pane. This takes you to a ’Publish Business’ pane on the right. Start by adding your Business Name in the text field labelled (Modern Cars in this example) and select a language and then click on the blue Add name to the right. This adds the business name. Below the Business Name is the descriptions field - free text can be added to describe the business. Enter a description and click the blue Add description link to add the description. You can add multiple descriptions in a variety of languages as required.

Categorizations can be used to describe the business according to which categories it falls into. This example uses a Used car dealership. As an example, view the NAICS taxonomy by clicking ’Show category tree’ and then expanding NAICS 2002 in the left hand panel. Expand the Retail Trade [44] entry by clicking the (+) plus sign next to it. You may need to drag the division between the left and right panes to be able to see all the category names. Similarly expand Motor Vehicle and Parts Dealers [441] then automobile Dealers [4411] and finally Used Car Dealers [441120]. Select ’Used Car Dealers [441120] and the ’Type’, ’Key Name’, ’Key Value’ fields under categorizations will be filled in with the relevant values. Click the blue ’Add categorization’ link to add the categorization details.

Once all the fields are filled in, click the Publish Business button at the bottom of the form or at the top. A page is displayed showing the business details and the business is published to the UDDI Registry.

2. **Add a Service**

   From the Publish tab, there is a **Show owned entities** link shows the businesses in the UDDI Registry owned by the current user. In our Modern Cars example, to add the description of a service provided by the business click the **Add service** link and a Publish Service form is shown. At the top of the form in the Service Name field you can add a name, then select it’s language and click the **Add name** link. You can also add a description (free text), one or more bindings (to add link points to the Service), and Categorizations (to add references to taxonomies to the service. After completion the required areas, clicking the ’Publish Service’ button will Publish the service to the UDDI Registry with the current form contents.

3. **Adding a new technical model**

   Clicking the **Add a technical model** link in the left frame opens up the Publish Technical Model form on the right. A tModel can only have one name so there is no blue Add link next to the Technical Model Name field. Beneath this are the descriptions (a free text area to describe the technical model), overview documents (which gives a URL pointing to an overview document) and Categorizations (taxonomies describing the technical model). For each of these fields there is a blue Add link which must be clicked to add the relevant data. At the bottom of the form is a **Publish Technical Model** link which creates the technical model in the UDDI Registry.

UDDI Registry Management Interfaces

This topic explains interfaces and tools you can use to programmatically manage UDDI nodes.

UDDI Registry Administrative (JMX) Interface

UDDI Registry Administrative (JMX) Interface provides a Java API that allows you to manage runtime configuration settings to control UDDI Registry runtime behavior, such as setting the maximum number of results that UDDI users can receive for inquiry requests, or creating publish limits for UDDI publishers. Sample client code is provided for you to build on.

User Defined Value Set Support in the UDDI Registry

User Defined Value Set Support in the UDDI Registry explains the tooling provided to manage your own categorization value sets, including loading value set data into a UDDI Registry node.

UDDI Utility Tools

UDDI Utility Tools explains the tooling and Java API for promoting version 2 entities from one UDDI registry to another while retaining entity keys. This is particularly useful for publishing canonical tModels with a predefined key.

UDDI Registry Administrative (JMX) Interface:
Each WebSphere UDDI Registry application registers an MBean with an MBean identifier of 'UddiNode'.

This MBean may be used by client applications to inspect and manage the runtime configuration of a UDDI application. This includes managing the activation state of and information about a UDDI node, updating properties and policies, setting publish tier limits, registration of UDDI publishers, and controlling value set support.

You can read and invoke the UddiNode attributes and operations using standard JMX interfaces. A client utility class UddiNodeProxy.java provides a ready-made application to connect to a UddiNode MBean and perform all the available operations. Example classes are also provided to drive UddiNodeProxy and demonstrate how to use the various UDDI management data types.

UddiNodeProxy Usage

The following jars required for compilation can be found in WAS_HOME/lib/:

- admin.jar
- management.jar
- uddiadmin.jar
- wsexception.jar

The UddiNodeProxy class provides a utility method to programmatically interrogate the UddiNode MBean and output all the available attributes, operations and notifications to System.out. For each operation, the return type, operation name and parameter types are output as well as the impact property which indicates how the operation changes the state of the UddiNode MBean (and the UDDI node). As for all MBeans, the value for the impact property can be one of:

ACTION:
state of MBean will be changed

INFO: of the MBean remains unchanged and will return information

ACTION_INFO:
state of the MBean will change and return some information

UNKNOWN:
the impact of invoking the operation is not known

1. Invoke outputMBeanInterface:`uddiNode.outputMBeanInterface();`

   Expected output:

   ```
   java.lang.String getNodeID() [INFO]

    name=jmx.attribute.changed
```

See ManageNodeInfoSample class for sample code that demonstrates the attributes and operations described in this section.

Managing UDDI Node States and Attributes

UDDI nodes can be in one of several states, depending on the way the UDDI application was installed (as a default configuration or one where the administrator controls when initialization occurs). The UddiNode MBean provides four read only attributes: nodeID, nodeState, nodeDescription and nodeApplicationName. In addition the following MBean operations change UDDI node state: activateNode, deactivateNode and initNode.

nodeID

The node ID is the unique identifier for a UDDI node. If the UDDI application is installed as a default configuration the node ID is automatically generated. If the UDDI application is set up manually, the node ID is set by the administrator. It must be a valid UDDI key.

```
String nodeID = uddiNode.getNode();

System.out.println("node ID: " + nodeId);
```

nodeState

The nodeState attribute can have one of the following values:

nodeState value	English text associated with state
node.state.uninitialized	Not initialized
node.state.initialized	Initialized
node.state.initPending	Initialization pending
node.state.initInProgress	Initialization in progress
node.state.activated	Activated
node.state.deactivated	Deactivated
node.state.unknown	Unknown

After installing a UDDI application using the default configuration, the UDDI node will be in activated state, that is, ready to receive and process UDDI API requests. The node ID and root key generator and some other properties are generated and cannot be changed. For a manually installed UDDI application where you want to specify the UDDI node ID and root key generator values, starting the UDDI application will put the UDDI node into initPending state. In this state, you can update all writable values up until the point you invoke the initNode operation. The initNode operation loads bas e tModels and value set data and writes all the configuration data to the UDDI node's database. During initialization the state is initInProgress. When initialization completes, the state changes momentarily to initialized and settles at activated. At this point the state can only be switched between activated and deactivated using deactivateNode and activateNode MBean operations.

Each node state value is in fact a message key which can be looked up in the messages.properties resource bundle. The attribute value can be retrieved using the getNodeState method of UddiNodeProxy:

1. Invoke getNodeState:
```
     String nodeStateKey = uddiNode.getNodeState();
```
2. Look up translated text from ResourceBundle and output:
```
     String messages = "com.ibm.uddi.v3.management.messages";

   ResourceBundle bundle = ResourceBundle.getBundle(messages,
                                                    Locale.ENGLISH);

   String nodeStateText =  bundle.getString(nodeStateKey);

   System.out.println("node state: " + nodeStateText);
```

nodeDescription

You can get the administrator assigned description for the UDDI node using the getNodeDescription method of UddiNodeProxy:

1. Invoke getNodeDescription and output:
```
     String nodeDescription = uddiNode.getNodeDescription();
   System.out.println("node description: " + nodeDescription);
```

nodeApplicationName

The nodeApplicationName attribute is useful for discovering where the UDDI application that corresponds to the UDDI node is installed. The value will be a concatenation of the cell, node and server names, separated by colons. Retrieve the application location using the getApplicationId method of UddiNodeProxy:

1. Invoke getApplicationId and output:
```
     String nodeApplicationId = uddiNode.getApplicationId();

     System.out.println("node application location: " +
                                        nodeApplicationId);
```

activateNode

Changes the state of the UDDI node to activated, if the UDDI node was previously deactivated.

1. . Invoke activateNode:
```
     uddiNode.activateNode();
```

deactivateNode

Changes the state of the UDDI node to deactivated, if the UDDI node was previously activated.

1. Invoke deactivateNode:
```
     uddiNode.deactivateNode();
```

initNode

Causes UDDI node initialization, and when this completes the state of the UDDI node is 'activated'.

1. Invoke initNode:

   ```
   uddiNode.initNode();
   ```

Managing Configuration Properties

UDDI node runtime behavior is affected by the setting of several configuration properties. The UddiNode MBean provides operations to inspect and update their values, as follows: getProperties, getProperty, updateProperty and updateProperties.

See ManagePropertiesSample class for sample code that demonstrates the operations described in this section.

get Properties

Returns collection of all configuration properties as ConfigurationProperty objects.

1. Invoke getProperties:

   ```
   List properties = uddiNode.getProperties();
   ```

2. Cast each collection member to ConfigurationProperty:

   ```
    if (properties != null) {
      for (Iterator iter = properties.iterator(); iter.hasNext();) {
           ConfigurationProperty property =
                            (ConfigurationProperty) iter.next();
           System.out.println(property);
      }
   }
   ```

Once you have the ConfigurationProperty objects you can inspect attributes like the ID, value, type, whether the property is read only, required for initialization, and get name and description message keys. For example, invoking the toString method returns results similar to:

```
ConfigurationProperty
id: operatorNodeIDValue
nameKey: property.name.operatorNodeIDValue
descriptionKey: property.desc.operatorNodeIDValue
type: java.lang.String
value: uddi:capnscarlet:capnscarlet:server1:default
unitsKey:
readOnly: true
required: true
usingMessageKeys: false
validValues: none
```

The nameKey and descriptionKey values can be used to look up the translated name and description for a given locale, using the messages.properties resource in uddiadmin.jar.

getProperty

Returns ConfigurationProperty object with the specified ID. Available property IDs are specified in PropertyConstants together with descriptions of the purpose of the corresponding properties.

1. Invoke getProperty:

   ```
     ConfigurationProperty property =
   uddiNode.getProperty(PropertyConstants.DATABASE_MAX_RESULT_COUNT);
   ```

2. To retrieve the value of the property you could use the getValue method which returns an Object, but in this case, the property is of type integer, so it‘s easier to retrieve the value using the convenience method getIntegerValue:

   ```
   int maxResults = property.getIntegerValue();
   ```

updateProperty

Updates the value of the ConfigurationProperty object with the specified ID. Available property IDs are specified in PropertyConstants together with descriptions of the purpose of the corresponding properties. Although you can invoke the setter methods in a ConfigurationProperty object, the only value that is updated in the UDDI node is the value. So to update a property, the steps are typically:

1. Create a ConfigurationProperty object and set its ID:
```
    ConfigurationProperty defaultLanguage = new ConfigurationProperty();
defaultLanguage.setId(PropertyConstants.DEFAULT_LANGUAGE);
```
2. Set the value:
```
defaultLanguage.setStringValue("ja");
```
3. Invoke updateProperty:
```
uddiNode.updateProperty(defaultLanguage);
```

updateProperties

Updates several ConfigurationProperty objects in a single request. Set up the ConfigurationProperty objects as for the updateProperty operation.

1. Add updated properties to a List:
```
List updatedProperties = new ArrayList();

updatedProperties.add(updatedProperty1);
updatedProperties.add(updatedProperty2);
```
2. Invoke updateProperties:
```
uddiNode.updateProperties(updatedProperties);
```

Managing Policies

Policies affecting behavior of the UDDI API are managed using the following UddiNode operations: getPolicyGroups, getPolicyGroup, getPolicy, updatePolicy and updatePolicies.

See ManagePoliciesSample class for sample code that demonstrates the attributes and operations described in this section.

getPolicyGroups

Returns collection of all policy groups as PolicyGroup objects.

1. Invoke getPolicyGroups:
```
List policyGroups = uddiNode.getPolicyGroups();
```
2. Cast each collection member to PolicyGroup:
```
  if (policyGroups != null) {
  for (Iterator iter = policyGroups.iterator(); iter.hasNext();) {
    PolicyGroup policyGroup = (PolicyGroup) iter.next();
    System.out.println(policyGroup);
  }
}
```

Each policy group has an ID, name and description key (which can be looked up in the messages.properties resource in uddiadmin.jar). While the PolicyGroup class does have a getPolicies method it is important to note that PolicyGroup objects returned by the getPolicyGroups operation do not contain any Policy objects. This is so clients can determine the known policy groups (and their IDs) without retrieving the entire set of policies in one request. To retrieve the policies within a policy group, you would use the getPolicyGroup operation.

getPolicyGroup

Returns the PolicyGroup object with the supplied ID.

1. Convert policy group ID to a String:

   ```
   String groupId = Integer.toString(PolicyConstants.REG_APIS_GROUP);
   ```

2. Invoke getPolicyGroup:

   ```
   PolicyGroup policyGroup = uddiNode.getPolicyGroup(groupId);
   ```

getPolicy

Returns the Policy object for the specified ID. Like a ConfigurationProperty, a Policy object has an ID, name and description keys, type, value and indicators specifying if the policy is read only or required for node initialization.

1. Convert policy ID to a String:

   ```
   String policyId = Integer.toString(
               PolicyConstants.REG_AUTHORIZATION_FOR_INQUIRY_API);
   ```

2. Invoke getPolicy:

   ```
   Policy policy = uddiNode.getPolicy(policyId);
   ```

updatePolicy

Updates the value of the Policy object with the specified ID. Available policy IDs are specified in PolicyConstants together with descriptions of the purpose of the corresponding policies. Although you can invoke the setter methods in a Policy object, the only value that is updated in the UDDI node is the value. So to update a policy, the steps are typically:

1. Create a Policy object and set its ID:

   ```
   Policy updatedPolicy = new Policy();
   String policyId =
         Integer.toString(PolicyConstants.REG_SUPPORTS_UUID_KEYS);
   updatedPolicy.setId(policyId);
   ```

2. Set the value:

   ```
   updatedPolicy.setBooleanValue(true);
   ```

3. Invoke updatePolicy:

   ```
   uddiNode.updatePolicy(updatedPolicy);
   ```

updatePolicies

Updates several Policy objects in a single request. Set up the Policy objects as for the updatePolicy operation.

1. Add updated policies to a List:

   ```
   List updatedPolicies = new ArrayList();

   updatedPolicies.add(updatedPolicy1);
   updatedPolicies.add(updatedPolicy2);
   ```

2. Invoke updatePolicies:

   ```
   uddiNode.updatePolicies(updatedPolicies);
   ```

Managing Tiers

Tiers control how many of each type of UDDI entities a publisher can save in the UDDI registry. A tier has an ID, an administrator defined name and description, and a set of limits, one for each type of entity. Tiers are managed using the following UddiNode operations: createTier, getTierDetail, getTierInfos, getLimitInfos, setDefaultTier, updateTier, deleteTier and getUserCount.

See ManageTiersSample class for sample code that demonstrates the attributes and operations described in this section.

createTier

Creates a new tier, with specified publish limits for each UDDI entity.

1. Set tier name and description in a TierInfo object.

   ```
   String tierName = "Tier 100";
   String tierDescription = "A tier with all limits set to 100.";

   TierInfo tierInfo = new TierInfo(null, tierName, tierDescription);
   ```

2. Define Limit objects for each UDDI entity:

   ```
    List limits = new ArrayList();

   Limit businessLimit = new Limit();
   businessLimit.setIntegerValue(100);

   businessLimit.setId(LimitConstants.BUSINESS_LIMIT);

   Limit serviceLimit = new Limit();
   serviceLimit.setIntegerValue(100);
   serviceLimit.setId(LimitConstants.SERVICE_LIMIT);

   Limit bindingLimit = new Limit();
   bindingLimit.setIntegerValue(100);
   bindingLimit.setId(LimitConstants.BINDING_LIMIT);

   Limit tModelLimit = new Limit();
   tModelLimit.setIntegerValue(100);
   tModelLimit.setId(LimitConstants.TMODEL_LIMIT);

   Limit assertionLimit = new Limit();
   assertionLimit.setIntegerValue(100);

   assertionLimit.setId(LimitConstants.ASSERTION_LIMIT);
   limits.add(businessLimit);
   limits.add(serviceLimit);
   limits.add(bindingLimit);
   limits.add(tModelLimit);
   limits.add(assertionLimit);
   ```

3. Create Tier object:

   ```
     Tier tier = new Tier(tierInfo, limits);
   ```

4. Invoke create Tier and retrieve created tier:

   ```
   Tier createdTier = uddiNode.createTier(tier);
   ```

5. Inspect generated tier ID of created tier:

   ```
   tierId = createdTier.getId();
   System.out.println("created tier has ID: " + tierId);
   ```

getTierDetail

Returns the Tier object for the given tier ID. The Tier class has getter methods for the tier ID, tier name and description (as set by the administrator), and the collection of Limit objects which specify how many of each UDDI entity type may be published by UDDI publishers allocated to the tier. The isDefault method indicates whether the tier is the default tier, that is, the tier that is allocated to UDDI publishers when auto registration is enabled.

1. Invoke getTierDetail:

   ```
    Tier tier = uddiNode.getTierDetail("2");
   ```

updateTier

Updates tier contents with the supplied Tier object.

1. Update an existing Tier object (which may have been newly instantiated, or returned by the getTierDetail or createTier operations). This example retains the tier name and description, and all the limit values except the limit being updated:

   ```
   modifiedTier.setName(tier.getName());
   modifiedTier.setDescription(tier.getDescription());

   Limit tModelLimit = new Limit();
   tModelLimit.setId(LimitConstants.TMODEL_LIMIT);
   tModelLimit.setIntegerValue(50);

   List updatedLimits = new ArrayList();
   updatedLimits.add(tModelLimit);

   modifiedTier.setLimits(updatedLimits);
   ```
2. Invoke updateTier:

   ```
   uddiNode.updateTier(modifiedTier);
   ```

getTierInfos

Returns collection of lightweight tier descriptor objects (TierInfo) which contain the tier ID, and tier name and description values, and whether the tier is the default tier.

1. Invoke getTierInfos:

   ```
   List tierInfos = uddiNode.getTierInfos();
   ```
2. Output content of each TierInfo:

   ```
   if (tierInfos != null) {

     for (Iterator iter = tierInfos.iterator(); iter.hasNext();) {
        TierInfo tierInfo = (TierInfo) iter.next();
        System.out.println(tierInfo);
     }
   }
   ```

setDefaultTier

Specifies the tier with the given tier ID is the default tier. The default tier is the tier that is allocated to UDDI publishers when auto registration is enabled. Typically this would be set to a tier with low publish limits to prevent casual users publishing too many entities.

1. Invoke setDefaultTier:

   ```
   uddiNode.setDefaultTier("4");
   ```

deleteTier

Removes the tier with the given tier ID. Tiers can only be removed if they have no UDDI publishers assigned to them, and the tier is not the default tier.

1. Invoke deleteTier:

   ```
   uddiNode.deleteTier("4");
   ```

getUserCount

Returns the number of UDDI publishers assigned to tier specified by the tier ID.

1. Invoke getUserCount:

   ```
   Integer userCount = uddiNode.getUserCount("4");
   System.out.println("users in tier 4: " + userCount.intValue());
   ```

getLimitInfos

Returns collection of Limit objects representing the limit values for each type of UDDI entity. Limits are used in Tier objects.

1. Invoke getLimitInfos:
   ```
   List limits = uddiNode.getLimitInfos();
   ```
2. Output the ID and limit value for each Limit object:
   ```
   for (Iterator iter = limits.iterator(); iter.hasNext();) {
     Limit limit = (Limit) iter.next();

     System.out.println("limit ID: "
                        + limit.getId()
                        + ", limit value: "
                        + limit.getIntegerValue());
   }
   ```

Managing UDDI Publishers

UDDI publishers are managed using the UddiNode MBean operations createUddiUser, createUddiUsers, updateUddiUser, deleteUddiUser, getUddiUser, getUserInfos, getEntitlementInfos, assignTier, getUserTier. An example is provided for each, making use of the UddiNodeProxy client class.

See ManagePublishersSample class for sample code that demonstrates the attributes and operations described in this section.

createUddiUser

Registers a single UDDI publisher, in a specified tier, with specified entitlements. The UddiUser class represents the UDDI publisher, and this is constructed using a user name (ID), a TierInfo object which specifies the tier ID to allocate the UDDI publisher to, and a collection of Entitlement objects which specify what the UDDI publisher is permitted to do.

Tip: to allocate the UDDI publisher default entitlements, set the entitlements parameter to null.

1. Create the UddiUser object:
   ```
   UddiUser user = new UddiUser("user1", new TierInfo("3"), null);
   ```
2. Invoke createUddiUser:
   ```
   uddiNode.createUddiUser(user);
   ```

createUddiUsers

Registers multiple UDDI publishers. This example shows how to register 7 UDDI publishers in one call, with default entitlements.

1. Create TierInfo objects for tiers that publishers will be allocated to:
   ```
   TierInfo tier1 = new TierInfo("1");
   TierInfo tier4 = new TierInfo("4");
   ```
2. Create UddiUser objects for each UDDI publisher, specifying tier to allocate to:
   ```
   UddiUser publisher1 = new UddiUser("Publisher1", tier4, null);
   UddiUser publisher2 = new UddiUser("Publisher2", tier4, null);
   UddiUser publisher3 = new UddiUser("Publisher3", tier4, null);
   UddiUser publisher4 = new UddiUser("Publisher4", tier1, null);
   UddiUser publisher5 = new UddiUser("Publisher5", tier1, null);
   UddiUser cts1 = new UddiUser("cts1", tier4, null);
   UddiUser cts2 = new UddiUser("cts2", tier4, null);
   ```
3. Add the UddiUser objects to a List:
   ```
   List uddiUsers = new ArrayList();

   uddiUsers.add(publisher1);
   uddiUsers.add(publisher2);
   ```

```
uddiUsers.add(publisher3);
uddiUsers.add(publisher4);
uddiUsers.add(publisher5);
uddiUsers.add(cts1);
uddiUsers.add(cts2);
```

4. Invoke createUddiUsers:

```
uddiNode.createUddiUsers(uddiUsers);
```

updateUddiUser

Updates a UDDI publisher with the details in the supplied UddiUser object. This is typically used to change the tier of one UDDI publisher or update their entitlements. Tip: only supply the entitlements you want to update – the remainder of available entitlements will retain their existing value.

1. Create Entitlement objects with appropriate permission. (the entitlement IDs are found in EntitlementConstants:

```
Entitlement publishUuiDKeyGenerator =
    new Entitlement(PUBLISH_UUID_KEY_GENERATOR, true);
Entitlement publishWithUuidKey =
    new Entitlement(PUBLISH_WITH_UUID_KEY, true);
```

2. Add Entitlement objects to a List:

```
List entitlements = new ArrayList();
entitlements.add(publishUuiDKeyGenerator);
entitlements.add(publishWithUuidKey);
```

3. Update a UddiUser object with the updated entitlements:

```
user.setEntitlements(entitlements);
```

4. Invoke updateUddiUser:

```
uddiNode.updateUddiUser(user);
```

getUddiUser

Retrieves details about a UDDI publisher in the form of a UddiUser object. This specifies the UDDI publisher ID, information about the tier they are assigned to and the entitlements they possess.

1. Invoke getUddiUser:

```
UddiUser user1 = uddiNode.getUddiUser("user1");
```

2. Output the contents of UddiUser:

```
System.out.println("retrieved user: " + user1);
```

getUserInfos

Returns a collection of UserInfo objects. Each UserInfo represents a UDDI publisher known to the UDDI node, and the name of the tier they are allocated to. To get details about a specific UDDI publisher, including the tier ID, and entitlements, use the getUddiUser operation.

1. Invoke getUserInfos:

```
List registeredUsers = uddiNode.getUserInfos();
```

2. Output the UserInfo objects:

```
System.out.println("retrieved registered users: ");
System.out.println(registeredUsers);
```

getEntitlementInfos

Returns a collection of Entitlement objects. Each entitlement is a property that controls whether permission is granted to a UDDI publisher to perform a specified action.

1. Invoke getEntitlementInfos:

```
List entitlementInfos = uddiNode.getEntitlementInfos();
```

2. Specify where to find message resources:

```
String messages = "com.ibm.uddi.v3.management.messages";
ResourceBundle bundle = ResourceBundle.getBundle(
                                     messages, Locale.ENGLISH);
```

3. Iterate through the Entitlement objects, displaying the ID, name and description:

```
for (Iterator iter = entitlementInfos.iterator(); iter.hasNext();) {
  Entitlement entitlement = (Entitlement) iter.next();

  StringBuffer entitlementOutput = new StringBuffer();

  String entitlementId = entitlement.getId();
  String entitlementName =
              bundle.getString(entitlement.getNameKey());
String entitlementDescription =
              bundle.getString(entitlement.getDescriptionKey());

  entitlementOutput.append("Entitlement id: ");
  entitlementOutput.append(entitlementId);
  entitlementOutput.append("\n  name: ");
  entitlementOutput.append(entitlementName);
  entitlementOutput.append("\n  description: ");
  entitlementOutput.append(entitlementDescription);

  System.out.println(entitlementOutput.toString());
}
```

deleteUddiUser

Removes the UDDI publisher with the specified user name (ID) from the UDDI registry.

1. Invoke deleteUddiUser:

```
uddiNode.deleteUddiUser("user1");
```

assignTier

Assigns UDDI publishers with supplied IDs to the specified tier. This is useful when you want to restrict several UDDI publishers, perhaps by assigning them all to a tier that doesn‘t allow publishing of any entities.

1. Create list of publisher IDs:

```
List uddiUserIds = new ArrayList();

uddiUserIds.add("Publisher1");
uddiUserIds.add("Publisher2");
uddiUserIds.add("Publisher3");
uddiUserIds.add("Publisher4");
uddiUserIds.add("Publisher5");
uddiUserIds.add("cts1");
uddiUserIds.add("cts2");
```

2. Invoke assignTier:

```
uddiNode.assignTier(uddiUserIds, "0");
```

getUserTier

Returns information about the tier a UDDI publisher is assigned to. The returned TierInfo has getters methods for retrieving the tier ID, tier name, tier description, and whether the tier is the default tier.

1. Invoke getUserTier:

```
TierInfo tierInfo = getUserTier("Publisher3");
```

2. Output the contents of the TierInfo object:

```
System.out.println(tierInfo);
```

Managing Value Sets

Value sets are represented in a UDDI registry as value set tModels, with a UDDI types keyedReference with value ’categorization‘. Such value sets are backed with a set of valid values and for user defined value sets, this data is loaded into the UDDI registry using UddiNode MBean operations (although it is more convenient to use the User defined value set tool for this purpose). Each value set can be controlled by policy as being supported or not supported. When a value set is supported by policy, it can be referenced within UDDI publish requests. The UddiNode operations available to manage value sets and their data are: getValueSets, getValueSetDetail, getValueSetProperty, updateValueSet, updateValueSets, loadValueSet, changeValueSetTModelKey, unloadValueSet and isExistingValueSet.

See ManageValueSetsSample class for sample code that demonstrates the attributes and operations described in this section.

getValueSets

Returns collection of ValueSetStatus objects.

1. Invoke getValueSets:

```
List valueSets = uddiNode.getValueSets();
```

2. Cast each element to ValueSetStatus and output contents:

```
for (Iterator iter = valueSets.iterator(); iter.hasNext();) {

  ValueSetStatus valueSetStatus = (ValueSetStatus) iter.next();
  System.out.println(valueSetStatus);
}
```

getValueSetDetail

Returns ValueSetStatus object for the given value set tModel key.

1. Invoke getValueSetDetail:

```
uddiNode.getValueSetDetail(
               "uddi:uddi.org:ubr:categorization:naics:2002");
```

2. Retrieve and display details:

```
String name = valueSetStatus.getName();
String displayName = valueSetStatus.getDisplayName();
boolean supported = valueSetStatus.isSupported();

System.out.println("name: " + name);
System.out.println("display name: " + displayName);
System.out.println("supported: " + supported);
```

3. Display value set properties:

```
List properties = valueSetStatus.getProperties();

for (Iterator iter = properties.iterator(); iter.hasNext();) {

  ValueSetProperty property = (ValueSetProperty) iter.next();
  System.out.println(property);
}
```

getValueSetProperty

Returns a property of a value set as a ValueSetProperty object. This is mainly for use by the WebSphere administrative console to render properties of a value set as a row in a table. For example, one such property is the keyedReference which indicates whether the value set is checked.

1. Invoke getValueSetProperty:

```
uddiNode.getValueSetProperty(
              "uddi:uddi.org:ubr:categorization:naics:2002",
              ValueSetPropertyConstants.VS_CHECKED);
```

2. Read and display boolean value of the property:

   ```
   boolean checked = valueSetProperty.getBooleanValue();

   System.out.println("checked: " + checked);
   ```

updateValueSet

Updates value set status. Only the supported attribute can be updated (all other setter methods are used by the UDDI application).

1. Create a ValueSetStatus object specifying the tModel key and the updated supported value:

   ```
   ValueSetStatus updatedStatus = new ValueSetStatus();
   updatedStatus.setTModelKey(
                 "uddi:uddi.org:ubr:categorization:naics:2002");
   updatedStatus.setSupported(true);
   ```

2. Invoke updateValueSet:

   ```
   uddiNode.updateValueSet(updatedStatus);
   ```

updateValueSets

Updates value set status for multiple value sets. As for the updateValueSet operation, only the supported attribute is updated.

1. Populate List with updated ValueSetStatus objects:

   ```
   List valueSets = new ArrayList();

   ValueSetStatus valueSetStatus = new ValueSetStatus();
   valueSetStatus.setTModelKey(
                 "uddi:uddi.org:ubr:categorization:naics:2002");
   valueSetStatus.setSupported(false);
   valueSets.add(valueSetStatus);

   valueSetStatus = new ValueSetStatus();
    valueSetStatus.setTModelKey(
                 "uddi:uddi.org:ubr:categorizationgroup:wgs84");
   valueSetStatus.setSupported(false);
   valueSets.add(valueSetStatus);

   valueSetStatus = new ValueSetStatus();
   valueSetStatus.setTModelKey(
                 "uddi:uddi.org:ubr:identifier:iso6523:icd");
   valueSetStatus.setSupported(false);
   valueSets.add(valueSetStatus);
   ```

2. Invoke updateValueSets:

   ```
   uddiNode.updateValueSets(valueSets);
   ```

loadValueSet

Loads values for a value set from a UDDI Registry V3/V2 taxonomy data file on the local file system. Note: there is also a loadValueSet operation that takes a ValueSetData object but this is only for use by the user defined value set tool.

1. Invoke loadValueSet:

   ```
   uddiNode.loadValueSet(
                       "C:/valuesets/myvalueset.txt",
                       "uddi:cell:node:server:myValueSet");
   ```

changeValueSetTModelKey

Any value set values that were allocated to one value set tModel are allocated to the new value set tModel.

1. Invoke changeValueSetTModelKey with old and new tModel keys:

```
uddiNode.changeValueSetTModelKey(
            "uddi:cell:node:server:myValueSet",
            "uddi:cell:node:server:myNewValueSet");
```

unloadValueSet

Unloads values for a value set with the given tModel key.

1. Invoke unloadValueSet:

```
uddiNode.unloadValueSet("uddi:myValueSet");
```

isExistingValueSet

Determines if value set data exists for the given tModel key.

1. Invoke isExistingValueSet and display result:

```
boolean exists = uddiNode.isExistingValueSet(
                "uddi:uddi.org:ubr:categorization:naics:2002");
System.out.println("NAICS 2002 is a value set: " + exists);
```

User-defined value set support in the UDDI registry:

In UDDI Version 2 this was called 'Custom Taxonomy Support'.

Data is worthless if it is lost within a mass of other data and cannot be distinguished or discovered. If a client of UDDI cannot effectively find information within a registry, the purpose of UDDI is considerably compromised. Providing the structure and modeling tools to address this problem is at the heart of UDDI's design. The verification of data within UDDI is core to its mission of description, discovery and integration. It achieves this by several means.

It allows users to define multiple value sets that can be used in UDDI. In such a way, multiple classification schemes can be overlaid on a single UDDI entity. This capability allows organizations to extend the set of such systems UDDI registries support. One is not tied to a single system, but can rather employ several different classification systems simultaneously.

While default value sets are shipped with the product, the UDDI Version 3 Private Registry provides tools enabling 'custom' value sets to be added, potentially enabling UDDI entities to be more specifically categorized when published and further enhancing the capability of client to find specific data.

These value sets can be either checked or unchecked, and this is indicated via a keyedReference in the categoryBag of the tModel that represents a value set (a ″categorization tModel″). These keyedReferences have the tModel key for uddi-org:types and are added to the categoryBag to further describe the behavior of the categorization tModel, as follows:

checked
: Marking a tModel with this classification asserts that it represents a categorization, identifier, or namespace tModel that has a validation service to check that category values are present in a specified value set.

unchecked
: Marking a tModel with this classification asserts that it represents a categorization, identifier, or namespace tModel that does not have a validation service.

The procedure defined below describes how to add additional user-defined value sets, and display their allowed values in the UDDI user console value set tree display. Rational Application Developer has a Web

Services Explorer user interface that also allows addition and display of custom checked value sets. The publisher of a value set categorization tModel may specify a 'display name' for use in UDDI user console implementations.

Procedure for adding a user defined value set

To add a user defined value set to the IBM WebSphere UDDI Registry requires you to perform three tasks:

- publish a categorization tModel
- load the user defined value set data
- set the value set to **supported** status using the Administration console.

Only when all are complete will the checked value set be referenced. Value set data must be provided for validating checked value sets.

Value set data may also be used by user consoles for unchecked value sets, but it is not a requirement and is usually only used for presentation of deprecated value sets, such as unspc-org:unspc and back-level compatibility.

If the value set is checked, any publish requests that have a categoryBag containing keyedReferences with the new categorization tModel will be validated. If there is value set data corresponding to the categorization tModel in the registry database, only valid values will be accepted. If there is no value set data in the database **all** values will be rejected, and the publish request will fail. If the categorization tModel is unchecked, all values will be allowed, regardless of whether there is a corresponding value set present in the UDDI Registry database. The value set tModel is not available for use until the administrator enables support for it using the Administration console, or the JMX interface.

Suggested approach

To introduce a new value set:

1. Publish the categorization tModel with a keyedReference of type 'uddi-org:categorization:types' with a key value of **categorization**, a keyedReference of type 'uddi-org:categorization:types' with a Key Name of **'Checked value set'** and a Key Value of **'checked'**, or a Key Name of **'Unchecked value set'** and a Key Value of **'unchecked'** and a keyedReference of type 'uddi-org:categorization:general_keywords' supplying the value set display name (as described below).
2. Load user defined value set data into the UDDI Registry database using the UDDIUserDefinedValueSet utility (described below).
3. Use the Administration Console to set the status of the value set to supported (as described in Value set settings). This can also be achieved directly using the JMX interface.

Note: The SOAP and EJB interfaces will be able to make use of categorization tModels as soon as they are published. However, the UDDI Registry user console will require a restart of the UDDI application because it currently gathers its list of categorizations for use in the value set tree display when the application starts.

Publishing a Checked Categorization tModel

This section describes how to publish a checked categorization tModel with the **'Checked value set'** Key Name for use by a user defined value set.

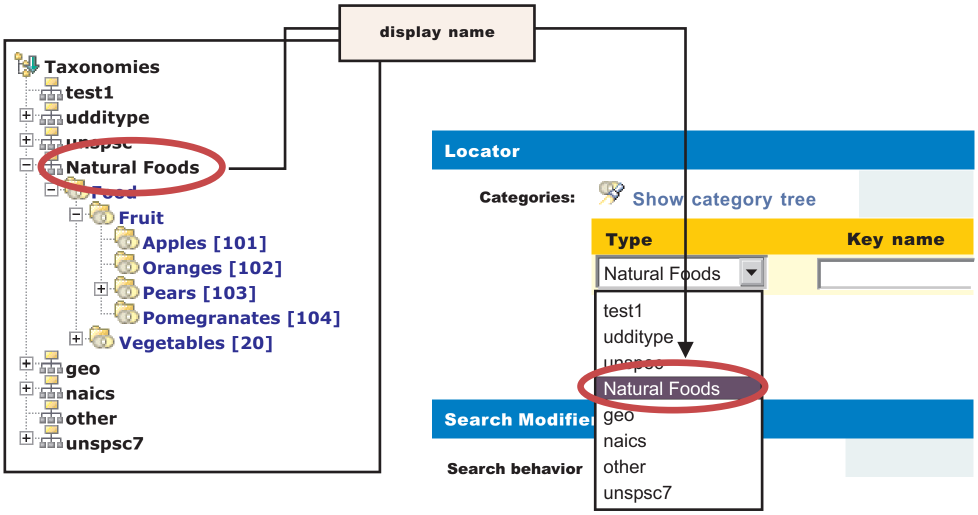
Publish a tModel to the IBM WebSphere UDDI Registry with a categoryBag containing keyedReferences as follows:

Note	tModelKey	KeyName	KeyValue

1	uddi:uddi-org:categorization:types In the UDDI Registry user interface this tModelKey can be chosen by selecting the category type of **UDDI Types**	**categorization**	**categorization**
2	uddi:uddi-org:categorization:types In the UDDI Registry user interface this tModelKey can be chosen by selecting the category type of **UDDI Types**	**Checked value set**	**checked**
3	uddi:uddi-org:categorization:general_keywords In the UDDI Registry user interface this tModelKey can be chosen by selecting the category type of **categorization:general_keywords**	**urn:x-ibm:uddi:customTaxonomy: displayName**	*<User Defined Value Set displayName>*

1. Indicates this tModel is a categorization tModel (required).
2. Indicates use of the tModel will be checked against a list of valid data (required). (Omitting this keyedReference, or explicitly specifying a value of 'unchecked' will indicate this categorization is unchecked).
3. Indicates special use of the general keywords value set, with a proprietary urn as the keyName value, defines a name for the user defined value set that is intended for use in user console implementations where the full tModel name might be too long. The value can be 1-255 characters (inclusive) long.

The displayName is intended to provide a way to label a value set such that, when the UDDI user console displays it in a value set tree or in a pull-down list of available value sets, the meaning is clear to the user without being restricted to 8 characters and without needing to be the same as the published tModelName, which could be as long as 255 characters. An example is shown below:



The urn:x-ibm:customTaxonomy:displayName should be unique if only to avoid confusion when displayed in user interfaces but this is not validated.

To publish a new categorization tModel using SOAP, the message would be:

```
<save_tModel generic="3.0" xmlns="urn:uddi-org:api_v3">
  <authInfo></authInfo>>
  <tModel tModelKey="">
    <name>Natural Foods tModel</name>
    <categoryBag>
      <keyedReference tModelKey="uddi:uddi.org:categorization:types" keyName=
           "categorization" keyValue="categorization"/>
      <keyedReference tModelKey="uddi:uddi.org:categorization:types" keyName=
           "Checked value set" keyValue="checked"/>
      <keyedReference tModelKey="uddi:uddi.org:categorization:general_keywords"
            keyName="urn:x-ibm:uddi:customTaxonomy:displayName"
            keyValue="Natural Foods"/>
    </categoryBag>
  </tModel>
</save_tModel>
```

Note: to specify an unchecked categorization substitute the key name **’Checked value set’** with **’Unchecked value set**’ and **’checked’** Key Value with **’unchecked’** or, more simply, omit the keyedReference completely.

Loading User Defined Value Set Data

User Defined Value Set Data File Format

Value set data is identified by a unique code value, an optional description and a parent code that specifies its relationship with other code values. Value set data must adhere to this format:

Column name	Maximum length	Description of use
Code	765	Unique value within the value set used for validation
description	765	Typically used by UDDI user consoles and optionally in the keyedReference as the keyName value
parentcode	765	Indicates which existing **code** is the logical parent of this one, and is used in tree displays

Typically columns are delimited in the value set data file by ’#’ characters as in this example:

```
00#Food#00
10#Fruit#00
101#Apples#10
102#Oranges#10
103#Pears#10
1031#Anjou#103
1032#Conference#103
1033#Bosc#103
104#Pomegranates#10
20#Vegetables#00
201#Carrots#20
202#Potatoes#20
203#Peas#20
204#Sprouts#20
```

In the example, ’Food’ is the description for the root node with child nodes of ’Fruit’ and ’Vegetables’ (both of these have parentcode values the same as the code value for ’Food’).

The value set data in the example file could then be rendered in a tree like this:

```
Food
  Fruit
    Apples
    Oranges
    Pears
      Anjou
      Conference
      Bosc
    Pomegranates
  Vegetables
    Carrots
    Potatoes
    Peas
    Sprouts
```

The file must be saved in UTF-8 format.

Custom Taxonomy files used in UDDI Version 2 are also supported by the utility.

UDDIUserDefinedValueSet

A utility is provided to load value set data into the IBM WebSphere UDDI Registry, assign existing value set data to another tModel and unload existing value set data. This utility uses the UDDI Registry's JMX interface and therefore requires a number of connection parameters.

```
Usage: UDDIUserDefinedValueSet[.sh|.bat] '{'function'}' [options]

function:
-load <path> <key>         Load value set data from specified file
-newKey <oldKey> <newKey>  Move value set to a new tModel
-unload <key>              Unload existing value set

options:
-properties <path>         Specify location of configuration file
-host <host name>          Application Server or Deployment Manager host
-port <port>               SOAP Lister port number
-node <node name>          Node running a UDDI server
-server <server name>      Server with UDDI deployed
-columnDelimiter <delim>   Character delimiter to denote field end
-stringDelimiter <delim>   Character delimiter to denote strings

Connector security parameters

-userName <name>
-password <password>
-trustStore <path>
-trustStorePassword <password>
-keyStore <name>
-keyStorePassword <password>
```

Note: Ensure that the command window from which the UDDIUserDefinedValueSet is run is using a suitable codepage and font for displaying the characters contained in the value set name. Use of an incorrect codepage/font may result in unclear messages on a successful load, and create difficulty using the -unload and -newKey options.

The UDDIUserDefinedValueSet .bat (for Windows) or UDDIUserDefinedValueSet.sh (for Unix platforms) is located in the WAS_HOME/bin directory.

If no connection parameters are supplied a connection is sought on the local host using firstly the Deployment Managers default SOAP port number, and, if there is no Deployment Manager running, the default Application Server SOAP port number.

Command arguments are case insensitive.

Usage examples

Load a value set data for a tModel on the local UDDI Registry using the '%' sign as a column marker in the valuesetdata.txt file:

```
UDDIUserDefinedValueSet.xxx -load valuesetdata.txt
    uddi:a708b8a7-35b5-451c-aafc-718ae071fcfe -columnDelimiter %
```

where .xxx is .bat for Windows or .sh for Unix platforms.

Move value set data from one checked tModel to another on a UDDI Registry in a Network Deployment:

```
UDDIUserDefinedValueSet.xxx –newKey uddi:a708b8a7-35b5-451c-aafc-718ae071fcfe
    uddi:b819c9b8-46c6-562d-bb0d-829bf1820d0f –host depmanagerhost.ibm.com –port
    8879 –node uddinode –server uddiserver -override
```

where .xxx is .bat for Windows or .sh for Unix platforms.

Unload a value set from a tModel from a server with security turned on supplying the connection and security parameters in myproperties.properties file, but supplying the server and password arguments on the command line (which augment or override those contained in the properties file):

```
UDDIUserDefinedValueSet.xxx –unload uddi:b819c9b8-46c6-562d-bb0d-829bf1820d0f
    –server uddiserver –properties myproperties.properties
    –password myrealpassword
```

where .xxx is .bat for Windows or .sh for Unix platforms.

The configuration file, if specified by the optional **-properties** parameter, determines a number of optional parameters. These parameters can be specified on the command line and, if so, override the values in the properties file. These parameters are largely JMX connection parameters and security parameters.

The string.delimiter is typically used where a description value contains the same character as the column delimiter character. For example, if the column.delimiter was set to ',' (a comma), and there was a value set description value of 'Fruits, citrus', you could include this in the value set data file by setting the string.delimiter to ″ (double quote) and enclosing the description in quotes: 'Fruits, citrus'. Note that the quote character is escaped with a backslash ('\') to indicate the literal character is to be used.

If an attempt is made to load a value set to a tModel that has existing value set data, a warning message is given. To override this error provide the **-override** argument. This argument is also required if moving value set data to a new tModel using **-newKey** where the tModel is **checked**, and also unloaded value set data for a **checked** tModel.

Command line arguments and example data	Property and example data	Comments
-columnDelimiter #	column.delimiter=#	Column delimiter used in value set data files
-stringDelimiter \″	string.delimiter=\″	Field delimiter (must be different to the column.delimiter value
-host ibm.com	host=ibm.com	Host name of the system running Deployment Manager or Application Server
-port 8880	port=8880	SOAP port number of Deployment Manager or Application Server
-node ibmNode	node=ibmNode	Name of the Node running the server with the UDDI Registry
-server server1	server=server1	Server running the UDDI Registry
-userName ibmuser	security.username=ibmuser	User name. Required if WebSphere security is turned on

-password mypassword	security.password=mypassword	Password
-trustStore /TrustStoreLocation	security.truststore=/TrustStoreLocation	Truststore file location
-keyStore ibmkeystore	security.keystore=ibmkeystore	Keystore name
-trustStorepassword trustpass	security.truststore.password=trustpass	Truststore password
-keyStorePassword keypass	security.keystore.password=keypass	Keystore password

Set the value set to supported

Use the Administration console to set the value set to **supported** by:

- Click *UDDI Nodes* > *<node>* and *Value Sets* (under Additional Properties on the right of the screen)
- Select the Value Set (by checking the box next to it)
- Click *Enable Support* above the list of Value Sets

Validation and Error Handling

The UDDI Registry user console performs validation while a save tModel request is being built, that is, before the publish occurs. For example, if the user tries to add two customTaxonomy:displayName keyedReferences the following message is displayed:

```
Advice: Only one 'urn:x-ibm:uddi:customTaxonomy:displayName' key name is allowed
for the 'Other' taxonomy.
```

If a keyedReference containing a keyName value that starts with 'urn:x-ibm:uddi:customTaxonomy:' is followed by anything other than 'displayName', the following message is displayed:

```
Advice: Only key name values of 'urn:x-ibm:uddi:customTaxonomy:displayName'
are supported.
```

For requests where the save_tModel message may have multiple tModels, if any one of the tModels is a categorization tModel and it fails validation, the request fails with a UDDIInvalidValueException (plus additional information explaining the likely cause), and none of the tModels is published. For example:

```
E_invalidValue (20200) A value that was passed in a keyValue attribute did not
pass validation.
This applies to checked categorizations, identifiers and other validated code lists.
The error text will clearly indicate the key and value combination that failed validation.
Invalid 'customTaxonomy:dbKey' keyValue [naics] in keyedReference.
KeyValue already in use by tModelKey[UUID:C0B9FE13-179F-413D-8A5B-5004DB8E5BB2]
```

UDDI Utility Tools:

The UDDI Utility Tools is a suite of functions that can be used to migrate/move/copy UDDI Version 2 entities, including child entities and their respective Version 2 entity keys, into a Version 3 UDDI Registry.

Note: The UDDI Version 3 publish API supports publisher assigned keys (the Version 2 API did not) and promotion of entities between Version 3 registries can be achieved using normal API functions. UDDI Utility Tools supplied in this release is functionally equivalent to the version supplied in WebSphere Application Server 5.1. However, it is important to know that all UDDI Utility Tools functions in this release are performed using the UDDI Version 2 API. You can export from Version 2 and 3 registries and import into the Version 3 registry, using Version 2 API types. Entities from a Version 3 registry are exported as Version 2 entities and, as such, elements such as digital signatures will not be present. See section Saving Version 3 entities with a supplied key for an example on how to use the Version 3 API to assign your own keys to Version 3 entities.

Other uses of the tool include:

- Search and select entities from a source UDDI Registry by specifying keys or search criteria

- Publishing canonical tModels in a UDDI Registry, including child entities
- Persist UDDI (Version 2) entities in an intermediate XML representation that can be used to customize and copy those entities to multiple target UDDI Registries
- Update existing entities in a target UDDI Registry, including child entities
- Delete selected entities from a target UDDI Registry

UDDI Utility Tools can be used by running the UDDIUtilityTools.jar file. This file is located in the WAS_HOME/UDDIReg/scripts directory. Alternatively, all of the functions of UDDI Utility Tools can be invoked through the supplied public Java API.

There are five main functions in UDDI Utility Tools:

Export

Given an entity type and key, or a list of entity types and keys, UDDI Utility Tools gets the UDDI entities from the specified registry and writes them to the UDDI Entity Definition File. The entity type for each key can be one of business, service, bindingTemplate or tModel. The Entity Definition File contains XML that exactly describes each of the specified entities, according to the UDDI Utility Tools schema (which includes the UDDI Version 2 schema). The UDDI Entity Definition File separates entities by type, and automatically detects and records tModels referenced by the specified entities. You can use the ’referenced tModels’ section of the file to ensure a target registry includes any referenced tModels before you try to import new entities to that registry.

Import

Given a list of UDDI entities (which can be supplied using the UDDI Entity Definition File generated by the export function, possibly with additional editing, or programmatically in a container object), the import function detects if the entities already exist in the target registry and, if they do not, creates a minimal entity (″stub″) with the specified key. The entities are then published updating the stubs with the supplied data and overwriting, or ignoring, existing entities as specified by the user. Note that the original key is maintained throughout.

Promote

Combines the export and import steps such that the specified entities are extracted (by key) from the source registry and then imported into the target registry in a single logical step. The generation of a UDDI Entity Definition File is optional for this function.

Delete

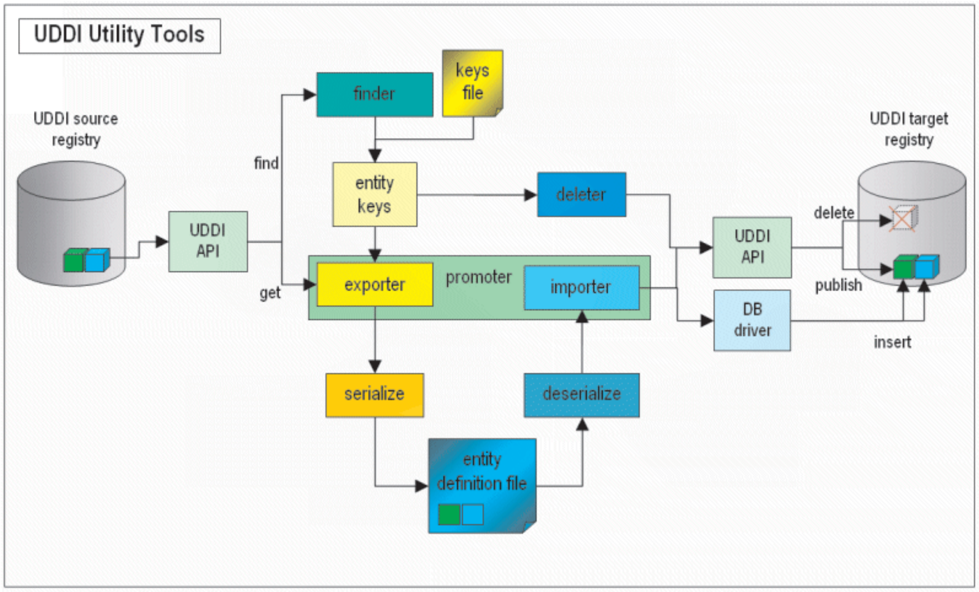
Deletes the specified entities from the target UDDI Registry. The entities to delete are specified as an entity type, or a list of entity types, and keys, in the same way as for the export function.

Find Matching Entities

Takes as input search criteria in the form of UDDI Inquiry API objects for each of the various entity types. The set of entities that match the search criteria are used to generate a list of entity keys, and this in turn can be used as input to the export, promote and delete functions.

Note: This function is available only through the programmatic API.

The relationship between the functions, their input and output, and the source and target UDDI Registries is shown in this conceptual overview diagram:



Setting up the configuration file

Configuration data for UDDI Utility Tools resides in a configuration properties file, which describes the runtime environment, UDDI and database locations and access information, logging information, security configuration, entity definition file location, and other flags to control whether referenced entities are to be imported and/or overwritten.

UDDI Utility Tools is distributed with a sample configuration properties file (UDDIUtilityTools.properties) and this is searched for by default in the current directory if no properties path is specified. By default, this file is located in the WAS_HOME/UDDIReg/scripts directory.

The most important property to set is the classpath, and this should include the current directory (.) and the UDDIUtilityTools.jar itself, plus all the dependent jars, most of which are located in the WebSphere AppServer lib directory. The classpath must include the database driver jar (for example db2java.zip). The other properties are well commented in the example properties file.

Below is an example properties file as distributed:

```
###############################################
# Runtime environment                         #
# (if invoking via java -jar...)              #
# "X Y" required around paths with spaces     #
###############################################
classpath=.;c:/Progra~1/WebSphere/utilitytools/UDDIUtilityTools.jar;
C:/WebSphere/AppServer/lib/soap.jar;C:/WebSphere/AppServer/java/jre/lib/ext/mail.jar;
C:/WebSphere/AppServer/java/jre/lib/ext/ibmjsse.jar;
C:/WebSphere/AppServer/java/jre/lib/ext/activation.jar;

```

Prerequisites

UDDI Utility Tools must have the following jar files available. Their locations should be specified in the classpath property in the UDDI Utility Tools properties file:

UDDIUtilityTools.jar
This is the tools jar itself. It MUST appear on the classpath.

uddi4jv2.jar
This is the UDDI4J classes and can be found in <WAS_HOME>/lib.

j2ee.jar
This contains some required J2EE classes.

soap.jar
This is the Apache SOAP implementation.

xerces.jar
This is the xerces XML parser.

DbDriver
This is the default driver needed to allow UUT to connect to your target database. For example, for DB2, it would be `$DB2_HOME/DB2java.zip`, for Oracle, it would be `$ORACLE_HOME/jdbc/lib/ojdbc14.jar` and for Cloudscape you need two jars. These are `WAS_HOME/cloudscape/lib/otherJars/db2jcc.jar` and `WAS_HOME/cloudscape/lib/db2jcc_license_c.jar`. The respective dbURL's and Drivers are: for DB2 jdbc:db2:*databasename* and COM.ibm.db2.jdbc.app.DB2Driver, for Oracle thin client jdbc:oracle:thin:@*host:*1521:*databasename* (the number specified is the default port number and this may change depending on your Oracle setup) and Oracle.jdbc.driver.OracleDriver, for Cloudscape jdbc:db2j:net://host:1527/*databasename* (databasename includes the path) and com.ibm.db2.jcc.DB2Driver. Note that if your destination database is Cloudscape you will need to make it network enabled so that it can handle multiple connections. See Configuring Cloudscape Version 5.1.38 for details on how to do this. For information on how to set up Cloudscape for multiple connections, see:

```
http://publib.boulder.ibm.com/infocenter/ws60help/index.jsp?topic=
   /com.ibm.websphere.base.doc/info/ae/ae/ tdat_cloudscape_setup.html
```

Apache SOAP, and therefore UDDI Utility Tools, has a requirement of having activation.jar and mail.jar java extensions available. These should NOT be placed on the classpath but rather the ext folder of the JRE that is used to run the tool. If SSL is needed then ibmjsse.jar must also be in the ext folder. If you are using the JRE as supplied with IBM WebSphere Application Server then these extensions will already be in place and no further action is necessary.

The Security provider configuration section in the above properties file shows the location of the default DummyClientTrustFile.jks file. If you are using your own truststore, ensure that the location is placed here.

The UDDI Entity Definition File

You generate this file by the export and promote functions, or you can choose to create it (either by hand, or by modifying a version of the file output by UDDI Utility Tools specifying the export function). It is the input to the import function.

Note: The extension to the uddi:tModel type to add a 'deleted' attribute is not currently used in UDDI Utility Tools.

The file is validated for well formedness and that it complies with the UDDI Utility Tools schema, shown here.

```
<?xml version="1.0" encoding="UTF-8" ?>

UDDI Entity Definition File example for canonical tModels

The example Entity Definition File following shows the five main sections for tModels, businesses, services, bindings and referencedTModels:

UDDI Utility Tools can be used to create new UDDI entities in a target UDDI Registry. A typical example of this is to introduce a new canonical tModel, which has a publicly known tModel key.

```
<?xml version="1.0" encoding="UTF-8"?>
<promote:uddiEntities xmlns="urn:uddi-org:api_v2" xmlns:promote="
     http://www.ibm.com/xmlns/prod/WebSphere/UDDIUtilityTools">

  <!-- tModels -->
  <promote:tModels>

    <tModel tModelKey="uuid:ee3966a8-faa5-416e-9772-128554343571" >
      <name>http://schemas.xmlsoap.org/ws/2002/07/policytmodel</name>
      <description>WS-PolicyAttachment policy expression</description>
    </tModel>

    <tModel tModelKey="uuid:ad61de98-4db8-31b2-a299-a2373dc97212" >
      <name>uddi-org:wsdl:address</name>
 <description xml:lang="en">
This tModel is used to specify the URL fact that the address must be obtained from
the WSDL deployment file.
      </description>
      <overviewDoc>
        <overviewURL>
http://www.oasis-open.org/committees/uddi-spec/doc/tn/
     uddi-spec-tc-tn-wsdl-v2.htm#Address
        </overviewURL>
      </overviewDoc>
    </tModel>

  </promote:tModels>

  <!-- businesses -->
  <promote:businesses>
  </promote:businesses>

  <!-- services -->
  <promote:services>
  </promote:services>

  <!-- bindings -->
  <promote:bindings>
  </promote:bindings>

  <!-- referenced tModels -->
  <promote:referencedTModels>
  </promote:referencedTModels>

</promote:uddiEntities>
```

Starting UDDI Utility Tools at a command prompt

Ensure the correct level of java is appropriate by setting the PATH statement to the level of java supplied with WebSphere. For example, from the command line, type:

On Windows:

```
set PATH=WAS_HOME\java\bin;%PATH%
```

On Unix and Linux platforms:

```
export PATH=WAS_HOME/java/bin:$PATH
```

If you are using DB2 on Unix and Linux platforms run the db2profile script before issuing the java command to start UDDI Utility Tools. This script is located within the DB2 instance home directory under sqllib and is invoked by typing:

```
. /$DB2_HOME/db2profile
```

Note: In the above example, notice that the '.' is followed by a single space character.

Note: On Unix and Linux platforms the DB2 user **must** have a db2profile at $HOME/sqllib/db2profile.

UDDI Utility Tools can be started using:

java - jar UDDIUtilityTools.jar <function> [options]
using a specified properties file that sets up classpath and other parameters, or it can be called using:

java CommandLineProcessor
where CommandLineProcessor is the class which processes command line arguments for UDDI Utility Tools, sets up configuration and invokes the appropriate function.

The usage is as follows:

```
Usage: java -jar UDDIUtilityTools.jar {function} [options]

function:
  -promote <entity source>   Promote entites between registries
  -export <entity source>    Extract entities from registry to XML
  -delete <entity source>    Delete entities from registry
  -import                    Create entities from XML to registry

where <entity source> is one of:
  -tmodel|-business|-service|-binding <key> Specify single entity type and key
  -keysFile | -f <filename>  Specify file containing entity types and keys

options:
  -properties <filename>     Specify path to configuration file
  -overwrite | -o            Overwrite an entity if it already exists
  -log | -v                  Output verbose messages
  -definitionFile <filename> Specify path to UDDI entity definition file
  -importReferenced          Import entities referenced by source entities

The following options override property settings in configuration file:
  -overwrite
  -log
  -definitionFile
  -importReferenced

Example: java -jar UDDIUtilityTools.jar -promote -keysFile C:/uddikeys.txt
```

Below are a set of UDDI Utility Tools command line examples:

To export a single business to the EDF file specified in a properties file in the current directory.

```
java -jar UDDIUtilityTools.jar -export -business 28B8B928-2B2E-4EC9-A647-1E40651E4752
```

As above but this time using a keys file to specify the entities to be exported

```
java -jar UDDIUtilityTools.jar -export -keysFile c:/myKeyFiles/keyFile01.txt
```

As above but also specifying verbose output to appear on the command line.

```
java -jar UDDIUtilityTools.jar -export -keysFile c:/myKeyFiles/keyFile02.txt -v
```

To import the contents of the default EDF specified in a UDDIUtilitiyTools.properties file in the current directory.

```
java -jar UDDIUtilityTools.jar -import
```

As above but also specifying that referenced tModels should be imported into the target registry.

```
java -jar UDDIUtilityTools.jar -import -importReferenced
```

To import the entities from an EDF at the specified location. Note the use of forward slashes even though this is an example on a Windows file system.

```
java -jar UDDIUtilityTools.jar -import -definitionFile c:/myEDFs/entities01.xml
```

To import the entities from the default EDF including referenced tModels. Overwrite specifies that any entities excluding referenced tModels that are found in the target registry should be overwritten.

```
java -jar UDDIUtilityTools.jar -import -overwrite -importReferenced
```

To promote a single service from a source to a target registry using the properties file at a specified location.

```
java -jar UDDIUtilityTools.jar -promote -service 67961D67-330F-4F14-8210-E74A58E710F3
-properties c:/UUT/myUUTProps.properties
```

To promote a set of entities specified in a keys file.

```
java -jar UDDIUtilityTools.jar -promote -keysFile c:/myKeyFiles/keyFile03.txt
```

As above but specifying that existing entities in the target registry get overwritten.

```
java -jar UDDIUtilityTools.jar -promote -keysFile c:/myKeyFiles/keyFile04.txt -overwrite
```

To promote a set of entities specified in a keys file including referenced tModels.

```
java -jar UDDIUtilityTools.jar -promote -keysFile c:/myKeyFiles/keyFile05.txt -importReferenced
```

To promote a set of entities specified in a keys file but also create an EDF containing the promoted entities.

```
java -jar UDDIUtilityTools.jar -promote -keysFile c:/myKeyFiles/keyFile06.txt
-definitionFile c:/myEDFs/entities02.xml
```

To logically delete a single tModel. Note that it is not possible to physically delete tModels.

```
java -jar UDDIUtilityTools.jar -delete -tModel UUID:1E2B9D1E-E53D-4D36-9D46-6CCC176C466A
```

To delete all the entities specified in the keys file. Note that with the exception tModels all other entities will be physically deleted from the target registry.

```
java -jar UDDIUtilityTools.jar -delete -keysFile c:/myKeyFiles/keyFile04.txt
```

A keys file example

Below is an example of the keys that are to be exported, promoted or deleted from the target registry:

```
#
# Keys of entities to be exported, promoted from source registry or deleted from
    target registry
#
# Note: keys must be comma separated and on SAME line
# Note: property names are case sensitive. ('tmodels=' will be ignored)

businesses=97C77097-AC6C-4CA0-A6C4-452F7045C470, 4975E949-581F-4FCA-AD5F-E08280E05F9F
services=BB3864BB-1578-4833-8179-14391F14791F
bindings=
tModels=273F1727-7BFF-4FB5-A1FD-BA5C45BAFD9C
```

Note: If the importReferenced property is set to true, the list of tModels in the referencedTModels section is imported to the target registry. Minimal entities are created if the referencedTModel is new. If the referencedTModel already exists it is never overwritten, regardless of the overwrite property value. This is so that commonly referenced tModels such as categorization tModels do not keep being updated unnecessarily.

Should you need to update a referencedTModel, you must manually move the referencedTModel definition to the tModels section in the entity definition file and set overwrite to true.

Content of the log files

Below shows examples of contents of two of the log files produced by running the tool. Note that some comments have been added in square brackets and in italic to highlight important points within the log file. The first is the messages.log which shows successful and unsuccessful operations for export, import and delete functions:

```

```

Starting UDDI Utility Tools through the API

UDDI Utility Tools provides a public API to functions for exporting, importing, promoting, finding and deleting UDDI entities. All of these functions can be invoked by using the PromoterAPI class. Usage of this class to perform these functions is typically to:

1. Create a Configuration object and populate it from a Properties object or from a configuration properties file.
2. Create a PromoterAPI object passing the Configuration in the constructor.
3. For keys based functions (export, delete and promote), set the keys by supplying a UDDIEntityKeys object, the location of the keys file, or, for one entity, by specifying an entity type and a key value.
4. Invoke the corresponding method for the function required: exportEntities, promoteEntities(boolean), importEntities, deleteEntities or extractKeysFromInquiry(FindTModel, FindBusiness, FindService, FindBinding, FindRelatedBusinesses).

There is some sample code for UDDI Utility Tools, demonstrating usage of the API classes, available from Samples Central.

The ″low-level″ API classes and methods have been deprecated in this release. Refer to the Javadoc welcome page for details.

Known limitations with UDDI Utility Tools and workarounds

There are some known limitations with UDDI Utility Tools and a workaround for each. See ″UDDI troubleshooting tips″ in the information center.

Cloudscape Restriction

The ’export’ function when referencing a source registry with a Cloudscape database is supported. However, the ’import’, ’promote’ and ’delete’ functions are not supported when referencing a target registry because of a limitation with the UDDI Registry when working with a Cloudscape database.

Saving Version 3 entities with a supplied key

An example of saving a Version 3 business with a defined key is shown below.

```
<?xml version="1.0" encoding="UTF-8"?>
<Envelope xmlns="http://schemas.xmlsoap.org/soap/envelope/">
  <Body>
    <save_business xmlns="urn:uddi-org:api_v3">
      <authInfo>a399c4a3-6387-47cd-a1bd-91f7bb91bdd7</authInfo>
      <businessEntity businessKey="uddi:mycompany-p1.com:computers">
        <name xml:lang="en">WithKey</name>
      </businessEntity>
    </save_business>
  </Body>
</Envelope>
```

Known limitations with UDDI Utility Tools and workarounds

There are known limitations with the UDDI Utility Tools and a workaround for each:

- PublisherAssertions are not supported and will not be promoted.

Workaround: After the user has promoted the businesses that are related, he must recreate the publisherAssertion relationship.

- Referenced businesses in service projections are not added automatically to the EDF in the same manner as referenced tModels.

  Workaround: Add the referenced business that will 'own' the projected service to the EDF. If the business is not present in the target registry, it should be placed before the service's owning business in the EDF.
- Cycle detection for service projections are not detected in the same manner as for referenced tModels.

  Workaround: If a circular reference is present between two or more service projections, break the cycle by removing one of the projections temporarily, perform the import and update the changed entity to reestablish the cycle in the target registry.
- tModels that were deleted (in the logical sense) in the source registry are imported and promoted as undeleted in the target registry. This is because, in the UDDI Version 2 specification, the deleted state of tModels is not exposed as API calls.

  Workaround: After importing the tModel, perform a delete. This is done using the UDDI Utility Tools delete function, or any other UDDI Registry API access method.
- BindingTemplates referenced by hostingRedirectors are not added automatically to the EDF in the same manner as referenced tModels.

  Workaround: Add the referenced bindingTemplate to the EDF.
- Businesses referenced by an 'owningBusiness' keyedReference are not automatically added to the EDF.

  Workaround: Import the referenced business into the target registry before importing the tModel that references it.
- The JSSE provider class, when security is enabled, is not configurable. It must be com.ibm.jsse.IBMJSSEProvider.
- A few combinations of command line arguments are not validated and prevented, for example, it is possible to specify -import with -keysFile <path to file> in the same command, although the &#8209;keysFile is ignored.

IBM Java API for XML Registries (JAXR) Provider for UDDI

Overview

The Java API for XML Registries (JAXR) is a Java client API for accessing both UDDI (Version 2 only) and ebXML registries. It is part of the J2EE 1.4 specification.

The JAXR API comprises the J2EE packages javax.xml.registry and javax.xml.registry.infomodel. J2EE API documentation can be found at http://java.sun.com/webservices/reference/api/index.html (this is a download site). More information on JAXR, including the JAXR Version 1.0 specification, can be found at http://java.sun.com/xml/jaxr/index.jsp.

Note that the preferred UDDI Java client APIs are UDDI4J Version 2 for UDDI Version 2, and the IBM UDDI Client for Java for UDDI Version 3.

JAXR Provider

The current JAXR specification (Version 1.0) defines a JAXR Provider as an implementation of the JAXR API. A JAXR Provider may be a JAXR Provider for UDDI, a JAXR Provider for ebXML, or a pluggable provider which supports both UDDI and ebXML. The IBM JAXR Provider for UDDI is a provider for UDDI only.

UDDI Versions

A JAXR Provider for UDDI accesses a UDDI Registry using the UDDI Version 2 SOAP APIs only. The IBM WebSphere UDDI Registry for UDDI Version 3 in WebSphere Application Server Version 6.0 supports the

UDDI Version 1, 2 and 3 SOAP APIs, and so the IBM JAXR Provider for UDDI can be used to access this registry. The IBM JAXR Provider can also be used to access the IBM WebSphere UDDI Registry for UDDI Version 2 in WebSphere Application Server Version 5.x. Note that to use the UDDI Version 3 SOAP APIs, JAXR cannot be used. The IBM UDDI Version 3 Client for Java is recommended for this.

Capability Level

The JAXR specification defines two Capability Profiles, Capability Level 0 and Capability Level 1. The JAXR API documentation categorizes each JAXR method as either Level 0 or Level 1. A JAXR provider for UDDI has Capability Level 0 and supports all Level 0 methods. A JAXR provider for ebXML has Capability Level 1 and supports all Level 0 and Level 1 methods. The IBM JAXR Provider for UDDI is a Capability Level 0 Provider, and supports only Level 0 methods.

JAXR for UDDI - getting started and advanced topics:

Getting started

A simple sample

The following sample program shows how to obtain the ConnectionFactory instance, create a Connection to the registry and save an Organization in the registry.

```
import java.net.PasswordAuthentication;
import java.util.ArrayList;
import java.util.Collection;
import java.util.HashSet;
import java.util.Properties;
import java.util.Set;

import javax.xml.registry.BulkResponse;
import javax.xml.registry.BusinessLifeCycleManager;
import javax.xml.registry.Connection;
import javax.xml.registry.ConnectionFactory;
import javax.xml.registry.JAXRException;
import javax.xml.registry.RegistryService;
import javax.xml.registry.infomodel.Key;
import javax.xml.registry.infomodel.Organization;

public class JAXRSample
{
    public static void main(String[] args) throws JAXRException
    {
        //Tell the ConnectionFactory to use the IBM JAXR Provider for UDDI
        System.setProperty("javax.xml.registry.ConnectionFactoryClass",
     "com.ibm.xml.registry.uddi.ConnectionFactoryImpl");
        ConnectionFactory connectionFactory = ConnectionFactory.newInstance();

        //Set the URLs for the UDDI inquiry and publish APIs.
        //These must be the URLs of the UDDI version 2 APIs.
        Properties props = new Properties();
        props.setProperty("javax.xml.registry.queryManagerURL", "http://localhost:9080/uddisoap/inquiryapi");
        props.setProperty("javax.xml.registry.lifeCycleManagerURL", "http://localhost:9080/uddisoap/publishapi");
        connectionFactory.setProperties(props);

        //Create a Connection to the UDDI registry accessible at the above URLs.
        Connection connection = connectionFactory.createConnection();

        //Set the user ID and password used to access the UDDI registry.
        PasswordAuthentication pa = new PasswordAuthentication("Publisher1", new char[]
    { 'p', 'a', 's', 's', 'w', 'o', 'r', 'd' });
        Set credentials = new HashSet();
        credentials.add(pa);
        connection.setCredentials(credentials);

        //Get the javax.xml.registry.BusinessLifeCycleManager interface, which contains
        //methods corresponding to UDDI publish API calls.
        RegistryService registryService = connection.getRegistryService();
        BusinessLifeCycleManager lifeCycleManager = registryService.getBusinessLifeCycleManager();

        //Create an Organization (UDDI businessEntity) with name "Organization 1".
        Organization org = lifeCycleManager.createOrganization("Organization 1");

        //Add the Organization to a Collection, ready to be saved in the UDDI registry.
        Collection orgs = new ArrayList();
        orgs.add(org);

        //Save the Organization in the UDDI registry.
        BulkResponse bulkResponse = lifeCycleManager.saveOrganizations(orgs);

        //Obtain the Organization's Key (the UDDI businessEntity's businessKey) from the response.
        if (bulkResponse.getExceptions() == null)
        {
            //1 Organization was saved, so 1 key will be returned in the response collection
            Collection responses = bulkResponse.getCollection();
            Key organizationKey = (Key)responses.iterator().next();
            System.out.println("\nOrganization Key = " + organizationKey.getId());
        }
    }
}
```

Classpath

The class libraries of the IBM JAXR Provider for UDDI are contained within the archive jaxruddi.jar, located in the WAS_HOME/lib directory. When using the JAXR API from within a J2EE application running under WebSphere Application Server Version 6.0, all required classes will automatically be on the classpath. When using the JAXR API from outside this environment, the following jars must be on the java classpath: bootstrap.jar, jaxruddi.jar, j2ee.jar, soap.jar and uddi4jv2.jar, which are all located in the WAS_HOME/lib directory.

javax.xml.registry.ConnectionFactory

To use the IBM JAXR Provider for UDDI, the name of the ConnectionFactory implementation class must first be specified by setting the System Property “javax.xml.registry.ConnectionFactoryClass” to “com.ibm.xml.registry.uddi.ConnectionFactoryImpl”. Failure to specify this will result in the value defaulting to “com.sun.xml.registry,common.ConnectionFactoryImpl”, which will not be found. This will result in a JAXRException when the ConnectionFactory.newInstance() method is called. The IBM JAXR Provider for UDDI does not support lookup of the ConnectionFactory via JNDI.

javax.xml.registry.Connection Properties

Connection specific properties must be specified by setting a java.util.Properties object on the JAXR ConnectionFactory before obtaining a Connection. The JAXR specification defines the full list of these properties. The table below lists the three most important properties, and what values they should take in order to use the IBM JAXR Provider for UDDI to access the IBM WebSphere UDDI Registry. The only required Connection property is “javax.xml.registry.queryManagerURL”, however it is recommended that “javax.xml.registry.lifeCycleManagerURL” is also set, and that the default value of “javax.xml.registry.security.authenticationMethod” is understood. The rest of the Connection properties defined in the JAXR specification are optional, and their values are not specific to the IBM WebSphere UDDI Registry. The IBM JAXR Provider for UDDI does not define any additional provider-specific properties.

Property	Description

javax.xml.registry.queryManagerURL	The URL of the IBM WebSphere UDDI Registry‘s inquiry API for UDDI Version 2. Typically this will be of the form: “http://<hostname>:<port>/uddisoap/inquiryapi”. This property is required.
javax.registry.xml.lifeCycleManagerURL	The URL of the IBM WebSphere UDDI Registry‘s publish API for UDDI v2. Typically this will be of the form: “http://<hostname>:<port>/uddisoap/publishapi”. If this property is not specified, it defaults to the value of the javax.xml.registry.queryManagerURL property, however the IBM UDDI Registry will typically have different URLs for the inquiry and publish APIs, and it is recommended to specifiy both properties.
javax.xml.registry.authenticationMethod	The method of authentication to use when authenticating with the registry. This may take one of two values, “UDDI_GET_AUTHTOKEN” and “HTTP_BASIC”. The default value is “UDDI_GET_AUTHTOKEN” if none is specified. See section Authentication and Security below for more information.

Authentication and security

Authentication

The javax.xml.registry.authenticationMethod Connection property tells the JAXR Provider which method to use when authenticating with the UDDI registry. The two supported values of this property are “UDDI_GET_AUTHTOKEN” and “HTTP_BASIC”. The IBM JAXR Provider for UDDI does not support the “CLIENT_CERTIFICATE” or “MS_PASSPORT” methods of authentication. If this property is not set, the default authentication method is “UDDI_GET_AUTHTOKEN”.

UDDI_GET_AUTHTOKEN

The JAXR Provider uses the UDDI V2 get_authToken API to authenticate with the registry. The get_authToken call is made automatically by the JAXR Provider when the Connection credentials are set, and the UDDI V2 authToken returned by the call is saved by the JAXR Provider for use on subsequent UDDI publish API calls.

HTTP_BASIC

The JAXR Provider uses HTTP basic authentication to authenticate with the registry. This is supported by WebSphere when WebSphere Global Security is on. No UDDI V2 get_authToken API call is made, instead the username and password are sent in the HTTP headers using HTTP basic authentication every time a UDDI API call is made (both inquiry and publish). If the UDDI Registry does not require HTTP basic authentication, the credentials are ignored.

USING SSL (Secure Sockets Layer)

SSL can be used to encrypt HTTP traffic between the IBM JAXR Provider for UDDI and the IBM WebSphere UDDI Registry. To use SSL, the JAXR client program should do the following:

1. When setting the “javax.xml.registry.queryManagerURL” and “javax.xml.registry.lifeCycleManagerURL” Connection properties, specify a URL with the protocol “https” and the correct port for using SSL to access the UDDI registry. The IBM WebSphere UDDI Registry‘s default port for https is 9443. Often only the lifeCycleManager URL (the UDDI Publish API URL) will require SSL.
2. Add a new Security Provider to the java.security.Security object, according to the JSSE (Java Secure Sockets Extension) implementation being used. If running under the IBM JVM in WAS 6.0, the IBM JSSE will automatically be on the classpath. Add the IBM Security Provider as follows:

   ```
   java.security.Security.addProvider(new com.ibm.jsse.JSSEProvider());
   ```

3. Set the System property “javax.net.ssl.trustStore” to be the file name of the client trust store file. This is a java key store (.jks) file and must contain the server certificate of the UDDI registry. Key store files can be managed using WebSphere‘s ikeyman tool
4. Set the System property “javax.net.ssl.trustStorePassword”. This is the password used to open the client trust store file.
5. If using an IBM JVM prior to that in WAS 6.0, it may be necessary to set the System property “java.protocol.handler.pkgs” to “com.ibm.net.ssl.internal.www.protocol”. For more information on SSL and the ikeyman tool refer to SSL and IKEYMAN in the Information Center.

Internal taxonomies

The IBM JAXR Provider for UDDI supplies the following internal taxonomies:

Taxonomy	ClassificationScheme name (UDDI tModel name)	ClassificationScheme id (UDDI Version 2 tModelKey)
NAICS 1997	ntis-gov:naics:1997	UUID:C0B9FE13-179F-413D-8A5B-5004DB8E5BB2
NAICS 2002	ntis-gov:naics:2002	UUID:C0B9FE13-179F-413D-8A5B-5004DB8E5BB2
UNSPSC 3.1	unspsc-org:unspsc:3-1	UUID:DB77450D-9FA8-45D4-A7BC-04411D14E384
UNSPSC 7	unspsc-org:unspsc	UUID:CD153257-086A-4237-B336-6BDCBDCC6634
ISO3166 2003	ubr-uddi-org:iso-ch:3166-2003	UUID:4E49A8D6-D5A2-4FC2-93A0-0411D8D19E88

The tModels corresponding to all of these taxonomies are available in the IBM UDDI Version 3 Registry. If using the IBM JAXR Provider to access an IBM UDDI Version 2 Registry, only the tModels corresponding to NAICS 1997, UNSPSC 3.1 and ISO3166 are available.

Custom internal taxonomies

A user may supply their own custom internal taxonomies. To create a new custom internal taxonomy and make it available to the JAXR provider, follow these steps:

1. Create a text file containing the taxonomy element data. As an example, look at the file geo-data.txt on the root of jaxruddi.jar. This is the taxonomy data file for the supplied ISO 3166 taxonomy. The first few lines are:

   ```
   geo#--#World#--
   geo#AE#United Arab Emirates#--
   geo#AF#Afghanistan#--
   geo#AG#Antigua And Barbuda#--
   geo#AI#Anguilla#--
   geo#AL#Albania#--
   geo#AM#Armenia#--
   geo#AN#Netherlands Antilles#--
   geo#AO#Angola#--
   geo#AQ#Antarctica#--
   geo#AR#Argentina#--
   geo#AR-A#Salta#AR
   geo#AR-B#Buenos Aires#AR
   ```

   Each line represents one element of the taxonomy, or one Concept in the taxonomy Concept tree. Each line has the form:

   ```
   <taxonomy ID>#<element name>#<parent element value>
   ```

Token	Description
<taxonomy ID>	The taxonomy ID is the same for every element of a taxonomy.
<element value>	The taxonomy ID is the same for every element of a taxonomy.
<element name>	The Concept name (UDDI keyName).

<parent element value>	This defines the element‘s parent element in the taxonomy tree. For every element (except the root element) in the data file, there should be another line which defines the element‘s parent element. The root element is denoted by defining itself as its own parent. There should be only one root element, and no parentless elements.
#	The delimiter character. This does not have to be “#” and can be defined for each taxonomy in the taxonomyConfig.properties file.

2. Save a ClassificationScheme (UDDI tModel) in the UDDI registry to represent the new internal taxonomy. This can be done using the javax.xml.registry.BusinessLifeCycleManager.saveClassificationSchemes() method.
3. Add the new taxonomy to the taxonomyConfig.properties file:
   a. Copy the supplied taxonomyConfig.properties file from the root of jaxruddi.jar.

      The content of the supplied taxonomyConfig.properties file is:

      ```
      naics-1997 = UUID:C0B9FE13-179F-413D-8A5B-5004DB8E5BB2, naics-1997-data.txt, #
      naics-2002 = UUID:1FF729F2-1948-46CF-B660-31EC107F1663, naics-2002-data.txt, #
      unspsc  = UUID:DB77450D-9FA8-45D4-A7BC-04411D14E384, unspsc-data.txt,     #
      unspsc7_data = UUID:CD153257-086A-4237-B336-6BDCBDCC6634, unspsc7-data.txt,    #
      iso3166-2003 = UUID:4E49A8D6-D5A2-4FC2-93A0-0411D8D19E88, iso3166-2003-data.txt,#
      ```

      This file has one line per supplied internal taxonomy, which is of the form:

      ```
      <taxonomy ID> = <tModelKey>,<data filename>,<data file delimiter>
      ```

Token	Description
<taxonomy ID>	This is used internally by the JAXR provider to identify each taxonomy. It does not have to be the same as the taxonomy ID in the corresponding taxonomy data file.
<tModelKey>	The tModelKey of the corresponding UDDI tModel. (The id of the corresponding JAXR ClassificationScheme).
<data filename>	The name of the corresponding taxonomy data file.
<data file delimiter>	The delimiter character used in the taxonomy data file. All supplied internal taxonomies use “#”, but user-supplied internal taxonomies may use different delimiters.

   b. Add a new line for the new taxonomy to the copy of the taxonomyConfig.properties file. Do not remove any existing taxonomies from the file as this will make them unavailable to the JAXR provider.
4. Add the copied taxonomyConfig.properties file to the java classpath ahead of jaxruddi.jar.
5. If any JAXR client programs are still running that were started before the new taxonomy was added to the taxonomyConfig.properties file, a new Connection must be created in order to pick up the new taxonomy.

Important notes on internal taxonomies

Each internal taxonomy is loaded into memory once per JAXR Connection. The taxonomy‘s ClassificationScheme is created when the Connection is created. At this time the associated UDDI tModel is obtained from the registry and used to populate the ClassificationScheme attributes. The taxonomy‘s Concept object tree is not created until the first time the ClassificationScheme is requested by the user. All subsequent requests for the same internal taxonomy using the same Connection will return the same object tree.

Modification of the object tree

Because there is only one ClassificationScheme and Concept object tree per internal taxonomy per Connection, a user should not attempt to modify programmatically any part of the Concept tree, because all future requests for this taxonomy using the same Connection will return the modified (and now possibly invalid) objects. Programmatic modification of the Concept tree will not result in any changes to the associated taxonomy data file. If a user wishes to make a change to the values in a user-defined internal taxonomy, they must first make the changes in the taxonomy data file, and then create a new Connection to pick up the changes in a new Concept tree.

Modification of the Concept tree

Because there is only one Concept object tree per internal taxonomy per Connection, a user should not attempt to modify programmatically any part of the Concept tree, because all future requests for this taxonomy using the same Connection will return the modified (and now possibly invalid) objects. Programmatic modification of the Concept tree will not result in any changes to the associated taxonomy data file. If a user wishes to make a change to the values in a user-defined internal taxonomy, they must first make the changes in the taxonomy data file, and then create a new Connection to pick up the changes in a new Concept tree.

Modification of the ClassificationScheme

Similarly, a user should not attempt to modify programmatically an internal ClassificationScheme, except in the case where a user wishes to modify and then save a user-defined internal ClassificationScheme. A new Connection is not required to pick up programmatic changes.

Logging and messages

UDDI4J Logging

The IBM JAXR Provider for UDDI uses UDDI4J Version 2 to communicate with the UDDI Registry. UDDI4J has its own logging which can be switched on by setting the value of the System property “org.uddi4j.logEnabled” to “true”. This outputs to the standard error log the XML request and response bodies of every UDDI request.

Trace

Entry, exit, exception, warning and debug trace is provided using commons-logging. See http://jakarta.apache.org/commons/logging/ for more information on commons-logging. Trace will only be created if the JAXR client configures it. Entry, exit and debug trace uses the debug level of logging. Exception and warning trace uses the info level of logging. Additionally, info level logging is provided before each UDDI4J request is made.

Standard error log messages

The InternalTaxonomyManager, EnumerationManager and PostalSchemeManager send warning messages to System.err if error conditions occur that do not warrant an exception, but that the user should be informed of. Examples of these are if a taxonomy data file contains an invalid line, or if a tModel corresponding to an internal taxonomy could not be found in the registry.

UDDI Registry Messages

The UDDI Registry issues messages to report events or errors. The messages are in the form `CWUDxnnnns` where:

x is a character descriptor identifying which UDDI component is involved
nnnn is the error code
s is one of I (Information), E (Error) or W (Warning)

The prefix *CWUDxnnnns:* is followed by text that describes the event or error. For some messages, the first word of the text is one of the form (MSN=SSSS). The SSSS provides a message sequence number (or MSN), which identifies the unique circumstance in which the message was issued, and is of use where the same message can be issued in more than one circumstance.

To help you diagnose problems and minimize the need to enable trace in any of the above components, view the messages table. You can view the messages by prefix or component, whichever is easiest for you to find in the table. All messages are documented with user/system action and explanation.

The text for the UDDI messages is contained in the following files:

- *setupuddimessages.jar* and *UDDICLoudscapeCreate.jar* for the CWUDD messages
- *jaxruddi.jar* for CWUDX messages
- *UDDIValueSetTools.jar* for CWUDV messages
- *UDDIUtilityTools.jar* for CWUDU messages
- *uddiresourcebundles.jar* for the remaining prefixes

which are placed, by the installation process, into the lib subdirectory of the WebSphere application server into which the UDDI Registry was installed (with the exception of UDDIUtilityTools.jar, which is placed into UDDIReg/scripts). If you will be running a console or log analyzer from another process; for example, to analyze the activity log, you must place a copy of the above jar files into a directory that is within the classpath of that process. Otherwise, the message lookup for the UDDI messages will fail.

UDDI Components Message Prefix Table **Click on individual links for message documentation for the component**	
CWUDDnnnns	UDDI Deploy and Removal
CWUDGnnnns	UDDI User Console
CWUDMnnnns	UDDI Management Interface
CWUDNnnnns	UDDI Node Management
CWUDQnnnns	UDDI Migration
CWUDRnnnns	UDDI Logging and Tracing

CWUDVnnnns	UDDI Value Set Tools
CWUDXnnnns	JAXR

CWUDDnnnns (Web Services UDDI Deployment and Removal) messages:

CWUDD0001I: Attempting to deploy UDDI Registry application.

Explanation: The UDDI deployment process is starting.

User Response: None..

CWUDD0002W: Failed to discard unsaved changes caught exception Exc. Value is: <Exception Message>

Explanation: This warning message indicates that changes in the wsadmin session previous to running the uddiDeploy.jacl script cannot be discarded. The <Exception Message> describes the error that occurred.

User Response: None.

CWUDD0003I: Application Manager found.

Explanation: An active Application Manager can be used to stop and start UDDI on the deployment server.

User Response: None.

CWUDD0004I: Application Manager unavailable, application will not be started/stopped.

Explanation: No active Application Manager can be found so there is no need to stop and start UDDI on the deployment server.

User Response: None.

CWUDD0005I: Application Manager not running, application will not be started/stopped.

Explanation: Application Manager has been found, but it is not running so there is no need to stop and start UDDI on the deployment server.

User Response: None.

CWUDD0006I: Checking for installed UDDI Registry application of name appname. Value is: <UDDI Application Name>

Explanation: The deployment script is checking for deployed UDDI applications.

User Response: None.

CWUDD0007I: Stopping application of name appname. Value is: <Application Name>

Explanation: Attempting to stop a deployed UDDI application.

User Response: None.

CWUDD0008W: Stopping application appname caught exception Exc. Application might not have been running on this server. Values are: <Application Name> <Exception Message>

Explanation: The UDDI application stop request failed.

User Response: Attempt to stop the UDDI application via the Administration Console and rerun the uddiDeploy.jacl script.

CWUDD0009I: Application appname stopped successfully. Value is: <Application Name>

Explanation: The UDDI application has stopped successfully.

User Response: None.

CWUDD0010I: Removing application appname. Value is: <Application Name>

Explanation: The deployment script is attempting to remove an existing UDDI application.

User Response: None.

CWUDD0011I: Application appname removed successfully. Value is: <Application Name>

Explanation: The UDDI application has been removed from the configuration.

User Response: None.

CWUDD0012I: Attempting to create default UDDI datasource.

Explanation: A default UDDI deployment has been requested and therefore a Cloudscape datasource will be created.

User Response: None.

CWUDD0013I: Multiple Cloudscape JDBC Providers found. Using first in list.

Explanation: The deployment script has detected a number of suitable Cloudscape JDBC providers and will use the first.

User Response: None.

CWUDD0014I: UDDI Datasource name successfully created. Value is: <Datasource Name>

Explanation: A Cloudscape datasource has been created for the default UDDI deployment.

User Response: None.

CWUDD0015I: Setting application classloader mode.

Explanation: The UDDI application requires PARENT_LAST class loading.

User Response: None.

CWUDD0016I: Altered classloader mode of application appname from oldmode to newmode. Values are: <Application Name> <Old Classloader Mode> <New Classloader Mode>

Explanation: The UDDI application class loader has been successfully changed.

User Response: None.

CWUDD0017I: Setting classloader mode for application modules.

Explanation: The UDDI application web modules require PARENT_LAST class loading.

User Response: None.

CWUDD0018I: Altered classloader mode of module modname in application appname from oldmode to newmode. Values are: <Web Module Name> <Application Name> <Old Classloader

Mode> <New Classloader Mode>

Explanation: The UDDI Web modules class loader mode has been successfully changed.

User Response: None.

CWUDD0019I: UDDI successfully deployed.

Explanation: UDDI has been successfully deployed.

User Response: None.

CWUDD0020I: Attempting to save new configuration.

Explanation: Attempting to save the configuration after removing any existing UDDI application.

User Response: None.

CWUDD0021I: Changes saved successfully.

Explanation: The configuration changes have been successfully saved.

User Response: None.

CWUDD0022I: Attempting to save new configuration.

Explanation: Attempting to save the configuration after installing the UDDI application ear.

User Response: None.

CWUDD0023W: Changes saved successfully.

Explanation: The configuration changes have been successfully saved.

User Response: None.

CWUDD0024I: Attempting to save new configuration.

Explanation: Attempting to save the configuration after changing the class loader modes.

User Response: None.

CWUDD0025I: Changes saved successfully.

Explanation: The configuration changes have been successfully saved.

User Response: None.

CWUDD1001W: Failed to discard unsaved changes caught exception Exc. Value is: <Exception Message>

Explanation: This warning message indicates that changes in the wsadmin session previous to running the uddiDeploy.jacl script cannot be discarded. The <Exception Message> describes the error that occurred.

User Response: None.

CWUDD1002I: Application Manager found.

Explanation: An active Application Manager can be used to stop and start UDDI on the deployment server.

User Response: None.

CWUDD1003I: Application Manager unavailable, application will not be started/stopped.

Explanation: No active Application Manager can be found so there is no need to stop and start UDDI on the deployment server.

User Response: None.

CWUDD1004I: Application Manager not running, application will not be started/stopped.

Explanation: Application Manager has been found, but is not running so there is no need to stop and start UDDI on the deployment server.

User Response: None.

CWUDD1005I: Stopping application of name appname. Value is: <Application Name>

Explanation: Attempting to stop a deployed UDDI application.

User Response: None.

CWUDD1006W: Stopping application appname caught exception Exc. Application might not have been running on this server. Values are: <Application Name> <Exception Message>

Explanation: The UDDI application stop request failed.

User Response: Attempt to stop the UDDI application via the Administration Console and rerun the uddiDeploy.jacl script.

CWUDD1007I: Application appname stopped successfully. Value is: <Application Name>

Explanation: The UDDI application has stopped executing.

User Response: None.

CWUDD1008I: Removing application appname. Value is: <Application Name>

Explanation: The removal script is attempting to remove the UDDI application.

User Response: None.

CWUDD1009I: Attempting to remove UDDI Registry application.

Explanation: The UDDI removal process is starting.

User Response: None.

CWUDD1010I: Application appname removed successfully. Value is: <Application Name>

Explanation: The UDDI application has been removed from the configuration.

User Response: None.

CWUDD1011I: Attempting to remove the default UDDI datasource.

Explanation: A default UDDI removal has been requested and therefore the Cloudscape datasource used for UDDI will be removed.

User Response: None.

CWUDD1012I: UDDI Datasource name successfully removed. Value is: <Datasource Name>

Explanation: The UDDI Cloudscape datasource has been removed from the configuration.

User Response: None.

CWUDD1013I: UDDI Datasource name does not exist. No action required. Value is: <Datasource Name>

Explanation: The default UDDI Cloudscape datasource does not exist in this configuration and therefore does not need to be removed.

User Response: None.

CWUDD1014I: UDDI Registry application and default UDDI datasource removed successfully.

Explanation: UDDI has been successfully removed from the configuration.

User Response: None.

CWUDD1015I: Attempting to save new configuration.

Explanation: Attempting to save the configuration after removing the UDDI application.

User Response: None.

CWUDD1016I: Changes saved successfully.

Explanation: The configuration changes have been successfully saved.

User Response: None.

CWUDD1017I: UDDI Registry application removed successfully.

Explanation: UDDI has been successfully removed from the configuration.

User Response: None.

CWUDD3001I: Commencing UDDI Cloudscape database creation

Explanation: This is an informational message. It indicates that creation of the UDDI Cloudscape database is being started.

User Response: None

CWUDD3002I: Path to scripts='<DBscriptsLocation>'.

Explanation: This is an informational message. It indicates the location (path) of the scripts for creating the UDDI database, in the <DBscriptsLocation> insert.

User Response: None

CWUDD3003I: Path of database='<DBlocation>'.

Explanation: This is an informational message. It indicates the location (path) to be used for the UDDI Cloudscape database, in the <DBlocation> insert.

User Response: None

CWUDD3004I: Database name='<DBname>'.

Explanation: This is an informational message. It indicates the name to be used for the UDDI Cloudscape database, in the <DBname> insert.

User Response: None

CWUDD3005I: Default profile requested

Explanation: This is an informational message. It indicates that the UDDI Cloudscape database is to be created as a default UDDI database, using the default UDDI profile.

User Response: None

CWUDD3006I: Default profile not requested

Explanation: This is an informational message. It indicates that the UDDI Cloudscape database is to be created as a non-default UDDI database.

User Response: None

CWUDD3007I: Attempting to create or connect to UDDI Cloudscape database container

Explanation: This is an informational message. It indicates that an attempt is being made to create, or connect to, the database container for the UDDI Cloudscape database.

User Response: None

CWUDD3008I: UDDI Cloudscape database container successfully created or connected to

Explanation: This is an informational message. It indicates that the database container for the UDDI Cloudscape database has been connected to successfully.

User Response: None

CWUDD3009I: UDDI Cloudscape database creation completed normally

Explanation: This is an informational message. It indicates that the UDDI Cloudscape database has been successfully created.

User Response: None

CWUDD3010I: Attempting to open DDL File List file of name FileName. Value is: FileName='<DDLlistFilename>'

Explanation: This is an informational message. It indicates that the DDL File List file, which lists the DDL Files (database scripts) to be used to create the UDDI Cloudscape database, has been successfully opened. The name of the DDL File List file is given in the <DDLlistFilename> insert.

User Response: None

CWUDD3011I: Reading the contents of the DDL File List file and verifying

Explanation: This is an informational message. It indicates that the contents of the DDL File List file are being read and verified.

User Response: None

CWUDD3012I: Comment from file: <DDLfileComment>

Explanation: This is an informational message. It indicates that a comment line has been read from the DDL File List file, and shows the comment in the <DDLfileComment> insert.

User Response: None

CWUDD3013I: Line from file: <DDLfileLine>

Explanation: This is an informational message. It indicates that a non-comment line has been read from the DDL File List file, and shows the line in the <DDLfileLine> insert.

User Response: None

CWUDD3014I: Extraneous attributes will be ignored

Explanation: This is an informational message. It indicates that more attributes have been specified than are required, and that the extraneous attributes will be ignored.

User Response: None

CWUDD3015I: Skipping the Default Profile record because Default Profile was not requested

Explanation: This is an informational message. It indicates that the default UDDI profile was not requested, and that therefore the record in the DDL File List file for setting up the default profile will be skipped.

User Response: None

CWUDD3016I: Attempting to populate the database container with schema structures.

Explanation: This is an informational message. It indicates that an attempt is being made to add schemas to the UDDI Cloudscape database container.

User Response: None

CWUDD3017I: Attempting to load the Cloudscape JDBC driver.

Explanation: This is an informational message. It indicates that an attempt is being made to load the JDBC driver class for Cloudscape.

User Response: None

CWUDD3018I: Cloudscape JDBC driver successfully loaded

Explanation: This is an informational message. It indicates that the JDBC driver for Cloudscape has been successfully loaded.

User Response: None

CWUDD3019I: Processing DDL file DDLFile using Term as the terminator. Values are: DDLFile=<DDLfilename>, Term=<terminator>.

Explanation: This is an informational message. It indicates that the DDLFile whose name is in the <DDLfilename> insert is being processed, with the character in the <terminator> insert being used as terminator.

User Response: None

CWUDD3020I: DDL file successfully processed. N statements processed. Value is: N=<numStatements>.

Explanation: This is an informational message. It indicates that the current DDL file has been successfully processed, and that the number of statements indicated by the <numStatements> insert were processed.

User Response: None

CWUDD3021I: End of file reached

Explanation: This is an informational message. It indicates that the end of the current DDL file has been reached.

User Response: None

CWUDD3022I: Converting SQL string Str to Cloudscape syntax. Value is: Str=<SQLstring>.

Explanation: This is an informational message. It indicates that the SQL string given in the <SQLstring> insert is being converted into an SQL syntax that is recognized by Cloudscape.

User Response: None

CWUDD3030I: UDDI Cloudscape database successfully completed

Explanation: This is an informational message. It indicates that creation of the UDDI Cloudscape database has completed successfully.

User Response: None

CWUDD4001E: An Exception Exc occurred during creation of UDDI Cloudscape database. Value is:

Explanation: An exception occurred during the attempt to create the UDDI Cloudscape database.

User Response: The <exception> insert provides information that should help you diagnose the cause of the problem.

CWUDD4002E: Abnormal exit from creation of UDDI Cloudscape database.

Explanation: The attempt to create the UDDI Cloudscape database is exiting abnormally.

User Response: Examine the preceding messages to determine the reason for the abnormal exit.

CWUDD4003E: Insufficient arguments supplied

Explanation: Insufficient arguments have been supplied for creating the UDDI Cloudscape database.

User Response: Retry the request, supplying the correct number of arguments.

CWUDD4004E: Usage is: java -jar <thisjar> <arg1> <arg2> <arg3> <arg4>

where:

- **<thisjar> = name of jar file for creating UDDI Cloudscape Database**
- **<arg1> = path to DDL (SQL) files**
- **<arg2> = path to location for UDDI Cloudscape database**
- **<arg3> = name of UDDI Cloudscape Database**
- **<arg4> = (optional), if specified must be the string DEFAULT**

Explanation: This message gives the correct usage syntax for creating the UDDI Cloudscape Database. It is issued when the incorrect syntax has been used.

User Response: Correct the syntax to match the usage indicated by the message. You might also need to specify the Cloudscape class library on the classpath, by using the -cp parameter on the java command. Refer to the Information Center documentation on setting up and deploying UDDI for more details.

CWUDD4005E: Creation of UDDI Cloudscape database was unsuccessful

Explanation: The attempt to create the UDDI Cloudscape database has been unsuccessful.

User Response: Examine the preceding messages to determine the reason for this failure.

CWUDD4006E: SQL Exception Exc encountered during database container creation. Value is: Exc=<exception>.

Explanation: An SQL exception occurred when attempting to create the database container for the UDDI Cloudscape database.

User Response: The <exception> insert should contain information which will help you to diagnose the problem.

CWUDD4007E: DDL File List file not found

Explanation: The DDL File List file, used to specify the DDL files to be used to create the UDDI Cloudscape database, could not be found.

User Response: The DDL File List file should be included in the UDDICloudscapeCreate.jar used to create the UDDI Cloudscape database, so this error indicates a possible corruption of that jar file. Check that you have a valid version of UDDICloudscapeCreate.jar.

CWUDD4008E: Invalid attribute Attr found in DDL File List file. Value should be true or false. Value is: Attr=<attribute>.

Explanation: An invalid attribute was found in the DDL File List file. The expected attribute is one of ’true’ or ’false’. The <attribute> insert indicates the value that was found.

User Response: The DDL File List file is included in the UDDICloudscapeCreate.jar used to create the UDDI Cloudscape database, so this error indicates a possible corruption of that jar file. Check that you have a valid version of UDDICloudscapeCreate.jar.

CWUDD4009E: Insufficient attributes found in DDL File List file.

Explanation: Insufficient attributes were found in the DDL File List file.

User Response: The DDL File List file should be included in the UDDICloudscapeCreate.jar used to create the UDDI Cloudscape database, so this error indicates a possible corruption of that jar file. Check that you have a valid version of UDDICloudscapeCreate.jar.

CWUDD4010E: SQL exception Exc encountered during database population. Value is: Exc=<exception>.

Explanation: An SQL exception has occurred while populating the UDDI Cloudscape database.

User Response: The <exception> insert contains the SQL exception which occurred. Use this to diagnose the problem.

CWUDD4011E: Delete existing UDDI Cloudscape database if it is to be overwritten with a new one.

Explanation: This message is issued when an exception has occurred while populating the UDDI Cloudscape database. A common cause of this problem is that a UDDI Cloudscape database already exists.

User Response: You can ignore this message if you want to keep the existing data in your existing UDDI Cloudscape Database. If you want to overwrite this with a new UDDI Cloudscape database, then you should delete the existing database, then and rerun the request. Previous messages will have shown the location and name of the UDDI Cloudscape database.

CWUDD4012E: Exception Exc occurred while trying to find the Cloudscape JDBC Provider. Value is: Exc=<exception>.

Explanation: An exception occurred while trying to find the Cloudscape JDBC driver class.

User Response: The <exception> insert contains the exception which occurred. Examine this to diagnose the problem.

CWUDD4013E: Ensure that the Cloudscape libraries are on the classpath

Explanation: This message is issued when an exception has occurred when trying to find the Cloudscape JDBC driver class. A common cause of this problem is that the classpath has not been set up to include the path to the Cloudscape class library.

User Response: Ensure that you have specified the Cloudscape class library on the request to create the Cloudscape UDDI database. Depending on how you issued the request, this might involve specifying the classpath on the wsadmin command used to invoke uddiDeploy.jacl, or on the java -jar command used to invoke the UDDICloudscapeCreate.jar file. Refer to the Information Center documentation on setting up and deploying UDDI for more details.

CWUDD4014E: Exception Exc occurred while processing SQL statement Str. Character positions within Str shown by StrPos.

Values are:

- **Exc=<exception>,**
- **<SQLstring>,**
- **StrPos=<charPositions>**

Explanation: An exception occurred while processing an SQL statement used to create the UDDI Cloudscape database. The message shows the SQL exception message in the <exception> insert, the SQL string which was being processed in the <SQLstring> insert, and a string of character positions in the <charPositions> insert.

User Response: Examine the exception message to determine the cause of the problem. If the exception message indicates the position at which the problem occurred, then use the <charPositions> string to identify that position in the SQLstring.

CWUDD4015E: There were no SQL statements in the DDL file.

Explanation: No SQL statements have been found in the DDL file that is currently being processed.

User Response: Previous messages will tell you the path to the database scripts (DDL files), and the DDL file which is currently being processed. Use this information to find the DDL file and check that it is valid.

CWUDD4016E: Exception Exc occurred while processing DDL file. Value is: Exc=<exception>.

Explanation: An exception occurred while processing the current DDL file.

User Response: Examine the exception message in the <exception> insert to diagnose the problem.

CWUDD4017E: Location of database scripts not specified.

Explanation: The request issued to create the Cloudscape database has not specified a location for the database scripts.

User Response: Retry the request, providing a location for the database scripts. If this message is issued when using the uddiDeploy.jacl script with the default option, then check that you are using a valid version of uddiDeploy.jacl.

CWUDD4018E: Location of database not specified.

Explanation: The request issued to create the Cloudscape database has not specified a location for the UDDI Cloudscape database.

User Response: Retry the request, providing a location for the UDDI Cloudscape database. If this message is issued when using the uddiDeploy.jacl script with the default option, then check that you are using a valid version of uddiDeploy.jacl.

CWUDD4019E: Name of database not specified.

Explanation: The request issued to create the Cloudscape database has not specified a name for the UDDI Cloudscape database.

User Response: Retry the request, providing a name for the UDDI Cloudscape database. If this message is issued when using the uddiDeploy.jacl script with the default option, then check that you are using a valid version of uddiDeploy.jacl.

CWUDD4020E: Invalid value specified for Default Profile parameter Parm, value should be GoodParm. Values are: Parm=<suppliedparm>, GoodParm=<expectedparm>.

Explanation: The request issued to create the Cloudscape database has specified an invalid value for the default profile parameter. The <suppliedparm> insert indicates the value that was supplied, and the <expectedparm> indicates the value that was expected.

User Response: Retry the request, specifying a valid value for the default profile parameter, or omit this parameter altogether if you do not want to create the UDDI Cloudscape database with a default profile. If this message is issued when using the uddiDeploy.jacl script with the default option, then check that you are using a valid version of uddiDeploy.jacl.

CWUDD4021E: An error occurred while loading the Cloudscape JDBC driver.

Explanation: An error occurred while attempting to load the Cloudscape JDBC driver class.

User Response: Examine the preceding messages for details of the error.

CWUDD6001E: Incorrect number of arguments passed to script.

Explanation: The wrong number of arguments were passed to the script. Arguments are Node Name, Server Name, and optionally the **default** keyword.

User Response: Retry with the correct arguments.

CWUDD6002E: Usage is: <Command format description>.

Explanation: The deployment script has not been called with the correct arguments.

User Response: Retry with the correct arguments.

CWUDD6003E: Failed to determine server ID caught exception Exc. Value is: <Exception Message>.

Explanation: An Exception occurred whilst trying to determine the Server ID.

User Response: Retry the deployment of UDDI. If the error persists, examine the Exception information on its cause. If the problem cannot be resolved, contact the IBM Customer Service Center.

CWUDD6004E: Failed to determine server ID, possibly due to invalid nodename or servername (check case).

Explanation: The Server ID could not be located for the given node name and server name.

User Response: Check the node name and server name are correct and are in the correct case.

CWUDD6005E: Failed to determine the list of JDBC providers caught exception Exc. Value is: <Exception Message>.

Explanation: The deployment script was unable to determine the list of JDBC providers.

User Response: Retry the deployment of UDDI. If the error persists, examine the Exception information on its cause. If the problem cannot be resolved, contact the IBM Customer Service Center.

CWUDD6006E: Failed to get JDBC provider name from id caught exception Exc. Value is: <Exception Message>.

Explanation: An Exception occurred whilst trying to determine the list of JDBC providers for the server.

User Response: Retry the deployment of UDDI. If the error persists, examine the Exception information on its cause. If the problem cannot be resolved, contact the IBM Customer Service Center.

CWUDD6007E: Attempt to create a Cloudscape JDBC provider caught exception Exc. Value is: <Exception Message>.

Explanation: A Cloudscape JDBC provider is required for the default deployment of UDDI and an Exception occurred whilst trying to create this JDBC provider.

User Response: Retry the deployment of UDDI. If the error persists, examine the Exception information on its cause. If the problem cannot be resolved, contact the IBM Customer Service Center.

CWUDD6008E: Failed to create datasource caught exception Exc. Value is: <Exception Message>.

Explanation: An Exception occurred whilst trying to create the UDDI Cloudscape datasource.

User Response: Retry the deployment of UDDI. If the error persists, examine the Exception information on its cause. If the problem cannot be resolved, contact the IBM Customer Service Center.

CWUDD6009E: Failed to create resource property set caught exception Exc. Value is: <Exception Message>.

Explanation: An Exception occurred whilst trying to J2EEResourcePropertySet.

User Response: Retry the deployment of UDDI. If the error persists, examine the Exception information on its cause. If the problem cannot be resolved, contact the IBM Customer Service Center.

CWUDD6010E: Failed to create ’databaseName’ resource property caught exception Exc. Value is: <Exception Message>.

Explanation: An Exception occurred whilst trying to create the J2EE Resource Property ’databaseName’.

User Response: Retry the deployment of UDDI. If the error persists, examine the Exception information on its cause. If the problem cannot be resolved, contact the IBM Customer Service Center.

CWUDD6011E: Failed to create ’shutdownDatabase’ resource property caught exception Exc. Value is: <Exception Message>.

Explanation: An Exception occurred whilst trying to create the J2EE Resource Property ’shutdownDatabase’.

User Response: Retry the deployment of UDDI. If the error persists, examine the Exception information on its cause. If the problem cannot be resolved, contact the IBM Customer Service Center.

CWUDD6012E: Failed to create ’datasourceName’ resource property caught exception Exc. Value is: <Exception Message>.

Explanation: An Exception occurred whilst trying to create the J2EE Resource Property ’datasourceName’.

User Response: Retry the deployment of UDDI. If the error persists, examine the Exception information on its cause. If the problem cannot be resolved, contact the IBM Customer Service Center.

CWUDD6013E: Failed to create ’description’ resource property caught exception Exc. Value is: <Exception Message>.

Explanation: An Exception occurred whilst trying to create the J2EE Resource Property ’description’.

User Response: Retry the deployment of UDDI. If the error persists, examine the Exception information on its cause. If the problem cannot be resolved, contact the IBM Customer Service Center.

CWUDD6014E: Failed to create ’connectionAttributes’ resource property caught exception Exc. Value is: <Exception Message>.

Explanation: An Exception occurred whilst trying to create the J2EE Resource Property ’connectionAttributes’.

User Response: Retry the deployment of UDDI. If the error persists, examine the Exception information on its cause. If the problem cannot be resolved, contact the IBM Customer Service Center.

CWUDD6015E: Failed to create ’createDatabase’ resource property caught exception Exc. Value is: <Exception Message>.

Explanation: An Exception occurred whilst trying to create the J2EE Resource Property ’createDatabase’.

User Response: Retry the deployment of UDDI. If the error persists, examine the Exception information on its cause. If the problem cannot be resolved, contact the IBM Customer Service Center.

CWUDD6016E: Attempt to locate the WebSphere Installation Directory failed.

Explanation: The installation directory of WebSphere Application Server could not be determined.

User Response: Verify that WebSphere Application Server has been correctly installed and that the **WAS_INSTALL_ROOT** WebSphere environment variable exists in the configuration.

CWUDD6017E: Uninstall of application appname caught exception Exc. Values are: <Application Name> <Exception Message>.

Explanation: An Exception occurred whilst trying to uninstall an existing UDDI application.

User Response: This message is self-explanatory.

CWUDD6018E: Install of UDDI application caught exception Exc. Value is: <Exception Message>.

Explanation: An Exception occurred whilst trying to install the UDDI application.

User Response: Retry the deployment of UDDI. If the error persists, examine the Exception information on its cause. If the problem cannot be resolved, contact the IBM Customer Service Center.

CWUDD6019E: Attempt to find application classloader failed with exception Exc. Value is: <Exception Message>.

Explanation: An Exception occurred whilst trying to locate the classloader for the UDDI application.

User Response: Retry the deployment of UDDI. If the error persists, examine the Exception information on its cause. If the problem cannot be resolved, contact the IBM Customer Service Center.

CWUDD6020E: Attempt to read current classloader mode failed with exception Exc. Value is: <Exception Message>.

Explanation: An Exception occurred whilst trying to determine the classloader mode of the UDDI application.

User Response: Retry the deployment of UDDI. If the error persists, examine the Exception information on its cause. If the problem cannot be resolved, contact the IBM Customer Service Center.

CWUDD6021E: Attempt to modify classloader mode to newmode failed with exception Exc. Values are: <Classloader Mode> <Exception Message>.

Explanation: An Exception occurred whilst trying to change the classloader mode of the UDDI application.

User Response: Retry the deployment of UDDI. If the error persists, examine the Exception information on its cause. If the problem cannot be resolved, contact the IBM Customer Service Center.

CWUDD6022E: Attempt to read new classloader mode failed with exception Exc. Value is: <Exception Message>.

Explanation: An Exception occurred whilst trying to verify the new classloader mode of the UDDI application.

User Response: Retry the deployment of UDDI. If the error persists, examine the Exception information on its cause. If the problem cannot be resolved, contact the IBM Customer Service Center.

CWUDD6023E: Attempt to read module list from application failed with exception Exc. Value is: <Exception Message>.

Explanation: An Exception occurred whilst trying to determine the list of modules held in the UDDI application.

User Response: Retry the deployment of UDDI. If the error persists, examine the Exception information on its cause. If the problem cannot be resolved, contact the IBM Customer Service Center.

CWUDD6024E: Attempt to locate URI attribute on module failed with exception Exc. Value is: <Exception Message>.

Explanation: An Exception occurred whilst trying to determine the URI attribute of the application module.

User Response: Retry the deployment of UDDI. If the error persists, examine the Exception information on its cause. If the problem cannot be resolved, contact the IBM Customer Service Center.

CWUDD6025E: Attempt to read current classloader mode from module failed with exception Exc. Value is: <Exception Message>.

Explanation: An Exception occurred whilst trying to determine the classloader mode of a UDDI module.

User Response: Retry the deployment of UDDI. If the error persists, examine the Exception information on its cause. If the problem cannot be resolved, contact the IBM Customer Service Center.

CWUDD6026E: Attempt to modify module classloader mode to newmode failed with exception Exc. Values are: <Classloader Mode> <Exception Message>.

Explanation: An Exception occurred whilst trying to change the classloader mode of a UDDI module.

User Response: Retry the deployment of UDDI. If the error persists, examine the Exception information on its cause. If the problem cannot be resolved, contact the IBM Customer Service Center.

CWUDD6027E: Attempt to read new module classloader mode failed with exception Exc. Value is: <Exception Message>.

Explanation: An Exception occurred whilst trying to verify the new classloader mode of a UDDI module.

User Response: Retry the deployment of UDDI. If the error persists, examine the Exception information on its cause. If the problem cannot be resolved, contact the IBM Customer Service Center.

CWUDD6028E: Attempt to create default UDDI Registry Cloudscape database failed with exception Exc. Value is: <Exception Message>.

Explanation: An Exception occurred whilst trying to create the default Cloudscape database.

User Response: Refer to messages displayed during creation to determine cause. If the problem cannot be resolved, contact the IBM Customer Service Center.

CWUDD6029E: Attempt to locate the Nodes Variable Map failed with exception Exc. Value is: <Exception Message>.

Explanation: An Exception occurred whilst trying to locate the configurations Variable Map for the given node.

User Response: Retry the deployment of UDDI. If the error persists, examine the Exception information on its cause. If the problem cannot be resolved, contact the IBM Customer Service Center.

CWUDD6030E: Error saving configuration, changes not saved due to exception Exc. Value is: <Exception Message>.

Explanation: An Exception occurred whilst trying to save the configuration after creating default datasource and removing an existing UDDI application.

User Response: Retry the deployment of UDDI. If the error persists, examine the Exception information on its cause. If the problem cannot be resolved, contact the IBM Customer Service Center.

CWUDD6031E: Error saving configuration, changes not saved due to exception Exc. Value is: <Exception Message>.

Explanation: An Exception occurred whilst trying to save the configuration after installing the UDDI application.

User Response: Retry the deployment of UDDI. If the error persists, examine the Exception information on its cause. If the problem cannot be resolved, contact the IBM Customer Service Center.

CWUDD6032E: Error saving configuration, changes not saved due to exception Exc. Value is: <Exception Message>.

Explanation: An Exception occurred whilst trying to save the final configuration.

User Response: Retry the deployment of UDDI. If the error persists, examine the Exception information on its cause. If the problem cannot be resolved, contact the IBM Customer Service Center.

CWUDD6033E: Incorrect argument passed to script.

Explanation: The wrong argument was passed to the script. Arguments are Node Name, Server Name, and optionally the **default** keyword.

User Response: Retry with the correct arguments.

CWUDD6034E: 'default' keyword is not allowed in a WebSphere Application Server Network Deployment configuration.

Explanation: A default Cloudscape UDDI Registry is not permitted in a WebSphere Application Server Network Deployment configuration. Please follow the UDDI Installation instructions on how to create a non default UDDI Registry database.

User Response: Retry with the correct arguments.

CWUDD7001E: Incorrect number of arguments passed to script.

Explanation: The wrong number of arguments were passed to the script. Arguments are Node Name, and optionally the **default** keyword.

User Response: Retry with the correct arguments.

CWUDD7002E: Usage is: <Command format description>.

Explanation: The removal script has not been called with the correct arguments.

User Response: Retry with the correct arguments.

CWUDD7003E: Failed to determine server ID caught exception Exc. Value is: <Exception Message>.

Explanation: An Exception occurred whilst trying to determine the Server ID.

User Response: Retry the removal of UDDI. If the error persists, examine the Exception information on its cause. If the problem cannot be resolved, contact the IBM Customer Service Center.

CWUDD7004E: Failed to determine server ID, possibly due to invalid nodename or servername (check case).

Explanation: The Server ID could not be located for the given node name and server name.

User Response: Check the node name and server name are correct and are in the correct case.

CWUDD7005E: Uninstall of application appname caught exception Exc. Values are: <Application Name> <Exception Message>.

Explanation: An Exception occurred whilst trying to uninstall the UDDI application.

User Response: Retry the removal of UDDI. If the error persists, examine the Exception information on its cause. If the problem cannot be resolved, contact the IBM Customer Service Center.

CWUDD7006E: Failed to remove default UDDI datasource caught exception Exc. Value is: <Exception Message>.

Explanation: An Exception occurred whilst trying to remove the UDDI Cloudscape datasource.

User Response: Retry the removal of UDDI. If the error persists, examine the Exception information on its cause. If the problem cannot be resolved, contact the IBM Customer Service Center.

CWUDD7007E: Error saving configuration, changes not saved due to exception Exc. Value is: <Exception Message>.

Explanation: An Exception occurred whilst trying to save the final configuration.

User Response: Retry the removal of UDDI. If the error persists, examine the Exception information on its cause. If the problem cannot be resolved, contact the IBM Customer Service Center.

CWUDD7008E: Incorrect argument passed to script.

Explanation: The wrong argument was passed to the script. Arguments are Node Name, Server Name, and optionally the **default** keyword.

User Response: Retry with the correct arguments.

CWUDD7009E: 'default' keyword is not allowed in a WebSphere Application Server Network Deployment configuration.

Explanation: A default Cloudscape UDDI Registry is not permitted in a WebSphere Application Server Network Deployment configuration. Therefore there is no default Cloudscape UDDI datasource to remove.

User Response: Retry with the correct arguments.

CWUDMnnnns (Web Services UDDI Management Interface) messages:

CWUDM0001E: Unexpected error in MBean operation: <operation name>

Explanation: An internal error occurred processing the specified UddiNode MBean operation.

User Response: Check database connectivity and UDDI application installation configuration. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0002E: MBean transaction failed. Commit flag was: <true|false>

Explanation: Failed to commit or rollback the current transaction.

User Response: Check database connectivity and UDDI application installation configuration. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0003E: MBean transaction did not begin.

Explanation: Failed to invoke begin method on the UserTransaction.

User Response: Check database connectivity and UDDI application installation configuration. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0004E: MBean transaction connection failed to release.

Explanation: Failed to release connection after transaction committed or rolled back.

User Response: Check database connectivity and UDDI application installation configuration. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0005E: MBean could not establish control with persistence manager.

Explanation: Message is self-explanatory.

User Response: Check database connectivity and UDDI application installation configuration. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0006E: MBean could not acquire connection for UDDI datasource.

Explanation: Message is self-explanatory.

User Response: Check database connectivity and UDDI application installation configuration. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0007E: UddiNode MBean with ObjectName <ObjectName value> could not be recognized.

Explanation: The UddiNode MBean for the UDDI application could not be unregistered from the MBeanServer.

User Response: Restart the UDDI application or the application server. If the problem cannot be resolved, contact your IBM Customer Service Center, supplying the ObjectName value reported in the message (if present).

CWUDM0008W: MBean notification for event <notification identifier> failed.

Explanation: Message is self-explanatory.

User Response: Check database connectivity and UDDI application installation configuration. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0009W: A UddiNode MBean is already registered.

Explanation: There is a UddiNode MBean registered in the same cell, node and server.

User Response: Ensure there is only one UDDI application deployed in the server. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0020E: Unable to retrieve UDDI node ID.

Explanation: A database error occurred.

User Response: Check database connectivity and UDDI application installation configuration. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0021E: Unable to retrieve UDDI node state.

Explanation: A database error occurred.

User Response: Check database connectivity and UDDI application installation configuration. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0022E: Unable to retrieve UDDI node application name.

Explanation: A database error occurred.

User Response: Check database connectivity and UDDI application installation configuration. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0023E: Unable to retrieve UDDI node description.

Explanation: A database error occurred.

User Response: Check database connectivity and UDDI application installation configuration. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0024E: Unable to activate UDDI node.

Explanation: An error occurred trying to activate the UDDI node.

User Response: Check the running state of the UDDI application. Restart the application if necessary. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0025I: Unable to activate a UDDI node that is not initialized.

Explanation: The UDDI node must be initialized (and in deactivated state) before it can be activated.

User Response: If the UDDI node is ready to be initialized, invoke the initialization operation.

CWUDM0026E: Unable to deactivate UDDI node.

Explanation: An error occurred trying to deactivate the UDDI node.

User Response: Check the running state of the UDDI application. Restart the application if necessary. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0027I: Unable to deactivate UDDI node that is not initialized.

Explanation: The UDDI node must be initialized (and activated) before it can be deactivated.

User Response: If the UDDI node is ready to be initialized, invoke the initialization operation.

CWUDM0028E: Unable to initialize UDDI node.

Explanation: An error occurred during UDDI node initialization.

User Response: Check the UDDI application installation and datasource settings. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0029I: Unable to initialize UDDI node because a required property is missing or invalid: <property name>.

Explanation: A configuration property that is required for UDDI node initialization has not been populated.

User Response: Supply a value for the required property.

CWUDM0030I: Initialize operation did not occur because the UDDI node is already initialized.

Explanation: A UDDI node can only be initialized once.

User Response: None.

CWUDM0031I: Initialize operation did not occur because the UDDI node is in default configuration and is already initialized.

Explanation: A UDDI node can only be initialized once.

User Response: None.

CWUDM0032I: The initialize operation is already in progress.

Explanation: A UDDI node can only be initialized once.

User Response: Wait until the current initialization operation completes.

CWUDM0050I: The UDDI publisher with user name <user ID> does not exist.

Explanation: An operation that requires a UDDI publisher ID could not find a publisher with that ID.

User Response: Check the UDDI publisher is registered with the UDDI node using the administrative functions available.

CWUDM0051E: Unable to create UDDI publisher with user name <user ID>.

Explanation: An error occurred trying to register the UDDI publisher.

User Response: Check UDDI application configuration and database connectivity. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0052I: Unable to create UDDI publisher for user name <user ID> because a UDDI publisher with that name already exists.

Explanation: The UDDI publisher is already registered.

User Response: None.

CWUDM0053E: Unable to delete UDDI publisher with user name <user ID>.

Explanation: An error occurred trying to register the UDDI publisher.

User Response: Check UDDI application configuration and database connectivity. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0054I: Unable to delete UDDI publisher with user name <user ID> because that UDDI publisher does not exist.

Explanation: The UDDI publisher is not registered so cannot be removed.

User Response: None.

CWUDM0055E: Unable to create a UDDI publisher with user name <user ID> because one or more entitlement identifiers are invalid.

Explanation: UddiUser objects must contain Entitlement objects with valid entitlement IDs.

User Response: Use valid entitlement IDs for Entitlement objects. Valid IDs can be found in the EntitlementConstants interface.

CWUDM0056E: Unable to update UDDI publisher with user name <user ID>.

Explanation: An error occurred trying to update the UDDI publisher.

User Response: Check UDDI application configuration and database connectivity. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0057E: Unable to update UDDI publisher with user name <user ID> because one or more entitlement identifiers are invalid.

Explanation: UddiUser objects must contain Entitlement objects with valid entitlement IDs.

User Response: Use valid entitlement IDs for Entitlement objects. Valid IDs can be found in the EntitlementConstants interface.

CWUDM0058I: Unable to update the UDDI publisher with user name <user ID> because that UDDI publisher does not exist.

Explanation: The UDDI publisher is not registered so cannot be updated.

User Response: None.

CWUDM0059E: Unable to retrieve information for UDDI publisher with user name <user ID>.

Explanation: A database error occurred performing the operation.

User Response: Check UDDI application configuration and database connectivity. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0060E: Unable to retrieve collection of UDDI publishers.

Explanation: A database error occurred performing the operation.

User Response: Check UDDI application configuration and database connectivity. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0061E: Unable to get tier assigned to UDDI publisher with user name <user ID>.

Explanation: This may be because the UDDI publisher with the specified user name does not exist, or because a database error occurred performing the operation.

User Response: Check the UDDI publisher exists. If it does, check UDDI application configuration and database connectivity. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0062E: Unable to create UDDI publishers with user names: <user IDs>.

Explanation: A database error occurred performing the operation.

User Response: Check UDDI application configuration and database connectivity. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0070E: Unable to create tier with ID: <tier ID>.

Explanation: A database error occurred performing the operation.

User Response: Check UDDI application configuration and database connectivity. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0071E: Unable to delete tier with ID: <tier ID>.

Explanation: This may because the tier with the specified ID does not exist, or because a database error occurred performing the operation.

User Response: Check the tier ID. If it does exist, check UDDI application configuration and database connectivity. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0072E: Unable to retrieve information for tier with ID: <tier ID>.

Explanation: This may be because the supplied tier ID is not an integer, or the tier with the ID does not exist, or because of a database error performing the operation.

User Response: Check the tier ID is an integer and the tier exists. If it does exist, check UDDI application configuration and database connectivity. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0073E: Unable to retrieve collection of tiers.

Explanation: A database error occurred performing the operation.

User Response: Check UDDI application configuration and database connectivity. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0074E: Unable to set default tier to tier ID: <tier ID>.

Explanation: This may be because the tier with the specified ID does not exist, or because a database error occurred performing the operation.

User Response: Check the tier ID. If it does exist, check UDDI application configuration and database connectivity. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0075E: Unable to update tier with ID: <tier ID>.

Explanation: This is most likely because the tier with the specified ID does not exist, or because a database error occurred performing the operation.

User Response: Check the tier ID. If it does exist, check UDDI application configuration and database connectivity. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0076E: Unable to get count of UDDI publishers for tier ID: <tier ID>.

Explanation: This may be because the tier with the specified ID does not exist, or because a database error occurred performing the operation.

User Response: Check the tier ID. If it does exist, check UDDI application configuration and database connectivity. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0077E: Unable to retrieve collection of entitlements.

Explanation: A database error occurred performing the operation.

User Response: Check UDDI application configuration and database connectivity. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0078E: Unable to retrieve collection of limits.

Explanation: A database error occurred performing the operation.

User Response: Check UDDI application configuration and database connectivity. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0079I: The default tier cannot be deleted.

Explanation: A tier must always exist that is designated as the tier assigned to UDDI publishers when auto-registration of UDDI publishers is enabled.

User Response: None.

CWUDM0080I: Unable to delete tier <tier ID> because it is currently assigned to a UDDI publisher.

Explanation: Tiers which have UDDI publishers assigned to them cannot be deleted.

User Response: If you want to remove the tier, assign the UDDI publishers to a different tier first.

CWUDM0100E: Unable to get configuration property information for property with ID: <property ID>

Explanation: A database error occurred performing the operation.

User Response: Check UDDI application configuration and database connectivity. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0101I: Unable to get configuration property information for property with ID: <property ID> because it does not exist.

Explanation: The configuration property with the specified ID does not exist.

User Response: None.

CWUDM0102E: Unable to retrieve collection of configuration properties.

Explanation: A database error occurred performing the operation.

User Response: Check UDDI application configuration and database connectivity. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0103E: Unable to update configuration properties.

Explanation: This may occur if any of the updated property objects fails validation. Check any cause exceptions for possible additional information. Alternatively database error may have occurred performing the operation.

User Response: Check UDDI application configuration and database connectivity. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0104E: Unable to update configuration property with ID: <property ID>

Explanation: This may occur if the updated property object fails validation. Check any cause exceptions for possible additional information. Alternatively a database error may have occurred performing the operation.

User Response: Check UDDI application configuration and database connectivity. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0105I: Unable to update configuration property with ID: <property ID> because it does not exist.

Explanation: The configuration property with the specified ID does not exist.

User Response: Use a valid configuration property ID. These can be found in PropertyConstants.

CWUDM0106I: Unable to update configuration properties because one or more properties do not exist in the UDDI node.

Explanation: One or more supplied configuration properties do not exist in the UDDI registry.

User Response: Use valid configuration property IDs. These can be found in PropertyConstants.

CWUDM0107E: Failed to retrieve required properties from database.

Explanation: This indicates a database error occurred when trying to initialize a UDDI node.

User Response: Check UDDI application configuration and database connectivity. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0120E: Unable to get policy information for policy with ID: <policy ID>.

Explanation: A database error occurred performing the operation.

User Response: Check UDDI application configuration and database connectivity. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0121I: Unable to get policy information for policy with ID: <policy ID> because it does not exist.

Explanation: The policy with the specified ID does not exist.

User Response: None.

CWUDM0122E: Unable to get policy group with group ID: <policy group ID>.

Explanation: A database error occurred performing the operation.

User Response: Check UDDI application configuration and database connectivity. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0123E: Unable to retrieve collection of policy groups.

Explanation: A database error occurred performing the operation.

User Response: Check UDDI application configuration and database connectivity. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0124E: Unable to update policies.

Explanation: This may occur if any of the updated policy objects fails validation. Check any cause exceptions for possible additional information. Alternatively a database error may have occurred performing the operation.

User Response: Ensure all policy IDs and values are valid. Check UDDI application configuration and database connectivity. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0125E: Unable to update policy with ID: <policy ID>.

Explanation: This may occur if the updated policy object fails validation or the ID isn't recognized. Check any cause exceptions for possible additional information. Alternatively a database error may have occurred performing the operation.

User Response: Check the policy ID and value are valid. Check UDDI application configuration and database connectivity. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0126I: Unable to get policy group information for policy group with ID: <policy group ID> because itdoes not exist.

Explanation: The policy group with the specified ID does not exist.

User Response: Use a valid policy group ID. These can be found in PolicyConstants.

CWUDM0127I: Unable to update policies because one or more policies do not exist in the UDDI node.

Explanation: One or more supplied policies do not exist in the UDDI registry.

User Response: Use valid policy IDs. These can be found in PolicyConstants.

CWUDM0128I: Unable to update policy with ID: <policy ID> because it does not exist.

Explanation: The policy with the specified ID does not exist.

User Response: Use a valid policy ID. These can be found in PolicyConstants.

CWUDM0140E: Unable to change value set tModelKey from <original tModel key> to <new tModel key>. **Explanation:** The original tModel key or new tModel key supplied could not be found in the UDDI registry, or possibly there was a database error.

User Response: Supply keys for tModels that exist in the UDDI registry. Check UDDI application configuration and database connectivity. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0141E: Unable to retrieve value set details for tModel key: <tModel key>.

Explanation: A database error occurred getting the value set details.

User Response: Check UDDI application configuration and database connectivity. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0142E: Unable to get value set property: <value set property ID> for value set with tModel key: <tModel key>.

Explanation: The value set property ID or tModel key supplied was not recognized.

User Response: Supply a valid value set property ID and tModel key. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0143E: Unable to retrieve value sets collection.

Explanation: A database error may have occurred.

User Response: Check UDDI application configuration and database connectivity. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0144E: Unable to determine if value set with tModel key: <tModel key> exists.

Explanation: The tModel key supplied is not valid or a database error may have occurred.

User Response: Ensure the tModel exists. Check UDDI application configuration and database connectivity. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0145E: Unable to load value set data for value set with tModel key: <tModel key> and file name <1>.

Explanation: The original tModel key or new tModel key supplied could not be found in the UDDI registry, or possibly there was a database error.

User Response: Ensure the tModel exists and the value set data object is populated. Check UDDI application configuration and database connectivity. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0146E: Unable to load value set data for value set with tModel key: <tModel key>.

Explanation: The tModel key is not recognized or a database error occurred.

User Response: Ensure the tModel exists and the value set data object is populated. Check UDDI application configuration and database connectivity. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0147E: Could not update value set status with tModel key: <tModel key>.

Explanation: The value set status object supplied is null or the tModel key is not known.

User Response: Supply a valid value set status object with tModel key for a value set tModel that exists. Check UDDI application configuration and database connectivity. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0148E: Could not update value set status with tModel key: <tModel key>, property: <value set property ID>.

Explanation: A database error occurred updating the supported status of the value set status.

User Response: Check UDDI application configuration and database connectivity. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0149E: Could not update value set status with tModel key: <tModel key>.

Explanation: One of the supplied value set status objects contained a tModel key which was not recognized.

User Response: Supply tModel keys for value set tModels that exist. Check UDDI application configuration and database connectivity. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0150E: Could not update value set status with tModel key: <tModel key>, property: <value set property ID>.

Explanation: A database error occurred updating the supported status of one of the value set status objects.

User Response: Check UDDI application configuration and database connectivity. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0151E: Unable to unload value set data with tModel key: <tModel key>.

Explanation: The tModel key is not recognized or a database error occurred.

User Response: Ensure the tModel exists. Check UDDI application configuration and database connectivity. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0170E: Loading of configuration file <configuration file URL> failed.

Explanation:

User Response: Check UDDI application configuration. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0171E: Parsing of configuration file <configuration file URL> failed.

Explanation:

User Response: Check UDDI application configuration. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0172W: An unexpected date format was found while parsing configuration file.

Explanation:

User Response: Check UDDI application configuration. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0180I: UDDI node was activated.

Explanation: The UDDI node is ready to accept UDDI API requests.

User Response: None.

CWUDM0181I: UDDI node was deactivated.

Explanation: The UDDI node is set to not accept UDDI API requests. This typically occurs when configuration settings are being updated by administrative tasks.

User Response: None.

CWUDM0182I: UDDI node initialized successfully.

Explanation: The UDDI node is ready to accept UDDI API requests.

User Response: None.

CWUDM0183I: UDDI publisher <user ID> was created.

Explanation: This message indicates the administrative operation completed successfully.

User Response: None.

CWUDM0184I: UDDI publisher <user ID> was updated.

Explanation: This message indicates the administrative operation completed successfully.

User Response: None.

CWUDM0185I: UDDI publisher <user ID> was deleted.

Explanation: This message indicates the administrative operation completed successfully.

User Response: None.

CWUDM0186I: Tier <tier ID> was created.

Explanation: This message indicates the administrative operation completed successfully.

User Response: None.

CWUDM0187I: Tier <tier ID> was updated.

Explanation: This message indicates the administrative operation completed successfully.

User Response: None.

CWUDM0188I: Tier <tier ID> was deleted.

Explanation: This message indicates the administrative operation completed successfully.

User Response: None.

CWUDM0189I: Configuration property <property ID> was updated to value <property value>.

Explanation: This message indicates the administrative operation completed successfully.

User Response: None.

CWUDM0190I: Policy <policy ID> was updated to value <policy value>.

Explanation: This message indicates the administrative operation completed successfully.

User Response: None.

CWUDM0191I: Default tier was set to <tier ID>.

Explanation: This message indicates the administrative operation completed successfully.

User Response: None.

CWUDM0192I: Loaded value set for tModel key <tModel key> from file <1>.

Explanation: This message indicates the administrative operation completed successfully.

User Response: None.

CWUDM0193I: Loaded value set for tModel key <tModel key>.

Explanation: This message indicates the administrative operation completed successfully.

User Response: None.

CWUDM0194I: Unloaded value set for tModel key <tModel key>.

Explanation: This message indicates the administrative operation completed successfully.

User Response: None.

CWUDM0195I: Updated value set supported status for tModel key <tModel key> to <supported status>.

Explanation: This message indicates the administrative operation completed successfully.

User Response: None.

CWUDM0196I: Changed tModel key for value set from <original tModel key> to <new tModel key>.

Explanation: This message indicates the administrative operation completed successfully.

User Response: None.

CWUDM0220W: <value or ID> is too short. The length must be in the range <minimum length> to <maximum length> characters.

Explanation: A value or ID of type String is shorter than expected.

User Response: Supply a value or ID that is in the expected range.

CWUDM0221W: <value or ID> is too long. The length must be in the range <minimum length> to <maximum length> characters.

Explanation: A value or ID of type String is longer than expected.

User Response: Supply a value or ID that is in the expected range.

CWUDM0222W: <value or ID> is read-only and cannot be updated.

Explanation: The configuration setting is marked as read only, which may be because the setting is for information only, or because the setting is configured once during UDDI node initialization, such as the UDDI node ID or root key generator.

User Response: None.

CWUDM0223W: <value or ID> is required.

Explanation: The configuration setting expects a value to be entered.

User Response: Supply a non-empty, valid value for the configuration setting.

CWUDM0224W: <value or ID> must be a valid URL value.

Explanation: The configuration property is expected to be a valid URL.

User Response: Supply a valid URL.

CWUDM0225W: <value or ID> must be a valid xml:lang value.

Explanation: The configuration property supplied is not a valid xml:lang value.

User Response: Supply a valid xml:lang value.

CWUDM0226W: <value or ID> must be of type: <value type>.

Explanation: The value or ID is not of the expected type.

User Response: Supply a value or ID of the correct type.

CWUDM0227W: <value or ID> cannot be a null value.

Explanation: A property ID was expected but a null value was supplied.

User Response: Supply a valid, non-null ID.

CWUDM0228W: <value or ID> must be in the range <minimum value> to <maximum value>.

Explanation: The value is not in the expected range

User Response: Supply a value in the expected range.

CWUDM0229W: The entitlement object with ID: <entitlement ID> is not valid.

Explanation: The UDDI application doesn't recognize the entitlement with the supplied ID.

User Response: Supply a valid entitlement ID, which can be found in EntitlementConstants.

CWUDM0230W: The limit object with ID: <limit ID> is not valid.

Explanation: The UDDI application doesn't recognize the limit with the supplied ID.

User Response: Supply a valid limit ID, which can be found in LimitConstants.

CWUDM0231W: <value> must be a valid UDDI key value.

Explanation: The value supplied was not a UDDI key.

User Response: UDDI keys must start with the text 'uddi:'. See the UDDI specification for further information about UDDI keys.

CWUDM0232W: <value> must be a valid UDDI key generator key.

Explanation: The value supplied was not a UDDI key generator.

User Response: UDDI key generator values must be valid UDDI keys and end in the string 'keygenerator'. See the UDDI specification for further information about UDDI keys.

CWUDM0240W: The configuration property ID cannot be null or empty.

Explanation: The ID supplied was null or empty.

User Response: Supply a non-null, non-empty ID, valid for the context in which it is used.

CWUDM0241W: The policy group ID cannot be null or empty.

Explanation: The ID supplied was null or empty.

User Response: Supply a non-null, non-empty ID, valid for the context in which it is used.

CWUDM0242W: The policy ID cannot be null or empty.

Explanation: The ID supplied was null or empty.

User Response: Supply a non-null, non-empty ID, valid for the context in which it is used.

CWUDM0243W: The entitlement ID cannot be null or empty.

Explanation: The ID supplied was null or empty.

User Response: Supply a non-null, non-empty ID, valid for the context in which it is used.

CWUDM0244W: The limit ID cannot be null or empty.

Explanation: The ID supplied was null or empty.

User Response: Supply a non-null, non-empty ID, valid for the context in which it is used.

CWUDM0245W: The user ID cannot be null or empty.

Explanation: The ID supplied was null or empty.

User Response: Supply a non-null, non-empty ID, valid for the context in which it is used.

CWUDM0246W: The tier ID cannot be null or empty.

Explanation: The ID supplied was null or empty.

User Response: Supply a non-null, non-empty ID, valid for the context in which it is used.

CWUDM0250W: The configuration property parameter cannot be null or empty.

Explanation: The parameter supplied was null or empty.

User Response: Supply a non-null, non-empty configuration property parameter.

CWUDM0251W: The policy group parameter cannot be null or empty.

Explanation: The parameter supplied was null or empty.

User Response: Supply a non-null, non-empty policy group parameter.

CWUDM0252W: The policy parameter cannot be null or empty.

Explanation: The parameter supplied was null or empty.

User Response: Supply a non-null, non-empty policy parameter.

CWUDM0253W: The entitlement parameter cannot be null or empty.

Explanation: The parameter supplied was null or empty.

User Response: Supply a non-null, non-empty entitlement parameter.

CWUDM0254W: The limit parameter cannot be null or empty.

Explanation: The parameter supplied was null or empty.

User Response: Supply a non-null, non-empty limit parameter.

CWUDM0255W: The user parameter cannot be null or empty.

Explanation: The parameter supplied was null or empty.

User Response: Supply a non-null, non-empty user (UDDI publisher) parameter.

CWUDM0256W: The tier parameter cannot be null or empty.

Explanation: The parameter supplied was null or empty.

User Response: Supply a non-null, non-empty tier parameter.

CWUDM0257I: The collection cannot be null.

Explanation: The collection (typically a list of properties, policies, tiers or users to update) parameter supplied was null.

User Response: Supply a non-null collection parameter.

CWUDNnnnns (Web Services UDDI Node Manager) messages:

CWUDN0001I: UDDI Node State change, new state:

Explanation: The UDDI has successfully changed to the identified new state.

User Response: None.

CWUDN0002I: Error, invalid Node State requested:

Explanation: The UDDI Registry detected a request for invalid state changes.

User Response: Contact the IBM Customer Service Center.

CWUDN0004E: Error, NodeManager, txnInit, failed getting persister control

Explanation: NodeManager initialization failure.

User Response: Contact the IBM Customer Service Center.

CWUDN0005E: Error, NodeManager, txnIInit, UDDIFatalErrorException during Init

Explanation: NodeManager initialization failure.

User Response: Contact the IBM Customer Service Center.

CWUDN0006E: Error, NodeManager, txnIInit, UDDIException during initialization.

Explanation: NodeManager initialization failure.

User Response: Contact the IBM Customer Service Center.

CWUDN0007E: Error, NodeManager, txnIInit, Exception during Init

Explanation: NodeManager initialization failure.

User Response: Contact the IBM Customer Service Center.

CWUDN0008E: Error, NodeManager, txnIInit, Throwable during Init

Explanation: NodeManager initialization failure.

User Response: Contact the IBM Customer Service Center.

CWUDN0009E: Error, NodeManager, txnIInit, rollback exception

Explanation: NodeManager initialization failure.

User Response: Contact the IBM Customer Service Center.

CWUDN0010E: Error, NodeManager, txnlInit, Throwable releasing connection

Explanation: NodeManager initialization failure.

User Response: Contact the IBM Customer Service Center.

CWUDN0011E: Error, NodeManager, txnlDestroy, failed getting Persister control

Explanation: NodeManager application stop or removal error.

User Response: Contact the IBM Customer Service Center.

CWUDN0012E: Error, NodeManager, txnlDestroy, UDDI Exception during destroy

Explanation: NodeManager application stop or removal error.

User Response: Contact the IBM Customer Service Center.

CWUDN0013E: Error, NodeManager, txnlDestroy, rollback Exception

Explanation: NodeManager application stop or removal error.

User Response: Contact the IBM Customer Service Center.

CWUDN0014E: Error, NodeManager, txnlDestroy, Exception releasing connection

Explanation: NodeManager application stop or removal error.

User Response: Contact the IBM Customer Service Center.

CWUDQnnnns (Web Services UDDI Migration) messages:

CWUDQ0001I: UDDI registry migration datasource is present.

Explanation: The UDDI migration datasource is defined when UDDI is started.

User Response: None.

CWUDQ0002I: UDDI registry migration has started.

Explanation: The UDDI database migration process has started. This may take some time to complete dependent on the size of your database.

User Response: None.

CWUDQ0003I: UDDI registry migration has completed.

Explanation: The UDDI database migration process has finished.

User Response: None.

CWUDQ0004W: UDDI registry not started due to migration errors.

Explanation: The UDDI registry has not been activated because migration errors were encountered.

User Response: Examine the messages produced during the migration process. Determine if the problem is user fixable, that is the Version 2 database is quiesced and so on. If the problem is fixable recreate the Version 3 UDDI database and restart the UDDI application. If the problem cannot be rectified contact your IBM Customer Service Center. It is still possible to use the UDDI Administration Console to start the UDDI registry.

CWUDQ0005I: <rows> rows have been inserted into table <table>.

Explanation: An informational message showing the number of database rows converted for each UDDI table.

User Response: None.

CWUDQ10001E: Row not inserted into <table>.

Explanation: A row was unable to be inserted into a database table.

User Response: See CWUDQ1003E for details of the SQL Exception details

CWUDQ1002E: Table <table> values are: <Key Values>.

Explanation: Contains the table in error and the significant key values of the row being migrated.

User Response: None.

CWUDQ1003E: SQL Exception during migration: <SQL Exception Message>.

Explanation: An SQL Exception has occurred during the migration process. The SQL Exception details are displayed in the message.

User Response: Examine the SQL Exception information on its cause. Message CWUDQ1002E contains table details and significant key values. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDQ1004E: <rows> rows have not been inserted into table <table>.

Explanation: A message showing the number of database rows not converted for a particular UDDI table.

User Response: None.

CWUDQ1005E: SQL Exception during key value extraction: <SQL Exception Message>.

Explanation: An SQL Exception occurred during the production of the CWUDQ1002E message.

User Response: None.

CWUDQ1006E: Exception during migration: <Exception Message>.

Explanation: An Exception has occurred during the migration process. The Exception details are displayed in the message.

User Response: Examine the Exception information on its cause. Message CWUDQ1002E contains table details and significant key values. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDRnnnns (Web Services UDDI Logging and Tracing) messages:

CWUDR0001E: Exception "<exception>" occurred while attempting to get UDDI Message Logger.

Explanation: This message is issued to stderr when an attempt to get the UDDI Message Logger fails with the indicated exception. Since the attempt to get the message logger failed, the message cannot be logged. No messages can be logged by this instance of the IBM WebSphere UDDI Registry.

User Response: Restart the UDDI registry. If the error persists, examine the WebSphere logs for information on its cause. If the problem cannot be resolved, then contact the IBM Customer Service Center.

CWUDR0002E: Exception "<exception>" occurred while attempting to get UDDI Trace Logger for "<component>".

Explanation: This message is logged when an attempt to get the UDDI Trace Logger for the specified component (or package) fails with the indicated exception. No trace entries can be logged for this component or package of the IBM WebSphere UDDI Registry.

User Response: Restart the UDDI registry. If the error persists, examine the WebSphere logs for information on its cause. If the problem cannot be resolved, then contact the IBM Customer Service Center.

CWUDSnnnns (Web Services UDDI SOAP Interface) messages:

CWUDS0001E: ParserPool found empty whilst attempting to process request. Request unsatisfied

Explanation: A SOAP request was received, but was unable to be dealt with, as there were no free Parsers within the ParserPool.

User Response: Consider increasing the number of Parsers within the ParserPool by modifying the Init Parameter on the SOAP servlets.

CWUDS0002E: Error locating schemas required for UDDI processing. SOAP Servlets unworkable.

Explanation: The SOAP servlet was unable to locate the schemas it requires in order to process SOAP requests. Without these, the servlet cannot process SOAP requests.

User Response: Check installation of UDDI was performed correctly. If the error persists, examine the WebSphere logs for information on its cause. If the problem cannot be resolved, then contact the IBM Customer Service Center.

CWUDS0003W: Servlet unable to locate init parameter 'defaultPoolSize'. Using internal defaults.

Explanation: The SOAP servlet was unable to locate the init parameter which sets the default size of the ParserPool. It will fall back to an internal default.

User Response: If this message occurred after attempting to make changes to the defaultPoolSize init parameter, ensure the changes were correct. If this message has appeared after installed, ensure installation was performed correctly.

CWUDS0004W: Servlet unable to understand init parameter 'defaultPoolSize'. Using internal defaults.

Explanation: The SOAP servlet was unable to parse the init parameter which sets the default size of the ParserPool. It will fall back to an internal default.

User Response: If this message occurred after attempting to make changes to the defaultPoolSize init parameter, ensure the changes were correct. If this message has appeared after installed, ensure installation was performed correctly.

CWUDS0005E: Error occurred during parser creation.

Explanation: An unspecified error occurred during the creation of a SOAP parser

User Response: Restart the UDDI registry. If the error persists, examine the WebSphere logs for information on its cause. If the problem cannot be resolved, then contact the IBM Customer Service Center.

CWUDS0006E: Internal configuration error.

Explanation: This error may occur if there was a failure creating a Parser, with accompanying message CWUDS0005. It may also occur if there was a problem acquiring the Persistence layer.

User Response: Restart the UDDI registry. If the error persists, examine the WebSphere logs for information on its cause. If the problem cannot be resolved, then please contact the IBM Customer Service Center.

CWUDS0007E: Error during servlet acquisition of persistence layer.

Explanation: The SOAP servlet was unable to acquire the persistence layer required for it to communicate with the UDDI datasource

User Response: Restart the UDDI registry. If the error persists, examine the WebSphere logs for information on its cause. If the problem cannot be resolved, then contact the IBM Customer Service Center.

CWUDS0008E: Error during servlet release of persistence layer.

Explanation: The persistence layer reported a problem when the SOAP servlet attempted to release it.

User Response: Restart the UDDI registry. If the error persists, examine the WebSphere logs for information on its cause. If the problem cannot be resolved, then contact the IBM Customer Service Center.

CWUDS0009E: Error during sending of response to client.

Explanation: An error occurred when sending a SOAP response message back to a client. The client may not have received the response

User Response: This error is recorded to enable logging of failed responses to clients. The error may be the fault of the client disconnecting before the reply could be sent, or may indicate a network problem. Examine the WebSphere logs for more information on its cause.

CWUDGnnnns (Web Services UDDI User Console) messages:

CWUDG0001I: IBM WebSphere UDDI Registry user console starting initialization.

Explanation: The user console control servlet is starting.

User Response: None.

CWUDG0002I: IBM WebSphere UDDI Registry user console finished initialization.

Explanation: The user console control servlet has completed startup successfully.

User Response: None.

CWUDG0003I: Reading init parameters.

Explanation: The user console control servlet has started reading external parameters in its init method

User Response: None.

CWUDG0004I: Finished reading init parameters.

Explanation: The user console control servlet has finished reading external parameters in its init method. This message indicates the user console is ready to accept client requests.

User Response: None.

CWUDG0005E: A serious error has occurred. Error message: <Message> error: <Throwable>. More information: <Additional information>.

Explanation: This error message indicates an unexpected error has occurred. The <Message> describes the error that has occurred and the <Throwable> is the type of error that was caught. <Additional information> may provide further information, if available.

User Response: A trace of the gui component is recommended. Contact IBM support with this information.

CWUDG0006E: A persistence error has occurred. Error message: <Message> error: <Throwable>. More information: <Additional information>.

Explanation: An error occurred while performing a database operation. The <Message> describes the error that occurred and the <Throwable> is the type of error that was caught. <Additional information> may provide further information, if available.

User Response: Check database connections and state. Provide IBM support with a trace, including the gui and persistence components.

CWUDG0007E: A User mismatch error has occurred. Error message: <Message> error: <Throwable>. More information: <Additional information>.

Explanation: The user id provided does not match the user id required or expected whilst performing an operation that requires authentication. The <Message> describes the error that occurred and the <Throwable> is the type of error that was caught. <Additional information> may provide further information, if available.

User Response: Check the user has authority for the operation being requested. If necessary, contact IBM support detailing the actions taken to recreate the problem.

CWUDG0008E: An invalid key was passed. Error message: <Message> error: <Throwable>. More information: <Additional information>.

Explanation: The requested operation is trying to retrieve information about an entity with a key that is invalid. This may occur if the entity has been deleted by another session. The <Message> describes the error that occurred and the <Throwable> is the type of error that was caught. <Additional information> may provide further information, if available.

User Response: Ask the client to close existing sessions and attempt the operation in a new browser session. If the problem persists, contact IBM support with a trace of the gui and api components.

CWUDG0009E: An invalid value was supplied. Error message: <Message> error: <Throwable>. More information: <Additional information>

Explanation: An invalid value was passed to an API call. The <Message> describes the error that occurred and the <Throwable> is the type of error that was caught. <Additional information> may provide further information, if available.

User Response: Contact IBM support with a trace of the gui and api components.

CWUDG0010E: Failed to introspect ActionForm properties. Exception: <Exception>.

Explanation: String properties of a form object could not be introspected which means that the form contents cannot be checked for invalid characters.

User Response: Contact IBM support with details of the Exception and a trace of the gui component.

CWUDG0011E: Failed to invoke reflected methods in ActionForm. Exception: <Exception>.

Explanation: A form object's declared public method for setting or getting a String value could not be invoked. This method is required to check for invalid characters.

User Response: Contact IBM support with details of the Exception and a trace of the gui component.

CWUDG0012E: User console initialization failed to connect to UDDI database. Exception: <Exception>.

Explanation: During user console initialization, connection to the database failed, and threw the exception specified.

User Response: Check the connection to the UDDI database. The included exception message may yield some clues to help you resolve the problem. If unresolved, contact IBM support with a trace of the gui component during startup.

CWUDG0013E: User console initialization failed to initialize tModels. Exception: <Exception>.

Explanation: Indicates that an error has occurred during initialization of ActionServlet, specifically when reading tModels (invoking init method in class TModelNames).

User Response: Check the state of the UDDI database. Visually inspect the TMODEL table and confirm it is populated with valid data. The included exception message may yield some clues to help you resolve the problem. If unresolved, contact IBM support with a trace of the gui component during startup.

CWUDG0014E: User console initialization failed to initialize taxonomies. Exception: <Exception>.

Explanation: Indicates that an error has occurred during initialization of ActionServlet, specifically when reading taxonomy data (invoking init method of CategoryTaxonomyTree).

User Response: Check the state of the UDDI database. The included exception message may yield some clues to help you resolve the problem. If unresolved, contact IBM support with a trace of the gui component during startup.

CWUDUnnnns (Web Services UDDI Utility Tools) messages:

```
CWUDU0001I: Usage: java -jar UDDIUtilityTools.jar '{'function'}' [options]
function:
  -promote entity source   Promote entities between registries
  -export entity source    Extract entities from registry to XML
  -delete entity source    Delete entities from registry
  -import                  Create entities from XML to registry

where entity source is one of:
  -tmodel|-business|-service|-binding key Specify single entity type and key
  -keysFile | -f filename  Specify file containing entity types and keys

options:
  -properties filename     Specify path to configuration file
  -overwrite | -o          Overwrite an entity if it already exists
  -log | -v                Output verbose messages
  -definitionFile filename Specify path to UDDI entity definition file
  -importReferenced        Import entities referenced by source entities

The following options override property settings in configuration file:
  -overwrite
  -log
  -definitionFile
  -importReferenced

Example: java -jar UDDIUtilityTools.jar -promote -keysFile C:/uddikeys.txt
```

Explanation: This is the usage message displayed at the command line when the user has entered an invalid combination of arguments or options.

User Response: Enter the command according to the usage message.

CWUDU0002I: ******** Starting UDDI Utility Tools ************

Explanation: This message is used as a marker in the message log file to indicate tool start points.

User Response: None.

CWUDU0003I: Promoting entityType<entity type> key<entity key>...

Explanation: Indicates which entity type (business, tModel and so on) is being promoted, and it's key value.

User Response: None.

CWUDU0004I: Bad entityType: received<incorrect entity type>, expected <tModel|business|service|binding>

Explanation: The user entered an incorrect entity type.

User Response: Use an entity type of tModel, business, service or binding.

CWUDU0005I: Promotion successful.

Explanation: Indicates the promote function completed successfully.

User Response: None.

CWUDU0006I: Import successful.

Explanation: Indicates the import function completed successfully.

User Response: None.

CWUDU0007I: Export successful.

Explanation: Indicates the export function completed successfully.

User Response: None.

CWUDU0008I: Delete successful.

Explanation: Indicates the delete function completed successfully.

User Response: None.

CWUDU0009I: Exporting entities ...

Explanation: Indicates the export function has started.

User Response: None.

CWUDU0010I: Exporting business, businessKey[<business key].

Explanation: Indicates that the businessEntity with the specified key is being exported.

User Response: None.

CWUDU0011I: Exporting service, serviceKey[<service key>].

Explanation: Indicates that the businessService with the specified key is being exported.

User Response: None.

CWUDU0012I: Exporting binding, bindingKey[<binding key>].

Explanation: Indicates that the bindingTemplate with the specified key is being exported.

User Response: None.

CWUDU0013I: Exporting tModel, tModelKey[<tModel key>].

Explanation: Indicates that the tModel with the specified key is being exported.

User Response: None.

CWUDU0014I: Exporting referenced tModel, tModelKey[<tModel key>].

Explanation: Indicates that the referenced tModel with the specified key is being exported.

User Response: None.

CWUDU0015I: Exported <entity count> entities.

Explanation: Indicates that the export function completed, and shows the number of entities exported.

User Response: None.

CWUDU0016I: Importing entities ...

Explanation: Indicates the import function has started.

User Response: None.

CWUDU0017I: Importing business, businessKey[<business key>].

Explanation: Indicates that the businessEntity with the specified key is being imported.

User Response: None.

CWUDU0018I: Importing service, serviceKey[<service key>].

Explanation: Indicates that the businessService with the specified key is being imported.

User Response: None.

CWUDU0019I: Importing binding, bindingKey[<binding key>]

Explanation: Indicates that the bindingTemplate with the specified key is being imported.

User Response: None.

CWUDU0020I: Importing tModel, tModelKey[<tModel key>].

Explanation: Indicates that the tModel with the specified key is being imported.

User Response: None.

CWUDU0021I: Importing referenced tModel, tModelKey[<tModel key>].

Explanation: Indicates that the referenced tModel with the specified key is being imported.

User Response: None.

CWUDU0022I: Imported <entity count> entities.

Explanation: Indicates that the import function completed, and shows the number of entities imported.

User Response: None.

CWUDU0023I: Deleting entities ...

Explanation: Indicates the delete function has started.

User Response: None.

CWUDU0024I: Deleting business, businessKey[<business key>].

Explanation: Indicates that the businessEntity with the specified key is being deleted.

User Response: None.

CWUDU0025I: Deleting service, serviceKey[<service key>].

Explanation: Indicates that the businessService with the specified key is being deleted.

User Response: None.

CWUDU0026I: Deleting binding, bindingKey[<binding key>].

Explanation: Indicates that the bindingTemplate with the specified key is being deleted.

User Response: None.

CWUDU0027I: Deleting tModel, tModelKey[<tModel key>].

Explanation: Indicates that the tModel with the specified key is being deleted.

User Response: None.

CWUDU0028I: Deleted <entity count> entities.

Explanation: Indicates that the delete function completed, and shows the number of entities deleted.

User Response: None.

CWUDU0029I: Serializing ...

Explanation: Indicates that generation of the Entity Definition File has started.

User Response: None.

CWUDU0030I: Serialized entities.

Explanation: Indicates that generation of the Entity Definition File completed successfully.

User Response: None.

CWUDU0031I: Deserializing ...

Explanation: Indicates that reading of the Entity Definition File and creation of UDDI entities has started.

User Response: None.

CWUDU0032I: Deserialized entities.

Explanation: Indicates that reading of the Entity Definition File and creation of UDDI entities completed successfully.

User Response: None.

CWUDU0033I: Function '<function>' completed successfully.

Explanation: Indicates the requested function completed successfully.

User Response: None.

CWUDU0034W: Function '<function>' did not complete successfully. See messages log for further information.

Explanation: Indicates the requested function did not complete successfully.

User Response: The messages log may yield further information if the verbose option is on. Check the configuration properties file setting are correct. If that does not identify the problem, try running with trace logging enabled. If that does not yield a solution, contact your IBM support center.

CWUDU0035W: Parser error: <warning description>

Explanation: The XML parser reports a warning about the content of the Entity Definition File.

User Response: Based on the context of the warning message, check the validity of the Entity Definition File.

CWUDU0036E: Parser error <error description>

Explanation: The XML parser reports an error about the content of the Entity Definition File.

User Response: Based on the context of the error message, check the validity of the Entity Definition File.

CWUDU0037E: Unrecognized parser feature: <feature description>

Explanation: A parser feature set by the UDDI Utility Tools is not recognized by the parser.

User Response: Check you are using the correct type and level of XML parser. If correct, contact your IBM support center.

CWUDU0038E: Unsupported parser feature: <feature description>

Explanation: A parser feature set by the UDDI Utility Tools is not supported by the parser.

User Response: Check you are using the correct type and level of XML parser. If correct, contact your IBM support center.

CWUDU0039E: Unrecognized parser property: <property description>, value: <value>

Explanation: A parser property set by the UDDI Utility Tools is not recognized by the parser.

User Response: Check you are using the correct type and level of XML parser. If correct, contact your IBM support center.

CWUDU0040E: Unsupported parser property: <property description>, value: <value>

Explanation: A parser property set by the UDDI Utility Tools is not supported by the parser.

User Response: Check you are using the correct type and level of XML parser. If correct, contact your IBM support center.

CWUDU0042E: Unable to find the configuration file: <filepath>

Explanation: UDDI Utility Tools cannot locate the specified configuration file.

User Response: UDDI Utility Tools looks for a default configuration properties with the file name 'UDDIUtilityTools.properties' in the current directory. Check that the configuration file has this name, or that the argument value supplied with the '-properties' option is pointing at a file that exists.

CWUDU0043E: An Exception occurred trying to read the configuration file.

Explanation: The configuration file could not be read.

User Response: Check the file path points to a valid file and that the current user has permission to read the file.

CWUDU0044W: Configuration file is missing the '<property name>' property.

Explanation: A required property is missing from the configuration file.

User Response: Add the missing property name and value to the configuration file. Check that the property name is not misspelled.

CWUDU0045W: Property: ’<property name>’ has value ’<property value>’. It must be either ’true’ or ’false’.

Explanation: A value was given to a property other than ’true’ or ’false’.

User Response: Set the property value to ’true’ or ’false’.

CWUDU0046W: Property: ’<property name>’ has value ’<property value>’. It must be an integer value.

Explanation: A value was given to a property other than an integer value.

User Response: Set the property value to an integer value.

CWUDU0047E: Unable to find the keyFile file: <keys file path>

Explanation: The keys file could not be located at the specified path.

User Response: Check the file name and path and correct and that the file exists.

CWUDU0048E: Unable to read the keyFile file: <keys file path>

Explanation: The keys file could not be read due to an IO error.

User Response: Check that the current user has permission to read the file.

CWUDU0049E: Unable to write to entity definition file: <entity definition file path>

Explanation: During serialization, the Entity Definition File could not be written to.

User Response: Check the file’s read only attribute is not set.

CWUDU0050E: Unable to find UDDI Entity definition file: <entity definition file path>

Explanation: The Entity Definition File could not be found at the specified file path.

User Response: Check the file path is correct and that the file exists.

CWUDU0051E: Unable to read UDDI Entity definition file: <entity definition file path>

Explanation: The Entity Definition File could not be read due to an IO error.

User Response: Check that the current user has permission to read the file.

CWUDU0052E: Unable to close the message file: <file path>

Explanation: The attempt to close the message log file failed.

User Response: The disk might be full. If so, clear some space or direct log output to a different disk.

CWUDU0053E: Unable to close the trace file: <file path>

Explanation: The attempt to close the trace log file failed.

User Response: The disk might be full. If so, clear some space or direct log output to a different disk.

CWUDU0054E: The logger was unable to find the file: <file path>

Explanation: The UDDI Utility Tools logger could not find the specified file.

User Response: None.

CWUDU0055E: ERROR OCCURRED ...

Explanation: General purpose error message used in development only.

User Response: None.

CWUDU0056E: Exception:

Explanation: General purpose message prefix used for reporting exceptions.

User Response: None.

CWUDU0057W: Only one function may be specified on the command line.

Explanation: Multiple function commands were entered on the command line.

User Response: Specify one function in accordance with the usage message.

CWUDU0058W: No function was specified.

Explanation: UDDI Utility Tools was invoked with no function specified.

User Response: Specify one function in accordance with the usage message.

CWUDU0059W: The function: <function> was not recognized.

Explanation: The function value did not match any of the allowed functions.

User Response: Specify one function in accordance with the usage message.

CWUDU0060W: The argument '<argument>' was not recognized.

Explanation: The argument value does not match any of the allowed arguments.

User Response: Specify arguments in accordance with the usage message.

CWUDU0061W: There was a missing value for <argument> argument.

Explanation: An expected value for the specified argument was not supplied.

User Response: Specify a value for the argument in accordance with the usage message.

CWUDU0062W: Unexpected argument: <argument> (entity key file is already specified).

Explanation: The entity type argument cannot be specified if the keysFile argument has already been specified.

User Response: Specify arguments in accordance with the usage message.

CWUDU0063W: Unexpected argument: <argument> (entity key is already specified).

Explanation: The keysFile argument cannot be specified if an entity type argument and key value has already been specified.

User Response: Specify arguments in accordance with the usage message.

CWUDU0064W: Argument: <argument> cannot be specified more than once.

Explanation: An argument was specified twice in the same command.

User Response: Specify arguments in accordance with the usage message.

CWUDU0065E: No entity keys were specified.

Explanation: A keys file or an entity type and key value must be specified for functions using keys.

User Response: Specify arguments in accordance with the usage message.

CWUDU0066E: Could not load Database driver: dbDriver<database driver>.

Explanation: The specified database driver could not be loaded.

User Response: Check the database driver value in the configuration file is valid, and the driver's class is present in the classpath property.

CWUDU0067E: Could not create Database connection: dbUrl, dbUser, (dbPasswd not shown).

Explanation: A connection could not be established with the database at the specified URL with the specified userid.

User Response: Check the database URL, userid and password values are correct n the configuration file, and that the database manager is running.

CWUDU0068E: Could not close the database connection.

Explanation: An attempt to close the database connection failed.

User Response: If the problem persists, contact your IBM support center.

CWUDU0069E: Could not create minimal entity for tModel.

Explanation: The minimal data necessary for a valid tModel could not be inserted in the target UDDI registry database.

User Response: Check the database URL, userid and password values are correct in the configuration file, and that the database manager is running.

CWUDU0070E: Could not create minimal entity for Service.

Explanation: The minimal data necessary for a valid businessService could not be inserted in the target UDDI registry database.

User Response: Check the database URL, userid and password values are correct in the configuration file, and that the database manager is running.

CWUDU0071E: Could not create minimal entity for Business.

Explanation: The minimal data necessary for a valid businessEntity could not be inserted in the target UDDI registry database.

User Response: Check the database URL, userid and password values are correct in the configuration file, and that the database manager is running.

CWUDU0072E: Could not create minimal entity for Binding.

Explanation: The minimal data necessary for a valid bindingTemplate could not be inserted in the target UDDI registry database.

User Response: Check the database URL, userid and password values are correct in the configuration file, and that the database manager is running.

CWUDU0073E: There was an error while trying to create an XML Document.

Explanation: An attempt to create the Entity Definition File failed.

User Response: Check the file path specified in the configuration file for the Entity Definition File is valid and is not set to be read only.

CWUDU0074E: There was an error parsing the entity definition file.

Explanation: An unspecified error occurred when parsing the Entity Definition File.

User Response: Check the entity definition file content is valid according to the UDDI Utility Tools schema file, promoter.xsd.

CWUDU0075E: One or more errors occurred while parsing the entity definition file. See message log for details.

Explanation: Errors occurred when parsing the Entity Definition File.

User Response: Check the entity definition file content is valid according to the UDDI Utility Tools schema file, promoter.xsd.

CWUDU0076W: One or more warnings were raised while parsing the entity definition file. See message log for details.

Explanation: Warnings occurred when parsing the Entity Definition File.

User Response: Check the entity definition file content is valid according to the UDDI Utility Tools schema file, promoter.xsd.

CWUDU0078E: Unable to obtain authinfo.

Explanation: AuthInfo could not be obtained from the UDDI registry with the given userid and password.

User Response: Check the userid and password property values are correct in the configuration file.

CWUDU0079E: The inquiryURL is malformed: <inquiry URL>.

Explanation: The inquiry URL specified in the configuration file is not valid.

User Response: Correct the value for the inquiry URLs (fromInquiryURL and toInquiryURL) in the configuration file.

CWUDU0080E: The publishURL is malformed: <publish URL>

Explanation: The publish URL specified in the configuration file is not valid.

User Response: Correct the value for the publish URL (toPublishURL) in the configuration file.

CWUDU0081E: Could not get tModel detail for tModelKey[<tModel key>].

Explanation: The get tModel operation failed on the source registry.

User Response: Check the key exists in the source registry.

CWUDU0082E: Could not get service detail for serviceKey[<service key>].

Explanation: The get service operation failed on the source registry.

User Response: Check the key exists in the source registry.

CWUDU0083E: Could not get business detail for businessKey[<business key>].

Explanation: The get business operation failed on the source registry.

User Response: Check the key exists in the source registry.

CWUDU0084E: Could not get binding detail for bindingKey[<binding key>].

Explanation: The get binding operation failed on the source registry.

User Response: check the key exists in the source registry.

CWUDU0085E: Could not save tModel for tModelKey[<tModel key>].

Explanation: The publish operation failed at the target registry.

User Response: Check the tModel is not referencing another entity (such as a tModel) that is not present in the target registry. This may occur if the 'importReferenced' property is set to 'false'. Specify referenced tModels in the referencedtModels section of the Entity Definition File and set 'importReferenced' property in the configuration file to 'true'.

CWUDU0086E: Could not save business for businessKey[<business key>].

Explanation: The publish operation failed at the target registry.

User Response: Check the businessEntity is not referencing another entity (such as a tModel) that is not present in the target registry. This may occur if the 'importReferenced' property is set to 'false'. Specify referenced tModels in the referencedtModels section of the Entity Definition File and set 'importReferenced' property in the configuration file to 'true'.

CWUDU0087E: Could not save service for parent businessKey[<business key>].

Explanation: The publish operation failed at the target registry.

User Response: Check the businessEntity specified as the parent of the businessService exists in the target registry.

CWUDU0088E: Could not save binding for parent serviceKey[<service key>].

Explanation: The publish operation failed at the target registry.

User Response: Check the businessService specified as the parent of the bindingTemplate exists in the target registry.

CWUDU0089W: Did not save service for serviceKey[<service key>] because parent business did not exist.

Explanation: The parent business for the specified businessService does not exist.

User Response: Check the key value for the parent entity is correct in the Entity Definition File, and that the entity exists in the target registry.

CWUDU0090W: Did not save binding for bindingKey[<binding key>] because parent service did not exist.

Explanation: The parent service for the specified bindingTemplate does not exist.

User Response: Check the key value for the parent entity is correct in the Entity Definition File, and that the entity exists in the target registry.

CWUDU0091E: Could not delete business for businessKey[<businness key>].

Explanation: The UDDI4J operation to delete the businessEntity with the specified key failed.

User Response: Check the userid and password property values in the configuration file and that the entity exists in the target UDDI registry.

CWUDU00921E: Could not delete service for serviceKey[<tModel key>].

Explanation: The UDDI4J operation to delete the businessService with the specified key failed.

User Response: Check the userid and password property values in the configuration file and that the entity exists in the target UDDI registry.

CWUDU0093E: Could not delete binding for bindingKey[<binding key>].

Explanation: The UDDI4J operation to delete the bindingTemplate with the specified key failed.

User Response: Check the userid and password property values in the configuration file and that the entity exists in the target UDDI registry.

CWUDU0094E: Could not delete tModel for tModelKey[<tModel key>].

Explanation: The UDDI4J operation to delete the tModel with the specified key failed.

User Response: Check the userid and password property values in the configuration file and that the entity exists in the target UDDI registry.

CWUDU0096W: <entity type><key value> is not a valid UUID.

Explanation: The key value entered does not comply with the format specified for a UUID in the UDDI specification.

User Response: Enter a valid UUID key.

CWUDU0097W: Did not save tModel for tModelKey[<tModel key>] as it already exists. Use the -overwrite argument to overwrite the tModel.

Explanation: The tModel was not saved because the overwrite property is false

User Response: If the desired action is to overwrite existing entities, specify -overwrite on the command line or set the overwrite property in the configuration file to true.

CWUDU0098W: Did not save business for businessKey[<business key>] as it already exists. Use the -overwrite argument to overwrite the business.

Explanation: The businessEntity was not saved because the overwrite property is false

User Response: If the desired action is to overwrite existing entities, specify -overwrite on the command line or set the overwrite property in the configuration file to true.

CWUDU0099W: Did not save service for serviceKey[<service key key>] as it already exists. Use the -overwrite argument to overwrite the service.

Explanation: The businessService was not saved because the overwrite property is false

User Response: If the desired action is to overwrite existing entities, specify -overwrite on the command line or set the overwrite property in the configuration file to true.

CWUDU0100W: Did not save binding for bindingKey[<binding key key>] as it already exists. Use the -overwrite argument to overwrite the binding.

Explanation: The bindingTemplate was not saved because the overwrite property is false

User Response: If the desired action is to overwrite existing entities, specify -overwrite on the command line or set the overwrite property in the configuration file to true.

CWUDU0101W: Bad entity type: received<entity type>, expected <tModel|business|service|binding>.

Explanation: The entered entity type was not recognized.

User Response: Specify arguments in accordance with the usage message.

CWUDU0102E: Promotion failed.

Explanation: The promote function failed to complete.

User Response: Check the configuration properties file has correct settings.

CWUDU0106E: Unable to commit transaction.

Explanation: The insertion of minimal entity data during the import function failed to commit to the database.

User Response: Check the database configuration. If necessary, turn on trace logging and look for the SQLException that is recorded.

CWUDU0107E: Unable to set auto-commit off on the database connection.

Explanation: UDDI Utility Tools needs to control commits of data changes, however the attempt to turn off auto-commit failed.

User Response: Check the database configuration. If necessary, turn on trace logging and look for the SQLExecption that is recorded.

CWUDU0109E: The import function requires a UDDI entity definition file to be specified.

Explanation: A required argument value was not supplied.

User Response: Specify -definition <path to Entity Definition File> on the command line, or set the value of the UDDIEntityDefinitionFile property in the configuration file to the path to the Entity Definition File.

CWUDU0110E: A cyclic dependency exists in the referenced tModels. The reference from tModel with key [<tModel key>] to the tModel with key [<tModel key>] completes the detected cycle.

Explanation: A cycle has been detected such that a tModel is being referenced by a tModel that it directly or indirectly references. This would cause the UDDI Utility Tools to enter an infinite loop trying to import referenced tModels, so the process is halted.

User Response: Edit the Entity Definition File and temporarily remove the reference to the tModel in the cycle, taking a note of the referenced details. After the import has successfully completed, update the tModel in the target registry to reintroduce the reference you previously removed. This can be done using the UDDI User Console, UDDI4J, or by creating a new Entity Definition File with just the tModel to be updated, and running the UDDI Utility Tools with the import function.

CWUDU0112E: An unexpected exception has occurred: <Exception message>.

Explanation: An unexpected error occurred.

User Response: Check configuration file settings and all registries and databases are active. If necessary, contact your IBM support center.

CWUDU0113E: Could not get a response from UDDI registry at URL: <URL>.

Explanation: A TransPortException occurred while performing an UDDI4J operation on the UDDI registry at the specified URL.

User Response: Check configuration properties for the UDDI registry in question and ensure the UDDI registry is active.

CWUDU0114E: An IOException occurred trying to invoke 'java'.

Explanation: When UDDI Utility Tools was invoked using the java -jar syntax, the invocation of the second JVM failed.

User Response: Check configuration property 'classpath' value is correct, and that Java is configured to run from the command line.

CWUDU0115I: Imported <entity count> entities and <referenced entity count> referenced entities.

Explanation: Indicate that the import step of the import or promote function has completed, showing the number of entities imported.

User Response: None.

CWUDU0116W: Not all minimal entities could be removed. The following remain in the database:

Explanation: A publish step was not successful which may have left one or more minimal entities in the target registry database. UDDI Utility Tools attempts to remove these minimal entities but in this case, the removal has failed. Following messages will indicate which minimal entities are left in the target registry.

User Response: You can attempt to remove the minimal entities using normal methods, such as the user console, UDDI4J, or using the delete function of the UDDI Utility Tools.

CWUDU0117W: Business minimal entities with businessKey [<business key>] has not been removed from the database.

Explanation: A business minimal entity was orphaned in the target registry database and attempts to remove it failed.

User Response: Identify the orphaned minimal entity in the target and attempt to remove using normal UDDI delete methods, or by using the delete function of the UDDI Utility Tools.

CWUDU0118W: Service minimal entity with serviceKey [<service key>] has not been removed from the database.

Explanation: A service minimal entity was orphaned in the target registry database and attempts to remove it failed.

User Response: Identify the orphaned minimal entity in the target registry and attempt to remove using normal UDDI delete methods, or by using the delete function of the UDDI Utility Tools.

CWUDU0119W: Binding Template minimal entity with bindingKey [<binding key>] has not been removed from the database.

Explanation: A binding minimal entity was orphaned in the target registry database and attempts to remove it failed.

User Response: Identify the orphaned minimal entity in the target registry and attempt to remove using normal UDDI delete methods, or by using the delete function of the UDDI Utility Tools.

CWUDU0120W: TModel minimal entity with tModelKey [<tModel key>] has not been removed from the database.

Explanation: A tModel minimal entity was orphaned in the target registry database and attempts to remove it failed.

User Response: Identify the orphaned minimal entity in the target registry and attempt to remove using normal UDDI delete methods, or by using the delete function of the UDDI Utility Tools.

CWUDU0121I: Created business minimal entity with businessKey [<business key>].

Explanation: Indicates the minimal data required for a businessEntity has successfully been inserted in the target UDDI registry database.

User Response: None.

CWUDU0122I: Created service minimal entity with serviceKey [<service key>].

Explanation: Indicates the minimal data required for a businessService has successfully been inserted in the target UDDI registry database.

User Response: None.

CWUDU0123I: Created binding template minimal entity with bindingKey [<binding key>].

Explanation: Indicates the minimal data required for a bindingTemplate has successfully been inserted in the target UDDI registry database.

User Response: None.

CWUDU0124I: Created tModel minimal entity with tModelKey [<tModel key>].

Explanation: Indicates the minimal data required for a tModel has successfully been inserted in the target UDDI registry database.

User Response: None.

CWUDU0125I: Deleted business minimal entity with businessKey [<business key>].

Explanation: Indicates the minimal data inserted for a businessEntity was successfully removed from the target UDDI registry database. This would normally happen after a publish operation has failed.

User Response: None.

CWUDU0126I: Deleted service minimal entity with serviceKey [<service key>].

Explanation: Indicates the minimal data required for a businessService was successfully removed from the target UDDI registry database. This would normally happen after a publish operation has failed.

User Response: None.

CWUDU0127I: Deleted binding template minimal entity with bindingKey [<binding key>].

Explanation: Indicates the minimal data required for a bindingTemplate was successfully removed from the target UDDI registry database. This would normally happen after a publish operation has failed.

User Response: None.

CWUDU0128I: Deleted tModel minimal entity with tModelKey [<tModel key>].

Explanation: Indicates the minimal data required for a tModel was successfully removed from the target UDDI registry database. This would normally happen after a publish operation has failed.

User Response: None.

CWUDU0129E: Find related businesses failed.

Explanation: The UDDI4J find related businesses operation did not complete.

User Response: Check the configuration properties for the source registry, such as fromInquiryURL.

CWUDU0130E: Find businesses failed.

Explanation: The UDDI4J find businesses operation did not complete.

User Response: Check the configuration properties for the source registry, such as fromInquiryURL.

CWUDU0131E: Find services failed.

Explanation: The UDDI4J find services operation did not complete.

User Response: Check the configuration properties for the source registry, such as fromInquiryURL.

CWUDU0132E: Find tModels failed.

Explanation: The UDDI4J find tModels operation did not complete.

User Response: Check the configuration properties for the source registry, such as fromInquiryURL.

CWUDU0133E: Find bindings failed.

Explanation: The UDDI4J find bindings operation did not complete.

User Response: Check the configuration properties for the source registry, such as fromInquiryURL.

CWUDU0134I: Performing inquiry request ...

Explanation: Indicated the find operation for selecting keys has started.

User Response: None.

CWUDU0135I: Extracted keys from inquiry results.

Explanation: Indicates the find operation to select keys has completed successfully.

User Response: None

CWUDU0136E: node ID value could not be found in UDDI database.

Explanation: The UDDI registries Node ID could not be found in the UDDI database.

User Response: Check that the UDDI application and database have initialized correctly.

CWUDU0137E: Unexpected database SQL exception: <SQL Exception Message>.

Explanation: An unexpected SQL Exception has been encountered.

User Response: Examine the SQL Exception Message to determine the cause of the problem.

CWUDU0138E: Could not delete minimal entity for tModel with tModelKey[<tModel Key>].

Explanation: The entity with the supplied tModel key could not be located and therefore deleted.

User Response: Ensure tModel key is correct.

CWUDU0139E: Could not delete minimal entity for Service with serviceKey[<Service Key>].

Explanation: The entity with the supplied Service key could not be located and therefore deleted.

User Response: Ensure Service key is correct.

CWUDU0140E: Could not delete minimal entity for Business with businessKey[<Business Key>].

Explanation: The entity with the supplied Business Key could not be located and therefore deleted.

User Response: Ensure Business key is correct.

CWUDU0141E: Could not delete minimal entity for Binding with bindingKey[<Binding Key>].

Explanation: The entity with the supplied Binding key could not be located and therefore deleted.

User Response:

CWUDU0142E: Invalid sequence number for service: <Sequence Number>.

Explanation: The ServiceStub has an invalid sequence number.

User Response: Ensure the sequence number is greater than zero.

CWUDU0143E: Invalid sequence number for binding: <Sequence Number>.

Explanation: The BindingStub has an invalid sequence number.

User Response: Ensure the sequence number is greater than zero.

CWUDVnnnns (Web Services UDDI Value Set Tools) messages:

CWUDV0001E: Unable to find the properties file: >Property File>.

Explanation: The named property file could not be located.

User Response: Supply the correct location of the property file.

CWUDV0002E: The column and string delimiters must not be the same.

Explanation: The column and string delimiters cannot be the same.

User Response: Supply different characters for the column and string delimiters.

CWUDV0003E: A tModel for key <tModel Key> can not be found.

Explanation: The tModel for the given key cannot be found.

User Response: Supply a correct tModel key.

CWUDV0004E: Invalid command arguments.

Explanation: A command argument has been supplied that is unknown.

User Response: Check your arguments with the Usage information given with this error message.

CWUDV0005E: Different tModel keys are required when using -newKey.

Explanation: Two unique tModel keys are required to move a Value Set from one tModel to another.

User Response: Supply two unique tModel keys.

CWUDV0006E: Unable to find the value set data file: <Value Set File>.

Explanation: The named value set file could not be located.

User Response: Supply the correct location of the value set file.

CWUDV0007E: There is an unterminated string on line <Line Number>:<Line>.

Explanation: The line at <Line Number> has a starting string delimiter, but not a finishing one.

User Response: Correct the line, or consider using a different string delimiter (-stringDelimiter)

CWUDV0008E: There were fewer fields than expected on line <Line Number>:<Line>.

Explanation: The line at <Line Number> does not contain enough fields.

User Response: Correct the line, of consider using a different column delimiter (-columnDelimiter).

CWUDV0009E: There were more fields than expected on line <Line Number>:<Line>.

Explanation: The line at <Line Number> contains too many fields.

User Response: Correct the line, or consider using a different column delimiter (-columnDelimiter).

CWUDV0010E: There is a duplicate Key Code at the same level on line <Line Number>.

Explanation: The Value Set file contains two or more Key Codes of the sasme value for the same parent key code.

User Response: Correct the line.

CWUDV0011E: An invalid Parent Key Code has been detected on line <Line Number>.

Explanation: The Value Set file contains a parent key code that is invalid in its context.

User Response: Correct the parent key code.

CWUDV0012E: The value set file contains a value <Column Contents> in column <Column Number> at line <Line Number> that is too long for the database table.

Explanation: The Value Set file contains a value that is too large.

User Response: Decrease the size of the value.

CWUDV0013E: An IO Exception has occurred: <IO Exception Message>.

Explanation: An IO Exception was received when trying to read the Value Set file.

User Response: Ensure the Value Set file is readable and is in UTF-8 format.

CWUDV0014E: There was a problem reading from the properties file: <IO Exception Message>.

Explanation: An IO Exception was received when trying to read the Value Set file.

User Response: Ensure the Value Set file is readable and is in UTF-8 format.

CWUDV0016E: Unable to find the UDDI JMX MBean. Verify UDDI is installed.

Explanation: The UDDI application could not be contacted.

User Response: Ensure UDDI is installed and running on the Host you have targeted. See arguments -host, -port, -node and -server.

CWUDV0017E: An unexpected Exception has occurred.

Explanation: An unexpected exception was received.

User Response: Examine the Exception stack trace on its cause. If the problem cannot be resolver, contact your IBM Customer Service Center.

CWUDV1001W: The tModel with key <tModel Key> is checked. To confirm this operation, enter the command with the -override argument.

Explanation: The targeted tModel has a ″checked″ status and therefore should not have its value set changed without care.

User Response: To confirm this operation, enter the command with the -override argument.

CWUDV1002W: The tModel with key <tModel Key> has existing value sets. To confirm this operation, enter the command with the -override argument.

Explanation: The targeted to be loaded already has a value set.

User Response: To confirm this operation and overwrite the existing value set, enter the command with the -override argument.

CWUDV1003W: UDDI Registry Message: <Number of Lines> lines of data file for tModel key <tModel Key>.

Explanation: UDDI Registry message was received.

User Response: Examine the message on its cause. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDV2001I: Loaded <Number of Lines> line of data file for tModel key <tModelKey>.

Explanation: An informational message that confirms the number of value set lines loaded for the tModel.

User Response:

CWUDV2002I: Changed value set from tModel key <tModel Key> to tModel key <tModel Key>.

Explanation: An informational message that confirms the change of value set from one tModel to another.

User Response: None.

CWUDV2003I: Unloaded value set for tModel key <tModel Key>.

Explanation: An informational message that confirms the removal of the value set for the tModel.

User Response: None.

CWUDXnnnns (Web Services JAXR) messages:

CWUDX0001E: Caught UDDIException on <UDDI API name>

Explanation: This is an Exception message. This message may be received in a RegistryException thrown by any of the following methods:

- Any method which necessitates sending a request to the UDDI registry.

The JAXR provider caught a org.uddi4j.UDDIException while sending a request to the UDDI registry.

User Response: The user should interrogate the cause UDDIException of the JAXRException for more information.

CWUDX0002E: Caught TransportException sending request to registry

Explanation: This is an Exception message. This message may be received in a RegistryException thrown by any of the following methods:

- Any method which necessitates sending a request to the UDDI registry.

The JAXR provider caught a org.uddi4j.TransportException while sending a request to the UDDI registry.

User Response: The user should interrogate the cause TransportException of the JAXRException for more information.

CWUDX0003E: AccessURI and TargetBinding are mutually exclusive

Explanation: This is an Exception message. This message may be received in an InvalidRequestException thrown by any of the following methods:

- ServiceBinding.setAccessURI(String uri)
- ServiceBinding.setTargetBinding(ServiceBinding binding)

An attempt was made to set both the AccessURI and the TargetBinding of a ServiceBinding.

User Response: The user should set only one of AccessURI and TargetBinding.

CWUDX0004E: Source object of an Association must be an Organization

Explanation: This is an Exception message. This message may be received in an UnexpectedObjectException thrown by the following method:

- Association.setSourceObject(RegistryObject srcObject)

The object passed to the setSourceObject method was not an Organization.

User Response: The user should only pass Organization objects to the setSourceObject method.

CWUDX0005E: Source and target objects of an Association must be set in order to save

Explanation: This is an Exception message. This message may be received in an InvalidRequestException thrown by any of the following methods:

- BusinessLifeCycleManager.confirmAssociation(Association assoc)
- BusinesslifeCycleManager.saveAssociations(Collection associations, boolean replace)
- LifeCycleManager.saveObjects(Collection objects) when objects are Associations

An attempt was made to save an Association that did not have both source and target objects set.

User Response: The user should only attempt to save Associations which have both source and target objects set.

CWUDX0006E: Target object of an Association must be an Organization

Explanation: This is an Exception message. This message may be received in an UnexpectedObjectException thrown by the following method:

- Association.setTargetObject(RegistryObject targetObject)

The object passed to the setTargetObject method was not an Organization.

User Response: The user should only pass Organization objects to the setTargetObject method.

CWUDX0007E: Format of associationKey is incorrect. Correct format is <sourceObjectKey>:<targetObjectKey>:<associationType> : <associationKey>

Explanation: This is an Exception message. This message may be received in an InvalidRequestException thrown by the following method:

- BusinessLifeCycleManager.deleteAssociations(Collection associationKeys)

The user passed an associationKey to the deleteAssociations method that did not have the correct format.

User Response: The user should ensure that associationKeys passed to the deleteAssociations method have the correct format.

CWUDX0008E: AssociationType Concept must come from the AssociationType enumberation, and have value either HasChild , HasParent, RelatedTo or EquivalentTo

Explanation: This is an Exception message. This message may be received in an InvalidRequestException thrown by any of the following methods:

- BusinessQueryManager.findAssociations(Collection findQualifiers, String sourceObjectId, String targetObjectId, Collection associationTypes)
- BusinessQueryManager.findCallerAssociations(Collection findQualifiers, Boolean confirmedByCaller, Boolean confirmedByOtherParty, Collection associationTypes)
- BusinessLifeCycleManager.confirmAssociation(Association assoc)
- BusinessLifeCycleManager.saveAssociations(Collection associations, boolean replace)
- LifeCycleManager.saveObjects(Collection objects) when objects are Associations

When finding Associations, the user passed a Concept in the associationTypes Collection that was from the AssociationType enumeration, but did not have a value that is valid for UDDI. When saving Associations, the user passed an Association whose associationType Concept was from the AssociationType enumeration, but did not have a value that is valid for UDDI.

User Response: The user should only use Concepts for associationTypes that are from the AssociationType enumeration and have value either HasChild, HasParent, RelatedTo or EquivalentTo.

CWUDX0009E: AssocationType Concept must come from the AssociationType enumeration

Explanation: This is an Exception message. This message may be received in an InvalidRequestException thrown by any of the following methods:

- BusinessQueryManager.findAssociations(Collection findQualifiers, String sourceObjectId, String targetObjectId, Collection associationTypes)
- BusinessQueryManager.findCallerAssociations(Collection findQualifiers, Boolean confirmedByCaller, Boolean confirmedByOtherParty, Collection associationTypes)

- BusinessLifeCycleManager.confirmAssociation(Association assoc)
- BusinessLifeCycleManager.saveAssociations(Collection associations, boolean replace)
- LifeCycleManager.saveObjects(Collection objects) when objects are Associations

When finding Associations, the user passed a Concept that was not from the AssociationType enumeration in the associationTypes Collection. When saving Associations, the user passed an Association whose associationType Concept was not from the AssociationType enumeration.

User Response: The user should only use Concepts from the AssociationType enumeration for associationTypes.

CWUDX0010E: Cannot create a ClassificationScheme from a taxonomy Concept

Explanation: This is an Exception message. This message may be received in an InvalidRequestException thrown by the following method:

- LifeCycleManager.createClassificationScheme(Concept concept)

The user passed a taxonomy Concept to the createClassificationScheme method.

User Response: This method is provided to allow for Concepts returned by the BusinessQueryManager.findConcepts call to be safely converted to ClassificationScheme. It is up to the programmer to make sure that the Concept is indeed semantically a ClassificationScheme.

CWUDX0011E: Connection is closed

Explanation: This is an Exception message. This message may be received in an InvalidRequestException thrown by any of the following methods:

- All methods of BusinessQueryManager and BusinessLifeCycleManager.
- The saveObjects and deleteObjects methods of LifeCycleManager.
- The saveObjects and deleteObjects methods of LifeCycleManager.

The user called a method that required a connection to the registry after they had closed the Connection by calling the Connection.close() method.

User Response: The user should not call methods that require a connection to the registry after the Connection has been closed.

CWUDX0012E: ConnectionFactory properties are not set

Explanation: This is an Exception message. This message may be received in an InvalidRequestException thrown by the following method:

- ConnectionFactory.createConnection()

The createConnection() method was called before the properties had been set on the ConnectionFactory.

User Response: Ensure that the ConnectionFactory properties have been set before attempting to create a Connection.

CWUDX0013E: Could not create DocumentBuilder

Explanation: This is an Exception message. This message may be received in a JAXRException thrown by the following method:

- RegistryService.makeRegistrySpecificRequest(String request)

The JAXR provider caught a javax.xml.parsers.ParserConfigurationException while attempting to initialize the XML parser.

User Response: The user should interrogate the cause ParserConfigurationException of the JAXRException for more information.

CWUDX0014E: Could not parse XML input stream

Explanation: This is an Exception message. This message may be received in a JAXRException thrown by the following method:

- RegistryService.makeRegistrySpecificRequest(String request)

The JAXR provider caught a java.io.IOException while attempting to parse the XML request.

User Response: The user should interrogate the cause IOException of the JAXRException for more information.

CWUDX0015E: Could not serialize XML response

Explanation: This is an Exception message. This message may be received in a JAXRException thrown by the following method:

- RegistryService.makeRegistrySpecificRequest(String request)

The JAXR provider caught a java.io.IOException while attempting to serialize the XML response.

User Response: The user should interrogate the cause IOException of the JAXRException for more information.

CWUDX0016E: Interface name of object to create not specified

Explanation: This is an Exception message. This message may be received in an InvalidRequestException thrown by the following method:

- LifeCycleManager.createObject(String interfaceName)

The user passed a null interfaceName to the createObject method.

User Response: The user should ensure they only pass a valid interfaceName to the createObject method.

CWUDX0017W: Enumeration data file <filename> contains an invalid line: <line>

Explanation: This warning message will go to System.err if the JAXR provider encounters an invalid line in an enumeration data file while the Connection is initialized. The JAXR provider will ignore the invalid line. Otherwise the JAXR provider will be unaffected.

User Response: The user should ensure that the enumeration data file is valid in order to use all members of the enumeration. The correct format of each line is <enumeration name><separator char><concept value>.

CWUDX0018E: Could not read enumeration data file: <filename>

Explanation: This is an Exception message. This message may be received in a JAXRException thrown by the following method:

- ConnectionFactory.createConnection(

The JAXR provider caught a java.io.IOException while attempting to read an enumeration data file.

User Response: The user should interrogate the cause IOException of the JAXRException for more information.

CWUDX0019W: enumerationConfig.properties file contains an invalid property value: <property value>

Explanation: This warning message will go to System.err if the JAXR provider encounters an invalid property value in the enumerationConfig.properties file while the Connection is initializsed. The JAXR provider will ignore the invalid property, and hence ignore the corresponding enumeration. Otherwise the JAXR provider will be unaffected.

User Response: The user should ensure that the enumerationConfig.properties file is valid in order to use all enumerations. The correct format of each line is <enumeration ID>=<enumeration name>,<data filename>,<separator char>

CWUDX0020E: An IOException occurred while attempting to read the enumerationConfig.properties file

Explanation: This is an Exception message. This message may be received in a JAXRException thrown by the following method:

- ConnectionFactory.createConnection()

The JAXR provider caught a java.io.IOException while attempting to read the enumerationConfig.properties file.

User Response: The user should interrogate the cause IOException of the JAXRException for more information.

CWUDX0021E: An IOException occurred while attempting to read the taxonomyConfig.properties file

Explanation: This is an Exception message. This message may be received in a JAXRException thrown by the following method:

- ConnectionFactory.createConnection()

The JAXR provider caught a java.io.IOException while attempting to read the taxonomyConfig.properties file.

User Response: The user should interrogate the cause IOException of the JAXRException for more information.

CWUDX0022E: External URI is malformed: <External URI>

Explanation: This is an Exception message. This message may be received in an InvalidRequestException thrown by the following method:

- ExternalLink.setExternalURI(String uri)

A malformed URI was passed to the setExternalURI method when URI validation has set to true by passing true to the ExternalLink.setValidateURI(boolean validate) method.

User Response: Either the user should ensure that the URI is well formed, or URI validation should be set to false.

CWUDX0023E: External URI is not accessible: <External URI>

Explanation: This is an Exception message. This message may be received in an InvalidRequestException thrown by the following method:

- ExternalLink.setExternalURI(String uri)

An inaccessible URI was passed to the setExternalURI method when URI validation has set to true by passing true to the ExternalLink.setValidateURI(boolean validate) method.

User Response: Either the user should ensure that the URI is accessible, or URI validation should be set to false.

CWUDX0024E: Invalid interface name: <interface name>

Explanation: This is an Exception message. This message may be received in an InvalidRequestException thrown by the following method:

- LifeCycleManager.createObject(String interfaceName)

The user passed an invalid interface name to the createObject method.

User Response: The user should only pass valid interface names to the createObject method. Valid interface names are public final static String fields of the LifeCycleManager class.

CWUDX0025E: Cannot change the ClassificationScheme of an internal Classification

Explanation: This is an Exception message. This message may be received in an InvalidRequestException thrown by the following method:

- Classification.setClassificationScheme(ClassificationScheme classificationScheme)

The user called the setClassificationScheme method of an internal Classification.

User Response: The user should not attempt to modify the ClassificationScheme of an internal Classification directly. The ClassificationScheme of an internal Classification is determined by the Classification's Concept and cannot be modified independently.

CWUDX0026E: Cannot change the name of an internal Classification

Explanation: This is an Exception message. This message may be received in an InvalidRequestException thrown by the following method:

- Classification.setName(InternationalString name

The user called the setName method of an internal Classification.

User Response: The user should not attempt to modify the name of an internal Classification directly. The name of an internal Classification is determined by the Classification's Concept and cannot be modified independently.

CWUDX0027E: Cannot change the value of an internal Classification

Explanation: This is an Exception message. This message may be received in an InvalidRequestException thrown by the following method:

- Classification.setValue(String value)

The user called the setValue method of an internal Classification.

User Response: The user should not attempt to modify the value of an internal Classification directly. The value of an internal Classification is determined by the Classification's Concept and cannot be modified independently.

CWUDX0028E: The Concept of an internal Classification must have a parent ClassificationScheme

Explanation: This is an Exception message. This message may be received in an InvalidRequestException thrown by the following method:

- Classification.setConcept(Concept concept)

The user passed a non-null Concept without a parent ClassificationScheme to the setConcept method.

User Response: Setting a Classification's Concept causes a Classification to become internal. The Classification's ClassificationScheme is then set to the parent ClassificationScheme of the Concept. If the Concept has no parent ClassificationScheme (that is, it is not a taxonomy Concept), that is invalid. The user should therefore only pass taxonomy Concepts to the setConcept method.

CWUDX0029E: Taxonomy Concepts cannot be saved as UDDI tModels

Explanation: This is an Exception message. This message may be received in an InvalidRequestException thrown by any of the following methods:

- BusinessLifeCycleManager.saveConcepts(Collection concepts)
- LifeCycleManager.saveObjects(Collection objects) when the objects are Concepts.

The user attempted to save a taxonomy Concept as a UDDI tModel in the registry.

User Response: Taxonomy Concepts cannot be saved as tModels in a UDDI registry. They are used to classify objects saved in the registry but cannot be saved independently. The user should not attempt to save taxonomy Concepts in the registry.

CWUDX0030E: The parent RegistryObject of a taxonomy Concept must be either a Concept or a ClassificationScheme

Explanation: This is an Exception message. This message may be received in an UnexpectedObjectException thrown by any of the following methods:

- LifeCycleManager.createConcept(RegistryObject parent, InternationalString name, String value)
- LifeCycleManager.createConcept(RegistryObject parent, String name, String value)

The user attempted to create a taxonomy Concept whose parent was not a Concept or a ClassificationScheme.

User Response: The parent of a taxonomy Concept can only be another Concept or a ClassificationScheme, so the user should only attempt to set one of these as the parent of a taxonomy Concept.

CWUDX0031E: Concept does not have a parent, therefore does not have a path

Explanation: This is an Exception message. This message may be received in an InvalidRequestException thrown by the following method:

- Concept.getPath()

The user called the getPath() method on a Concept that was not a taxonomy Concept. Only taxonomy Concepts have parents.

User Response: Only taxonomy Concepts have parents, therefore only taxonomy Concepts have paths. The user should not attempt to call the getPath() method on a Concept that is not a taxonomy Concept.

CWUDX0032E: Concept does not have a value, therefore does not have a path

Explanation: This is an Exception message. This message may be received in an InvalidRequestException thrown by the following method:

- Concept.getPath()

The user called the getPath() method on a Concept that did not have a value.

User Response: A Concept must have a value in order to have a path, so the user should not attempt to call the getPath() method on Concepts that do not have a value.

CWUDX0033E: Concept's parent ClassificationScheme does not have an ID, therefore the Concept does not have a path

Explanation: This is an Exception message. This message may be received in an InvalidRequestException thrown by the following method:

- Concept.getPath()

The user called the getPath() method on a Concept whose ClassificationScheme did not have an ID.

User Response: A Concept's ClassificationScheme must have an ID in order for the Concept to have a path. The user should not attempt to call the getPath() method on a Concept whose ClassificationScheme does not have an ID.

CWUDX0034E: The ConnectionFactory property javax.xml.registry.uddi.maxRows does not contain a parsable integer:<javax.xml.registry.uddi.maxrows property value>

Explanation: This is an Exception message. This message may be received in an InvalidRequestException thrown by the following method:

- ConnectionFactory.createConnection()

The user called the createConnection method when the ConnectionFactory property javax.xml.registry.uddi.maxRows did not contain a parsable integer.

User Response: The user should ensure that if the javax.xml.registry.uddi.maxRows ConnectionFactory property is set that it contains a parsable integer.

CWUDX0035E: Invalid UDDI XML String

Explanation: This is an Exception message. This message may be received in a JAXRException thrown by the following method:

- RegistryService.makeRegistrySpecificRequest(String xmlString)

The String passed to the makeRegistrySpecificRequest method was not valid XML.

User Response: The user should ensure that the String passed to the makeRegistrySpecificRequest method is valid XML.

CWUDX0036E: The ConnectionFactory property javax.xml.registry.lifeCycleManagerURL specifies a malformed URL

Explanation: This is an Exception message. This message may be received in an InvalidRequestException thrown by the following method:

- ConnectionFactory.createConnection()

The user called the createConnection method when the ConnectionFactory property javax.xml.registry.lifeCycleManagerURL contained a malformed URL.

User Response: The user should ensure that the javax.xml.registry.lifeCycleManagerURL ConnectionFactory property contains a well formed URL.

CWUDX0037E: The ConnectionFactory property javax.xml.registry.queryManagerURL specifies a malformed URL

Explanation: This is an Exception message. This message may be received in an InvalidRequestException thrown by the following method:

- ConnectionFactory.createConnection()

The user called the createConnection method when the ConnectionFactory property javax.xml.registry.queryManagerURL contained a malformed URL.

User Response: The user should ensure that the javax.xml.registry.queryManagerURL ConnectionFactory property contains a well formed URL.

CWUDX0038E: Multiple matches on find ClassificationScheme by name

Explanation: This is an Exception message. This message may be received in an InvalidRequestException thrown by the following method:

- BusinessQueryManager.findClassificationSchemeByName(Collection findQualifiers, String namePattern)

More than one ClassificationScheme was found that matched the search criteria.

User Response: The user should narrow their search criteria to find only one ClassificationScheme.

CWUDX0039E: Invalid objectType: <object type>

Explanation: This is an Exception message. This message may be received in an InvalidRequestException thrown by any of the following methods:
- LifeCycleManager.deleteObjects(Collection keys, String objectType)
- QueryManager.getRegistryObjects(String objectType)
- QueryManager.getRegistryObject(String id, String objectType)
- QueryManager.getRegistryObjects(Collection objectKeys, String objectType)

The user passed an invalid objectType to one of the above methods.

User Response: The user should ensure they pass a valid objectType to the above methods. The valid objectTypes for these methods are:

```
LifeCycleManager.CLASSIFICATION_SCHEME
LifeCycleManager.CONCEPT
LifeCycleManager.ORGANIZATION
LifeCycleManager.SERVICE
LifeCycleManager.SERVICE_BINDING
```

The deletObjects method also accepts an objectType of LifeCycleManager.ASSOCIATION.

CWUDX0040E: Cannot save objects of type: <object class>

Explanation: This is an Exception message. This message may be received in an UnexpectedObjectException thrown by the following method:
- LifeCyclemanager.saveObjects(Collection objects)

An object was passed to the saveObjects method of a type that cannot be saved directly in the registry.

User Response: The user should ensure that objects passed to the saveObjects method are of a valid type. Valid types are Association, ClassificationScheme, Concept, Organization, Service and ServiceBinding.

CWUDX0041E: RegistryObject is a ClassificationScheme not a Concept: <RegistryObject ID>

Explanation: This is an Exception message. This message may be received in a FindException thrown by any of the following methods:
- QueryManager.getRegistryObject(String id, String objectType)
- QueryManager.getRegistryObjects(Collection objectKeys, String objectType)

An objectType of LifeCycleManager.CONCEPT was passed to one of the above methods, but the id or one of the objectKeys was that of a ClassificationScheme.

User Response: The user should ensure that they specify the correct objectType corresponding to the object keys.

CWUDX0042E: RegistryObject is a Concept not a ClassificationScheme: <RegistryObject ID>

Explanation: This is an Exception message. This message may be received in a FindException thrown by any of the following methods:
- QueryManager.getRegistryObject(String id, String objectType)
- QueryManager.getRegistryObjects(Collection objectKeys, String objectType)

An objectType of LifeCycleManager.CLASSIFICATIONSCHEME was passed to one of the above methods, but the id or one of the objectKeys was that of a Concept.

User Response: The user should ensure that they specify the correct objectType corresponding to the object keys.

CWUDX0043E: RequestID not found: <RequestID>

Explanation: This is an Exception message. This message may be received in an InvalidRequestException thrown by the following method:
- RegistryService.getBulkResponse(String requestId

The requestId specified was not found.

User Response: The user should only pass valid requestIds to the getBulkResponse method. Note that once the getBulkResponse method has been called once for a particular requestId, that requestId is removed from the cache and subsequent calls to getBulkResponse passing that requestId will result in an InvalidRequestException.

CWUDX0044E: <concept path> is not a valid path of a concept in a defined internal taxonomy

Explanation: This message will go to System.err when a Connection is created if the javax.xml.registry.semanticEquivalences ConnectionFactory property defines a semantic equivalence between a Concept in the PostalAddressAttributes enumeration and a Concept which has not been defined in any internal taxonomy.

User Response: The user should ensure that the Concept paths used in the javax.xml.registry.semanticEquivalences ConnectionFactory property have been defined in a internal taxonomy.

CWUDX0045W: Semantic equivalence pair does not have exactly 2 elements: <keyPair>

Explanation: This message will go to System.err when a Connection is created if the javax.xml.registry.semanticEquivalences ConnectionFactory contains a keyPair which contains more than two elements.

User Response: The user should ensure that the javax.xml.registry.semanticEquivalences ConnectionFactory property has the correct format, as defined in the JAXR specification.

CWUDX0046E: Semantic equivalence pair does not contain a key in the postalAddressAttributes enumeration: <keyPair>

Explanation: This message will go to System.err when a Connection is created if the javax.xml.registry.semanticEquivalences ConnectionFactory contains a keyPair which does not contain the path of a Concept in the PostalAddressAttributes enumeration. Semantic equivalences for a UDDI JAXR providers are only allowed for Concepts in the PostalAddressAttributes enumeration.

User Response: The user should only attempt to define semantic equivalences for Concepts in the PostalAddressAttributes enumeration.

CWUDX0047E: Invalid Slot name: <Slot name>

Explanation: This is an Exception message. This message may be received in an InvalidRequestException thrown by any of the following methods:

- All methods of the ExtensibleObject interface.

The user passed an invalid slot name to one of the methods of the ExtensibleObject interface.

User Response: The user should ensure that the slot name is valid for the particular instance of ExtensibleObject.

CWUDX0048E: A Slot instance cannot have duplicate values

Explanation: This is an Exception message. This message may be received in an InvalidRequestException thrown by the following method:

- Slot.setValues(Collection values)

The user passed a collection of values to the setValues method that contained duplicate values.

User Response: The user should pass only a collection of unique values to setValues method.

CWUDX0049E: A sortCode Slot must have only 1 value

Explanation: This is an Exception message. This message may be received in an InvalidRequestException thrown by the following method:

- PostalAddress.addSlot(Slot slot)

The user passed a Slot with name Slot.SORT_CODE_SLOT and multiple values to the addSlot method.

User Response: When adding a Slot with name Slot.SORT_CODE_SLOT to a PostalAddress, the user should ensure that it only has 1 value.

CWUDX0050E: A specificationLink can only have one ExternalLink

Explanation: This is an Exception message. This message may be received in an InvalidRequestException thrown by any of the following methods:

- SpecificationLink.addExternalLink(ExternalLink externalLink)
- SpecificationLink.addExternalLinks(Collection externalLinks)
- SpecificationLink.setExternalLinks(Collection externalLinks)

The user attempted to give a SpecificationLink more than one ExternalLink. A SpecificationLink may only have one ExternalLink.

User Response: The user should give a SpecificationLink a maximum of one ExternalLink.

CWUDX0051E: A SpecificationLink can only have one UsageParameter

Explanation: This is an Exception message. This message may be received in an InvalidRequestException thrown by the following method:

- SpecificationLink.setUsageParameters(Collection usageParameters)

The user attempted to give the SpecificationLink more than one usage parameter. A SpecificationLink can only have one usage parameter.

User Response: The user should give a SpecificationLink a maximum of one usage parameter.

CWUDX0052E: SpecificationObject must be a Concept with no parent

Explanation: This is an Exception message. This message may be received in an InvalidRequestException thrown by any of the following methods:

- SpecificationLink.setSpecificationObject(RegistryObject obj)

The user attempted to set a Concept with a parent (that is, a taxonomy Concept) as the specification object of the SpecificationLink.

User Response: The user must set a specification Concept as the specification object of a SpecificationLink.

CWUDX0053E: SpecificationObject must be a Concept

Explanation: This is an Exception message. This message may be received in an UnexpectedObjectException thrown by the following method:

- SpecificationLink.setSpecificationObject(RegistryObject obj)

The user attempted to set a RegistryObject that was not a Concept as the specification object of a SpecificationLink.

User Response: The user must set a specification Concept as the specification object of a SpecificationLink.

CWUDX0054E: Invalid escape sequence found during SQL-92 LIKE Processing: <escape sequence>

Explanation: This is an Exception message. This message may be received in a JAXRException thrown by any of the following methods:

- BusinessQueryManager.findClassificationSchemeByName(Collection findQualifiers, String namePattern)
- BusinessQueryManager.findClassificationSchemes(Collection findQualifiers, Collection namePatterns, Collection classifications, Collection externalLinks)

The user passed a namePattern to one of the above methods which contained an invalid escape sequence.

User Response: The user should ensure that namePatterns do not contain invalid escape sequences.

CWUDX0055E: Invalid escape sequence found terminating pattern during SQL-92 LIKE processing: <escape sequence>

Explanation: This is an Exception message. This message may be received in a JAXRException thrown by any of the following methods:

- BusinessQueryManager.findClassificationSchemeByName(Collection findQualifiers, String namePattern)
- BusinessQueryManager.findClassificationSchemes(Collection findQualifiers, Collection namePatterns, Collection classifications, Collection externalLinks)

The user passed a namePattern to one of the above methods which contained an invalid escape sequence terminating the pattern.

User Response: The user should ensure that namePatterns do not contain invalid escape sequences.

CWUDX0056E: The System property http.proxyPort does not contain a parsable integer: <Value of http.proxyPort property>

Explanation: This is an Exception message. This message may be received in a java.lang.NumberFormatException thrown by the following method:

- ConnectionFactory.createConnection()

The user called the createConnection() method when the System property http.proxyPort contained a String that was not parsable as an integer.

User Response: The user should ensure that if the System property http.proxyPort is set it contains a parsable integer.

CWUDX0057W: Taxonomy data file <filename> contains an invalid line: <invalid line>

Explanation: This message will go to System.err when a Connection is created if a taxonomy data file contains an invalid line.

User Response: The format of each line is <taxonomy ID><Concept name><Concept value><Concept parent>

CWUDX0058W: Warning: Unable to locate parentConcept named <parent Concept name> for concept named <Concept name> in taxonomy datafile <filename>

Explanation: This message will go to System.err when a Connection is created if a taxonomy data file contains an line for a Concept whose parent cannot be located in that file.

User Response: The user should ensure that a parent exists for each Concept in the taxonomy data file.

CWUDX0059E: Could not read taxonomy data file: <filename>

Explanation: This is an Exception message. This message may be received in a JAXRException thrown by any of the following methods:

- ConnectionFactory.createConnection()

The JAXR provider caught a java.io.IOException while attempting to read the taxonomy data file.

User Response: The user should interrogate the cause IOException of the JAXRException for more information.

CWUDX0060W: taxonomyConfig.properties file contains an invalid property value: <property value>

Explanation: This warning message will go to System.err if the JAXR provider encounters an invalid property value in the taxonomyConfig.properties file while the Connection is initialized. The JAXR provider will ignore the invalid property, and hence ignore the corresponding taxonomy. Otherwise the JAXR provider will be unaffected.

User Response: The user should ensure that the taxonomyConfig.properties file is valid in order to use all taxonomies. The correct format of each line is <taxonomy ID>=<tModelKey>,<data filename>,<separator char>.

CWUDX0061E: Expecting object of type: <objectType String>. Got object of type: <object class>

Explanation: This is an Exception message. This message may be received in an UnexpectedObjectException thrown by the following method:

- All methods which accept objects of ambiguous type.

The user passed an object to a method that was not expecting an object of that type.

User Response: The user should only pass objects of the appropriate type to JAXR methods.

CWUDX0062E: Expecting object of type String or LocalizedString. Got object of type: <object class>

Explanation: This is an Exception message. This message may be received in an UnexpectedObjectException thrown by any of the following methods:

- All query methods which accept a Collection of namePattern objects.

The user passed an object which was not a String or a LocalizedString as a namePattern to a query method.

User Response: The user should only use Strings of LocalizedStrings as namePattern objects.

CWUDX0063E: The ConnectionFactory property javax.xml.registry.queryManagerURL is not specified

Explanation: This is an Exception message. This message may be received in an InvalidRequestException thrown by the following method:

- ConnectionFactory.createConnection(

The user attempted to create a Connection without specifying the javax.xml.registry.queryManagerURL ConnectionFactory property.

User Response: The user must specify the javax.xml.registry.queryManagerURL ConnectionFactory property before attempting to create a Connection.

CWUDX0064E: Unsupported value for the ConnectionFactory property

Explanation: This is an Exception message. This message may be received in an InvalidRequestException thrown bythe following method:

- ConnectionFactory.createConnection()

The user attempted to create a Connection with an invalid value of the javax.xml.registry.security.authenticationMethod ConnectionFactory property.

User Response: The user should only use a valid vale for this property. Valid values are UDDI_GET_AUTHTOKEN and HTTP_BASIC.

UDDI Registry samples

The UDDI samples, and documentation on how to use them, are available through the Web Services UDDI samples link on the Samples Central page of the IBM WebSphere Developer Domain Web site.

Removing and reinstalling UDDI Registry

An IBM WebSphere UDDI Registry node consists of a WebSphere application, a store of data (using a relational database management system - RDBMS) referred to as the UDDI database and a means to connect the application to the data (a data source and related elements). All the data relating to UDDI is stored within the UDDI database and therefore exits irrespective of the UDDI application.

With these facts in mind, consider the following options:

- • To remove a node from a WebSphere Application Server the database need not be deleted. Only the UDDI application and any associated resources such as the data source used (and J2C Authentication Data if used) need to be removed as the data in the UDDI database is separate from the UDDI application.
- • It is not necessary to remove the UDDI application to start a new UDDI Registry node. Instead, a new, replacement node can be created by changing the datasource which the UDDI application uses to access new UDDI database.

Remove the UDDI application if you no longer want a UDDI facility on a particular WebSphere Application Server (the UDDI Registry node may subsequently be move to a different WebSphere Application Server).

Reinstall the UDDI application if you wish to continue to provide the UDDI facility on a particular WebSphere Application Server.

Reinstall the UDDI application if you wish to continue to provide the UDDI facility on a particular WebSphere Application Server.

To reinstall a UDDI Registry node, see Reinstalling the UDDI application, or to remove a UDDI application or to remove a UDDI Registry node, see ″Removing a UDDI Node″ in the information center.

Removing a UDDI Registry node

- Remove the UDDI Registry application from an application server.

  You might want to do this in order to reinstall the application because it has become corrupted for some reason, or to apply service. See also the topic on Reinstalling the UDDI Registry application.
- Delete the UDDI Registry database. You might want to do this in order to use a different database product as the persistence store for your UDDI data, to delete all your UDDI Registry data in order to publish fresh data (for example, if you have completed a test cycle), or to cause the UDDI Registry node to re-initialize with new UDDI property settings (for example, to move from a default UDDI node to a customized UDDI node). Note that deleting a UDDI Registry database will cause all UDDI data for that UDDI Registry to be lost.
- Completely remove a UDDI Registry node from an application server. You might want to do this in order to move the UDDI Registry to a different application server, or to remove a UDDI Registry that has been used for testing.

Depending on what you wish to achieve, complete **one** of the following steps:

1. **Removing a UDDI Registry application**

   To remove the UDDI application from an application server, run the wsadmin script uddiRemove.jacl, which was installed into the WAS_HOME\bin directory when you installed WebSphere

   At a command prompt enter:

   ```
   wsadmin -f uddiRemove.jacl
                  nodename
                  servername
                  [default]
                  > removeuddi.log
   ```

   where
   - *nodename* and *servername* are the name of the WebSphere node and application server in which the UDDI application is deployed (these are the names that you specified when you ran uddiDeploy.jacl to install the UDDI application).
   - [default] is optional. Specifying *default* will remove the UDDI Cloudscape datasource but **not** the UDDI Cloudscape database. This is only applicable if *default* was used when the uddiDeploy.jacl script was run to deploy the UDDI Registry, and is only applicable in a standalone application server environment.
   - by default output will go to the screen, but, optionally, you can specify '> *removeuddi.log*' to direct the output to a log file (where removeuddi.log can be any log name of your choice).

   For example:

   ```
   wsadmin -f uddiRemove.jacl MyNode server1
   ```

   will remove the UDDI application from server server1 running in node MyNode, and will send any messages to the screen.

   Note: If running in a Network Deployment configuration, the default option cannot be used, and the command must be executed against the deployment manager profile.
2. **Deleting a UDDI Registry database**

   Note that this will cause all UDDI data in that UDDI Registry to be destroyed.
   - For DB2, use the database facilities to delete the UDDI database.
   - For Oracle, delete the schemas IBMUDI30 and IBMUDS30.
   - For Cloudscape, delete the directory tree containing the UDDI database. By default, this will be located in WAS_HOME:/profiles/profile_name/databases/com.ibm.uddi/UDDI30.
3. **Completely Remove a UDDI Registry node**

   To completely remove a UDDI Registry node from an application server, you need to remove the UDDI registry application and database, and also the resources that were used to reference the UDDI Registry database.

   a. Run uddiRemove.jacl as described above, to remove the UDDI Registry application.

b. Delete the UDDI Registry database, as described above.

c. This last step is only needed if you ran uddiRemove without the default option (use of the default option will perform this step for you, but is only valid if the UDDI Registry was previously deployed using uddiDeploy.jacl with the default option).

   - Delete the UDDI datasource that references the UDDI Registry database (this will have been created when the UDDI Registry was set up), any UDDI JDBC provider that was created (if you did not reuse an existing JDBC provider), and any J2C Authentication Data Entry that was created.

Reinstalling the UDDI Registry application

Perform this task if you want to continue providing UDDI services with your existing UDDI database but require that the UDDI application code be changed.

If you wish to reinstall the UDDI application, follow the instructions below:

1. 1. Execute the following command

   ```
   wsadmin [-conntype none] –f uddiDeploy.jacl <node> <server>
   ```

   which will uninstall the UDDI application and install the uddi.ear located in WAS_HOME/installableApps, resulting in a reinstalled UDDI application.

   Note: No JDBC Providers, Data Sources or J2C Application data will be created, changed or deleted during this process.

Configuring the UDDI Registry Application

The UDDI Registry is supplied as a J2EE application file, uddi.ear.

You can configure the following aspects of the UDDI Registry:

- Configuring security roles
- Multiple language encoding support in UDDI
- Customizing the UDDI User Console (GUI)
- Configuring SOAP API and GUI services
- Configuring WebSphere to use HTTPS and SSL

Configuring UDDI Security Roles

Each interface to the UDDI Registry (either through Version 1 and 2 SOAP, Version 3 SOAP, EJB or the GUI) is supplied with two roles:

Publish role(s) and custody transfer
mapped to AllAuthenticatedUsers. By default, this is configured to use SSL (that is HTTPS), but this only applies when WebSphere security is enabled.

Inquiry role
mapped to Everyone. By default, this is configured to use HTTP (that is not SSL).

In addition UDDI Version 3 SOAP has an additional role for version 3 SOAP Custody Transfer, which is mapped in the same way as the Publish Role.

The security role mappings can be altered by users through the Administration Console.

Authentication uses the standard WebSphere facilities and there is no separate registration function for the Registry. If WebSphere security is enabled, you will need to supply your WebSphere userid and password for Publish functions (unless you have changed the supplied Publish role).

You will need to set up WebSphere security configuration to be used by UDDI. It is expected that, for development use, security will be disabled and security will be enabled for production environments.

The V3 SOAP services also support the use of the V3 Security API set get_authToken and discard_authToken, but its use is optional, and defined by a combination of UDDI Policy and Security Roles.

- If security is enabled, and the service's Role is set to AllAuthenticated Users, WebSphere security takes priority over UDDI authentication, but if the Publish (or Custody Transfer) Role is mapped to Everyone and policy is set to require Authorization for publish (or Custody Transfer) (see WebSphere Administration console (UDDI => UDDI Nodes => UDDI NodeID => Policy Groups => APIs => General Properties)) then an authToken is required, and the user and password supplied in get_authToken will be checked by WebSphere.
- If security is disabled, Role Mapping does not apply, and the use of the V3 Security API set is defined by policy. If the 'Use authInfo if provided' option is checked (see WebSphere Administrative console (UDDI => UDDI Nodes => General Properties)) the userid supplied in get_authToken is used (but the password will not be checked). If 'Use authInfo if provided' is not checked the default user, set to UNAUTHENTICATED by default (but configurable, see WebSphere Administrative console (UDDI => UDDI Nodes => General Properties => Default user ID)) is used.

The V1/2 SOAP interface also supports the UDDI API for get_authToken and discard_authToken API but use of this is optional.

- If security is disabled and get_authToken is not called, the default user, UNAUTHENTICATED, is used.
- If security is disabled and get_authToken is called, the specified userid is used (but the password is not checked).
- If WebSphere security is enabled, it takes priority over UDDI authentication, but if the Publish role is mapped to Everyone, get_authToken must be used and the userid and password will be checked by WebSphere.

The Security Roles provided with the UDDI Registry are as follows:

- GUI_Publish_User
- GUI_Inquiry_User
- SOAP_Publish_User
- SOAP_Inquiry_user
- EJB_Inquiry_Role
- EJB_Publish_Role
- V3 SOAP_Inquiry_User_Role
- V3 SOAP_Publish_User_Role
- V3 SOAP_CustodyTransfer_User_Role
- V3 SOAP_Security_User_Role

Multiple language encoding support in UDDI

UDDI API

UDDI Version 3 supports both UTF-8 and UTF-16 encoding. Internally UTF-16 characters are stored as UTF-8. This is transparent to the user application.

UDDI User Console

The UDDI user console only supports UTF-8 encoding. To enable this, you must configure the application server into which the UDDI Registry application is installed with UTF-8 encoding enabled. To do this, refer to ″Configuring application servers for UTF-8 encoding″ elsewhere in the WebSphere Information Center.

Customizing the UDDI User Console (GUI)

The look and feel of the UDDI console is determined by the styles defined in the *.css* files which are located in the /v3gui.war/theme directory of the installed UDDI Registry application directory. The UDDI Registry application directory will be one of the following, depending on where you have installed the UDDI Registry:

- If you have installed the UDDI Registry into an application server within a deployment manager cell, the directory is WAS_HOME/profiles/installedApps/<currentcell>/UDDIRegistry.<nodename>.<servername>.ear/v3gui.war
- If you have installed the UDDI Registry into a single application server which is not part of a deployment manager cell, the directory is <WAS_HOME>\profiles\<profile name>\installedApps\<node_name>\UDDIRegistry.<nodename>.<servername>.ear\v3gui.war under the installedApps directory of the WebSphere Application Server in which you have installed the UDDI registry application as shown in the example below.

Style class definitions in these files can be edited to alter the overall theme of the user console, including font attributes, layout and colors.

Configuring SOAP API and GUI service

Configuring V1/V2 SOAP API services

You can configure the following Version 1 and Version 2 SOAP interface properties:

- *defaultPoolSize* - the number of SOAP parsers with which to initialize the parser pool for the SOAP interface. You can set this independently for the Publish (uddipublish) and Inquiry (uddi) APIs. For example, if you expect more inquiries than publish requests through the SOAP interface, you can set a larger pool size for the Inquiry API. The default initial size for both APIs is 10.
- Whether the API is to be secure (accessed using HTTPS) or insecure (accessed using HTTP). The default for Publish is to use HTTPS and Inquiry to use HTTP.

To configure these properties after the UDDI application has been installed:

- Edit the active deployment descriptor (web.xml) for the V1/2 SOAP module (soap.war) . This file is located in the soap.war\WEB-INF subdirectory of the saved configuration data for the deployed uddi.ear application. For example:

```
WAS_HOME\AppServer\profiles\<hostname>Profile01\config\cells\
  <hostname>Node01Cell\applications\UDDI V3 Registry\soap.war\WEB-INF\web.xml)
```

- To modify defaultPoolSize for V1/2 Publish modify the ’param-value‘ element in the servlet with ’servlet-name‘ = uddipublish
- To modify defaultPoolSize for V1/2 Inquiry modify the ’param-value‘ element in the ’servlet‘ with ’servlet-name‘ = uddi
- To modify the user data constraint transport guarantee for V1/2 publish which determines whether the Publish service is to be confidential (accessed using HTTPS) or insecure (using HTTP) find the ’security-constraint‘ with id = ’UDDIPublishTransportConstraint‘ and set its ’user-data-constraint‘ ’transport-guarantee‘ to CONFIDENTIAL or NONE
- Stop and restart the application server for the changes to take effect

Configuring V3 SOAP API services

You can configure the following Version 3 SOAP interface properties:

- Whether the Publish, Custody Transfer, Security and Inquiry API services are to be secure (accessed using HTTPS) or insecure (accessed using HTTP). The default for Publish, CustodyTransfer and Security APIs is to use HTTPS and Inquiry to use HTTP

To configure these properties after the UDDI application has been installed:

- • Edit the active deployment descriptor (web.xml) for the v3 SOAP module (v3soap.war) . This file is located in the v3soap.war\WEB-INF subdirectory of the saved configuration data for the deployed uddi.ear application. For example:

```
WAS_HOME\AppServer\profiles\<hostname>Profile01\config\cells\
  <hostname>Node01Cell\applications\UDDI V3 Registry\v3soap.war\WEB-INF\web.xml)
```

- To modify the user data constraint transport guarantee for V3 publish which determines whether the V3 Publish service is to be confidential (accessed using HTTPS) or insecure (using HTTP) find the ’security-constraint‘ with ’display-name‘ = ’AxisServlet Publish Resource Collection‘ and set its ’user-data-constraint‘ ’transport-guarantee‘ to CONFIDENTIAL or NONE
- To modify the user data constraint transport guarantee for V3 custody transfer which determines whether the V3 Custody Transfer service is to be confidential (accessed using HTTPS) or insecure (via HTTP) find the ’security-constraint‘ with ’display-name‘ = ’AxisServlet CustodyTransfer Resource Collection‘ and set its ’user-data-constraint‘ ’transport-guarantee‘ to CONFIDENTIAL or NONE
- • To modify the user data constraint transport guarantee for V3 security which determines whether the V3 Security service is to be confidential (accessed using HTTPS) or insecure (via HTTP) find the ’security-constraint‘ with ’display-name‘ = ’AxisServlet Security Resource Collection‘ and set its ’user-data-constraint‘ ’transport-guarantee‘ to CONFIDENTIAL or NONE
- To modify the user data constraint transport guarantee for V3 inquiry which determines whether the V3 Inquiry service is to be confidential (accessed using HTTPS) or insecure (via HTTP) find the ’security-constraint‘ with ’display-name‘ = ’AxisServlet Inquiry Resource Collection‘ and set its ’user-data-constraint‘ ’transport-guarantee‘ to CONFIDENTIAL or NONE
- Stop and restart the application server for the changes to take effect.

Configuring V3 GUI services

You can configure the following Version 3 GUI properties:

- Whether the Publish and Inquiry API services are to be secure (accessed using HTTPS) or insecure (accessed using HTTP). The default for Publish, is to use HTTPS and Inquiry to use HTTP

To configure these properties after the UDDI application has been installed:

- Edit the active deployment descriptor (web.xml) for the V3 GUI module (v3gui.war) . This file is located in the v3gui.war\WEB-INF subdirectory of the saved configuration data for the deployed uddi.ear application. For example:

```
WAS_HOME\AppServer\profiles\<hostname>Profile01\config\cells\
    <hostname>Node01Cell\applications\UDDI V3 Registry\v3gui.war\WEB-INF\web.xml)
```

- To modify the user data constraint transport guarantee for V3 publish which determines whether the V3 Publish service is to be confidential (accessed using HTTPS) or insecure (via HTTP) find the ’security-constraint id‘ = ’UDDIPublishSecurityContraint‘ and set its ’user-data-constraint‘ ’transport-guarantee‘ to CONFIDENTIAL or NONE
- To modify the user data constraint transport guarantee for V3 inquiry which determines whether the V3 Inquiry service is to be confidential (accessed using HTTPS) or insecure (via HTTP) find the ’security-constraint id‘ =‘ ’UDDIInquireSecurityConstraint‘ and set its ’user-data-constraint‘ ’transport-guarantee‘ to CONFIDENTIAL or NONE
- Stop and restart the application server for the changes to take effect

Configuring WebSphere to use HTTPS and SSL

To support the use of secure access with the IBM WebSphere UDDI Registry, you must configure WebSphere to use HTTPS and SSL. Refer to Secure Sockets Layer settings for custom properties elsewhere in this Information Center for configuring SSL in WebSphere Application Server. It is assumed throughout the information for the UDDI Registry that, where SSL is used, it has been configured on port 9443.

Managing the UDDI Registry

You can use either the WebSphere Application Server administrative console or the Java Management Extensions (JMX) management interface to manage UDDI Registries.

In previous version of WebSphere Application Server and UDDI a properties file was used, but from WebSphere Application Server Version 6, all policies and properties are managed through either the JMX management interface or the administrative console.

JMX can be used to programmatically monitor and configure UDDI registries, and is explained in ″Using administrative programs (JMX)″ in the information center. See IBM WebSphere Registry Administrative Interface for full details on using the UDDI administrative interface. To manage UDDI registries using the WebSphere Application Server administrative console, start from the UDDI link in the left navigation pane as described below.

Using the UDDI management functions available in the WebSphere Application Server administrative console, you can perform the following operations:

- view and manage the status of all UDDI nodes in a cell
- initialize UDDI nodes with required settings
- configure general properties that affect UDDI runtime behavior
- manage UDDI policy settings
- create, view and update UDDI publishers
- create, view and update publisher tiers which limit how many UDDI entries may be published
- view and manage the status of value sets

UDDI node collection

To configure node properties, policies, value set status and user entitlements, complete the following steps:

From the administrative console, expand **UDDI** in the navigation pane then click **UDDI Nodes**. This displays the collection of UDDI nodes in the cell.

Each UDDI node is represented by a UDDI Node ID, Description, UDDI Application Name and Status. The Status can be either *Initialization Pending*, *Activated* or *Deactivated*. To activate UDDI nodes that are *Deactivated*, select them by checking the corresponding check boxes in the Select column and click the *Activate* button. Similarly to deactivate UDDI nodes, select them and click the *Deactivate* button.

To manage an individual UDDI node, click on its UDDI Node ID link. This takes you to the Configuration page where you can manage its general properties, initialize it if the status is set to *Initialization Pending*, and access pages for managing policies, UDDI publishers, tiers and value sets. Refer to UDDI node settings for details on the next available topic.

Important: To be able to manage a UDDI node, the associated UDDI application must be running. If the application is not running you will not see the UDDI node in the list of available choices.

UDDI node settings:

This topic contains details of the general properties that you can configure for a UDDI node.

To view this administrative console page, click **UDDI** → **UDDI Nodes** > *UDDI_node_id*.

By clicking on a node in the UDDI node ID column the UDDI node detail page is displayed. The UDDI node detail page displays a set of General Properties for the UDDI node, some of which may be editable depending on the state of the node. There are also links to Additional Properties (Value sets, Tiers and UDDI Publishers) and links to Policy Groups where UDDI node policy may be viewed and changed.

Unless the UDDI node has been installed as a default UDDI node (as defined in ″UDDI Registry terminology″ in the information center) there are some important general properties that need to be set before the UDDI node can be initialized. These properties are all marked as being required (indicated by the presence of a '*' next to the input field). You may set the values as many times as you wish before initialization. However, once the UDDI node has been initialized, these properties will become read only for the lifetime of that UDDI node. It is very important to set these properties correctly. Other general properties of the UDDI node may be set before, and after, initialization.

Once the general properties have been set to appropriate values, you can click *OK* (which saves your changes and exits the page), or *Apply* (which saves your changes and leaves you on the same page). At this point the changes will have been stored.

If the UDDI node is in the *Not Initialized* state, indicated on the UDDI node detail page by the presence of an *Initialize* button (above the General Properties section), the UDDI node can be initialized by clicking the *Initialize* button. This operation may take a while to complete. It is important to remember to save any changes you have made to the general properties by clicking *Apply* or *OK* before the *Initialize* button is pressed.

The other UDDI settings that a UDDI administrator can manage are shown to the right of the screen and are described in the following topics:

- Value set collection

  This topic contains details of the value sets settings that you can configure for a UDDI node.
- Tier collection

  This topic contains details of the UDDI publisher tiers that you can configure for a UDDI node.
- UDDI Publisher collection

  This topic contains details of the publishers that have been registered with the UDDI node.
- Policy groups

  This topic contains links to the detailed settings information for every policy group that you can configure for a UDDI node.

UDDI Node ID:

The unique identifier given to a UDDI node in a UDDI registry. This must be a valid UDDI key.

The value for the node ID will also be the domain key for this UDDI node.

Required	Yes
Data type	String
Default	A valid domain key for this UDDI node

UDDI node description:

The user supplied description of this UDDI node.

Required	Yes
Data type	String

Root key generator:

Specifies the root key space of the registry.

Registries intending to become affiliate registries may want to specify a root key space in a partition below the root key generator of the parent root registry, for example, uddi:thisregistry.com:keygenerator.

Required	Yes
Data type	String
Default	uddi:default:keygenerator

Prefix for generated discoveryURLs:

The URL prefix for the GET servlet.

The URL prefix applied to generated discoveryURLs in businessEntity elements so they can be returned on HTTP GET requests. The format is 'http://hostname:port/uddisoap/', where 'uddisoap' is the UDDI version 2 SOAP servlet's context root. This property applies to UDDI version 2 API requests only.

Required	Yes
Data type	String
Default	http://localhost:9080/uddisoap

Maximum inquiry result set size:

The maximum size of result set which the registry will process for an inquiry API request. If the result set exceeds this value, an E_resultSetTooLarge error is returned to the user. Setting the value higher allows larger result sets but may cause increased response times.

Note: If this value is set too low users will get an E_resultSetTooLarge error message, whereas setting to too high might cause increased response times. If the value is set too low and users use imprecise search criteria the likelihood of receiving the E_resultSetTooLarge is increased.

Data type	Integer
Default	500
Range	0 to 1024

Maximum inquiry response set size:

For inquiry API requests, this value controls the maximum number of results returned in each response. If the number of results in the result set is greater than this value, the response will only include a subset of results. The user can retrieve remaining results using the listDescription feature as described in the UDDI specification. Setting this value too low will require the user to make more requests to retrieve the remainder of the result set.

Note: This value can not be higher than the value set for ″Maximum inquiry results″. Setting this value too low increases the number of requests needed to achieve the full result set.

Data type	Integer
Default	500
Range	0 to 1024

Maximum search names:

The maximum number of names that can be supplied in an inquiry API request. Increasing this value can significantly slow response times of the UDDI node.

This can be used to control the complexity of requests that this UDDI node will allow. The recommendation is to not set this value above 8.

Data type	Integer
Default	5
Range	1 to 64

Maximum search keys:

The maximum number of keys that can be supplied in an inquiry API request. This limits the number of references that can be specified in categoryBag, identifierBag, tModelBag and discoveryURLs. Increasing this value can significantly increase response times for the UDDI node.

This can be used to control the complexity of requests that this UDDI node will allow. The recommended setting for this is 5 or less.

In exceptional cases, the UDDI node may reject complex requests with excessive numbers of keys even if the value of maxSearchKeys is not exceeded.

Data type	Integer
Default	5
Range	1 to 64

Key space requests require digital signature:

Specifies whether tModel:keyGenerator requests must be digitally signed.

Use tier limits:

Specifies whether an approval manager is used to check publication tier limits.

If set to false, the number of UDDI entities that can be published is unlimited.

Use authInfo credentials if provided:

Specifies if authInfo contents in UDDI API requests are used to validate users when WebSphere global security is off. If this setting is true, the UDDI node will use the request's authInfo element, otherwise the default user name is used.

Data type	Integer
Default	True

Authentication token expiry period:

The period after which authentication tokens are invalidated (in minutes), and a new authToken is required.

Note: The setting should be sufficient to ensure operational success. Longer settings can increase the risk of illegal authToken use.

Data type	Integer
Default	30
Range	1 to 10080 (minutes - 1 week)

Automatically register UDDI publishers:

Specifies if UDDI publishers are automatically registered, and assigned to the default tier.

Automatically registered UDDI publishers are given default entitlements.

Default user name:

Specifies the user name used for publish operations when WebSphere security is disabled.

Data type	String
Default	UNAUTHENTICATED

Default language code:

Applies only to UDDI Version 1 and Version 2 requests, the default language code to be used for xml:lang when not otherwise specified.

Data type	String
Default	en

Value set collection:

Use this page to view and configure the value sets that have been installed in a UDDI node.

To view this administrative console page, click **UDDI** → **UDDI Nodes** > *UDDI_node_id* >**Value Sets**.

Value sets in a UDDI node are either supported or not supported by policy. Value sets in a UDDI node are either supported or not supported by policy. By default, new value sets are *not* supported. When you have published a value set tModel and loaded value set data, you can control whether other UDDI entities can reference this value set tModel by setting the *Supported* policy.

To enable support for one or more value sets, select the value sets by clicking on the appropriate check boxes in the *Select* column. Click the *Enable Support* button. The supported field for all the selected value sets will be updated to reflect the new status.

To disable support for a value set, which may be necessary before it is removed from the UDDI node, select the value sets in the same manner as for enabling support. Click the *Disable Support* button.

Clicking on a value set name in the list takes you to the general properties page for that value set as described in Value set settings.

Name:

The name of the tModel that represents the value set.

tModelkey:

The key for the tModel that represents the value set.

Supported:

Indicates whether references to this value set are supported by policy in this UDDI node.

Value set settings:

Use this page to view the attributes of a value set in a UDDI node.

To view this administrative console page, click **UDDI** → **UDDI Nodes** > *UDDI_node_id* >**Value Sets** > *value_set_name*.

This page shows the values of keyedReferences in the tModel that represents this value set. It also shows the *Supported* status of the value set as described on the Value set collection page. All properties are read-only. The *Supported* status can be changed on the Value Set page.

Unvalidatable:

Specifies whether this value set is unvalidatable. This is set by the value set tModel publisher to indicate if the value set is available or not for use by publish requests.

Checked:

Specifies whether this value set is checked. If set to true, UDDI entities that reference this value set will be validated to ensure their values are present in this value set.

Cached:

Specifies whether this value set is cached in this UDDI node.

Externally cacheable:

Specifies whether this value set is externally cacheable.

Externally validated:

Specifies whether this value set is externally validated.

Supported:

Specifies whether this value set is supported by policy in this UDDI node.

Last cached:

Specifies the date when this value set was last cached in the UDDI node.

Tier collection:

This topic contains a list of the available tiers for the UDDI node. You can also create new tiers and delete tiers from this page.

To view this administrative console page, click **UDDI** → **UDDI Nodes** > *UDDI_node_id* >**Tiers**.

This page shows the available tiers for the UDDI node. Clicking a tier name will show the General Properties for the specific tier as detailed in Tier settings. To delete a Tier from the list, select the relevant name and click *Delete*. Clicking *New* will take you to the General Properties page with the same properties as described in Tier settings.

One of the tiers in the collection will be marked as the default tier, indicated by *(default)* appearing next to the tier's name. The default tier will be assigned to UDDI publishers that are registered automatically when automatic user registration is turned on. To set the default tier, select the appropriate tier in the collection and press the *Set default* button. Note that it is not possible to delete a tier if it is currently marked as the default tier, or it is currently assigned to a UDDI publisher.

Name:

The name of the tier.

Description:

User supplied descriptive text about the tier.

UDDI Tier settings:

This topic contains details of the general properties that you can configure for a UDDI publisher tier.

To view this administrative console page, click **UDDI** → **UDDI Nodes** > *UDDI_node_id* >**Tiers** > *tier_name*.

Name:

The name of the tier.

Required	Yes
Data type	String
Range	1 to 255

Description:

The user supplied description of the tier.

Data type	String
Default	Empty
Range	0 to 255

Maximum businesses:

The maximum number of businesses that UDDI publishers in this tier are allowed to publish in this tier.

Maximum services:

The maximum number of services UDDI publishers in this tier are allowed to publish.

Maximum bindings:

The maximum number of bindings UDDI publishers in this tier are allowed to publish.

Maximum tModels:

The maximum number of tModels UDDI publishers in this tier are allowed to publish.

Maximum publisher assertions:

The maximum number of publisher assertions UDDI publishers in this tier are allowed to add.

For each of the maximum fields described above, the data is:

Required	Yes
Data type	Integer
Default	0
Range	0 to 2147483647 (for all intents and purposes, unlimited)

UDDI Publisher collection:

This page shows the WebSphere users that are currently registered as UDDI publishers.

To view this administrative console page, click **UDDI** → **UDDI Nodes** > *UDDI_node_id* >**UDDI Publishers**.

To create a UDDI publisher click on the New button. This opens the UDDI publisher settings page where details about the publisher can be entered.

It is possible to assign multiple publishers to a tier without having to edit each one individually. To do this select the appropriate publishers in the collection table. From the selection box at the top of the collection table choose from one of the tiers available on the UDDI node. Finally, click the *Assign tier* button to update the selected publishers.

To delete publishers select them in the collection table and then press the *Delete* button.

After the users have been registered as UDDI publishers, their entitlements can be edited as described in UDDI Publisher settings.

User name:

The name of the UDDI publisher.

Tier:

The publication limits tier to which the UDDI publisher has been assigned.

Create UDDI Publishers:

Use this page to register existing WebSphere Application Server users as UDDI publishers. Create each UDDI publisher individually using the New button on the UDDI publisher collection page.

To view this administrative console page, click **UDDI** → **UDDI Nodes** > *UDDI_node_id* >**UDDI Publishers** → **New**.

Users known to the application server can be registered as UDDI publishers.

Assign entitlements and a tier to the selected group

UDDI publishers are given permission to perform specific actions with entitlements. Set the entitlements for the selected UDDI publishers with the check-box next to each entitlement.

After the users have been registered as UDDI publishers, their entitlements can be edited as described in UDDI Publisher settings.

User name:

The name of the UDDI publisher to be created. This should be a user known to the application server.

Allowed to publish keyGenerator:

The UDDI publisher has permission to publish tModel:keyGenerator.

If false, UDDI publishers cannot publish keyGenerators of any kind. In this situation all the entitlement settings are disregarded, irrespective of how they are set.

Allowed to publish keyGenerator with a domain key:

The UDDI publisher has permission to publish tModel:keyGenerator with a domain key.

Allowed to publish keyGenerator with a derived key:

The UDDI publisher has permission to publish tModel:keyGenerator with a derived key.

The tModel:keyGenerator is a request for key space. An example of a legal derived key is uddi:tempuri.com:fish:buyingService where the key is based on the derivedKey ″uddi:tempuri.com:fish″. the string 'buyingService' is the key's key specific string (KSS).

Allowed to publish keyGenerator with UUID keys:

The UDDI publisher user has permission to publish tModel:keyGenerator providing a UUID key.

Allowed to publish with UUID key:

The UDDI publisher has permission to publish elements providing a UUID key.

Allowed to subscribe:

The UDDI publisher can register requests to receive notifications of specific registry content changes.

Tier:

The tier to which the selected UDDI publishers are assigned.

UDDI Publisher settings:

Use this page to view and edit the properties of UDDI publishers.

To view this administrative console page, click **UDDI** → **UDDI Nodes** > *UDDI_node_id* >**UDDI Publishers** > *user_name*.

This page shows the entitlements and publication limits tier for a particular UDDI publisher.

Allowed to publish keyGenerator:

The UDDI publisher has permission to publish tModel:keyGenerator.

If false, UDDI publishers cannot publish keyGenerators of any kind. In this situation the following permissions ('Allowed to publish keyGenerator with a domain key', 'Allowed to publish keyGenerator with a derived key', 'Allowed to publish keyGenerator with UUID keys', 'Allowed to publish with UUID keys' and 'Allowed to subscribe') will be disregarded irrespective of how they are set.

Allowed to publish keyGenerator with a domain key:

The UDDI publisher has permission to publish tModel:keyGenerator with a domain key.

Allowed to publish keyGenerator with a derived key:

The UDDI publisher has permission to publish tModel:keyGenerator with a derived key.

The tModel:keyGenerator is a request for key space. An example of a legal derived key is uddi:tempuri.com:fish:buyingService where the key is based on the derivedKey ″uddi:tempuri.com:fish″. the string 'buyingService' is the key's key specific string (KSS).

Allowed to publish keyGenerator with UUID keys:

The UDDI publisher user has permission to publish tModel:keyGenerator providing a UUID key.

Allowed to publish with UUID key:

The UDDI publisher has permission to publish elements providing a UUID key.

Allowed to subscribe:

The UDDI publisher can register requests to receive notifications of specific registry content changes.

Tier:

The tier to which the UDDI publisher is assigned.

Policy groups:

This topic contains links to the detailed settings information for every policy group that you can configure for a UDDI Registry node.

To view this administrative console page, click **UDDI** → **UDDI Nodes** > *UDDI_node_id*.

To the right of the page is a list of the Policy Groups that can be acted upon. Clicking on a specific group will open the page for the group required.

The policy groups available to act upon are:
- “UDDI keying policy settings”
- “UDDI user policy settings”
- “UDDI node API policy settings” on page 1124
- “UDDI data custody policy settings” on page 1124
- “UDDI value set policy” on page 1125
- “UDDI node miscellaneous” on page 1125

UDDI keying policy settings:

This topic contains details of the UDDI keying settings that you can configure for a UDDI Registry.

To view this administrative console page, click **UDDI** → **UDDI Nodes** > *UDDI_node_id* >**UDDI Keying**.

Registry key generation:

Allows publishers to publish key generator tModels.

Defines whether a given UDDI node or publisher is allowed to register a key generator tModel. When true, this allows the set of publishers to be managed using the facilities provided in the UDDI Publisher settings

Registry support of UUID keys:

Allow publisher supplied uuidKeys in publish requests.

If true, this allows the set of publishers to be managed using the facilities provided in UDDI Publisher settings

UDDI user policy settings:

This topic contains details of the user policy settings that you can configure for a UDDI Registry node.

To view this administrative console page, click **UDDI** → **UDDI Nodes** > *UDDI_node_id* >**User policies**.

Allow transfer of ownership:

When true, data ownership can be transferred between owners within the UDDI node.

UDDI node API policy settings:

This topic contains details of the API settings that you can configure for a UDDI Registry node.

To view this administrative console page, click **UDDI** → **UDDI Nodes** > *UDDI_node_id* > **APIs**.

Authorization for inquiry:

Specifies if authorization using the authInfo element is required for inquiry API requests.

Typically, UDDI registries are configured not to require authorization for registry API requests. This setting is only relevant if the V3SOAP_Inquiry_User_Role is set to *everyone* and WebSphere Application Server global security is on. If WebSphere Application Server global security is off, this setting is ignored. If WebSphere Application Server global security is on and the V3SOAP_Inquiry_User_role is not set to *everyone*, this setting is ignored.

Authorization for publish:

Specifies if authorization using the authInfo element is required for publish API requests.

Typically, UDDI registries are configured not to require authorization for registry API requests. This setting is only relevant if the V3SOAP_Publish_User_Role is set to *everyone* and WebSphere Application Server global security is on. If WebSphere Application Server global security is off, this setting is ignored. If WebSphere Application Server global security is on and the V3SOAP_Publish_User_role is not set to *everyone*, this setting is ignored.

Authorization for custody transfer:

Specifies if authorization using the authInfo element is required for custody transfer API requests.

Typically, UDDI registries are configured not to require authorization for registry API requests. This setting is only relevant if the V3SOAP_CustodyTransfer_User_Role is set to *everyone* and WebSphere Application Server global security is on. If WebSphere Application Server global security is off, this setting is ignored. If WebSphere Application Server global security is on and the V3SOAP_CustodyTransfer_User_role is not set to *everyone*, this setting is ignored.

UDDI data custody policy settings:

This topic contains details of the data custody settings that you can configure for a UDDI Registry node.

To view this administrative console page, click **UDDI** → **UDDI Nodes** > *UDDI_node_id* >**Data custody**.

Transfer token expiration period:

The length of time (in minutes) after the issue of a transfer token before it expires.

Note: Setting too large a value might expose the UDDI registry to a risk of misuse.

Data type	Integer
Default	1440
Range	1 to 2147483647 (for all intents and purposes, unlimited)

UDDI value set policy:

This topic contains details of the value set policy settings that you can configure for a UDDI Registry node.

To view this administrative console page, click **UDDI** → **UDDI Nodes** > *UDDI_node_id* >**Value Set Policy**.

Enable checked value sets:

Specifies if checked value sets are supported. When false, publish requests containing references to checked value sets are be rejected.

UDDI node miscellaneous:

This topic contains details of the miscellaneous settings that you can configure for a UDDI node.

To view this administrative console page, click **UDDI** → **UDDI Nodes** > *UDDI_node_id* > **Miscellaneous**.

Node generates discoveryURLs:

Defines whether the UDDI node generates discoveryURLs.

Node supports HTTP Get Service:

Specifies if the UDDI node supports an HTTP GET service for access to the XML representations of UDDI data structures.

URL prefix for V3 GET servlet:

The URL prefix for the UDDI version 3 GET servlet

The prefix for the URL to the GET servlet used to retrieve the XML representation of a published entity. When a businessEntity is published, if the policy for Node Discovery URLs is set to true, the discoveryURL value is generated based on the prefix value. Otherwise, the discoveryURL value will be empty.

The UDDI Version 3 specification recommends that discoveryURLs are **not** generated as they can affect the use of digital signatures. If you do enable generation of discoveryURLs, it is recommended that the URL prefix is not changed after the point at which the policy to enable generation of discoveryURLs is enabled. Not doing so will mean discoveryURLs generated using the earlier URL prefix would no longer work.

Data type	URL
Default	http://localhost:9080/uddiv3soap/

UDDI Registry Administrative Interface Overview

The UDDI Registry Administrative Interface allows you to inspect and manage the runtime configuration of a UDDI application. This includes managing the the information and the activation state about a UDDI node, updating properties and policies, setting publish tier limits, registration of UDDI publishers, and controlling value set support. The operations of the UDDI Registry Administrative Interface can be read and invoked using standard JMX (Java Management Extensions) interfaces.

The use of JMX is explained in ″Using administrative programs (JMX)″ in the information center. See the IBM WebSphere UDDI Registry Administrative Interface for full details on using the UDDI administrative interface.

Backing up and restoring the UDDI Registry database

If you want to protect the data in your UDDI Registry database, you can back up and restore the database using the facilities of the database product your UDDI node is on.

Cloudscape

To back-up a Cloudscape based registry, ensure that the UDDI application is stopped (and hence, not accessing the Cloudscape database), and ensure that no other application is using the Cloudscape UDDI30 database, then make a copy of the UDDI30 directory using the file system that the directory resides upon.

Non-Cloudscape

Use the appropriate import and export tools for the database being used to contain the UDDI Registry.

- Backup

  Include elements in schemas named IBMUDI30 and IBMUDS30
- Restore

  For restoration we recommend deleting the schemas IBMUDI30 and IBMUDS30, recreating database structures using the original scripts - with slight modifications - and importing the previously saved data, as described in the steps below:

  1. Delete the schemas IBMUDI30 and IBMUDS30 *this will result in any IBM UDDI structures being destroyed.*
  2. Create database structures (for DB2 see Creating a DB2 database, for Oracle see Creating an Oracle database or, for Cloudscape, see Creating a Cloudscape database for details) as per the original creation **except** that the final step (xxxxxx_**70**xxxx.*) must not be run *this will result in a virgin, and almost empty, database into which your backed-up data may be imported.*
  3. Delete all rows in the table IBMUDS30.UDDIDBSCHEMAVER *to avoid a clash between a row inserted by the scripts and the row backed-up using the command:*

     ```
     delete from IBMUDS30.UDDIDBSCHEMAVER
     ```
  4. Restore the previously backed-up data in schemas IBMUDI30 and IBMUDS30

Data access resources

Task overview: Accessing data from applications

Various enterprise information systems (EIS) use different methods for storing data. These *backend* data stores might be relational databases, procedural transaction programs, or object-oriented databases. IBM WebSphere Application Server provides several options for accessing an information system’s backend data store:

- Programming directly to the database through the JDBC 2.0 optional package API or the JDBC 3.0 API.
- Programming to the procedural backend transaction through various J2EE Connector Architecture (JCA) 1.0 or 1.5 compliant connectors.
- Programming in the bean-managed persistence (BMP) bean or servlets indirectly accessing the backend store through either the JDBC API or JCA compliant connectors.
- Using container-managed persistence (CMP) beans.
- Using embedded Structured Query Language in Java (SQLJ) support with applications that use DB2 as a backend database.

- Using the IBM data access beans, which also use the JDBC API, but give you a rich set of features and function that hide much of the complexity associated with accessing relational databases.

For all of these options, *except for using the JCA 1.0 or 1.5 compliant connectors*, the prerequisite Web site details which databases and drivers are currently supported. See ″Hardware and software requirements″ in the information center for more information.

1. Develop data access applications. Develop your application to access data using the various ways available through the WebSphere Application Server. You can access data through APIs, container-managed persistence beans, bean-managed persistence beans, session beans, or Web components.
2. Assemble data access applications using the assembly tool. Assemble your application by creating and mapping resource references.
3. Prepare for deployment: Ensure that the appropriate database objects are available. Create or configure any databases or tables required, set necessary configuration parameters to handle expected load, and configure any necessary JDBC providers and data source objects for servlets, enterprise beans, and client applications to use.
4. Install the application on your application server.

Resource adapter

A resource adapter is a system-level software driver that a Java application uses to connect to an enterprise information system (EIS).

A resource adapter plugs into an application server and provides connectivity between the EIS, the application server, and the enterprise application.

An application server vendor extends its system once to support the J2EE Connector Architecture (JCA) and is then assured of seamless connectivity to multiple EISs. Likewise, an EIS vendor provides one standard resource adapter with the capability to plug into any application server that supports the connector architecture.

WebSphere Application Server provides the WebSphere Relational Resource Adapter (RRA) implementation. This resource adapter provides data access through JDBC calls to access the database dynamically. The connection management is based on the JCA connection management architecture. It provides connection pooling, transaction, and security support. WebSphere Application Server version 6.0 supports JCA versions 1.0 and 1.5.

Data access for container-managed persistence (CMP) beans is managed by the WebSphere Persistence Manager indirectly. The JCA specification supports persistence manager delegation of the data access to the JCA resource adapter without knowing the specific backend store. For the relational database access, the persistence manager uses the relational resource adapter to access the data from the database. You can find the supported database platforms for the JDBC API at the WebSphere Application Server prerequisite Web site.

J2EE Connector Architecture resource adapters:

A J2EE Connector Architecture (JCA) resource adapter is any resource adapter conforming to the JCA Specification.

The product supports any resource adapter that implements version 1.0 or 1.5 of this specification. IBM supplies resource adapters for many enterprise systems separately from the WebSphere Application Server package, including (but not limited to): the Customer Information Control System (CICS), Host On-Demand (HOD), Information Management System (IMS), and Systems, Applications, and Products (SAP) R/3 .

The general approach to writing an application that uses a JCA resource adapter is to develop EJB session beans or services with tools such as Rational Application Developer. The session bean uses the *javax.resource.cci* interfaces to communicate with an enterprise information system through the resource adapter.

WebSphere relational resource adapter settings:

Use this page to view the default WebSphere relational resource adapter settings.

This is the WebSphere-provided relational resource adapter for handling data access to any relational data base. This adapter is preinstalled by WebSphere Application Server. Although the default relational resource adapter settings are viewable, you cannot make changes to them.

To view this administrative console page, click **Resources** > **Resource Adapters** > **WebSphere Relational Resource Adapter**.

Name:

Specifies the name of the resource provider.

Data type	String

Description:

Specifies a description of the relational resource adapter.

Data type	String

Archive path:

Specifies the path to the Resource Adapter Archive (RAR) file containing the module for this resource adapter.

Data type	String

Class path:

Specifies a list of paths or Java Archive (JAR) file names, which together form the location for the resource provider classes.

Data type	String

Native path:

Specifies a list of paths that forms the location for the resource provider native libraries.

Data type	String

WebSphere Relational Resource Adapter:

The WebSphere Relational Resource Adapter (RRA) provides enterprise applications deployed on WebSphere Application Server access to relational databases.

The WebSphere RRA is installed and runs as part of WebSphere Application Server, and needs no further administration.

The RRA supports both the configuration and use of JDBC data sources and J2EE Connection Architecture (JCA) connection factories. The RRA supports the configuration and use of data sources implemented as either JDBC data sources or J2EE Connector Architecture connection factories. Data sources can be used directly by applications, or they can be configured for use by container-managed persistence (CMP) entity beans.

For more information about the WebSphere Relational Resource Adapter, see the following topics:

- For information about resource adapters, see “Resource adapter” on page 1127
- For information about resource adapters and data access, see “Data access portability features”
- For RRA settings, see “WebSphere relational resource adapter settings” on page 1128
- For information about CMP connection factories, see “Connection factory” on page 1133
- For information about enterprise beans, see ″Introduction: EJB applications″ in the information center

Data access portability features: The WebSphere Application Server relational resource adapter (RRA) provides a portability feature that enables applications to access data from different databases without changing the application. In addition, WebSphere Application Server enables you to plug in a data source that is not supported by WebSphere persistence. However, the data source *must* be implemented as either the *XADataSource* type or the *ConnectionPoolDataSource* type, and it must be in compliance with the JDBC 2.x specification.

You can achieve application portability through the following:

DataStoreHelper interface

With this interface, each data store platform can plug in its own private data store specific functions that the relational resource adapter run time uses. WebSphere Application Server provides an implementation for each supported JDBC provider.

In addition, the interface also provides a GenericDataStoreHelper class for unsupported data sources to use. You can subclass the GenericDataStoreHelper class or other WebSphere provided helpers to support any new data source.

Note: If you are configuring data access through a user-defined JDBC provider, do not implement the DataStoreHelper interface directly. Either subclass the GenericDataStoreHelper class or subclass one of the DataStoreHelper implementation classes provided by IBM (if your database behavior or SQL syntax is similar to one of these provided classes).

For more information, see the API documentation **DataStoreHelper** topic (as listed in the API documentation index).

The following code segment shows how a new data store helper is created to add new error mappings for an unsupported data source.

```
public class NewDSHelper extends GenericDataStoreHelper
{
  public NewDSHelper(java.util.Properties dataStoreHelperProperties)
  {
    super(dataStoreHelperProperties);
    java.util.Hashtable myErrorMap = null;
    myErrorMap = new java.util.Hashtable();
    myErrorMap.put(new Integer(-803), myDuplicateKeyException.class);
    myErrorMap.put(new Integer(-1015), myStaleConnectionException.class);
    myErrorMap.put("S1000", MyTableNotFoundException.class);
    setUserDefinedMap(myErrorMap);
    ...
  }
}
```

WSCallHelper class

This class provides two methods that enable you to use vendor-specific methods and classes that do not conform to the standard JDBC APIs (and are not part of WebSphere Application Server extension packages).

- **jdbcCall() method**

  By using the static jdbcCall() method, you can invoke vendor-specific, nonstandard JDBC methods on your JDBC objects. (For more information, see the API documentation **WSCallHelper** topic.) The following code segment illustrates using this method with a DB2 data source:

  ```
  Connection conn = ds.getConnection();
  // get connection attribute
  String connectionAttribute =(String) WSCallHelper.jdbcCall(DataSource.class, ds,
   "getConnectionAttribute", null, null);
  // setAutoClose to false
  WSCallHelper.jdbcCall(java.sql.Connection.class,
  conn, "setAutoClose",
  new Object[] { new Boolean(false)},
  new Class[] { boolean.class });
  // get data store helper
  DataStoreHelper dshelper = WSCallHelper.getDataStoreHelper(ds);
  ```

- **jdbcPass() method**

  Use this method to exploit the nonstandard JDBC classes that some database vendors provide. These classes contain methods that require vendors' proprietary JDBC objects to be passed as parameters.

  In particular, implementations of Oracle can involve use of nonstandard classes furnished by the vendor. Methods contained within these classes include:

  ```
  oracle.sql.ArrayDescriptor ArrayDescriptor.createDescriptor(java.lang.String,
      java.sql.Connection)
  oracle.sql.ARRAY new ARRAY(oracle.sql.ArrayDescriptor, java.sql.Connection,
      java.lang.Object)
  oracle.xml.sql.query.OracleXMLQuery(java.sql.Connection, java.lang.String)
  oracle.sql.BLOB.createTemporary(java.sql.Connection, boolean, int)
  oracle.sql.CLOB.createTemporary(java.sql.Connection, boolean, int)
  oracle.xdb.XMLType.createXML(java.sql.Connection, java.lang.String)
  ```

  The following code examples demonstrate the difference between a call to the XMLType.createXML() method over a direct connection to Oracle, and a call to the same method within WebSphere Application Server.

  1. Over a direct connection:

     ```
     XMLType poXML = XMLType.createXML(conn, poString);
     ```

  2. Within Application Server, using the jdbcPass() method:

     ```
     XMLType poXML (XMLType)(WSCallHelper.jdbcPass(XMLType.class,
     "createXML", new Object[]{conn,poString},
      new Class[]{java.sql.Connection.class, java.lang.String.class},
      new int[]{WSCallHelper.CONNECTION,WSCallHelper.IGNORE}));
     ```

  There are two different jdbcPass() methods available, one for use in invoking static methods, another for use when invoking non-static methods. See the API documentation **WSCallHelper** topic.

  Note: Because of the possible problems that can occur by passing an underlying object to a method, WebSphere Application Server strictly controls which methods are allowed to be invoked using the jdbcPass() method support. If you require support for a method that is not listed previously in this document, please contact WebSphere Application Server support with information on the method you require.

  WARNING: Use of the jdbcPass() method causes the JDBC object to be used outside of WebSphere's protective mechanisms. Performing certain operations (such as setting autoCommit, or transaction isolation settings, etc.) outside of these protective mechanisms will cause problems with the future use of these pooled connections. IBM does not guarantee stability of the object after invocation of this method; it is the user's responsibility to ensure that invocation of this method does not perform operations that harm the object. Use at your own risk.

Example: Developing your own DataStoreHelper class: The DataStoreHelper interface supports each data store platform plugging in its own private data store specific functions that are used by the Relational Resource Adapter run time.

```
package com.ibm.websphere.examples.adapter;

import java.sql.SQLException;
import javax.resource.ResourceException;

import com.ibm.websphere.appprofile.accessintent.AccessIntent;
import com.ibm.websphere.ce.cm.*;
import com.ibm.websphere.rsadapter.WSInteractionSpec;

/**
* Example DataStoreHelper class, demonstrating how to create a user-defined DataStoreHelper.
* Implementation for each method is provided only as an example.  More detail would likely be
* required for any custom DataStoreHelper created for use by a real application.
*/
public class ExampleDataStoreHelper extends com.ibm.websphere.rsadapter.GenericDataStoreHelper
{
    static final long serialVersionUID = 8788931090149908285L;

    public ExampleDataStoreHelper(java.util.Properties props)
    {
        super(props);

        // Update the DataStoreHelperMetaData values for this helper.
        getMetaData().setGetTypeMapSupport(false);

        // Update the exception mappings for this helper.
        java.util.Map xMap = new java.util.HashMap();

        // Add an Error Code mapping to StaleConnectionException.
        xMap.put(new Integer(2310),  StaleConnectionException.class);
        // Add an Error Code mapping to DuplicateKeyException.
        xMap.put(new Integer(1062),  DuplicateKeyException.class);
        // Add a SQL State mapping to the user-defined ColumnNotFoundException
        xMap.put("S0022",            ColumnNotFoundException.class);
        // Undo an inherited StaleConnection SQL State mapping.
        xMap.put("S1000",            Void.class);

        setUserDefinedMap(xMap);

        // Note: If you are extending a helper class, it is
        // normally not necessary to issue 'getMetaData().setHelperType(...)'
        // because your custom helper will inherit the helper type from its
        // parent class.  However, certain applications may need to differentiate
        // between a custom helper and an existing helper of the same type,
        // so WebSphere has provided the value 'DataStoreHelper.CUSTOM_HELPER'
        // for this purpose.  If this functionality is needed by your application
        // insert the following line into your code:
        // getMetaData().setHelperType(DataStoreHelper.CUSTOM_HELPER);

    }

    public void doStatementCleanup(java.sql.PreparedStatement stmt) throws SQLException
    {
        // Clean up the statement so it may be cached and reused.
        stmt.setCursorName("");
        stmt.setEscapeProcessing(true);
        stmt.setFetchDirection(java.sql.ResultSet.FETCH_FORWARD);
        stmt.setMaxFieldSize(0);
        stmt.setMaxRows(0);
        stmt.setQueryTimeout(0);
    }

    public int getIsolationLevel(AccessIntent intent) throws ResourceException
    {
        // Determine an isolation level based on the AccessIntent.

        if (intent == null) return java.sql.Connection.TRANSACTION_SERIALIZABLE;

        return intent.getConcurrencyControl() == AccessIntent.CONCURRENCY_CONTROL_OPTIMISTIC ?
               java.sql.Connection.TRANSACTION_READ_COMMITTED :
               java.sql.Connection.TRANSACTION_REPEATABLE_READ;
    }
        public int getLockType(AccessIntent intent) {
           if ( intent.getConcurrencyControl() == AccessIntent.CONCURRENCY_CONTROL_PESSIMISTIC) {
              if ( intent.getAccessType() == AccessIntent.ACCESS_TYPE_READ ) {
                  return WSInteractionSpec.LOCKTYPE_SELECT;
              }
              else {
                  return WSInteractionSpec.LOCKTYPE_SELECT_FOR_UPDATE;
               }
           }
           return WSInteractionSpec.LOCKTYPE_SELECT;
        }

    public int getResultSetConcurrency(AccessIntent intent) throws ResourceException
    {
        // Determine a ResultSet concurrency based on the AccessIntent.

        return intent == null || intent.getAccessType() == AccessIntent.ACCESS_TYPE_READ ?
               java.sql.ResultSet.CONCUR_READ_ONLY :
               java.sql.ResultSet.CONCUR_UPDATABLE;
    }

    public int getResultSetType(AccessIntent intent) throws ResourceException
    {
        // Determine a ResultSet type based on the AccessIntent.

        if (intent == null) return java.sql.ResultSet.TYPE_SCROLL_INSENSITIVE;

        return intent.getCollectionAccess() == AccessIntent.COLLECTION_ACCESS_SERIAL ?
               java.sql.ResultSet.TYPE_FORWARD_ONLY :
               java.sql.ResultSet.TYPE_SCROLL_SENSITIVE;
    }
}
```

ColumnNotFoundException

```
package com.ibm.websphere.examples.adapter;

import java.sql.SQLException;
import com.ibm.websphere.ce.cm.PortableSQLException;

/**
* Example PortableSQLException subclass, which demonstrates how to create a user-defined
* exception for exception mapping.
*/
public class ColumnNotFoundException extends PortableSQLException
```

```
{
    public ColumnNotFoundException(SQLException sqlX)
    {
        super(sqlX);
    }
}
```

Connection factory

An application component uses a *connection factory* to access a connection instance, which the component then uses to connect to the underlying enterprise information system (EIS).

Examples of connections include database connections, Java Message Service connections, and SAP R/3 connections.

CMP Connection Factories collection:

Use this page to view existing CMP connection factories settings.

These are the connection factories used by a container-managed persistence (CMP) bean to access any backend data store. A CMP Connection Factory is used by EJB model 2.x Entities with CMP version 2.x. Connection factories listed on this page are created automatically under the WebSphere Relational Resource Adapter when you check the box *Use this DataSource in container managed persistence (CMP)* in the General Properties area on the Data Source page. You cannot modify the settings for a CMP Connection Factory, and you can not delete CMP Connection Factories from this collection. To remove the CMP Connection Factory object, you must navigate to the data source associated with the CMP Connection Factory and uncheck the *Use this DataSource for CMP* checkbox.

To view this administrative console page, click **Resources** >**Resource Adapters** >*WebSphere Relational Resource Adapter* > **CMP Connection Factories**.

Name:

Specifies a list of the display names for the resources.

Data type	String

JNDI Name:

Specifies the JNDI name of the resource.

Data type	String

Description:

Specifies a description for the resource.

Data type	String

Category:

Specifies a category string which can be used to classify or group the resource.

Data type	String

CMP connection factory settings:

Use this page to view the settings of a connection factory that is used by a CMP bean to access any backend data store. This connection factory is only in ″read″ mode. It cannot be modified or deleted.

To view this administrative console page, click **Resources** >**Resource Adapters** > *WebSphere Relational Resource Adapter*> **CMP Connection Factories** > *connection_factory*

Name:

Specifies the display name for the resource.

Data type	String

JNDI name:

Specifies the JNDI name of the resource.

Data type	String

Description:

Specifies a description for the resource.

Data type	String

Category:

Specifies a category string which can be used to classify or group the resource.

Data type	String

Authentication Preference:

Specifies which of the authentication mechanisms that are defined for the corresponding resource adapter applies to this connection factory. This property is deprecated starting with version 6.0.

For example, if two authentication mechanism entries are defined for a resource adapter (*KerbV5* and *Basic Password*), this specifies one of those two types. If the authentication mechanism preference specified is not an authentication mechanism available on the corresponding resource adapter, it is ignored.

Data type	String

Component-managed authentication alias:

References authentication data for component-managed signon to the resource.

Data type	Drop-down list

Container-managed authentication alias:

References authentication data for container-managed signon to the resource. This property is deprecated starting with version 6.0.

Data type	Drop-down list

JDBC providers

Installed applications use JDBC providers to access data from databases.

For applications that need access to relational databases, the JDBC provider and data source together are functionally equivalent to the J2EE Connector Architecture (JCA) connection factory. The WebSphere Application Server prerequisite Web site has a current list of supported providers. See ″Hardware and software requirements″ in the information center for more information.

Data sources

Installed applications uses a *data source* to access the data from the database.

A data source is associated with a JDBC provider that supplies the specific JDBC driver implementation class. The data source represents the J2EE Connector Architecture (JCA) connection factory for the relational resource adapter. Application components use the data source to access connection instances to a specific database; a connection pool is associated with each data source.

You can create multiple data sources with different settings, and associate them with the same JDBC provider. (One reason to do this is to provide access to different databases.) JDBC providers that are supported by WebSphere Application Server are required to implement one or both of the following data source interfaces, which are defined by Sun Microsystems. These interfaces enable the application to run in a single-phase or two-phase transaction protocol.

- *ConnectionPoolDataSource* - a data source that supports application participation in local and global transactions, excepting two-phase commit transactions. When a connection pool data source is involved in a global transaction, transaction recovery is not provided by the transaction manager. The application is responsible for providing the backup recovery process if multiple resource managers are involved.
- *XADataSource* - a data source that supports application participation in any single-phase or two-phase transaction environment. When this data source is involved in a global transaction, the WebSphere Application Server transaction manager provides transaction recovery.

In WebSphere Application Server releases prior to version 5.0, the function of data access was provided by a single connection manager (CM) architecture. This connection manager architecture remains available to support J2EE 1.2 applications, but another connection manager architecture is provided, based on the JCA architecture supporting the new J2EE 1.3 application style (also for J2EE 1.4 applications).

These two separate architectures are represented by two types of data sources. To choose the right data source, administrators must understand the nature of their applications, EJB modules, and enterprise beans.

- Data source (Version 4.0) - This data source runs under the original CM architecture. Applications using this data source behave as if they were running in Version 4.0.
- Data source - This data source uses the JCA standard architecture to provide support for J2EE version 1.3 applications and beyond. It runs under the JCA connection manager and the relational resource adapter.

Choice of data source

- J2EE 1.2 application - all EJB 1.1 enterprise beans, JDBC applications, or Servlet 2.2 components must use the **4.0** data source.
- J2EE 1.3 (and subsequent releases) application -
  - EJB 1.1 Module - all EJB 1.x beans must use the **4.0** data source.
  - EJB 2.0 (and subsequent releases) Module - enterprise beans that include container-managed persistence (CMP) Version 1.x, 2.0, and beyond must use the **new** data source.
  - JDBC applications and Servlet 2.3+ components - must use the **new** data source.

Data access beans

Data access beans provide a rich set of features and function, while hiding much of the complexity associated with accessing relational databases.

They are Java classes written to the Enterprise JavaBeans specification.

You can use the data access beans in JavaBeans-compliant tools, such as the IBM *Rational Application Developer*. Because the data access beans are also Java classes, you can use them like ordinary classes.

The data access beans (in the package *com.ibm.db*) offer the following capabilities:

Feature

Details

Caching query results

You can retrieve SQL query results all at once and place them in a cache. Programs using the result set can move forward and backward through the cache or jump directly to any result row in the cache.

For large result sets, the data access beans provide ways to retrieve and manage *packets*, subsets of the complete result set.

Updating through result cache

Programs can use standard Java statements (rather than SQL statements) to change, add, or delete rows in the result cache. You can propagate changes to the cache in the underlying relational table.

Querying parameter support

The base SQL query is defined as a Java String, with parameters replacing some of the actual values. When the query runs, the data access beans provide a way to replace the parameters with values made available at run time. Default mappings for common data types are provided, but you can specify whatever your Java program and database require.

Supporting metadata

A *StatementMetaData* object contains the base SQL query. Information about the query (*metadata*) enables the object to pass parameters into the query as Java data types.

Metadata in the object maps Java data types to SQL data types (as well as the reverse). When the query runs, the Java-datatyped parameters are automatically converted to SQL data types as specified in the metadata mapping.

When results return, the metadata object automatically converts SQL data types back into the Java data types specified in the metadata mapping.

Connection management architecture

The connection management architecture for both relational and procedural access to enterprise information systems (EIS) is based on the J2EE Connector Architecture (JCA) specification. The Connection Manager (CM), which pools and manages connections within an application server, is capable of managing connections obtained through both resource adapters (RAs) defined by the JCA specification, and data sources defined by the JDBC 2.0 (and later) Extensions specification.

To make data source connections manageable by the CM, the WebSphere Application Server provides a resource adapter (the WebSphere Relational Resource Adapter) that enables JDBC data sources to be managed by the same CM that manages JCA connections. From the CM point of view, JDBC data sources and JCA connection factories look the same. Users of data sources do not experience any programmatic or behavioral differences in their applications because of the underlying JCA architecture. JDBC users still configure and use data sources according to the JDBC programming model.

Applications migrating from previous versions of WebSphere Application Server might experience some behavioral differences because of the specification changes from various J2EE requirements levels. These differences are not related to the adoption of the JCA architecture.

If you have J2EE 1.2 applications using the JDBC API that you wish to run in WebSphere Application Server 6.0, the JDBC CM from Application Server version 4.0 is still provided as a configuration option. Using this configuration option enables J2EE 1.2 applications to run unaltered. If you migrate a Version 4.0 application to Version 6.0, using the Version 6.0 migration tools, the application automatically uses the Version 4.0 connection manager after migration. However, EJB 2.x modules in J2EE 1.3 (or later versions) applications cannot use the JDBC CM from WebSphere Application Server Version 4.0.

Connection pooling:

When accessing any database, establishing connections is an expensive operation. *Connection pooling* enables administrators to establish a pool of database connections that applications can share on an application server. When connection pooling capabilities are used, performance improvements up to 20 times the normal results are realized.

Each time a resource attempts to access a backend store (such as a database), the resource must connect to that data store. A connection requires resources to create, maintain, and then release the connection when it is no longer required.

The total data store overhead for an application is particularly high for Web-based applications because Web users connect and disconnect more frequently. In addition, user interactions are typically shorter. Often, more effort is spent connecting and disconnecting than is spent during the interactions. Also, because Internet requests can arrive from virtually anywhere, you can find usage volumes large and difficult to predict.

To help lessen these overhead problems, the WebSphere Application Server enables administrators to establish a pool of backend connections that applications can share on an application server. Connection pooling spreads the connection overhead across several user requests, thereby conserving resources for future requests.

WebSphere Application Server supports JDBC 3.0 APIs to provide support for connection pooling and connection reuse. The connection pool is used to direct JDBC calls within the application, as well as for enterprise beans using the database.

Each entity bean transaction requires an additional connection to the database specifically to handle the transaction. Take this into account when calculating the number of data source connections.

On UNIX platforms, a separate DB2 process is created for each connection and these processes quickly affect performance on systems with low memory and cause errors.

If clones are used, one data pool exists for each clone. This is important when configuring the database maximum connections.

Benefits of connection pooling: Connection pooling can improve the response time of any application that requires connections, especially Web-based applications. When a user makes a request over the Web to a resource, the resource accesses a data source. With connection pooling, most user requests do not incur the overhead of creating a new connection because the data source can locate and use an existing connection from the pool of connections. When the request is satisfied and the response is returned to the user, the resource returns the connection to the connection pool for reuse. The overhead of a disconnection is avoided. Each user request incurs a fraction of the cost for connecting or disconnecting. After the initial resources are used to produce the connections in the pool, additional overhead is insignificant because the existing connections are reused.

When to use connection pooling: Use WebSphere connection pooling in an application that meets any of the following criteria:

- It cannot tolerate the overhead of obtaining and releasing connections whenever a connection is used.
- It requires Java Transaction API (JTA) transactions within WebSphere Application Server.

- It needs to share connections among multiple users within the same transaction.
- It needs to take advantage of product features for managing local transactions within the application server.
- It does not manage the pooling of its own connections.
- It does not manage the specifics of creating a connection, such as the database name, user name, or password

How connections are pooled together: Whenever you configure a unique data source or connection factory, you are required to give it a unique Java Naming and Directory Interface (JNDI) name. This JNDI name, along with its configuration information, is used to create a *connection pool*. A separate connection pool exists for each configured data source or connection factory.

A separate instance of a given configured connection pool is created on each application server that uses that data source or connection factory. For example, if you run a three server cluster in which all of the servers use *myDataSource*, and myDataSource has a *maximum connections* setting of 10, then you can generate up to 30 connections (three servers times 10 connections). Be sure to consider this fact when determining how many connections to your backend resource you can support.

It is also important to note that when using *connection sharing*, it is only possible to share connections obtained from the same connection pool.

Avoiding a deadlock: Deadlock can occur if the application requires more than one concurrent connection per thread, and the database connection pool is not large enough for the number of threads. Suppose each of the application threads requires two concurrent database connections and the number of threads is equal to the maximum connection pool size. Deadlock can occur when both of the following are true:

- Each thread has its first database connection, and all are in use.
- Each thread is waiting for a second database connection, and none would become available since all threads are blocked.

To prevent the deadlock in this case, the **Maximum Connections** value for the database connection pool should be increased by at least one. Doing this allows for at least one of the waiting threads to obtain its second database connection and to avoid a deadlock.

To avoid deadlock, code the application to use, at most, one connection per thread. If the application is coded to require *C* concurrent database connections per thread, the connection pool must support at least the following number of connections, where *T* is the maximum number of threads.

```
T * (C - 1) + 1
```

The connection pool settings are directly related to the number of connections that the database server is configured to support. If the maximum number of connections in the pool is raised, and the corresponding settings in the database are not raised, the application fails and SQL exception errors are displayed in the `stderr.log` file.

Deferred Enlistment: In the WebSphere Application Server environment, *deferred enlistment* is a term used to refer to the technique of waiting until a connection is first used to enlist it in its unit of work (UOW) scope.

In one example, the technique works like this: a component calls getConnection() from within a global transaction, and at some point later in time, the component uses the connection. The call that uses the connection is intercepted, and the XA resource for that connection is enlisted with the transaction service (which in turn calls XAResource.start()). Next, the actual call is sent to the resource manager.

In contrast, if a component gets a connection within a global transaction without deferred enlistment, then the connection is enlisted in the transaction and has all the overhead associated with that transaction. For XA connections, this includes the two phase commit (2PC) protocol to the resource manager. Deferred enlistment offers better performance in the case where a connection is obtained, but not used within the UOW scope. This saves all the overhead of participating in the UOW when it is not needed.

The WebSphere Application Server relational resource adapter automatically supports deferred enlistment without any additional configuration needed.

Lazy Transaction Enlistment Optimization: The J2EE Connector Architecture (JCA) Version 1.5 specification calls the deferred enlistment technique *lazy transaction enlistment optimization*. This support comes through a marker interface (LazyEnlistableManagedConnection) and a new method on the connection manager (LazyEnlistableConnectionManager()):

```
package javax.resource.spi;
import javax.resource.ResourceException;
import javax.transaction.xa.Xid;

interface LazyEnlistableConnectionManager { // application server
    void lazyEnlist(ManagedConnection) throws ResourceException;
}

interface LazyEnlistableManagedConnection { // resource adapter
}
```

A resource adapter is not required to support this functionality. Check with the resource adapter provider if you need to know if the resource adapter provides this functionality.

Connection and connection pool statistics: Performance Monitoring Infrastructure (PMI) method calls that are supported in the two existing Connection Managers (JDBC and J2C) are still supported in this version of WebSphere Application Server. The calls include:
- ManagedConnectionsCreated
- ManagedConnectionsAllocated
- ManagedConnectionFreed
- ManagedConnectionDestroyed
- BeginWaitForConnection
- EndWaitForConnection
- ConnectionFaults
- Average number of ManagedConnections in the pool
- Percentage of the time that the connection pool is using the maximum number of ManagedConnections
- Average number of threads waiting for a ManagedConnection
- Average percent of the pool that is in use
- Average time spent waiting on a request
- Number of ManagedConnections that are in use
- Number of Connection Handles
- FreePoolSize
- UseTime

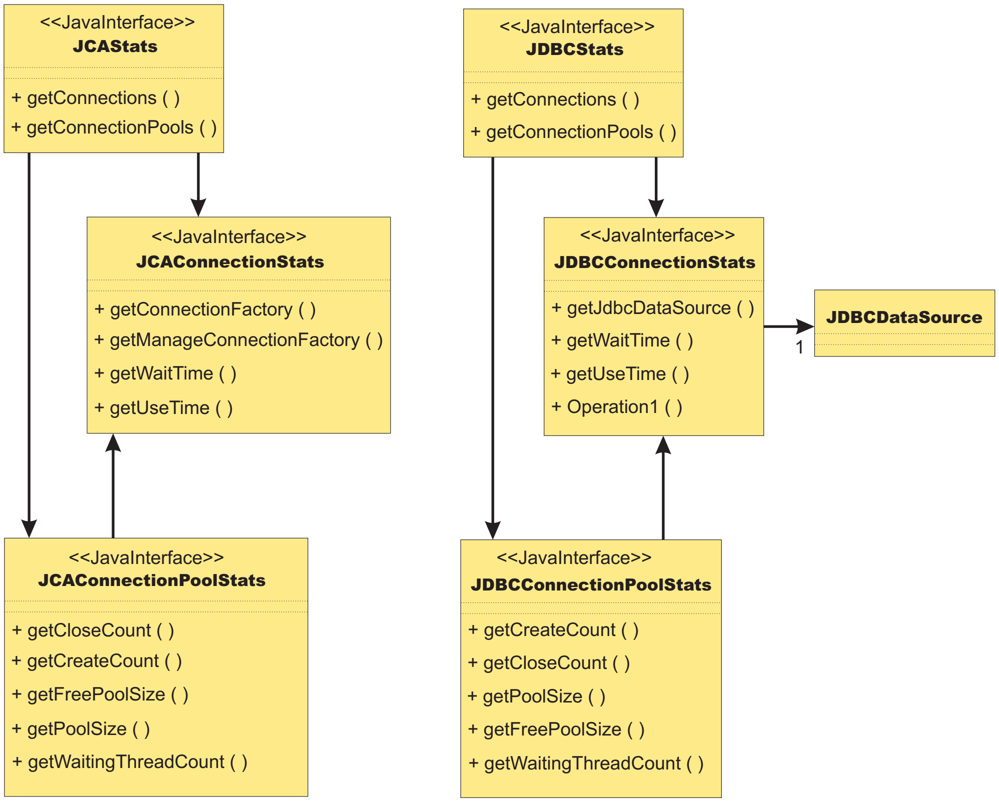
Java Specification Request (JSR) 77 requires statistical data to be accessed through managed beans (Mbeans) to facilitate this. The Connection Manager passes the ObjectNames of the Mbeans created for this pool. In the case of Java Message Service (JMS) *null* is passed in. The interface used is :

```
PmiFactory.createJ2CPerf(
    String pmiName, // a unique Identifier for JCA /JDBC.  This is the
                    // ConnectionFactory name.

    ObjectName providerName,// the ObjectName of the J2CResourceAdapter
                            // or JDBCProvider Mbean

    ObjectName factoryName // the ObjectName of the J2CConnectionFactory
                           // or DataSourceMbean.
)
```

The following Unified Modeling Language (UML) diagram shows how JSR 77 requires statistics to be reported :



In WebSphere Application Server Version 5.x, the JCAStats interface was implemented by the J2CResourceAdapter Mbean, and the JDBCStats interface was implemented by the JDBCProvider Mbean. The JCAConnectionStats and JDBCConnectionStats interfaces are not implemented because they collect statistics for non pooled connections - which are not present in the JCA 1.0 Specification. JCAConnectionPoolStats, and JDBCConnectionPoolStats do not have a direct implementing Mbean; those statistics are gathered through a call to PMI. A J2C resource adapter, and JDBC provider each contain a list of ConnectionFactory or DataSource ObjectNames, respectively. The ObjectNames are used by PMI to find the appropriate connection pool in the list of PMI modules.

The JCA 1.5 Specification allows an exception from the matchManagedConnection() method that indicates that the resource adapter requests that the connection not be pooled. In that case, statistics for that connection are provided separately from the statistics for the connection pool.

Connection life cycle:

A ManagedConnection object is always in one of three states: *DoesNotExist*, *InFreePool*, or *InUse*.

Before a connection is created, it must be in the DoesNotExist state. After a connection is created, it can be in either the InUse or the InFreePool state, depending on whether it is allocated to an application.

Between these three states are *transitions*. These transitions are controlled by *guarding conditions*. A guarding condition is one in which *true* indicates when you can take the transition into another legal state. For example, you can make the transition from the InFreePool state to InUse state only if:

- the application has called the data source or connection factory getConnection() method (the *getConnection* condition)
- a free connection is available in the pool with matching properties (the *freeConnectionAvailable* condition)
- and one of the two following conditions are true:
  - the getConnection() request is on behalf of a resource reference that is marked unsharable

– the getConnection() request is on behalf of a resource reference that is marked shareable but no shareable connection in use has the same properties.

This transition description follows:

InFreePool > InUse:
getConnection AND
freeConnectionAvailable AND
NOT(shareableConnectionAvailable)

Here is a list of guarding conditions and descriptions.

Condition	Description
ageTimeoutExpired	Connection is older then its ageTimeout value.
close	Application calls close method on the Connection object.
fatalErrorNotification	A connection has just experienced a fatal error.
freeConnectionAvailable	A connection with matching properties is available in the free pool.
getConnection	Application calls getConnection method on a data source or connection factory object.
markedStale	Connection is marked as stale, typically in response to a fatal error notification.
noOtherReferences	There is only one connection handle to the managed connection, and the Transaction Service is not holding a reference to the managed connection.
noTx	No transaction is in force.
poolSizeGTMin	Connection pool size is greater than the minimum pool size (minimum number of connections)
poolSizeLTMax	Pool size is less than the maximum pool size (maximum number of connections)
shareableConnectionAvailable	The getConnection() request is for a shareable connection, and one with matching properties is in use and available to share.
TxEnds	The transaction has ended.
unshareableConnectionRequest	The getConnection() request is for an unshareable connection.
unusedTimeoutExpired	Connection is in the free pool and not in use past its unused timeout value.

Getting connections: The first set of transitions covered are those in which the application requests a connection from either a data source or a connection factory. In some of these scenarios, a new connection to the database results. In others, the connection might be retrieved from the connection pool or shared with another request for a connection.

DoesNotExist

Every connection begins its life cycle in the DoesNotExist state. When an application server starts, the connection pool does not exist. Therefore, there are no connections. The first connection is not created until an application requests its first connection. Additional connections are created as needed, according to the guarding condition.

```
getConnection AND
NOT(freeConnectionAvailable) AND
poolSizeLTMax AND
(NOT(shareableConnectionAvailable) OR
unshareableConnectionRequest)
```

This transition specifies that a connection object is not created unless the following conditions occur:

- The application calls the getConnection() method on the data source or connection factory
- No connections are available in the free pool (NOT(freeConnectionAvailable))
- The pool size is less than the maximum pool size (poolSizeLTMax)
- If the request is for a sharable connection and there is no sharable connection already in use with the same sharing properties (NOT(shareableConnectionAvailable)) OR the request is for an unsharable connection (unshareableConnectionRequest)

All connections begin in the DoesNotExist state and are only created when the application requests a connection. The pool grows from 0 to the maximum number of connections as applications request new connections. The pool is **not** created with the minimum number of connections when the server starts.

If the request is for a sharable connection and a connection with the same sharing properties is already in use by the application, the connection is shared by two or more requests for a connection. In this case, a new connection is not created. For users of the JDBC API these sharing properties are most often *userid/password* and *transaction context*; for users of the Resource Adapter Common Client Interface (CCI) they are typically *ConnectionSpec*, *Subject*, and *transaction context*.

InFreePool

The transition from the InFreePool state to the InUse state is the most common transition when the application requests a connection from the pool.

```
InFreePool>InUse:
getConnection AND
freeConnectionAvailable AND
(unshareableConnectionRequest OR
NOT(shareableConnectionAvailable))
```

This transition states that a connection is placed in use from the free pool if:

- the application has issued a getConnection() call
- a connection is available for use in the connection pool (freeConnectionAvailable),
- and one of the following is true:
  - the request is for an unsharable connection (unsharableConnectionRequest)
  - no connection with the same sharing properties is already in use in the transaction. (NOT(sharableConnectionAvailable)).

Any connection request that a connection from the free pool can fulfill does not result in a new connection to the database. Therefore, if there is never more than one connection used at a time from the pool by any number of applications, the pool never grows beyond a size of one. This number can be less than the minimum number of connections specified for the pool. One way that a pool grows to the minimum number of connections is if the application has multiple concurrent requests for connections that must result in a newly created connection.

InUse

The idea of connection sharing is seen in the transition on the InUse state.

```
InUse>InUse:
getConnection AND
ShareableConnectionAvailable
```

This transition indicates that if an application requests a shareable connection (getConnection) with the **same** sharing properties as a connection that is already in use (ShareableConnectionAvailable), the existing connection is shared.

The same user (*user name* and *password*, or *subject*, depending on authentication choice) can share connections but only within the same transaction and only when all of the sharing properties match. For JDBC connections, these properties include the *isolation level*, which is configurable on the resource-reference (IBM WebSphere extension) to data source default. For a resource adapter factory connection, these properties include those specified on the ConnectionSpec object. Because a transaction is normally associated with a single thread, you should **never** share connections across threads.

Note: It is possible to see the same connection on multiple threads at the same time, but this situation is an error state usually caused by an application programming error.

Returning connections: All of the transitions discussed previously involve getting a connection for application use. With that goal, the transitions result in a connection closing, and either returning to the free pool or being destroyed. Applications should explicitly close connections (note: the connection that the user gets back is really a connection handle) by calling close() on the connection object. In most cases, this action results in the following transition:

```
InUse>InFreePool:
(close AND
noOtherReferences AND
NoTx AND
UnshareableConnection)
OR
(ShareableConnection AND
TxEnds)
```

Conditions that cause the transition from the InUse state are:

- If the application or the container calls close() (producing the close condition) and there are no references (the noOtherReferences condition) either by the application (in the application sharing condition) or by the transaction manager (in the NoTx condition, meaning that the transaction manager holds a reference when the connection is enlisted in a transaction), the connection object returns to the free pool.
- If the connection was enlisted in a transaction but the transaction manager ends the transaction (the txEnds condition), and the connection was a shareable connection (the ShareableConnection condition), the connection closes and returns to the pool.

When the application calls close() on a connection, it is returning the connection to the pool of free connections; it is **not** closing the connection to the data store. When the application calls close() on a currently shared connection, the connection is *not returned* to the free pool. Only after the application drops the last reference to the connection, and the transaction is over, is the connection returned to the pool. Applications using unsharable connections must take care to close connections in a timely manner. Failure to do so can starve out the connection pool, making it impossible for any application running on the server to get a connection.

When the application calls close() on a connection enlisted in a transaction, the connection is not returned to the free pool. Because the transaction manager must also hold a reference to the connection object, the connection cannot return to the free pool until the transaction ends. Once a connection is enlisted in a transaction, you cannot use it in any other transaction by any other application until after the transaction is complete.

There is a case where an application calling close() can result in the connection to the data store closing and bypassing the connection return to the pool. This situation happens if one of the connections in the pool is considered stale. A connection is considered stale if you can no longer use it to contact the data store. For example, a connection is marked stale if the data store server is shut down. When a connection is marked as stale, the entire pool is cleaned out by default because it is very likely that all of the connections are stale for the same reason (or you can set your configuration to clean just the failing connection). This cleansing includes marking all of the currently InUse connections as stale so they are destroyed upon closing. The following transition states the behavior on a call to close() when the connection is marked as stale:

```
InUse>DoesNotExist:
close AND
markedStale AND
NoTx AND
noOtherReferences
```

This transition states that if the application calls close() on the connection and the connection is marked as stale during the pool cleansing step (markedStale), the connection object closes to the data store and is not returned to the pool.

Finally, you can close connections to the data store and remove them from the pool.

This transition states that there are three cases in which a connection is removed from the free pool and destroyed.

1. If a fatal error notification is received from the resource adapter (or data source). A fatal error notification (FatalErrorNotification) is received from the resource adaptor when something happens to the connection to make it unusable. All connections currently in the free pool are destroyed.
2. If the connection is in the free pool for longer than the unused timeout period (UnusedTimeoutExpired) and the pool size is greater than the minimum number of connections (poolSizeGTMin), the connection is removed from the free pool and destroyed. This mechanism enables the pool to shrink back to its minimum size when the demand for connections decreases.
3. If an age timeout is configured and a given connection is older than the timeout. This mechanism provides a way to recycle connections based on age.

Unshareable and shareable connections:

WebSphere Application Server supports both *unshareable* and *shareable* connections. An unshareable connection is not shared with other components in the application. The component using this connection has full control of this connection.

You can share a shareable connection with other components within the same transaction as long as each *getConnection()* request has the same connection properties. To enable connection sharing for data sources, the following connection properties must be the same:

- Java Naming and Directory Interface (JNDI) name. While not actually a connection property, this requirement simply means that you can only share connections from the same data source in the same server.
- Resource authentication
- In relational databases:
  - Isolation level (corresponds to access intent policies applied to CMP beans)
  - Readonly
  - Catalog
  - TypeMap

To enable connection sharing for resource adapters within the same transaction, the following connection properties must be the same:

- JNDI name. While not actually a connection property, this requirement simply means that you can only share connections from the same resource adapter in the same server.
- Resource authentication

In addition, the *ConnectionSpec* object used to get the connection must also be the same. For more information on sharing a connection with a CMP bean, see Sharing a connection with a CMP bean.

Java Message Service (JMS) connections cannot be shared with non-JMS connections.

Access to a resource marked as unshareable means that there is a one-to-one relationship between the connection handle a component is using and the physical connection with which the handle is associated. This access implies that every call to the getConnection() method returns a connection handle solely for the requesting user. Typically, you must choose unshareable if you might do things to the connection that could result in unexpected behavior occurring in another application that is sharing the connection (for example, unexpectedly changing the isolation level).

Marking a resource as shareable allows for greater scalability. Instead of creating new physical connections on every getConnection() invocation, the physical connection (that is, managed connection) is shared through multiple connection handles, as long as each getConnection request has the same connection properties. However, sharing a connection means that each user must not do anything to the connection that could change its behavior and disrupt a sharing partner (for example, changing the isolation level). The user also cannot code an application that assumes sharing to take place because it is up to the run time to decide whether or not to share a particular connection.

For WebSphere Application Server, all sharing of connections is relative to the current Unit of Work (UOW) boundary. Anyone within a specific transaction, when getting a connection from a specific connection pool, gets a handle to the same physical connection (if the sharing properties are the same).

Factors that determine sharing: The listing here is not an exhaustive one. The product might or might not share connections under different circumstances.

- Only connections acquired with the same resource reference (resource-ref) that specifies the res-sharing-scope as shareable are candidates for sharing. The resource reference properties of res-sharing-scope and res-auth and the IBM extension isolationLevel help determine if it is possible to share a connection. IBM extension isolationLevel is stored in IBM deployment descriptor extension file; for example: ibm-ejb-jar-ext.xmi.
- You can only share connections that are requested with the same properties.
- Connection Sharing only occurs between different component instances if they are within a transaction (container- or user-initiated transaction).
- Connection Sharing only occurs within a sharing boundary. Current sharing boundaries include *Transactions* and *LocalTransactionContainment* (LTC) boundaries.
- Connection Sharing rules within an LTC Scope:
  - For shareable connections, only *Connection Reuse* is allowed within a single component instance. Connection reuse occurs when the following actions are taken with a connection: get, use, commit/rollback, close; get, use, commit/rollback, close. Note that if you use the LTC resolution-control of *ContainerAtBoundary* then no start/commit is needed because that action is handled by the container.

    The connection returned on the second *get* is the same connection as that returned on the first *get* (if the same properties are used). Because the connection use is serial, only one connection handle to the underlying physical connection is used at a time, so true connection sharing does not take place. The term "*reuse*" is more accurate.

    More importantly, the *LocalTransactionContainment* boundary enclosing both *get* actions is not complete; no cleanUp() method is invoked on the ManagedConnection object. Therefore the second *get* action inherits all of the connection properties set during the first getConnection() call.
- Shareable connections between transactions (either container-managed transactions (CMT), bean-managed transactions (BMT), or LTC transactions) follow these caching rules:
  - In general, setting properties on shareable connections is not allowed because a user of one connection handle might not anticipate a change made by another connection handle. This limitation is part of the J2EE 1.3 standard.
  - General users of resource adapters can set the connection properties on the connection factory getConnection() call by passing them in a *ConnectionSpec*.

    However, the properties set on the connection during one transaction are not guaranteed to be the same when used in the next transaction. Because it is not valid to share connections outside of a sharing scope, connection handles are moved off of the physical connection with which they are currently associated when a transaction ends. That physical connection is returned to the free connection pool. Connections are cleaned before going in the free pool. The next time the handle is used, it is automatically associated with an appropriate connection. The appropriateness is based on the security login information, connection properties, and (for the JDBC API) the *isolation level* specified in the extended resource reference, passed in on the original request that returned the current handle. Any properties set on the connection after it was retrieved are lost.

  - For JDBC users, WebSphere Application Server provides an extension to enable passing the connection properties through the ConnectionSpec.

    Use caution when setting properties and sharing connections in a local transaction scope. Ensure that other components with which the connection is shared are expecting the behavior resulting from your settings.

- You cannot set the isolation level on a shareable connection for the JDBC API using a relational resource adapter in a global transaction. The product provides an extension to the resource reference to enable you to specify the isolation level. If your application requires the use of multiple isolation levels, create multiple resource references and map them to the same data source or connection factory.

Sharing a connection with a CMP bean: WebSphere Application Server allows you to share a physical connection between a CMP bean, a BMP bean, and a JDBC application to reduce the resource allocation or deadlock scenarios. There are several ways to ensure that all of these entity beans and the JDBC applications are sharing the same physical connection.

- **Sharing a connection between CMP beans or methods**

  When all CMP bean methods use the same access intent, they all share the same physical connection. A different access intent policy triggers the allocation of a different physical connection. For example, a CMP bean has two methods; method 1 is associated with `wsPessimisticUpdate` intent, whereas method 2 has `wsOptimisticUpdate` access intent. Method 1 and method 2 cannot share the same physical connection within a transaction. In other words, an XA data source is required to run in a global transaction.

  You can experience some deadlocks from a database if both methods try to access the same table. Therefore, sharing a connection is determined by the access intents that are defined in the CMP methods.

- **Sharing a connection between CMP and BMP beans**

  There are two options to ensure that both CMP and BMP beans share the same physical connection:

  - Define the same access intent on both CMP and BMP bean methods. Because both use the same access intent, they share the same physical connection. The advantage to using this option is that the backend is transparent to a BMP bean; however, this BMP is not portable because it uses the WebSphere extended API to handle the isolation level. For more information, refer to the code example in Example: Accessing data using IBM extended APIs to share connections between container-managed and bean-managed persistence beans.
  - Determine the isolation level that the access intent uses on a CMP bean method, then use the corresponding isolation level that is specified on the resource reference to look up a data source and a connection. This option is more of a manual process, and the isolation level might be different from database to database. For more information refer to the isolation level and access intent mapping table: Access intent isolation levels and update locks and the Isolation level and resource reference section.

- **Sharing a connection between CMP and a JDBC application that is used by a servlet or a session bean**

  Determine the isolation level that the access intent uses on a CMP bean method, then use the corresponding isolation level specified on the resource reference to look up a data source and a connection. For more information refer to Access intent isolation levels and update locks and Isolation level and resource reference.

Connection sharing violations: There is a new exception, the `SharingViolation` exception, that the resource adapter can issue whenever an operation violates sharing requirements. Possible violations include changing connection attributes, security settings, or isolation levels, among others. When such a mutable operation is performed against a managed connection, the `SharingViolation` exception can occur when both of the following conditions are true:

- The number of connection handles associated with the managed connection is more than one.
- The managed connection is associated with a transaction, either local or XA.

Both the component and the J2C run time might need to detect this `SharingViolation` exception, depending on when and how the managed connection becomes unshareable. If the managed connection becomes unshareable because of an operation through the connection handle (for example, you change the isolation level), then the component needs to process the exception. If the managed connection becomes unshareable without being recognized by the application server (due to some component interaction with the connection handle), then the resource adapter can reject the creation of a connection handle by issuing the `SharingViolation` exception.

Connection handles:

A connection handle is a representation of a physical connection.

To use a backend resource (such as a relational database) in WebSphere Application Server you must get a connection to that resource. When you call the *getConnection()* method, you get a *connection handle* returned. The handle is not the physical connection. The physical connection is managed by the connection manager.

There are two significant configurations that affect how connection handles are used and how they behave. The first is the *res-sharing-scope*, which is defined by the resource-reference used to look up the DataSource or Connection Factory. This property tells the connection manager whether or not you can share this connection.

The second factor that affects connection handle behavior is the *usage pattern*. There are essentially two usage patterns. The first is called the *get/use/close* pattern. It is used within a single method and without calling another method that might get a connection from the same data source or connection factory. An application using this pattern does the following:

1. gets a connection
2. does its work
3. commits (if appropriate)
4. closes the connection.

The second usage pattern is called the *cached handle* pattern. This is where an application:

1. gets a connection
2. begins a global transaction
3. does work on the connection
4. commits a global transaction
5. does work on the connection again

A cached handle is a connection handle that is held across transaction and method boundaries by an application. Keep in mind the following considerations for using cached handles:

- Cached handle support requires some additional connection handle management across these boundaries, which can impact performance. For example, in a JDBC application, *Statements*, *PreparedStatements*, and *ResultSets* are closed implicitly after a transaction ends, but the connection remains valid.
- You are encouraged **not** to cache the connection across the transaction boundary for shareable connections; the get/use/close pattern is preferred.
- Caching of connection handles across servlet methods is limited to JDBC and Java Message Service (JMS) resources. Other non-relational resources, such as Customer Information Control System (CICS) or IMS objects, currently cannot have their connection handles cached in a servlet; you need to get,

use, and close the connection handle within each method invocation. (This limitation only applies to single-threaded servlets because multithreaded servlets do not allow caching of connection handles.)

The following code segment shows the cached connection pattern.

```
Connection conn = ds.getConnection();
ut.begin();
conn.prepareStatement("....."); --> Connection runs in global transaction mode
...
ut.commit();
conn.prepareStatement(".....");   ---> Connection still valid but runs in autoCommit(True);
...
```

Unshareable connections: Some characteristics of connection handles retrieved with a *res-sharing-scope* of **unshareable** are described in the following sections.

The possible benefits of unshared connections

- Your application always maintains a direct link with a physical connection (managed connection).
- The connection always has a one-to-one relationship between the connection handle and the managed connection.
- In most cases, the connection does not close until the application closes it.
- You can use a cached unshared connection handle across multiple transactions.
- The connection can have a performance advantage in some cached handle situations. Because unshared connections do not have the overhead of moving connection handles off managed connections at the end of the transaction, there is less overhead in using a cached unshared connection.

The possible drawbacks of unshared connections

- Inefficient use of your connection resources. For example, if within a single transaction you get more than one connection (with the same properties) using the same data source or connection factory (same resource-ref) then you use multiple physical connections when you use unshareable connections.
- Wasted connections. It is important not to keep the connection handle open (that is, your application does not call the *close()* method) any longer then it is needed. As long as an unshareable connection is open, the physical connection is unavailable to any other component, even if your application is not currently using that connection. Unlike a shareable connection, an ushareable connection is not closed at the end of a transaction or servlet call.
- Deadlock considerations. Depending on how your components interact with the database within a transaction, using unshared connections can lead to deadlock in the database. For example, within a transaction, component A gets a connection to data source X and updates table 1, and then calls component B. Component B gets another connection to data source X, and updates/reads table 1 (or even worse the same row as component A). In some circumstances, depending on the particular database, its locking scheme, and the transaction isolation level, a deadlock can occur.

  In the same scenario, but with a *shared* connection, deadlock does not occur because all the work is done on the same connection. It is worth noting that when writing code that uses shared connections, you use a strategy that calls for multiple work items to be performed on the same connection, possibly within the same transaction. If you decide to use an unshareable connection, you must set the *maximum connections* property on the connection factory or data source correctly. An exception might occur for waiting connection requests if you exceed the maximum connections value, and unshareable connections are not being closed before the connection wait time-out is exceeded.

Shareable connections: Some characteristics of connection handles that are retrieved with a *res-sharing-scope* of **shareable** are described in the following sections.

The possible benefits of shared connections

- Within an instance of connection sharing, application components can share a managed connection with one or more connection handles, depending on how the handle is retrieved and which connection properties are used.

- They can more efficiently use resources. Shareable connections are not valid outside of their sharing boundary. For this reason, at the end of a sharing boundary (such as a transaction) the connection handle is no longer associated with the managed connection it was using within the sharing boundary (this applies only when using the cached handle pattern). The managed connection is returned to the free connection pool for reuse. Connection resources are not held longer than the end of the current sharing scope.

  If the cached handle pattern is used, then the next time the handle is used within a new sharing scope, the application server run time ensures that the handle is reassociated with a managed connection that is appropriate for the current sharing scope, and has the same properties with which the handle was originally retrieved. Remember that it is not appropriate to change properties on a shareable connection. If properties are changed, other components that share the same connection might experience unexpected behavior. Futhermore, when using cached handles, the value of the changed property might not be remembered across sharing scopes.

The possible drawbacks of shared connections

- Sharing within a single component (such as an enterprise bean and its related Java objects) is not always supported. The current specification allows resource adapters the choice of only allowing one active connection handle at a time.

  If a resource adapter chooses to implement this option then the following scenario results in an *invalid handle exception*: A component using shareable connections gets a connection and uses it. Without closing the connection, the component calls a utility class (Java object) that gets a connection handle to the same managed connection and uses it. Because the resource adapter only supports one active handle, the first connection handle is no longer valid. If the utility object returns without closing its handle, the first handle is not valid and triggers an exception at any attempt to use it.

  Note: This exception occurs only when calling a utility object (a Java object).

  Not all resource adapters have this limitation; it occurs only in certain implementations. The WebSphere Relational Resource Adapter (RRA) does not have this limitation. Any data source used through the RRA does not have this limitation. If you encounter a resource adapter with this limitation you can work around it by serializing your access to the managed connection. If you always close your connection handle before getting another (or close your handle before calling code that gets another handle), and before returning from a method, you can allow two pieces of code to share the same managed connection. You simply cannot use the connection for both events at the same time.
- Trying to change the *isolation level* on a shareable JDBC-based connection in a global transaction (that is supported by the RRA) causes an exception. The correct way to get connections with different transaction isolation levels is by configuring the IBM extended resource-reference.
- Closing connection handles for shareable connections by an application is NOT supported and causes errors. However, you can avoid this limitation by using the Relational Resource Adapter.

Lazy connection association optimization: In WebSphere Application Server Version 5.0, the Java 2 Platform, Enterprise Edition (J2EE) Connector (J2C) connection manager implemented *smart handle* support. This technology enables allocation of a connection handle to an application while the managed connection associated with that connection handle is used by other applications (assuming that the connection is not being used by the original application). This concept is part of the J2EE Connector Architecture (JCA) 1.5 specification. (You can find it in the JCA 1.5 specification document in the section entitled ″Lazy Connection Association Optimization.″) Smart handle support introduces use a method on the ConnectionManager object, the *LazyAssociatableConnectionManager()* method , and a new marker interface, the *DissociatableManagedConnection* class. You must configure the provider of the resource adapter to make this functionality available in your environment. (In the case of the RRA, WebSphere Application Server itself is the provider.) The following code snippet shows how to include smart handle support:

```
package javax.resource.spi;
import javax.resource.ResourceException;

interface LazyAssociatableConnectionManager { // application server
    void associateConnection(
        Object connection, ManagedConnectionFactory mcf,
        ConnectionRequestInfo info) throws ResourceException;
}

interface DissociatableManagedConnection { // resource adapter
    void dissociateConnections() throws ResourceException;
}
```

This DissociatableManagedConnection interface introduces another state to the Connection object: *inactive*. A Connection can now be active, closed, and inactive. The connection object enters the inactive state when a corresponding ManagedConnection object is cleaned up. The connection stays inactive until an application component attempts to re-use it. Then the resource adapter calls back to the connection manager to re-associate the connection with an active ManagedConnection object.

Connections and transactions:

All connection usage occurs within the scope of either a global transaction or a local transaction containment (LTC) boundary.

Connection behavior depends on your current operating scope. This article discusses some of the common characteristics you see when using connections in one of the transaction scopes.

You can only share connections within a global transaction scope (assuming other sharing rules are met). However, you can *serially reuse* connections within an LTC scope. A get/use/close connection pattern followed by another instance of get/use/close (to the same data source or connection factory) enables you to reuse the same connection. See the “Unshareable and shareable connections” on page 1144 topic for more details.

JDBC AutoCommit behavior

All JDBC connections, when first obtained through a getConnection() call, contain the setting AutoCommit = TRUE by default.

- If you operate within an LTC and have its resolution-control set to *Application*, then AutoCommit remains *TRUE* unless changed by the application.
- If you operate within an LTC and have its resolution-control set to *ContainerAtBoundary*, then the application should **not** touch the AutoCommit setting. The WebSphere Application Server run time sets the AutoCommit value to *FALSE* before work begins, then commits or rolls back the work as appropriate at the end of the LTC scope.
- If you use a connection within a global transaction, the database ignores the AutoCommit setting so that the transaction service that controls the commit and rollback processing can manage the transaction. This action takes place upon first use of the connection to do work, regardless of the user changing the AutoCommit setting. After the transaction completes, the AutoCommit value returns to the value it had before the first use of the connection. So even if the AutoCommit value is set to *TRUE* before the connection is used in a global transaction, you need not set the value to *FALSE* since the value is ignored by the database. In this example, after the transaction completes, the AutoCommit value of the connection returns to *TRUE*.
- If you use multiple distinct connections within a global transaction, all work is guaranteed to commit or roll back together. This is not the case for a local transaction containment (LTC scope). Within an LTC, work done on one connection commits or rolls back independently from work done on any other connection within the LTC.

One-phase commit and two-phase commit resources: One-phase commit resources are such that work being done on a one phase connection cannot mix with other connections and ensure that the work done on all of the connections completes or fails atomically . The product does not allow more than one one-phase commit connection in a global transaction. Futhermore, it does not allow a one-phase commit connection in a global transaction with one or more two-phase commit connections. You can coordinate only multiple two-phase commit connections within a global transaction.

WebSphere Application Server provides *last participant support* that enables a single one-phase commit resource to participate in a global transaction with one or more two-phase commit resources.

Note that any time you do multiple getConnection() calls using a resource reference that specifies res-sharing-scope=Unshareable , then you get multiple physical connections. This situation also occurs when res-sharing-scope=Shareable, but the sharing rules are broken. In either case, if you run in a global transaction, ensure the resources involved are enabled for two-phase commit (also sometimes referred to as *JTA Enabled*). Failure to do so results in an XA exception that logs the following message: `WTRN0063E: An illegal attempt to enlist a one phase capable resource with existing two phase capable resources has occurred.`

Passing client information to a database: Some databases enable you to set client information on the database connections using a backend-specific proprietary connection API. For some databases (such as DB2) you can also set the client information as a data source property. WebSphere Application Server before Version 6.0 only enables setting the client information as a data source property. This capability is somewhat limited, however, because the client information cannot be dynamically changed on the data source or the connections obtained from that data source. Also, setting the client information on the data source causes all connections created from that data source to have the same information. For example, if you set the ApplicationName as part of the data source *clientInformation*, all connections from that data source have the same application name. Because many different applications can access the same data source, this might not be desired.

With WebSphere Application Server Version 6.0, you can set the client information on some connections and not others, and you can set different client information on different database connections from the same data source. You can pass client information in one of two ways:

- Explicitly, by calling a proprietary API, *setClientInformation(Properties)* on the com.ibm.websphere.rsadapter.WSConnection.
- Implicitly, using the *WAS.clientinfo* trace string. You can enable this dynamically from the administrative console just like a normal trace. For more information about passing client information implicitly, see “Setting client information implicitly” on page 1152.

The API is defined on the *WSConnection* class which is part of the *com.ibm.websphere.rsadapter* package. You must cast your database connection in your applications to *com.ibm.websphere.rsadapter.WSConnection* before calling the API, as this is a WebSphere Application Server proprietary API. The API takes a properties object as an input parameter that provides the flexibility of adding new client information if and when it is introduced by the backend database, without any changes to this API itself.

```
public void setClientInformation (Properties props)throws SQLException;
```

For an example of using this API, see “Example: setClientInformation(Properties) API.”

Example: setClientInformation(Properties) API:

Usage Scenario

This API enables you to set client information on the WebSphere Application Server connection. Some of the client information is passed on to the backend database if that database supports such functionality.

Example

```
import com.ibm.websphere.rsadapter.WSConnection;
.....
try {
   InitialContext ctx = new InitialContext();
   //Perform a naming service lookup to get the DataSource object.
   DataSource ds = (javax.sql.DataSource)ctx.lookup("java:comp/jdbc/myDS");
  }catch (Exception e) {System.out.println("got an exception during lookup: " + e);}

  WSConnection conn = (WSConnection) ds.getConnection();
```

```
Properties props = new properties();
props.setProperty(WSConnection.CLIENT_ID, "user123");
props.setProperty(WSConnection.CLIENT_LOCATION, "127.0.0.1");
props.setProperty(WSConnection.CLIENT_ACCOUNTING_INFO, "accounting");
props.setProperty(WSConnection.CLIENT_APPLICATION_NAME, "appname");
props.setProperty(WSConnection.CLIENT_OTHER_INFO, "cool stuff");
conn.setClientInformation(props);
conn.close()
```

Parameters

props contains the client information to be passed. Possible values are:

- WSConnection.CLIENT_ACCOUNTING_INFO
- WSConnection.CLIENT_LOCATION
- WSConnection.CLIENT_ID
- WSConnection.CLIENT_APPLICATION_NAME
- WSConnection.CLIENT_OTHER_INFO
- WSConnection.OTHER_CLIENT_TYPE

Refer to the WSConnection documentation for more details on which client information is passed to the backend database. To reset the client information, call the method with a null parameter.

Exceptions

This API creates an SQL exception if the database issues an exception when setting the data.

Setting client information implicitly: You can choose to *explicitly* pass client information of application requests to database connections by calling an IBM proprietary API, setClientInformation(Properties), on the com.ibm.websphere.rsadapter.WSConnection object within your application code. In some cases, however, you might want WebSphere Application Server to handle the passing of client information to database connections. This method of setting the client information is referred to as *implicit*. You might choose the implicit method because:

- You want to keep your application free of proprietary APIs, *or*
- Your application uses container-managed persistence (CMP), in which case you cannot use the proprietary API to set client information on database connections.

The WebSphere Application Server trace facility provides the capability for setting client information implicitly. You can designate one of two special trace groups to enable or disable client information passing: `WAS.clientinfo` trace or `WAS.clientinfopluslogging` trace .

Note:

Connection sharing:

In the case of connection sharing, setting the client information implicitly is done only on the first acquired connection handle. If connection sharing is enabled and two or more getConnection() methods are called (resulting in two handles on the same connection), then only the first getConnection() call causes the client information to be implicitly passed to the back-end database. This is not true for the explicit case; every setClientinformation() method is driven down to the database regardless of connection sharing.

Implicit/explicit co-existence:

When both explicit and implicit are used, some combination of the explicitly set data and implicitly set data is combined, but for the most part the explicit takes precedence. For example, if the application sets the client accounting information to ″myAccountingInfo″, the final accountingInfo string that is passed to the backend database looks something like:

```
000325_WSRdbManagedConnectionImpl@1234_myAccountingInfo: where 000325 is the
 thread id, WSRdbManagedConnectionImpl@1234 is the websphere connection instance.
```

Client information reset:

In the implicit case, client information is reset when the connection is put back in the pool and only if the WAS.clientinfo and WAS.clientinfopluslogging are disabled (that is, WAS.clientinfo=all=disabled:WAS.clientinfopluslogging=all=disabled).

In the explicit case however, the reset is done only when the application issues setClientInformation(null) on the WSConnection.

WAS.clientinfo trace

By default, the implicit mechanism is disabled. You can turn on this mechanism dynamically (without stopping and starting your application server) or statically by setting the WebSphere Application Server trace group *WAS.clientinfo=all=enabled*.

The information implicitly collected and set on the database connection consists of the *user name*, *user location* and *application name*.

Note: User name and user location can only be implicitly collected and set on the database connection if you enable WebSphere global security.

username

Name of the user that initiated the application request. This option is collected and passed to the backend database (when supported) only if WebSphere global security is enabled. Information here is collected by calling *WSSecurityHelper.getFirstCaller()*.

user location

In the form of cell:node:server. This option is collected and passed to the backend database (when appropriate) only when WebSphere global security is enabled. Information here is collected by calling *WSSecurityHelper.getFirstServer().*

application name

Name of the application running. This value is the output of *getApplication()* from the *J2EEName* object. This value is collected regardless of the Global Security setting.

WAS.clientinfopluslogging trace

When debugging database problems, such as deadlocks, there is a set of information that is needed to help with the debugging effort. This information is typically obtained by enabling RRA trace, and EJB container trace. However, there are some cases where timing is an issue when reproducing a given problem. Having too much tracing information can alter the behavior of the application (such as change the timing), and the problem might no longer occur.

Because of this, a new trace group is provided where only a minimum set of information is collected. This trace group is *WAS.clientinfopluslogging*. This function sets the client information implicitly on the connection (just like the WAS.clientinfo trace), as well as logs and traces important application activities. Those activities are:

- SQL Strings that were run (such as, select userId from tabl1 where id=? for update).
- Start, commit, and rollback of transactions.
- EJB calls (such as, Create, Remove, findByPrimaryKey, and so on).

Cache instances

An application uses a cache instance to store, retrieve, and share data objects within the dynamic cache.

Each cache instance can be configured independently for Java Naming and Directory Interface (JNDI) name, cache size, priority, and disk offload. Objects that are stored in a particular cache instance are not affected by other cache instances. This means that if you store an object named **object_1** with a value of `object_data` in *cache_instance_x*, you can also store an object with the same name, but different value in *cache_instance_y*.

Objects that are stored in a particular cache instance are available to applications on other servers by accessing a cache instance of the same name. The two servers must be within the same replication domain to share data.

There are two types of cache instances, object cache instances and servlet cache instances.

An object cache instance is a location in addition to the default shared dynamic cache where Java 2 Platform, Enterprise Edition (J2EE) applications can store, distribute, and share objects. After configuring object cache instances, you can use the DistributedMap or DistributedObjectCache interfaces in the `com.ibm.websphere.cache` package to programmatically access your cache instances. See the for more information about the DistributedMap or DistributedObjectCache interfaces.

Servlet cache instances are locations in addition to the default dynamic cache where dynamic cache can store, distribute, and share the output and the side effects of an invoked servlet. By configuring a servlet cache instance, your applications have greater flexibility and better tuning of cache resources. The Java Naming and Directory Interface (JNDI) name that is specified for the cache instance in the administrative console maps to the <cache-instance> element in the `cachespec.xml` configuration file. Any <cache-entry> elements that are specified within a <cache-instance> element are created in that specific cache instance. Any <cache-entry> elements that are specified outside of a <cache-instance> element are stored in the default dynamic cache instance. See ″Using servlet cache instances″ in the information center for more information.

Resource adapter archive file

A Resource Adapter Archive (RAR) file is a Java archive (JAR) file used to package a resource adapter for the Java 2 Connector (J2C) Architecture for WebSphere Application Server.

A RAR file can contain the following:
- Enterprise information system (EIS) supplied resource adapter implementation code in the form of JAR files or other runnable components, such as dynamic link lists.
- Utility classes.
- Static documents, such as HTML files, images, and sound files.

The standard file extension of a RAR file is *.rar*.

Data access : Resources for learning

Use the following links to find relevant supplemental information about data access. The information resides on IBM and non-IBM Internet sites, whose sponsors control the technical accuracy of the information.

These links are provided for convenience. Often, the information is not specific to this product but is useful all or in part for understanding the product. When possible, links are provided to technical papers and Redbooks that supplement the broad coverage of the release documentation with in-depth examinations of particular product areas.

Deploying data access applications

Before installing a data access application into the WebSphere Application Server environment, you must first ensure that the appropriate database objects are available. This action includes creating and configuring any databases or tables required, setting necessary configuration parameters to handle expected load, and configuring any necessary JDBC providers and data source objects for servlets, enterprise beans, and client applications to use.

1. If your database configuration does not already exist:
   a. Create a database to hold the data.
   b. Create tables required by your application.
      If your application uses entity enterprise beans to access the data
      You can create the tables using the data definition language (DDL) generated from the enterprise bean configuration. For more information, see Recreating database tables from the exported table data definition language.
      If your application does not use entity beans
      You must use your database server interfaces to create the tables.
   c. See Minimum required properties for vendor-specific data sources for certain vendors' databases requirements.
2. Migrate Version 4.0 data access applications
3. If your enterprise application contains a Web application or an EJB application that uses connection pooling to access a relational database, see "Creating and configuring a JDBC provider and data source" on page 1164.
4. If your application requires access to a non-relational database, you need to configure a resource adapter and a connection factory rather than a JDBC provider and a data source.
5. If your enterprise application contains an application client that accesses a relational database, see Configuring data access for application clients.
6. Consider the security of lookups with component managed authentication. See Security of lookups with component managed authentication for more information.

Relationship of assembly and administrative console data access settings

This article provides miscellaneous tips for using supported databases. See also the related links.

Always consult the product documentation for a list of the database brands and versions that are supported by your particular WebSphere Application Server version, edition, and FixPak.

Notes about various databases

- When using local DB2 databases for data access by session clients on AIX Version 4.3.3 or later versions, in some cases you cannot establish multiple connections for session clients. This is because AIX , by default, does not permit 32-bit applications to attach to more than 11 shared memory segments per process. Of these 11 shared segments, a maximum of 10 can be used for local DB2 connections. To use EXTSHM with DB2 and avoid stale connections when there are large numbers of session clients, do the following:
  – In DB2 client environment (that is the WebSphere Application Server run time environment in this case):

    ```
    export EXTSHM=ON
    ```

  – In DB2 UDB Server environment:

```
    export EXTSHM=ON
    db2set DB2ENVLIST=EXTSHM
```

- When using Sybase 11.x, you might encounter the following error when HttpSession persistence is enabled:

  ```
  DBPortability W Could not create database table: "sessions"
  com.sybase.jdbc2.jdbc.SybSQLException: The 'CREATE TABLE' command is not
  allowed within a multi-statement transaction in the 'database_name' database
  ```

  where *database_name* is the name of the database for holding sessions.

  If you encounter the error, issue the following commands at the Sybase command line:

  ```
  use database_name
  go
  sp_dboption db,"ddl in tran ",true
  go
  ```
- Sybase 12.0 does not support local transaction modes with a JTA enabled data source. To use a connection from a JTA enabled data source in a local transaction, install Sybase patch EBF9422.

Additional administrative tasks for specific databases

For your convenience, this article provides instructions for enabling some popular database drivers, and performing other administrative tasks often required to provide data access to applications running on WebSphere Application Server. These tasks are performed outside of the WebSphere Application Server administrative tools, often using the database product tools. Always refer to the documentation accompanying your database driver as the authoritative and complete source of driver information.

See the Supported hardware, software, and APIs for the latest information about supported databases, drivers, and operating systems.

Enabling JDBC 2.0

Ensure that your operating system environment is set up to support JDBC 2.0. This action is required to use data sources created through WebSphere Application Server.

The following steps make it possible to find the appropriate JDBC 2.0 driver for use with WebSphere Application Server administration:

Enabling JDBC 2.0 with DB2 on Windows NT systems

To enable JDBC 2.0 use on Windows NT systems:

- For DB2 Version 7.2
  1. Stop the DB2 JDBC Applet Server service.
  2. Run the following batch file:

     ```
     SQLLIB\java12\usejdbc2.bat
     ```
  3. Stop WebSphere Application Server (if it is running) and start it again.
- For DB2 Version 8.1
  - JDBC 2.0 is supported by default, there are no additional steps for you to perform.

Perform the steps once for each system.

Determining the level of the JDBC API in use for DB2 on Windows NT systems

To determine the JDBC level in use on your system:

- For DB2 Version 7.2
  - If JDBC 2.0 is in use, this file exists:

    ```
    SQLLIB\java12\inuse
    ```
  - If JDBC 1.0 is in use, this file exists:

    ```
    SQLLIB\java11\inuse
    ```

    or no *java11* directory exists.
- For DB2 Version 8.1
  - Go to directory *SQLLIB\samples\java*, compile and run the class *db2JDBCVersion.java*.

Enabling JDBC 2.0 with DB2 on UNIX systems

- For DB2 Version 7.2
  - Before starting WebSphere Application Server, call *$INSTHOME/sqllib/java12/usejdbc2* to use JDBC 2.0. For convenience, you might want to put this in your root user's startup script. For example, on AIX, add the following to the root user's *.profile*:

    ```
    if [ -f /usr/lpp/db2_07_01/java12/usejdbc2 ] ; then
        . /usr/lpp/db2_07_01/java12/usejdbc2
    fi
    ```
- For DB2 Version 8.1
  - JDBC 2.0 is supported by default, there are no additional steps for you to perform.

Determining the level of the JDBC API in use for DB2 on UNIX systems

- For DB2 Version 7.2
  - To determine if you are using JDBC 2.0, you can echo *$CLASSPATH*. If it contains

    ```
    $INSTHOME/sqllib/java12/db2java.zip
    ```

    then JDBC 2.0 is in use.

    If it contains

    ```
    $INSTHOME/sqllib/java/db2java.zip
    ```

    then JDBC 1.0 is in use.
- For DB2 Version 8.1
  - Go to directory *sqllib/samples/java*, compile and run the class *db2JDBCVersion.java*.

Sourcing the db2profile script on UNIX systems

Before starting WebSphere Application Server to host applications requiring data access, source the *db2profile*:

```
. ~db2inst1/sqllib/db2profile
```

where *db2inst1* is the user created during DB2 installation.

Using Java Transaction API drivers

Instructions are available for using Java Transaction API (JTA) drivers on particular operating systems. See your operating system documentation for more information.

The goal of this section is to provide information about the steps that make DB2 work well with applications utilizing XA classes -- that is, those whose *dataSourceClasses* implement *javax.sql.XADataSource*.

Using Java Transaction API drivers for DB2 on Windows NT systems

To enable JTA drivers for DB2 on Windows NT systems, follow these steps:

1. Bind the necessary packages to the database. From the **DB2 Command Line Processor** window, issue the following commands:

   ```
   db2=> connect to mydb2jta
   db2=> bind db2home\bnd\@db2cli.lst
   db2=> bind db2home\bnd\@db2ubind.lst
   db2=> disconnect mydb2jta
   ```

   where *mydb2jta* is the name of the database to enable for the JTA, and *db2home* is the DB2 root installation directory path (for example, *D:\ProgramFiles\SQLLIB\bnd\@db2cli.lst*).
2. Specify the following settings when you use an IBM WebSphere Application Server administrative client (such as the administrative console) to configure a JDBC driver:
   - **Server class path** = `%DB2_ROOT%/Sqllib/java/db2java.zip`
   - **Implementation class name** = `COM.ibm.db2.jdbc.DB2XADataSource`

Using Java Transaction API drivers for DB2 on UNIX systems

To enable JTA drivers on UNIX systems, follow these steps:

1. Stop all DB2 services.
2. Stop the IBM WebSphere Application Server administrative service.
3. Stop any other processes that use the *db2java.zip* file.
4. Make sure that you already enabled JDBC 2.0.

5. Start the DB2 services.
6. Bind the necessary packages to the database. From the DB2 command-line process or window, issue the following commands:

   ```
   db2=> connect to mydb2jta
   db2=> bind db2home\bnd\@db2cli.lst
   db2=> bind db2home\bnd\@db2ubind.lst
   db2=> disconnect mydb2jta
   ```
7. Specify the following settings when you use an IBM WebSphere Application Server administrative client (such as the administrative console) to configure a JDBC driver:
   - **Server class path** = `$INSTHOME/sqllib/java12/db2java.zip`

     For example, if *$INSTHOME* is `/home/test`, the path will be `/home/test/sqllib/java12/db2java.zip`
   - **Implementation class name** = `COM.ibm.db2.jdbc.DB2XADataSource`

For Oracle 8.1.7 two phase commit support

You can use the Oracle 8.1.7 thin driver for JTA two-phase support with the following restrictions:

- The thin driver that comes shipped with 8.1.7 might or might not work. Future patches from Oracle might work as well, but are not tested. The driver that was available from the Oracle Technology Network Web site as of February 20, 2001 does work and is the recommended driver. Later versions on this Web site are expected to work, but are not tested.

  To obtain the driver from the Oracle support Web site, visit:

  `http://technet.oracle.com/`

  You need to be a registered user for the Oracle Technology Network to get the driver from this site. Contact Oracle for access. After you have access download the 8.1.7 driver for the platforms you use and follow the instructions for installing the new driver.
- You must use the 8.1.7 driver with 8.1.7 databases, 8.1.6 databases do not support the recover() and forget() methods and other problems are encountered running with 8.1.6. Oracle does not support JTA with 8.1.6.
- For Oracle, you can only use JTA with container-managed persistence (CMP) beans.
- For the bean to create the table, you must start the bean with the JTA set to *false*. After the bean creates the table, you can set the JTA back to *true*.
- Configure an entity bean that accesses Oracle with JTA set to *true* as follows:
  - Click **deployment descriptor properties** > **Transactions** > Remote tab. Set the Transaction Attribute to *TX_REQUIRED*.
  - Click **Isolation** > Remote tab. Set the Isolation Level to *TRANSACTION_READ_COMMITTED*.
- Configure a session bean that is used with an entity bean that accesses Oracle with JTA set to *true* as follows:
  - Click **deployment descriptor properties** > **Transactions** > Remote tab. Set the Transaction Attribute to *TX_BEAN_MANAGED*.
  - Click **Isolation** > Remote tab. Set the Isolation Level to *TRANSACTION_READ_COMMITTED*.

Using Java Transaction API drivers for Sybase products on AIX systems

To enable Java Transaction API (JTA) drivers for use with Sybase products on the AIX operating system, follow these steps:

1. Enable the Data Transaction Manager (DTM) by issuing these commands (one per line) at a command prompt:

   ```
   isql -Usa -Ppassword -Sservername
   sp_configure "enable DTM", 1
   go
   ```
2. Stop the Sybase Adaptive Server database and start it again.
3. Grant the appropriate role authorization to the enterprise bean user at a command prompt:

   ```
   isql -Usa -Ppassword -Sservername
   grant role dtm_tm_role to EJB
   go
   ```

Notes about Sybase Java Transaction API drivers

Do not use a Sybase Java Transaction API (JTA) connection in an enterprise bean method with an unspecified transaction context. A Sybase JTA connection does not support the local transaction mode. The implication is that you must use the Sybase JTA connection in a global transaction context.

Recreating database tables from the exported table data definition language:

When the WebSphere Application Server deployment tooling deploys an EJB jar file containing container-managed persistence (CMP) enterprise beans, it selects the target database and creates a corresponding `Table.ddl` file. This file contains the SQL statement necessary to generate the database table for your CMP beans. You must then run the `ddl` file on your database server to create the tables.

Following is an example of how to use such a `Table.ddl` file for DB2, on Windows and z/OS:

1. The container-managed bean (CMP) enterprise bean JAR file has a *Table.ddl* file that the assembly tool generates. Extract the *Table.ddl* file to a working directory such as *C:\temp*.
2. Run this command -- **C:\temp>db2cmd** A new command window appears in which you enter the following commands.
3. Run this command -- **C:\temp>db2 connect to *dbname***
4. Run this command -- **C:\temp>db2 -tf Table.ddl** The command runs and creates tables for your CMP enterprise bean.
5. Run this command -- **C:\temp>db2 disconnect all**

   Note: If you use DB2 on Unix, use these same commands. Simply run them from a user with permissions for DB2, rather than from a DB2 command window.

Installing J2EE Connector resource adapters

1. Click **Resources**.
2. Click **Resource Adapters**.
3. Select the *scope* at which you want to define this resource adapter. (This scope becomes the scope of your connection factory.) You can choose cell, node, cluster, or server. For more information, see ″Administrative console scope settings″ in the information center.
4. Click **Install RAR**. The Install RAR button opens a dialog that enables you to install a J2EE Connector Architecture (JCA) connector and create a resource adapter for it. You can also use the **New** button, but the New button creates only a new resource adapter (the JCA connector must already be installed on the system).

   Note: When installing a RAR file using this dialog, the scope you define on the Resource Adapters page has no effect on where the RAR file is installed. You can install RAR files only at the *node* level. The node on which the file is installed is determined by the scope on the **Install RAR** page. (The scope you set on the Resource Adapters page determines the scope of the new resource adapters, which you can install at the server, node, or cell level.)
5. Browse to find the appropriate RAR file.
   - If your RAR file is located on your local workstation, select **Local path** and browse to find the file.
   - If your RAR file is located on your server, select **Server path** and specify the fully qualified path to the file.
6. Click **Next**.
7. Enter the resource adapter name and any other properties needed under *General Properties*. If you install a J2C Resource Adapter that includes *Native path* elements, consider the following: If you have more than one native path element, and one of the native libraries (native library A) is dependent on another library (native library B), then you must copy native library B to a *system* directory. Because of limitations on Windows NT and most Unix platforms, an attempt to load a native library does not look in the current directory.

8. Click **OK**.

Installing resource adapters within applications:

1. Assemble an application with resource adapter archive (RAR) modules in it. See ″Assembling applications″ in the information center.
2. Install the application following the steps in Installing a new application. In the **Map modules to servers** step, specify target servers or clusters for each RAR file. Be sure to map all other modules that use the resource adapters defined in the RAR modules to the same targets. Also, specify the Web servers as targets that serve as routers for requests to this application. The plug-in configuration file (`plugin-cfg.xml`) for each Web server is generated based on the applications that are routed through it.

   Note: When installing a RAR file onto a server, WebSphere Application Server looks for the manifest (MANIFEST.MF) for the connector module. It looks first in the *connectorModule.jar* file for the RAR file and loads the manifest from the *_connectorModule.jar* file. If the class path entry is in the manifest from the *connectorModule.jar* file, then the RAR uses that class path.

   To ensure that the installed connector module finds the classes and resources that it needs, check the **Class path** setting for the RAR using the console. For more information, see “Resource Adapter settings” on page 1162 and “WebSphere relational resource adapter settings” on page 1128.
3. Click **Finish** > **Save** to save the changes.
4. Create connection factories for the newly installed application.
   a. Open the administrative console.
   b. Click **Applications** > **Enterprise Applications** > *application name*.
   c. Click **Connector Modules** in the Related Items section of the page.
   d. Click *filename.rar*.
   e. Click **Resource adapter** in the Additional Properties section of the page.
   f. Click **J2C Connection Factories** in the Additional Properties section of the page.
   g. Click on an existing connection factory to update it, or **New** to create a new one.

   If you install a J2C Resource Adapter that includes *Native path* elements, consider the following: If you have more than one native path element, and one of the native libraries (native library A) is dependent on another library (native library B), then you must copy native library B to a *system* directory. Because of limitations on Windows NT and most Unix platforms, an attempt to load a native library does not look in the current directory.

   After you create and save the connection factories, you can modify the resource references defined in various modules of the application and specify the Java Naming and Directory Interface (JNDI) names of the connection factories wherever appropriate.

   Note: A given native library can only be loaded one time for each instance of the Java virtual machine (JVM). Because each application has its own classloader, separate applications with embedded RAR files cannot both use the same native library. The second application receives an exception when it tries to load the library.

   If any application deployed on the application server uses an embedded RAR file that includes native path elements, then you must always ensure that you shut down the application server cleanly, with no outstanding transactions. If the application server does not shut down cleanly it performs *recovery* upon server restart and loads any required RAR files and native libraries. On completion of recovery, do not attempt any application-related work. Shut down the server and restart it. No further recovery is attempted by the application server on this restart, and normal application processing can proceed.

Resource Adapters collection:

This page contains the list of installed and configured resource adapters and is used to install new resource adapters, create additional configurations of installed resource adapters or delete resource adapter configurations.

A resource adapter is an implementation of the J2EE Connector Architecture (JCA) Specification that provides access for applications to resources outside of the server or provides access for an enterprise information system (EIS) to applications on the server. It can provide application access to resources such as DB2, CICS, SAP and PeopleSoft. It can provide an EIS with the ability to communicate with message-driven beans that are configured on the server. Some resource adapters are provided by IBM; however, third party vendors can provide their own resource adapters. A resource adapter implementation is provided in a resource adapter archive file; this file has an extension of *.rar*. A resource adapter can be provided as a standalone adapter or as part of an application, in which case it is referred to as an embedded adapter. Use this panel to install a standalone resource adapter archive file. Embedded adapters are installed as part of the application installation. This panel can be used to work with either kind of adapter.

To view this administrative console page, click **Resources** >**Resource Adapters**.

Scope:

Specifies the level to which this resource adapter is visible. For general information, see *Administrative console scope settings* in the Related Reference section.

Some considerations that you should keep in mind for this particular panel are:

- Changing the scope enables you to see which resource adapter definitions exist at that level.
- Changing the scope **does not** have any effect on installation. Installations are always done under a scope of **node**, no matter what you set the scope to.
- When you create a new resource adapter from this panel, you must change the scope to what you want it to be **before** clicking **New**.

Name:

Specifies the name of the resource adapter.

A string with no spaces meant to be a meaningful text identifier for the resource adapter.

Data type	String

Resource Adapter settings:

Use this page to specify settings for a Resource Adapter.

A resource adapter is an implementation of the J2EE Connector Architecture (JCA) Specification that provides access for applications to resources outside of the server or provides access for an enterprise information system (EIS) to applications on the server. It can provide application access to resources such as DB2, CICS, SAP and PeopleSoft. It can provide an EIS with the ability to communicate with message driven beans that are configured on the server. Some resource adapters are provided by IBM; however, third party vendors can provide their own resource adapters. A resource adapter implementation is provided in a resource adapter archive file; this file has an extension of *.rar*. A resource adapter can be provided as a standalone adapter or as part of an application, in which case it is referred to as an embedded adapter. Use this panel to install a standalone resource adapter archive file. Embedded adapters are installed as part of the application installation.

To view this administrative console page, click **Resources** >**Resource Adapters** > *resource_adapter*.

Scope:

Specifies the level to which this resource definition is visible. For general information, see *Administrative console scope settings* in the Related Reference section.

The Scope field is a read only string field that shows where the particular definition for a resource adapter is located. This is set either when the resource adapter is installed (which can only be at the node level) or when a new resource adapter definition is added.

Name:

Specifies the name of the resource adapter definition.

This property is required.

A string with no spaces meant to be a meaningful text identifier for the resource adapter.

Data type	String

Description:

Specifies a text description of the resource adapter.

A free-form text string to describe the resource adapter and its purpose.

Data type	String

Archive path:

Specifies the path to the RAR file containing the module for this resource adapter.

This property is required.

Data type	String

Class path:

Specifies a list of paths or JAR file names which together form the location for the resource adapter classes.

This includes any additional libraries needed by the resource adapter. The resource adapter code base itself is automatically added to the class path, but if anything outside the RAR is needed it can be specified here.

Data type	String

Native path:

Specifies a list of paths which forms the location for the resource adapter native libraries.

The resource adapter code base itself is automatically added to the class path, but if anything outside the RAR is needed it can be specified here.

Data type	String

ThreadPool Alias:

Specifies the name of a thread pool that is configured in the server that is used by the resource adapter's Work Manager.

If there is no thread pool configured in the server with this name, the default configured thread pool instance, named *Default*, is used. This property is only necessary if this resource adapter uses Work Manager.

Data type	String

Pretesting pooled connections to ensure validity

When a database fails, pooled connections that are not valid might exist in the free pool. This scenario is likely to occur when you have a failingConnectionOnly purge policy, which mandates that only failing connections be removed from the pool. Whether the remaining connections in the pool are valid varies with the cause of the failure. Connection pretesting is a way to test connections from the free pool before giving them to the client.

If your application uses pooled connections, you can enable the PreTest Connections feature in the administrative console to help prevent your application from obtaining connections that are no longer valid.

The feature is particularly useful for routine database outages. Because these outages are usually scheduled for periods of low use, connections to the database are likely to be in the free pool rather than in active use. Active connections are not pretested; pretesting impedes performance during normal operation. Pretesting ensures that users do not waste time trying to resume connections that became bad before the outage.

1. In the administrative console, click **Resources** > **JDBC providers**.
2. Select a provider and click **Data Sources** under Additional properties.
3. Select a data source and click **WebSphere Application Server data source properties** under Additional properties.
4. Select the **PreTest Connections** check box.
5. Type a value for the PreTest Connection Retry Interval, which is measured in seconds. This property determines the frequency with which a new connection request is made after a pretest operation fails.
6. Type a valid SQL statement for the PreTest SQL String. Use a reliable SQL command, with minimal performance impact; this statement is processed each time a connection is obtained from the free pool.

   For example, you might specify SELECT COUNT(*) from TESTTABLE. (For an Oracle database, use SELECT USER FROM DUAL.)

Creating and configuring a JDBC provider and data source

Determine which version of data source you need. If you are using the Enterprise JavaBean (EJB) 1.0 specification or the Java Servlet 2.2 specification, you need the version 4.0 data source; see the topic Data Sources (Version 4). If you are using more advanced releases of these specifications, see the topic Data Source collection .

1. Create a JDBC provider.

   From the administrative console, see Creating a JDBC provider using the administrative console.

   OR

   Using the wsadmin scripting client, see ″Configuring a JDBC provider using scripting″ in the information center.

OR

Using the Java Management Extensions (JMX) API, see Creating a JDBC provider and data source using the Java Management Extensions API.

2. Create a data source.

   From the administrative console, see Creating a data source using the administrative console.

   OR

   Using the wsadmin scripting client, see ″Configuring new data sources using scripting″ in the information center. (For V4 data sources, see ″Configuring new WAS40 data sources using scripting.″)

   OR

   Using the JMX API, see Creating a JDBC provider and data source using the Java Management Extensions API.
3. Bind the resource reference. See ″Binding to a data source″ in the information center.
4. Test the connection (for non-container-managed persistence usage). See Test connection.

   Note: When you save the data source configuration, it is saved in the *resource.xml* file. You should not need to modify the **jdbc-resource-provider-templates.xml**. However, special consideration should be taken if you need to update the **jdbc-resource-provider-templates.xml file**. For details, consult J2EE Connector Architecture migration tips.

Verifying a connection:

Many connection problems can be easily fixed by verifying some configuration parameters. This article provides a checklist of steps that you must complete to enable a successful connection. Click on the link for more information on a specific step.

If your connection is still not successful after completing these steps and reviewing the applicable information, check the SystemOut.log for warning or exception messages. Then use the technical support search function to find known problems.

1. Create the authentication data alias.
2. Create the JDBC provider.
3. Create a data source.
4. Save the data source.
5. If you created a new authentication alias, restart the server for which you need to verify connectivity.
6. Test the connection

   You can test your connection from the data source collection view or the data source details view. Access either view in the administrative console, and then select a connection from the list. Click the **Test Connection** button on the connection.

Creating and configuring a JDBC provider using the administrative console:

An application installed on WebSphere Application Server accesses a relational database through a JDBC provider, which is essentially a system-level software driver. For at-a-glance information on which provider type is appropriate for your database configuration and application requirements, see the JDBC provider table.

You can easily establish a JDBC provider from the administrative console.

1. Open the administrative console.
2. Click **Resources** > **JDBC Providers**.
3. Select the *scope* of your definition. (This scope becomes the scope of your data source.) You can choose cell, node, cluster, or server. For more information, see ″Administrative console scope settings″ in the information center.

4. Click **New**.

   Note: If Java script is disabled for your browser, you do not see the three drop-down lists that are described in the next three steps (for database type, provider type, and implementation type) . Instead, you see a single drop-down box that lists *all* JDBC provider choices simultaneously (inclusive of every database, provider, and implementation type).
5. Use the first drop-down list to select the database type of the JDBC provider you need to create. If the list of supported JDBC provider types does not include the JDBC provider that you want to use, select the **User-Defined JDBC Provider**. Then consult the JDBC provider vendor's documentation for information on specific properties required for data sources associated with this provider, and skip to step eight of this list.
6. From the second drop-down list, select your JDBC provider type.
7. From the third drop-down list, select the implementation type necessary for your application. If your application does not require that connections support two-phase commit transactions, choose **Connection Pool Data Source**. Choose **XA Data Source**, however, if your application requires connections that support two-phase commit transactions. Applications using this data source configuration have the benefit of container-managed transaction recovery.
8. Click **Next** to view the general property settings page for your JDBC provider.
9. Ensure that all required properties have valid values. For more information, see JDBC Provider settings.
10. Click **Apply** to view the page with your new JDBC provider settings. Note that two active data source links now appear under the **Additional Properties** heading on this page. To set up a data source, click the link that corresponds to the type required by your application, the Version 4 data source or the later version data source. (For more information, refer to the section entitled ″Choice of data source″ in the "Data sources" on page 1135 topic.)
11. Click **OK** to return to the JDBC providers page, where your new JDBC provider appears in the list.

For more information about creating a data source for association with your JDBC provider, see "Creating and configuring a data source using the administrative console" on page 1171.

JDBC Provider collection:

Use this page to view a JDBC provider.

To view this administrative console page, click **Resources** > **JDBC Providers** in the console navigation tree.

Notice the *Scope* of your JDBC provider. If you pick anything other than the default of *Node* the provider might not be available in other scope contexts. New items created in this view are created within the selected scope.

Name:

Specifies a text identifier for this provider.

For example, this field can be *DB2 JDBC Provider (XA)*.

Data type	String

Description:

Specifies a text string describing this provider.

Data type	String

JDBC provider settings:

Use this page to create or modify JDBC provider settings.

To view this administrative console page, click **Resources** > **JDBC Providers** > *JDBC_provider*.

Name:

Specifies the name of the resource provider.

Data type	String

Description:

Specifies a text description for the resource provider.

Data type	String

Class path:

Specifies a list of paths or JAR file names which together form the location for the resource provider classes.

For example, *D:/SQLLIB/java/db2java.zip*.

Class path entries are separated by using the ENTER key and must not contain path separator characters (such as ';' or ':'). Class paths contain variable (symbolic) names which you can substitute using a variable map. Check the driver installation notes for the specific required JAR file names.

Data type	String

Native Library Path:

Specifies a list of paths that forms the location for the resource provider native libraries.

Native path entries are separated by using the ENTER key and must not contain path separator characters (such as ';' or ':'). Native paths can contain variable (symbolic) names which you can substitute using a variable map.

Data type	String

Implementation class name:

Specifies the Java class name of the JDBC driver implementation.

This class is available in the driver file mentioned in the class path description above. For example, *COM.ibm.db2.jdbc.DB2XADataSource*.

Note: If you modify the implementation class name of the JDBC provider after you have created the provider, you might disconnect the provider from the template used to create it. As a result, data sources created from this JDBC provider do not have an associated template; you must manually configure a working data source through setting custom properties.

Data type	String

New JDBC Provider:

Use this page to create a new JDBC provider.

To view this administrative console page, click **Resources** >**JDBC Providers** > **New**.

Step 1: Select the database type:

Choose a supported database type.

If the list of supported database types does not include the type that you want to use, select **User-Defined**. You might need to consult the documentation for the database for more information on specific properties that database requires.

Data type	Drop-down list

Step 2: Select the JDBC provider type:

Choose a supported JDBC Provider type.

Only JDBC provider types that are appropriate for the database type you selected in step 1 will appear in the list. For at-a-glance information on which provider type is appropriate for your database configuration and application requirements, see the JDBC provider table.

Data type	Drop-down list

Step 3: Select the implementation type:

Choose a supported implementation type.

Only the implementation types supported by the JDBC provider you selected in step 2 will appear in the list.

Note: If two choices appear on the implementation type list, select **Connection Pool DataSource** if your application runs in a single phase or local transaction. Otherwise, choose **XA DataSource** to run in a global transaction.

Data type	Drop-down list

JDBC provider summary:

Database type	JDBC Provider	Transaction support	Version and other considerations
DB2 on Windows, UNIX, or workstation-based LINUX	DB2 Universal JDBC Provider	One phase only	
	DB2 Universal JDBC Provider (XA)	One and two phase	
	DB2 legacy CLI-based Type 2 JDBC Provider	One phase only	
	DB2 legacy CLI-based Type 2 JDBC Provider (XA)	One and two phase	
DB2 UDB for iSeries	DB2 UDB for iSeries (Native)	One phase only	Recommended for use with WebSphere Application Server **run on iSeries**
	DB2 UDB for iSeries (Native XA)	One and two phase	Recommended for use with WebSphere Application Server **run on iSeries**
	DB2 UDB for iSeries (Toolbox)	One phase only	Recommended for use with WebSphere Application Server run on Windows, UNIX, or workstation-based LINUX
	DB2 UDB for iSeries (Toolbox XA)	One and two phase	Recommended for use with WebSphere Application Server run on Windows, UNIX, or workstation-based LINUX
	DB2 legacy CLI-based Type 2 JDBC Provider	One phase only	**-***Only* for use with WebSphere Application Server run on Windows, UNIX, or workstation-based LINUX **-** Requires the DB2 Connect driver (available from DB2)
	DB2 legacy CLI-based Type 2 JDBC Provider (XA)	One and two phase	**-***Only* for use with WebSphere Application Server run on Windows, UNIX, or workstation-based LINUX **-** Requires the DB2 Connect driver (available from DB2)

Database type	JDBC Provider	Transaction support	Version and other considerations
DB2 on z/OS	DB2 for z/OS Local JDBC Provider (RRS)	One and two phase	*Only* for use with WebSphere Application Server **run on z/OS**
	DB2 Universal JDBC Provider	One phase only	*Only* for use with WebSphere Application Server run on Windows, UNIX, or workstation-based LINUX
	DB2 Universal JDBC Provider (XA)	One and two phase	*Only* for use with WebSphere Application Server run on Windows, UNIX, or workstation-based LINUX
	DB2 legacy CLI-based Type 2 JDBC Provider	One phase only	**-***Only* for use with WebSphere Application Server run on Windows, UNIX, or workstation-based LINUX **-** Requires the DB2 Connect program (available from DB2)
	DB2 legacy CLI-based Type 2 JDBC Provider (XA)	One and two phase	**-***Only* for use with WebSphere Application Server run on Windows, UNIX, or workstation-based LINUX **-** Requires the DB2 Connect program (available from DB2)
Cloudscape	Cloudscape JDBC Provider	One phase only	**-** Not for use in clustering environment: Cloudscape is accessible from a single JVM only **-** Does not support Version 4 data sources
	Cloudscape JDBC Provider (XA)	One and two phase	**-** Not for use in clustering environment: Cloudscape is accessible from a single JVM only **-** Does not support Version 4 data sources
	Cloudscape Network Server using Universal JDBC driver	One phase only	Does not support Version 4 data sources
Informix	Informix JDBC Driver	One phase only	
	Informix JDBC Driver (XA)	One and two phase	
Sybase	Sybase JDBC Driver	One phase only	
	Sybase JDBC Driver (XA)	One and two phase	
Oracle	Oracle JDBC Driver	One phase only	
	Oracle JDBC Driver (XA)	One and two phase	

Database type	JDBC Provider	Transaction support	Version and other considerations
MS SQL Server	DataDirect ConnectJDBC type 4 driver for MS SQL Server	One phase only	Only for use with the corresponding driver from DataDirect Technologies
	DataDirect ConnectJDBC type 4 driver for MS SQL Server (XA)	One and two phase	Only for use with the corresponding driver from DataDirect Technologies
	WebSphere embedded ConnectJDBC driver for MS SQL Server	One phase only	- Not available for Application Server on z/OS - Cannot be used outside of WebSphere Application Server environment
	WebSphere embedded ConnectJDBC driver for MS SQL Server (XA)	One and two phase	- Not available for Application Server on z/OS - Cannot be used outside of WebSphere Application Server environment

Creating and configuring a data source using the administrative console:

After you create a JDBC provider, you must create a data source to access the backend data store. Application components use the data source to access connection instances to your database; a connection pool is associated with each data source. The product supports two different versions of data source:

- Version 4.0, for use with the Enterprise JavaBeans (EJB) 1.0 specification and the Java Servlet 2.2 specification
- The latest standard version for use with more advanced releases of these specifications

1. Open the administrative console.
2. Click **Resources** > **JDBC Providers**.
3. Choose the JDBC resource provider under which you want to create your data source. The detail page for this provider is displayed.
4. Under Additional Properties, click the **Data Sources** link that is appropriate for your application. The Data sources or Data sources (Version 4) page is displayed.
5. Click **New** to display the Data source settings page.
6. Verify that all the required properties have valid values.

   For data sources of the latest standard version:

   a. Select a DataStoreHelper class name from the list entitled DataStoreHelpers provided by WebSphere Application Server, or leave the default selection as is. If you want to use a data store helper other than those available in the drop-down list, click **Specify a user-defined DataStoreHelper**. Type a fully qualified class name in the field that is provided.
   b. The next section of properties varies according to the database selection, provider type, and implementation that you chose for your JDBC provider. These properties are either required or highly recommended for your data source. Provide valid values for these settings if you do not want to accept the default values.
   c. Click **Component-managed Authentication Alias** if your database requires a user ID and password for a connection. This alias is used only when the application resource reference is using `res-auth = Application`.

      Important:(For components with `res-auth=Container`) Both the Container-managed Authentication Alias and Mapping-Configuration Alias settings are deprecated. They are superseded by the specification of a login configuration on the resource-reference mapping at deployment time. You must now use this login setting to define the aliases at deployment.

   d. If you chose XA Data Source as the implementation type of your JDBC provider, you need to specify the alias used during transaction recovery processing. An additional section entitled Authentication Alias for XA Recovery is available. Select either **Use Application Authentication Alias** to use the same value that you chose for component-managed authentication, or select **Specify:** to choose a different alias from the drop-down list.

7. Click **Apply** to view a page with your new data source settings. Additional properties and Related items sections are now available on this page. Additional properties contains the Connection pool, Custom properties, and WebSphere Application Server data source properties choices. (If you are using a Version 4 data source, however, you see only the first two choices.)
   a. Click on the first link to define settings that affect the behavior of the Java 2 Connector (J2C) connection pool manager.
   a. Go to the Custom properties page to view and modify additional properties that the database vendor might require for the connection of its product to an application server.
   b. Use the WebSphere Application Server data source properties page to input settings that exclusively affect the WebSphere Application Server connection to the database.
   c. The Related items section (applicable only to later version data sources, not Version 4 data sources) contains the J2C Authentication data entries choice. Here, you can specify a list of user IDs and passwords for J2C security to use.
8. Click **Save**.
9. Return to the data source page to confirm that your new data source is displayed in the list.

You are now ready to install the application for which you configured the data sources. During installation, you can bind resource references to these data sources.

Data source collection:

Use this page to create or modify a data source.

To view this administrative console page, click **Resources** > **JDBC Providers** > *JDBC_provider* > **Data sources**.

Note: If you are using the Enterprise JavaBean (EJB) 1.0 specification and the Java Servlet 2.2 specification, you must use the **Data sources (Version 4)** console page.

Name:

Specifies the display name of this data source.

Data type	String

JNDI name:

Specifies the Java Naming and Directory Interface (JNDI) name for this data source.

Data type	String

Description:

Specifies a text description of the data source.

Data type	String

Category:

Specifies a string that you can use to classify or group a data source.

Data type	String

Data source settings:

Use this page to create a data source for association with your JDBC provider. Think of the data source as a pooled set of connections necessary for conducting transactions between your application and database.

To view this administrative console page, click **Resources** > **JDBC Providers** > *JDBC_provider* > **Data sources** > **New** (if you are creating a new data source) or > *data_source* (if you are viewing an established data source).

Note: If your application uses an Enterprise JavaBean (EJB) 1.1 or a Java Servlet 2.2 module, you must use the **Data sources (Version 4)** > *data_source* console page.

Name:

Specifies the display name for the data source.

Valid characters for this name include letters and numbers, but NOT most of the special characters. For example you can set this field to *Test Data Source*. But any name starting with a period (•) or containing special characters (\ / , : ; ″ * ? < > | = + & % ' `) is not a valid name.

Data type	String

JNDI name:

Specifies the Java Naming and Directory Interface (JNDI) name.

Distributed computing environments often employ naming and directory services to obtain shared components and resources. Naming and directory services associate names with locations, services, information, and resources.

Naming services provide name-to-object mappings. Directory services provide information on objects and the search tools required to locate those objects.

There are many naming and directory service implementations, and the interfaces to them vary. JNDI provides a common interface that is used to access the various naming and directory services.

For example, you can use the name *jdbc/markSection*.

If you leave this field blank a JNDI name is generated from the name of the data source. For example, a data source name of markSection generates a JNDI name of *jdbc/markSection*.

After you set this value, save it, and restart the server, you can see this string when you run the dump name space tool.

Data type	String

Container-managed persistence:

Specifies if this data source is used for container-managed persistence of enterprise beans.

If this field is checked, a CMP Connector Factory that corresponds to this data source is created for the relational resource adapter.

Data type	Checkbox
Default	Enabled (The field is checked.)

Description:

Specifies a text description for the resource.

Data type	String

Category:

Specifies a category string you can use to classify or group the resource.

Data type	String

Data store helper class name:

Specifies the name of the DataStoreHelper implementation class that extends the capabilities of your selected JDBC driver implementation class to perform database-specific functions.

WebSphere Application Server provides a set of DataStoreHelper implementation classes for each of the JDBC provider drivers it supports. These implementation classes are in the package com.ibm.websphere.rsadapter. For example, if your JDBC provider is DB2, then your default DataStoreHelper class is com.ibm.websphere.rsadapter.DB2DataStoreHelper. The administrative console page you are viewing, however, might make multiple DataStoreHelper class names available to you in a drop-down list; be sure to select the one required by your database configuration. Otherwise, your application might not work correctly. If you want to use a DataStoreHelper other than those displayed in the drop-down list, select **Specify a user-defined DataStoreHelper** and type a fully qualified class name. Refer to the Information Center topic ″Example: Developing your own DataStoreHelper class.″

Data type	Drop-down list or string (if **user-defined DataStoreHelper** is selected)

Important data source properties: These properties are specific to the data source that corresponds to your selected JDBC provider. They are either required by the data source, or are especially useful for the data source. You can find a complete list of the properties required for all supported JDBC providers in the topic ″Vendor-specific data sources minimum required settings″ in the Information Center.

Component-managed Authentication Alias:

This alias is used for database authentication at run time.

The **Component-managed Authentication Alias** is only used when the application resource reference is using *res-auth = Application*.

If your database (for example, Cloudscape) does not support *user ID* and *password*, then do not set the alias in the component-managed authentication alias or container-managed authentication alias fields. Otherwise, you see the warning message in the system log to indicate that the user and password are not valid properties. (This message is only a warning message; the data source is still created successfully.)

If you do not set an alias (component-managed or otherwise), and your database requires the user ID and password to get a connection, then you receive an exception during run time.

Data type	Drop-down list

Container-managed Authentication Alias (deprecated):

Specifies authentication data (a string path converted to userid and password) for container-managed sign-on to the resource.

Note: Beginning with WebSphere Application Server Version 6.0, the container-managed authentication alias is superseded by the specification of a login configuration on the resource-reference mapping at deployment time, for components with *res-auth=Container*.

Choose from aliases defined under **Security**>**JAAS Configuration**> **J2C Authentication Data**.

To define a new alias not already appearing in the pick list:
- Click **Apply** to expose Related Items.
- Click **J2C Authentication Data Entries**.
- Define an alias.
- Click the connection factory name at the top of the *J2C Authentication Data Entries* page to return to the connection factory page.
- Select the alias.

Data type	Drop-down list

Mapping-Configuration Alias (deprecated):

Allows users to select from the **Security** > **JAAS Configuration** > **Application Logins Configuration** list.

Note: Beginning with WebSphere Application Server Version 6.0, the Mapping-Configuration Alias is superseded by the specification of a login configuration on the resource-reference mapping at deployment time, for components with *res-auth=Container*.

The **DefaultPrincipalMapping** JAAS configuration maps the authentication alias to the userid and password. You may define and use other mapping configurations.

Data type	Drop-down list

Authentication Alias for XA Recovery:

This optional field is used to specify the authentication alias that should be used during XA recovery processing.

If the resource adapter does not support XA transactions, then this field will not be displayed. The default value will come from the selected alias for application authentication (if specified).

Use Component-managed Authentication Alias

Selecting this radio button specifies that the alias set for Component-managed Authentication is used at XA recovery time.

Data type	Radio button

Specify:

Selecting this radio button enables you to choose an authentication alias from a drop-down list of configured aliases.

Data type	Radio button

WebSphere Application Server data source properties collection:

Use this page to view the WebSphere Application Server data source properties. These properties apply to the WebSphere Application Server connection, rather than to the database connection.

To view this administrative console page, click **Resources** >**JDBC Providers** > *JDBC_provider* > **Data sources** > *data_source* > **WebSphere Application Server connection properties**.

Statement Cache Size:

Specifies the number of free statements that are cached per connection.

The WebSphere Application Server data source optimizes the processing of prepared statements. A prepared statement is a precompiled SQL statement that is stored in a prepared statement object. This object is used to efficiently execute the given SQL statement multiple times.

If the cache is not large enough, useful entries are discarded to make room for new entries. To determine the largest value for your cache size to avoid any cache discards, add the number of uniquely prepared statements and callable statements (as determined by the *sql* string, concurrency, and the scroll type) for each application that uses this data source on a particular server. This value is the maximum number of possible prepared statements that are cached on a given connection over the life of the server. Setting the cache size to this value means you never have cache discards. In general, the more statements your application has, the larger the cache should be. For example, if the application has 5 SQL statements, set the statement cache size to 5, so that each connection has 5 statements.

You can also use the Tivoli Performance Viewer to minimize cache discards. Use a standard workload that represents a typical number of incoming client requests, use a fixed number of iterations, and use a standard set of configuration settings. **Note:** The higher the statement cache, the more system resources are delayed. Therefore, if you set the number too high, you could lack resources because your system is not able to open that many prepared statements.

In test applications, tuning the statement cache improved throughput by 10-20%. However, because of potential resource limitations, this might not always be possible.

Data type	Integer
Default	Depends on the database. Most are 10. Informix Version 7.3, 9.2, or 9.3 without latest fix must be 0. A default of 0 means there is no cache statement.

Enable Multithreaded Access Detection: If checked, the application server detects the existence of access by multiple threads.

Enable WebSphere Connection Pooling: If checked, the application server sets up connect pools for this datasource.

Enable Database Reauthentication: If checked, there is not be an exact match on connections retrieved out of the WebSphere Application Server connection pool (that is, connection pool search criteria do not include user name and password). Instead, the reauthentication of connection is done in the *doConnectionSetupPerTransaction()* of the DataStoreHelper class. Note that WebSphere Application Server runtime does NOT provide connection reauthentication implementation. Therefore, when this box is checked you MUST extend the DataStoreHelper class to provide implementation of the *doConnectionSetupPerTransaction()* method where the reauthentication takes place. Failure to do that results in wrong connections being handed out to users. For more information, refer to the Javadoc API documentation for *com.ibm.websphere.rsadapter.DataStoreHelper#doConnectionSetupPerTransaction(...)*.

Connection reauthentication can help improve performance by reducing the overhead of opening and closing connections, particularly for applications that always request connections with different user names and passwords.

Enable JMS One Phase Optimization Support: If checked, the application server allows JMS to get optimized connections from this data source. This property prevents JDBC applications from sharing connections with CMP applications.

PreTest Connections: If checked, the application server tries to connect to this data source before it attempts to send data to or receive data from this data source. If you select this property, you can specify how often, in seconds, the application server retries to make a connection if the initial attempt fails.

PreTest Connection Retry Interval: When **PreTest Connection** is checked, use this property to specify how long, in seconds, the application server waits before retrying to make a connection if the initial attempt fails.

PreTest SQL String:

Specifies the string of data that the application server sends to the database to test the connection.

Data type	Integer

Data sources (Version 4):

Use this page to view the settings of a Version 4.0 style data source.

These Version 4.0 data sources use the WebSphere Application Server Version 4.0 Connection Manager architecture. All EJB 1.1 modules must use a Version 4.0 data source.

To view this administrative console page, click **Resources** > **JDBC Providers** > *JDBC_provider* > **Data sources (Version 4)**.

Name:

Specifies a text identifier of the data source.

Data type	String

JNDI Name:

Specifies the Java Naming and Directory Interface (JNDI) name of the data source.

Data type	String

Description:

Specifies a text description of the data source.

Data type	String

Category:

Specifies a text string that you can use to classify or group the data source.

Data type	String

Data source (Version 4) settings:

Use this page to create a Version 4.0 style data source. This data source uses the WebSphere Application Server Version 4.0 connection manager architecture. All of your EJB1.x modules must use this data source.

To view this administrative console page, click **Resources** > **JDBC Providers** > *JDBC_provider* > **Data Sources (Version 4)** > *data_source*.

Scope:

Specifies the level to which this resource definition is visible -- the cell, node, or server level.

Resources such as JDBC providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates which are defined at more general scopes.

Note that no matter what the scope of a defined resource, the resource's properties only apply at an individual server level. For example, if you define the scope of a data source at the cell level, all users in that cell can look up and use that data source, which is unique within that cell. However, resource property settings are local to each server in the cell. For example, if you define *max connections* to 10, then each server in that cell can have 10 connections.

Cell The most general scope. Resources defined at the cell scope are visible from all nodes and servers, unless they are overridden. To view resources defined in the cell scope, do not specify a server or a node name in the scope selection form.

Node The default scope for most resource types. Resources defined at the node scope override any duplicates defined at the cell scope and are visible to all servers on the same node, unless they are overridden at a server scope on that node. To view resources defined in a node scope, do not specify a server, but select a node name in the scope selection form.

Server
The most specific scope for defining resources. Resources defined at the server scope override any duplicate resource definitions defined at the cell scope or parent node scope and are visible only to a specific server. To view resources defined in a server scope, specify a server name as well as a node name in the scope selection form.

When resources are created, they are always created into the current scope selected in the panel. To view resources in other scopes, specify a different node or server in the scope selection form.

Data type	String

Name:

Specifies the display name for the resource.

For example, you can set this field to *Test Data Source*.

Data type	String

JNDI Name:

Specifies the Java Naming and Directory Interface (JNDI) name.

Distributed computing environments often employ naming and directory services to obtain shared components and resources. Naming and directory services associate names with locations, services, information, and resources.

Naming services provide name-to-object mappings. Directory services provide information on objects and the search tools required to locate those objects.

There are many naming and directory service implementations, and the interfaces to them vary. JNDI provides a common interface that is used to access the various naming and directory services.

For example, you can use the name *jdbc/markSection*.

If you leave this field blank a JNDI name is generated from the name of the data source. For example, a data source name of markSection generates a JNDI name of *jdbc/markSection*.

After you set this value, save it, and restart the server, you can see this string when you run the dump name space tool.

Data type	String

Description:

Specifies a text description for the resource.

Data type	String

Category:

Specifies a category string that you can use to classify or group the resource.

Data type	String

Database Name:

Specifies the name of the database that this data source accesses.

For example, you can call the database *SAMPLE*.

Data type	String

Default User ID:

Specifies the user name to use for connecting to the database.

For example, you can use the ID *db2admin*.

Data type	String

Default Password:

Specifies the password used for connecting to the database.

For example, you can use the password *db2admin*.

Data type	String

Custom properties collection:

Use this page to view and configure the custom properties of a J2EE resource provider.

You can configure custom property collections for numerous resource types. According to the resource type with which a collection is associated, your ability to add, delete, and modify individual properties and settings varies. Begin the configuration process by clicking on the *Required* field to sort those column values in descending order. All of the required (true) values are then sorted at the beginning of the page. Be sure to set all required properties.

Name:

Specifies the property name.

You must ensure that the resource provider has the setting for this name.

Data type	String

Value:

Specifies the property value.

Data type	Variable; see “Custom property settings” for more information.

Description:

Specifies text to describe any bounds or well-defined values for this property.

Data type	String

Required:

Specifies whether this property is required for the resource provider.

Data type	Boolean or Check box

Custom property settings:

Use this page to view and set custom properties that might be required for resource providers and resource factories.

According to the resource type with which a property collection is associated, your ability to modify individual property settings varies. Therefore, consider the following descriptions as a general reference for custom property settings. (The administrative console page that you are using to configure your custom property may only allow you to modify a subset of the following settings.)

Required:

Specifies properties that are required for this resource.

Data type	Check box

Name:

Specifies the name associated with this property (PortNumber, ConnectionURL, etc).

Data type	String

Value:

Specifies the value associated with this property in this property set.

Data type	Determined by the **Type** setting, which you select from a drop-down list. If the type is `java.lang.String` then the value is of type String; if the type is `java.lang.Integer`, then the value is of type Integer; and so on.

Description:

Specifies text to describe any bounds or well-defined values for this property.

Data type	String

Type:

Specifies the fully qualified Java data type of this property .

There are specific types that are valid:
- java.lang.Boolean
- java.lang.String
- java.lang.Integer
- java.lang.Double
- java.lang.Byte
- java.lang.Short
- java.lang.Long
- java.lang.Float
- java.lang.Character

Data type	Drop-down list

Custom Properties (Version 4) collection:

Use this page to view properties for a Version 4.0 data source.

To view this administrative console page, click **Resources** > **JDBC Providers** > *JDBC_provider* > **Data Sources (Version 4)** > *data_source* > **Custom Properties**

Name:

Specifies the name of the custom property

Data type	String

Value:

Specifies the value of the custom property.

Data type	Integer

Description:

Specifies text to describe any bounds or well-defined values for this property.

Data type	String

Required:

Specifies properties that are required for this resource.

Data type	String

Custom property (Version 4) settings:

Use this page to add properties for a Version 4.0 data source.

To view this administrative console page, click **Resources** >**JDBC Providers**> *JDBC_provider* > **Data Sources (Version 4)** > *data_source* > **Custom Properties** > *custom_property*.

Scope:

Specifies the level to which this resource definition is visible -- the cell, node, or server level.

Resources such as JDBC providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates which are defined at more general scopes.

Note that no matter what the scope of a defined resource, the resource's properties only apply at an individual server level. For example, if you define the scope of a data source at the cell level, all users in that cell can look up and use that data source, which is unique within that cell. However, resource property settings are local to each server in the cell. For example, if you define *max connections* to 10, then each server in that cell can have 10 connections.

Cell The most general scope. Resources defined at the cell scope are visible from all nodes and servers, unless they are overridden. To view resources defined in the cell scope, do not specify a server or a node name in the scope selection form.

Node The default scope for most resource types. Resources defined at the node scope override any duplicates defined at the cell scope and are visible to all servers on the same node, unless they are overridden at a server scope on that node. To view resources defined in a node scope, do not specify a server, but select a node name in the scope selection form.

Server
The most specific scope for defining resources. Resources defined at the server scope override any duplicate resource definitions defined at the cell scope or parent node scope and are visible only to a specific server. To view resources defined in a server scope, specify a server name as well as a node name in the scope selection form.

When resources are created, they are always created into the current scope selected in the panel. To view resources in other scopes, specify a different node or server in the scope selection form.

Data type	String

Required:

Specifies properties that are required for this resource.

Data type	Check box

Name:

Specifies the name associated with this property (PortNumber, ConnectionURL, etc).

Data type	String

Value:

Specifies the value associated with this property in this property set.

Data type	Integer

Description:

Specifies text to describe any bounds or well-defined values for this property.

Data type	String

Type:

Specifies the fully qualified Java type of this property (java.lang.Integer, java.lang.Byte).

Data type	String

Creating and configuring a JDBC provider and data source using the Java Management Extensions API:

If your application requires access to a JDBC connection pool from a J2EE 1.3 or 1.4 level WebSphere Application Server component, you can create the necessary JDBC provider and data source objects using the Java Management Extensions (JMX) API exclusively. Alternatively, you can use the JMX API in combination with the WSadmin - scripting tool.

Note: Use the JMX API to create only data sources for which the product does *not* provide a template. For every JDBC provider WebSphere Application Server supports, the product provides a corresponding data source template. You can create supported providers and associated data sources through the administrative console, or by using the WSadmin - scripting tool. For a complete list of supported JDBC providers (and therefore a complete list of data sources that must be created using a template), refer to the topic “Vendor-specific data sources minimum required settings” on page 1220.

These steps outline the general procedure for using the JMX API to create a JDBC provider and data source, on WebSphere Application Server running on Windows platforms:

1. Set your classpath.

You need two JAR files in your classpath -- *wsexception.jar* and *wasjmx.jar*. The following command is an example for setting your classpath (shown on 2 lines for publication):

```
set classpath=%classpath%;D:\WebSphere\AppServer\lib\wsexception.jar;
  D:\WebSphere\AppServer\lib\wasjmx.jar
```

2. Look up the host and get an administration client handle.
3. Get a configuration service handle.
4. Update the *resource.xml* file using the configuration service as desired.
   a. Add a JDBC provider.
   b. Add the data source.
   c. Add the connection factory. (This step is necessary only for data sources that must support container-managed persistence.)
5. Reload the *resource.xml* file to bind the newly created data source into the JNDI namespace. Perform this step if you want to use the newly created data source right away without restarting the application server.
   a. Locate the DataSourceConfigHelper MBean using the name.
   b. Put together the signature and parameters for the call.
   c. Invoke the reload() call.

Example: Using the Java Management Extensions API to create a JDBC driver and data source for container-managed persistence:

```
//
// "This program may be used, executed, copied, modified and distributed without royalty for the
// purpose of developing, using, marketing, or distributing."
//

      try {
         cds.run(args);
      } catch (com.ibm.ws.exception.WsException ex) {
         System.out.println("Caught this " + ex   );
         ex.printStackTrace();
         //ex.getCause().printStackTrace();
      } catch (Exception ex) {
         System.out.println("Caught this " + ex );
         ex.printStackTrace();
      }
   }

   /**
    * This method creates the datasource using JMX.
* The datasource created here is only written into resources.xml.
    * It is not bound into namespace until the server is restarted, or an application started
    */
   public void run(String[] args) throws Exception {

      try {
         // Initialize the AdminClient.
         Properties adminProps = new Properties();
         adminProps.setProperty(AdminClient.CONNECTOR_TYPE, AdminClient.CONNECTOR_TYPE_SOAP);
         adminProps.setProperty(AdminClient.CONNECTOR_HOST, "localhost");
         adminProps.setProperty(AdminClient.CONNECTOR_PORT, "8880");
         AdminClient adminClient = AdminClientFactory.createAdminClient(adminProps);

         // Get the ConfigService implementation.
         com.ibm.websphere.management.configservice.ConfigServiceProxy configService =
         new com.ibm.websphere.management.configservice.ConfigServiceProxy(adminClient);

         Session session = new Session();

         // Use this group to add to the node scoped resource.xml.
         ObjectName node1 = ConfigServiceHelper.createObjectName(null, "Node", null);
         ObjectName[] matches = configService.queryConfigObjects(session, null, node1, null);
         node1 = matches[0];     // use the first node found

         // Use this group to add to the server1 scoped resource.xml.
         ObjectName server1 = ConfigServiceHelper.createObjectName(null, "Server", "server1");
         matches = configService.queryConfigObjects(session, null, server1, null);
         server1 = matches[0];   // use the first server found

         // Create the JDBCProvider
         String providerName = "DB2 JDBC Provider (XA)";
         System.out.println("Creating JDBCProvider " + providerName );

         // Prepare the attribute list
         AttributeList provAttrs = new AttributeList();
         provAttrs.add(new Attribute("name", providerName));
         provAttrs.add(new Attribute("implementationClassName",
                                "COM.ibm.db2.jdbc.DB2XADataSource"));
         provAttrs.add(new Attribute("description","DB2 JDBC2-compliant XA Driver"));

         //create it
         ObjectName jdbcProv =
           configService.createConfigData(session,node1,"JDBCProvider",
                                     "resources.jdbc:JDBCProvider",provAttrs);
         // now plug in the classpath
configService.addElement(session,jdbcProv,"classpath",dbclasspath,-1);

// Search for RRA so we can link it to the datasource
         ObjectName rra =
           ConfigServiceHelper.createObjectName(null, "J2CResourceAdapter", null);
         matches = configService.queryConfigObjects(session, node1, rra, null);
         rra = matches[0]; // use the first J2CResourceAdapter segment for builtin_rra

         // Prepare the attribute list
         AttributeList dsAttrs = new AttributeList();
         dsAttrs.add(new Attribute("name", dsName));
         dsAttrs.add(new Attribute("jndiName", "jdbc/" + dsName));
         dsAttrs.add(new Attribute("datasourceHelperClassname",
                                   "com.ibm.websphere.rsadapter.DB2DataStoreHelper"));
         dsAttrs.add(new Attribute("statementCacheSize", new Integer(10)));
         dsAttrs.add(new Attribute("relationalResourceAdapter",
            rra)); // this is where we make the link to "builtin_rra"
         dsAttrs.add(new Attribute("description", "JDBC Datasource for mark section CMP 2.0 test"));
         dsAttrs.add(new Attribute("authDataAlias",authDataAlias));

         // Create the datasource
         System.out.println("  **  Creating datasource");
         ObjectName dataSource =
           configService.createConfigData(session,jdbcProv,"DataSource",
           "resources.jdbc:DataSource",dsAttrs);

         // Add a propertySet.
         AttributeList propSetAttrs = new AttributeList();
         ObjectName resourcePropertySet =
           configService.createConfigData(session,dataSource,"propertySet","",propSetAttrs);

         // Add resourceProperty databaseName
         AttributeList propAttrs1 = new AttributeList();
         propAttrs1.add(new Attribute("name", "databaseName"));
         propAttrs1.add(new Attribute("type", "java.lang.String"));
         propAttrs1.add(new Attribute("value", dbName));

         configService.addElement(session,resourcePropertySet,"resourceProperties",propAttrs1,-1);

// Now Create the corresponding J2CResourceAdapter Connection Factory object.
         ObjectName jra = ConfigServiceHelper.createObjectName(null,"J2CResourceAdapter",null);

         // Get all the J2CResourceAdapter, and I want to add my datasource
         System.out.println("  **  Get all J2CResourceAdapter's");
         ObjectName[] jras = configService.queryConfigObjects(session, node1, jra, null);

         int i=0;

         for (;i< jras.length;i++) {
            System.out.println(ConfigServiceHelper.getConfigDataType(jras[i])+ " " + i + " = "
                 + jras[i].getKeyProperty(SystemAttributes._WEBSPHERE_CONFIG_DATA_DISPLAY_NAME)
                     + "\nFrom scope ="
                     + jras[i].getKeyProperty(SystemAttributes._WEBSPHERE_CONFIG_DATA_ID));
            // quit on the first builtin_rra
            if (jras[i].getKeyProperty(SystemAttributes._WEBSPHERE_CONFIG_DATA_DISPLAY_NAME)
                .equals("WebSphere Relational Resource Adapter")) {
               break;
            }
         }

         if (i >= jras.length) {
            System.out.println(
              "Did not find builtin_rra J2CResourceAdapter object creating CF anyways" );
         } else {
            System.out.println(
              "Found builtin_rra J2CResourceAdapter object at index " + i + " creating CF" );
         }

         // Prepare the attribute list
         AttributeList cfAttrs = new AttributeList();
         cfAttrs.add(new Attribute("name", dsName + "_CF"));
```

```
        cfAttrs.add(new Attribute("authMechanismPreference","BASIC_PASSWORD"));
        cfAttrs.add(new Attribute("authDataAlias",authDataAlias));
        cfAttrs.add(new Attribute("cmpDatasource",
            dataSource ));  // this is where we make the link to DataSource's xmi:id
        ObjectName cf =
           configService.createConfigData(session,jras[i],"CMPConnectorFactory",
                                          "resources.jdbc:CMPConnectorFactory",cfAttrs);

        // ===== start Security section
        System.out.println("Creating an authorization data alias " + authDataAlias);

// Find the parent security object
        ObjectName security = ConfigServiceHelper.createObjectName(null, "Security", null);
        ObjectName[] securityName =
          configService.queryConfigObjects(session, null, security, null);

      }
   }
}
```

Example: Creating a JDBC provider and data source using Java Management Extensions API and the scripting tool: The following code is a JACL (WSadmin - scripting tool) script used to create a data source.

Note: Use this script to create only data sources for which the product does *not* provide a template. For every JDBC provider WebSphere Application Server supports, the product provides a corresponding data source template. See the topic ″Creating configuration objects using the wsadmin tool″ in the information center for instructions on how to use the `createUsingTemplate` command to establish these data sources. For a complete list of supported JDBC providers (and therefore a complete list of data sources that must be created using a template), refer to the topic “Vendor-specific data sources minimum required settings” on page 1220.

This script:

- Creates a data source *fvtDS_1*
- Creates a 4.0 data source *fvtDS_3*
- Creates a container-managed persistence (CMP) data source linked to *fvtDS_1*

```
#AWE --  Set up XA DB2 data sources, both Version 4.0 and J2EE Connector
         architecture (JCA)-compliant data sources

#UPDATE THESE VALUES:
#The classpath that will be used by your database driver
set driverClassPath "c:/sqllib/java/db2java.zip"

set server "server1"

set fvtbase "c:/wssb/fvtbase"

#Users and passwords..
set defaultUser1 "dbuser1"
set defaultPassword1 "dbpwd1"

 authDataAlias "alias1"}}

$AdminConfig save
```

Test connection service:

WebSphere Application Server provides a test connection service for testing connections to the data sources that you configure for database access.

If the definition of your data source includes WebSphere variables, see the ″Configuring WebSphere variables″ topic to verify that you define them correctly. A `variable cannot be found` exception results from attempted use of a data source that is configured with undefined variables.

Activating the test connection service

There are three ways to activate the test connection service: through the administrative console, the wsadmin tool, or a Java stand-alone program. Each process invokes the same methods on the same MBean.

Administrative console

WebSphere Application Server allows you to test a connection from the administrative console by simply pushing a button: the *Data source collection*, *Data source settings*, *Version 4 data source collection*, and *Version 4 data source settings* pages all have **Test Connection** buttons. After you define and save a data source, you can click this button to ensure that the parameters in the data source definition are correct. On the collection page, you can select several data sources and test them all at once. Note that there are certain conditions that must be met first. For more information, see Testing a connection with the administrative console.

WsAdmin tool

The wsadmin tool provides a scripting interface to a full range of WebSphere Application Server administration activities. Because the Test Connection functionality is implemented as a method on an MBean, and wsadmin can invoke MBean methods, wsadmin can be utilized to test connections to data sources. You have two options for testing a data source connection through wsadmin:

The *AdminControl* object of wsadmin has a testConnection operation that tests the configuration properties of a data source object. For information, see Testing a connection using wsadmin.

You can also test a connection by invoking the MBean operation. Use ″Example: Testing data source connection using wsadmin″ in the information center as a guide for this technique.

Java stand-alone program

Finally, you can test a connection by executing the `testConnection()` method on the `DataSourceCfgHelper` MBean. This method allows you to pass the configuration ID of the configured data source. The Java program connects to a running Java Management Extensions (JMX) server to access the MBean. In a base installation of Application Server, you connect to the JMX server running in the application server, usually on port 8880.

The return value from this invocation is either 0, a positive number, or an exception. 0 indicates that the operation completed successfully, with no warnings. A positive number indicates that the operation completed successfully, with the number of warnings. An exception indicates that the test of the connection failed.

You can find an example of this code in Example: Test a connection using testConnection(ConfigID).

Testing a connection with the administrative console:

After you have defined and saved a data source, you can click the **Test Connection** button to ensure that the parameters in the data source definition are correct. On the collection panel, you can select multiple data sources and test them all at once. Be sure that the following conditions are met before using the Test Connection button.

1. Depending on your specific needs, a valid *Authentication Data alias* might need to exist and be supplied on the data source panels.
2. If you are testing a connection using a WebSphere Application Server Version 4.0 type of data source, ensure that the *user* and *password* information is filled in.
3. If you used a WebSphere Environment entry for the class path or other fields, such as *${DB2_JDBC_DRIVER_PATH}/db2java.zip*, make sure that you assign it a value in the *WebSphere Variables* page. Note that if you add a new WebSphere environment variable, or modify it , the process (application server) might need restarting.
4. Click **Test Connection**.

   A Test Connection operation can have three different outcomes, each resulting in a different message being displayed in the messages panel of the page on which you press the Test Connection button.
   a. The test can complete successfully, meaning that a connection is successfully obtained to the database using the configured data source parameters. The resulting message states: Test Connection for data source *DataSourceName* on process *ProcessName* at node *NodeName* was successful.
   b. The test can complete successfully with warnings. This means that while a connection is successfully obtained to the database, warnings were issued. The resulting message states: Test Connection for data source *DataSourceName* on process *ProcessName* at node *NodeName* was successful with warning(s). View the JVM Logs for more details.

      The **View the JVM Logs** text is a hyperlink that takes you to the JVM Logs console screen for the process.
   c. The test can fail. A connection to the database with the configured parameters is not obtained. The resulting message states: Test Connection failed for data source *DataSourceName* on process *ProcessName* at node *NodeName* with the following exception: *ExceptionText*. View the JVM Logs for more details.

      Again, the text for **View the JVM Logs** is a hyperlink to the appropriate logs screen.

Testing a connection using wsadmin:

The *AdminControl* object of wsadmin has a testConnection operation that tests the configuration properties of a data source object. It takes a *configuration ID* as an argument.

Note: There is no way to pass a user ID and password to this invocation. This invocation can only be used for databases that do not require a user ID and password to make a connection (such as DB2 on a Windows machine), or for data sources that have a component-managed or container-managed authentication alias set on the data source object.

1. Invoke the getid() method for your data source.
2. Set the value of the *configuration id* to a variable.

   ```
   set myds [$AdminConfig getid /JDBCProvider:mydriver/DataSource:mydatasrc/]
   ```

   where */JDBCProvider:mydriver/DataSource:mydatasrc/* is the data source you want to test. After you have the configuration ID of the data source, you can test the connection to the database.
3. Test the connection to the database.

   ```
   $AdminControl testConnection $myds
   ```

Example: Test a connection using testConnection(ConfigID): This program uses JMX to connect to a running server and invoke the *testConnection* method on the *DataSourceCfgHelper* MBean.

```
/**
 * Description
 * Resource adapter test program to make sure that the MBean interfaces work.
 * Following interfaces are tested
 *

```

Configuring J2EE Connector connection factories in the administrative console

1. Click **Resources**.
2. Click **Resource Adapters**.
3. Select a resource adapter under Resource Adapters.
4. Click **J2C Connection Factories** under Additional Properties .
5. Click **New**.
6. Specify *General Properties* .
7. Select the authentication preference.

8. Select aliases for **component-managed authentication**, **container-managed authentication**, or both. If none are available, or you want to define a different one, click **Apply** > **J2C Authentication Data Entries** under Related Items.
   a. Click **J2C Auth Data Entries** under Related Items.
   b. Click **New**.
   c. Specify General Properties.
   d. Click **OK**.
9. Click **OK**.
10. Click the J2C connection factory you just created.
11. Under *Additional Properties* click **Connection Pool**.
12. Change any values desired by clicking the property name.
13. Click **OK**.
14. Click **Custom Properties** under *Additional Properties*.
15. Click any property name to change its value. Note that **UserName** and **Password** if present, are overridden by the **component-managed authentication** alias you specified in a previous step.
16. Click **Save**.

Connection pool settings:

Use this page to configure connection pool settings.

This administrative console page is common to a range of resource types; for example, JDBC data sources and JMS queue connection factories. To view this page, the path depends on the type of resource, but generally you select an instance of the resource provider, then an instance of the resource type, then click **Connection Pool**. For example: click **Resources** > **JDBC Providers** > *JDBC_provider* > **Data Sources** > *data_source* > **Connection Pool**.

Connection Timeout:

Specifies the interval, in seconds, after which a connection request times out and a ConnectionWaitTimeoutException is thrown.

This value indicates the number of seconds a request for a connection waits when there are no connections available in the free pool and no new connections can be created, usually because the maximum value of connections in the particular connection pool has been reached. For example, if Connection Timeout is set to 300, and the maximum number of connections are all in use, the pool manager waits for 300 seconds for a physical connection to become available. If a physical connection is not available within this time, the pool manager initiates a `ConnectionWaitTimeout` exception. It usually does not make sense to retry the getConnection() method; if a longer wait time is required you should increase the Connection Timeout setting value. If a `ConnectionWaitTimeout` exception is caught by the application, the administrator should review the expected connection pool usage of the application and tune the connection pool and database accordingly.

If the Connection Timeout is set to 0, the pool manager waits as long as necessary until a connection becomes available. This happens when the application completes a transaction and returns a connection to the pool, or when the number of connections falls below the value of Maximum Connections, allowing a new physical connection to be created.

If Maximum Connections is set to 0, which enables an infinite number of physical connections, then the Connection Timeout value is ignored.

Data type	Integer
Units	Seconds

Default	180
Range	0 to max int

Maximum Connections:

Specifies the maximum number of physical connections that you can create in this pool.

These are the physical connections to the backend resource. Once this number is reached, no new physical connections are created and the requester waits until a physical connection that is currently in use returns to the pool, or a `ConnectionWaitTimeout` exception is issued.

For example, if the Maximum Connections value is set to 5, and there are five physical connections in use, the pool manager waits for the amount of time specified in Connection Timeout for a physical connection to become free.

If Maximum Connections is set to 0, the connection pool is allowed to grow infinitely. This also has the side effect of causing the Connection Timeout value to be ignored.

If multiple standalone application servers use the same data source, there is one pool for each application server. If clones are used, one data pool exists for each clone. Knowing the number of data pools is important when configuring the database maximum connections.

You can use the Tivoli Performance Viewer to find the optimal number of connections in a pool. If the number of concurrent waiters is greater than 0, but the CPU load is not close to 100%, consider increasing the connection pool size. If the Percent Used value is consistently low under normal workload, consider decreasing the number of connections in the pool.

Data type	Integer
Default	10
Range	0 to max int

Minimum Connections:

Specifies the minimum number of physical connections to maintain.

If the size of the connection pool is at or below the minimum connection pool size, the Unused Timeout thread does not discard physical connections. However, the pool does not create connections solely to ensure that the minimum connection pool size is maintained. Also, if you set a value for Aged Timeout, connections with an expired age are discarded, regardless of the minimum pool size setting.

For example if the Minimum Connections value is set to 3, and one physical connection is created, the Unused Timeout thread does not discard that connection. By the same token, the thread does not automatically create two additional physical connections to reach the Minimum Connections setting.

Data type	Integer
Default	1
Range	0 to max int

Reap Time:

Specifies the interval, in seconds, between runs of the pool maintenance thread.

For example, if Reap Time is set to 60, the pool maintenance thread runs every 60 seconds. The *Reap Time* interval affects the accuracy of the *Unused Timeout* and *Aged Timeout* settings. The smaller the interval, the greater the accuracy. If the pool maintenance thread is enabled, set the Reap Time value less than the values of Unused Timeout and Aged Timeout. When the pool maintenance thread runs, it discards any connections remaining unused for longer than the time value specified in Unused Timeout, until it reaches the number of connections specified in *Minimum Connections*. The pool maintenance thread also discards any connections that remain active longer than the time value specified in Aged Timeout.

The Reap Time interval also affects performance. Smaller intervals mean that the pool maintenance thread runs more often and degrades performance.

To disable the pool maintenance thread set Reap Time to 0, or set both Unused Timeout and Aged Timeout to 0. The recommended way to disable the pool maintenance thread is to set Reap Time to 0, in which case Unused Timeout and Aged Timeout are ignored. However, if Unused Timeout and Aged Timeout are set to 0, the pool maintenance thread runs, but only physical connections which timeout due to non-zero timeout values are discarded.

Data type	Integer
Units	Seconds
Default	180
Range	0 to max int

Unused Timeout:

Specifies the interval in seconds after which an unused or idle connection is discarded.

Set the Unused Timeout value higher than the Reap Timeout value for optimal performance. Unused physical connections are only discarded if the current number of connections exceeds the Minimum Connections setting. For example, if the unused timeout value is set to 120, and the pool maintenance thread is enabled (Reap Time is not 0), any physical connection that remains unused for two minutes is discarded. Note that accuracy of this timeout, as well as performance, is affected by the Reap Time value. See Reap Time for more information.

Data type	Integer
Units	Seconds
Default	1800
Range	0 to max int

Aged Timeout:

Specifies the interval in seconds before a physical connection is discarded.

Setting *Aged Timeout* to 0 supports active physical connections remaining in the pool indefinitely. Set the Aged Timeout value higher than the Reap Timeout value for optimal performance. For example, if the Aged Timeout value is set to 1200, and the Reap Time value is not 0, any physical connection that remains in existence for 1200 seconds (20 minutes) is discarded from the pool. Note that accuracy of this timeout, as well as performance, are affected by the Reap Time value. See Reap Time for more information.

Data type	Integer
Units	Seconds
Default	0
Range	0 to max int

Purge Policy:

Specifies how to purge connections when a *stale connection* or *fatal connection error* is detected.

Valid values are **EntirePool** and **FailingConnectionOnly**. JCA data sources can have either option. WebSphere Version 4.0 data sources always have a purge policy of **EntirePool**.

Data type
String

Default
EntirePool

Range

EntirePool
All connections in the pool are marked stale. Any connection not in use is immediately closed. A connection in use is closed and issues a stale connection Exception during the next operation on that connection. Subsequent getConnection() requests from the application result in new connections to the database opening. When using this purge policy, there is a slight possibility that some connections in the pool are closed unnecessarily when they are not stale. However, this is a rare occurrence. In most cases, a purge policy of EntirePool is the best choice.

FailingConnectionOnly
Only the connection that caused the stale connection exception is closed. Although this setting eliminates the possibility that valid connections are closed unnecessarily, it makes recovery from an application perspective more complicated. Because only the currently failing connection is closed, there is a good possibility that the next getConnection() request from the application can return a connection from the pool that is also stale, resulting in more stale connection exceptions.

The connection pretest function attempts to insulate an application from pooled connections that are not valid. When a backend resource, such as a database, goes down, pooled connections that are not valid might exist in the free pool. This is especially true when the purge policy is failingConnectionOnly; in this case, the failing connection is removed from the pool. Depending on the failure, the remaining connections in the pool might not be valid.

Connection pool advanced settings:

Use this page to specify connection pooling related settings.

Properties-shared partitions, free pool partitions, and free pool distribution table size are properties related to reducing the time a thread needs to wait for a synchronization lock.

Partition support is always enabled. The default values of 0 should be used enabling the connection pool to pick the best values for performance. In some cases where large multiprocessor systems are used, adjusting the partition support properties might help performance.

To view this administrative console page, click **Resources** > **Resource Adapters** > *resource_adapter* > **J2C Connection Factories** > *connection_factory* > **Connection Pool** > **Advanced Connection Pool**.

Number of shared partitions:

Specifies the number of partitions that are created in each of the shared pools.

Data type	integer
Default value	0
Range	0 to max int

Number of free pool partitions:

Specifies the number of partitions that are created in each of the free pools.

Data type	integer
Default value	0
Range	0 to max int

Free pool distribution table size:

The free pool distribution table size is used for better distribution of the Subject and CRI hash values within a hash table to minimize collisions for faster retrieval of a matching free connection.

If there are many incoming requests with varying credentials, this value can help with the distribution of finding a free pool for a connection for that user. Larger values are more common for installations that have many different credentials accessing the resource. Smaller values (1) should be used if the same credentials apply to all incoming requests for the resource.

Data type	integer
Default value	0
Range	0 to max int

Surge threshold:

Specifies the number of connections created before surge protection is activated.

Surge protection is designed to prevent overloading of a data source when too many connections are created at the same time. Surge protection is controlled by two properties, *surge threshold* and *surge creation interval*.

The surge threshold property specifies the number of connections created before surge protection is activated. After you reach the specified number of connections, you enter *surge mode*.

The surge creation interval property specifies the amount of time, in seconds, between the creation of connections when in surge mode.

For example, assume the follow settings:
- maxConnections = 50
- surgeThreshold = 10
- surgeCreationInterval = 30 seconds

If the connection pool receives 15 connection requests, 10 connections are created at about the same time. The 11th connection is created 30 seconds after the first 10 connections. The 12th connection is created 30 seconds after the 11th connection. Connections continue to be created every 30 seconds until there are no more new connections needed or you reach the maxConnections value.

Surge connection support starts if the surge threshold is > -1 and the surge creation interval is > 0. The surge threshold property has a default value of -1, which indicates that it is turned off.

wsadmin examples

```
$AdminControl getAttribute $objectname surgeCreationInterval
$AdminControl setAttribute $objectname surgeCreationInterval 30
$AdminControl getAttribute $objectname surgeThreshold
$AdminControl setAttribute $objectname surgeThreshold 15
```

Data type	integer
Default value	-1
Range	-1 to max int

Surge creation interval:

Specifies the amount of time between connection creates when you are in surge protection mode.

If the number of connections specified in the surge threshold property have been made, each request for a new connection must wait to be created on the surge creation interval. This property has a default value of 20, which indicates that at least 20 seconds should pass between connections being created. Valid values for this property are any positive integer.

Data type	integer
Default value	20
Range	0 to max int

Stuck timer time:

A *stuck* connection is an active connection that is not responding or returning to the connection pool. If the pool appears to be stuck (you have reached the stuck threshold), a resource exception is given to all new connection requests until the pool is unstuck. The stuck timer time property is the interval for the timer. This is how often the connection pool checks for stuck connections. The default value is 5 seconds.

If an attempt to change the stuck time, stuck timer time, or stuck threshold properties using the wsadmin scripting tool fails, an `IllegalState` exception occurs. The pool cannot have any active requests or active connections during this request. For the stuck connection support to start, all three stuck property values must be greater than 0 and maximum connections must be greater than 0.

Also, the stuck timer time, if it is set, must be less than the stuck time value. In fact, it is suggested that the stuck timer time should be one-quarter to one-sixth the value of stuck time so that the connection pool checks for stuck connections 4 to 6 times before a connection is declared stuck. This reduces the likelihood of false positives

wsadmin examples

```
$AdminControl getAttribute $objectname stuckTime
$AdminControl setAttribute $objectname stuckTime 30
$AdminControl getAttribute $objectname stuckTimerTime
$AdminControl setAttribute $objectname stuckTimerTime 15
$AdminControl getAttribute $objectname stuckThreshold
$AdminControl setAttribute $objectname stuckThreshold 10
```

Data type	integer
Default value	5
Range	0 to max int

Stuck time:

A *stuck* connection is an active connection that is not responding or returning to the connection pool. If the pool appears to be stuck (you have reached the stuck threshold), a resource exception is given to all new connection requests until the pool is unstuck. The stuck time property is the interval, in seconds, allowed for a single active connection to be in use to the backend resource before it is considered to be stuck.

Data type	integer
Default value	0
Range	0 to max int

Stuck threshold:

A *stuck* connection is an active connection that is not responding or returning to the connection pool. If the pool appears to be stuck (you have reached the stuck threshold), a resource exception is given to all new connection requests until the pool is unstuck. An application can explicitly catch this exception and continue processing. The pool will continue to periodically check for stuck connections when the number of stuck connections is past the threshold. If the number of stuck connections drops below the stuck threshold, the pool will detect this during its periodic checks and enable the pool to begin servicing requests again. The stuck threshold is the number of connections that need to be considered stuck for the pool to be in stuck mode.

Data type	integer
Default value	0
Range	0 to max int

Connection pool (Version 4) settings:

Use this page to create a connection pool for a Version 4.0 data source.

To view this administrative console page, click **Resources** > **JDBC Providers** > *JDBC_provider* > **Data Sources (Version 4)** > *data_source* > **Connection Pool**.

Scope:

Specifies the level to which this resource definition is visible -- the cell, node, or server level.

Resources such as JDBC providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates which are defined at more general scopes.

Note that no matter what the scope of a defined resource, the resource's properties only apply at an individual server level. For example, if you define the scope of a data source at the cell level, all users in that cell can look up and use that data source, which is unique within that cell. However, resource property settings are local to each server in the cell. For example, if you define *max connections* to 10, then each server in that cell can have 10 connections.

Cell The most general scope. Resources defined at the cell scope are visible from all nodes and servers, unless they are overridden. To view resources defined in the cell scope, do not specify a server or a node name in the scope selection form.

Node The default scope for most resource types. Resources defined at the node scope override any duplicates defined at the cell scope and are visible to all servers on the same node, unless they are overridden at a server scope on that node. To view resources defined in a node scope, do not specify a server, but select a node name in the scope selection form.

Server
The most specific scope for defining resources. Resources defined at the server scope override

any duplicate resource definitions defined at the cell scope or parent node scope and are visible only to a specific server. To view resources defined in a server scope, specify a server name as well as a node name in the scope selection form.

When resources are created, they are always created into the current scope selected in the panel. To view resources in other scopes, specify a different node or server in the scope selection form.

Data type	String

Minimum Pool Size:

Specifies the minimum number of connections to maintain in the pool.

The minimum pool size can affect the performance of an application. Smaller pools require less overhead when the demand is low because fewer connections are held open to the database. When the demand is high, the first applications experience a slow response because new connections are created if all others in the pool are in use.

Data type	Integer
Default	1
Range	Any non-negative integer.

Maximum Pool Size:

Specifies the maximum number of connections to maintain in the pool.

If the maximum number of connections is reached and all connections are in use, additional requests for a connection wait up to the number of seconds specified as the connection timeout. The maximum pool size can affect the performance of an application. Larger pools require more overhead when demand is high because there are more connections open to the database at peak demand. These connections persist until idled out of the pool. If the maximum value is smaller, longer wait times or possible connection timeout errors during peak times can occur. Ensure that the database can support the maximum number of connections in the application server, in addition to any load that it has outside of the application server.

Data type	Integer
Default	10
Range	Any positive integer

Connection Timeout:

Specifies the maximum number of seconds an application waits for a connection from the pool before timing out and issuing a `ConnectionWaitTimeout` exception to the application.

Setting this value to 0 disables the connection timeout.

Data type	Integer
Units	Seconds
Default	180
Range	Any non-negative integer

Idle Timeout:

Specifies the maximum number of seconds that an idle (unallocated) connection can remain in the pool before being removed to free resources.

Connections need to idle out of the pool because keeping connections open to the database can cause database memory problems. However, not all connections are idled out of the pool, even if they are older than the Idle Timeout setting. A connection is not idled if removing the connection would cause the pool to shrink below its minimum size. Setting this value to 0 disables the idle timeout.

Data type	Integer
Units	Seconds
Default	1800
Range	Any non-negative integer

Orphan Timeout:

Specifies the maximum number of seconds that an application can hold a connection without using it before the connection returns to the pool

If there is no activity on an allocated connection for longer than the Orphan Timeout setting, the connection is marked for orphaning. After another Orphan Timeout number of seconds, if the connection still has no activity, the connection returns to the pool. If the application tries to use the connection again, it is issued a stale connection exception. Connections that are enlisted in a transaction are not orphaned. Setting this value to 0 disables the orphan timeout.

Data type	Integer
Units	Seconds
Default	1800
Range	Any non-negative integer

Statement Cache Size:

Specifies the number of cached prepared statements to keep per connection.

The largest value you would need to set your cache size to if you do not want any cache discards is determined as follows: for each application that uses this data source on a particular server, add up the number of unique prepared statements (as determined by the *sql* string, concurrency, and the scroll type). This is the maximum number of possible prepared statements that can be cached on a given connection over the life of the server. Setting the cache size to this value means you never have cache discards. This provides better performance. However, because of potential resource limitations, this might not always be possible.

Data type	Integer
Default	10
Range	Any non-negative integer

Auto Connection Cleanup:

Specifies whether or not the connection pooling software automatically closes connections from this data source at the end of a transaction.

The default is *false*, which indicates that when a transaction completes, WebSphere Application Server closes the connection and returns it to the pool. Any use of the connection after the transaction has ended results in a stale connection exception because the connection is closed and has returned to the pool. This mechanism ensures that connections are not held indefinitely by the application. If the value is set to *true*, the connection is not returned to the pool at the end of a transaction. In this case, the application must return the connection to the pool by calling *close()*. If the application does not close the connection, the pool can run out of connections for other applications to use.

Data type	Check box
Default	False (clear)

Configuring connection factories for resource adapters within applications:

1. Click **Applications**.
2. Click **Install New Application**.
3. Browse to find the appropriate EAR file, which contains an RAR file.
4. Click **Next**.
5. Select **resource ref mapping to a J2C Connection Factory**, then click **Next**.
6. After the application installs, click **Applications**.
7. Select the application just installed.
8. Click **Connector Modules** under Related Items.
9. Select an RAR file name on the Connector Modules page.
10. Click **Resource Adapter** under Additional Properties.
11. Click **J2C Connection Factories** under Additional Properties.
12. Click **New**.
13. Specify General Properties.
14. Select a **Component-managed authentication alias** if any application components with *Application* or *Per connection factory* authentication specified in the resource reference are going to be getting connections from this connection factory using the empty-argument getConnection() method. For resources supporting XA, you can optionally specify an Authentication alias for XA recovery. If a desired alias is not available, or you want to define a different one, click **Apply** > **J2C Authentication Data Entries** under Related Items.
    a. Click **J2C Auth Data Entries** under Related Items.
    b. Click **New**.
    c. Specify General Properties.
    d. Click **OK**.
15. Click **OK**.
16. Click the J2C connection factory you just created.
17. Click **Connection Pool** under Additional Properties .
18. Change any values desired by clicking on the property name.
19. Click **OK**.
20. Click **Custom Properties** under Additional Properties.
21. Click any property name to change its value. Note that **UserName** and **Password** if present, are overridden by the **component-managed authentication** alias you specified in a previous step.
22. Click **Save**.

J2C Connection Factories collection:

Use this page to select a connection factory, which represents one set of connection configuration values.

Application components such as enterprise beans have resource reference descriptors that refer to the connection factory, not the resource adapter. The connection factory is really a configuration properties list holder. In addition to the arbitrary set of configuration properties defined by the vendor of the resource adapter, there are several standard configuration properties that apply to the connection factory. These standard properties are used by the Java 2 Connectors connection pool manager in the application server run time and are not known by the vendor-supplied resource adapter code.

To view this administrative console page, click **Resources** > **Resource Adapters** > *resource_adapter* > **J2C Connection Factories**.

Name:

Specifies a list of the connection factory display names.

Data type	String

JNDI name:

Specifies the Java Naming and Directory Interface (JNDI) name of this connection factory.

Data type	String

Description:

Specifies a text description of this connection factory.

Data type	String

Category:

Specifies a string that you can use to classify or group this connection factory.

Data type	String

J2C Connection Factories settings:

Use this page to specify settings for a connection factory.

To view this administrative console page, click **Resources** > **Resource Adapters** > *resource_adapter* > **J2C Connection Factories** > *connection_factory*.

Name:

Specifies a list of connection factory display names.

This is a required property.

Data type	String

JNDI Name:

Specifies the JNDI name of this connection factory.

For example, the name could be *eis/myECIConnection*.

After you set this value, save it and restart the server. You can see this string when you run the *dumpNameSpace* tool. This is a required property. If you do not specify a JNDI name, it is filled in by default using the Name field.

Data type	String
Default	eis/*display name*

Description:

Specifies a text description of this connection factory.

Data type	String

Connection Factory Interface:

Specifies the fully qualified name of the Connection Factory Interfaces supported by the resource adapter.

This is a required property. For new objects, the list of available classes is provided by the resource adapter in a drop-down list. After you create the connection factory, the field is a read only text field.

Data type	Drop-down list or text

Category:

Specifies a string that you can use to classify or group this connection factory.

Data type	String

Authentication Alias for XA Recovery:

This optional field is used to specify the authentication alias that should be used during XA recovery processing.

If the resource adapter does not support XA transactions, then this field will not be displayed. The default value will come from the selected alias for application authentication (if specified).

Use Component-managed Authentication Alias
Selecting this radio button specifies that the alias set for component-managed authentication is used at XA recovery time.

Data type	Radio button

Specify:
Selecting this radio button enables you to choose an authentication alias from a drop-down list of configured aliases.

Data type	Radio button

Component-managed Authentication Alias:

Specifies authentication data for component-managed signon to the resource.

Choose from aliases defined under **Security**>**JAAS Configuration**> **J2C Authentication Data**.

To define a new alias not already appearing in the pick list:
- Click **Apply** to expose Related Items.
- Click **J2C Authentication Data Entries**.
- Define an alias.
- Click the connection factory name at the top of the *J2C Authentication Data Entries* page to return to the connection factory page.

- Select the alias.

Data type	Pick-list

Container-managed Authentication Alias (deprecated):

Specifies authentication data (a string path converted to userid and password) for container-managed signon to the resource.

Note: Beginning with WebSphere Application Server Version 6.0, the container-managed authentication alias is superseded by the specification of a login configuration on the resource-reference mapping at deployment time, for components with *res-auth=Container*.

Choose from aliases defined under **Security**>**JAAS Configuration**> **J2C Authentication Data**.

To define a new alias not already appearing in the pick list:
- Click **Apply** to expose Related Items.
- Click **J2C Authentication Data Entries**.
- Define an alias.
- Click the connection factory name at the top of the *J2C Authentication Data Entries* page to return to the connection factory page.
- Select the alias.

Data type	Pick-list

Authentication Preference (deprecated):

Specifies the authentication mechanisms defined for this connection factory.

Note: Beginning with WebSphere Application Server Version 6.0, the authentication preference is superseded by the combination of the <res-auth> application component deployment descriptor setting and the specification of a login configuration on the resource-reference mapping at deployment time.

This setting specifies which of the authentication mechanisms defined for the corresponding resource adapter applies to this connection factory. Common values, depending on the capabilities of the resource adapter, are: *KERBEROS*, *BASIC_PASSWORD*, and *None*.

If None is chosen, the application component is expected to manage authentication (<res-auth>Application</res-auth>). In this case, the user ID and password are taken from one of the following:
- The component-managed authentication alias
- UserName, Password Custom Properties
- Strings passed on the getConnection method

For example, if two authentication mechanism entries are defined for a resource adapter in the *ra.xml* document:
- <authentication-mechanism-type>BasicPassword</authentication-mechanism-type>
- <authentication-mechanism-type>Kerbv5</authentication-mechanism-type>

the authentication preference specifies the mechanism to use for container-managed authentication. An exception is issued during server startup if a mechanism that is not supported by the resource adapter is selected.

Data type	Pick-list
Default	BASIC_PASSWORD

Mapping-Configuration Alias (deprecated):

Allows users to select from the **Security** > **JAAS Configuration** > **Application Logins Configuration** list.

Note: Beginning with WebSphere Application Server Version 6.0, the Mapping-Configuration Alias is superseded by the specification of a login configuration on the resource-reference mapping at deployment time, for components with *res-auth=Container*.

The **DefaultPrincipalMapping** JAAS configuration maps the authentication alias to the userid and password. You may define and use other mapping configurations.

Data type	Pick-list

J2C Connection Factory advanced settings:

Use this page to specify settings for a connection factory.

To view this administrative console page, click **Resources** > **Resource Adapters** > *resource_adapter* > **J2C Connection Factories** > *connection_factory* > **Advanced Connection Factory Properties**.

Manage cached handles:

Specifies whether cached handles (handles held in `inst vars` in a bean) should be tracked by the container.

Data type	Checkbox

Log missing transaction contexts:

Specifies whether or not the container logs that there is a missing transaction context when a connection is obtained.

Data type	Checkbox

Connection factory JNDI name tips: Distributed computing environments often employ naming and directory services to obtain shared components and resources. Naming and directory services associate names with locations, services, information, and resources.

Naming services provide name-to-object mappings. Directory services provide information on objects and the search tools required to locate those objects. There are many naming and directory service implementations, and the interfaces to them vary.

Java Naming and Directory Interface (JNDI) provides a common interface that is used to access the various naming and directory services. After you have set this value, saved it, and restarted the server, you should be able to see this string when you invoke name space dump tool.

For WebSphere Application Server specifically, when you create a data source the default JNDI name is set to *jdbc/data_source_name*. When you create a connection factory, its default name is *eis/j2c_connection_factory_name*. You can, of course, override these values by specifying your own.

In addition, if you click the checkbox for the *Use this data source for container managed persistence (CMP)* option when you create the data source, another reference is created with the name of *eis/jndi_name_of_datasource_CMP*. For example, if a data source has a JNDI name of *jdbc/myDatasource*, the CMP JNDI name is *eis/jdbc/myDatasource_CMP*. This name is used internally by CMP and is provided simply for informational purposes.

When creating a connection factory or data source, a JNDI name is given by which the connection factory or data source can be looked up by a component. Preferably an ″indirect″ name with the *java:comp/env* prefix should be used and must be used in future releases. An ″indirect″ name makes any resource-reference data associated with the application available to the connection management runtime, to better manage resources based on the res-auth, res-isolation-level, res-sharing-scope, and res-resolution-control settings.

Though you can use a direct JNDI name, this naming method is deprecated in Version 6 of WebSphere Application Server. Application Server assigns default values to the resource-reference data when you use this method. An informational message, resembling the following, is logged to document the defaults:

```
J2CA0294W: Deprecated usage of direct JNDI lookup of resource jdbc/IOPEntity.
  The following default values are used: [Resource-ref settings]

 res-auth:                 1 (APPLICATION)
 res-isolation-level:      0 (TRANSACTION_NONE)
 res-sharing-scope:        true (SHAREABLE)
 loginConfigurationName:   null
 loginConfigProperties:    null
[Other attributes]

 res-resolution-control:   999 (undefined)
isCMP1_x:                 false (not CMP1.x)
isJMS:                 false (not JMS)
```

These default values can lead to unexpected behavior in your resources. For example, an application component (such as a JAAS login module) that accesses a resource with container-managed authentication data might fail to authenticate with the backend resource. Because the res-auth setting is assigned the default level of *Application*, rather than *Container*, the application server cannot find it.

This message can occur when you try using the fully qualified names of resources when looking up resources through Java Naming Directory Interface (JNDI). The J2EE programming model recommends the use of resource references and the local JNDI java:comp/env context. To correct this problem, modify the application to use the preferred J2EE programming model with resource references and the local JNDI java:comp/env context.

Security of lookups with component managed authentication

External Java clients (stand alone clients or servers from other cells) with Java Naming and Directory Interface (JNDI) access can look up a Java 2 Connector (J2C) resource such as a data source or Java Message Service (JMS) queue. However, they are not permitted to take advantage of the component managed *authentication alias* defined on the resource. This alias is a default value used when the *user* and *password* are not supplied on the getConnection() call. Therefore, if an external client needs to get a connection, it must assume responsibility for the authentication by passing it through arguments on the getConnection() call.

Any client running in the WebSphere Application Server process (such as a Servlet or an enterprise bean) within the same cell that can look up a resource in the JNDI namespace can obtain connections without explicitly providing authentication data on the getConnection() call. In this case, if the component‘s res-auth setting is **Application**, authentication is taken from the component-managed authentication alias defined on the connection factory. With res-auth set to **Container**, authentication is taken from the login configuration defined on the component‘s resource-reference. It is important to note that J2C authentication alias is per **cell**. An enterprise bean or Servlet in one application server cannot look up a resource in another server process which is in a different cell, because the alias would not be resolved.

Configuring data access for the Application Client

Configuring data access for the Application Client involves specifying the resource reference and associated database information required for data access. This specification is done as part of the assembly and deployment steps for the Application Client.

There are two tools needed to configure data sources used by J2EE application clients:

- An assembly tool such as the Application Server Toolkit (AST) or Rational Web Developer for defining the resource reference in the deployment descriptor; and
- The Application Client Resource Configuration Tool (ACRCT) for defining the connection to the database in the client deployment environment.

Data access from an application client uses the JDBC driver connection functions directly from the client side. It does not take advantage of the additional pooling support available in the WebSphere Application Server run time. Configuring data access for an application client does not require configuration of a JDBC provider and data source on the WebSphere Application Server server machine.

If you want to take advantage of the pooling and additional database functions provided by WebSphere Application Server, it is recommended that your client application utilize an enterprise bean running on the server side to perform data access.

Defining an application client resource reference using an assembly tool

1. Assemble your application client module as described in Assembling application clients.
2. Create a new resource reference:
   a. In a Project Explorer view, right-click your application client module and click **Open With > Deployment Descriptor Editor**.
   b. On the **References** tab, click **Add > Resource reference > Next**.
   c. On the Resource Reference page, enter the **Name** of this resource reference. The Application Client for WebSphere Application Server run time uses this name for two purposes: to bind the object into the *java:comp/env* portion of the JNDI namespace, and to find client specific configuration information. If the code for the Application Client performs a lookup for *java:comp/env/jdbc/myDB*, the name of the resource reference should be *jdbc/myDB*.
   d. For **Type**, select *javax.sql.DataSource* for JDBC connections.
   e. For **Authentication**, select *Application* if your client application intends to provide authentication information. If the Application Client for WebSphere Application Server run time provides the authentication information (as configured by the Application Client Resource Configuration tool), select *Container*.
   f. Ignore the **Sharing scope** setting; it is unused in an application client resource reference. All Application Client resources are not shared.
   g. Click **Finish**.
   h. Close the deployment descriptor and save your changes.

The JNDI name field appears under **WebSphere Bindings** after your add the reference.

Client configuration with the ACRCT:

There are two client resources for you to configure in the Application Client Resource Configuration Tool (ACRCT) to enable data access from an application client: a data source provider and a data source.

Notes

Note: The following WebSphere objects, which can be bound into the server name space, are not supported on the client:

- Java 2 Connector (J2C) objects

- Connection manager objects

The WebSphere Application Server Client does not provide client database drivers. If your client application uses a database directly, rather than using an enterprise bean, you must provide the database drivers on the client machine. This action can involve contacting your database vendor to acquire client database driver code and licenses.

Instead of accessing the database directly, it is recommended that your client application use an enterprise bean. Accessing a database through an enterprise bean eliminates the need to have database drivers on the client machine because the database access is handled by the enterprise bean running on the WebSphere Application Server. Enterprise beans can also take advantage of the additional database functions provided by the WebSphere Application Server run time.

1. Configure a new data source provider as described in Configuring new data source providers. This provider describes the JDBC database implementation for your client application.
2. Enter the following information on the **General** tab:
   a. A **name** for this data source provider.
   b. Optional: A **description**.
   c. The **classpath** to the data source provider implementation classes or JAR files. This is optional if the implementation classes or JAR files are already in the class path configuration of the client.
   d. The name of the **implementation class**. For example, for DB2 this value is *COM.ibm.db2.jdbc.DB2DataSource*. Remember this class must implement the *javax.sql.DataSource* class. The ACRCT does not verify this class and you receive an error when you run your client application if the class does not implement *javax.sql.DataSource*.

   Use the **Custom** tab to configure non-standard properties of the data source provider. This panel enables you to enter property-value pairs. During run time the *implementation class name* is created and any custom properties added on this panel are set on the newly created data source object using reflection. Any properties configured on this panel must have an appropriate set method on the data source class. For example, assume there is a property called *use2Phase* and its value should be 1. On the custom panel you enter the value *use2Phase* into the **name** column and the value *1* into the **value** column. The Application Client for WebSphere Application Server run time then uses reflection to find a property on the data source class called, typically *setUse2Phase* and call that method passing the value of 1. See your database product documentation for valid properties on your data source implementation.
3. Click **OK**.
4. Configure a new data source as described in Configuring new data sources for application clients. This describes the client properties of the database your client application uses.
5. Enter the following information on the **General** tab:
   a. A **Name**. This field is required and identifies a name for the Application Client Resource Configuration Tool to use. This name is **not** used by your client application program.
   b. Optional: A **description**.
   c. The **JNDI name**. This field is required and must match the value entered in the **Name** field on the Add Resource Reference page of the assembly tool. In the example above, set this value to *jdbc/myDB*.
   d. Optional: The **Database Name**.
   e. Optional: Your *userid* in the **User** field.
   f. Optional: Your *password* in the **Password** field. This password does not display.
   g. Your password again to confirm in the **Re-Enter password** field. Note: The **User** and **Password** fields are used only when the **Authentication** field on the Add Resource Reference page of the assembly tool is set to *Container*.

Configuring Cloudscape Version 5.1.60x

Cloudscape provides the following two separate frameworks for running Cloudscape with WebSphere Application Server:

- Embedded: This framework is the same as the one for Cloudscape Version 5.0. To use this framework, define a Cloudscape JDBC provider. See the Cloudscape section in the minimum required settings article for more information.

  You must use the embedded framework if you are running XA. Cloudscape does not support XA on Network Server.
- Network Server: This framework was a new feature in Cloudscape Version 5.1, and removes these limitations that existed in earlier versions of Cloudscape:
  - inability to access a remote Cloudscape instance
  - only one JVM can boot up the same database instance

  The following steps describe how to configure and run the Network Server framework.

1. Start the Network Server on the machine that hosts the database instance.

   To start the Network Server, run the **startNetworkServer.bat** file, which is located in the `WAS_HOME/cloudscape/bin/networkserver` directory. On UNIX platforms, the file is **startNetwokServer.sh**.
2. Update the **db2j.properties** file, which is located in the `WAS_HOME/cloudscape` directory, if necessary.

   Cloudscape should work without any modifications to this file.

   Use the entries in the **db2j.properties** file to turn on trace, change the port number on which Network Server listens, and enable other functions of the Network Server framework. The default port number on which the Network Server listens is port 1527.

   For more information on this file, see the Cloudscape documentation at www.ibm.com/software/data/cloudscape/pubs/collateral.html.
3. Define a Cloudscape Network Server using Universal JDBC driver to connect Cloudscape with WebSphere Application Server using the Network Server framework.
4. Stop the Network Server by invoking the **stopNetworkServer.bat** file.

   You can find this file in the `WAS_HOME/cloudscape/bin/networkserver` directory. On UNIX platforms, the file is **stopNetworkServer.sh**.
5. Review additional tools available in the Network Server framework.

   Find these tools in the `WAS_HOME/cloudscape/bin/networkserver` directory. These tools are:
   - `sysinfo`
   - `cview`
   - `ij`
   - `dropSYSIBM` Use this tool to drop the SYSIBM schema and its contents.
6. Create a SYSIBM schema.

   If you do not create the SYSIBM schema, you cannot see the datatypes when you create tables using the `cview` graphical user interface. The **db2j.drda.loadSYSIBM** property in the **db2j.properties** file controls whether the schema is created on the first connection to the database. The **db2j.drda.loadSYSIBM** property default value is true.

   Note: When you run ij, surround the dbname by double quotation marks (″ ″) if it includes the full path name; for example: ij> connect ’″c:temp;create=true″’

   This is ’ ″ ″ ’ without spaces.

Cloudscape Version 5.1.60x post installation instructions:

After installing Cloudscape Version 5.1.60x, you must complete the following steps before you can access the database.

1. Upgrade or migrate any existing database instances.
   a. Backup an existing database.

You must complete a backup in case you have to access the previous version of Cloudscape. After you migrate a database, you cannot access your old database unless you perform a backup.

b. Migrate an existing database by doing the following:
   - Set the ***connectionAttributes*** custom property to `upgrade=true`.

     The data source is located in the WebSphere Application Server administrative console under the JDBC providers.
   - If you are using the cview interface, located in the `WAS_HOME/cloudscape51/bin/embedded` directory, click **`yes`** when you see the *upgrade database* prompt.

     Note: Ensure you migrate **`defaultDB`**, which is located in the `WAS_HOME/bin/DefaultDB` directory.

2. Set or change the class path definitions in any existing JDBC providers, which are defined to use Cloudscape. Cloudscape JAR files will not load when WebSphere Application Server is active.

   Use the WebSphere Application Server environment variable **`${CLOUDSCAPE_JDBC_DRIVER_PATH}\db2j.jar`** to point to the new version of Cloudscape.

   The **`CLOUDSCAPE_JDBC_DRIVER_PATH`** environment variable is defined in WebSphere Application Server with a value of `WAS_HOME/cloudscape/lib`.

3. If the application server is running Cloudscape as a persistent store for UDDI in previous versions, additional steps are necessary.

   The server SystemOut log might issue this message:

   ```
   The data source class name com.ibm.db2j.jdbc.db2jConnectionPoolDataSource could not be found.
   ```

   This is because the Cloudscape JAR file has moved to from its location in version 5.x to a new location in version 5.1x.

   To correct this situation, do the following:

   a. Upgrade the database to Cloudscape 5.1.60x.

   b. Rerun the install script, ***or*** edit the class path field in the data source.

DB2 tuning parameters

DB2 has many parameters that you can configure to optimize database performance. For complete DB2 tuning information, refer to the DB2 UDB Administration Guide: Performance.

DB2 logging

- **Description:** DB2 has corresponding log files for each database that provides services to administrators, including viewing database access and the number of connections. For systems with multiple hard disk drives, you can gain large performance improvements by setting the log files for each database on a different hard drive from the database files.
- **How to view or set:** At a DB2 command prompt, issue the command: **db2 update db cfg for [database_name] using newlogpath [fully_qualified_path]**.
- **Default value:** Logs reside on the same disk as the database.
- **Recommended value:** Use a separate high-speed drive, preferably performance enhanced through RAID.

For more information about using AIX with DB2 see ″Tuning operating systems″ in the information center.

DB2 configuration advisor

Located in the DB2 Control Center, this advisor calculates and displays recommended values for the DB2 buffer pool size, the database, and the database manager configuration parameters, with the option of applying these values. See more information about the advisor in the online help facility within the Control Center.

Use TCP/IP sockets for DB2 on Linux

- **Description:** On Linux platforms, whether the DB2 server resides on a local machine with WebSphere Application Server or on a remote machine, configure the DB2 application databases to use TCP/IP sockets for communications with the database.

- **How to view or set:** Locate the directions for configuring DB2 on Linux in the *Installing your application serving environment* PDF. This document specifies setting DB2COMM for TCP/IP and corresponding changes required in the `etc/service` file.
- **Default value:** Shared memory for local databases
- **Recommended value:** On Linux, change the specification for the DB2 application databases and any session databases from shared memory to TCP/IP sockets.

Number of connections to DB2 - MaxAppls and MaxAgents

When configuring the data source settings for the databases, confirm the DB2 MaxAppls setting is greater than the maximum number of connections for the data source. If you are planning to establish clones, set the MaxAppls value as the maximum number of connections multiplied by the number of clones. The same relationship applies to the session manager number of connections. The MaxAppls setting must be equal to or greater than the number of connections. If you are using the same database for session and data sources, set the MaxAppls value as the sum of the number of connection settings for the session manager and the data sources.

For example, MaxAppls = (# of connections set for data source + # of connections in session manager) x # of clones.

After calculating the MaxAppls settings for the WebSphere database and each of the application databases, verify that the MaxAgents setting for DB2 is equal to or greater than the sum of all of the MaxAppls values, for example, MaxAgents = sum of MaxAppls for all databases.

DB2 buffpage

- **Description:** Improves database system performance. Buffpage is a database configuration parameter. A buffer pool is a memory storage area where database pages containing table rows or index entries are temporarily read and changed. Data is accessed much faster from memory than from disk.
- **How to view or set:** To view the current value of buffpage for database *x*, issue the DB2 command **get db cfg for x** and look for the value **BUFFPAGE**. To set **BUFFPAGE** to a value of *n*, issue the DB2 command **update db cfg for x** using **BUFFPAGE *n*** and set **NPAGES** to -1 as follows:

```
db2   <-- go to DB2 command mode, otherwise the following "select" does not work as is
    connect to x    <-- (where x is the particular DB2 database name)
    select * from syscat.bufferpools
       (and note the name of the default, perhaps: IBMDEFAULTBP)
       (if NPAGES is already -1, there is no need to issue following command)
    alter bufferpool IBMDEFAULTBP size -1
    (re-issue the above "select" and NPAGES now equals -1)
```

  You can collect a snapshot of the database while the application is running and calculate the buffer pool hit ratio as follows:

  1. Collect the snapshot:
     a. Issue the **update monitor switches using bufferpool on** command.
     b. Make sure that bufferpool monitoring is on by issuing the **get monitor switches** command.
     c. Clear the monitor counters with the **reset monitor all** command.
  2. Run the application.
  3. Issue the **get snapshot for all databases** command before all applications disconnect from the database, otherwise statistics are lost.
  4. Issue the **update monitor switches using bufferpool off** command.
  5. Calculate the hit ratio by looking at the following database snapshot statistics:
     – Buffer pool data logical reads
     – Buffer pool data physical reads
     – Buffer pool index logical reads
     – Buffer pool index physical reads
- **Default value:** 250
- **Recommended value:** Continue increasing the value until the snapshot shows a satisfactory hit rate.

The buffer pool hit ratio indicates the percentage of time that the database manager did not need to load a page from disk to service a page request. That is, the page was already in the buffer pool. The greater the buffer pool hit ratio, the lower the frequency of disk input and output. Calculate the buffer pool hit ratio as follows:

- P = buffer pool data physical reads + buffer pool index physical reads
- L = buffer pool data logical reads + buffer pool index logical reads
- Hit ratio = (1-(P/L)) * 100%

DB2 query optimization level

- **Description:** Sets the amount of work and resources that DB2 puts into optimizing the access plan. When a database query is executed in DB2, various methods are used to calculate the most efficient access plan. The range is from zero to 9. An optimization level of 9 causes DB2 to devote a lot of time and all of its available statistics to optimizing the access plan.
- **How to view or set:** The optimization level is set on individual databases and can be set with either the command line or with the DB2 Control Center. Static SQL statements use the optimization level specified on the **prep** and **bind** commands. If the optimization level is not specified, DB2 uses the default optimization as specified by the dft_queryopt setting. Dynamic SQL statements use the optimization class specified by the current query optimization special register, which is set using the SQL Set statement. For example, the following statement sets the optimization class to 1:

  ```
  Set current query optimization = 1
  ```

  If the current query optimization register is not set, dynamic statements are bound using the default query optimization class.
- **Default value:** 5
- **Recommended value:** Set the optimization level for the needs of the application. Use high levels only when there are very complicated queries.

DB2 reorgchk

- **Description:** Obtains the current statistics for data and rebinding. Use this parameter because SQL statement performance can deteriorate after many updates, deletes or inserts.
- **How to view or set:** Use the DB2 **reorgchk update statistics on table all** command to issue runstats on all user and system tables for the database to which you are currently connected. Rebind packages using the **bind** command. If runstats exists, issue the **db2 -v ″select tbname, nleaf, nlevels, stats_time from sysibm.sysindexes″** command on DB2 CLP. If no runstats exist, nleaf and nlevels are -1, and stats_time has an empty entry , for example ″-″. If runstats was previously done, the real-time stamp from completion of the runstats also displays under stats_time. If you think the time shown for the previous runstats is too old, execute runstats again.
- **Default value:** None
- **Recommended value:** None

DB2 MinCommit

- **Description:** Delays the writing of log records to a disk until a minimum number of commits is performed, reducing the database manager overhead associated with writing log records. For example, if MinCommit is set to 2, a second commit causes output to the transaction log for the first and second commits. The exception occurs when a one-second timeout forces the first commit to be output if a second commit does not occur within one second.

  In test applications, up to 90% of the disk input and output was related to the DB2 transaction log. Changing MinCommit from 1 to 2 reduced the results to 45%.

  Adjust this parameter if the disk input and output wait is more than 5% and there is DB2 transaction log activity from multiple sources. When a lot of activity occurs from multiple sources, it is less likely that a single commit has to wait for another commit, or the one second timeout. Do not adjust this parameter if you have an application with a single thread performing a series of commits because each commit can hit the one second delay.
- **How to view or set:**

1. Issue the DB2 **get db cfg for *xxxxxx***command, where *xxxxxx* is the name of the application database, to list database configuration parameters.
2. Look for ″Group commit count (MINCOMMIT)″.
3. Set a new value by issuing the DB2 **update db cfg for *xxxxxx* using mincommit *n*** command, where *xxxxxx* is the name of the application database and *n* is a value between 1 and 25 inclusive.

The new setting takes effect immediately.

The following are several metrics that are related to DB2 MinCommit:

– The disk input and output wait can be observed on AIX with the command **vmstat 5**. This shows statistics every 5 seconds. Look for the *wa* column under the CPU area.

– The percentage of time a disk is active can be observed on AIX with the command **iostat 5**. This shows statistics every 5 seconds. Look for the *%tm_act* column.

– The DB2 **get snapshot for db on *xxxxxx*** command , where *xxxxxx* is the name of the application database, shows counters for log pages read and log pages written.

- **Default value:** 1.
- **Recommended value:** 1 or 2, if the circumstance permits.

DB2 Deadlock Event Monitor

- **Description:**For DB2 V8 or later, deadlock event monitor is turned on by default when a database is created. This event monitor captures critical information about all connections involved in deadlock when the particular event occurs. Although there is not much overhead on faster SMP systems, it can be turned off.
- **How to view or set:** In DB2 command window, issue following commands:

```
db2 connect to [db name]
db2 set event monitor db2detaildeadlock state 0
db2 drop event monitor db2detaildeadlock
db2 connect reset
db2 terminate
```

.

- **Default value:** Event monitor is ON by default.
- **Recommended value:** Turn OFF event monitor, if it is not required.

For more information about using AIX with DB2 see ″Tuning operating systems.″.

Vendor-specific data sources minimum required settings

Use this table as an at-a-glance reference of JDBC providers that can be defined for use with WebSphere Application Server Version 6.x. A list that contains detailed descriptions for all of these providers follows the table.

Database type	JDBC Provider	Transaction support	Version and other considerations
DB2 on Windows, UNIX, or workstation-based LINUX	DB2 Universal JDBC Provider	One phase only	
	DB2 Universal JDBC Provider (XA)	One and two phase	
	DB2 legacy CLI-based Type 2 JDBC Provider	One phase only	
	DB2 legacy CLI-based Type 2 JDBC Provider (XA)	One and two phase	

Database type	**JDBC Provider**	**Transaction support**	**Version and other considerations**
DB2 UDB for iSeries	DB2 UDB for iSeries (Native)	One phase only	Recommended for use with WebSphere Application Server **run on iSeries**
	DB2 UDB for iSeries (Native XA)	One and two phase	Recommended for use with WebSphere Application Server **run on iSeries**
	DB2 UDB for iSeries (Toolbox)	One phase only	Recommended for use with WebSphere Application Server run on Windows, UNIX, or workstation-based LINUX
	DB2 UDB for iSeries (Toolbox XA)	One and two phase	Recommended for use with WebSphere Application Server run on Windows, UNIX, or workstation-based LINUX
	DB2 legacy CLI-based Type 2 JDBC Provider	One phase only	**-***Only* for use with WebSphere Application Server run on Windows, UNIX, or workstation-based LINUX **-** Requires the DB2 Connect driver (available from DB2)
	DB2 legacy CLI-based Type 2 JDBC Provider (XA)	One and two phase	**-***Only* for use with WebSphere Application Server run on Windows, UNIX, or workstation-based LINUX **-** Requires the DB2 Connect driver (available from DB2)

Database type	JDBC Provider	Transaction support	Version and other considerations
DB2 on z/OS	DB2 for z/OS Local JDBC Provider (RRS)	One and two phase	*Only* for use with WebSphere Application Server **run on z/OS**
	DB2 Universal JDBC Provider	One phase only	*Only* for use with WebSphere Application Server run on Windows, UNIX, or workstation-based LINUX
	DB2 Universal JDBC Provider (XA)	One and two phase	*Only* for use with WebSphere Application Server run on Windows, UNIX, or workstation-based LINUX
	DB2 legacy CLI-based Type 2 JDBC Provider	One phase only	**-***Only* for use with WebSphere Application Server run on Windows, UNIX, or workstation-based LINUX **-** Requires the DB2 Connect program (available from DB2)
	DB2 legacy CLI-based Type 2 JDBC Provider (XA)	One and two phase	**-***Only* for use with WebSphere Application Server run on Windows, UNIX, or workstation-based LINUX **-** Requires the DB2 Connect program (available from DB2)
Cloudscape	Cloudscape JDBC Provider	One phase only	**-** Not for use in clustering environment: Cloudscape is accessible from a single JVM only **-** Does not support Version 4 data sources
	Cloudscape JDBC Provider (XA)	One and two phase	**-** Not for use in clustering environment: Cloudscape is accessible from a single JVM only **-** Does not support Version 4 data sources
	Cloudscape Network Server using Universal JDBC driver	One phase only	Does not support Version 4 data sources
Informix	Informix JDBC Driver	One phase only	
	Informix JDBC Driver (XA)	One and two phase	
Sybase	Sybase JDBC Driver	One phase only	
	Sybase JDBC Driver (XA)	One and two phase	
Oracle	Oracle JDBC Driver	One phase only	
	Oracle JDBC Driver (XA)	One and two phase	

Database type	JDBC Provider	Transaction support	Version and other considerations
MS SQL Server	DataDirect ConnectJDBC type 4 driver for MS SQL Server	One phase only	Only for use with the corresponding driver from DataDirect Technologies
	DataDirect ConnectJDBC type 4 driver for MS SQL Server (XA)	One and two phase	Only for use with the corresponding driver from DataDirect Technologies
	WebSphere embedded ConnectJDBC driver for MS SQL Server	One phase only	- Not available for Application Server on z/OS - Cannot be used outside of WebSphere Application Server environment
	WebSphere embedded ConnectJDBC driver for MS SQL Server (XA)	One and two phase	- Not available for Application Server on z/OS - Cannot be used outside of WebSphere Application Server environment

Detailed JDBC provider list

The following list contains a description of every JDBC provider that can be defined for use with WebSphere Application Server Version 6.x. It also shows the supported data source classes and their required properties. Specific fields are designated for the *user* and *password* properties. Inclusion of a property in the list does not imply that you should add it to the data source properties list. Rather, inclusion in the list means that a value is typically required for that field.

Use these links to find your provider information:
- DB2 on Windows, UNIX, or workstation-based LINUX
- DB2 UDB for iSeries
- DB2 on z/OS, connecting to Application Server on Windows, UNIX, or workstation-based LINUX
- Cloudscape
- Informix
- Sybase
- Oracle
- MS SQL Server

DB2 on Windows, UNIX, or workstation-based LINUX

1. **DB2 Universal JDBC Provider**

   The DB2 Universal JDBC Driver is an architecture-neutral JDBC driver for distributed and local DB2 access. Because the Universal Driver architecture is independent of any particular JDBC driver connectivity or target platform, it allows both Java connectivity (Type 4) or Java Native Interface (JNI) based connectivity (Type 2) in a single driver instance to DB2.

   This JDBC driver allows applications to use both JDBC and Structured Query Language in Java (SQLJ) access.

   The DB2 Universal JDBC Driver Provider supports one phase data source:

   ```
   com.ibm.db2.jcc.DB2ConnectionPoolDataSource
   ```

   Requires JDBC driver files:
   - `db2jcc.jar` After you install DB2, you can find this jar file in the DB2 *java* directory. For Type 4 JDBC driver support from a client machine where DB2 is not installed, copy this file to the local machine. If you install any fixes or upgrades to DB2, you must update this file as well. You must

also set the ***DB2UNIVERSAL_JDBC_DRIVER_PATH*** path variable to point to the **db2jcc.jar** file. See the Cloudscape section for more information on the ***DB2UNIVERSAL_JDBC_DRIVER_PATH*** path variable.

Note: To find out the version of the universal driver you are using, issue this DB2 command:

```
java com.ibm.db2.jcc.DB2Jcc -version
```

The output for the above example is:

```
IBM DB2 JDBC Universal Driver Architecture 2.2.xx
```

- **db2jcc_license_cu.jar** This is the DB2 Universal JDBC driver license file that allows access to the DB2 Universal database. Use this jar file or the next one to gain access to the database. This jar file ships with WebSphere Application Server in a directory defined by **${UNIVERSAL_JDBC_DRIVER_PATH}**environment variable.
- **db2jcc_license_cisuz.jar** This is the DB2 Universal JDBC driver license file that allows access to the following databases:
  - DB2 Universal
  - DB2 for iSeries
  - DB2 for z/OS
  - SQLDS

  The **db2jcc_license_cisuz.jar** does not ship with Websphere Application Server and should be located in the same directory as the db2jcc.jar file, so that the ***DB2UNIVERSAL_JDBC_DRIVER_PATH*** points to both.

```
The classpath for this provider is set as follows:

   <classpath>${DB2UNIVERSAL_JDBC_DRIVER_PATH}/db2jcc.jar </classpath>
   <classpath>${UNIVERSAL_JDBC_DRIVER_PATH}/db2jcc_license_cu.jar</classpath>
   <classpath>${DB2UNIVERSAL_JDBC_DRIVER_PATH}/db2jcc_license_cisuz.jar</classpath>
```

Note: The license jar files are independent of each other; therefore, order does not matter.

Requires **DataStoreHelper** class:

```
com.ibm.websphere.rsadapter.DB2UniversalDataStoreHelper
```

Requires a valid authentication alias.

Requires properties:

- **databaseName** This is an actual database name if the **driverType** is set to **4**, or a locally cataloged database name if the **driverType** is set to **2**.
- **driverType** The JDBC connectivity type of a data source. *There are two permitted values: 2 and 4*. If you want to use Universal JDBC Type 2 driver, set this value to 2. If you want to use Universal JDBC Type 4 driver, set this value to 4.
- **serverName** The TCP/IP address or host name for the Distributed Relational Database Architecture (DRDA) server. Provide a value for this property only if your **driverType** is set to **4**. This property is not required if your **driverType** is set to **2**.
- **portNumber** The TCP/IP port number where the DRDA server resides. Provide a value for this property only if your **driverType** is set to **4**. This property is not required if your **driverType** is set to **2**.

2. **DB2 Universal JDBC Provider (XA)**

   The DB2 Universal JDBC Provider (XA) is an architecture-neutral JDBC provider for distributed and local DB2 access. Whether you use this provider for Java connectivity or Java Native Interface (JNI) based connectivity depends on the version of DB2 you are running. Application Server Version 6.0 minimally requires DB2 8.1 Fix Pack 6. This version of DB2 only supports XA connectivity over the Java Native Interface (JNI) based connectivity (Type 2) driver. In order to use XA connectivity with the Type 4 driver, DB2 8.1 Fix Pack 7 or higher is required.

   The DB2 Universal JDBC Driver (XA) supports two phase transactions and the more advanced data source option offered by Application Server (as opposed to the other option, Version 4 data sources). This driver also allows applications to use both JDBC and SQLJ access.

The DB2 Universal JDBC Driver Provider supports the two phase data source:

`com.ibm.db2.jcc.DB2XADataSource`

Requires JDBC driver files:

- **`db2jcc.jar`** After you install DB2, you can find this `.jar` file in the DB2 java directory. For Type 4 JDBC driver support from a client machine where DB2 is not installed, copy this file to the local machine. If you install any fixes or upgrades to DB2, you must update this file as well. You must also set the ***DB2UNIVERSAL_JDBC_DRIVER_PATH*** environment variable to point to the `db2jcc.jar` file. See the Cloudscape section for more information on the ***DB2UNIVERSAL_JDBC_DRIVER_PATH*** environment variable.

  Note: To find the level of universal driver you are using, issue the following DB2 command:

  ```
  java com.ibm.db2.jcc.DB2Jcc -version
  ```

  example output of the above:

  ```
  IBM DB2 JDBC Universal Driver Architecture 2.2.xx
  ```
- **`db2jcc_license_cu.jar`** This is the DB2 Universal JDBC driver license file that allows access to the DB2 Universal database. Use this jar file or the next one to gain access to the database. This jar file ships with WebSphere Application Server in the *WAS_HOME/universalDriver/lib* directory.
- **`db2jcc_license_cisuz.jar`** This is the DB2 Universal JDBC driver license file that allows access to the following databases:
  - DB2 Universal
  - DB2 for iSeries
  - DB2 for z/OS
  - SQLDS

  You must use the right license jar file to access a specific database backend.

Requires **`DataStoreHelper`** class:

`com.ibm.websphere.rsadapter.DB2UniversalDataStoreHelper`

Requires a valid authentication alias.

Requires properties:

- **databaseName** This is an actual database name if the **driverType** is set to **4**, or a locally cataloged database name if the **driverType** is set to **2**.
- **driverType** The JDBC connectivity type of a data source. *There are two permitted values: 2 and 4*. If you want to use Universal JDBC Type 2 XA driver, set this value to 2. If you want to use Universal JDBC Type 4 XA driver (which requires DB2 8.1 Fix Pack 7 or higher), set this value to 4.
- **serverName** The TCP/IP address or host name for the Distributed Relational Database Architecture (DRDA) server. Provide a value for this property only if your **driverType** is set to **4**. This property is not required if your **driverType** is set to **2**.
- **portNumber** The TCP/IP port number where the DRDA server resides. Provide a value for this property only if your **driverType** is set to **4**. This property is not required if your **driverType** is set to **2**.

3. **DB2 legacy CLI-based Type 2 JDBC Driver**

   The DB2 legacy CLI-based Type 2 JDBC Driver Provider is built on top of DB2 CLI (Call Level Interface). It uses the DB2 CLI interface to communicate with DB2 UDB servers.

   DB2 legacy CLI-based Type 2 JDBC Driver supports one phase data source:

   `COM.ibm.db2.jdbc.DB2ConnectionPoolDataSource`

   Requires JDBC driver files: **`db2java.zip`** (Note: If you run SQLJ in DB2 Version 8, **`db2jcc.jar`** is also required.)

   Requires **`DataStoreHelper`** class:

   `com.ibm.websphere.rsadapter.DB2DataStoreHelper`

   Does not require a valid authentication alias if Application Server is running on the same machine as the database. Otherwise, connectivity through this driver does require an alias.

   Requires properties:

- **databaseName** The name of the database from which the data source obtains connections. Example: *Sample*.

4. **DB2 legacy CLI-based Type 2 JDBC Driver (XA)**

   The DB2 legacy CLI-based Type 2 JDBC Driver (XA) is built on top of DB2 CLI (Call Level Interface). It uses the DB2 CLI interface to communicate with DB2 UDB servers.

   DB2 legacy CLI-based Type 2 JDBC Driver (XA) supports two phase data source:

   `COM.ibm.db2.jdbc.DB2XADataSource`

   Requires JDBC driver files: **`db2java.zip`** (Note: If you run SQLJ in DB2 Version 8, **`db2jcc.jar`** is also required.)

   Requires **`DataStoreHelper`** class:

   `com.ibm.websphere.rsadapter.DB2DataStoreHelper`

   Does not require a valid authentication alias if Application Server is running on the same machine as the database. Otherwise, connectivity through this driver does require an alias.

   Requires properties:

   - **databaseName** The name of the database from which the data source obtains connections. Example: *Sample*.

For more information on DB2, visit the DB2 Web site at: http://www.ibm.com/software/data/db2/.

For information on configuring WebSphere Application Server for DB2 access, see the ″Configuring DB2″ article in the information center.

DB2 UDB for iSeries

1. **DB2 UDB for iSeries (Native)**

   The iSeries Developer Kit for Java contains this Type 2 JDBC driver that is built on top of the iSeries DB2 Call Level Interface (CLI) native libraries. Only use this driver for local DB2 connections on iSeries. It is not recommended for remote access. Use this driver for iSeries V5R2, or later releases.

   DB2 UDB for iSeries (Native V5R2 and later) supports one phase data source:

   `com.ibm.db2.jdbc.app.UDBConnectionPoolDataSource`

   Requires JDBC driver files: **`db2_classes.jar`**

   Requires **`DataStoreHelper`** class:

   `com.ibm.websphere.rsadapter.DB2AS400DataStoreHelper`

   Does not require an authentication alias.

   Requires properties:

   - **databaseName** The name of the relational database to which the data source connections are established. This name must appear in the iSeries Relational Database Directory. The default is *LOCAL.

2. **DB2 UDB for iSeries (Native XA)**

   The iSeries Developer Kit for Java contains this XA-compliant Type 2 JDBC driver built on top of the iSeries DB2 Call Level Interface (CLI) native libraries. Only use this driver for local DB2 connections on iSeries. It is not recommended for remote access. Use this driver for iSeries V5R2 or later releases.

   DB2 UDB for iSeries (Native XA - V5R2 and later) supports two phase data source:

   `com.ibm.db2.jdbc.app.UDBXADataSource`

   Requires JDBC driver files: **`db2_classes.jar`**

   Requires **`DataStoreHelper`** class:

   `com.ibm.websphere.rsadapter.DB2AS400DataStoreHelper`

   Does not require an authentication alias.

   Requires properties:

- **databaseName** The name of the relational database to which the data source connections are established. This name must appear in the iSeries Relational Database Directory. The default is *LOCAL.

3. **DB2 UDB for iSeries (Toolbox)**

   This JDBC driver, also known as iSeries Toolbox driver for Java, is provided in the DB2 for iSeries database server. Use this driver for remote DB2 connections on iSeries. We recommend you use this driver instead of the IBM Developer Kit for Java JDBC Driver to access remote DB2 UDB for iSeries systems.

   DB2 UDB for iSeries (Toolbox) supports one phase data source:

   `com.ibm.as400.access.AS400JDBCConnectionPoolDataSource`

   Requires JDBC driver files: **`jt400.jar`**

   Requires **`DataStoreHelper`** class:

   `com.ibm.websphere.rsadapter.DB2AS400DataStoreHelper`

   Does not require an authentication alias if WebSphere Application Server and DB2 UDB for iSeries are installed in the same server. If they are installed in different servers, the user ID and password are required.

   Requires properties:
   - **serverName** The name of the server from which the data source obtains connections. Example: *myserver.mydomain.com*.

4. **DB2 UDB for iSeries (Toolbox XA)**

   This XA compliant JDBC driver, also known as iSeries Toolbox XA compliant driver for Java, is provided in the DB2 for iSeries database server. Use this driver for remote DB2 connections on iSeries. We recommend you use this driver instead of the IBM Developer Kit for Java JDBC Driver to access remote DB2 UDB for iSeries systems.

   DB2 UDB for iSeries (Toolbox XA) supports two phase data source:

   `com.ibm.as400.access.AS400JDBCXADataSource`

   Requires JDBC driver files: **`jt400.jar`**

   Requires **`DataStoreHelper`** class:

   `com.ibm.websphere.rsadapter.DB2AS400DataStoreHelper`

   Does not require an authentication alias if WebSphere Application Server and DB2 UDB for iSeries are installed in the same server. If they are installed in different servers, the user ID and password are required.

   Requires properties:
   - **serverName** The name of the server from which the data source obtains connections. Example: *myserver.mydomain.com*.

5. **DB2 legacy CLI-based Type 2 JDBC Driver**

   The DB2 legacy CLI-based Type 2 JDBC Driver Provider is built on top of DB2 CLI (Call Level Interface). It uses the DB2 CLI interface to communicate with DB2 UDB servers. This provider is intended for *remote* connections to DB2 running on iSeries; for use with Application Server on Windows, UNIX, or workstation-based LINUX, it therefore requires the DB2 Connect Driver (which is available from DB2).

   DB2 legacy CLI-based Type 2 JDBC Driver supports one phase data source:

   `COM.ibm.db2.jdbc.DB2ConnectionPoolDataSource`

   Requires JDBC driver files: **`db2java.zip`** (Note: If you run SQLJ in DB2 Version 8, **`db2jcc.jar`** is also required.)

   Requires **`DataStoreHelper`** class:

   `com.ibm.websphere.rsadapter.DB2DataStoreHelper`

   Does not require a valid authentication alias.

   Requires properties:

- **databaseName** The name of the database from which the data source obtains connections. Example: *Sample*.

6. **DB2 legacy CLI-based Type 2 JDBC Driver (XA)**

   The DB2 legacy CLI-based Type 2 JDBC Driver (XA) is built on top of DB2 CLI (Call Level Interface). It uses the DB2 CLI interface to communicate with DB2 UDB servers. This provider is intended for *remote* connections to DB2 running on iSeries; for use with Application Server on Windows, UNIX, or workstation-based LINUX, it therefore requires the DB2 Connect Driver (which is available from DB2).

   DB2 legacy CLI-based Type 2 JDBC Driver (XA) supports two phase data source:

   `COM.ibm.db2.jdbc.DB2XADataSource`

   Requires JDBC driver files: **`db2java.zip`** (Note: If you run SQLJ in DB2 Version 8, **`db2jcc.jar`** is also required.)

   Requires **`DataStoreHelper`** class:

   `com.ibm.websphere.rsadapter.DB2DataStoreHelper`

   Does not require a valid authentication alias.

   Requires properties:

   - **databaseName** The name of the database from which the data source obtains connections. Example: *Sample*.

7. **DB2 UDB for iSeries (Native - Version 5 Release 1 and earlier)** -- Deprecated

   This JDBC provider is deprecated because it corresponds to a version of the iSeries operating system that WebSphere Application Server Version 6.x does not support. You must now use iSeries V5R2 or a later release of the iSeries operating system, for which the WebSphere Application Server administrative console lists one native iSeries DB2 non-XA provider: DB2 UDB for iSeries (Native).

   The iSeries Developer Kit for Java contains this Type 2 JDBC driver that is built on top of the iSeries DB2 Call Level Interface (CLI) native libraries. Only use this driver for local DB2 connections on iSeries. It is not recommended for remote access. Use this driver for iSeries V5R1, or earlier releases.

   DB2 UDB for iSeries (Native V5R1 and earlier) supports one phase data source:

   `com.ibm.db2.jdbc.app.DB2StdConnectionPoolDataSource`

   Requires JDBC driver files: **`db2_classes.jar`**

   Requires **`DataStoreHelper`** class:

   `com.ibm.websphere.rsadapter.DB2AS400DataStoreHelper`

   Does not require an authentication alias.

   Requires properties:

   - **databaseName** The name of the relational database to which the data source connections are established. This name must appear in the iSeries Relational Database Directory. The default is *LOCAL.

8. **DB2 UDB for iSeries (Native XA - Version 5 Release 1 and earlier)** -- Deprecated

   This JDBC provider is deprecated because it corresponds to a version of the iSeries operating system that WebSphere Application Server Version 6.x does not support. You must now use iSeries V5R2 or a later release of the iSeries operating system, for which the administrative console lists one native iSeries DB2 XA provider: DB2 UDB for iSeries (Native XA).

   The iSeries Developer Kit for Java contains this XA-compliant Type 2 JDBC driver built on top of the iSeries DB2 Call Level Interface (CLI) native libraries. Only use this driver for local DB2 connections on iSeries. It is not recommended for remote access. Use this driver for iSeries V5R1, or earlier releases.

   DB2 UDB for iSeries (Native XA - V5R1 and earlier) supports two phase data source:

   `com.ibm.db2.jdbc.app.DB2StdXADataSource`

   Requires JDBC driver files: **`db2_classes.jar`**

   Requires **`DataStoreHelper`** class:

   `com.ibm.websphere.rsadapter.DB2AS400DataStoreHelper`

   Does not require an authentication alias.

   Requires properties:

- **databaseName** The name of the relational database to which the data source connections are established. This name must appear in the iSeries Relational Database Directory. The default is *LOCAL.

For more information on DB2 UDB for iSeries, visit the DB2 Web site at: http://www.ibm.com/software/data/db2/

DB2 on z/OS, connecting to Application Server on Windows, UNIX, or workstation-based LINUX

1. **DB2 Universal JDBC Provider**

   The DB2 Universal JDBC Driver is an architecture-neutral JDBC driver for distributed and local DB2 access. Because the Universal Driver architecture is independent of any particular JDBC driver connectivity or target platform, it allows both Java connectivity (Type 4) or Java Native Interface (JNI) based connectivity (Type 2) in a single driver instance to DB2. Starting with WebSphere Application Server Version 5.0.2, the product now supports both Type 2 and Type 4 JDBC drivers. To use the Type 4 driver, you must install DB2 Version 8.1 or a later version. To use the Type 2 driver, you must install DB2 Version 8.1 Fix Pack 2 or a later version.

   This JDBC driver allows applications to use both JDBC and Structured Query Language in Java (SQLJ) access.

   The DB2 Universal JDBC Driver Provider supports one phase data source:

   `com.ibm.db2.jcc.DB2ConnectionPoolDataSource`

   Requires JDBC driver files:

   - **`db2jcc.jar`** After you install DB2, you can find this jar file in the DB2 *java* directory. For Type 4 JDBC driver support from a client machine where DB2 is not installed, copy this file to the local machine. If you install any fixes or upgrades to DB2, you must update this file as well. You must also set the ***DB2UNIVERSAL_JDBC_DRIVER_PATH*** path variable to point to the **`db2jcc.jar`** file. See the Cloudscape section for more information on the ***DB2UNIVERSAL_JDBC_DRIVER_PATH*** path variable.

     Note: To find out the version of the universal driver you are using, issue this DB2 command:

     ```
     java com.ibm.db2.jcc.DB2Jcc -version
     ```

     The output for the above example is:

     ```
     IBM DB2 JDBC Universal Driver Architecture 2.2.xx
     ```
   - **`db2jcc_license_cu.jar`** This is the DB2 Universal JDBC driver license file that allows access to the DB2 Universal database. Use this jar file or the next one to gain access to the database. This jar file ships with WebSphere Application Server in a directory defined by **${UNIVERSAL_JDBC_DRIVER_PATH}**environment variable.
   - **`db2jcc_license_cisuz.jar`** This is the DB2 Universal JDBC driver license file that allows access to the following databases:
     - DB2 Universal
     - DB2 for iSeries
     - DB2 for z/OS
     - SQLDS

     The **db2jcc_license_cisuz.jar** does not ship with Websphere Application Server and should be located in the same directory as the db2jcc.jar file, so that the ***DB2UNIVERSAL_JDBC_DRIVER_PATH*** points to both.

   ```
   The classpath for this provider is set as follows:

      <classpath>${DB2UNIVERSAL_JDBC_DRIVER_PATH}/db2jcc.jar </classpath>
      <classpath>${DB2UNIVERSAL_JDBC_DRIVER_PATH}/db2jcc_license_cu.jar</classpath>
      <classpath>${DB2UNIVERSAL_JDBC_DRIVER_PATH}/db2jcc_license_cisuz.jar</classpath>
   ```

   Note: The license jar files are independent of each other; therefore, order does not matter.

   Requires **`DataStoreHelper`** class:

`com.ibm.websphere.rsadapter.DB2UniversalDataStoreHelper`

Requires a valid authentication alias.

Requires properties:

- **databaseName** This is an actual database name if the **driverType** is set to **4**, or a locally cataloged database name if the **driverType** is set to **2**.
- **driverType** The JDBC connectivity type of a data source. *There are two permitted values: 2 and 4*. If you want to use Universal JDBC Type 2 driver, set this value to 2. If you want to use Universal JDBC Type 4 driver, set this value to 4.
- **serverName** The TCP/IP address or host name for the Distributed Relational Database Architecture (DRDA) server. Provide a value for this property only if your **driverType** is set to **4**. This property is not required if your **driverType** is set to **2**.
- **portNumber** The TCP/IP port number where the DRDA server resides. Provide a value for this property only if your **driverType** is set to **4**. This property is not required if your **driverType** is set to **2**.

2. **DB2 Universal JDBC Provider (XA)**

   The DB2 Universal JDBC Driver (XA) is an architecture-neutral JDBC driver for distributed and local DB2 access. In WebSphere Application Server Version 5.0.2, this driver only supports Java Native Interface (JNI) based connectivity (Type 2) in a single driver instance to DB2. To use this driver, you must install DB2 Version 8.1 Fix Pack 2 or a later version. This driver supports two phase transactions and the WebSphere Application Server Version 5.0 data source. This driver allows applications to use both JDBC and SQLJ access.

   The DB2 Universal JDBC Driver Provider supports the two phase data source:

   `com.ibm.db2.jcc.DB2XADataSource`

   Requires JDBC driver files:

   - **`db2jcc.jar`** After you install DB2, you can find this `.jar` file in the DB2 java directory. For Type 4 JDBC driver support from a client machine where DB2 is not installed, copy this file to the local machine. If you install any fixes or upgrades to DB2, you must update this file as well. You must also set the ***DB2UNIVERSAL_JDBC_DRIVER_PATH*** environment variable to point to the `db2jcc.jar` file. See the Cloudscape section for more information on the ***DB2UNIVERSAL_JDBC_DRIVER_PATH*** environment variable.

     Note: To find the level of universal driver you are using, issue the following DB2 command:

     ```
     java com.ibm.db2.jcc.DB2Jcc -version
     ```

     example output of the above:

     ```
     IBM DB2 JDBC Universal Driver Architecture 2.2.xx
     ```
   - **`db2jcc_license_cu.jar`** This is the DB2 Universal JDBC driver license file that allows access to the DB2 Universal database. Use this jar file or the next one to gain access to the database. This jar file ships with WebSphere Application Server in the *WAS_HOME/universalDriver/lib* directory.
   - **`db2jcc_license_cisuz.jar`** This is the DB2 Universal JDBC driver license file that allows access to the following databases:
     - DB2 Universal
     - DB2 for iSeries
     - DB2 for z/OS
     - SQLDS

     You must use the right license jar file to access a specific database backend.

   Requires **`DataStoreHelper`** class:

   `com.ibm.websphere.rsadapter.DB2UniversalDataStoreHelper`

   Requires a valid authentication alias.

   Requires properties:

   - **databaseName** This is a locally cataloged database name.
   - **driverType** This is the JDBC connectivity type of a data source. *If you are running a version of DB2 prior to DB2 V8.1 FP6, you are restricted to using only the type 2 driver.*

- **serverName** The TCP/IP address or host name for the Distributed Relational Database Architecture (DRDA) server. Provide a value for this property only if your **driverType** is set to **4**. This property is not required if your **driverType** is set to **2**.
- **portNumber** The TCP/IP port number where the DRDA server resides. Provide a value for this property only if your **driverType** is set to **4**. This property is not required if your **driverType** is set to **2**.

3. **DB2 legacy CLI-based Type 2 JDBC Driver**

   The DB2 legacy CLI-based Type 2 JDBC Driver Provider is built on top of DB2 CLI (Call Level Interface). It uses the DB2 CLI interface to communicate with DB2 UDB servers. For use with Application Server on Windows, UNIX, or workstation-based LINUX, this provider requires DB2 Connect (which is available from DB2).

   DB2 legacy CLI-based Type 2 JDBC Driver supports one phase data source:

   `COM.ibm.db2.jdbc.DB2ConnectionPoolDataSource`

   Requires JDBC driver files: **`db2java.zip`** (Note: If you run SQLJ in DB2 Version 8, **`db2jcc.jar`** is also required.)

   Requires **`DataStoreHelper`** class:

   `com.ibm.websphere.rsadapter.DB2DataStoreHelper`

   Does not require a valid authentication alias.

   Requires properties:

   - **databaseName** The name of the database from which the data source obtains connections. Example: *Sample*.

4. **DB2 legacy CLI-based Type 2 JDBC Driver (XA)**

   The DB2 legacy CLI-based Type 2 JDBC Driver (XA) is built on top of DB2 CLI (Call Level Interface). It uses the DB2 CLI interface to communicate with DB2 UDB servers. For use with Application Server on Windows, UNIX, or workstation-based LINUX, this provider requires DB2 Connect (which is available from DB2).

   DB2 legacy CLI-based Type 2 JDBC Driver (XA) supports two phase data source:

   `COM.ibm.db2.jdbc.DB2XADataSource`

   Requires JDBC driver files: **`db2java.zip`** (Note: If you run SQLJ in DB2 Version 8, **`db2jcc.jar`** is also required.)

   Requires **`DataStoreHelper`** class:

   `com.ibm.websphere.rsadapter.DB2DataStoreHelper`

   Does not require a valid authentication alias.

   Requires properties:

   - **databaseName** The name of the database from which the data source obtains connections. Example: *Sample*.

For more information on DB2 for z/OS, visit the DB2 Web site at: http://www.ibm.com/software/data/db2/.

Cloudscape

1. **Cloudscape JDBC Provider**

   The Cloudscape JDBC Provider provides the JDBC access to the Cloudscape database. This Cloudscape JDBC driver used the embedded framework. You cannot use any Version 4.0 data sources with Cloudscape.

   Cloudscape JDBC Provider supports one phase data source:

   `com.ibm.db2j.jdbc.DB2jConnectionPoolDataSource`

   Requires JDBC driver files: **`db2j.jar.`**

   Requires **`DataStoreHelper`** class:

   `com.ibm.websphere.rsadapter.CloudscapeDataStoreHelper`

   Does not require a valid authentication alias.

Requires properties:

- **databaseName** The name of the database from which the data source obtains connections. If you do not specify a fully qualified path name, Application Server uses the default location of `WAS_HOME./cloudscape` (or the equivalent default for a UNIX or LINUX environment).
  - Example database path name for Windows: `c:\`*`temp`*`\`*`sampleDB`*
  - Example database path name for UNIX or LINUX: `/`*`tmp`*`/`*`sampleDB`*

  If no database currently exists for the path name you want to specify, simply append `;create=true` to the path name to create a database dynamically. (For example: `c:\`*`temp`*`\`*`sampleDB`*`;create=true`)

2. **Cloudscape JDBC Provider (XA)**

   The Cloudscape JDBC Provider (XA) provides the XA-compliant JDBC access to the Cloudscape database. This Cloudscape JDBC driver uses the embedded framework. You cannot use any Version 4.0 data sources with Cloudscape.

   Cloudscape JDBC Provider (XA) supports two phase data source:

   `com.ibm.db2j.jdbc.DB2jXADataSource`

   Requires JDBC driver files: **`db2j.jar`**

   Requires **`DataStoreHelper`** class:

   `com.ibm.websphere.rsadapter.CloudscapeDataStoreHelper`

   Does not require a valid authentication alias.

   Requires properties:

   - **databaseName** The name of the database from which the data source obtains connections. If you do not specify a fully qualified path name, Application Server uses the default location of `WAS_HOME./cloudscape` (or the equivalent default for a UNIX or LINUX environment).
     - Example database path name for Windows: `c:\`*`temp`*`\`*`sampleDB`*
     - Example database path name for UNIX or LINUX: `/`*`tmp`*`/`*`sampleDB`*

     If no database currently exists for the path name you want to specify, simply append `;create=true` to the path name to create a database dynamically. (For example: `c:\`*`temp`*`\`*`sampleDB`*`;create=true`)

3. **Cloudscape Network Server using Universal JDBC driver**

   This Cloudscape driver takes advantage of the Network Server support that the DB2 universal Type 4 JDBC driver provides. You cannot use any Version 4.0 data sources with Cloudscape.

   Cloudscape uses the DB2 Universal Driver when using the Network Server. It supports one phase data source:

   `com.ibm.db2.jcc.DB2ConnectionPoolDataSource`

   Requires JDBC driver files:

   - **`db2jcc.jar`** If you install and run DB2, you must use the **`db2jcc.jar`** file that comes with DB2. To do that, the classpath in the JDBC template for Cloudscape network server is set to be:

     ```
     <classpath>${DB2UNIVERSAL_JDBC_DRIVER_PATH}/db2jcc.jar</classpath>

     <classpath>${CLOUDSCAPE_JDBC_DRIVER_PATH}/db2j.jar</classpath>

     <classpath>${CLOUDSCAPE51_JDBC_DRIVER_PATH}/db2j.jar</classpath>

     <classpath>${UNIVERSAL_JDBC_DRIVER_PATH}/db2jcc.jar</classpath>
     ```

     which means that the db2jcc.jar from DB2 always takes precedence. Note that this also means that you must set the DB2 environment variable **DB2UNIVERSAL_JDBC_DRIVER_PATH** in WebSphere when you set up your DB2 datasource. This is instead of hard coding the path of the db2jcc.jar for DB2 datasources.
   - **`db2jcc_license_cu.jar`** This file is the DB2 Universal JDBC license file that provides access to the Cloudscape databases using the **Network Server** framework. Use this file to gain access to the database. This file ships with WebSphere and is located in **${UNIVERSAL_JDBC_DRIVER_PATH}**.

     Note: **UNIVERSAL_JDBC_DRIVER_PATH**is a WebSphere environment variable that is already defined to the location in Websphere Application Server where the license jar file above is located, and will only be used if the **DB2UNIVERSAL_JDBC_DRIVER_PATH** is not set. DB2 users should ensure that **DB2UNIVERSAL_JDBC_DRIVER_PATH** is set to avoid loading multiple vesions of the db2jcc.jar file.

Note: **DB2UNIVERSAL_JDBC_DRIVER_PATH** is a WebSphere environment variable that you must set to point to the location of db2jcc.jar file (that comes with DB2). This variable is set only if you create a db2 provider. See the DB2 section for more information on the **DB2UNIVERSAL_JDBC_DRIVER_PATH** path variable.

Note: Cloudscape requires only db2jcc_license_c.jar; however, WebSphere Application Server uses db2jcc_license_cu.jar because this works for both DB2 UDB and Cloudscape.

Requires **DataStoreHelper** class:

```
com.ibm.websphere.rsadapter.CloudscapeNetworkServerDataStoreHelper
```

Note: The administrative console incorrectly lists the DB2UniversalDataStoreHelper as the default value for the **DataStoreHelper** class. You must change the default value to `com.ibm.websphere.rsadapter.CloudscapeNetworkServerDataStoreHelper`. Also change the custom properties, using the instructions in the customer property section.

Requires a valid authentication alias.

Requires properties:

- **databaseName** The name of the database from which the data source obtains connections. If you do not specify a fully qualified path name, Application Server uses the default location of `WAS_HOME./cloudscape` (or the equivalent default for a UNIX or LINUX environment).
  - Example database path name for Windows: `c:\`*`temp`*`\`*`sampleDB`*
  - Example database path name for UNIX or LINUX: `/`*`tmp`*`/`*`sampleDB`*

  If no database currently exists for the path name you want to specify, simply append `;create=true` to the path name to create a database dynamically. (For example: `c:\`*`temp`*`\`*`sampleDB`*`;create=true`)
- **driverType** Only the Type 4 driver is allowed.
- **serverName** The TCP/IP address or the host name for the Distributed Relational Database Architecture (DRDA) server.
- **portNumber** The TCP/IP port number where the DRDA server resides. The default value is port ***1527***.
- **retrieveMessagesfromServerOnGetMessage** This property is required by WebSphere Application Server, not the database. The default value is ***false***. You must set the value of this property to ***true***, to enable text retrieval using the **SQLException.getMessage()** method.

See the Cloudscape setup instructions for more information on configuring the Cloudscape Network Server.

For more information on IBM Cloudscape, visit the Cloudscape Web site at: http://www.ibm.com/software/data/cloudscape/

Informix

1. **Informix JDBC Driver**

   The Informix JDBC Driver is a Type 4 JDBC driver that provides JDBC access to the Informix database.

   Informix JDBC Driver supports one phase data source:

   ```
   com.informix.jdbcx.IfxConnectionPoolDataSource
   ```

   Requires JDBC driver files:

   ```
   ifxjdbc.jar
   ifxjdbcx.jar
   ```

   Requires **DataStoreHelper** class:

   ```
   com.ibm.websphere.rsadapter.InformixDataStoreHelper
   ```

   Requires a valid authentication alias.

Requires properties:

- **serverName** The name of the Informix instance on the server. Example: *ol_myserver*.
- **portNumber** The port on which the instances listen. Example: *1526*.
- **ifxIFXHOST** Either the IP address or the host name of the machine that is running the Informix database to which you want to connect. Example: *myserver.mydomain.com*.
- **databaseName** The name of the database from which the data source obtains connections. Example: *Sample*.
- **informixLockModeWait** Although not required, this property enables you to set the number of seconds that Informix software waits for a lock. By default, Informix code throws an exception if it cannot immediately acquire a lock. Example: *2*.

2. **Informix JDBC Driver (XA)**

   The Informix JDBC Driver (XA) is a Type 4 JDBC driver that provides XA-compliant JDBC access to the Informix database.

   Informix JDBC Driver (XA) supports two phase data source:

   `com.informix.jdbcx.IfxXADataSource`

   Requires JDBC driver files:

   ```
   ifxjdbc.jar
   ifxjdbcx.jar
   ```

   Requires **`DataStoreHelper`** class:

   `com.ibm.websphere.rsadapter.InformixDataStoreHelper`

   Requires a valid authentication alias.

   Requires properties:

   - **serverName** The name of the Informix instance on the server. Example: *ol_myserver*.
   - **portNumber** The port on which the instances listen. Example: *1526*.
   - **ifxIFXHOST** Either the IP address or the host name of the machine that is running the Informix database to which you want to connect. Example: *myserver.mydomain.com*.
   - **databaseName** The name of the database from which the data source obtains connections. Example: *Sample*.
   - **informixLockModeWait** Although not required, this property enables you to set the number of seconds that Informix software waits for a lock. By default, Informix code throws an exception if it cannot immediately acquire a lock. Example: *2*.

For more information on Informix, visit the Informix Web site at: http://www.ibm.com/software/data/informix/

Sybase

1. **Sybase JDBC Driver**

   The Sybase JDBC Driver is a Type 4 JDBC driver that provides JDBC access to the Sybase database.

   Sybase JDBC Driver supports one phase data source:

   `com.sybase.jdbc2.jdbc.SybConnectionPoolDataSource`

   Requires JDBC driver files: **`jconn2.jar`**.

   Requires **`DataStoreHelper`** class:

   `com.ibm.websphere.rsadapter.SybaseDataStoreHelper`

   Requires a valid authentication alias.

   Requires properties:

   - **serverName** The name of the database server. Example: *myserver.mydomain.com*.
   - **databaseName** The name of the database from which the data source obtains connections. Example: *Sample*.
   - **portNumber** The TCP/IP port number through which all communications to the server take place. Example: *4100*.
   - **connectionProperties** A custom property required for applications containing EJB 2.0 enterprise beans. Value: `SELECT_OPENS_CURSOR=true`(Type: java.lang.String)

2. **Sybase JDBC Driver (XA)**

The Sybase JDBC Driver (XA) is a Type 4 JDBC driver that provides XA-compliant JDBC access to the Sybase database.

Sybase JDBC Driver (XA) supports two phase data source:

`com.sybase.jdbc2.jdbc.SybXADataSource`

Requires JDBC driver files: **`jconn2.jar`**.

Requires **`DataStoreHelper`** class:

`com.ibm.websphere.rsadapter.SybaseDataStoreHelper`

Requires a valid authentication alias.

Requires properties:

- **serverName** The name of the database server. Example: *myserver.mydomain.com*
- **databaseName** The name of the database from which the data source obtains connections. Example: *Sample*.
- **portNumber** The TCP/IP port number through which all communications to the server take place. Example: *4100*.
- **connectionProperties** A custom property required for applications containing EJB 2.0 enterprise beans. Value: `SELECT_OPENS_CURSOR=true`(Type: java.lang.String)

For more information on Sybase, visit the Sybase Web site at: http://www.sybase.com/

Oracle

1. **Oracle JDBC Driver**

   The Oracle JDBC Driver provides JDBC access to the Oracle database. This JDBC driver supports both Type 2 JDBC access and Type 4 JDBC access.

   Oracle JDBC Driver supports one phase data source:

   `oracle.jdbc.pool.OracleConnectionPoolDataSource`

   Requires JDBC driver files: **`ojdbc14.jar`**. (Note: If you require Oracle trace, use **`ojdbc14_g.jar`**.)

   Requires **`DataStoreHelper`** class:

   `com.ibm.websphere.rsadapter.OracleDataStoreHelper`

   (Note: If you are running Oracle10g, use `com.ibm.websphere.rsadapter.Oracle10gDataStoreHelper`.

   Requires a valid authentication alias.

   Requires properties:

   - **URL** The URL that indicates the database from which the data source obtains connections. Example: *jdbc:oracle:thin:@myServer:1521:myDatabase*, where *myServer* is the server name, *1521* is the port it is using for communication, and *myDatabase* is the database name.
2. **Oracle JDBC Driver (XA)**

   The Oracle JDBC Driver (XA) provides XA-compliant JDBC access to the Oracle database. This JDBC driver supports both Type 2 JDBC access and Type 4 JDBC access.

   Oracle JDBC Driver (XA) supports two phase data source:

   `oracle.jdbc.xa.client.OracleXADataSource`

   Requires JDBC driver files: **`ojdbc14.jar`**. (Note: If you require Oracle trace, use **`ojdbc14_g.jar`**.)

   Requires **`DataStoreHelper`** class:

   `com.ibm.websphere.rsadapter.OracleDataStoreHelper`

   Requires a valid authentication alias.

   Requires properties:

   - **URL** The URL that indicates the database from which the data source obtains connections. Example: *jdbc:oracle:thin:@myServer:1521:myDatabase*, where *myServer* is the server name, *1521* is the port it is using for communication, and *myDatabase* is the database name.

For more information on Oracle, visit the Oracle Web site at: http://www.oracle.com/

MS SQL Server

1. **DataDirect ConnectJDBC type 4 driver for MS SQL Server**

   DataDirect ConnectJDBC type 4 driver for MS SQL Server is a Type 4 JDBC driver that provides JDBC access to the MS SQL Server database. This provider is for use only with the Connect JDBC driver purchased from DataDirect Technologies.

   This JDBC provider supports this data source:

   `com.ddtek.jdbcx.sqlserver.SQLServerDataSource`

   Requires JDBC driver files:

   `sqlserver.jar`,
   `base.jar` `and` **`util.jar`**

   (The **`spy.jar`** file is optional. You need this file to enable spy logging. The **`spy.jar`** file is not in the same directory as the other three jar files. Instead, it is located in the `../spy/` directory.)

   Requires **`DataStoreHelper`** class:

   `com.ibm.websphere.rsadapter.ConnectJDBCDataStoreHelper`

   Requires a valid authentication alias.

   Requires properties:
   - **serverName** The name of the server in which MS SQL Server resides. Example: *`myserver.mydomain.com`*
   - **portNumber** The TCP/IP port that MS SQL Server uses for communication. Port 1433 is the default.
   - **databaseName** The name of the database from which the data source obtains connections. Example: *Sample*.

2. **DataDirect ConnectJDBC type 4 driver for MS SQL Server (XA)**

   DataDirect ConnectJDBC type 4 driver for MS SQL Server (XA) is a Type 4 JDBC driver which provides XA-compliant JDBC access to the MS SQL Server database. This provider is for use only with the Connect JDBC driver purchased from DataDirect Technologies.

   This JDBC provider supports this data source:

   `com.ddtek.jdbcx.sqlserver.SQLServerDataSource.`

   Requires JDBC driver files:

   `sqlserver.jar`,
   `base.jar` `and` **`util.jar.`**

   (The **`spy.jar`** file is optional. You need this file to enable spy logging. The **`spy.jar`** file is not in the same directory as the other three jar files. Instead, it is located in the `../spy/ directory`.)

   Requires **`DataStoreHelper`** class:

   `com.ibm.websphere.rsadapter.ConnectJDBCDataStoreHelper`

   Requires a valid authentication alias.

   Requires properties:
   - **serverName** The name of the server in which MS SQL Server resides. Example: *`myserver.mydomain.com`*
   - **portNumber** The TCP/IP port that MS SQL Server uses for communication. Port 1433 is the default.
   - **databaseName** The name of the database from which the data source obtains connections. Example: *Sample*.

   For more information on the DataDirect ConnectJDBC driver, visit the DataDirect Web site at: http://www.datadirect-technologies.com/

3. **WebSphere embedded ConnectJDBC driver for MS SQL Server**

   WebSphere embedded ConnectJDBC driver for MS SQL Server is a Type 4 JDBC driver that provides JDBC access to the MS SQL Server database. This JDBC driver ships with WebSphere Application Server. Only use this provider with the Connect JDBC driver embedded in WebSphere; it cannot be used with a Connect JDBC driver purchased separately from DataDirect Technologies.

   This JDBC provider supports this data source:

   `com.ibm.websphere.jdbcx.sqlserver.SQLServerDataSource.`

   Requires JDBC driver files:

sqlserver.jar
base.jar and
util.jar.

(The **spy.jar** file is optional. You need this file to enable spy logging. The **spy.jar** file for the WebSphere embedded Connect JDBC driver ships with WebSphere Application Server. All the files are located in the WAS_HOME/lib/ directory.)

Requires **DataStoreHelper** class:

com.ibm.websphere.rsadapter.WSConnectJDBCDataStoreHelper

Requires a valid authentication alias.

Requires properties:

- **serverName** The name of the server in which MS SQL Server resides. Example: *myserver.mydomain.com*
- **portNumber** The TCP/IP port that MS SQL Server uses for communication. Port 1433 is the default.
- **databaseName** The name of the database from which the data source obtains connections. Example: *Sample*.

4. **WebSphere embedded ConnectJDBC driver for MS SQL Server (XA)**

WebSphere embedded ConnectJDBC driver for MS SQL Server (XA) is a Type 4 JDBC driver which provides XA-compliant JDBC access to the MS SQL Server database. This JDBC driver ships with WebSphere Application Server. Use this provider with the Connect JDBC driver embedded in WebSphere. Do not use it with a Connect JDBC driver purchased separately from DataDirect Technologies.

This JDBC provider supports this data source:

com.ibm.websphere.jdbcx.sqlserver.SQLServerDataSource.

Requires JDBC driver files:

sqlserver.jar
base.jar and
util.jar.

(The **spy.jar** file is optional. You need this file to enable spy logging. The **spy.jar** file for the WebSphere embedded Connect JDBC driver ships with WebSphere Application Server. All the files are located in the WAS_HOME/lib/ directory.)

Requires **DataStoreHelper** class:

com.ibm.websphere.rsadapter.WSConnectJDBCDataStoreHelper

Requires a valid authentication alias.

Requires properties:

- **serverName** The name of the server in which MS SQL Server resides. Example: *myserver.mydomain.com*
- **portNumber** The TCP/IP port that MS SQL Server uses for communication. Port 1433 is the default.
- **databaseName** The name of the database from which the data source obtains connections. Example: *Sample*.

Whether you need to support one or two phase transactions with the WebSphere embedded Connect JDBC XA driver, you must install Stored Procedures for the Java Transaction API (JTA) on your machine that runs Microsoft SQL. The WebSphere Application Server installation disks provide a base level of Stored Procedures for JTA. (You can find the most current version of the software on the WebSphere Application Server-embedded DataDirect Technologies product update Web page.) Install Stored Procedures for JTA by performing the following steps:

a. Determine whether you are running the 32-bit or 64-bit MS SQL Server and select the appropriate sqljbc.dll and instjdbc.sql files.
b. Stop your MS SQL Server service.
c. Copy the sqljdbc.dll file into your %SQL_SERVER_INSTALL%\Binn\ directory.
d. Restart the MS SQL Server service.
e. Run theinstjdbc.sql script. (The script can be run by the MS SQL Server Query Analyzer or the ISQL utility).

You can download the latest patches and upgrades to the WebSphere embedded Connect JDBC driver from the following FTP site:

`ftp://ftp.software.ibm.com/software/websphere/info/tools/DataDirect/datadirect.htm`

5. **DataDirect SequeLink type 3 JDBC driver for MS SQL Server** -- Deprecated

   Because this JDBC provider is deprecated in WebSphere Application Server Version 6.0, it is no longer an available option in the administrative console. In its place, use one of the Connect JDBC providers, which are described previously in this section.

   DataDirect SequeLink type 3 JDBC driver for MS SQL Server is a type 3 JDBC driver that provides JDBC access to MS SQL Server via SequeLink server.

   This JDBC provider supports this data source:

   `com.ddtek.jdbcx.sequelink.SequeLinkDataSource`

   Requires JDBC driver files:

   `sljc.jar` `and`
   `spy-sl.jar`

   (The JDBC driver shipped with WebSphere Application Server requires the **`sljc.jar`** and the **`spy-sl.jar`** files. The JDBC driver purchased from DataDirect requires the **`sljc.jar`** and the **`spy.jar`** files. The **`spy.jar`** and **`spy-sl.jar`** files are optional. You need these files to enable spy logging.)

   Requires **`DataStoreHelper`** class:

   `com.ibm.websphere.rsadapter.SequeLinkDataStoreHelper`

   Requires a valid authentication alias.

   Requires properties:
   - **serverName** The name of the server in which SequeLink Server resides. Example: *`myserver.mydomain.com`*
   - **portNumber** The TCP/IP port that SequeLink Server uses for communication. By default, SequeLink Server uses port 19996.
   - **databaseName** The name of the database from which the data source obtains connections. Example: *Sample*.

6. **DataDirect SequeLink type 3 JDBC driver for MS SQL Server (XA)** -- Deprecated

   Because this JDBC provider is deprecated in WebSphere Application Server Version 6.0, it is no longer an available option in the administrative console. In its place, use one of the Connect JDBC providers, which are described previously in this section.

   DataDirect SequeLink type 3 JDBC driver for MS SQL Server (XA) is a type 3 JDBC driver that provides XA-compliant JDBC access to MS SQL Server via the SequeLink server.

   This JDBC provider supports this data source:

   `com.ddtek.jdbcx.sequelink.SequeLinkDataSource`

   Requires JDBC driver files:

   `sljc.jar` `and`
   `spy-sl.jar`

   (The JDBC driver shipped with WebSphere Application Server requires the **`sljc.jar`** and the **`spy-sl.jar`** files. The JDBC driver purchased from DataDirect requires the **`sljc.jar`** and the **`spy.jar`** files. The **`spy.jar`** and **`spy-sl.jar`** files are optional. You need these files to enable spy logging.)

   Requires **`DataStoreHelper`** class:

   `com.ibm.websphere.rsadapter.SequeLinkDataStoreHelper`

   Requires a valid authentication alias.

   Requires properties:
   - **serverName** The name of the server in which SequeLink Server resides. Example: *`myserver.mydomain.com`*
   - **portNumber** The TCP/IP port that SequeLink Server uses for communication. By default, SequeLink Server uses port 19996.
   - **databaseName** The name of the database from which the data source obtains connections. Example: *Sample*.

Both of the WebSphere-embedded SequeLink JDBC drivers require installation of SequeLink Server on all machines running MS SQL Server. See the readme.html file found in the DataDirect folder on the WebSphere Application Server CD for instructions on how to install SequeLink Server. (Only install SequeLink Server from the WebSphere Application Server CD if you are using the SequeLink JDBC driver embedded in WebSphere. Otherwise, install a copy of SequeLink Server purchased from DataDirect Technologies.)

From the following FTP site, you can download the latest patches and upgrades for the version of SequeLink Server that is used with the WebSphere-embedded SequeLink JDBC driver:

`ftp://ftp.software.ibm.com/software/websphere/info/tools/DataDirect/datadirect.htm`

For more information on the DataDirect SequeLink type 3 JDBC driver, visit the DataDirect Web site at:

`http://www.datadirect-technologies.com/`

7. **Microsoft JDBC driver for MSSQLServer 2000** -- Deprecated

   Because this JDBC provider is deprecated in WebSphere Application Server Version 6.0, it is no longer an available option in the administrative console. In its place, use one of the Connect JDBC providers, which are described previously in this section.

   Microsoft JDBC driver for MSSQLServer 2000 is a type 4 JDBC driver that provides JDBC access to the MS SQL Server database.

   This JDBC provider supports this data source:

   `com.microsoft.jdbcx.sqlserver.SQLServerDataSource`

   Requires JDBC driver files:

   `mssqlserver.jar,`
   `msbase.jar` `and` **`msutil.jar`**

   (The **`spy.jar`** file is optional. You need it to enable spy logging. However, Microsoft does not ship the **`spy.jar`** file. Contact Microsoft about this issue.)

   Requires **`DataStoreHelper`** class:

   `com.ibm.websphere.rsadapter.ConnectJDBCDataStoreHelper`

   Requires a valid authentication alias.

   Requires properties:
   - **serverName** The name of the server in which MS SQL Server resides. Example: *`myserver.mydomain.com`*
   - **portNumber** The TCP/IP port that MS SQL Server uses for communication. Port 1433 is the default.
   - **databaseName** The name of the database from which the data source obtains connections. Example: *Sample*.

8. **Microsoft JDBC driver for MSSQLServer 2000 (XA)** -- Deprecated

   Because this JDBC provider is deprecated in WebSphere Application Server Version 6.0, it is no longer an available option in the administrative console. In its place, use one of the Connect JDBC providers, which are described previously in this section.

   Microsoft JDBC driver for MSSQLServer 2000 (XA) is a type 4 JDBC driver that provides XA-compliant JDBC access to the MS SQL Server database.

   This JDBC provider supports this data source:

   `com.microsoft.jdbcx.sqlserver.SQLServerDataSource`

   Requires JDBC driver files:

   `mssqlserver.jar,`
   `msbase.jar` `and` **`msutil.jar`**

   (The **`spy.jar`** file is optional. You need it to enable spy logging. However, Microsoft does not ship the **`spy.jar`** file. Contact Microsoft about this issue.)

   Requires **`DataStoreHelper`** class:

   `com.ibm.websphere.rsadapter.ConnectJDBCDataStoreHelper`

   Requires a valid authentication alias.

   Requires properties:

- **serverName** The name of the server in which MS SQL Server resides. Example: `myserver.mydomain.com`
- **portNumber** The TCP/IP port that MS SQL Server uses for communication. Port 1433 is the default.
- **databaseName** The name of the database from which the data source obtains connections. Example: *Sample*.

For more information on the Microsoft JDBC driver, visit the Microsoft Web site at:

```
http://www.microsoft.com/sql
```

Connector modules collection

Use this page to view established connector modules, which are resource adaptor (RAR) files that have been packaged into deployable components compliant with the J2EE Connector Architecture (JCA).

To view this administrative console page, click **Applications** >**Enterprise Applications** > *application* > **Connector Modules**.

You must generate a connector module for every resource adapter (RAR file) in the application. You do this through an assembly tool, which creates an instance of the connector module object for the RAR file. To learn more about the process, see the topic ″Assembling resource adapter (connector) modules″ in the Information Center.

Remove: Removes a module from the deployed application. The module is deleted from the application in the WebSphere Application Server configuration repository and also from all the nodes where the application is installed and running (or expected to run). If the application is running on a node when the module file is deleted from the node as a result of configuration synchronization then the application is stopped, the module file is deleted from the node's file system, and then the application is restarted.

Update: Opens a wizard that helps you update module in an application. If a module has the same URI as a module already existing in the application, the new module replaces the existing module. If the new module does not exist in the application, it is added to the deployed application. If the application is running on a node when the module file is updated on the node as a result of configuration synchronization then the application is stopped, the module file is updated on the node's file system, and then the application is restarted.

Remove File: Deletes a file from a module of a deployed application. The file is also deleted from all the nodes where the module is installed after configuration is synchronized with nodes. If the application is running on a node when the module file is updated on the node as a result of configuration synchronization then the application is stopped, the module file is updated on the node's file system, and then the application is restarted.

URI:

Specifies the logical path to the resource that will be serviced by the product.

Name:

Specifies the display name of the connector module.

Connector module settings:

Use this page to view the settings of connector modules, which are resource adapter (RAR) files that have been packaged into deployable components compliant with the J2EE Connector Architecture (JCA).

To view this administrative console page, click **Applications** > **Enterprise Applications** > *application* > **Connector Modules** > *connector_module*.

The following field descriptions refer to properties that are set when you create connector modules using an assembly tool. To learn more about the process, see the topic ″Assembling resource adapter (connector) modules″ in the Information Center.

Remove: Removes a module from the deployed application. The module is deleted from the application in the WebSphere Application Server configuration repository and also from all the nodes where the application is installed and running (or expected to run). If the application is running on a node when the module file is deleted from the node as a result of configuration synchronization then the application is stopped, the module file is deleted from the node's file system, and then the application is restarted.

Update: Opens a wizard that helps you update module in an application. If a module has the same URI as a module already existing in the application, the new module replaces the existing module. If the new module does not exist in the application, it is added to the deployed application. If the application is running on a node when the module file is updated on the node as a result of configuration synchronization then the application is stopped, the module file is updated on the node's file system, and then the application is restarted.

Remove File: Deletes a file from a module of a deployed application. The file is also deleted from all the nodes where the module is installed after configuration is synchronized with nodes. If the application is running on a node when the module file is updated on the node as a result of configuration synchronization then the application is stopped, the module file is updated on the node's file system, and then the application is restarted.

Uri:

Specifies the logical path to the resource that is serviced by WebSphere Application Server.

Data type	String

Name:

Specifies the display name of the connector module.

Data type	String

altDD:

Specifies the alternate DD of the connector module.

The alternate DD URI for a given module.

Data type	String

Starting weight:

Specifies the startup priority of the connector module over others.

When your application contains multiple modules, the starting weight you specify determines this module's startup priority over other modules during server startup. Modules with lower startup order are started first.

Data type	String

Messaging resources

Learning about messaging with WebSphere Application Server

Use this topic to learn about the use of asynchronous messaging for enterprise applications with WebSphere Application Server.

WebSphere Application Server supports asynchronous messaging as a method of communication based on the Java Message Service (JMS) and Java Connector Architecture (JCA) programming interfaces. These interfaces provide a common way for Java programs (clients and J2EE applications) to create, send, receive, and read asynchronous requests, as messages.

Besides using the programming interfaces directly to explicitly poll for messages, WebSphere Application Server also supports the use of message-driven beans as asynchronous message consumers. A message-driven bean is invoked by the EJB container when a message arrives at the destination that it is configured to listen on, without an application having to explicitly poll the destination.

To handle non-JMS requests inbound to WebSphere Application Server from enterprise information systems, message-driven beans use a Java Connector Architecture (JCA) 1.5 resource adapter written for that purpose. In the JCA 1.5 specification, such message-driven beans are commonly called message endpoints or simply endpoints.

Message-driven beans that implement the javax.jms.MessageListener interface can be used for JMS messaging. For JMS messaging, message-driven beans can use a JMS provider that has a JCA 1.5 resource adapter, such as the default messaging provider that is part of WebSphere Application Server version 6.

With a JCA 1.5 resource adapter, you deploy EJB 2.1 message-driven beans as JCA resources to use a J2C activation specification. If a JMS provider does not have a JCA 1.5 resource adapter, such as the V5 Default Messaging and WebSphere MQ, you must configure JMS message-driven beans against a listener port (as in WebSphere Application Server version 5).

You can use the WebSphere administrative console to administer the WebSphere Application Server support for asynchronous messaging. For example, you can configure JCA resource adapters, J2C activation specifications, JMS providers, and JMS resources, and can control the activity of messaging services.

To learn more about WebSphere messaging support, see the following topics:

- JMS providers
- Styles of messaging in applications
- Using JMS interfaces to explicitly poll for messages
- Using message-driven beans to automatically retrieve messages
- ″Components of JMS support″ in the information center.
- Components of message-driven bean support
- Security considerations for asynchronous messaging

JMS providers

This topic provides an overview of the support for JMS providers by WebSphere Application Server.

IBM WebSphere Application Server supports asynchronous messaging through the use of a JMS provider and its related messaging system. JMS providers must conform to the JMS specification version 1.1. To use message-driven beans the JMS provider must support the optional Application Server Facility (ASF) function defined within that specification, or support an inbound resource adapter as defined in the JCA specification version 1.5.

The service integration technologies of IBM WebSphere Application Server can act as a messaging system when you have configured a service integration bus that is accessed through the default messaging provider. This support is installed as part of WebSphere Application Server, administered through the administrative console, and is fully integrated with the WebSphere Application Server runtime.

WebSphere Application Server also includes support for the following JMS providers:

WebSphere MQ
Provided for use with supported versions of WebSphere MQ.

Generic
Provided for use with any 3rd party messaging system. If you want to use message-driven beans, the messaging system must support ASF.

For backwards compatibility with earlier releases, WebSphere Application Server also includes support for the V5 default messaging provider which enables you to configure resources for use with the WebSphere Application Server version 5 Embedded Messaging system. The V5 default messaging provider can also be used with a service integration bus.

WebSphere applications can use messaging resources provided by any of these JMS providers. However the choice of provider is most often dictated by requirements to use or integrate with an existing messaging system. For example, you may already have a messaging infrastructure based on WebSphere MQ. In this case you may either connect directly using the included support for WebSphere MQ as a JMS provider, or configure a service integration bus with links to a WebSphere MQ network and then access the bus through the default messaging provider.

Styles of messaging in applications

This topic describes the ways that applications can use point-to-point and publish/subscribe messaging.

Applications can use the following styles of asynchronous messaging:

Point-to-Point
Point-to-point applications use queues to pass messages between each other. The applications are called point-to-point, because a client sends a message to a specific queue and the message is picked up and processed by a server listening to that queue. It is common for a client to have all its messages delivered to one queue. Like any generic mailbox, a queue can contain a mixture of messages of different types.

Publish/subscribe
Publish/subscribe systems provide named collection points for messages, called topics. To send messages, applications publish messages to topics. To receive messages, applications subscribe to topics; when a message is published to a topic, it is automatically sent to all the applications that are subscribers of that topic. By using a topic as an intermediary, message publishers are kept independent of subscribers.

Both styles of messaging can be used in the same application.

Applications can use asynchronous messaging in the following ways:

One-way
An application sends a message, and does not want a response. This pattern of use is often referred to as a datagram.

Request / response
An application sends a request to another application and expects to receive a response in return.

One-way and forward
An application sends a request to another application, which sends a message to yet another application.

These messaging techniques can be combined to produce a variety of asynchronous messaging scenarios.

For more information about how such messaging scenarios are used by WebSphere enterprise applications, see the following topics:

- An overview of asynchronous messaging with JMS
- An overview of asynchronous messaging with message-driven beans

For more information about these messaging techniques and the Java Message Service (JMS), see Sun's Java Message Service (JMS) specification documentation (http://developer.java.sun.com/developer/technicalArticles/Networking/messaging/).

For more information about message-driven bean and inbound messaging support, see Sun's Enterprise JavaBeans specification (http://java.sun.com/products/ejb/docs.html).

For information about JCA inbound messaging processing, see Sun's J2EE Connector Architecture specification (http://java.sun.com/j2ee/connector/download.html).

Using JMS interfaces to explicitly poll for messages

This topic provides an overview of applications that use JMS interfaces to explicitly poll for messages on a destination then retrieve messages for processing by business logic beans (enterprise beans).

WebSphere Application Server supports asynchronous messaging as a method of communication based on the Java Message Service (JMS) programming interfaces. JMS provides a common way for Java programs (clients and J2EE applications) to create, send, receive, and read asynchronous requests, as JMS messages.

The base support for asynchronous messaging using JMS, shown in the following figure, provides the common set of JMS interfaces and associated semantics that define how a JMS client can access the facilities of a JMS provider. This enables WebSphere J2EE applications, as JMS clients, to exchange messages asynchronously with other JMS clients by using JMS destinations (queues or topics).

Applications can use both point-to-point and publish/subscribe messaging (referred to as "messaging domains" in the JMS specification), while supporting the different semantics of each domain.

WebSphere Application Server supports applications that use JMS 1.1 domain-independent interfaces (referred to as the "common interfaces" in the JMS specification). With JMS 1.1, the preferred approach for implementing applications is to use the common interfaces. The JMS 1.1 common interfaces provide a simpler programming model than domain-specific interfaces. Also, applications can create both queues and topics in the same session and coordinate their use in the same transaction.

The common interfaces are also parents of domain-specific interfaces. These domain-specific interfaces (provided for JMS 1.0.2 in WebSphere Application Server version 5) are supported only to provide inter-operation and backward compatibility with applications that have already been implemented to use those interfaces.

A WebSphere application can use the JMS interfaces to explicitly poll a JMS destination to retrieve an incoming message, then pass the message to a business logic bean. The business logic bean uses standard JMS calls to process the message; for example, to extract data or to send the message on to another JMS destination.

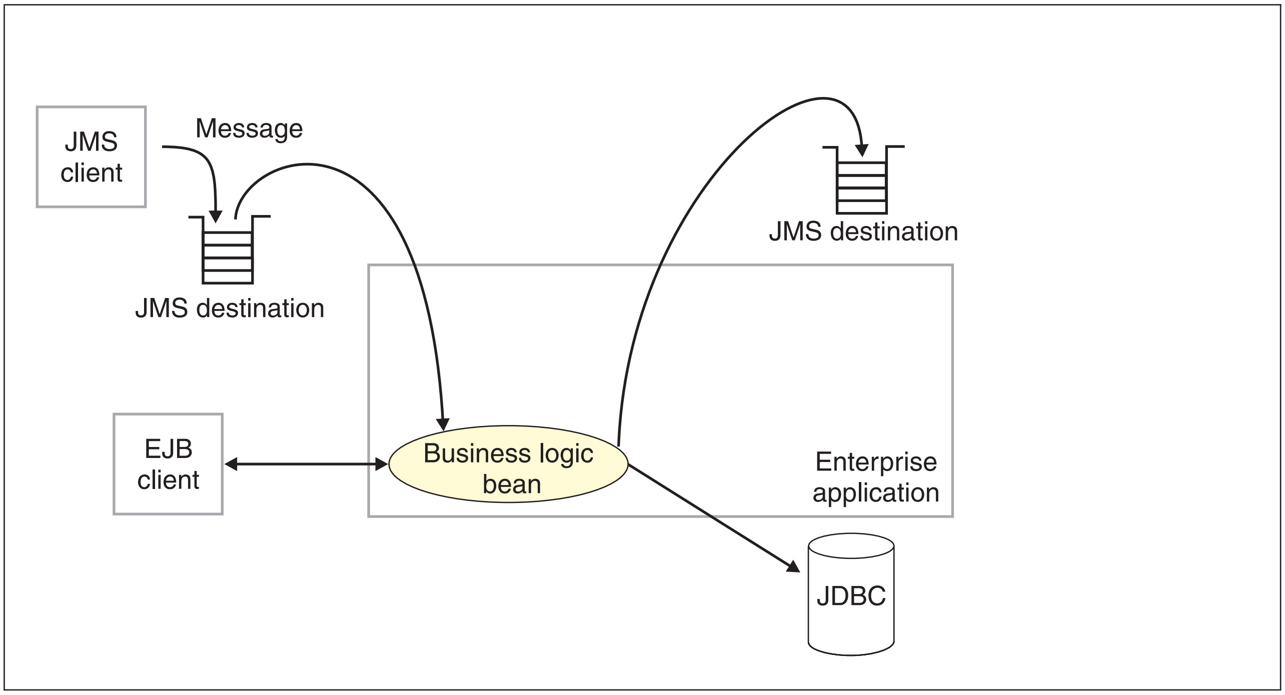

Figure 3. Asynchronous messaging using JMS. This figure shows an enterprise application polling a JMS destination to retrieve an incoming message, which it processes with a business logic bean. The business logic bean uses standard JMS calls to process the message; for example, to extract data or to send the message on to another JMS destination. For more information, see the text that accompanies this figure.

WebSphere applications can use standard JMS calls to process messages, including any responses or outbound messaging. Responses can be handled by an enterprise bean acting as a sender bean, or handled in the enterprise bean that receives the incoming messages. Optionally, this process can use two-phase commit within the scope of a transaction. This level of functionality for asynchronous messaging is called bean-managed messaging, and gives an enterprise bean complete control over the messaging infrastructure; for example, for connection and session pool management. The application server has no role in bean-managed messaging.

WebSphere applications can also use message-driven beans, as described in related topics.

For more details about JMS, see Sun's Java Message Service (JMS) specification documentation.

Using message-driven beans to automatically retrieve messages

WebSphere Application Server supports the use of message-driven beans as asynchronous message consumers.

Messaging with message-driven beans is shown in the figure Messaging with message-driven beans.

A client sends messages to the destination (or endpoint) for which the message-driven bean is deployed as the message listener. When a message arrives at the destination, the EJB container invokes the message-driven bean automatically without an application having to explicitly poll the destination. The message-driven bean implements some business logic to process incoming messages on the destination.

Message-driven beans can be configured as listeners on a Java Connector Architecture (JCA) 1.5 resource adapter or against a listener port (as in WebSphere Application Server version 5). With a JCA 1.5 resource adapter, message-driven beans can handle generic message types, not just JMS messages. This makes message-driven beans suitable for handling generic requests inbound to WebSphere Application Server from enterprise information systems through the resource adapter. In the JCA 1.5 specification, such message-driven beans are commonly called message endpoints or simply endpoints.

All message-driven beans must implement the MessageDrivenBean interface. For JMS messaging, a message-driven bean must also implement the message listener interface, javax.jms.MessageListener.

A message driven bean can be registered with the EJB timer service for time-based event notifications if it implements the javax.ejb.TimedObject interface in addition to the message listener interface.

You are recommended to develop a message-driven bean to delegate the business processing of incoming messages to another enterprise bean, to provide clear separation of message handling and business processing. This also enables the business processing to be invoked by either the arrival of incoming messages or, for example, from a WebSphere J2EE client.

Messages arriving at a destination being processed by a message-driven bean have no client credentials associated with them; the messages are anonymous. Security depends on the role specified by the RunAs Identity for the message-driven bean as an EJB component. For more information about EJB security, see EJB component security.

For JMS messaging, message-driven beans can use a JMS provider that has a JCA 1.5 resource adapter, such as the default messaging provider that is part of WebSphere Application Server version 6. With a JCA 1.5 resource adapter, you deploy EJB 2.1 message-driven beans as JCA 1.5-compliant resources, to use a J2C activation specification. If the JMS provider does not have a JCA 1.5 resource adapter, such as the V5 Default Messaging and WebSphere MQ, you must configure JMS message-driven beans against a listener port (as in WebSphere Application Server version 5).

Message-driven beans - JCA components:

This topic provides an overview of the administrative components that you configure for message-driven beans as listeners on a Java Connector Architecture (JCA) 1.5 resource adapter.

Components for a JCA resource adapter

To handle non-JMS requests inbound to WebSphere Application Server from enterprise information systems, message-driven beans use a Java Connector Architecture (JCA) 1.5 resource adapter written for that purpose.

With a Java Connector Architecture (JCA) 1.5 resource adapter, a message-driven bean acts as a listener on a specific endpoint. In the JCA 1.5 specification, such message-driven beans are commonly called message endpoints or simply endpoints.

Each application configuring one or more endpoints must specify the resource adapter that sends messages to the endpoint.

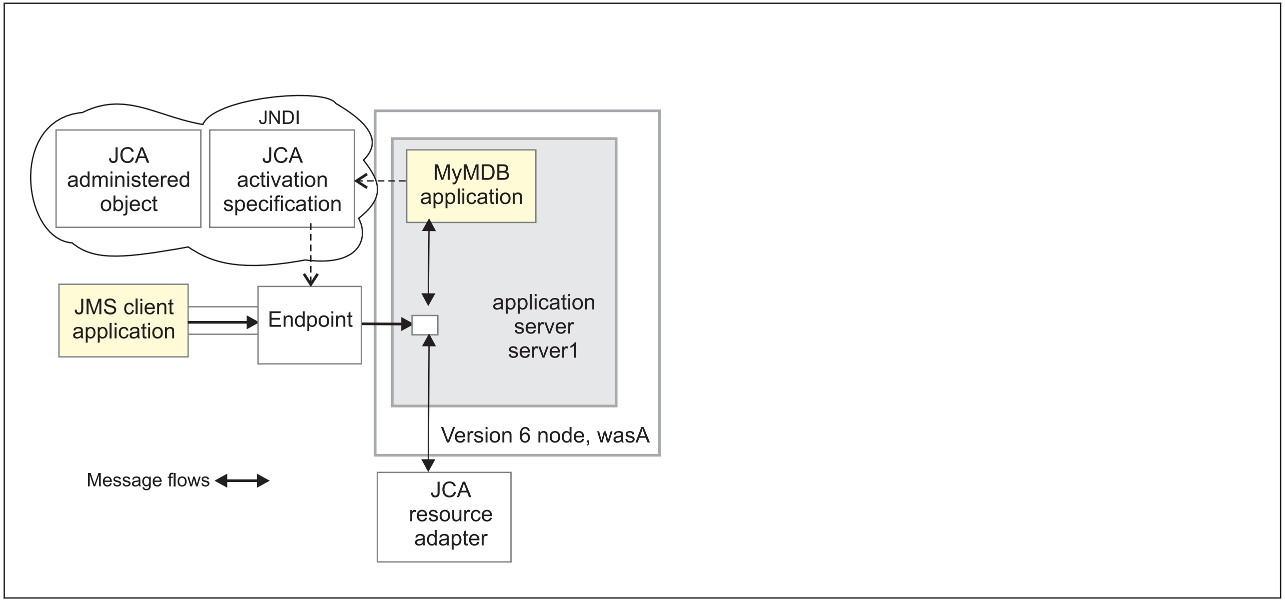

Figure 4. Message-driven bean components for a JCA resource adapter. This figure shows the main components of WebSphere support for message-driven beans for use with an external JCA resource adapter.

The administrator creates a J2C activation specification to provide information to the deployer about the configuration properties of an endpoint instance (message-driven bean) related to the processing of the inbound messages. Properties specified on an activation specification can be overridden by appropriately named activation-configuration properties in the deployment descriptor of an associated EJB 2.1 message-driven bean.

When a deployed message-driven bean is installed, it is associated with an activation specification for an endpoint. When a message arrives on the endpoint, the message is passed to a new instance of a message-driven bean for processing.

Administered object definitions and classes are provided by a resource adapter when you install it. Using this information, the administrator can create and configure J2C administered objects with JNDI names that are then available for applications to use. Some messaging styles may need applications to use special administered objects for sending and synchronously receiving messages (through connection objects using programming interfaces specific to a messaging style). Administered objects can also be used to perform transformations on an asynchronously-received message in a way that is specific to a message provider. Administered objects can be accessed by a component by using either a message destination reference (preferred) or a resource environment reference.

Components for a JCA messaging provider

Message-driven beans that implement the javax.jms.MessageListener interface can be used for JMS messaging. For JMS messaging, message-driven beans can use a JCA-based messaging provider such as the default messaging provider that is part of WebSphere Application Server and configure message-driven beans to use a JCA activation specification.

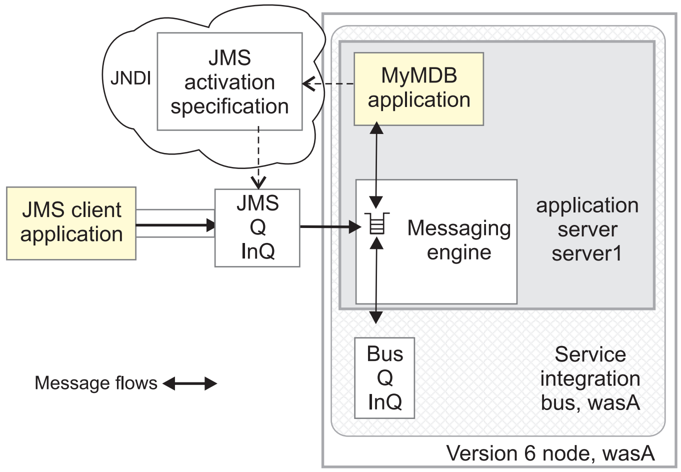

Figure 5. Message-driven bean components for the default messaging provider. This figure shows the main components of WebSphere support for message-driven beans for use with the default messaging provider.

With the default messaging provider, a message-driven bean acts as a listener on a specific JMS destination.

The administrator creates a JMS activation specification to provide information to the deployer about the configuration properties of a message-driven bean related to the processing of the inbound messages. For example, a JMS activation specification specifies the name of the service integration bus to connect to, and includes information about the message acknowledgement modes, message selectors, destination types, and whether or not durable subscriptions are shared across connections with members of a server cluster. Properties specified on an activation specification can be overridden by appropriately named activation-configuration properties in the deployment descriptor of an associated EJB 2.1 message-driven bean.

The administrator also creates other administered objects that configure the JMS destination and the associated resources of a service integration bus that are used to implement messaging with that JMS destination. For more information about JMS resources and service integration, see ″Learning about the default messaging provider″ in the information center.

J2C activation specification configuration and use:

This topic provides an overview about the configuration and use of J2C activation specifications, used in the deployment of message-driven beans for JCA 1.5 resources.

J2C activation specifications are part of the configuration of inbound messaging support that can be part of a JCA 1.5 resource adapter. Each JCA 1.5 resource adapter that supports inbound messaging defines one or more `messagelistener` types in its deployment descriptor (ra.xml). The messagelistener type is the interface that the resource adapter uses to communicate inbound messages to the message endpoint. A message-driven bean (MDB) is a message endpoint and implements one of the messagelistener-type interfaces provided by the resource adapter. By allowing multiple message listener types, a resource adapter can support a variety of different protocols. For example, the interface javax.jms.MessageListener, is a type of message listener that supports JMS messaging. For each messagelistener-type that a resource adapter implements, the resource adapter defines an associated activation specification (`activationspec` in the ra.xml). The activation specification is used to set configuration properties for a particular use of the inbound support for the receiving endpoint.

When an application containing a message-driven bean is deployed, the deployer must select a resource adapter that supports the same messagelistener type that the message-driven bean implements. As part of the message-driven bean deployment, the deployer needs to specify the properties to set on the J2C activation specification. Later, during application startup, a J2C activation specification instance is created, and these properties are set and used to activate the endpoint (that is, to configure the resource adapter‘s inbound support for the specific message-driven bean).

J2C activation specification configuration options and precedence:
Resource adapter scoped configuration

A J2C activation specification configuration instance can be created and modified under an installed resource adapter at the cell, node, or server scope. This activation specification configuration is created based on a particular message listener type for the given resource adapter. Valid properties available for configuration are determined by introspection of the ActivationSpec class instance provided with the resource adapter. When created, an ActivationSpec class instance is referenced by its JNDI name. This activation specification configuration is needed during the deployment of a message-driven bean for the resource adapter.

Configuring a J2C activation specification instance at the cell, node, or server level offers two distinct advantages:

- The activation specification configuration information can be share among multiple message-driven beans across multiple applications.
- Updates to the configuration properties can be made without the need to redeploy the application.

Application-based configuration

Applications with message-driven beans have the option of specifying all, some, or none of the properties needed by the ActivationSpec class. These properties, specified as activation-config properties in the application‘s deployment descriptor, are configured when the application is assembled. To change any of these properties requires redeploying the application. These properties are unique to this applications use and are not shared with other message-driven beans. Any properties defined in the application’s deployment descriptor take precedence over those defined by the resource adapter-scoped definition. This allows application developers to choose the best defaults for their applications.

To deploy and activate a message-driven bean with respect to application specification configuration properties would be as follows:

1. Use JNDI to look up a J2C activation specification configuration instance, which is based on its resource adapter-scoped definition.
2. Set the properties needed by the ActivationSpec class to the values defined by the cell, node, or server definition. If any of the properties are also defined as activation-config properties of the application, use the value defined by the activation-config property.
3. During application startup, the server activates the MDB endpoint by calling the resource adapter and passing a configured instance of the ActivationSpec.
4. Note that a resource adapter can specify in its deployment descriptor if a given ActivationSpec property is required. If it is required, and it is not supplied either by the cell, node or server definition, or an activation-config property from the applications deployment descriptor, then an exception is raised as part of the sequence to activate the message-driven bean.

WebSphere activation specification optional binding properties:

J2C authentication alias
If you provide values for user name and password as custom properties on an activation specification, you may not want to have those values exposed in clear text for security reasons. WebSphere security allows you to securely define an authentication alias for such cases.

Configuration of activation specifications, both as an administrative object and during application deployment enable you to use the authentication alias instead of providing the user name and password.

If you set the authentication alias field, then you should not set the user name and password custom properties fields. Also, authentication alias properties set as part of application deployment take precedence over properties set on an activation specification administrative object.

Only the authentication alias is ever written to file in an unencrypted form, even for purposes of transaction recovery logging. The security service is used to protect the real user name and password.

During application startup, when the activation specification is being initialized as part of endpoint activation, the server uses the authentication alias to retrieve the real user name and password from security then set it on the activation specification instance.

Destination JNDI name

For resource adapters that support JMS you need to associate javax.jms.Destinations with an activation specification, such that the resource adapter can service messages from the JMS destination. In this case, the administrator configures a J2C Administered Object which implements the javax.jms.Destination interface and binds it into JNDI.

You can configure a J2C Administered Object to use an ActivationSpec class that implements a setDestination(javax.jms.Destination) method. In this case, you can specify the destination JNDI name (that is, the JNDI name for the J2C Administered object that implements the javax.jms.Destination).

A destination JNDI name set as part of application deployment take precedence over properties set on an activation specification administrative object.

During application startup, when the activation specification is being initialized as part of endpoint activation, the server uses the destination JNDI name to look up the destination administered object then set it on the activation specification instance.

Message-driven beans - transaction support: Message-driven beans can handle messages read from destinations (or endpoints) within the scope of a transaction. If transaction handling is specified for a destination, the message-driven bean starts a global transaction *before* it reads any incoming message from that destination. When the message-driven bean processing has finished, it commits or rolls back the transaction (using JTA transaction control).

All messages retrieved from a specific destination have the same transactional behavior.

If messages are queued to be sent within a global transaction they are sent when the transaction is committed. If the processing of a message causes the transaction to be rolled back, then the message that caused the bean instance to be invoked is left on the JMS destination.

Asynchronous messaging - security considerations

This topic describes considerations that you should be aware of if you want to use security for asynchronous messaging with WebSphere Application Server.

Security for messaging operates as a part of the WebSphere Application Server global security, and is enabled only when global security is enabled.

When global security is enabled, JMS connections made to the JMS provider are authenticated, and access to JMS resources owned by the JMS provider are controlled by access authorizations. Also, all requests to create new connections to the JMS provider must provide a user ID and password for authentication. The user ID and password do not need to be provided by the application. If authentication is successful, then the JMS connection is created; if the authentication fails then the connection request is ended.

Standard J2C authentication is used for a request to create a new connection to the JMS provider. If your resource authentication (res-auth) is set to Application, set the alias in the Component-managed Authentication Alias. If the application that tries to create a connection to the JMS provider specifies a user ID and password, those values are used to authenticate the creation request. If the application does not specify a user ID and password, the values defined by the Component-managed Authentication Alias are used. If the connection factory is not configured with a Component-managed Authentication Alias, then you receive a runtime JMS exception when an attempt is made to connect to the JMS provider.

Restriction:

1. User IDs longer than 12 characters cannot be used for authentication with the version 5 default messaging provider or WebSphere MQ. For example, the default Windows NT user ID, **Administrator**, is not valid for use, because it contains 13 characters. Therefore, an authentication alias for a WebSphere JMS provider or WebSphere MQ connection factory must specify a user ID no longer than 12 characters.
2. If you want to use Bindings transport mode for JMS connections to WebSphere MQ, you set the property **Transport type**=BINDINGS on the WebSphere MQ Queue Connection Factory. You must also choose one of the following options:
   - To use security credentials, ensure that the user specified is the currently logged on user for the WebSphere Application Server process. If the user specified is not the current logged on user for the WebSphere Application Server process, then the WebSphere MQ JMS Bindings authentication throws the error `MQJMS2013 invalid security authentication supplied for MQQueueManager` error.
   - Do not specify security credentials. On the WebSphere MQ Connection Factory, ensure that both the **Component-managed Authentication Alias** and the **Container-managed Authentication Alias** properties are not set.

Authorization to access messages stored by the default messaging provider is controlled by authorization to access the service integration bus destinations on which the messages are stored. For information about authorizing permissions for individual bus destinations, see ″Administering destination permissions″ in the information center.

Installing and configuring a JMS provider

This topic describes the different ways that you can use JMS providers with WebSphere Application Server. A JMS provider enables use of the Java Message Service (JMS) and other message resources in WebSphere Application Server.

IBM WebSphere Application Server supports asynchronous messaging through the use of a JMS provider and its related messaging system. JMS providers must conform to the JMS specification version 1.1. To use message-driven beans the JMS provider must support the optional Application Server Facility (ASF) function defined within that specification, or support an inbound resource adapter as defined in the JCA specification version 1.5.

The service integration technologies of IBM WebSphere Application Server can act as a messaging system when you have configured a service integration bus that is accessed through the default messaging provider. This support is installed as part of WebSphere Application Server, administered through the administrative console, and is fully integrated with the WebSphere Application Server runtime.

WebSphere Application Server also includes support for the following JMS providers:

WebSphere MQ
Provided for use with supported versions of WebSphere MQ.

Generic
Provided for use with any 3rd party messaging system. If you want to use message-driven beans, the messaging system must support ASF.

For more information about the support for JMS providers, see “JMS providers” on page 1242.

For more information about installing and using JMS providers, see the following topics:

- Installing the default messaging provider
- Using WebSphere MQ as a JMS provider. ″Installing WebSphere MQ as a JMS provider.″

  Note:
  - You can install WebSphere MQ in addition to the default messaging provider. The preferred solution for publish/subscribe messaging with WebSphere MQ as a JMS provider is a full message broker such as WebSphere MQ Event Broker.
  - If you install WebSphere MQ as a JMS provider, you can use the WebSphere administrative console to administer the JMS resources provided by WebSphere MQ, such as queue connection factories. However, you cannot administer MQ security, which is administered through WebSphere MQ.

  For more information about scenarios and considerations for using WebSphere MQ with IBM WebSphere Application Server, see the White Papers and Red books provided by WebSphere MQ; for example, through the WebSphere MQ library Web page at http://www-3.ibm.com/software/ts/mqseries/library/
- Installing another JMS provider, which must conform to the JMS specification and, to use message-driven beans, support the ASF function. If you want to use a JMS provider other than the default messaging provider or WebSphere MQ, you should complete the following steps:
  1. Installing and configuring the JMS provider and its resources by using the tools and information provided with the product.
  2. Define the JMS provider to WebSphere Application Server as a generic messaging provider.

  Note: You can use the WebSphere administrative console to administer JMS connection factories and destinations (within WebSphere Application Server) for a generic provider, but cannot administer the JMS provider or its resources outside of WebSphere Application Server.

Installing the default messaging provider

Use this task to install the default messaging provider of IBM WebSphere Application Server.

The default messaging provider is installed as a fully-integrated component of WebSphere Application Server, and needs no separate installation steps.

However, ensure that there is enough space in the file systems where you want to store messaging data.

You can use the WebSphere administrative console to define JMS resources for the default messaging provider.

For more information about the default messaging provider, see ″Using the default messaging provider″ in the information center.

Using asynchronous messaging

These topics describe how to use asynchronous messaging with WebSphere Application Server, to enable enterprise applications to use JMS resources and message-driven beans.

WebSphere Application Server supports asynchronous messaging as a method of communication based on the Java Message Service (JMS) programming interface. This JMS support is provided by one or more JMS providers, and associated services and resources, that you configure for use by enterprise applications. You can deploy EJB 2.1 applications that use the JMS 1.1 interfaces and EJB 2.0 applications that use the JMS 1.0.2 interfaces.

You can use the WebSphere administrative console to administer the WebSphere Application Server support for asynchronous messaging. For example, you can configure messaging providers and their resources, and can control the activity of messaging services.

For more information about implementing WebSphere enterprise applications that use asynchronous messaging, see the following topics:

- Learning about messaging with WebSphere
- Installing a messaging provider
- Using the default messaging provider
- “Maintaining Version 5 default messaging resources”
- “Using JMS resources of WebSphere MQ” on page 1286
- “Using JMS resources of a generic provider” on page 1353
- “Administering support for message-driven beans” on page 1361
- Programming to use asynchronous messaging
- Troubleshooting WebSphere messaging

Maintaining Version 5 default messaging resources

This topic is the entry-point into a set of topics about maintaining messaging resources provided for WebSphere Application Server version 5 applications by the default messaging provider.

WebSphere application server version 5 applications can use JMS resources provided by the default messaging provider of WebSphere application server version 6. You can use the WebSphere administrative console to manage the JMS connection factories and destinations for WebSphere Application Server version 5 applications. Such JMS resources are maintained as V5 Default Messaging resources.

V5 Default Messaging provides a JMS transport to a messaging engine of a service integration bus that supports the default messaging provider of WebSphere Application Server version 6. The messaging engine emulates the service of a version 5 JMS server.

You can also use the administrative console to manage a JMS server on a Version 5 node.

For more information about maintaining Version 5 default messaging resources, see the following topics:

- “Listing version 5 default messaging resources” on page 1254

- “Configuring Version 5 default JMS resources” on page 1277
- “Managing Version 5 JMS servers in a deployment manager cell” on page 1280
- “Configuring authorization security for a Version 5 default messaging provider” on page 1281

Listing version 5 default messaging resources

Complete this task to display administrative lists of JMS resources for use by WebSphere application server version 5 applications.

You can use the WebSphere administrative console to display lists of the following types of JMS resources for use by WebSphere application server version 5 applications. You can use the panels displayed to select JMS resources to configure, administer, create, or delete (where appropriate).

To display administrative lists of Version 5 default JMS resources, complete the following general steps:

1. Start the WebSphere administrative console.
2. Display the version 5 default messaging provider. In the navigation pane, expand **Resources** → **JMS Providers** → **V5 Default Messaging**.
3. **Optional:** Change the **Scope** setting to the level at which the JMS queue connection factory is visible to applications. If you define a Version 5 JMS resource at the Cell scope level, all users in the cell can look up and use that JMS resource. However, the JMS resource has only the subset of properties that apply to WebSphere Application Server Version 5. If you want to define a JMS resource at Cell level for use on non-Version 5 nodes, you should define the JMS resource for the Version 6 default messaging provider.
4. In the content pane, under Additional Resources, click the link for the type of JMS resource. This displays a list of any existing resources of the selected type. For more information about the settings panels displayed for resources, see the related reference topics.

JMS provider settings:

Use this panel to view the configuration properties of the selected JMS provider. *You cannot change these properties.*

To view this page, use the administrative console to complete one of the following steps:

- In the navigation pane, click **Resources** → **JMS Providers** → **WebSphere MQ**.
- In the navigation pane, click **Resources** → **JMS Providers** → **V5 Default Messaging**.
- In the navigation pane, click **Resources** → **JMS Providers** → **Generic** → *provider_name*.

If you want to browse or change JMS resources of the JMS provider, complete the following steps:

1. **(Optional)** In the content pane, change the **Scope** setting to the level at which JMS resources are visible to applications.
2. Under Additional Properties, click the link for the type of resource . For more information about the administrative console panels for the types of JMS resources, see the related topics.

Scope:

The level to which this resource definition is visible; the cell, node, or server level.

Resources such as messaging providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates which are defined at more general scopes.

When JMS resources are created for this messaging provider, they are always created into the provider scope selected in this panel. To browse or change resources in other scopes, select the required level option, then click **Apply**, before clicking the link for the type of resource.

Note that no matter what the scope of a defined resource, the resource's properties only apply at an individual server level. For example, if you define the scope of a data source at the Cell level, all users in that Cell can look up and use that data source, which is unique within that Cell. However, resource property settings are local to each server in the Cell.

Cell The most general scope. Resources defined at the Cell scope are visible from all Nodes and servers, unless they are overridden. To view resources defined in the cell scope, do not specify a server or a node name in the scope selection form.

Node The default scope for most resource types. Resources defined at the Node scope override any duplicates defined at the Cell scope and are visible to all servers on the same node, unless they are overridden at a server scope on that node. To view resources defined in a node scope, do not specify a server, but select a node name in the scope selection form.

Server
The most specific scope for defining resources. Resources defined at the Server scope override any duplicate resource definitions defined at the Cell scope or parent Node scope and are visible only to a specific server. To view resources defined in a server scope, specify a server name as well as a node name in the scope selection form.

Data type	String

Name:

The name by which the JMS provider is known for administrative purposes.

Data type	String
Default	WebSphereJMSProvider

Description:

A description of the JMS provider, for administrative purposes within IBM WebSphere Application Server.

Data type	String

Classpath:

The Java classpath for WebSphere MQ as a JMS provider. The list of paths or JAR file names that together form the location for the JMS provider classes.

[JMS Providers > WebSphere MQ and JMS Providers > Generic only]

Data type	String
Default	**[WebSphere MQ]** $MQJMS_LIB_ROOT

Native Library Path:

The native library path for WebSphere MQ as a JMS provider. An optional path to any native libraries needed by the JMS provider.

[JMS Providers > WebSphere MQ and JMS Providers > Generic only]

Data type	String
Default	**[WebSphere MQ]** $MQJMS_LIB_ROOT

The Native Library Path property is set to the directory where the WebSphere MQ Java feature is installed.

External initial context factory:

The Java classname of the initial context factory for the JMS provider.

[JMS Providers > Generic only]

For example, for an LDAP service provider the value has the form: `com.sun.jndi.ldap.LdapCtxFactory`.

Data type	String
Default	Null

External provider URL:

The JMS provider URL for external JNDI lookups.

[JMS Providers > Generic only]

For example, an LDAP URL for a messaging provider has the form: `ldap://hostname.company.com/contextName`.

Data type	String
Default	Null

Version 5 JMS server collection:

On a WebSphere Application Server Version 5 node, a JMS server provides the functions of the JMS provider. Use this panel to list JMS servers on WebSphere Application Server Version 5 nodes within the administration domain, or to select a JMS server to view or change its configuration properties.

There can be at most one JMS server on each Version 5 node in the administration domain, and any application server within the domain can access JMS resources served by any JMS server on any node in the domain.

To view this page, use the administrative console to complete the following step:

1. In the navigation pane, select **Servers** → **Version 5 JMS Servers**.

To browse or change the properties of a JMS server, select its name in the list displayed.

To act on one or more of the JMS servers listed, click the check box next to the server name, then use the buttons provided.

version 5 JMS server settings:

The JMS functions on a version 5 node within a deployment manager cell are served by a JMS server. Use this panel to view or change the configuration properties of the selected JMS server.

JMS servers are supported only to aid migration of WebSphere Application Server version 5 nodes to WebSphere Application Server version 6.

You can use this panel to configure a general set of JMS server properties, which add to the default values of properties configured automatically for the version 5 default messaging provider.

Note: JMS servers make use of WebSphere MQ properties and, in general, the default values of those properties are adequate. However, if you are running high messaging loads, you may need to change some WebSphere MQ properties; for example, properties for log file locations, file pages, and buffer pages. For more information about configuring WebSphere MQ properties, see the *WebSphere MQ System Administration* book, SC33-1873, which is available from the IBM Publications Center or from the WebSphere MQ collection kit, SK2T-0730.

Name:

The name by which the JMS server is known for administrative purposes within IBM WebSphere Application Server.

This name should not be changed.

Data type	String
Units	Not applicable
Default	WebSphere Internal JMS Server
Range	Not applicable

Description:

A description of the JMS server, for administrative purposes within IBM WebSphere Application Server.

This string should not be changed.

Data type	String
Default	WebSphere Internal JMS Server

Number of threads:

The number of concurrent threads to be used by the publish/subscribe matching engine

The number of concurrent threads should only be set to a small number.

Data type	Integer
Units	Threads
Default	1
Range	Greater than or equal to 1.

Queue Names:

The names of the queues hosted by this JMS server. Each queue name must be added on a separate line.

Each queue listed in this field must have a separate queue administrative object with the same administrative name. To make a queue available to applications, define a WebSphere queue and add its name to this field on the JMS Server panel for the host on which you want the queue to be hosted.

Data type	String
Units	Queue name
Range	Each entry in this field is a queue name of up to 45 characters, which must match exactly (including use of upper- and lowercase characters) the WebSphere queue administrative object defined for the queue.

Initial State:

The state that you want the JMS server to have when it is next restarted.

Data type	Enum
Default	Started
Range	**Started** The JMS server is started automatically. **Stopped** The JMS server is not started automatically. If any deployed enterprise applications are to use JMS server functions provided by the JMS server, the system administrator must start the JMS server manually or select the Started value of this property then restart the JMS server. To restart a JMS server on a version 5 node, stop then restart that JMS server.

Version 5 WebSphere Queue connection factory collection:

Use this panel to list JMS queue connection factories for point-to-point messaging, for use by WebSphere Application Server version 5 applications. These configuration properties control how connections are created between the JMS provider and the default messaging system that it uses.

This panel shows a list of the JMS queue connection factories with a summary of their configuration properties.

To view this page, use the administrative console to complete the following steps:

1. In the navigation pane, click **Resources** → **JMS Providers** → **V5 Default Messaging**.
2. **(Optional)** In the content pane, change the **Scope** setting to the level at which JMS resources are visible to applications. If you define a Version 5 JMS resource at the Cell scope level, all users in the cell can look up and use that JMS resource. However, the JMS resource has only the subset of properties that apply to WebSphere Application Server Version 5. If you want to define a JMS resource at Cell level for use on non-Version 5 nodes, you should define the JMS resource for the Version 6 default messaging provider.
3. Under Additional Resources, click **WebSphere queue connection factories**. This displays a list of any existing JMS queue connection factories.

To define a new JMS queue connection factory, click **New**.

To browse or change the properties of a connection factory, select its name in the list displayed.

To act on one or more of the connection factories listed, click the check box next to the name of the connection factory, then use the buttons provided.

Version 5 WebSphere queue connection factory settings:

Use this panel to browse or change the configuration properties of the selected JMS queue connection factory for point-to-point messaging for use by WebSphere Application Server version 5 applications.

A WebSphere queue connection factory is used to create JMS connections to the default messaging provider for use by WebSphere Application Server version 5 applications.

To view this page, use the administrative console to complete the following steps:

1. In the navigation pane, click **Resources** → **JMS Providers** → **V5 Default Messaging**.
2. **(Optional)** In the content pane, change the **Scope** setting to the level at which JMS resources are visible to applications. If you define a Version 5 JMS resource at the Cell scope level, all users in the cell can look up and use that JMS resource.

3. Under Additional Resources, click **WebSphere queue connection factories**. This displays a list of any existing JMS queue connection factories.
4. Click the name of the JMS queue connection factory that you want to work with.

A queue connection factory for the embedded WebSphere JMS provider has the following properties:

Scope:

Specifies the level to which this resource definition is visible to applications.

Resources such as messaging providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates which are defined at more general scopes.

The scope displayed is for information only, and cannot be changed on this panel. If you want to browse or change this resource (or other resources) at a different scope, change the scope on the messaging provider settings panel, then click **Apply**, before clicking the link for the type of resource.

Data type	String

Name:

The name by which this JMS queue connection factory is known for administrative purposes within IBM WebSphere Application Server. The name must be unique within the JMS connection factories across the WebSphere administrative domain.

Data type	String
Default	Null

JNDI name:

The JNDI name that is used to bind the JMS connection factory into the name space.

As a convention, use the fully qualified JNDI name; for example, in the form jms/*Name*, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type	String

Description:

A description of this connection factory for administrative purposes within IBM WebSphere Application Server.

Data type	String
Default	Null

Category:

A category used to classify or group this connection factory, for your IBM WebSphere Application Server administrative records.

Data type	String

Node:

The WebSphere node name of the administrative node where the JMS server runs for this connection factory. Connections created by this factory connect to that JMS server.

Data type	Enum
Default	Null
Range	Pull-down list of Version 5 nodes in the WebSphere administrative domain.

Component-managed Authentication Alias:

This alias specifies a user ID and password to be used to authenticate connection to the messaging provider for application-managed authentication.

This property provides a list of the J2C authentication data entry aliases that have been defined to WebSphere Application Server. You can select a data entry alias to be used to authenticate the creation of a new connection to the JMS provider.

If you have enabled global security for WebSphere Application Server, select the alias that specifies the user ID and password used to authenticate the creation of a new connection to the messaging provider. The use of this alias depends on the resource authentication (res-auth) setting declared in the connection factory resource reference of an application component's deployment descriptors.

Note: User IDs longer than 12 characters cannot be used for authentication with the Version 5 default messaging provider. For example, the default Windows NT user ID, **Administrator**, is not valid because it contains 13 characters. Therefore, an authentication alias for a WebSphere queue connection factory must specify a user ID no longer than 12 characters.

Container-managed Authentication Alias:

This alias specifies a user ID and password to be used to authenticate connection to the messaging provider for container-managed authentication.

This field is deprecated in 6.0. The specification of a login configuration and associated properties on the component resource reference determines the container-managed authentication strategy when the res-auth value is Container. If the 'DefaultPrincipalMapping' login configuration is used, the associated property is a container-managed authentication alias. This field is used only in the absence of a loginConfiguration on the component resource reference. To define a new alias, see the related item J2EE Connector Architecture (J2C) authentication data entries.

This property provides a list of the J2C authentication data entry aliases that have been defined to WebSphere Application Server. You can select a data entry alias to be used to authenticate the creation of a new connection to the JMS provider.

If you have enabled global security for WebSphere Application Server, select the alias that specifies the user ID and password used to authenticate the creation of a new connection to the messaging provider. The use of this alias depends on the resource authentication (res-auth) setting declared in the connection factory resource reference of an application component's deployment descriptors.

Note: User IDs longer than 12 characters cannot be used for authentication with the Version 5 default messaging provider. For example, the default Windows NT user ID, **Administrator**, is not valid because it contains 13 characters. Therefore, an authentication alias for a WebSphere topic connection factory must specify a user ID no longer than 12 characters.

Mapping-Configuration Alias:

The module used to map authentication aliases.

This field is deprecated in 6.0. The specification of a login configuration and associated properties on the component resource reference determines the container-managed authentication strategy when the res-auth value is Container. This field is used only in the absence of a loginConfiguration on the component resource reference.

This field provides a list of the modules that have been configured on the **Security** → **JAAS Configuration** → **Application Logins Configuration** property. For more information about the mapping configurations, see Java Authentication and Authorization service configuration entry settings.

Data type	Enum
Default	Null
Range	**ClientContainer** The client container maps authentication aliases. **WSLogin** The WSLogin module maps authentication aliases. **DefaultPrincipalMapping** The JAAS configuration maps an authentication alias to its userid and password.

XA Enabled:

Specifies whether the connection factory is for XA or non-XA coordination of messages and controls if the application server uses XA QCF/TCF. Enable XA if multiple resources are not used in the same transaction.

If you clear this checkbox property (for non-XA coordination), the JMS session is still enlisted in a transaction, but uses the resource manager local transaction calls (session.commit and session.rollback) instead of XA calls. This can lead to an improvement in performance. However, this means that only a single resource can be enlisted in a transaction in WebSphere Application Server.

Last participant support enables you to enlist one non-XA resource with other XA-capable resources.

For a WebSphere Topic Connection Factory with the **Port** property set to `DIRECT` this property does not apply, and always adopts non-XA coordination.

Data type	Checkbox
Default	Selected (enabled for XA coordination)
Range	**Selected** The connection factory is enabled for XA-coordination of messages **Cleared** The connection factory is not enabled for XA coordination of messages
Recommended	Do not enable XA coordination when the message queue or topic received is the only resource in the transaction. Enable XA coordination when other resources, including other queues or topics, are involved.

Connection pool:

Specifies an optional set of connection pool settings.

Connection pool properties are common to all J2C connectors.

The application server pools connections and sessions with the messaging provider to improve performance. You need to configure the connection and session pool properties appropriately for your applications, otherwise you may not get the connection and session behavior that you want.

Change the size of the connection pool if concurrent server-side access to the JMS resource exceeds the default value. The size of the connection pool is set on a per queue or topic basis.

Session pool:

An optional set of session pool settings.

This link provides a panel of optional connection pool properties, common to all J2C connectors.

The application server pools connections and sessions with the messaging provider to improve performance. You need to configure the connection and session pool properties appropriately for your applications, otherwise you may not get the connection and session behavior that you want.

Session pool settings:

Use this page to configure session pool settings.

This administrative console page is common to a range of resource types; for example, JMS queue connection factories. To view this page, the path depends on the type of resource, but generally you select an instance of the resource provider, then an instance of the resource type, then click **Session pools**. For example: click **Resources** → **JMS Providers** → **V5 Default Messaging** → **WebSphere queue connection factories** → *connection_factory* → **Session pools**.

Connection Timeout:

Specifies the interval, in seconds, after which a connection request times out and a ConnectionWaitTimeoutException is thrown.

The wait is necessary when the maximum value of connections (**Max Connections**) to a particular connection pool is reached . For example, if *Connection Timeout* is set to 300 and the maximum number of connections is reached, the Pool Manager waits for 300 seconds for an available physical connection. If a physical connection is *not* available within this time, the Pool Manager throws a ConnectionWaitTimeoutException. It usually does not make sense to retry the getConnection() method, because if a longer wait time is required, you should set the **Connection Timeout** setting to a higher value. Therefore, if this exception is caught by the application, the administrator should review the expected usage of the application and tune the connection pool and the database accordingly.

If Connection Timeout is set to 0, the Pool Manager waits as long as necessary until a connection is allocated (which happens when the number of connections falls below the value of **Max Connections**).

If Max Connections is set to 0, which enables an infinite number of physical connections, then the Connection Timeout value is ignored.

Data type	Integer
Units	Seconds
Default	180

Range	0 to max int

Max Connections:

Specifies the maximum number of physical connections that you can create in this pool.

These are the physical connections to the backend resource. Once this number is reached, no new physical connections are created and the requester waits until a physical connection that is currently in use returns to the pool, or a ConnectionWaitTimeoutException is thrown.

For example, if the Max Connections value is set to 5, and there are five physical connections in use, the pool manager waits for the amount of time specified in Connection Timeout for a physical connection to become free.

If Max Connections is set to 0, the Connection Timeout value is ignored.

For better performance, set the value for the connection pool lower than the value for the Max Connections option in the Web container. Lower settings, such as 10-30 connections, perform better than higher settings, such as 100.

If clones are used, one data pool exists for each clone. Knowing the number of data pools is important when configuring the database maximum connections.

You can use the Tivoli Performance Viewer to find the optimal number of connections in a pool. If the number of concurrent waiters is greater than 0, but the CPU load is not close to 100%, consider increasing the connection pool size. If the Percent Used value is consistently low under normal workload, consider decreasing the number of connections in the pool.

Data type	Integer
Default	10
Range	0 to max int

Min Connections:

Specifies the minimum number of physical connections to maintain.

Until this number is reached, the pool maintenance thread does not discard physical connections. However, no attempt is made to bring the number of connections up to this number. If you set a value for Aged Timeout, the minimum is not maintained. All connections with an expired age are discarded.

For example if the **Min Connections** value is set to 3, and one physical connection is created, the Unused Timeout thread does not discard that connection. By the same token, the thread does not automatically create two additional physical connections to reach the **Min Connections** setting.

Data type	Integer
Default	1
Range	0 to max int

Reap Time:

Specifies the interval, in seconds, between runs of the pool maintenance thread.

For example, if **Reap Time** is set to 60, the pool maintenance thread runs every 60 seconds. The Reap Time interval affects the accuracy of the **Unused Timeout** and **Aged Timeout** settings. The smaller the interval, the greater the accuracy. If the pool maintenance thread is enabled, set the Reap Time value less than the values of Unused Timeout and Aged Timeout. When the pool maintenance thread runs, it discards any connections remaining unused for longer than the time value specified in Unused Timeout, until it reaches the number of connections specified in **Min Connections**. The pool maintenance thread also discards any connections that remain active longer than the time value specified in Aged Timeout.

The Reap Time interval also affects performance. Smaller intervals mean that the pool maintenance thread runs more often and degrades performance.

To disable the pool maintenance thread set Reap Time to 0, or set both Unused Timeout and Aged Timeout to 0. The recommended way to disable the pool maintenance thread is to set Reap Time to 0, in which case Unused Timeout and Aged Timeout are ignored. However, if Unused Timeout and Aged Timeout are set to 0, the pool maintenance thread runs, but only physical connections which timeout due to non-zero timeout values are discarded.

Data type	Integer
Units	Seconds
Default	180
Range	0 to max int

Unused Timeout:

Specifies the interval in seconds after which an unused or idle connection is discarded.

Set the Unused Timeout value higher than the Reap Timeout value for optimal performance. Unused physical connections are only discarded if the current number of connections not in use exceeds the **Min Connections** setting. For example, if the unused timeout value is set to 120, and the pool maintenance thread is enabled (Reap Time is not 0), any physical connection that remains unused for two minutes is discarded. Note that accuracy of this timeout, as well as performance, is affected by the **Reap Time** value. For more information, see Reap Time.

Data type	Integer
Units	Seconds
Default	1800
Range	0 to max int

Aged Timeout:

Specifies the interval in seconds before a physical connection is discarded.

Setting **Aged Timeout** to 0 supports active physical connections remaining in the pool indefinitely. Set the Aged Timeout value higher than the **Reap Timeout** value for optimal performance. For example, if the Aged Timeout value is set to 1200, and the Reap Time value is not 0, any physical connection that remains in existence for 1200 seconds (20 minutes) is discarded from the pool. Note that accuracy of this timeout, as well as performance, are affected by the Reap Time value. For more information, see Reap Time.

Data type	Integer
Units	Seconds
Default	0
Range	0 to max int

Purge Policy:

Specifies how to purge connections when a *stale connection* or *fatal connection error* is detected.

Valid values are **EntirePool** and **FailingConnectionOnly**. JCA data sources can have either option. WebSphere Version 4.0 data sources always have a purge policy of **EntirePool**.

Data type
String

Default
FailingConnectionOnly

Range

EntirePool
All connections in the pool are marked stale. Any connection not in use is immediately closed. A connection in use is closed and throws a *StaleConnectionException* during the next operation on that connection. Subsequent *getConnection* requests from the application result in new connections to the database opening. When using this purge policy, there is a slight possibility that some connections in the pool are closed unnecessarily when they are not stale. However, this is a rare occurrence. In most cases, a purge policy of EntirePool is the best choice.

FailingConnectionOnly
Only the connection that caused the *StaleConnectionException* is closed. Although this setting eliminates the possibility that valid connections are closed unnecessarily, it makes recovery from an application perspective more complicated. Because only the currently failing connection is closed, there is a good possibility that the next *getConnection* request from the application can return a connection from the pool that is also stale, resulting in more stale connection exceptions.

Version 5 WebSphere topic connection factory collection:

Use this panel to list JMS topic connection factories for publish/subscribe messaging, for use by WebSphere Application Server version 5 applications. These configuration properties control how connections are created between the JMS provider and the default messaging system that it uses.

This panel shows a list of JMS topic connection factories with a summary of their configuration properties.

To view this page, use the administrative console to complete the following steps:
1. In the navigation pane, click **Resources → JMS Providers → V5 Default Messaging**.
2. **(Optional)** In the content pane, change the **Scope** setting to the level at which JMS resources are visible to applications. If you define a Version 5 JMS resource at the Cell scope level, all users in the cell can look up and use that JMS resource. However, the JMS resource has only the subset of properties that apply to WebSphere Application Server Version 5. If you want to define a JMS resource at Cell level for use on non-Version 5 nodes, you should define the JMS resource for the Version 6 default messaging provider.
3. Under Additional Resources, click **WebSphere topic connection factories**. This displays a list of any existing JMS topic connection factories.

To define a new JMS topic connection factory, click **New**.

To view or change the properties of a connection factory, select its name in the list displayed.

To act on one or more of the connection factories listed, click the check box next to the name of the connection factory, then use the buttons provided.

WebSphere topic connection factory settings:

Use this panel to browse or change the configuration properties of the selected JMS topic connection factory for publish/subscribe messaging by WebSphere Application Server version 5 applications.

A WebSphere topic connection factory is used to create JMS connections to the default messaging provider for use by WebSphere Application Server version 5 applications.

To view this page, use the administrative console to complete the following steps:

1. In the navigation pane, click **Resources** → **JMS Providers** → **V5 Default Messaging**.
2. **(Optional)** In the content pane, change the **Scope** setting to the level at which JMS resources are visible to applications. If you define a Version 5 JMS resource at the Cell scope level, all users in the cell can look up and use that JMS resource.
3. Under Additional Resources, click **WebSphere topic connection factories**. This displays a list of any existing JMS topic connection factories.
4. Click the name of the JMS topic connection factory that you want to work with.

A JMS topic connection factory for use with the Version 5 default messaging provider has the following properties.

Scope:

Specifies the level to which this resource definition is visible to applications.

Resources such as messaging providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates which are defined at more general scopes.

The scope displayed is for information only, and cannot be changed on this panel. If you want to browse or change this resource (or other resources) at a different scope, change the scope on the messaging provider settings panel, then click **Apply**, before clicking the link for the type of resource.

Data type	String

Name:

The name by which this JMS topic connection factory is known for administrative purposes within IBM WebSphere Application Server. The name must be unique within the JMS connection factories across the WebSphere administrative domain.

Data type	String
Default	Null

JNDI name:

The JNDI name that is used to bind the topic connection factory into the name space.

As a convention, use the fully qualified JNDI name; for example, in the form jms/*Name*, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type	String

Description:

A description of this topic connection factory for administrative purposes within IBM WebSphere Application Server.

Data type	String
Default	Null

Category:

A category used to classify or group this topic connection factory, for your IBM WebSphere Application Server administrative records.

Data type	String

Node:

The WebSphere node name of the administrative node where the JMS server runs for this connection factory. Connections created by this factory connect to that JMS server.

Data type	Enum
Default	Null
Range	Pull-down list of nodes in the WebSphere administrative domain.

Port:

Which of the two ports that connections use to connect to the JMS server. The QUEUED port is for full-function JMS publish/subscribe support, the DIRECT port is for non-persistent, non-transactional, non-durable subscriptions only.

Note: Message-driven beans cannot use the direct listener port for publish/subscribe support. Therefore, any topic connection factory configured with **Port** set to `Direct` cannot be used with message-driven beans.

Data type	Enum
Units	Not applicable
Default	QUEUED
Range	**QUEUED** The listener port used for full-function JMS-compliant, publish/subscribe support. **DIRECT** The listener port used for direct TCP/IP connection (non-transactional, non-persistent, and non-durable subscriptions only) for publish/subscribe support.

Component-managed Authentication Alias:

This alias specifies a user ID and password to be used to authenticate connection to the messaging provider for application-managed authentication.

This property provides a list of the J2C authentication data entry aliases that have been defined to WebSphere Application Server. You can select a data entry alias to be used to authenticate the creation of a new connection to the JMS provider.

If you have enabled global security for WebSphere Application Server, select the alias that specifies the user ID and password used to authenticate the creation of a new connection to the messaging provider. The use of this alias depends on the resource authentication (res-auth) setting declared in the connection factory resource reference of an application component's deployment descriptors.

Note: User IDs longer than 12 characters cannot be used for authentication with the Version 5 default messaging provider. For example, the default Windows NT user ID, **Administrator**, is not valid because it contains 13 characters. Therefore, an authentication alias for a WebSphere topic connection factory must specify a user ID no longer than 12 characters.

Container-managed Authentication Alias:

This alias specifies a user ID and password to be used to authenticate connection to the messaging provider for container-managed authentication.

This field is deprecated in 6.0. The specification of a login configuration and associated properties on the component resource reference determines the container-managed authentication strategy when the res-auth value is Container. If the 'DefaultPrincipalMapping' login configuration is used, the associated property is a container-managed authentication alias. This field is used only in the absence of a loginConfiguration on the component resource reference. To define a new alias, see the related item J2EE Connector Architecture (J2C) authentication data entries.

This property provides a list of the J2C authentication data entry aliases that have been defined to WebSphere Application Server. You can select a data entry alias to be used to authenticate the creation of a new connection to the JMS provider.

If you have enabled global security for WebSphere Application Server, select the alias that specifies the user ID and password used to authenticate the creation of a new connection to the JMS provider. The use of this alias depends on the resource authentication (res-auth) setting declared in the connection factory resource reference of an application component's deployment descriptors.

Note: User IDs longer than 12 characters cannot be used for authentication with the embedded WebSphere JMS provider. For example, the default Windows NT user ID, **Administrator**, is not valid for use with embedded WebSphere messaging, because it contains 13 characters. Therefore, an authentication alias for a WebSphere JMS provider connection factory must specify a user ID no longer than 12 characters.

Mapping-Configuration Alias:

The module used to map authentication aliases.

This field is deprecated in 6.0. The specification of a login configuration and associated properties on the component resource reference determines the container-managed authentication strategy when the res-auth value is Container. This field is used only in the absence of a loginConfiguration on the component resource reference.

This field provides a list of the modules that have been configured on the **Security** → **JAAS Configuration** → **Application Logins Configuration** property. For more information about the mapping configurations, see Java Authentication and Authorization service configuration entry settings.

Data type	Enum
Default	Null
Range	**ClientContainer** The client container maps authentication aliases. **WSLogin** The WSLogin module maps authentication aliases. **DefaultPrincipalMapping** The JAAS configuration maps an authentication alias to its userid and password.

Clone Support:

Select this checkbox to enable clone support to allow the same durable subscription across topic clones.

Data type	Enum
Default	Cleared
Range	**Selected** Clone support is enabled. **Cleared** Clone support is disabled.

If you select this property, you must also specify a value for the **Client ID** property.

Client ID:

The JMS client identifier used for connections to the queue manager.

Data type	String
Range	A valid JMS client ID

XA Enabled:

Specifies whether the connection factory is for XA or non-XA coordination of messages and controls if the application server uses XA QCF/TCF. Enable XA if multiple resources are not used in the same transaction.

If you clear this checkbox property (for non-XA coordination), the JMS session is still enlisted in a transaction, but uses the resource manager local transaction calls (session.commit and session.rollback) instead of XA calls. This can lead to an improvement in performance. However, this means that only a single resource can be enlisted in a transaction in WebSphere Application Server.

Last participant support enables you to enlist one non-XA resource with other XA-capable resources.

For a WebSphere Topic Connection Factory with the **Port** property set to `DIRECT` this property does not apply, and always adopts non-XA coordination.

Data type	Checkbox
Default	Selected (enabled for XA coordination)
Range	**Selected** The connection factory is enabled for XA-coordination of messages **Cleared** The connection factory is not enabled for XA coordination of messages

Recommended	Do not enable XA coordination when the message queue or topic received is the only resource in the transaction. Enable XA coordination when other resources, including other queues or topics, are involved.

Connection pool:

Specifies an optional set of connection pool settings.

Connection pool properties are common to all J2C connectors.

The application server pools connections and sessions with the messaging provider to improve performance. You need to configure the connection and session pool properties appropriately for your applications, otherwise you may not get the connection and session behavior that you want.

Change the size of the connection pool if concurrent server-side access to the JMS resource exceeds the default value. The size of the connection pool is set on a per queue or topic basis.

Session pool:

An optional set of session pool settings.

This link provides a panel of optional connection pool properties, common to all J2C connectors.

The application server pools connections and sessions with the JMS provider to improve performance. You need to configure the connection and session pool properties appropriately for your applications, otherwise you may not get the connection and session behavior that you want.

Version 5 WebSphere queue destination collection:

Use this panel to list JMS queue for point-to-point messaging for use by WebSphere Application Server version 5 applications.

This panel shows a list of the JMS queue destinations with a summary of their configuration properties.

To view this page, use the administrative console to complete the following steps:
1. In the navigation pane, click **Resources** → **JMS Providers** → **V5 Default Messaging**.
2. **(Optional)** In the content pane, change the **Scope** setting to the level at which JMS resources are visible to applications. If you define a Version 5 JMS resource at the Cell scope level, all users in the cell can look up and use that JMS resource. However, the JMS resource has only the subset of properties that apply to WebSphere Application Server Version 5. If you want to define a JMS resource at Cell level for use on non-Version 5 nodes, you should define the JMS resource for the Version 6 default messaging provider.
3. Under Additional Resources, click **WebSphere queue destinations**. This displays a list of any existing JMS queue destinations.

To define a new JMS queue destination, click **New**.

To view or change the properties of a queue destination, select its name in the list displayed.

To act on one or more of the queue destinations listed, click the check box next to the name of the queue, then use the buttons provided.

Version 5 WebSphere queue destination settings:

Use this panel to view or change the configuration properties of the selected JMS queue destination for point-to-point messaging by WebSphere Application Server version 5 applications.

A queue destination is used to configure a JMS queue of the default messaging provider for use by WebSphere Application Server version 5 applications. Connections to the queue are created by the associated V5 Default Messaging WebSphere queue connection factory.

To view this page, use the administrative console to complete the following steps:
1. In the navigation pane, click **Resources** → **JMS Providers** → **V5 Default Messaging**.
2. **(Optional)** In the content pane, change the **Scope** setting to the level at which JMS resources are visible to applications. If you define a Version 5 JMS resource at the Cell scope level, all users in the cell can look up and use that JMS resource. However, the JMS resource has only the subset of properties that apply to WebSphere Application Server Version 5. If you want to define a JMS resource at Cell level for use on non-Version 5 nodes, you should define the JMS resource for the Version 6 default messaging provider.
3. Under Additional Resources, click **WebSphere queue destinations**. This displays a list of any existing JMS queue destinations.
4. Click the name of the JMS queue destination that you want to work with.

A JMS queue for use with the internal WebSphere JMS provider has the following properties.

Scope:

Specifies the level to which this resource definition is visible to applications.

Resources such as messaging providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates which are defined at more general scopes.

The scope displayed is for information only, and cannot be changed on this panel. If you want to browse or change this resource (or other resources) at a different scope, change the scope on the messaging provider settings panel, then click **Apply**, before clicking the link for the type of resource.

Data type	String

Name:

The name by which the queue is known for administrative purposes within IBM WebSphere Application Server.

To enable applications to use this queue, you must add the queue name to the Queue Names field on the panel for the JMS server that hosts the queue.

Data type	String

JNDI name:

The JNDI name that is used to bind the queue into the application server's name space.

As a convention, use the fully qualified JNDI name; for example, in the form jms/*Name*, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type	String

Description:

A description of the queue, for administrative purposes

Data type	String
Default	Null

Category:

A category used to classify or group this queue, for your IBM WebSphere Application Server administrative records.

Data type	String

Persistence:

Whether all messages sent to the destination are persistent, non-persistent, or have their persistence defined by the application

Data type
Enum

Default
APPLICATION DEFINED

Range

APPLICATION DEFINED
Messages on the destination have their persistence defined by the application that put them onto the queue.

NON PERSISTENT
Messages on the destination are not persistent.

PERSISTENT
Messages on the destination are persistent. When a persistent message is put to a queue, all of the message data is written to the messaging log (under the *embedded_messaging_install*\log directory) to make recovery of the message possible.

Priority:

Whether the message priority for this destination is defined by the application or the **Specified priority** property

Data type	Enum
Default	APPLICATION DEFINED

Range	**APPLICATION DEFINED** The priority of messages on this destination is defined by the application that put them onto the destination. **QUEUE DEFINED** [WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties. **SPECIFIED** The priority of messages on this destination is defined by the **Specified priority** property.*If you select this option, you must define a priority on the **Specified priority** property.*

Specified priority:

If the **Priority** property is set to `Specified`, type here the message priority for this queue, in the range 0 (lowest) through 9 (highest)

If the **Priority** property is set to `Specified`, messages sent to this queue have the priority value specified by this property.

Data type	Integer
Units	Message priority level
Default	0
Range	0 (lowest priority) through 9 (highest priority)

Expiry:

Whether the expiry timeout for this queue is defined by the application or the **Specified expiry** property, or messages on the queue never expire (have an unlimited expiry timeout)

Data type	Enum
Default	APPLICATION DEFINED
Range	**APPLICATION DEFINED** The expiry timeout for messages on this queue is defined by the application that put them onto the queue. **UNLIMITED** Messages on this queue have no expiry timeout, so those messages never expire. **SPECIFIED** The expiry timeout for messages on this queue is defined by the **Specified expiry** property.*If you select this option, you must define a timeout on the **Specified expiry** property.*

Specified expiry:

If the **Expiry timeout** property is set to `Specified`, type here the number of milliseconds (greater than 0) after which messages on this queue expire

Data type	Integer
Units	Milliseconds
Default	0

Range	Greater than or equal to 0 • 0 indicates that messages never timeout • Other values are an integer number of milliseconds

Version 5 WebSphere topic destination collection:

Use this panel to list JMS topic destinations for publish/subscribe messaging with the default messaging provider on a Version 5 node in the deployment manager cell.

This panel shows a list of JMS topic destinations with a summary of their configuration properties.

To view this page, use the administrative console to complete the following steps:
1. In the navigation pane, click **Resources** → **JMS Providers** → **V5 Default Messaging**.
2. **(Optional)** In the content pane, change the **Scope** setting to the level at which JMS resources are visible to applications. If you define a Version 5 JMS resource at the Cell scope level, all users in the cell can look up and use that JMS resource. However, the JMS resource has only the subset of properties that apply to WebSphere Application Server Version 5. If you want to define a JMS resource at Cell level for use on non-Version 5 nodes, you should define the JMS resource for the Version 6 default messaging provider.
3. Under Additional Resources, click **WebSphere topic destinations**. This displays a list of any existing JMS topic destinations.

To define a new JMS topic connection factory, click **New**.

To browse or change the properties of a topic destination, select its name in the list displayed.

To act on one or more of the topic destinations listed, click the check box next to the name of the topic, then use the buttons provided.

Version 5 WebSphere topic destination settings:

Use this panel to browse or change the configuration properties of the selected JMS topic destination for publish/subscribe messaging by WebSphere application server version 5 applications.

A WebSphere topic destination is used to configure the properties of a JMS topic for the default messaging provider on a Version 5 node in the deployment manager cell. Connections to the topic are created by the associated topic connection factory.

To view this page, use the administrative console to complete the following steps:
1. In the navigation pane, click **Resources** → **JMS Providers** → **V5 Default Messaging**.
2. **(Optional)** In the content pane, change the **Scope** setting to the level at which JMS resources are visible to applications. If you define a Version 5 JMS resource at the Cell scope level, all users in the cell can look up and use that JMS resource. However, the JMS resource has only the subset of properties that apply to WebSphere Application Server Version 5. If you want to define a JMS resource at Cell level for use on non-Version 5 nodes, you should define the JMS resource for the Version 6 default messaging provider.
3. Under Additional Resources, click **WebSphere topic destinations**. This displays a list of any existing JMS topic destinations.
4. Click the name of the JMS topic destination that you want to work with.

A JMS topic destination for use with the Version 5 default messaging provider has the following properties.

Scope:

Specifies the level to which this resource definition is visible to applications.

Resources such as messaging providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates which are defined at more general scopes.

The scope displayed is for information only, and cannot be changed on this panel. If you want to browse or change this resource (or other resources) at a different scope, change the scope on the messaging provider settings panel, then click **Apply**, before clicking the link for the type of resource.

Data type	String

Name:

The name by which the topic is known for administrative purposes within IBM WebSphere Application Server.

Data type	String

JNDI name:

The JNDI name that is used to bind the topic into the application server's name space.

As a convention, use the fully qualified JNDI name; for example, in the form jms/*Name*, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type	String

Description:

A description of the topic, for administrative purposes within IBM WebSphere Application Server.

Data type	String
Default	Null

Category:

A category used to classify or group this topic, for your IBM WebSphere Application Server administrative records.

Data type	String

Topic:

The name of the topic as defined to the JMS provider.

Data type	String
Default	Null
Range	The topic value can be dot notation and include wildcard characters.

Persistence:

Whether all messages sent to the destination are persistent, non-persistent, or have their persistence defined by the application

Data type	Enum
Default	APPLICATION DEFINED
Range	**APPLICATION DEFINED** Messages on the destination have their persistence defined by the application that put them onto the queue. **NON-PERSISTENT** Messages on the destination are not persistent. **PERSISTENT** Messages on the destination are persistent.

Priority:

Whether the message priority for this destination is defined by the application or the **Specified priority** property

Data type	Enum
Units	Not applicable
Default	APPLICATION DEFINED
Range	**APPLICATION DEFINED** The priority of messages on this destination is defined by the application that put them onto the destination. **QUEUE DEFINED** [WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties. **SPECIFIED** The priority of messages on this destination is defined by the **Specified priority** property. *If you select this option, you must define a priority on the **Specified priority** property.*

Specified priority:

If the **Priority** property is set to `Specified`, type here the message priority for this queue, in the range 0 (lowest) through 9 (highest)

If the **Priority** property is set to `Specified`, messages sent to this queue have the priority value specified by this property.

Data type	Integer
Units	Message priority level
Default	0
Range	0 (lowest priority) through 9 (highest priority)

Expiry:

Whether the expiry timeout for this queue is defined by the application or the **Specified expiry** property, or messages on the queue never expire (have an unlimited expiry timeout)

Data type	Enum
Units	Not applicable
Default	APPLICATION DEFINED
Range	**APPLICATION DEFINED** The expiry timeout for messages on this queue is defined by the application that put them onto the queue. **UNLIMITED** Messages on this queue have no expiry timeout, so those messages never expire. **SPECIFIED** The expiry timeout for messages on this queue is defined by the **Specified expiry** property. *If you select this option, you must define a timeout on the **Specified expiry** property.*

Specified expiry:

If the **Expiry timeout** property is set to `Specified`, type here the number of milliseconds (greater than 0) after which messages on this queue expire

Data type	Integer
Units	Milliseconds
Default	0
Range	Greater than or equal to 0 • 0 indicates that messages never timeout • Other values are an integer number of milliseconds

Configuring Version 5 default JMS resources

Use the following tasks to configure the JMS connection factories and destinations WebSphere application server version 5 applications.

You only need to complete these tasks if you have WebSphere application server version 5 applications that need to use JMS resources provided by the default messaging provider. Such JMS resources are maintained as V5 Default Messaging resources.

- Configuring a Version 5 default JMS queue connection factory
- Configuring a Version 5 default JMS topic connection factory
- Configuring a Version 5 default JMS queue destination
- Configuring a Version 5 default JMS topic destination

Configuring a Version 5 queue connection factory:

Use this task to browse or change the properties of a JMS queue connection factory for point-to-point messaging with the default messaging provider on a Version 5 node in the deployment manager cell. This task contains an optional step for you to create a new JMS queue connection factory.

To configure a JMS queue connection factory for use by WebSphere application server version 5 applications, use the administrative console to complete the following steps:

1. Display the version 5 default messaging provider. In the navigation pane, expand **Resources** → **JMS Providers** → **V5 Default Messaging**.
2. **Optional:** Change the **Scope** setting to the level at which the JMS queue connection factory is visible to applications. If you define a Version 5 JMS resource at the Cell scope level, all users in the cell can look up and use that JMS resource.

3. In the content pane, under Additional Properties, click **WebSphere queue connection factories** This displays any existing JMS queue connection factories for the Version 5 messaging provider in the content pane.
4. To browse or change an existing JMS queue connection factory, click its name in the list. Otherwise, to create a new connection factory, complete the following steps:
   a. Click **New** in the content pane.
   b. Specify the following required properties. You can specify other properties, as described in a later step.

      Name The name by which this JMS queue connection factory is known for administrative purposes within IBM WebSphere Application Server.

      JNDI Name
      The JNDI name that is used to bind the JMS queue connection factory into the name space.

   c. Click **Apply**. This defines the JMS queue connection factory to WebSphere Application Server, and enables you to browse or change additional properties.
5. **Optional:** Change properties for the queue connection factory, according to your needs.
6. Click **OK**.
7. Save any changes to the master configuration.
8. To have the changed configuration take effect, stop then restart the application server.

Configuring a Version 5 JMS topic connection factory:

Use this task to browse or change a JMS topic connection factory for publish/subscribe messaging by WebSphere application server version 5 applications.

To configure a JMS topic connection factory for use by WebSphere application server version 5 applications, use the administrative console to complete the following steps:

1. Display the version 5 default messaging provider. In the navigation pane, expand **Resources** → **JMS Providers** → **V5 Default Messaging**.
2. **Optional:** Change the **Scope** setting to the level at which the JMS topic connection factory is visible to applications. If you define a Version 5 JMS resource at the Cell scope level, all users in the cell can look up and use that JMS resource.
3. In the content pane, under Additional Properties, click **WebSphere topic connection factories** This displays any existing JMS topic connection factories for the Version 5 messaging provider in the content pane.
4. To browse or change an existing JMS topic connection factory, click its name in the list. Otherwise, to create a new connection factory, complete the following steps:
   a. Click **New** in the content pane.
   b. Specify the following required properties. You can specify other properties, as described in a later step.

      Name The name by which this JMS topic connection factory is known for administrative purposes within IBM WebSphere Application Server.

      JNDI Name
      The JNDI name that is used to bind the JMS topic connection factory into the name space.

   c. Click **Apply**. This defines the JMS topic connection factory to WebSphere Application Server, and enables you to browse or change additional properties.
5. **Optional:** Change properties for the topic connection factory, according to your needs.
6. Click **OK**.
7. Save any changes to the master configuration.

8. To have the changed configuration take effect, stop then restart the application server.

Configuring a Version 5 WebSphere queue destination:

Use this task to browse or change the properties of a JMS queue destination for point-to-point messaging by WebSphere Application Server version 5 applications. This task contains an optional step for you to create a new topic destination.

To configure a JMS queue destination for use by WebSphere application server version 5 applications, use the administrative console to complete the following steps:

1. Display the version 5 default messaging provider. In the navigation pane, expand **Resources** → **JMS Providers** → **V5 Default Messaging**.
2. **Optional:** Change the **Scope** setting to the level at which the JMS destination is visible to applications. If you define a Version 5 JMS resource at the Cell scope level, all users in the cell can look up and use that JMS resource.
3. In the content pane, under Additional Properties, click **WebSphere queue destinations** This displays any existing queue destinations for the Version 5 default messaging provider in the content pane.
4. To browse or change an existing JMS queue destination, click its name in the list. Otherwise, to create a new queue destination, complete the following steps:
   a. Click **New** in the content pane.
   b. Specify the following required properties. You can specify other properties, as described in a later step.

      Name The name by which this queue destination is known for administrative purposes within IBM WebSphere Application Server.

      JNDI Name
      The JNDI name that is used to bind the queue destination into the name space.

   c. Click **Apply**. This defines the queue destination to WebSphere Application Server, and enables you to browse or change additional properties.
5. **Optional:** Change properties for the queue destination, according to your needs.
6. Click **OK**.
7. Save any changes to the master configuration.
8. To make a queue destination available to applications, you need to host the queue on a JMS server. To add a new queue to a JMS server or to change an existing queue on a JMS server, you define the administrative name of the queue to the JMS server, as described in Managing Version 5 JMS servers in a deployment manager cell.
9. To have the changed configuration take effect, stop then restart the application server.

Configuring a version 5 WebSphere topic destination:

Use this task to browse or change the properties of a JMS topic destination for publish/subscribe messaging by WebSphere application server version 5 applications.. This task contains an optional step for you to create a new topic destination.

To configure a JMS topic destination for use WebSphere application server version 5 applications, use the administrative console to complete the following steps:

1. Display the version 5 default messaging provider. In the navigation pane, expand **Resources** → **JMS Providers** → **V5 Default Messaging**.
2. **Optional:** Change the **Scope** setting to the level at which the JMS destination is visible to applications. If you define a Version 5 JMS resource at the Cell scope level, all users in the cell can look up and use that JMS resource.

3. In the content pane, under Additional Properties, click **WebSphere topic destinations** This displays any existing JMS topic destinations for the Version 5 default messaging provider in the content pane.
4. To browse or change an existing JMS topic destination, click its name in the list. Otherwise, to create a new topic destination, complete the following steps:
   a. Click **New** in the content pane.
   b. Specify the following required properties. You can specify other properties, as described in a later step.

      Name The name by which this topic destination is known for administrative purposes within IBM WebSphere Application Server.

      JNDI Name
      The JNDI name that is used to bind the topic destination into the name space.

      Topic The name of the topic in the default messaging provider, to which messages are sent.
   c. Click **Apply**. This defines the topic destination to WebSphere Application Server, and enables you to browse or change additional properties.
5. **Optional:** Change properties for the topic destination, according to your needs.
6. Click **OK**.
7. Save any changes to the master configuration.
8. To have the changed configuration take effect, stop then restart the application server.

Managing Version 5 JMS servers in a deployment manager cell

Use this task to manage JMS servers on WebSphere Application Server version 5 nodes in a deployment manager cell.

The use of JMS servers is only intended to support migration from WebSphere Application Server version 5 nodes to WebSphere Application Server version 6.

In a WebSphere Application Server deployment manager cell, each Version 5 node can have at most one JMS server, and any Version 5 application server within the cell can use JMS resources served by any of those JMS servers. Applications on WebSphere Application Server version 6 can also use JMS resources served by any of those JMS servers.

You can use the WebSphere administrative console to display a list of all version 5 JMS servers, to show and control their runtime status. You can also configure a general set of JMS server properties, which add to the default values of properties configured automatically for the version 5 default messaging provider.

Note: In general, the default values of properties for the version 5 default messaging provider are adequate for JMS servers. However, if you are running high messaging loads, you may need to change some WebSphere MQ properties; for example, WebSphere MQ properties for log file locations, file pages, and buffer pages. For more information about configuring WebSphere MQ properties, see the *WebSphere MQ System Administration* book, SC33-1873, which is available from the IBM Publications Center or from the WebSphere MQ collection kit, SK2T-0730.

To manage a version 5 JMS server, use the administrative console to complete the following steps:
1. In the navigation pane, select **Servers → JMS Servers** This displays a table of the JMS servers, showing their runtime status.
2. **Optional:** If you want to change the runtime status of a JMS server, complete the following steps:
   a. In the table of JMS servers, select the JMS servers that you want to act on.
      - To act on one or more specific JMS servers, select the check box next to the JMS server name.
      - To act on all JMS servers, select the check box next to the JMS servers title of the table.
   b. Click one of the actions displayed to change the status of the JMS servers; for example, click **Stop** to stop a JMS server.

The status of the JMS servers that you have acted on is updated to show the result of your actions.

3. **Optional:** If you want to change the properties of a JMS server, complete the following steps:
   a. Click the name of the server
   b. Set one or more of the following configuration properties:

      Initial state
      If you want the JMS server to be started automatically when the application server is next started, set this property to `Started`.

      Number of threads
      Set the number of concurrent threads to be used by the publish/subscribe matching engine. The number of concurrent threads should only be set to a small number.
4. **Optional:** If you want the JMS server to host a new JMS queue, add the queue name to the Queue Names field.

   The name must match the name of a JMS Queue administrative object, including the use of upper- and lowercase.
5. **Optional:** If you want to stop the JMS server hosting a JMS queue, remove the queue name from the Queue Names field.
6. Click **OK**.
7. Save your changes to the master configuration.
8. To have the changed configuration take effect, stop then restart the JMS server.

Configuring authorization security for a Version 5 default messaging provider

Use this task to configure authorization security for the default messaging provider on a WebSphere Application Server version 5 node in a deployment manager cell.

To configure authorization security for the version 5 default messaging provider complete the following steps.

Note: Security for the version 5 default messaging provider is enabled when you enable global security for WebSphere Application Server on the version 5 node. For more information about enabling global security, see Managing secured applications.

1. Configure authorization settings to access JMS resources owned by the embedded WebSphere JMS provider. Authorization to access JMS resources owned by the embedded WebSphere JMS provider is controlled by settings in the `*WAS_install_root*\config\cells\*your_cell_name*\integral-jms-authorizations.xml` file.

   The settings grant or deny authenticated userids access to internal JMS provider resources (queues or topics). As supplied, the integral-jms-authorisations.xml file grants the following permissions:
   - Read and write permissions to all queues.
   - Pub, sub, and persist to all topics.

   To configure authorization settings, edit the integral-jms-authorisations.xml file according to the information in this topic and in that file. Please note the file is in Unicode, which requires a binary FTP to the host from a workstation.
2. Edit the queue-admin-userids element to create a list of userids with administrative access to all queues. Administrative access is needed to create queues and perform other administrative activities on queues. For example, consider the following queue-admin-userids section:

   ```
   <queue-admin-userids>
       <userid>adminid1</userid>
       <userid>adminid2</userid>
   </queue-admin-userids>
   ```

   In this example the userids adminid1 and adminid2 are defined to have administrative access to all queues.

3. Edit the queue-default-permissions element to define the default queue access permissions. These permissions are used for queues for which you do not define specific permissions (in queue sections). If this section is not specified, then access permissions exist only for those queues for which you have specifically created queue elements.

   For example, consider the following queue-default-permissions element:

   ```
   <queue-default-permissions>
     <permission>write</permission>
   </queue-default-permissions>
   ```

   In this example the default access permission for all queues is **write**. This can be overridden for a specific queue by creating a queue element that sets its access permission to **read**.

4. If you want to define specific access permissions for a queue, create a queue element, then define the following elements:

   For example, consider the following queue element:

   ```
   <queue>
     <name>q1</name>
     <public>
     </public>
     <authorize>
       <userid>useridr</userid>
       <permission>read</permission>
     </authorize>
     <authorize>
       <userid>useridw</userid>
       <permission>write</permission>
     </authorize>
     <authorize>
       <userid>useridrw</userid>
       <permission>read</permission>
       <permission>write</permission>
     </authorize>
   </queue>
   ```

   In this example for the queue q1, the userid useridr has read permission, the userid useridw has write permission, the userid useridrw has both read and write permissions, and all other userids have no access permissions (<public></public>).

5. Edit topic elements to define the access permissions for publish/subscribe topic destinations.

   For topics, you can grant and deny access permissions. Full permission inheritance is supported on topics. If you do not define specific access permissions for a userid on a specific topic then permissions are inherited first from the public permissions on that topic then from the parent topic. The inheritance of access permissions continues until the root topic from which the root permissions are assumed.

   a. If you want to define default access permissions for the root topic, edit a topic element with an empty name element. If you omit such a topic section, topics have no default topic permissions other than those defined by specific topic elements. For example, consider the following topic element for the root topic:

      ```
      <topic>
         <name></name>
         <public>
           <permission>+pub</permission>
         </public>
       </topic>
      ```

      In this example, the default access permission for all topics is set to publish. This can be overridden by other topic elements for specific topic names.

   b. If you want to define access permissions for a specific topic, create a topic element with the name for the topic then define the access permissions in the public and authorize elements of the topic element. For example, consider the following topic section:

```
<topic>
  <name>a/b/c</name>
  <public>
    <permission>+sub</permission>
  </public>
  <authorize>
    <userid>useridpub</userid>
    <permission>+pub</permission>
  </authorize>
</topic>
```

In this example, the subscribe permission is granted to anyone accessing any topic whose name starts with a/b/c. Also, the userid useridpub is granted publish permission for any topic whose name starts with a/b/c.

6. Save the integral-jms-authorizations.xml file.

If the dynamic update setting is selected, changes to the integral-jms-authorizations.xml file become active when the changed file is saved, so there is no need to stop and restarted the JMS server. If the dynamic update setting is not selected, you need to stop and restart the JMS server to make changes active.

Authorization settings for Version 5 default JMS resources:

Use the integral-jms-authorisations.xml file to view or change the authorization settings for JMS resources owned by the default messaging provider on WebSphere Application Server version 5 nodes.

Authorization to access default JMS resources owned by the default messaging provider on WebSphere Application Server nodes is controlled by the following settings in the *was_install*\config\cells\your_cell_name\integral-jms-authorisations.xml file.

This structure of the settings in integral-jms-authorisations.xml is shown in the following example. Descriptions of these settings are provided after the example. To configure authorization settings, follow the instructions provided in Configuring authorization security for the Version 5 JMS providers

```
<integral-jms-authorizations>

  <dynamic-update>true</dynamic-update>

  <queue-admin-userids>
    <userid>adminid1</userid>
    <userid>adminid2</userid>
  </queue-admin-userids>

  <queue-default-permissions>
    <permission>write</permission>
  </queue-default-permissions>

  <queue>
    <name>q1</name>
    <public>
    </public>
    <authorize>
      <userid>useridr</userid>
      <permission>read</permission>
    </authorize>
    <authorize>
      <userid>useridw</userid>
      <permission>write</permission>
    </authorize>
  </queue>

  <queue>
    <name>q2</name>
    <public>
      <permission>write</permission>
    </public>
    <authorize>
      <userid>useridr</userid>
      <permission>read</permission>
    </authorize>
  </queue>

  <topic>
    <name></name>
    <public>
      <permission>+pub</permission>
    </public>
  </topic>

  <topic>
    <name>a/b/c</name>
    <public>
      <permission>+sub</permission>
    </public>
    <authorize>
      <userid>useridpub</userid>
      <permission>+pub</permission>
    </authorize>
  </topic>

</integral-jms-authorizations>
```

dynamic-update: Controls whether or not the JMS Server checks dynamically for updates to this file.

true (Default) Enables dynamic update support.

false Disables dynamic update checking and improves authorization performance.

queue-admin-userids: This element lists those userids with administrative access to all Version 5 default queue destinations. Administrative access is needed to create queues and perform other administrative activities on queues. You define each userid within a separate userid sub element:

<userid>*adminid***</userid>**

Where *adminid* is a user ID that can be authenticated by IBM WebSphere Application Server.

queue-default-permissions: This element defines the default queue access permissions that are assumed if no permissions are specified for a specific queue name. These permissions are used for queues for which you do not define specific permissions (in queue elements). If this element is not specified, then no access permissions exist unless explicitly authorized for individual queues.

You define the default permission within a separate permission sub element:

<permission>*read-write***</permission>**

Where *read-write* is one of the following keywords:

read By default, userids have read access to Version 5 default queue destinations.

write By default, userids have write access to Version 5 default queue destinations.

queue: This element contains the following authorization settings for a single queue destination:

name The name of the queue.

public The default public access permissions for the queue. This is used only for those userids that have no specific authorize element. If you leave this element empty, or do not define it at all, only those userids with authorize elements can access the queue.

You define each default permission within a separate permission element.

authorize

The access permissions for a specific userid. Within each authorize element, you define the following elements:

userid The userid that you want to assign a specific access permission.

permission

An access permission for the associated userid.

You define each permission within a separate permission element. Each permission element can contain the keyword read or write to define the access permission.

For example, consider the following queue element:

```
<queue>
  <name>q1</name>
  <public>
  </public>
  <authorize>
    <userid>useridr</userid>
    <permission>read</permission>
  </authorize>
  <authorize>
    <userid>useridw</userid>
    <permission>write</permission>
  </authorize>
  <authorize>
    <userid>useridrw</userid>
    <permission>read</permission>
    <permission>write</permission>
  </authorize>
</queue>
```

topic: This element contains the following authorization settings for a single topic destination:

Each topic element has the following sub elements:

name The name of the topic, without wildcards or other substitution characters.

public The default public access permissions for the topic. This is used only for those userids that have no specific authorize element. If you leave this element empty, or do not define it at all, only those userids with authorize elements can access the topic.

You define each default permission within a separate permission element.

authorize

The access permissions for a specific userid. Within each authorize element, you define the following elements:

userid The userid that you want to assign a specific access permission.

permission

An access permission for the associated userid.

You define each permission within a separate permission element. Each permission element can contain one of the following keywords to define the access permission:

+pub Grant publish permission

+sub Grant subscribe permission

+persist

Grant persist permission

-pub Deny publish permission

-sub Deny subscribe permission

-persist

Deny persist permission

JMS components on version 5 nodes

To provide messaging support on a WebSphere Application Server version 5 node, there is at most one JMS server and some number of JMS resources configured for the default messaging JMS provider on that node.

A JMS server on a version 5 node serves the JMS resources (connection factories and destinations) for that node. The JMS server is managed as a separate process to application servers on the same node. Any application server within the domain can access JMS resources served by any JMS server on any node in the domain.

A connection factory encapsulates the configuration properties used to create connections with the JMS provider, to enable applications to access JMS destinations.

Using JMS resources of WebSphere MQ

This topic is the entry-point into a set of topics about enabling WebSphere applications to use JMS resources provided by WebSphere MQ.

You can install WebSphere MQ as a JMS provider to WebSphere Application Server. WebSphere applications can use the JMS 1.1 interfaces or JMS 1.0.2 interfaces to access JMS resources provided by WebSphere MQ, in addition to JMS resources provided by the default messaging provider (or a generic messaging provider).

You can use the WebSphere administrative console to administer the JMS connection factories and destinations provided by WebSphere MQ.

In a mixed-version WebSphere Application Server deployment manager cell, you can administer WebSphere MQ resources on both Version 6 and Version 5 nodes. For Version 5 nodes, the administrative console presents the subset of resources and properties that are applicable to WebSphere Application Server Version 5.

For more information about using WebSphere MQ as a messaging provider to WebSphere Application Server, see the following topics:

- “Installing WebSphere MQ as a JMS provider”
- “Listing JMS resources for WebSphere MQ” on page 1288
- “Configuring JMS resources for the WebSphere MQ messaging provider” on page 1346

Installing WebSphere MQ as a JMS provider

Use this task to install and configure WebSphere MQ with support for the Java Message Service (JMS), for use as a JMS provider to WebSphere Application Server.

If you have a messaging infrastructure based on WebSphere MQ, you may either connect directly using the included support for WebSphere MQ as a JMS provider, or configure a service integration bus with links to a WebSphere MQ network and then access the bus through the default messaging provider.

- **(UNIX platforms only)** Before you install WebSphere MQ on a UNIX platform, create and mount a journalized file system called /var/mqm for your messaging working data. Use a partition strategy with a separate volume for the WebSphere MQ data. This means that other system activity is not affected if a large amount of messaging work builds up in /var/mqm. You can also create separate file systems for your log data (var/mqm/log) and error files (var/mqm/errors). You should store log files on a different physical volume from the messaging queues (var/mqm). This ensures data integrity in the case of a hardware failure. If you are creating separate file systems, allow a minimum of 30 MB of storage for /var/mqm, 20 MB of storage for /var/mqm/log, and 4 MB of storage for /var/mqm/errors.
  - The /var file system is used to store all the security logging information for the system, and is used to store the temporary files for email and printing. Therefore, it is critical that you maintain free space in /var for these operations. If you do not create a separate file system for messaging data, and /var fills up, all security logging will be stopped on the system until some free space is available in /var. Also, email and printing will no longer be possible until some free space is available in /var.
  - It is not recommended to install Rational Application Developer and WebSphere Application Server on the same machine when using WebSphere MQ.
  - For more information a security logging issue, see ″Security and WebSphere MQ″ in the information center.
  - For more information about creating file systems for WebSphere MQ, and WebSphere MQ space requirements for /var file systems, see the section “Preparing for Installation: Creating WebSphere MQ file systems” in the appropriate WebSphere MQ *Quick Beginnings* book.
  - For other installation prerequisites, see the appropriate WebSphere MQ *Quick Beginnings* book, as follows:

- *WebSphere MQ for Windows, Quick Beginnings*, GC34-6073
- *WebSphere MQ for AIX, Quick Beginnings*, GC34-6076
- *WebSphere MQ for Solaris, Quick Beginnings*, GC34-6075
- *WebSphere MQ for HP-UX, Quick Beginnings*, GC34-6077
- *WebSphere MQ for Linux for Intel and Linux for zSeries, Quick Beginnings*, GC34-6078

You can get these books from the WebSphere MQ messaging platform-specific books Web page at http://www-3.ibm.com/software/ts/mqseries/library/manualsa/manuals/platspecific.html

To install and configure WebSphere MQ for use as a JMS provider to IBM WebSphere Application Server, complete the following steps:

1. Install a supported version of WebSphere MQ, with the required MQ features, as described in the installation instructions provided with WebSphere MQ.

   To identify the a supported version of WebSphere MQ, see the Supported hardware and software Web page at http://www.ibm.com/software/webservers/appserv/doc/latest/prereq.html.

   For information about installing WebSphere MQ, or migrating to a supported version of WebSphere MQ from an earlier version, see the appropriate WebSphere MQ *Quick Beginnings* book, as listed above.

   (RHEL 3.0 and SLES 8) After you install WebSphere MQ on any of the following platforms, but before you try to accept the license, apply the fix located at: http://l3.hursley.ibm.com/cgi-bin/ViewPRB.pl?1812. Otherwise, you may see a segmentation fault error when attempting to run the `mqlicense.sh -accept` command to accept the WebSphere MQ license agreement. Also, export the following variable: `LD_ASSUME_KERNEL=2.4.19`

   - Red Hat Enterprise Linux (RHEL) 3.0 on Intel or s390
   - SUSE Linux Enterprise Server (SLES) 8 on Intel
2. If you want to use WebSphere MQ - Publish/Subscribe support, you need to provide a Publish/Subscribe broker.

   For example, you can do this by using either WebSphere MQ Event Broker or WebSphere MQ Integrator (formerly MQSeries Integrator). For more information about these products, see the following Web sites:
   - WebSphere MQ Event Broker Web site at http://www-4.ibm.com/software/ts/mqseries/platforms/#eventb
   - WebSphere MQ Integrator Web site at http://www-4.ibm.com/software/ts/mqseries/platforms/#integrator
3. Follow the WebSphere MQ instructions for verifying your installation setup.
4. AIX For AIX, see the WebSphere MQ readme.txt for additional steps.
5. If you want to install IBM WebSphere Application Server on the same host as WebSphere MQ, and have not yet done so, install IBM WebSphere Application Server.
6. Set the MQJMS_LIB_ROOT environment variable to the directory where WebSphereMQ\Java\lib is installed. IBM WebSphere Application Server uses the MQJMS_LIB_ROOT to locate the WebSphere MQ libraries for the WebSphere MQ JMS Provider.

This task has installed WebSphere MQ for use as a JMS provider for WebSphere Application Server.

You can configure JMS resources to be provided by WebSphere MQ, by using the WebSphere administrative console to define WebSphere MQ resources.

(UNIX platforms only) Restrict access to the messaging errors directories and logging files, by using the following commands. This is part of the procedure to secure the directories and log files needed for WebSphere MQ, as described in Securing messaging directories and log files.

1. For the /var/mqm/errors directory:

```
chmod 3777 /var/mqm/errors
chown mqm:mqm /var/mqm/errors

touch /var/mqm/errors/AMQERR01.LOG
chown mqm:mqm /var/mqm/errors/AMQERR01.LOG
chmod 666 /var/mqm/errors/AMQERR01.LOG

touch /var/mqm/errors/AMQERR02.LOG
chown mqm:mqm /var/mqm/errors/AMQERR02.LOG
chmod 666 /var/mqm/errors/AMQERR02.LOG

touch /var/mqm/errors/AMQERR03.LOG
chown mqm:mqm /var/mqm/errors/AMQERR03.LOG
chmod 666 /var/mqm/errors/AMQERR03.LOG
```

2. For the /var/mqm/qmgrs/@SYSTEM/errors directory:

```
chmod 3777 /var/mqm/qmgrs/@SYSTEM/errors
chown mqm:mqm /var/mqm/qmgrs/@SYSTEM/errors

touch /var/mqm/qmgrs/@SYSTEM/errors/AMQERR01.LOG
chown mqm:mqm /var/mqm/qmgrs/@SYSTEM/errors/AMQERR01.LOG
chmod 666 /var/mqm/qmgrs/@SYSTEM/errors/AMQERR01.LOG

touch /var/mqm/qmgrs/@SYSTEM/errors/AMQERR02.LOG
chown mqm:mqm /var/mqm/qmgrs/@SYSTEM/errors/AMQERR02.LOG
chmod 666 /var/mqm/qmgrs/@SYSTEM/errors/AMQERR02.LOG

touch /var/mqm/qmgrs/@SYSTEM/errors/AMQERR03.LOG
chown mqm:mqm /var/mqm/qmgrs/@SYSTEM/errors/AMQERR03.LOG
chmod 666 /var/mqm/qmgrs/@SYSTEM/errors/AMQERR03.LOG
```

Listing JMS resources for WebSphere MQ

Use this task with the WebSphere administrative console to list the JMS resources provided by WebSphere MQ as a messaging provider.

You can use the WebSphere administrative console to display lists of the following types of JMS resources provided by WebSphere MQ. You can use the panels displayed to select JMS resources to administer, or to create or delete JMS resources (where appropriate).

To display administrative lists of JMS resources for WebSphere MQ, complete the following general steps:

1. Start the WebSphere administrative console.
2. In the navigation pane, click **Resources** → **JMS Providers** → **WebSphere MQ**
3. If appropriate, in the content pane, change the scope of the WebSphere MQ messaging provider. If the scope is set to node or server scope for a Version 5 node, the administrative console presents the subset of resources and properties that are applicable to WebSphere Application Server Version 5.
4. In the content pane, under Additional Resources, click the link for the type of JMS resource. This displays a list of any existing resources of the selected type. For more information about the settings panels displayed for resources, see the related reference topics.

WebSphere MQ connection factory collection:

The unified JMS connection factories configured in the WebSphere MQ messaging provider, for both point-to-point and publish/subscribe messaging.

This panel shows a list of the WebSphere MQ unified JMS connection factories with a summary of their configuration properties. In a deployment manager cell, these connection factories are not available for Version 5 nodes.

This type of connection factory is sometimes called a “unified” or “domain-independent” JMS connection factory, and supports the JMS 1.1 domain-independent interfaces (referred to as the ″common interfaces″

in the JMS specification). This enables applications to use the same, common, interfaces for both point-to-point and publish/subscribe messaging. A unified JMS connection factory also supports the domain-specific (queue and topic) interfaces, as used in JMS 1.0.2, so applications can still use those interfaces.

To view this page, use the administrative console to complete the following steps:
1. In the navigation pane, expand **Resources** → **JMS Providers** → **WebSphere MQ**.
2. In the content pane, ensure that the scope is set to cell scope or to node or server scope for a Version 6 node.
3. In the content pane, under Additional Resources, click **WebSphere MQ connection factories**. This displays a list of any existing JMS queue connection factories.

To define a new connection factory, click **New**.

To view or change the properties of a queue connection factory, click its name in the list displayed.

To act on one or more of the connection factories listed, select the check boxes next to the names of the objects that you want to act on, then use the buttons provided.

WebSphere MQ connection factory settings:

Use this panel to view or change the configuration properties of the selected JMS connection factory for use with WebSphere MQ as a JMS provider. These configuration properties control how connections are created to associated JMS queues and topics.

This type of connection factory is sometimes called a “unified” or “domain-independent” JMS connection factory, and supports the JMS 1.1 domain-independent interfaces (referred to as the ″common interfaces″ in the JMS specification). This enables applications to use the same, common, interfaces for both point-to-point and publish/subscribe messaging. A unified JMS connection factory also supports the domain-specific (queue and topic) interfaces, as used in JMS 1.0.2, so applications can still use those interfaces.

To view this page, use the administrative console to complete the following steps:
1. In the navigation pane, expand **Resources** → **JMS Providers** → **WebSphere MQ**.
2. In the content pane, ensure that the scope is set to cell scope, or to node or server scope for a Version 6 node.
3. In the content pane, under Additional Resources, click **WebSphere MQ connection factories**.
4. Click the name of the JMS connection factory that you want to work with.

A unified JMS connection factory for the WebSphere MQ JMS provider has the following properties.

Note:
- The property values that you specify must match the values that you specified when configuring WebSphere MQ for JMS resources. For more information about configuring WebSphere MQ JMS resources, see the WebSphere MQ *Using Java* book. and the *WebSphere MQ System Administration* book, SC33-1873, which are available from the WebSphere MQ messaging platform-specific books Web page at http://www-3.ibm.com/software/ts/mqseries/library/manualsa/manuals/platspecific.html, the IBM Publications Center, or from the WebSphere MQ collection kit, SK2T-0730.
- In WebSphere MQ, names can have a maximum of 48 characters, with the exception of channels which have a maximum of 20 characters.
- For more information about setting SSL properties for WebSphere MQ, see the section SSL properties in the *WebSphere MQ Using Java* book.

Scope:

Specifies the level to which this resource definition is visible to applications.

Resources such as messaging providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates which are defined at more general scopes.

The scope displayed is for information only, and cannot be changed on this panel. If you want to browse or change this resource (or other resources) at a different scope, change the scope on the messaging provider settings panel, then click **Apply**, before clicking the link for the type of resource.

Data type	String

Name:

The name by which this JMS connection factory is known for administrative purposes within IBM WebSphere Application Server. The name must be unique within the JMS connection factories across the WebSphere administrative domain.

Data type	String

JNDI name:

The JNDI name that is used to bind the connection factory into the name space.

As a convention, use the fully qualified JNDI name; for example, in the form jms/*Name*, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type	String

Description:

A description of this connection factory for administrative purposes within IBM WebSphere Application Server.

Data type	String
Default	Null

Category:

A category used to classify or group this connection factory, for your IBM WebSphere Application Server administrative records.

Data type	String

Authentication mechanism preference:

The authentication mechanism to be used for connections to WebSphere MQ created by this connection factory.

If WebSphere MQ is not configured to support the authentication mechanism preference, it is ignored.

Data type	Enum
Default	BASIC PASSWORD
Range	**BASIC PASSWORD** Authentication is performed based on a user ID and password provided by an authentication alias. The authentication alias used is obtained from one of the following properties: • Component-managed Authentication Alias, for application-managed authentication. • Container-managed Authentication Alias, for container-managed authentication. **KerbV5** Authentication is performed based on SSL certificates.

Component-managed authentication alias:

This alias specifies a user ID and password to be used to authenticate connection to a JMS provider for application-managed authentication.

This property provides a list of the J2C authentication data entry aliases that have been defined to WebSphere Application Server. You can select a data entry alias to be used to authenticate the creation of a new connection to the JMS provider.

If you have enabled global security for WebSphere Application Server, select the alias that specifies the user ID and password used to authenticate the creation of a new connection to the JMS provider. The use of this alias depends on the resource authentication (res-auth) setting declared in the connection factory resource reference of an application component's deployment descriptors.

Restriction:

1. User IDs longer than 12 characters cannot be used for authentication with WebSphere MQ. For example, the default Windows user ID, **Administrator**, is not valid because it contains 13 characters. Therefore, an authentication alias for a WebSphere MQ queue connection factory must specify a user ID no longer than 12 characters.
2. If you want to use Bindings transport mode on JMS queue connections to WebSphere MQ, you set the **Transport type** property to BINDINGS on the WebSphere MQ Queue Connection Factory. You must also choose one of the following options:
   - To use security credentials, ensure that the user specified is the currently logged on user for the WebSphere Application Server process. If the user specified is not the current logged on user for the WebSphere Application Server process, then the WebSphere MQ JMS Bindings authentication throws the error `MQJMS2013 invalid security authentication supplied for MQQueueManager`.
   - Do not specify security credentials. On the WebSphere MQ Connection Factory, ensure that both the **Component-managed Authentication Alias** and the **Container-managed Authentication Alias** properties are not set.

Container-managed authentication alias:

This alias specifies a user ID and password to be used to authenticate connection to a JMS provider for container-managed authentication.

This property provides a list of the J2C authentication data entry aliases that have been defined to WebSphere Application Server. You can select a data entry alias to be used to authenticate the creation of a new connection to the JMS provider.

If you have enabled global security for WebSphere Application Server, select the alias that specifies the user ID and password used to authenticate the creation of a new connection to the JMS provider. The use of this alias depends on the resource authentication (res-auth) setting declared in the connection factory resource reference of an application component's deployment descriptors.

Restriction:

1. User IDs longer than 12 characters cannot be used for authentication with WebSphere MQ. For example, the default Windows user ID, **Administrator**, is not valid because it contains 13 characters. Therefore, an authentication alias for a WebSphere MQ queue connection factory must specify a user ID no longer than 12 characters.
2. If you want to use Bindings transport mode on JMS queue connections to WebSphere MQ, you set the **Transport type** property to BINDINGS on the WebSphere MQ Queue Connection Factory. You must also choose one of the following options:
   - To use security credentials, ensure that the user specified is the currently logged on user for the WebSphere Application Server process. If the user specified is not the current logged on user for the WebSphere Application Server process, then the WebSphere MQ JMS Bindings authentication throws the error `MQJMS2013 invalid security authentication supplied for MQQueueManager`.
   - Do not specify security credentials. On the WebSphere MQ Connection Factory, ensure that both the **Component-managed Authentication Alias** and the **Container-managed Authentication Alias** properties are not set.

Mapping-configuration alias:

The module used to map authentication aliases.

This field provides a list of the modules that have been configured on the **Security → JAAS Configuration → Application Logins Configuration** property. For more information about the mapping configurations, see Java Authentication and Authorization service configuration entry settings.

Data type	Enum
Default	Null
Range	**ClientContainer** The client container maps authentication aliases. **WSLogin** The WSLogin module maps authentication aliases. **DefaultPrincipalMapping** The JAAS configuration maps an authentication alias to its userid and password.

Manage cached handles:

Whether or not cached handles (held in inst vars in a bean) should be tracked by the container.

Tracking handles can cause a large performance overhead if used at runtime; however, for debugging purposes it can be useful to enable handle management.

Data type	Check box
Default	Cleared

Range

Cleared
Cached handles are not tracked by the container.

Selected
Cached handles are tracked by the container. You should select this option only for debugging purposes, because this can cause a large performance overhead.

Log missing transaction contexts:

Whether or not the container logs when there is a missing transaction context at the time that a connection is created.

Data type	Check box
Default	Selected

Range

Selected
When a connection is created, any missing transaction contexts are logged in the activity log.

Cleared
Missing transaction contexts are not logged.

Queue manager:

The name of the WebSphere MQ queue manager for this connection factory. Connections created by this factory connect to that queue manager.

Data type	String
Default	Null
Range	A valid WebSphere MQ queue manager name, as 1 through 48 ASCII characters

Host:

The name of the host on which the WebSphere MQ queue manager runs, for client connection only.

Data type	String
Default	Null
Range	A valid TCP/IP hostname

Port:

The TCP/IP port number used for connection to the WebSphere MQ queue manager, for client connection only.

This port must be configured on the WebSphere MQ queue manager.

Data type	Integer
Default	Null
Range	A valid TCP/IP port number, configured on the WebSphere MQ queue manager.

Channel:

The name of the channel used for connection to the WebSphere MQ queue manager, for client connection only.

Data type	String
Default	Null
Range	1 through 20 ASCII characters

Transport type:

Specifies whether to use the WebSphere MQ client connection or JNI bindings for connection to the WebSphere MQ queue manager. WebSphere MQ as the JMS provider controls the communication protocols between JMS clients and JMS servers. Tune the transport type when you are using non-ASF nonpersistent, non-durable, non-transactional messaging or when you want to satisfy security issues and the client is local to the queue manager node.

Data type	Enum
Units	Not applicable
Default	BINDINGS
Range	**BINDINGS** JNI bindings are used to connect to the queue manager. BINDINGS is a shared memory protocol and can only be used when the queue manager is on the same node as the JMS client and comes at some security risks that should be addressed through the use of EJB roles. **CLIENT** WebSphere MQ client connection is used to connect to the queue manager. CLIENT is a typical TCP-based protocol.
Recommended	BINDINGS is faster by 30% or more, but it lacks security. When you have security concerns, CLIENT is more desirable than BINDINGS.

Model queue definition:

The name of the model queue definition that can be used by the queue manager to create temporary queues if a queue requested does not already exist.

Data type	String
Default	Null
Range	1 through 48 ASCII characters

Client ID:

The JMS client identifier used for connections to the WebSphere MQ queue manager.

Data type	String
Default	Null

CCSID:

The coded character set identifier for use with the WebSphere MQ queue manager.

This coded character set identifier (CCSID) must be one of the CCSIDs supported by WebSphere MQ.

Data type	String
Units	Integer
Default	Null
Range	1 through 65535

For more information about supported CCSIDs, and about converting between message data from one coded character set to another, see the *WebSphere MQ System Administration* and the *WebSphere MQ Application Programming Reference* books. These are available from the WebSphere MQ messaging multiplatform and platform-specific books Web pages; for example, at http://www-3.ibm.com/software/ts/mqseries/library/manualsa/manuals/platspecific.html, the IBM Publications Center, or from the WebSphere MQ collection kit, SK2T-0730.

Enable message retention:

Whether or not unwanted messages are left on the queue. If this option is not enabled, unwanted messages are dealt with according to their disposition options.

Data type	Check box
Default	Cleared
Range	**Selected** Unwanted messages are left on the queue. **Cleared** Unwanted messages are dealt with according to their disposition options.

XA enabled:

Specifies whether the connection factory is for XA or non-XA coordination of messages and controls if the application server uses XA QCF/TCF. Enable XA if multiple resources are not used in the same transaction.

If you clear this property, the JMS session is still enlisted in a transaction, but uses the resource manager local transaction calls (session.commit and session.rollback) instead of XA calls. This can lead to an improvement in performance. However, this means that only a single resource can be enlisted in a transaction in WebSphere Application Server.

Last participant support enables you to enlist one non-XA resource with other XA-capable resources.

Data type	Check box
Units	Not applicable
Default	Selected (XA enabled)
Range	**Selected** The connection factory is for XA-coordination of messages **Cleared** The connection factory is for non-XA coordination of messages
Recommended	Do not enable XA when the message queue received is the only resource in the transaction. Enable XA when other resources, including other queues or topics, are involved.

Enable return methods during shutdown:

Whether or not applications return from a method call if the queue manager has entered a controlled shutdown.

Data type Checkbox

Default Selected

Range

Selected

Applications return from a method call if the queue manager has entered a controlled shutdown.

Cleared

Applications do not return from a method call if the queue manager has entered a controlled shutdown.

Local server address:

The range of local ports to be used when making a connection to a WebSphere MQ queue manager

If a JMS application attempts to connect to a WebSphere MQ queue manager in client mode, a firewall might allow only those connections that originate from specified ports or a range of ports. In this situation, you can use this property to specify a port, or a range of points, that the application can bind to.

Data type String

Default Null

Range A string in the format:

```
[ip-addr][(low-port[,high-port])]
```

For example:

- 9.20.4.98

  The channel binds to address 9.20.4.98 locally
- 9.20.4.98(1000)

  The channel binds to address 9.20.4.98 locally and uses port 1000
- 9.20.4.98(1000,2000)

  The channel binds to address 9.20.4.98 locally and uses a port in the range 1000 to 2000
- (1000)

  The channel binds to port 1000 locally
- (1000,2000)

  The channel binds to a port in the range 1000 to 2000 locally

You can specify a host name instead of an IP address.

For direct connections, this property applies only when multicast is used and the value of the property must not contain a port number. If it does contain a port number, the connection is rejected. Therefore, the only valid values of the property are null, an IP address, or a host name.

Polling interval:

The interval, in milliseconds, between scans of all receivers during asynchronous message delivery

Data type Integer

Units	milliseconds
Default	5000
Range	1 through 2147483647

Rescan interval:

The interval in milliseconds between which a topic is scanned to look for messages that have been added to a topic out of order.

This interval controls the scanning for messages that have been added to a topic out of order with respect to a WebSphere MQ browse cursor.

Data type	Integer
Units	milliseconds
Default	5000
Range	1 through 2147483647

SSL cipher suite:

The cipher suite to use for SSL connection to WebSphere MQ.

Set this property to a valid cipher suite provided by your JSSE provider; it must match the CipherSpec named on the SVRCONN channel named by the **Channel** property.

You must set this property if the **SSL Peer Name** property is to be set.

SSL CRL:

A list of zero or more Certificate Revocation List (CRL) servers used to check for SSL certificate revocation. (Use of this property requires a WebSphere MQ JVM at Java 2 version 1.4.)

The value is a space-delimited list of entries of the form:

```
ldap://hostname:[port]
```

optionally followed by a single / (forward slash). If *port* is omitted, the default LDAP port of 389 is assumed. At connect-time, the SSL certificate presented by the server is checked against the specified CRL servers. For more information about CRL security, see the section “Working with Certificate Revocation Lists” in the *WebSphere MQ Security book*; for example at: http://publibfp.boulder.ibm.com/epubs/html/csqzas01/csqzas012w.htm#IDX2254.

SSL peer name:

For SSL, a distinguished name skeleton that must match the name provided by the WebSphere MQ queue manager. The distinguished name is used to check the identifying certificate presented by the server at connect-time.

The SSL Peer Name property is ignored if **SSL cipher suite** property is not specified.

This property is a list of attribute name and value pairs separated by commas or semicolons. For example:

```
CN=QMGR.*, OU=IBM, OU=WEBSPHERE
```

The example given checks the identifying certificate presented by the server at connect-time. For the connection to succeed, the certificate must have a Common Name beginning QMGR., and must have at least two Organizational Unit names, the first of which is IBM and the second WEBSPHERE. Checking is not case-sensitive.

For more details about distinguished names and their use with WebSphere MQ, see the *WebSphere MQ Security* book; for example, the section “Distinguished Names” at http://publibfp.boulder.ibm.com/epubs/html/csqzas01/csqzas010p.htm#HDRDCDN.

Temporary queue prefix:

The prefix that is used for names of temporary JMS queues created by applications that use this connection factory.

Data type	String
Default	Null

Enable MQ connection pooling:

Whether or not to use WebSphere MQ connection pooling.

Data type	Checkbox	
Default	Selected	
Range	**Selected** The connection factory uses WebSphere MQ connection pooling. When a connection is no longer required, instead of destroying it, it can be pooled, and later reused. This can provide a substantial performance enhancement for repeated connections to the same queue manager.	**Cleared** The connection factory does not use WebSphere MQ connection pooling. When a connection is no longer required, it is destroyed. To use the same queue manager a new connection is created.

Broker control queue:

The name of the publish/subscribe broker’s control queue, to which publisher and subscriber applications send all command messages (except publications and requests to delete publications).

Data type	String
Default	Null
Range	1 through 48 ASCII characters

Broker queue manager:

The name of the WebSphere MQ queue manager that provides the publish/subscribe message broker.

Data type	String
Default	Null
Range	1 through 48 ASCII characters

Broker publication queue:

The name of the broker's input queue (stream queue) that receives all publication messages for the default stream. Applications can also send requests to delete publications on the default stream to this queue.

Data type	String
Units	En_US ASCII characters
Default	Null
Range	1 through 48 ASCII characters

Broker subscription queue:

The name of the broker's queue from which non-durable subscription messages are retrieved. The subscriber specifies the name of the queue when it registers a subscription.

Data type	String
Default	Null
Range	1 through 48 ASCII characters

Broker CC subscription queue:

The name of the broker's queue from which non-durable subscription messages are retrieved for a ConnectionConsumer. This property applies only for use of the Web container.

Data type	String
Default	Null
Range	1 through 48 ASCII characters

Broker version:

Whether the message broker is provided by the WebSphere MQ MA0C Supportpac or newer versions of WebSphere message broker products.

Data type	Enum
Default	Advanced
Range	**Advanced** The message broker is provided by newer versions of WebSphere message broker products, such as WebsSphere MQ Integrator and Event Broker. **Basic** The message broker is provided by the WebSphere MQ MA0C SupportPac (MQSeries - Publish/Subscribe) or MQSI working in MA0C compatibility mode.

Publish/subscribe cleanup level:

The level of cleanup provided by the Publish/subscribe cleanup utility

To avoid the problems associated with non-graceful closure of subscriber objects, WebSphere MQ as a JMS provider provides a Publish/Subscribe cleanup utility that attempts to detect any earlier JMS publish/subscribe problems. If a large number of problems are detected, some performance degradation may be observed while resources are cleaned up. This utility runs transparently on a background thread and should not affect other WebSphere MQ operations.

Data type	Enum

Default SAFE

Range

SAFE The Cleanup thread attempts to remove unconsumed subscription messages, or temporary queues, for failed subscriptions. This mode of cleanup does not interfere with the operation of other JMS applications.

ASPROP
The style of cleanup to use is determined by the system property com.ibm.mq.jms.cleanup, which is queried at JVM startup. This property can be set on the java command-line using the -D option, and should be set to NONE, SAFE or STRONG. Any other value causes an exception. If not set, the property defaults to SAFE. This allows easy JVM-wide change to the Cleanup level without needing to update every topic connection factory used by the system.

NONE In this special mode, no cleanup is performed; and no cleanup thread exists. Additionally, if the application is using the single-queue approach, unconsumed messages can be left on the queue.

This option can be useful if the application is distant from the queue manager, and especially if it only publishes rather than subscribes. However, some application should perform cleanup on the queue manager to deal with any unconsumed messages - this could be a JMS application with CLEANUP(SAFE) or CLEANUP(STRONG), or the WebSphere MQ manual cleanup utility.

STRONG
The cleanup thread performs as CLEANUP(SAFE), but also clears the SYSTEM.JMS.REPORT.QUEUE of any unrecognized messages.

Publish/subscribe cleanup interval:

The interval, in milliseconds, between background executions of the publish/subscribe cleanup utility.

Data type	Integer
Default	60000
Range	1 through 2147483647

Message selection:

Whether message selection is done at the broker or client.

Data type Enum

Default BROKER

Range

BROKER
Message selection is done at the broker.

CLIENT
Message selection is done at the client.

Publish acknowledgement interval:

The interval, in number of messages, between publish requests that require acknowledgement from the broker.

Data type	Integer
Default	25
Range	1 through 2147483647

Enable sparse subscriptions:

Select this option to support subscriptions that receive infrequent matching messages.

Data type	Checkbox
Default	Cleared
Range	**Selected** Subscriptions can receive infrequent matching messages. This value requires that the subscription queue can be opened for browse. **Cleared** Sparse subscriptions are not supported. Subscriptions receive frequent matching messages.

Publish/subscribe status interval:

The interval, in milliseconds, between transactions to refresh publish/subscribe status.

Data type	Integer
Default	60000
Range	1 through 2147483647

Persistent subscriptions store:

Where WebSphere MQ stores persistent data relating to active JMS subscriptions.

Data type	Enum
Default	MIGRATE

Range

MIGRATE
This option dynamically selects the queue-based or broker-based subscription store based on the levels of queue manager and publish/subscribe broker installed. If both queue manager and broker are capable of supporting SUBSTORE(BROKER), this behaves as SUBSTORE(BROKER); otherwise it behaves as SUBSTORE(QUEUE). Additionally, SUBSTORE(MIGRATE) transfers durable subscription information from the queue-based subscription store to the broker-based store.

QUEUE
Subscription information is stored on SYSTEM.JMS.ADMIN.QUEUE and SYSTEM.JMS.PS.STATUS.QUEUE on the local queue manager.

BROKER
Subscription information is stored by the publish/subscribe broker used by the application. This option requires recent levels of queue manager and publish/subscribe broker. This subscription store requires recent levels of both queue manager and publish/subscribe broker. It is designed to provide improved resilience.

Enable multicast transport:

Whether or not this connection factory uses multicast transport.

With multicast, messages are delivered to all consumers. This is useful in environments where there are a large number of clients that all want to receive the same messages, because with multicast only one copy of each message is sent. Multicast reduces the total amount of network traffic. Reliable multicast is standard multicast with a reliability layer added.

Data type	Enum
Default	NOTUSED

Range

NOTUSED
This connection factory does not use multicast transport.

ENABLED
This connection factory uses multicast transport, but does not provide a reliable multicast connection.

ENABLED_IF_AVAILABLE
This connection factory uses multicast transport if the message broker supports it.

ENABLED_RELIABLE
This connection factory uses reliable multicast transport

ENABLED_RELIABLE_IF_AVAILABLE
This connection factory uses reliable multicast transport if the message broker supports it.

Enable clone support:

Select this check box to enable clone support to allow the same durable subscription across topic clones.

Data type	check box
Default	Cleared
Range	**Selected** Clone support is enabled. **Cleared** Clone support is disabled.

If you select this property, you must also specify a value for the **Client ID** property.

Direct broker authentication:

Whether the broker uses basic or certificate-based authentication for direct connections.

This property selects the authentication on a direct connections (if the TRANSPORT property is set to DIRECT).

Data type	Enum
Default	NONE
Range	**NONE** Direct broker authentication is not used. **PASSWORD** Password-based authentication is used for direct connections. Authentication is performed based on a user ID and password provided by an authentication alias. The authentication alias used is obtained from one of the following properties: • Component-managed Authentication Alias, for application-managed authentication. • Container-managed Authentication Alias, for container-managed authentication. **CERTIFICATE** Certificate-based authentication is used for direct connections. The SSLPEERNAME and SSLCRL properties are used to perform the authentication checks. You can use certificate-based authentication when connecting directly to a WebSphere Business Integration Event Broker or WebSphere Business Integration Message Broker broker.

Proxy host name:

Host name of the Web Scale proxy host.

A direct connection is made to the proxy server, which forwards the connection request to the message broker.

If the TRANSPORT property is set to DIRECT, the type of connection to the message broker depends on the value of this property, according to the following rules:

- If this property is set to the empty string, a direct connection is made to the broker identified by the HOSTNAME and PORT.
- If this property is set to a value other than the empty string, a direct connection is made to the broker through the proxy server identified by this property and the PROXYPORT property.

Data type	String
Default	Null

Proxy port:

Port number of the Web Scale proxy port.

A direct connection is made to this port on the proxy server identified by the PROXYHOSTNAME property, which forwards the connection request to the message broker. For more information, see the description of the PROXYHOSTNAME property.

Data type	Integer
Default	0

Connection pool:

Specifies an optional set of connection pool settings.

Connection pool properties are common to all J2C connectors.

The application server pools connections and sessions with the JMS provider to improve performance. This is independent from any WebSphere MQ connection pooling. You need to configure the connection and session pool properties appropriately for your applications, otherwise you may not get the connection and session behavior that you want.

Change the size of the connection pool if concurrent server-side access to the JMS resource exceeds the default value. The size of the connection pool is set on a per queue or topic basis.

Session pools:

An optional set of session pool settings.

This link provides a panel of optional connection pool properties, common to all J2C connectors.

The application server pools connections and sessions with the JMS provider to improve performance. This is independent from any WebSphere MQ connection pooling. You need to configure the connection and session pool properties appropriately for your applications, otherwise you may not get the connection and session behavior that you want.

Custom properties:

An optional set of name and value pairs for custom properties passed to WebSphere MQ.

WebSphere MQ queue connection factory collection:

The queue connection factories configured in the WebSphere MQ messaging provider, for point-to-point messaging with JMS queues.

This panel shows a list of the WebSphere MQ queue connection factories with a summary of their configuration properties.

To view this page, use the administrative console to complete the following steps:
1. In the navigation pane, expand **Resources** → **JMS Providers** → **WebSphere MQ**.
2. If appropriate, in the content pane, change the scope of the WebSphere MQ messaging provider. If the scope is set to node or server scope for a Version 5 node, the administrative console presents the subset of resources and properties that are applicable to WebSphere Application Server Version 5.
3. In the content pane, under Additional Resources, click **WebSphere MQ Queue Connection Factory**. This displays a list of any existing JMS queue connection factories.

To view or change the properties of a queue connection factory, click its name in the list displayed.

To act on one or more of the connection factories listed, select the check boxes next to the names of the objects that you want to act on, then use the buttons provided.

WebSphere MQ queue connection factory settings:

Use this panel to view or change the configuration properties of the selected queue connection factory for use with the WebSphere MQ JMS provider. These configuration properties control how connections are created to the associated JMS queue destination.

A WebSphere MQ queue connection factory is used to create JMS connections to queues provided by WebSphere MQ for point-to-point messaging.

To view this page, use the administrative console to complete the following steps:
1. In the navigation pane, expand **Resources** → **JMS Providers** → **WebSphere MQ**.
2. If appropriate, in the content pane, change the scope of the WebSphere MQ messaging provider. If the scope is set to node or server scope for a Version 5 node, the administrative console presents the subset of resources and properties that are applicable to WebSphere Application Server Version 5.
3. In the content pane, under Additional Resources, click **WebSphere MQ Queue Connection Factories**. This displays a list of any existing JMS queue connection factories.
4. Click the name of the JMS connection factory that you want to work with.

A queue connection factory for the WebSphere MQ JMS provider has the following properties.

Note:
- The property values that you specify must match the values that you specified when configuring WebSphere MQ for JMS resources. For more information about configuring WebSphere MQ for JMS resources, see the WebSphere MQ *Using Java* book. and the *WebSphere MQ System Administration* book, SC33-1873, which are available from the WebSphere MQ messaging platform-specific books Web page at http://www-3.ibm.com/software/ts/mqseries/library/manualsa/manuals/platspecific.html, the IBM Publications Center, or from the WebSphere MQ collection kit, SK2T-0730.
- In WebSphere MQ, names can have a maximum of 48 characters, with the exception of channels which have a maximum of 20 characters.

Scope:

Specifies the level to which this resource definition is visible to applications.

Resources such as messaging providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates which are defined at more general scopes.

The scope displayed is for information only, and cannot be changed on this panel. If you want to browse or change this resource (or other resources) at a different scope, change the scope on the messaging provider settings panel, then click **Apply**, before clicking the link for the type of resource.

Data type	String

Name:

The name by which this queue connection factory is known for administrative purposes within IBM WebSphere Application Server.

Data type	String

JNDI name:

The JNDI name that is used to bind the connection factory into the name space.

As a convention, use the fully qualified JNDI name; for example, in the form jms/*Name*, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type	String

Description:

A description of this connection factory for administrative purposes within IBM WebSphere Application Server.

Data type	String
Default	Null

Category:

A category used to classify or group this connection factory, for your IBM WebSphere Application Server administrative records.

Data type	String

Component-managed authentication alias:

This alias specifies a user ID and password to be used to authenticate connection to a JMS provider for application-managed authentication.

This property provides a list of the J2C authentication data entry aliases that have been defined to WebSphere Application Server. You can select a data entry alias to be used to authenticate the creation of a new connection to the JMS provider.

If you have enabled global security for WebSphere Application Server, select the alias that specifies the user ID and password used to authenticate the creation of a new connection to the JMS provider. The use of this alias depends on the resource authentication (res-auth) setting declared in the connection factory resource reference of an application component's deployment descriptors.

Restriction:

1. User IDs longer than 12 characters cannot be used for authentication with WebSphere MQ. For example, the default Windows user ID, **Administrator**, is not valid because it contains 13 characters. Therefore, an authentication alias for a WebSphere MQ queue connection factory must specify a user ID no longer than 12 characters.
2. If you want to use Bindings transport mode on JMS queue connections to WebSphere MQ, you set the **Transport type** property to BINDINGS on the WebSphere MQ Queue Connection Factory. You must also choose one of the following options:
   - To use security credentials, ensure that the user specified is the currently logged on user for the WebSphere Application Server process. If the user specified is not the current logged on user for the WebSphere Application Server process, then the WebSphere MQ JMS Bindings authentication throws the error `MQJMS2013 invalid security authentication supplied for MQQueueManager`.
   - Do not specify security credentials. On the WebSphere MQ Connection Factory, ensure that both the **Component-managed Authentication Alias** and the **Container-managed Authentication Alias** properties are not set.

Container-managed authentication alias:

This alias specifies a user ID and password to be used to authenticate connection to a JMS provider for container-managed authentication.

This property provides a list of the J2C authentication data entry aliases that have been defined to WebSphere Application Server. You can select a data entry alias to be used to authenticate the creation of a new connection to the JMS provider.

If you have enabled global security for WebSphere Application Server, select the alias that specifies the user ID and password used to authenticate the creation of a new connection to the JMS provider. The use of this alias depends on the resource authentication (res-auth) setting declared in the connection factory resource reference of an application component's deployment descriptors.

Restriction:

1. User IDs longer than 12 characters cannot be used for authentication with WebSphere MQ. For example, the default Windows user ID, **Administrator**, is not valid because it contains 13 characters. Therefore, an authentication alias for a WebSphere MQ queue connection factory must specify a user ID no longer than 12 characters.
2. If you want to use Bindings transport mode on JMS queue connections to WebSphere MQ, you set the **Transport type** property to BINDINGS on the WebSphere MQ Queue Connection Factory. You must also choose one of the following options:
   - To use security credentials, ensure that the user specified is the currently logged on user for the WebSphere Application Server process. If the user specified is not the current logged on user for the WebSphere Application Server process, then the WebSphere MQ JMS Bindings authentication throws the error `MQJMS2013 invalid security authentication supplied for MQQueueManager`.
   - Do not specify security credentials. On the WebSphere MQ Connection Factory, ensure that both the **Component-managed Authentication Alias** and the **Container-managed Authentication Alias** properties are not set.

Mapping-configuration alias:

The module used to map authentication aliases.

This field provides a list of the modules that have been configured on the **Security** → **JAAS Configuration** → **Application Logins Configuration** property. For more information about the mapping configurations, see Java Authentication and Authorization service configuration entry settings.

Data type	Enum
Default	Null
Range	**ClientContainer** The client container maps authentication aliases. **WSLogin** The WSLogin module maps authentication aliases. **DefaultPrincipalMapping** The JAAS configuration maps an authentication alias to its userid and password.

Host:

The name of the host on which the WebSphere MQ queue manager runs, for client connection only.

Data type	String
Default	Null
Range	A valid TCP/IP hostname

Port:

The TCP/IP port number used for connection to the WebSphere MQ queue manager, for client connection only.

This port must be configured on the WebSphere MQ queue manager.

Data type	Integer
Default	0
Range	A valid TCP/IP port number, configured on the WebSphere MQ queue manager.

Transport type:

Whether the WebSphere MQ client connection or JNI bindings are used for connection to the WebSphere MQ queue manager.

WebSphere MQ, as the messaging provider, controls the communication protocols between JMS clients and JMS servers. Tune the transport type when you are using non-ASF non-persistent, non-durable, non-transactional messaging or when you want to satisfy security issues and the client is local to the queue manager node.

Data type	Enum
Units	Not applicable
Default	BINDINGS
Range	**BINDINGS** JNI bindings are used to connect to the queue manager. BINDINGS is a shared memory protocol and can only be used when the queue manager is on the same node as the JMS client and comes at some security risks that should be addressed through the use of EJB roles. **CLIENT** WebSphere MQ client connection is used to connect to the queue manager. CLIENT is a typical TCP-based protocol.

Recommended	BINDINGS is faster by 30% or more, but it lacks security. When you have security concerns, BINDINGS is more desirable than CLIENT.

Channel:

The name of the channel used for connection to the WebSphere MQ queue manager, for client connection only.

Data type	String
Default	Null
Range	1 through 20 ASCII characters

Queue manager:

The name of the WebSphere MQ queue manager for this connection factory. Connections created by this factory connect to that queue manager.

Data type	String
Default	Null
Range	A valid WebSphere MQ queue manager name, as 1 through 48 ASCII characters

Model queue definition:

The name of the model queue definition that can be used by the queue manager to create temporary queues if a queue requested does not already exist.

Data type	String
Default	Null
Range	1 through 48 ASCII characters

Client ID:

The JMS client identifier used for connections to WebSphere MQ.

Data type	String
Range	A valid JMS client ID, as ASCII characters

CCSID:

The coded character set identifier for use with the WebSphere MQ queue manager.

This coded character set identifier (CCSID) must be one of the CCSIDs supported by WebSphere MQ.

Data type	String
Units	Integer
Default	Null
Range	1 through 65535

For more information about supported CCSIDs, and about converting between message data from one coded character set to another, see the *WebSphere MQ System Administration* and the *WebSphere MQ Application Programming Reference* books. These are available from the WebSphere MQ messaging multi-platform and platform-specific books Web pages; for example, at http://www-3.ibm.com/software/ts/mqseries/library/manualsa/manuals/platspecific.html, the IBM Publications Center, or from the WebSphere MQ collection kit, SK2T-0730.

Enable message retention:

Whether or not unwanted messages are left on the queue. If this option is not enabled, unwanted messages are dealt with according to their disposition options.

Data type	Enum
Default	Selected
Range	**Selected** Unwanted messages are left on the queue. **Cleared** Unwanted messages are dealt with according to their disposition options.

XA enabled:

Specifies whether the connection factory is for XA or non-XA coordination of messages and controls if the application server uses XA. Enable XA if multiple resources are not used in the same transaction.

If you clear this property (non-XA), the JMS session is still enlisted in a transaction, but uses the resource manager local transaction calls (session.commit and session.rollback) instead of XA calls. This can lead to an improvement in performance. However, this means that only a single resource can be enlisted in a transaction in WebSphere Application Server.

Last participant support enables you to enlist one non-XA resource with other XA-capable resources.

Data type	Checkbox
Default	Selected
Range	**Selected** The connection factory is for XA-coordination of messages **Cleared** The connection factory is for non-XA coordination of messages
Recommended	Do not select to enable XA when the message queue received is the only resource in the transaction. Enable XA if transactions involve other resources, including other queues or topics.

Enable return methods during shutdown:

Whether or not applications return from a method call if the queue manager has entered a controlled shutdown.

Data type	Checkbox
Default	Selected
Range	**Selected** Applications return from a method call if the queue manager has entered a controlled shutdown. **Cleared** Applications do not return from a method call if the queue manager has entered a controlled shutdown.

Local server address:

The local server address

If a JMS application attempts to connect to a WebSphere MQ queue manager in client mode, a firewall might allow only those connections that originate from specified ports or a range of ports. In this situation, you can use this property to specify a port, or a range of points, that the application can bind to.

Data type	String
Default	Null
Range	A string in the format: `[ip-addr][(low-port[,high-port])]` For example: • 9.20.4.98 The channel binds to address 9.20.4.98 locally • 9.20.4.98(1000) The channel binds to address 9.20.4.98 locally and uses port 1000 • 9.20.4.98(1000,2000) The channel binds to address 9.20.4.98 locally and uses a port in the range 1000 to 2000 • (1000) The channel binds to port 1000 locally • (1000,2000) The channel binds to a port in the range 1000 to 2000 locally You can specify a host name instead of an IP address. For direct connections, this property applies only when multicast is used and the value of the property must not contain a port number. If it does contain a port number, the connection is rejected. Therefore, the only valid values of the property are null, an IP address, or a host name.

Polling interval:

The interval, in milliseconds, between scans of all receivers during asynchronous message delivery

Data type	Integer
Units	milliseconds
Default	5000
Range	1 through 2147483647

Rescan interval:

The interval in milliseconds between which a queue is scanned to look for messages that have been added to a queue out of order.

This interval controls the scanning for messages that have been added to a queue out of order with respect to a WebSphere WebSphere MQ browse cursor.

Data type	Integer
Units	milliseconds
Default	5000
Range	1 through 2147483647

SSL Cipher Suite:

The cipher suite to use for SSL connection to WebSphere MQ.

Set this property to a valid cipher suite provided by your JSSE provider; it must match the CipherSpec named on the SVRCONN channel named by the **Channel** property.

You must set this property if the **SSL Peer Name** property is to be set.

SSL CRL:

A list of zero or more Certificate Revocation List (CRL) servers used to check for SSL certificate revocation. (Use of this property requires a WebSphere MQ JVM at Java 2 version 1.4.)

The value is a space-delimited list of entries of the form:

```
ldap://hostname:[port]
```

optionally followed by a single / (forward slash). If *port* is omitted, the default LDAP port of 389 is assumed. At connect-time, the SSL certificate presented by the server is checked against the specified CRL servers. For more information about CRL security, see the section “Working with Certificate Revocation Lists” in the *WebSphere MQ Security book*; for example at: http://publibfp.boulder.ibm.com/epubs/html/csqzas01/csqzas012w.htm#IDX2254.

SSL Peer Name:

For SSL, a distinguished name skeleton that must match the name provided by the WebSphere MQ queue manager. The distinguished name is used to check the identifying certificate presented by the server at connect-time.

The SSL Peer Name property is ignored if **SSL Cipher Suite** property is not specified.

This property is a list of attribute name and value pairs separated by commas or semicolons. For example:

```
CN=QMGR.*, OU=IBM, OU=WEBSPHERE
```

The example given checks the identifying certificate presented by the server at connect-time. For the connection to succeed, the certificate must have a Common Name beginning QMGR., and must have at least two Organizational Unit names, the first of which is IBM and the second WEBSPHERE. Checking is not case-sensitive.

For more details about distinguished names and their use with WebSphere MQ, see the *WebSphere MQ Security* book; for example, the section “Distinguished Names” at http://publibfp.boulder.ibm.com/epubs/html/csqzas01/csqzas010p.htm#HDRDCDN.

Temporary queue prefix:

The prefix that is used for names of temporary JMS queues created by applications that use this connection factory.

Data type	String
Default	Null

Use connection pooling:

Whether or not to use WebSphere MQ connection pooling.

Data type	Checkbox	
Default	Selected	
Range	**Selected** The connection factory uses WebSphere MQ connection pooling. When a connection is no longer required, instead of destroying it, it can be pooled, and later reused. This can provide a substantial performance enhancement for repeated connections to the same queue manager.	**Cleared** The connection factory does not use WebSphere MQ connection pooling. When a connection is no longer required, it is destroyed. To use the same queue manager a new connection is created.

Connection pool:

An optional set of connection pool settings.

Connection pool properties are common to all J2C connectors.

The application server pools connections and sessions with the JMS provider to improve performance. This is independent from any WebSphere MQ connection pooling. You need to configure the connection and session pool properties appropriately for your applications, otherwise you may not get the connection and session behavior that you want.

Change the size of the connection pool if concurrent server-side access to the JMS resource exceeds the default value. The size of the connection pool is set on a per queue or topic basis.

Session pool:

An optional set of session pool settings.

This link provides a panel of optional connection pool properties, common to all J2C connectors.

The application server pools connections and sessions with the JMS provider to improve performance. This is independent from any WebSphere MQ connection pooling. You need to configure the connection and session pool properties appropriately for your applications, otherwise you may not get the connection and session behavior that you want.

WebSphere MQ topic connection factory collection:

The topic connection factories configured in the WebSphere MQ messaging provider for publish/subscribe messaging with JMS topics.

This panel shows a list of the WebSphere MQ topic connection factories with a summary of their configuration properties.

To view this administrative console page, use the administrative console to complete the following steps:
1. In the navigation pane, expand **Resources** → **JMS Providers** → **WebSphere MQ**.

2. If appropriate, in the content pane, change the scope of the WebSphere MQ messaging provider. If the scope is set to node or server scope for a Version 5 node, the administrative console presents the subset of resources and properties that are applicable to WebSphere Application Server Version 5.
3. In the content pane, under Additional Resources, click **WebSphere MQ Topic Connection Factory**. This displays a list of any existing queue connection factories.

To view or change the properties of a connection factory, click its name in the list displayed.

To act on one or more of the connection factories listed, select the check boxes next to the names of the objects that you want to act on, then use the buttons provided.

WebSphere MQ topic connection factory settings:

Use this panel to view or change the configuration properties of the selected topic connection factory for use with the WebSphere MQ as a JMS provider. These configuration properties control how connections are created to the associated JMS topic destination.

A WebSphere MQ topic connection factory is used to create JMS connections to topic destinations provided by WebSphere MQ for publish/subscribe messaging.

To view this page, use the administrative console to complete the following steps:
1. In the navigation pane, expand **Resources** → **JMS Providers** → **WebSphere MQ**.
2. If appropriate, in the content pane, change the scope of the WebSphere MQ messaging provider. If the scope is set to node or server scope for a Version 5 node, the administrative console presents the subset of resources and properties that are applicable to WebSphere Application Server Version 5.
3. In the content pane, under Additional Resources, click **WebSphere MQ Topic Connection Factories**. This displays a list of any existing JMS topic connection factories.
4. Click the name of the JMS connection factory that you want to work with.

A WebSphere MQ topic connection factory has the following properties.

Note:
- The property values that you specify must match the values that you specified when configuring WebSphere MQ for JMS resources. For more information about configuring WebSphere MQ for JMS resources, see the WebSphere MQ *Using Java* book.
- In WebSphere MQ, names can have a maximum of 48 characters, with the exception of channels which have a maximum of 20 characters.
- For more information about setting the SSL properties for WebSphere MQ, see the section SSL properties in the *WebSphere MQ Using Java* book.

Scope:

Specifies the level to which this resource definition is visible to applications.

Resources such as messaging providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates which are defined at more general scopes.

The scope displayed is for information only, and cannot be changed on this panel. If you want to browse or change this resource (or other resources) at a different scope, change the scope on the messaging provider settings panel, then click **Apply**, before clicking the link for the type of resource.

Data type	String

Name:

The name by which this topic connection factory is known for administrative purposes within IBM WebSphere Application Server.

Data type	String

JNDI name:

The JNDI name that is used to bind the topic connection factory into the name space.

As a convention, use the fully qualified JNDI name; for example, in the form jms/*Name*, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type	String

Description:

A description of this topic connection factory for administrative purposes within IBM WebSphere Application Server.

Data type	String
Default	Null

Category:

A category used to classify or group this topic connection factory, for your IBM WebSphere Application Server administrative records.

Data type	String

Component-managed authentication alias:

This alias specifies a user ID and password to be used to authenticate connection to a JMS provider for application-managed authentication.

This property provides a list of the J2C authentication data entry aliases that have been defined to WebSphere Application Server. You can select a data entry alias to be used to authenticate the creation of a new connection to the JMS provider.

If you have enabled global security for WebSphere Application Server, select the alias that specifies the user ID and password used to authenticate the creation of a new connection to the JMS provider. The use of this alias depends on the resource authentication (res-auth) setting declared in the connection factory resource reference of an application component's deployment descriptors.

Restriction:

1. User IDs longer than 12 characters cannot be used for authentication with WebSphere MQ. For example, the default Windows user ID, **Administrator**, is not valid because it contains 13 characters. Therefore, an authentication alias for a WebSphere MQ queue connection factory must specify a user ID no longer than 12 characters.

2. If you want to use Bindings transport mode on JMS queue connections to WebSphere MQ, you set the **Transport type** property to BINDINGS on the WebSphere MQ Queue Connection Factory. You must also choose one of the following options:
    - To use security credentials, ensure that the user specified is the currently logged on user for the WebSphere Application Server process. If the user specified is not the current logged on user for the WebSphere Application Server process, then the WebSphere MQ JMS Bindings authentication throws the error `MQJMS2013 invalid security authentication supplied for MQQueueManager`.
    - Do not specify security credentials. On the WebSphere MQ Connection Factory, ensure that both the **Component-managed Authentication Alias** and the **Container-managed Authentication Alias** properties are not set.

Container-managed authentication alias:

This alias specifies a user ID and password to be used to authenticate connection to a JMS provider for container-managed authentication.

This property provides a list of the J2C authentication data entry aliases that have been defined to WebSphere Application Server. You can select a data entry alias to be used to authenticate the creation of a new connection to the JMS provider.

If you have enabled global security for WebSphere Application Server, select the alias that specifies the user ID and password used to authenticate the creation of a new connection to the JMS provider. The use of this alias depends on the resource authentication (res-auth) setting declared in the connection factory resource reference of an application component's deployment descriptors.

Restriction:

1. User IDs longer than 12 characters cannot be used for authentication with WebSphere MQ. For example, the default Windows user ID, **Administrator**, is not valid because it contains 13 characters. Therefore, an authentication alias for a WebSphere MQ queue connection factory must specify a user ID no longer than 12 characters.
2. If you want to use Bindings transport mode on JMS queue connections to WebSphere MQ, you set the **Transport type** property to BINDINGS on the WebSphere MQ Queue Connection Factory. You must also choose one of the following options:
    - To use security credentials, ensure that the user specified is the currently logged on user for the WebSphere Application Server process. If the user specified is not the current logged on user for the WebSphere Application Server process, then the WebSphere MQ JMS Bindings authentication throws the error `MQJMS2013 invalid security authentication supplied for MQQueueManager`.
    - Do not specify security credentials. On the WebSphere MQ Connection Factory, ensure that both the **Component-managed Authentication Alias** and the **Container-managed Authentication Alias** properties are not set.

Mapping-configuration alias:

The module used to map authentication aliases.

This field provides a list of the modules that have been configured on the **Security** → **JAAS Configuration** → **Application Logins Configuration** property. For more information about the mapping configurations, see Java Authentication and Authorization service configuration entry settings.

Data type	Enum
Default	Null

Range	**ClientContainer** The client container maps authentication aliases. **WSLogin** The WSLogin module maps authentication aliases. **DefaultPrincipalMapping** The JAAS configuration maps an authentication alias to its userid and password.

Host:

The name of the host on which the WebSphere MQ queue manager runs, for client connection only.

Data type	String
Default	Null
Range	A valid TCP/IP hostname

Port:

The TCP/IP port number used for connection to the WebSphere MQ queue manager, for client connection only.

This port must be configured on the WebSphere MQ queue manager.

Data type	Integer
Default	Null
Range	A valid TCP/IP port number, configured on the WebSphere MQ queue manager.

Transport type:

Specifies whether to use the WebSphere MQ client connection or JNI bindings for connection to the WebSphere MQ queue manager. WebSphere MQ as the JMS provider controls the communication protocols between JMS clients and JMS servers. Tune the transport type when you are using non-ASF nonpersistent, non-durable, non-transactional messaging or when you want to satisfy security issues and the client is local to the queue manager node.

Data type	Enum
Units	Not applicable
Default	BINDINGS

Range

BINDINGS

JNI bindings are used to connect to the queue manager. BINDINGS is a shared memory protocol and can only be used when the queue manager is on the same node as the JMS client and comes at some security risks that should be addressed through the use of EJB roles.

CLIENT

WebSphere MQ client connection is used to connect to the queue manager. CLIENT is a typical TCP-based protocol.

DIRECT

For a WebSphere MQ message broker using DIRECT mode. DIRECT is a lightweight sockets protocol used in non-transactional, non-durable and non-persistent Publish/Subscribe messaging. DIRECT works only for clients and message-driven beans using the non-ASF protocol.

The type of connection to the message broker depends on the value of the PROXYHOSTNAME property, according to the following rules:

- If the PROXYHOSTNAME property is set to the empty string, a direct connection is made to the broker identified by the HOSTNAME and PORT.
- If the PROXYHOSTNAME property is set to a value other than the empty string, a direct connection is made to the broker through the proxy server identified by this property and the PROXYPORT property.

Recommended

DIRECT is the fastest transport type and should be used where possible. Use BINDINGS when you want to satisfy additional security tasks and the queue manager is local to the JMS client. QUEUED is fallback for all other cases.
Note: WebSphere MQ 5.3 before CSD2 with the DIRECT setting can lose messages when used with message-driven beans and under load. This also happens with client-side based applications unless the broker's maxClientQueueSize is set to 0. You can set this to 0 with the command `#wempschangeproperties WAS_nodeName_server1 -e default -o DynamicSubscriptionEngine -n maxClientQueueSize -v 0 -x executionGroupUUID`, where executionGroupUUID can be found by starting the broker and looking in the Event Log/Applications for event 2201. This value is usually ffffffff-0000-0000-000000000000.

Channel:

The name of the channel used for connection to the WebSphere MQ queue manager, for client connection only.

Data type	String
Default	Null
Range	1 through 20 ASCII characters

Queue manager:

The name of the WebSphere MQ queue manager for this connection factory. Connections created by this factory connect to that queue manager.

Data type	String
Default	Null
Range	A valid WebSphere MQ queue manager name, as 1 through 48 ASCII characters

Broker control queue:

The name of the publish/subscribe broker's control queue, to which publisher and subscriber applications send all command messages (except publications and requests to delete publications).

Data type	String
Default	Null
Range	1 through 48 ASCII characters

Broker queue manager:

The name of the WebSphere MQ queue manager that provides the publish/subscribe message broker.

Data type	String
Default	Null
Range	1 through 48 ASCII characters

Broker publication queue:

The name of the broker's input queue (stream queue) that receives all publication messages for the default stream. Applications can also send requests to delete publications on the default stream to this queue.

Data type	String
Units	En_US ASCII characters
Default	Null
Range	1 through 48 ASCII characters

Broker subscription queue:

The name of the broker's queue from which non-durable subscription messages are retrieved. The subscriber specifies the name of the queue when it registers a subscription.

Data type	String
Default	Null
Range	1 through 48 ASCII characters

Broker CC subscription queue:

The name of the broker's queue from which non-durable subscription messages are retrieved for a ConnectionConsumer. This property applies only for use of the Web container.

Data type	String
Default	Null
Range	1 through 48 ASCII characters

Broker version:

Whether the message broker is provided by the WebSphere MQ MA0C Supportpac or newer versions of WebSphere message broker products.

Data type	Enum
Default	Advanced

Range	**Advanced** The message broker is provided by newer versions of WebSphere message broker products, such as WebSphere Business Integration Message Broker and Event Broker. **Basic** The message broker is provided by the WebSphere MQ MA0C SupportPac (MQSeries - Publish/Subscribe) or MQSI working in MA0C compatibility mode.

Model queue definition:

The name of the model queue definition that the broker can use to create dynamic queues for non-default streams if the stream queue does not already exist

The name of the model queue definition that the broker can use to create dynamic queues to receive publications for streams other than the default stream. This is only used if the stream queue does not already exist. If this model queue definition does not exist, all stream queues must be defined by the administrator.

Data type	String
Default	Null
Range	1 through 48 ASCII characters

Enable clone support:

Select this check box to enable clone support to allow the same durable subscription across topic clones.

Data type	Check box
Default	Cleared
Range	**Selected** Clone support is enabled. **Cleared** Clone support is disabled.

If you select this property, you must also specify a value for the **Client ID** property.

Client ID:

The JMS client identifier used for connections to WebSphere MQ.

Data type	String
Range	A valid JMS client ID, as ASCII characters

CCSID:

The coded character set identifier for use with the WebSphere MQ queue manager.

This coded character set identifier (CCSID) must be one of the CCSIDs supported by WebSphere MQ.

Data type	String
Units	Integer
Default	Null
Range	1 through 65535

For more information about supported CCSIDs, and about converting between message data from one coded character set to another, see the *WebSphere MQ System Administration* and the *WebSphere MQ Application Programming Reference* books. These are available from the WebSphere MQ messaging multiplatform and platform-specific books Web pages; for example, at http://www-3.ibm.com/software/ts/mqseries/library/manualsa/manuals/platspecific.html, the IBM Publications Center, or from the WebSphere MQ collection kit, SK2T-0730.

XA Enabled:

Specifies whether the connection factory is for XA or non-XA coordination of messages and controls if the application server uses XA. Enable XA if multiple resources are not used in the same transaction.

If you clear this property (non-XA), the JMS session is still enlisted in a transaction, but uses the resource manager local transaction calls (session.commit and session.rollback) instead of XA calls. This can lead to an improvement in performance. However, this means that only a single resource can be enlisted in a transaction in WebSphere Application Server.

Last participant support enables you to enlist one non-XA resource with other XA-capable resources.

Data type	Checkbox
Default	Selected
Range	**Selected** The connection factory is for XA-coordination of messages **Cleared** The connection factory is for non-XA coordination of messages
Recommended	Do not select to enable XA when the message queue received is the only resource in the transaction. Enable XA if transactions involve other resources, including other queues or topics.

Publish/subscribe cleanup level:

The level of cleanup provided by the Publish/subscribe cleanup utility

To avoid the problems associated with non-graceful closure of subscriber objects, WebSphere MQ as a JMS provider provides a Publish/Subscribe cleanup utility that attempts to detect any earlier JMS publish/subscribe problems. If a large number of problems are detected, some performance degradation may be observed while resources are cleaned up. This utility runs transparently on a background thread and should not affect other WebSphere MQ operations.

Data type	Enum
Default	SAFE

Range

SAFE
The Cleanup thread attempts to remove unconsumed subscription messages, or temporary queues, for failed subscriptions. This mode of cleanup does not interfere with the operation of other JMS applications.

ASPROP
The style of cleanup to use is determined by the system property com.ibm.mq.jms.cleanup, which is queried at JVM startup. This property can be set on the java command-line using the -D option, and should be set to NONE, SAFE or STRONG. Any other value causes an exception. If not set, the property defaults to SAFE. This allows easy JVM-wide change to the Cleanup level without needing to update every topic connection factory used by the system.

NONE
In this special mode, no cleanup is performed; and no cleanup thread exists. Additionally, if the application is using the single-queue approach, unconsumed messages can be left on the queue.

This option can be useful if the application is distant from the queue manager, and especially if it only publishes rather than subscribes. However, some application should perform cleanup on the queue manager to deal with any unconsumed messages - this could be a JMS application with CLEANUP(SAFE) or CLEANUP(STRONG), or the WebSphere MQ manual cleanup utility.

STRONG
The cleanup thread performs as CLEANUP(SAFE), but also clears the SYSTEM.JMS.REPORT.QUEUE of any unrecognized messages.

Publish/subscribe cleanup interval:

The interval, in milliseconds, between background executions of the publish/subscribe cleanup utility.

Data type	Integer
Default	60000
Range	1 through 2147483647

Message selection:

Whether message selection is done at the broker or client.

Data type	Enum
Default	BROKER

Range

BROKER
Message selection is done at the broker.

CLIENT
Message selection is done at the client.

Publish acknowledgement interval:

The interval, in number of messages, between publish requests that require acknowledgement from the broker.

Data type	Integer
Default	25
Range	1 through 2147483647

Enable sparse subscriptions:

Select this option to support subscriptions that receive infrequent matching messages.

Data type	Checkbox
Default	Cleared
Range	

Selected
Subscriptions can receive infrequent matching messages. This value requires that the subscription queue can be opened for browse.

Cleared
Sparse subscriptions are not supported. Subscriptions receive frequent matching messages.

Publish/subscribe status interval:

The interval, in milliseconds, between transactions to refresh publish/subscribe status.

Data type	Integer
Default	60000
Range	1 through 2147483647

Persistent subscriptions store:

Where WebSphere MQ stores persistent data relating to active JMS subscriptions.

Data type	Enum
Default	MIGRATE
Range	

MIGRATE
This option dynamically selects the queue-based or broker-based subscription store based on the levels of queue manager and publish/subscribe broker installed. If both queue manager and broker are capable of supporting SUBSTORE(BROKER), this behaves as SUBSTORE(BROKER); otherwise it behaves as SUBSTORE(QUEUE). Additionally, SUBSTORE(MIGRATE) transfers durable subscription information from the queue-based subscription store to the broker-based store.

QUEUE
Subscription information is stored on SYSTEM.JMS.ADMIN.QUEUE and SYSTEM.JMS.PS.STATUS.QUEUE on the local queue manager.

BROKER
Subscription information is stored by the publish/subscribe broker used by the application. This option requires recent levels of queue manager and publish/subscribe broker. This subscription store requires recent levels of both queue manager and publish/subscribe broker. It is designed to provide improved resilience.

Enable multicast transport:

Whether or not this connection factory uses multicast transport.

With multicast, messages are delivered to all consumers. This is useful in environments where there are a large number of clients that all want to receive the same messages, because with multicast only one copy of each message is sent. Multicast reduces the total amount of network traffic. Reliable multicast is standard multicast with a reliability layer added.

Data type
Enum

Default
NOTUSED

Range

NOTUSED
This connection factory does not use multicast transport.

ENABLED
This connection factory uses multicast transport, but does not provide a reliable multicast connection.

ENABLED_IF_AVAILABLE
This connection factory uses multicast transport if the message broker supports it.

ENABLED_RELIABLE
This connection factory uses reliable multicast transport

ENABLED_RELIABLE_IF_AVAILABLE
This connection factory uses reliable multicast transport if the message broker supports it.

Direct broker authentication:

Whether the broker uses basic or certificate-based authentication for direct connections.

This property selects the authentication on a direct connections (if the TRANSPORT property is set to DIRECT).

Data type
Enum

Default
NONE

Range

NONE Direct broker authentication is not used.

PASSWORD
Password-based authentication is used for direct connections. Authentication is performed based on a user ID and password provided by an authentication alias. The authentication alias used is obtained from one of the following properties:

- Component-managed Authentication Alias, for application-managed authentication.
- Container-managed Authentication Alias, for container-managed authentication.

CERTIFICATE
Certificate-based authentication is used for direct connections. The SSLPEERNAME and SSLCRL properties are used to perform the authentication checks.

You can use certificate-based authentication when connecting directly to a WebSphere Business Integration Event Broker or WebSphere Business Integration Message Broker broker.

Proxy host name:

Host name of the Web Scale proxy host.

A direct connection is made to the proxy server, which forwards the connection request to the message broker.

If the TRANSPORT property is set to DIRECT, the type of connection to the message broker depends on the value of this property, according to the following rules:

- If this property is set to the empty string, a direct connection is made to the broker identified by the HOSTNAME and PORT.
- If this property is set to a value other than the empty string, a direct connection is made to the broker through the proxy server identified by this property and the PROXYPORT property.

Data type	String
Default	Null

Proxy port:

Port number of the Web Scale proxy port.

A direct connection is made to this port on the proxy server identified by the PROXYHOSTNAME property, which forwards the connection request to the message broker. For more information, see the description of the PROXYHOSTNAME property.

Data type	Integer
Default	0

Enable return methods during shutdown:

Whether or not applications return from a method call if the queue manager has entered a controlled shutdown.

Data type	Checkbox
Default	Selected
Range	**Selected** Applications return from a method call if the queue manager has entered a controlled shutdown. **Cleared** Applications do not return from a method call if the queue manager has entered a controlled shutdown.

Local server address:

The range of local ports to be used when making a connection to a WebSphere MQ queue manager

If a JMS application attempts to connect to a WebSphere MQ queue manager in client mode, a firewall might allow only those connections that originate from specified ports or a range of ports. In this situation, you can use this property to specify a port, or a range of points, that the application can bind to.

Data type	String
Default	Null

Range

A string in the format:

`[ip-addr][(low-port[,high-port])]`

For example:

- 9.20.4.98

  The channel binds to address 9.20.4.98 locally
- 9.20.4.98(1000)

  The channel binds to address 9.20.4.98 locally and uses port 1000
- 9.20.4.98(1000,2000)

  The channel binds to address 9.20.4.98 locally and uses a port in the range 1000 to 2000
- (1000)

  The channel binds to port 1000 locally
- (1000,2000)

  The channel binds to a port in the range 1000 to 2000 locally

You can specify a host name instead of an IP address.

For direct connections, this property applies only when multicast is used and the value of the property must not contain a port number. If it does contain a port number, the connection is rejected. Therefore, the only valid values of the property are null, an IP address, or a host name.

Polling interval:

The interval, in milliseconds, between scans of all receivers during asynchronous message delivery

Data type	Integer
Units	milliseconds
Default	5000
Range	1 through 2147483647

Rescan interval:

The interval in milliseconds between which a topic is scanned to look for messages that have been added to a topic out of order.

This interval controls the scanning for messages that have been added to a topic out of order with respect to a WebSphere MQ browse cursor.

Data type	Integer
Units	milliseconds
Default	5000
Range	1 through 2147483647

SSL cipher suite:

The cipher suite to use for SSL connection to WebSphere MQ.

Set this property to a valid cipher suite provided by your JSSE provider; it must match the CipherSpec named on the SVRCONN channel named by the **Channel** property.

You must set this property if the **SSL Peer Name** property is to be set.

SSL CRL:

A list of zero or more Certificate Revocation List (CRL) servers used to check for SSL certificate revocation. (Use of this property requires a WebSphere MQ JVM at Java 2 version 1.4.)

The value is a space-delimited list of entries of the form:

```
ldap://hostname:[port]
```

optionally followed by a single / (forward slash). If *port* is omitted, the default LDAP port of 389 is assumed. At connect-time, the SSL certificate presented by the server is checked against the specified CRL servers. For more information about CRL security, see the section “Working with Certificate Revocation Lists” in the *WebSphere MQ Security book*; for example at: http://publibfp.boulder.ibm.com/epubs/html/csqzas01/csqzas012w.htm#IDX2254.

SSL peer name:

For SSL, a distinguished name skeleton that must match the name provided by the WebSphere MQ queue manager. The distinguished name is used to check the identifying certificate presented by the server at connect-time.

The SSL Peer Name property is ignored if **SSL Cipher Suite** property is not specified.

This property is a list of attribute name and value pairs separated by commas or semicolons. For example:

```
CN=QMGR.*, OU=IBM, OU=WEBSPHERE
```

The example given checks the identifying certificate presented by the server at connect-time. For the connection to succeed, the certificate must have a Common Name beginning QMGR., and must have at least two Organizational Unit names, the first of which is IBM and the second WEBSPHERE. Checking is not case-sensitive.

For more details about distinguished names and their use with WebSphere MQ, see the *WebSphere MQ Security* book; for example, the section “Distinguished Names” at http://publibfp.boulder.ibm.com/epubs/html/csqzas01/csqzas010p.htm#HDRDCDN.

Enable MQ Connection Pooling:

Whether or not to use WebSphere MQ connection pooling.

Data type	Checkbox
Default	Selected
Range	**Selected** The connection factory uses WebSphere MQ connection pooling. When a connection is no longer required, instead of destroying it, it can be pooled, and later reused. This can provide a substantial performance enhancement for repeated connections to the same queue manager. **Cleared** The connection factory does not use WebSphere MQ connection pooling. When a connection is no longer required, it is destroyed. To use the same queue manager a new connection is created.

Connection pool:

Specifies an optional set of connection pool settings.

Connection pool properties are common to all J2C connectors.

The application server pools connections and sessions with the JMS provider to improve performance. This is independent from any WebSphere MQ connection pooling. You need to configure the connection and session pool properties appropriately for your applications, otherwise you may not get the connection and session behavior that you want.

Change the size of the connection pool if concurrent server-side access to the JMS resource exceeds the default value. The size of the connection pool is set on a per queue or topic basis.

Session pools:

An optional set of session pool settings.

This link provides a panel of optional connection pool properties, common to all J2C connectors.

The application server pools connections and sessions with the JMS provider to improve performance. This is independent from any WebSphere MQ connection pooling. You need to configure the connection and session pool properties appropriately for your applications, otherwise you may not get the connection and session behavior that you want.

WebSphere MQ queue destination collection:

The queue destinations configured in the WebSphere MQ messaging provider for point-to-point messaging with JMS queues.

This panel shows a list of the WebSphere MQ queue destinations with a summary of their configuration properties.

To view this administrative console page, use the administrative console to complete the following steps:
1. In the navigation pane, expand **Resources** → **JMS Providers** → **WebSphere MQ**.
2. If appropriate, in the content pane, change the scope of the WebSphere MQ messaging provider. If the scope is set to node or server scope for a Version 5 node, the administrative console presents the subset of resources and properties that are applicable to WebSphere Application Server Version 5.
3. In the content pane, under Additional Resources, click **WebSphere MQ Queue Destinations**. This displays a list of any existing JMS queue destinations.

To create a new queue destination, click **New**.

To browse or change the properties of a queue destination, select its name in the list displayed.

To act on one or more of the queue destinations listed, click the check box next to the name of the queue, then use the buttons provided.

WebSphere MQ queue settings:

Use this panel to browse or change the configuration properties of the selected JMS queue destination for point-to-point messaging with WebSphere MQ as a messaging provider.

A WebSphere MQ queue destination is used to configure the properties of a JMS queue. Connections to the queue are created by the associated JMS queue connection factory for WebSphere MQ as a messaging provider.

To view this page, use the administrative console to complete the following steps:

1. In the navigation pane, expand **Resources** → **Messaging Providers** → **WebSphere MQ**.
2. If appropriate, in the content pane, change the scope of the WebSphere MQ messaging provider. If the scope is set to node or server scope for a Version 5 node, the administrative console presents the subset of resources and properties that are applicable to WebSphere Application Server Version 5.
3. In the content pane, under Additional Resources, click **WebSphere MQ Queue Destinations**. This displays a list of any existing JMS queue destinations.
4. Click the name of the JMS queue destination that you want to work with.

A queue for use with the WebSphere MQ JMS provider has the following properties.

Note:

- The property values that you specify must match the values that you specified when configuring WebSphere MQ for JMS resources. For more information about configuring WebSphere MQ for JMS resources, see the WebSphere MQ *Using Java* book.
- In WebSphere MQ, names can have a maximum of 48 characters, with the exception of channels which have a maximum of 20 characters.

Scope:

Specifies the level to which this resource definition is visible to applications.

Resources such as messaging providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates which are defined at more general scopes.

The scope displayed is for information only, and cannot be changed on this panel. If you want to browse or change this resource (or other resources) at a different scope, change the scope on the messaging provider settings panel, then click **Apply**, before clicking the link for the type of resource.

Data type	String

Name:

The name by which the queue is known for administrative purposes within IBM WebSphere Application Server.

Data type	String

JNDI name:

The JNDI name that is used to bind the queue into the name space.

As a convention, use the fully qualified JNDI name; for example, in the form jms/*Name*, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type	String

Description:

A description of the queue, for administrative purposes

Data type	String
Default	Null

Category:

A category used to classify or group this queue, for your IBM WebSphere Application Server administrative records.

Data type	String

Persistence:

Whether all messages sent to the destination are persistent, non-persistent, or have their persistence defined by the application

Data type	Enum
Default	Application defined
Range	**Application defined** Messages on the destination have their persistence defined by the application that put them onto the queue. **Queue defined** Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties. **Persistent** Messages on the destination are persistent. **Non persistent** Messages on the destination are not persistent.

Priority:

Whether the message priority for this destination is defined by the application or the **Specified priority** property

Data type	Enum
Default	Application defined
Range	**Application defined** The priority of messages on this destination is defined by the application that put them onto the destination. **Queue defined** Messages on the destination have their persistence defined by the WebSphere MQ destination definition properties. **Specified** The priority of messages on this destination is defined by the **Specified priority** property.*If you select this option, you must define a priority you must define a priority on the* ***Specified Priority*** *property.*

Specified priority:

If the **Priority** property is set to `Specified`, type here the message priority for this destination, in the range 0 (lowest) through 9 (highest)

Data type	Integer
Units	Message priority level
Default	0
Range	0 (lowest priority) through 9 (highest priority)

Expiry:

Whether the expiry timeout for this destination is defined by the application or the **Specified Expiry** property, or messages on the destination never expire (have an unlimited expiry timeout)

Data type	Enum
Default	APPLICATION DEFINED
Range	**APPLICATION DEFINED** The expiry timeout for messages on this destination is defined by the application that put them onto the destination. **SPECIFIED** The expiry timeout for messages on this destination is defined by the **Specified Expiry** property.*If you select this option, you must define a timeout on the* ***Specified Expiry*** *property.* **UNLIMITED** Messages on this destination have no expiry timeout, so those messages never expire.

Specified expiry:

If the **Expiry Timeout** property is set to `Specified`, type here the number of milliseconds (greater than 0) after which messages on this destination expire.

Data type	Integer
Units	Milliseconds
Default	0
Range	Greater than or equal to 0 • 0 indicates that messages never timeout • Other values are an integer number of milliseconds

Base queue name:

The name of the queue to which messages are sent, on the queue manager specified by the **Base Queue Manager Name** property.

Data type	String
Default	Null
Range	1 through 48 ASCII characters

Base queue manager name:

The name of the WebSphere MQ queue manager to which messages are sent

This queue manager provides the queue specified by the **Base Queue Name** property.

Data type	String
Units	En_US ASCII characters
Default	Null
Range	A valid WebSphere MQ Queue Manager name, as 1 through 48 ASCII characters

CCSID:

The coded character set identifier for use with the WebSphere MQ queue manager.

This coded character set identifier (CCSID) must be one of the CCSIDs supported by WebSphere MQ.

Data type	String
Units	Integer
Default	Null
Range	1 through 65535

For more information about supported CCSIDs, and about converting between message data from one coded character set to another, see the *WebSphere MQ System Administration* and the *WebSphere MQ Application Programming Reference* books. These are available from the WebSphere MQ messaging multiplatform and platform-specific books Web pages; for example, at http://www.ibm.com/software/ts/mqseries/library/ manualsa/manuals/platspecific.html, the IBM Publications Center, or from the WebSphere MQ collection kit, SK2T-0730.

Use native encoding:

Whether or not the destination should use native encoding (appropriate encoding values for the Java platform).

Data type	Check box
Default	Cleared
Range	**Cleared** Native encoding is not used, so specify the properties below for integer, decimal, and floating point encoding. **Selected** Native encoding is used (to provide appropriate encoding values for the Java platform). For more information about encoding properties, see the WebSphere MQ *Using Java* document.

Integer encoding:

If native encoding is not enabled, select whether integer encoding is normal or reversed.

Data type	Enum
Default	NORMAL

Range	**NORMAL** Normal integer encoding is used. **REVERSED** Reversed integer encoding is used. For more information about encoding properties, see the WebSphere MQ *Using Java* document.

Decimal encoding:

If native encoding is not enabled, select whether decimal encoding is normal or reversed.

Data type	Enum
Units	Not applicable
Default	NORMAL
Range	**NORMAL** Normal decimal encoding is used. **REVERSED** Reversed decimal encoding is used. For more information about encoding properties, see the WebSphere MQ *Using Java* document.

Floating point encoding:

If native encoding is not enabled, select the type of floating point encoding.

Data type	Enum
Default	IEEENORMAL
Range	**IEEENORMAL** IEEE normal floating point encoding is used. **IEEEREVERSED** IEEE reversed floating point encoding is used. **S390** S390 floating point encoding is used. For more information about encoding properties, see the WebSphere MQ *Using Java* document.

Target client:

Whether the receiving application is JMS-compliant or is a traditional WebSphere MQ application

Data type	Enum
Default	JMS
Range	**JMS** The target is a JMS-compliant application. **MQ** The target is a non-JMS, traditional WebSphere MQ application.

Queue manager host:

The name of host for the queue manager on which the queue destination is created.

Data type	String
Default	Null
Range	A valid TCP/IP hostname

Queue manager port:

The number of the port used by the queue manager on which this queue is defined.

Data type	String
Units	A valid TCP/IP port number.
Default	Null
Range	A valid TCP/IP port number. This port must be configured on the WebSphere MQ queue manager.

Server connection channel name:

The name of the channel used for connection to the WebSphere MQ queue manager.

Data type	String
Default	Null
Range	1 through 20 ASCII characters

User name:

The user ID used, with the **Password** property, for authentication when connecting to the queue manager to define the queue destination.

*If you specify a value for the **User name** property, you must also specify a value for the **Password** property.*

Data type	String
Default	Null

Password:

The password, used with the **User name** property, for authentication when connecting to the queue manager to define the queue destination.

*If you specify a value for the **User name** property, you must also specify a value for the **Password** property.*

Data type	String
Default	Null

WebSphere MQ queue settings (MQ Config):

Use this panel to browse or change the configuration properties defined to WebSphere MQ for the selected queue destination.

To view this page, use the administrative console to complete the following steps:
1. In the navigation pane, expand **Resources** → **JMS Providers** → **WebSphere MQ**.
2. If appropriate, in the content pane, change the scope of the WebSphere MQ messaging provider. If the scope is set to node or server scope for a Version 5 node, the administrative console presents the subset of resources and properties that are applicable to WebSphere Application Server Version 5.
3. In the content pane, under Additional Resources, click **WebSphere MQ Queue Destinations**. This displays a list of any existing JMS queue destinations.
4. Click the name of the JMS queue destination that you want to work with.
5. Under Additional Resources, click **MQ Config**.

A WebSphere MQ queue destination is used to configure the properties of a JMS queue. A queue for use with the WebSphere MQ JMS provider has the following extra properties defined to WebSphere MQ.

Notes

Note:

- To be able to browse or change these MQ Config properties, the WebSphere MQ Queue Manager on which the queue resides must be configured for remote administration and be running. You must also have installed the WebSphere MQ client. If you have not done this, the administrative console displays messages like the following:

  ```
  The WMQQueueDefiner MBean has encountered an error.
  WMSG0331E: The MQ Client is required for this functionality, but it is not installed.
  ```
- These MQ Config properties can be used only to view or change the properties of local queues. You cannot use MQ Config to administer alias or remote queues.
- Some properties displayed are read-only and cannot be changed.
- The property values that you specify must match the values that you specified when configuring WebSphere MQ JMS resources. For more information about configuring WebSphere MQ JMS resources, see the *WebSphere MQ: Using Java* book; for example from the WebSphere MQ multiplatform library Web page at http://www.ibm.com/software/ts/mqseries/library/manualsa/manuals/crosslatest.html.
- In WebSphere MQ, names can have a maximum of 48 characters, with the exception of channels which have a maximum of 20 characters.

Base Queue Name:

The name of the local queue to which messages are sent, on the queue manager specified by the **Base Queue Manager Name** property.

Data type	String

Base Queue Manager Name:

The name of the WebSphere MQ queue manager to which messages are sent.

This queue manager provides the queue specified by the **Base Queue Name** property.

Data type	String

Queue Manager Host:

The name of host for the queue manager on which the queue destination is created.

Data type	String

Queue Manager Port:

The number of the port used by the queue manager on which this queue is defined.

Data type	Integer
Range	A valid TCP/IP port number. This port must be configured on the WebSphere MQ queue manager.

Server Connection Channel Name:

The name of the channel used for connection to the WebSphere MQ queue manager.

Data type	String
Range	1 through 20 ASCII characters

User ID:

The user ID used, with the **Password** property, for authentication when connecting to the queue manager to define the queue destination.

*If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.*

Data type	String

Password:

The password, used with the **User ID** property, for authentication when connecting to the queue manager to define the queue destination.

*If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.*

Data type	String

Description:

The WebSphere MQ queue description, for administrative purposes within WebSphere MQ.

Data type	String
Default	Null
Range	1 through 64 ASCII characters.

Inhibit Put:

Whether or not put operations are allowed for this queue.

Data type	Enum
Default	Put Inhibited
Range	**Put Allowed** Put operations are allowed for this queue. **Put Inhibited** Put operations are not allowed for this queue.

Persistence:

Whether messages on the queue are persistent or non-persistent.

Data type	Enum
Default	Persistent
Range	**Persistent** Messages on the queue are persistent. **Non persistent** Messages on the queue are not persistent.

Cluster Name:

The name of the cluster to which the WebSphere MQ queue manager belongs.

If you specify a value for **Cluster Name**, you should not specify a value for **Cluster Name List**. Cluster names must conform to the rules described in the *WebSphere MQ MQSC Command Reference* book.

Data type	String
Default	Null
Range	A valid WebSphere MQ name for a queue manager cluster, as 1 through 48 ASCII characters

Cluster Name List:

The name of the cluster namelist to which the WebSphere MQ queue manager belongs.

If you specify a value for **Cluster Name**, you should not specify a value for **Cluster Name List**. Cluster names must conform to the rules described in the *WebSphere MQ MQSC Command Reference* book.

Data type	String
Default	Null
Range	A valid WebSphere MQ name for a list of queue manager clusters, as 1 through 48 ASCII characters

Default Binding:

The default binding to be used when the queue is defined as a cluster queue.

Data type	Enum
Default	On Open
Range	**On Open** The queue handle is bound to a specific instance of the cluster queue when the queue is opened. **Not Fixed** The queue handle is not bound to any particular instance of the cluster queue. This allows the queue manager to select a specific queue instance when the message is put, and to change that selection subsequently should the need arise.

Inhibit Get:

Whether or not get operations are allowed for this queue.

Data type	Enum
Default	Get Inhibited
Range	**Get Inhibited** Get operations are not allowed for this queue. **Get Allowed** Get operations are allowed for this queue.

Maximum Queue Depth:

The maximum number of messages allowed on the queue.

Data type	Integer
Units	Number of messages
Default	0
Range	A value greater than or equal to zero, and less than or equal to 640 000. For more information about the maximum value allowed, see the *WebSphere MQ MQSC Command Reference*. If this value is reduced, any messages that are already on the queue are not affected, even if the number of messages exceeds the new maximum.

Maximum Message Length:

The maximum length, in bytes, of messages on this queue.

Data type	Integer
Units	Number of bytes
Default	0
Range	A value greater than or equal to zero, and less than or equal to the maximum message length for the queue manager and WebSphere MQ platform. For more information about the maximum value allowed, see the *WebSphere MQ MQSC Command Reference*. If this value is reduced, any message that is already on the queue are not affected, even if the message length exceeds the new maximum.

Shareability:

Whether multiple applications can get messages from this queue.

Data type	Enum
Default	Shareable
Range	**Shareable** More than one application instance can get messages from the queue. **Not Shareable** Only one application instance can get messages from the queue.

Input Open Option:

The default share option for applications opening this queue for input

Data type	Enum
Default	Exclusive
Range	**Exclusive** The open request is for exclusive input from the queue. **Shared** The open request is for shared input from the queue.

Message Delivery Sequence:

The order in which messages are delivered from the queue in response to get requests.

Data type	Enum	
Default	FIFO	
Range	**FIFO**	Messages are delivered in first in first out (FIFO) order. Priority is ignored for messages on this queue.
	Priority	Messages are delivered in first-in-first-out (FIFO) order within priority. This is the default supplied with WebSphere MQ, but your installation might have changed it.

Backout Threshold:

The maximum number of times that a message can be backed out. If this threshold is reached, the message is requeued on the backout queue specified by the **Backout Requeue Name** property.

The WebSphere MQ queue manager keeps a record of the number of times that each message has been backed out. When this number reaches a configurable threshold, the connection consumer requeues the message on a named backout queue. If this requeue fails for any reason, the message is removed from the queue and either requeued to the dead-letter queue, or discarded.

Data type	Integer	
Default	0	
Range	**0**	Never requeue messages
	1 or more	The number of times that a message has been backed, at which the message is requeued on a named backout queue.

Backout Requeue Name:

The name of the backout queue to which messages are requeued if they have been backed out more than the backout threshold.

The WebSphere MQ queue manager keeps a record of the number of times that each message has been backed out. When this number reaches a configurable threshold, the connection consumer requeues the message on a named backout queue. If this requeue fails for any reason, the message is removed from the queue and either requeued to the dead-letter queue, or discarded.

Data type	String
Default	Null
Range	1 through 48 characters.

Harden Get Backout:

Whether hardening should be used to ensure that the count of the number of times that a message has been backed out is accurate.

Data type	Enum
Default	Hardened

Range	**Hardened** The count is hardened. **Not Hardened** The count is not hardened. This is the default supplied with WebSphere MQ, but your installation might have changed it.

Default Priority:

The default message priority for this destination, used if no priority is provided with a message.

Data type	Integer
Default	0
Range	0 (lowest priority) through 9 (highest priority)

WebSphere MQ topic destination collection:

The JMS topic destinations configured in the WebSphere MQ messaging provider for point-to-point messaging with JMS topics. Use this panel to create or delete topic destinations, or to select a topic destination to view or change its configuration properties.

This panel shows a list of JMS topic destinations with a summary of their configuration properties.

To view this administrative console page, use the administrative console to complete the following steps:
1. In the navigation pane, expand **Resources** → **JMS Providers** → **WebSphere MQ**.
2. If appropriate, in the content pane, change the scope of the WebSphere MQ messaging provider. If the scope is set to node or server scope for a Version 5 node, the administrative console presents the subset of resources and properties that are applicable to WebSphere Application Server Version 5.
3. In the content pane, under Additional Resources, click **WebSphere MQ Topic Destinations**. This displays a list of any existing JMS topic destinations.

To create a new topic destination, click **New**.

To view or change the properties of a topic destination, select its name in the list displayed.

To act on one or more of the topic destinations listed, click the check box next to the name of the topic, then use the buttons provided.

WebSphere MQ topic settings:

Use this panel to browse or change the configuration properties of the selected JMS topic destination for publish/subscribe messaging with WebSphere MQ as a messaging provider.

A WebSphere MQ topic destination is used to configure the properties of a JMS topic for WebSphere MQ as a messaging provider. Connections to the topic are created by the associated topic connection factory.

To view this page, use the administrative console to complete the following steps:
1. In the navigation pane, expand **Resources** → **JMS Providers** → **WebSphere MQ**.
2. If appropriate, in the content pane, change the scope of the WebSphere MQ messaging provider. If the scope is set to node or server scope for a Version 5 node, the administrative console presents the subset of resources and properties that are applicable to WebSphere Application Server Version 5.
3. In the content pane, under Additional Resources, click **WebSphere MQ Topic Destinations**. This displays a list of any existing JMS topic destinations.
4. Click the name of the JMS topic destination that you want to work with.

A WebSphere MQ topic has the following properties.

Note:

- The property values that you specify must match the values that you specified when configuring WebSphere MQ for JMS resources. For more information about configuring WebSphere MQ for JMS resources, see the WebSphere MQ *Using Java* book.
- In WebSphere MQ, names can have a maximum of 48 characters, with the exception of channels which have a maximum of 20 characters.

Scope:

Specifies the level to which this resource definition is visible to applications.

Resources such as messaging providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates which are defined at more general scopes.

The scope displayed is for information only, and cannot be changed on this panel. If you want to browse or change this resource (or other resources) at a different scope, change the scope on the messaging provider settings panel, then click **Apply**, before clicking the link for the type of resource.

Data type	String

Name:

The name by which the topic is known for administrative purposes within IBM WebSphere Application Server.

Data type	String

JNDI name:

The JNDI name that is used to bind the topic into the name space.

As a convention, use the fully qualified JNDI name; for example, in the form jms/*Name*, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type	String

Description:

A description of the topic, for administrative purposes within IBM WebSphere Application Server.

Data type	String
Default	Null

Category:

A category used to classify or group this topic, for your IBM WebSphere Application Server administrative records.

Data type	String

Persistence:

Whether all messages sent to the destination are persistent, non-persistent, or have their persistence defined by the application

Data type	Enum
Default	APPLICATION DEFINED
Range	**APPLICATION DEFINED** Messages on the destination have their persistence defined by the application that put them onto the destination. **QUEUE DEFINED** Messages on the destination have their persistence defined by the WebSphere MQ destination definition properties. **PERSISTENT** Messages on the destination are persistent. **NON PERSISTENT** Messages on the destination are not persistent.

Priority:

Whether the message priority for this destination is defined by the application or the **Specified Priority** property

Data type	Enum
Default	APPLICATION DEFINED
Range	**APPLICATION DEFINED** The priority of messages on this destination is defined by the application that put them onto the destination. **QUEUE DEFINED** Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties. **SPECIFIED** The priority of messages on this destination is defined by the **Specified Priority** property. *If you select this option, you must define a priority on the **Specified Priority** property.*

Specified priority:

If the **Priority** property is set to `Specified`, type here the message priority for this destination, in the range 0 (lowest) through 9 (highest)

Data type	Integer
Units	Message priority level
Default	0
Range	0 (lowest priority) through 9 (highest priority)

Expiry:

Whether the expiry timeout for this destination is defined by the application or the **Specified Expiry** property, or messages on the queue never expire (have an unlimited expiry timeout)

Data type	Enum
Default	APPLICATION DEFINED
Range	**APPLICATION DEFINED** The expiry timeout for messages on this destination is defined by the application that put them onto the destination. **SPECIFIED** The expiry timeout for messages on this destination is defined by the **Specified Expiry** property. *If you select this option, you must define a timeout on the **Specified Expiry** property.* **UNLIMITED** Messages on this destination have no expiry timeout, so those messages never expire.

Specified expiry:

If the **Expiry Timeout** property is set to `Specified`, type here the number of milliseconds (greater than 0) after which messages on this destination expire.

Data type	Integer
Units	Milliseconds
Default	0
Range	Greater than or equal to 0 • 0 indicates that messages never timeout • Other values are an integer number of milliseconds

Base topic name:

The name of the WebSphere MQ topic to which messages are sent.

Data type	String
Range	Depends on the broker used. For details, see the documentation for your broker; for example the *WebSphere MQ Event Broker* library at http://www-3.ibm.com/software/ts/mqseries/library/manualsa/manuals/wsmqebv21.htm

CCSID:

The coded character set identifier for use with WebSphere MQ.

This coded character set identifier (CCSID) must be one of the CCSIDs supported by WebSphere MQ.

Data type	String
Units	Integer
Default	Null
Range	1 through 65535

For more information about supported CCSIDs, and about converting between message data from one coded character set to another, see the *WebSphere MQ System Administration* and the *WebSphere MQ*

Application Programming Reference books. These are available from the WebSphere MQ messaging multiplatform and platform-specific books Web pages; for example, at http://www-3.ibm.com/software/ts/mqseries/library/manualsa/manuals/platspecific.html, the IBM Publications Center, or from the WebSphere MQ collection kit, SK2T-0730.

Use native encoding:

Whether or not the destination should use native encoding (appropriate encoding values for the Java platform).

Data type	Check box
Units	Not applicable
Default	Cleared
Range	**Cleared** Native encoding is not used, so specify the properties below for integer, decimal, and floating point encoding. **Selected** Native encoding is used (to provide appropriate encoding values for the Java platform).

For more information about encoding properties, see the WebSphere MQ *Using Java* document.

Integer encoding:

If native encoding is not enabled, select whether integer encoding is normal or reversed.

Data type	Enum
Default	NORMAL
Range	**NORMAL** Normal integer encoding is used. **REVERSED** Reversed integer encoding is used.

For more information about encoding properties, see the WebSphere MQ *Using Java* document.

Decimal encoding:

If native encoding is not enabled, select whether decimal encoding is normal or reversed.

Data type	Enum
Default	NORMAL
Range	**NORMAL** Normal decimal encoding is used. **REVERSED** Reversed decimal encoding is used.

For more information about encoding properties, see the WebSphere MQ *Using Java* document.

Floating point encoding:

If native encoding is not enabled, select the type of floating point encoding.

Data type	Enum

Default	IEEENORMAL
Range	**IEEENORMAL** IEEE normal floating point encoding is used. **IEEEREVERSED** IEEE reversed floating point encoding is used. **S390** S390 floating point encoding is used.

For more information about encoding properties, see the WebSphere MQ *Using Java* document.

Target client:

Whether the receiving application is JMS-compliant or is a traditional WebSphere MQ application

Data type	Enum
Default	JMS
Range	**JMS** The target is a JMS-compliant application. **MQ** The target is a non-JMS, traditional WebSphere MQ application.

Broker durable subscription queue:

The name of the broker's queue from which durable subscription messages are retrieved

The subscriber specifies the name of the queue when it registers a subscription.

Data type	String
Default	Null
Range	1 through 48 ASCII characters

Broker CC durable subscription queue:

The name of the broker's queue from which durable subscription messages are retrieved for a ConnectionConsumer. This property applies only for use of the Web container.

Data type	String
Default	Null
Range	1 through 48 ASCII characters

Enable multicast:

Whether or not this topic destination uses multicast transport.

With multicast, messages are delivered to all consumers. This is useful in environments where there are a large number of clients that all want to receive the same messages, because with multicast only one copy of each message is sent. Multicast reduces the total amount of network traffic. Reliable multicast is standard multicast with a reliability layer added.

Data type	Enum
Default	NOTUSED

Range

NOTUSED
This destination does not use multicast transport.

ENABLED
This destination uses multicast transport, but does not provide a reliable multicast connection.

ENABLED_IF_AVAILABLE
This destination uses multicast transport if the message broker supports it.

ENABLED_RELIABLE
This destination uses reliable multicast transport

ENABLED_RELIABLE_IF_AVAILABLE
This destination uses reliable multicast transport if the message broker supports it.

Configuring JMS resources for the WebSphere MQ messaging provider

Use the following tasks to configure the connection factories and destinations for the WebSphere MQ JMS provider.

You only need to complete these tasks if WebSphere Application Server supports enterprise applications that use JMS resources provided by WebSphere MQ. To enable use of resources provider by WebSphere MQ, you must have installed and configured WebSphere MQ JMS support, as described in ″Installing and configuring WebSphere MQ as the JMS provider″ in the information center.

You can use the WebSphere administrative console to configure JMS connections factories, JMS queues, and JMS topics for WebSphere MQ as the messaging provider.

Using the administrative console, if you set the scope of the WebSphere MQ messaging provider to cell scope or to node scope for a WebSphere Application Server version 6 node, you can configure JMS 1.1 resources and properties. This includes unified JMS connection factories for use by both point-to-point and publish/subscribe JMS 1.1 applications. With JMS 1.1, this approach is preferred to the domain-specific queue connection factory and topic connection factory. If you set the scope to a WebSphere Application Server Version 5 node, you can only configure domain-specific JMS resources, and the subset of properties that apply to WebSphere Application Server Version 5.

For more information about configuring JMS resources for the WebSphere MQ messaging provider, see the following topics. These topics include optional steps for you to create a new JMS resource.

Configuring resources for WebSphere Application Server version 6:
- Configuring a unified JMS connection factory
- Configuring a JMS queue connection factory
- Configuring a JMS topic connection factory
- Configuring a JMS queue
- Configuring a JMS topic
- Enabling WebSphere MQ JMS connection pooling

Configuring a unified JMS connection factory, for WebSphere MQ:

Use this task to browse or configure a unified JMS connection factory for use with WebSphere MQ as a messaging provider. This task contains an optional step for you to create a new unified JMS connection factory.

This topic describes how to configure a unified JMS connection factory for WebSphere MQ as a messaging provider on an Application Server version 6 node. With JMS 1.1, this approach is preferred to the domain-specific JMS queue connection factory and JMS topic connection factory.

If you want to configure a JMS queue connection factory or topic factory, see the related tasks.

To browse or configure a unified JMS connection factory for use with WebSphere MQ as a messaging provider, use the administrative console to complete the following steps:

1. Display the WebSphere MQ messaging provider. In the navigation pane, expand **Resources** → **JMS Providers** → **WebSphere MQ**.
2. **Optional:** Change the **Scope** setting to the level at which the connection factory is visible to applications.
3. In the contents pane, under Additional Properties, click **WebSphere MQ Connection Factories** This displays a table listing any existing unified JMS connection factories, with a summary of their properties.
4. To browse or change the properties of an existing unified JMS connection factory, click its name in the list. Otherwise, to create a new connection factory, complete the following steps:
   a. Click **New** in the content pane.
   b. Specify the following required properties. You can specify other properties, as described in a later step.

      Name The name by which this connection factory is known for administrative purposes within IBM WebSphere Application Server.

      JNDI name
      The JNDI name that is used to bind the connection factory into the name space.

      CCSID
      The coded character set identifier for use with the WebSphere MQ queue manager; for example: `850`.

   c. Click **Apply**. This defines the JMS connection factory to WebSphere Application Server, and enables you to browse or change additional properties.
5. **Optional:** Change properties for the unified JMS connection factory, according to your needs.
6. **Optional:** Change connection pool properties and session pool properties, according to your needs.
7. Click **OK**.
8. Save any changes to the master configuration.
9. To have the changed configuration take effect, stop then restart the application server.

Configuring a JMS queue connection factory, for WebSphere MQ:

Use this task to browse or change a JMS queue connection factory for use with WebSphere MQ as a messaging provider. This task contains an optional step for you to create a new JMS queue connection factory.

With JMS 1.1, the preferred approach is to use unified JMS connection factories instead of the domain-specific JMS queue connection factory and JMS topic connection factory. If you want to configure a unified JMS connection factory, see “Configuring a unified JMS connection factory, for WebSphere MQ” on page 1346.

To browse or configure a JMS queue connection factory for use with WebSphere MQ as a messaging provider, use the administrative console to complete the following steps:

1. Display the WebSphere MQ messaging provider. In the navigation pane, expand **Resources** → **JMS Providers** → **WebSphere MQ**.
2. **Optional:** Change the **Scope** setting to the level at which the connection factory is visible to applications.
3. In the contents pane, under Additional Properties, click **WebSphere MQ Queue Connection Factories** This displays a table listing any existing JMS queue connection factories, with a summary of their properties.

4. To browse or change an existing JMS queue connection factory, click its name in the list. Otherwise, to create a new connection factory, complete the following steps:
   a. Click **New** in the content pane.
   b. Specify the following required properties. You can specify other properties, as described in a later step.

      Name The name by which this connection factory is known for administrative purposes within IBM WebSphere Application Server.

      JNDI name
      The JNDI name that is used to bind the connection factory into the name space.

      CCSID
      The coded character set identifier for use with the WebSphere MQ queue manager; for example: `850`.
   c. Click **Apply**. This defines the connection factory to WebSphere Application Server, and enables you to browse or change additional properties.
5. **Optional:** Change properties for the queue connection factory, according to your needs.
6. **Optional:** Change connection pool properties and session pool properties, according to your needs.
7. Click **OK**.
8. Save any changes to the master configuration.
9. To have the changed configuration take effect, stop then restart the application server.

Configuring a JMS topic connection factory, for WebSphere MQ:

Use this task to browse or configure a JMS topic connection factory for publish/subscribe messaging with WebSphere MQ as a messaging provider. This task contains an optional step for you to create a new JMS topic connection factory.

With JMS 1.1, the preferred approach is to use unified JMS connection factories instead of the domain-specific JMS queue connection factory and JMS topic connection factory. If you want to configure a unified JMS connection factory, see "Configuring a unified JMS connection factory, for WebSphere MQ" on page 1346.

To configure a topic connection factory for use with the WebSphere MQ as a messaging provider, use the administrative console to complete the following steps:

1. Display the WebSphere MQ messaging provider. In the navigation pane, expand **Resources** → **JMS Providers** → **WebSphere MQ**.
2. **Optional:** Change the **Scope** setting to the level at which the connection factory is visible to applications.
3. In the contents pane, under Additional Properties, click **WebSphere MQ Topic Connection Factories** This displays a table listing any existing JMS topic connection factories, with a summary of their properties.
4. To browse or change an existing JMS topic connection factory, click its name in the list. Otherwise, to create a new connection factory, complete the following steps:
   a. Click **New** in the content pane.
   b. Specify the following required properties. You can specify other properties, as described in a later step.

      Name The name by which this destination is known for administrative purposes within IBM WebSphere Application Server.

      JNDI Name
      The JNDI name that is used to bind the destination into the name space.

CCSID
The coded character set identifier for use with the WebSphere MQ queue manager; for example: `850`.

c. Click **Apply**. This defines the destination to WebSphere Application Server, and enables you to browse or change additional properties.

5. **Optional:** Change properties for the topic connection factory, according to your needs.
6. **Optional:** Change connection pool properties and session pool properties, according to your needs.
7. Click **OK**.
8. Save any changes to the master configuration.
9. To have the changed configuration take effect, stop then restart the application server.

Configuring a JMS queue destination, for WebSphere MQ:

Use this task to browse or change a JMS queue destination for point-to-point messaging with WebSphere MQ as a messaging provider. This task contains an optional step for you to create a new JMS queue destination.

To browse or configure a JMS queue destination for use with WebSphere MQ as a messaging provider, use the administrative console to complete the following steps:

1. Display the WebSphere MQ messaging provider. In the navigation pane, expand **Resources** → **JMS Providers** → **WebSphere MQ**.
2. **Optional:** Change the **Scope** setting to the level at which the JMS destination is visible to applications.
3. In the contents pane, under Additional Properties, click **WebSphere MQ queue destinations** This displays a table listing any existing JMS queue destinations, with a summary of their properties.
4. To browse or change the properties of an existing JMS queue destination, click its name in the list. Otherwise, to create a new queue, complete the following steps:

   a. Click **New** in the content pane.

   b. Specify the following required properties. You can specify other properties, as described in a later step.

   Name The name by which this queue destination is known for administrative purposes within IBM WebSphere Application Server.

   JNDI name
   The JNDI name that is used to bind the queue destination into the name space.

   Base Queue Name
   The name of the queue to which messages are sent, on the queue manager specified by the **Base Queue Manager Name** property.

   CCSID
   The coded character set identifier for use with the WebSphere MQ queue manager; for example: `850`.

   c. Click **Apply**. This defines the queue destination to WebSphere Application Server, and enables you to browse or change additional properties.
5. **Optional:** Change properties for the queue destination, according to your needs.
6. **Optional:** If you want WebSphere Application Server to try to use the WebSphere MQ queue manager’s remote administration utilities to create the queue, configure the WebSphere MQ Queue Connection properties.

   If you have already created your underlying queue in WebSphere MQ using its administration tools (such as runmqsc or MQ Explorer), you do not need to configure any of the WebSphere MQ Queue Connection properties. You only need to configure these properties if you want WebSphere Application Server to try to use the WebSphere MQ queue manager’s remote administration utilities to create the queue.

To be able to browse or change these MQ Config properties, you must have installed the WebSphere MQ client. If you have not done this, the administrative console displays messages like the following:

```
The WMQQueueDefiner MBean has encountered an error.
WMSG0331E: The MQ Client is required for this functionality, but it is not installed.
```

Note: For any changes to these properties to take effect on the queue manager, the WebSphere MQ Queue Manager on which the queue resides (or will reside) must be configured for remote administration and be running.

For more details about these properties, see WebSphere MQ config properties for the queue destination.

7. Click **OK**.
8. Save any changes to the master configuration.
9. To have the changed configuration take effect, stop then restart the application server.

Configuring a JMS topic destination, for WebSphere MQ:

Use this task to browse or change a JMS topic destination for publish/subscribe messaging with WebSphere MQ as a messaging provider. This task contains an optional step for you to create a new JMS topic destination.

To configure a JMS topic destination for use with WebSphere MQ as a messaging provider, use the administrative console to complete the following steps:

1. Display the WebSphere MQ messaging provider. In the navigation pane, expand **Resources** → **JMS Providers** → **WebSphere MQ**.
2. **Optional:** Change the **Scope** setting to the level at which the JMS destination is visible to applications.
3. In the contents pane, under Additional Properties, click **WebSphere MQ topic destinations** This displays a table listing any existing JMS topic destinations, with a summary of their properties.
4. To browse or change an existing JMS topic destination, click its name in the list. Otherwise, to create a new topic destination, complete the following steps:
   a. Click **New** in the content pane.
   b. Specify the following required properties. You can specify other properties, as described in a later step.

      Name The name by which this connection factory is known for administrative purposes within IBM WebSphere Application Server.

      JNDI Name
      The JNDI name that is used to bind the connection factory into the name space.

      Base Topic Name
      The name of the WebSphere MQ topic to which messages are sent.

      CCSID
      The coded character set identifier for use with the WebSphere MQ queue manager; for example: `850`.
   c. Click **Apply**. This defines the topic destination to WebSphere Application Server, and enables you to browse or change additional properties.
5. **Optional:** Change properties for the topic destination, according to your needs.
6. Click **OK**.
7. Save any changes to the master configuration.
8. To have the changed configuration take effect, stop then restart the application server.

Configuring WebSphere MQ connection pooling:

Use this task to browse or change properties of WebSphere MQ connection pooling for JMS connections from an application server to WebSphere MQ as a JMS provider.

To enable WebSphere MQ connection pooling for an application server, use the administrative console to complete the following steps:

1. Display the Message Listener Service properties for the application server
   a. In the navigation pane, click **Servers** → **Application Servers**
   b. In the content pane, click the name of the application server.
   c. Under Additional Properties, click **Message Listener Service properties**.
2. Select Custom Properties, to enable WebSphere MQ connection pooling, add the following custom properties:
   mqjms.pooling.threshold
   The maximum number of unused connections in the pool.
   mqjms.pooling.timeout
   The timeout in milliseconds for unused connections in the pool.
3. Click **OK**.
4. Save any changes to the master configuration.
5. To have the changed configuration take effect, stop then restart the application server.

WebSphere MQ JMS connection pooling: To improve the overall performance of JMS within the system, the message listener service enables the connection pooling facility provided by the WebSphere MQ JMS implementation. This support does not affect the performance of a message listener, because it retains its connections while listening on a destination, but does affect the overall JMS system performance. When a connection is no longer required, WebSphere MQ can pool the connection then reuse it later instead of destroying it.

Note: This support is only available for use with WebSphere MQ as a JMS provider.

To enable WebSphere MQ connection pooling and configure the characteristics of the WebSphere MQ connection pool, see Enabling WebSphere MQ JMS connection pooling.

Securing WebSphere MQ messaging directories and log files

Use this task to restrict access to the /var/mqm directories and log files needed for WebSphere MQ as a JMS provider.

You need to set the permissions described in this topic, to reduce the risk of severe security exposures.

Note: The /var file system is used to store all the security logging information for the system, and is used to store the temporary files for email and printing. Therefore, it is critical that you maintain free space in /var for these operations and prevent unauthorized access to the file system. If you do not create a separate file system for messaging data, and /var fills up, all security logging will be stopped on the system until some free space is available in /var. Also, email and printing will no longer be possible until some free space is available in /var.

This procedure involves steps that you complete at different stages of installing and using IBM WebSphere Application Server, as described below. The steps are also described at appropriate points in other tasks, but are collected here for completeness.

This procedure applies only to the ordinary UNIX file system. If your site uses access-control lists, secure the files by using that mechanism. Any site-specific requirements can affect the desired owner, group and corresponding privileges. For example, on AIX, complete the following steps:

1. Before installing WebSphere MQ, create and mount a journalized file system called /var/mqm. Use a partition strategy with a separate volume for the messaging data. This means that other system activity is not affected if a large amount of messaging work builds up in /var/mqm.

2. Install WebSphere MQ as a messaging provider.

   As part of this stage, the installation program creates the /var/mqm/errors and /var/mqm/qmgrs/@SYSTEM/errors directories used to hold messaging logging files.

3. Restrict access to the /var/mqm/errors directory and the logging files, by using the following commands:

   ```
   chmod 3777 /var/mqm/errors
   chown mqm:mqm /var/mqm/errors

   touch /var/mqm/errors/AMQERR01.LOG
   chown mqm:mqm /var/mqm/errors/AMQERR01.LOG
   chmod 666 /var/mqm/errors/AMQERR01.LOG

   touch /var/mqm/errors/AMQERR02.LOG
   chown mqm:mqm /var/mqm/errors/AMQERR02.LOG
   chmod 666 /var/mqm/errors/AMQERR02.LOG

   touch /var/mqm/errors/AMQERR03.LOG
   chown mqm:mqm /var/mqm/errors/AMQERR03.LOG
   chmod 666 /var/mqm/errors/AMQERR03.LOG
   ```

4. Restrict access to the /var/mqm/qmgrs/@SYSTEM/errors directory and the logging files, by using the following commands:

   ```
   chmod 3777 /var/mqm/qmgrs/@SYSTEM/errors
   chown mqm:mqm /var/mqm/qmgrs/@SYSTEM/errors

   touch /var/mqm/qmgrs/@SYSTEM/errors/AMQERR01.LOG
   chown mqm:mqm /var/mqm/qmgrs/@SYSTEM/errors/AMQERR01.LOG
   chmod 666 /var/mqm/qmgrs/@SYSTEM/errors/AMQERR01.LOG

   touch /var/mqm/qmgrs/@SYSTEM/errors/AMQERR02.LOG
   chown mqm:mqm /var/mqm/qmgrs/@SYSTEM/errors/AMQERR02.LOG
   chmod 666 /var/mqm/qmgrs/@SYSTEM/errors/AMQERR02.LOG

   touch /var/mqm/qmgrs/@SYSTEM/errors/AMQERR03.LOG
   chown mqm:mqm /var/mqm/qmgrs/@SYSTEM/errors/AMQERR03.LOG
   chmod 666 /var/mqm/qmgrs/@SYSTEM/errors/AMQERR03.LOG
   ```

5. For each application server that uses JMS resources provided by WebSphere MQ, restrict access to the server's /var/mqm/qmgrs/*long_server_name*/errors directory and its messaging logging files. You should restrict access to the server's directory and logging files, as soon after creating the application server as possible.

   To restrict access to the server's directory and logging files, use the following commands:

   ```
   chmod 3775 /var/mqm/qmgrs/long_server_name/errors
   chown mqm:mqm /var/mqm/qmgrs/long_server_name/errors

   touch /var/mqm/qmgrs/long_server_name/errors/AMQERR01.LOG
   chown mqm:mqm /var/mqm/qmgrs/long_server_name/errors/AMQERR01.LOG
   chmod 666 /var/mqm/qmgrs/long_server_name/errors/AMQERR01.LOG

   touch /var/mqm/qmgrs/long_server_name/errors/AMQERR02.LOG
   chown mqm:mqm /var/mqm/qmgrs/long_server_name/errors/AMQERR02.LOG
   chmod 666 /var/mqm/qmgrs/long_server_name/errors/AMQERR02.LOG

   touch /var/mqm/qmgrs/long_server_name/errors/AMQERR03.LOG
   chown mqm:mqm /var/mqm/qmgrs/long_server_name/errors/AMQERR03.LOG
   chmod 666 /var/mqm/qmgrs/long_server_name/errors/AMQERR03.LOG
   ```

   Where *long_server_name* is the long name assigned to the server, in the following form: `WAS_nodename_server_name`. For example, if you created an application server called `server1` to run on the node called `appnode1`, the long server name would be: `WAS_appnode1_server1`.

This task has restricted access to the /var/mqm directories and log files needed for WebSphere MQ as a JMS provider, such that only the user ID mqm or members of the mqm user group have write access.

Using JMS resources of a generic provider

This topic is the entry-point into a set of topics about enabling WebSphere applications to use JMS resources provided by a generic messaging provider (other than a WebSphere default messaging provider or WebSphere MQ).

You can install a messaging provider other than the default messaging provider or WebSphere MQ. WebSphere applications can use the JMS 1.1 interfaces or JMS 1.0.2 interfaces to access JMS resources provided by the generic messaging provider, in addition to JMS resources provided by the default messaging provider or WebSphere MQ (if installed).

You can use the WebSphere administrative console to administer the JMS connection factories and destinations provided by generic messaging providers.

In a mixed-version WebSphere Application Server deployment manager cell, you can administer generic messaging resources on both Version 6 and Version 5 nodes. For Version 5 nodes, the administrative console presents the subset of resources and properties that are applicable to WebSphere Application Server Version 5.

For more information about using a generic messaging provider to WebSphere Application Server, see the following topics:
- Defining a generic messaging provider
- “Displaying administrative lists of generic messaging resources” on page 1354
- “Configuring JMS resources for a generic messaging provider” on page 1360

Defining a generic messaging provider

Use this task to define a new messaging provider to WebSphere Application Server, for use instead of the default messaging provider or a WebSphere MQ as a messaging provider.

Before starting this task, you should have installed and configured the messaging provider and its resources by using the tools and information provided with the messaging provider.

To define a new generic messaging provider to WebSphere Application Server, use the administrative console to complete the following steps:

1. In the navigation pane, click **JMS Providers** → **Generic**. This displays the existing generic messaging providers in the content pane.
2. To define a new generic messaging provider, click **New** in the content pane. Otherwise, to change the definition of an existing messaging provider, click the name of the provider. This displays the properties used to define the messaging provider in the content pane.
3. Specify the following required properties. You can specify other properties, as described in a later step.

   Name The name by which this messaging provider is known for administrative purposes within IBM WebSphere Application Server.

   External initial context factory
   The Java classname of the initial context factory for the JMS provider.

   External provider URL
   The JMS provider URL for external JNDI lookups.
4. **Optional:** Click **Apply**. This enables you to specify additional properties.
5. **Optional:** Specify other properties for the messaging provider.

   Under Additional Properties, you can use the **Custom Properties** link to specify custom properties for your initial context factory, in the form of standard javax.naming properties.
6. Click **OK**.
7. Save the changes to the master configuration.
8. To have the changed configuration take effect, stop then restart the application server.

You can now configure JMS resources for the generic messaging provider, as described in “Configuring JMS resources for a generic messaging provider” on page 1360.

Displaying administrative lists of generic messaging resources

Use this task with the WebSphere administrative console to display administrative lists of JMS resources provided by a messaging provider other than the default messaging provider or WebSphere MQ.

You can use the WebSphere administrative console to display lists of the following types of JMS resources provided by a generic messaging provider. You can use the panels displayed to select JMS resources to administer, or to create or delete JMS resources (where appropriate).

To display administrative lists of JMS resources for a generic messaging provider, complete the following general steps:

1. Start the WebSphere administrative console.
2. In the navigation pane, click **Resources** → **JMS Providers** → **Generic**
3. If appropriate, in the content pane, change the scope of the generic messaging provider. If the scope is set to node or server scope for a Version 5 node, the administrative console presents the subset of resources and properties that are applicable to WebSphere Application Server Version 5.
4. In the content pane, under Additional Resources, click the link for the type of JMS resource. This displays a list of any existing resources of the selected type. For more information about the settings panels displayed for resources, see the related reference topics.

JMS provider collection:

Use this panel to list JMS providers, or to select a JMS provider to view or change its configuration properties.

To view this administrative console page, click **Resources** → **JMS providers** → **Generic**

To view or change the properties of a JMS provider or its resources, select its name in the list displayed.

To define a new generic JMS provider, click **New**.

To act on one or more of the JMS providers listed, click the check boxes next to the names of the objects that you want to act on, then use the buttons provided.

Name The name by which this JMS provider is known for administrative purposes.

Description
A description of this JMS provider for administrative purposes.

Generic JMS connection factory collection:

The JMS connection factories configured in the associated generic messaging provider for both point-to-point and publish/subscribe messaging. Use this panel to create or delete JMS connection factories, or to select a connection factory to browse or change its configuration properties.

This panel shows a list of the generic JMS connection factories with a summary of their configuration properties.

To view this administrative console page, use the administrative console to complete the following steps:

1. In the navigation pane, expand **Resources** → **JMS Providers** → **Generic**.
2. In the content pane, click the name of the generic messaging provider that you want to support the JMS connection factory.
3. Under Additional Properties, click **JMS connection factories**.

To define a new JMS connection factory, click **New**.

To view or change the properties of a JMS connection factory, select its name in the list displayed.

To act on one or more of the JMS connection factories listed, click the check boxes next to the names of the objects that you want to act on, then use the buttons provided.

Generic JMS connection factory settings:

Use this panel to browse or change the configuration properties of the selected JMS connection factory for use with the associated generic JMS provider. These configuration properties control how connections are created to the JMS destinations on the provider.

A JMS connection factory is used to create connections to JMS destinations. The JMS connection factory is created by the associated JMS provider.

To view this page, use the administrative console to complete the following steps:

1. In the navigation pane, expand **Resources** → **JMS Providers** → **Generic**.
2. In the content pane, click the name of the messaging provider that you want to support the JMS connection factory.
3. If appropriate, in the content pane, change the scope of the generic messaging provider.
4. Under Additional Properties, click **JMS connection factories**.
5. Click the name of the JMS connection factory that you want to work with.

A JMS connection factory for a generic JMS provider (other than the default messaging provider or WebSphere MQ as a JMS provider) has the following properties:

Scope:

Specifies the level to which this resource definition is visible to applications.

Resources such as messaging providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates which are defined at more general scopes.

The scope displayed is for information only, and cannot be changed on this panel. If you want to browse or change this resource (or other resources) at a different scope, change the scope on the messaging provider settings panel, then click **Apply**, before clicking the link for the type of resource.

Data type	String

Name:

The name by which this JMS connection factory is known for administrative purposes within IBM WebSphere Application Server. The name must be unique within the associated messaging provider.

Data type	String

Type:

Whether this connection factory is for creating JMS queue destinations or JMS topic destinations.

Select one of the following options:

QUEUE
A JMS queue connection factory for point-to-point messaging.

TOPIC
A JMS topic connection factory for publish/subscribe messaging.

JNDI name:

The JNDI name that is used to bind the connection factory into the WebSphere Application Server name space.

As a convention, use the fully qualified JNDI name; for example, in the form jms/*Name*, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type	String

Description:

A description of this connection factory for administrative purposes within IBM WebSphere Application Server.

Data type	String
Default	Null

Category:

A category used to classify or group this connection factory, for your IBM WebSphere Application Server administrative records.

Data type	String

External JNDI name:

The JNDI name that is used to bind the connection factory into the name space of the generic messaging provider.

As a convention, use the fully qualified JNDI name; for example, in the form jms/*Name*, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type	String

Component-managed Authentication Alias:

This alias specifies a user ID and password to be used to authenticate connection to a JMS provider for application-managed authentication.

This property provides a list of the J2C authentication data entry aliases that have been defined to WebSphere Application Server. You can select a data entry alias to be used to authenticate the creation of a new connection to the JMS provider.

If you have enabled global security for WebSphere Application Server, select the alias that specifies the user ID and password used to authenticate the creation of a new connection to the JMS provider. The use of this alias depends on the resource authentication (res-auth) setting declared in the connection factory resource reference of an application component's deployment descriptors.

Container-managed Authentication Alias:

This alias specifies a user ID and password to be used to authenticate connection to a JMS provider for container-managed authentication.

This property provides a list of the J2C authentication data entry aliases that have been defined to WebSphere Application Server. You can select a data entry alias to be used to authenticate the creation of a new connection to the JMS provider.

If you have enabled global security for WebSphere Application Server, select the alias that specifies the user ID and password used to authenticate the creation of a new connection to the JMS provider. The use of this alias depends on the resource authentication (res-auth) setting declared in the connection factory resource reference of an application component's deployment descriptors.

Mapping-Configuration Alias:

The module used to map authentication aliases.

This field provides a list of the modules that have been configured on the **Global Security** → **JAAS Configuration** → **Application Logins Configuration** property. For more information about the mapping configurations, see Java Authentication and Authorization service configuration entry settings.

Data type	Enum
Default	Null
Range	**ClientContainer** The client container maps authentication aliases. **WSLogin** The WSLogin module maps authentication aliases. **DefaultPrincipalMapping** The JAAS configuration maps an authentication alias to its userid and password.

Connection pool:

Specifies an optional set of connection pool settings.

Connection pool properties are common to all J2C connectors.

The application server pools connections and sessions with the messaging provider to improve performance. You need to configure the connection and session pool properties appropriately for your applications, otherwise you may not get the connection and session behavior that you want.

Change the size of the connection pool if concurrent server-side access to the JMS resource exceeds the default value. The size of the connection pool is set on a per queue or topic basis.

Session pool:

An optional set of session pool settings.

This link provides a panel of optional connection pool properties, common to all J2C connectors.

The application server pools connections and sessions with the messaging provider to improve performance. You need to configure the connection and session pool properties appropriately for your applications, otherwise you may not get the connection and session behavior that you want.

Custom properties:

An optional set of name and value pairs for custom properties passed to the messaging provider.

Generic JMS destination collection:

The JMS destinations configured in the associated messaging provider for point-to-point and publish/subscribe messaging. Use this panel to create or delete JMS destinations, or to select a JMS destination to browse or change its configuration properties.

To view this page, use the administrative console to complete the following steps:
1. In the navigation pane, click **Resources** → **JMS Providers** → **Generic**.
2. In the content pane, click the name of the messaging provider that you want to support the JMS destination.
3. Under Additional Properties, click **JMS destinations**.

To define a new JMS destination, click **New**.

To view or change the properties of a JMS destination, select its name in the list displayed.

To act on one or more of the JMS destinations listed, click the check boxes next to the names of the objects that you want to act on, then use the buttons provided.

Generic JMS destination settings:

Use this panel to browse or change the configuration properties of the selected JMS destination for use with the associated JMS provider.

A JMS destination is used to configure the properties of a JMS destination for the associated generic messaging provider (not the default messaging provider or WebSphere MQ). Connections to the JMS destination are created by the associated JMS connection factory.

To view this page, use the administrative console to complete the following steps:
1. In the navigation pane, click **Resources** → **JMS Providers** → **Generic**.
2. In the content pane, click the name of the messaging provider that you want to support the JMS destination.
3. Under Additional Properties, click **JMS destinations**.
4. Click the name of the JMS destination that you want to work with.

A JMS destination for use with a generic messaging provider has the following properties.

Scope:

Specifies the level to which this resource definition is visible to applications.

Resources such as messaging providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates which are defined at more general scopes.

The scope displayed is for information only, and cannot be changed on this panel. If you want to browse or change this resource (or other resources) at a different scope, change the scope on the messaging provider settings panel, then click **Apply**, before clicking the link for the type of resource.

Data type	String

Name:

The name by which the queue is known for administrative purposes within IBM WebSphere Application Server.

Data type	String

Type:

Whether this JMS destination is a queue (for point-to-point) or topic (for publish/subscribe).

Select one of the following options:

Queue
A JMS queue destination for point-to-point messaging.

Topic A JMS topic destination for publish/subscribe messaging.

JNDI name:

The JNDI name that is used to bind the queue into the application server's name space.

As a convention, use the fully qualified JNDI name; for example, in the form jms/*Name*, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type	String

Description:

A description of the queue, for administrative purposes

Data type	String

Category:

A category used to classify or group this queue, for your IBM WebSphere Application Server administrative records.

Data type	String

External JNDI name:

The JNDI name that is used to bind the queue into the application server's name space.

As a convention, use the fully qualified JNDI name; for example, in the form jms/*Name*, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type	String

Configuring JMS resources for a generic messaging provider

Use the following tasks to configure the JMS connection factories and destinations for a generic messaging provider (not the default messaging provider or WebSphere MQ).

You only need to complete these tasks if your WebSphere Application Server environment uses a messaging provider other than the default messaging provider or WebSphere MQ to support enterprise applications that use JMS. To enable use of such a generic messaging provider, you must have installed and configured the messaging provider, as described in ″Defining a new JMS provider to WebSphere Application Server″ in the information center.

To configure JMS resources for a generic messaging provider, complete the following tasks:
- Configuring a JMS connection factory
- Configuring a JMS destination

Configuring a JMS connection factory, generic JMS provider:

Use this task to browse or change the properties of a JMS connection factory for use with a generic JMS provider (other than the default messaging provider or WebSphere MQ).

To configure a JMS connection factory for use with a generic JMS provider, use the administrative console to complete the following steps:

1. Display the generic messaging provider. In the navigation pane, expand **Resources** → **JMS Providers** → **Generic**.
2. **Optional:** Change the **Scope** setting to the level at which the connection factory is visible to applications.
3. In the content pane, under Additional Properties, click **JMS connection factories** This displays a table listing any existing JMS connection factories, with a summary of their properties.
4. To browse or change an existing JMS connection factory, click its name in the list. Otherwise, to create a new connection factory, complete the following steps:
   a. Click **New** in the content pane.
   b. Specify the following required properties. You can specify other properties, as described in a later step.

      Name The name by which this JMS connection factory is known for administrative purposes within IBM WebSphere Application Server.

      Type Select whether the connection factory is for JMS queues (QUEUE) or JMS topics (TOPIC).

      JNDI Name
      The JNDI name that is used to bind the JMS connection factory into the WebSphere Application Server name space.

      External JNDI Name
      The JNDI name that is used to bind the JMS connection factory into the name space of the messaging provider.

   c. Click **Apply**. This defines the JMS connection factory to WebSphere Application Server, and enables you to browse or change additional properties.
5. **Optional:** Change properties for the JMS connection factory, according to your needs.
6. Click **OK**.
7. Save any changes to the master configuration.
8. To have the changed configuration take effect, stop then restart the application server.

Configuring a JMS destination, a generic JMS provider:

Use this task to browse or change the properties of a JMS destination for use with a generic JMS provider (other than the default messaging provider or WebSphere MQ).

To configure a JMS destination for use with a generic JMS provider, use the administrative console to complete the following steps:

1. Display the generic messaging provider. In the navigation pane, expand **Resources** → **JMS Providers** → **Generic**.
2. **Optional:** Change the **Scope** setting to the level at which the connection factory is visible to applications.
3. In the content pane, under Additional Properties, click **JMS destinations** This displays a table listing any existing JMS destinations, with a summary of their properties.
4. To browse or change an existing JMS destination, click its name in the list. Otherwise, to create a new destination, complete the following steps:
   a. Click **New** in the content pane.
   b. Specify the following required properties. You can specify other properties, as described in a later step.

      Name The name by which this JMS destination is known for administrative purposes within IBM WebSphere Application Server.

      Type Select whether the destination is for JMS queues (QUEUE) or JMS topics (TOPIC).

      JNDI Name
      The JNDI name that is used to bind the JMS destination into the WebSphere Application Server name space.

      External JNDI Name
      The JNDI name that is used to bind the JMS destination into the name space of the messaging provider.

   c. Click **Apply**. This defines the JMS destination to WebSphere Application Server, and enables you to browse or change additional properties.
5. **Optional:** Change properties for the JMS destination, according to your needs.
6. Click **OK**.
7. Save any changes to the master configuration.
8. To have the changed configuration take effect, stop then restart the application server.

Administering support for message-driven beans

Use these tasks to manage resources used to support message-driven beans. These tasks are in addition to the tasks for administering resource adapters, JMS providers and the resources they provide.

You can use the WebSphere administrative console to configure the following resources for message-driven beans:

- J2C activation specifications for JCA 1.5-compliant message-driven beans. Activation specifications must be provided when the application's resources are configured using the default messaging provider or any generic J2C Resource Adapter that supports inbound messaging.
- The message listener service, listener ports, and listeners for EJB 2.0 message-driven beans deployed against listener ports. Listener ports must be provided when using the JMS providers: V5 Default Messaging, WebSphere MQ, or Generic.

You can update the configuration data at any time, but some updates only take effect when the appropriate server is next started.

For information about administering support for message-driven beans, see the following topics:

- Configuring JMS activation specifications, default messaging provider
- "Configuring a J2C activation specification"
- "Configuring a J2C administered object" on page 1364
- Configuring message listener resources for EJB 2.0 message-driven beans

For other information about administering JMS providers and the messaging resources they provide, see the list of related topics.

Configuring a J2C activation specification

Use this task to configure a J2C activation specification used to deploy message-driven beans with an external resource adapter.

Use this task if you want to use a message-driven bean as a listener on a Java Connector Architecture (JCA) 1.5 resource adapter other than the default messaging JMS provider.

To configure a J2C activation specification for an external resource adapter, use the administrative console to complete the following steps. This task contains an optional step for you to create a new activation specification.

1. Display the external resource adapter. In the navigation pane, click **Resources** → **Resource Adapters** → *adapter_name*. This displays in the content pane a table of properties for the external resource adapter, including links to the types of J2C resources that it provides.
2. **Optional:** Change the **Scope** setting to the scope level at which the activation specification is to be visible to applications, according to your needs.
3. In the content pane, under the Activation specifications heading, click **J2C Activation Specifications**. This lists any existing J2C activation specifications for the external resource adapter in the content pane.
4. Display the properties of the J2C activation specification. If you want to display an existing J2C activation specification, click one of the names listed.

   Alternatively, if you want to create a new J2C activation specification, click **New**, then specify the following required properties:

   Name Type the name by which the activation specification is known for administrative purposes. The JNDI name is automatically generated based on the value for the Name property.

   Message listener type
   Select the message listener type that this activation specification instance should support. This list is based on the deployment descriptor of the external resource adapter.

   Depending on the external resource adapter, there can be additional required properties that need to be supplied. To provide values for these properties, click **Custom properties**. When creating a new activation specification, you may need to click **Apply** before this custom property selection is available.
5. Specify properties for the activation specification, according to your needs .
6. Click **OK**.
7. Save your changes to the master configuration.

J2C Activation Specifications collection:

This page contains a list of J2C activation specifications for a resource adapter configuration and is used to create new J2C activation specifications, to select J2C activation specifications for configuration changes, or to delete J2C activation specifications.

Activation specification definitions and classes are provided by a resource adapter when it is installed. Using this information, the administrator can create and configure J2C activation specifications with JNDI names that are then available for applications to use. The resource adapter uses a J2C activation specification to configure a specific endpoint instance. Each application configuring one or more endpoints must specify the resource adapter that sends messages to the endpoint. The application must use the activation specification to provide the configuration properties related to the processing of the inbound messages.

To view this administrative console page, click **Resources** >**Resource Adapters** > *resource_adapter* > **J2C Activation Specifications**.

Name:

Specifies the display name of the J2C activation specification instance.

A string with no spaces meant to be a meaningful text identifier for the J2C activation specification.

Data type	String

JNDI name:

Specifies the Java Naming and Directory Interface (JNDI) name for the J2C activation specification instance.

Data type	String

Description:

A free-form text string to describe the J2C activation specification instance.

Data type	String

Message Listener Type:

The Message Listener Type that is used by this activation specification.

The list of available classes is provided by the resource adapter.

Data type	String

J2C Activation Specifications settings:

Use this page to specify the settings for a J2C activation specification.

The resource adapter uses a J2C activation specification to configure a specific endpoint instance. Each application configuring one or more endpoints must specify the resource adapter that sends messages to the endpoint. The application must use the activation specification to provide the configuration properties related to the processing of the inbound messages.

To view this administrative console page, click **Resources** >**Resource Adapters** > *resource_adapter* > **J2C Activation Specifications** > *activation_specification*.

Name:

Specifies the display name of the J2C activation specification instance.

A string with no spaces meant to be a meaningful text identifier for the J2C activation specification. Name is required

Data type	String

JNDI name:

Specifies the Java Naming and Directory Interface (JNDI) name for the J2C activation specification instance.

The JNDI name is required. If you do not specify one, it is created from the Name field. If not specified, the JNDI name defaults to *eis/[name]*

Data type	String

Description:

A free-form text string to describe the J2C activation specification instance.

Data type	String

Authentication alias:

This optional field is used to bind the J2C activation specification to an authentication alias (configured through the security JAAS screens).

This alias is used to access a user name and password that are set on the configured J2C activation specification. This field is only meaningful if the J2C activation specification you are configuring has a UserName and Password field.

Data type	Text

Message Listener Type:

The Message Listener Type used by this activation specification.

For new objects, the list of available classes is provided by the resource adapter in a drop-down list. After you create the activation specification, the field is a read only text field.

Data type	Drop-down list or text

Destination JNDIName:

The destination JNDIName field only appears when a message of type javax.jms.Destination with name *Destination* is received.

Configuring a J2C administered object

Use this task to configure a J2C administered object used to configure objects with an external resource adapter.

Use this task if you want to use a message-driven bean as a listener on a Java Connector Architecture (JCA) 1.5 resource adapter other than the default messaging JMS provider.

To configure a J2C administered object for an external resource adapter, use the administrative console to complete the following steps. This task contains an optional step for you to create a new administered object.

1. Display the external resource adapter. In the navigation pane, click **Resources** → **Resource Adapters** → *adapter_name*. This displays in the content pane a table of properties for the external resource adapter, including links to the types of J2C resources that it provides.
2. **Optional:** Change the **Scope** setting to the scope level at which the activation specification is to be visible to applications, according to your needs.
3. In the content pane, under the Activation specifications heading, click **J2C Administered Objects**. This lists any existing J2C administered objects for the external resource adapter in the content pane.
4. Display the properties of the J2C administered object. If you want to display an existing J2C administered object, click one of the names listed.

   Alternatively, if you want to create a new J2C administered object, click **New**, then specify the following required properties:

   Name Type the name by which the J2C administered object is known for administrative purposes. The JNDI name is automatically generated based on the value for the Name property.

   Administered object class
   Select the administered object class that this instance should support. This list is based on the deployment descriptor of the external resource adapter.

   Depending on the external resource adapter, there can be additional required properties that need to be supplied. To provide values for these properties, click **Custom properties**. When creating a new administered object, you may need to click **Apply** before this custom property selection is available.
5. Specify properties for the activation specification, according to your needs .
6. Click **OK**.
7. Save your changes to the master configuration.

J2C Administered Objects collection:

Use this page to specify administered object settings for a Resource Adapter.

Administered object definitions and classes are provided by a resource adapter when you install it. Using this information, the administrator can create and configure J2C administered objects with JNDI names that are then available for applications to use. Some messaging styles may need applications to use special administered objects for sending and synchronously receiving messages (through connection objects using messaging style specific APIs). It is also possible that administered objects may be used to perform transformations on an asynchronously received message in a message provider-specific way. Administered objects can be accessed by a component by using either a resource environment reference or a message destination reference (preferred).

To view this administered console page, click **Resources** >**Resource Adapters** > *resource_adapter* > **J2C Administered Objects**.

JNDI Name:

Specifies the JNDI name of the administered object.

Data type	String

Name:

Specifies display name assigned to this administered object.

Data type	String

Description:

Specifies a description for the administered object.

Data type	String

Administered Object Class:

Specifies the Administered Object class that is associated with this administered object. This class must be one that is provided by the resource adapter.

Data type	String

J2C Administered Object settings:

Use this page to specify the settings for an administered object.

Administered object definitions and classes are provided by a resource adapter when you install it. Using this information, the administrator can create and configure J2C administered objects with JNDI names that are then available for applications to use. Some messaging styles may need applications to use special administered objects for sending and synchronously receiving messages (through connection objects using messaging style specific APIs). It is also possible that administered objects may be used to perform transformations on an asynchronously received message in a message provider-specific way. Administered objects can be accessed by a component by using either a resource environment reference or a message destination reference (preferred).

To view this administrative console page, click **Resources** >**Resource Adapters** > *resource_adapter* > **J2C Administered Objects** > *administered_object*.

Name:

Specifies the name of the J2C administered object instance.

A string with no spaces meant to be a meaningful text identifier for the administered object. This name is required.

Data type	String

JNDI name:

Specifies the Java Naming and Directory Interface (JNDI) name that this administered object is bound under.

The JNDI name is required. If you do not specify one, it is created from the Name field. If not specified, the JNDI name defaults to *eis/[name]*

Data type	String

Description:

Specifies a text description of the J2C administered object instance.

Data type	String

Administered Object Class:

For new objects, the list of available classes is provided by the resource adapter in a drop-down list. You can only select classes from this list.

After you create the administered object, you cannot modify the Administered Object Class; it is read only.

Data type	Drop-down list or Text

Configuring message listener resources for message-driven beans

Use the following tasks to configure resources needed by the message listener service to support message-driven beans for use with a JMS provider that does not have a JCA 1.5 resource adapter.

For JMS messaging, message-driven beans can use a JMS provider that has a JCA 1.5 resource adapter, such as the default messaging provider that is part of WebSphere Application Server version 6. With a JCA 1.5 resource adapter, you deploy EJB 2.1 message-driven beans as JCA resources to use a J2C activation specification. If the JMS provider does not have a JCA 1.5 resource adapter, such as the V5 Default Messaging and WebSphere MQ, you must configure JMS message-driven beans against a listener port (as in WebSphere Application Server version 5).

If you want to deploy an enterprise application to use JMS message-driven beans with a JMS provider that does not have a JCA 1.5 resource adapter, use the following task descriptions:

- Configuring the message listener service
- Adding a new listener port
- Configuring a listener port
- Deleting a listener port
- Configuring security for EJB 2.0 message-driven beans
- Administering listener ports

Configuring the message listener service:

Use this task to configure the properties of the message listener service for an application server, to support message-driven beans deployed against listener ports.

If the JMS provider does not have a JCA 1.5 resource adapter, such as the V5 Default Messaging and WebSphere MQ, you must configure JMS message-driven beans against a listener port (as in WebSphere Application Server version 5).

If you want to deploy an enterprise application to use message-driven beans with listener ports, you can use this task to browse or change the configuration of the message listener service for an application server.

To configure the message listener service for an application server, use the administrative console to complete the following steps:

1. Display the listener service settings page:
   a. In the navigation pane, select **Servers** → **Application Servers**
   b. In the content pane, click the name of the application server.
   c. Under Communications, click **Messaging** → **Message Listener Service**
2. **Optional:** Browse or change the value of properties for the message-driven bean thread pool.
   a. Click **Thread Pool**
   b. Change the following properties, to suit your needs:

      Minimum size
      The minimum number of threads to allow in the pool.

      Maximum size
      The maximum number of threads to allow in the pool.

Thread inactivity timeout
The number of milliseconds of inactivity that should elapse before a thread is reclaimed. A value of 0 indicates not to wait and a negative value (less than 0) means to wait forever.

Note: The administrative console does not allow you to set the inactivity timeout to a negative number. To do this you must modify the value directly in the config.xml file.

Allow thread allocation beyond maximum thread size
Select this check box to enable the number of threads to increase beyond the maximum size configured for the thread pool.

c. Click **OK**.

3. **Optional:** Specify any of the following optional properties that you need, as **Custom properties** of the message listener service:

   NON.ASF.RECEIVE.TIMEOUT, MQJMS.POOLING.TIMEOUT, MQJMS.POOLING.THRESHOLD, MAX.RECOVERY.RETRIES, and RECOVERY.RETRY.INTERVAL.

   For more information about these custom properties, see Custom Properties.

   To browse or change the properties, complete the following steps:

   a. Click **Custom properties**

   b. For each custom property, specify a value to suit your needs.

      If you have not specified a property before:

      1) Click **New**.
      2) Type the name of the property.
      3) Type the value of the property.
      4) Click **OK**.
4. Save your changes to the master configuration.
5. To have the changed configuration take effect, stop then restart the Application Server.

Message listener service:

The message listener service is an extension to the JMS functions of the JMS provider. It provides a listener manager that controls and monitors one or more JMS listeners, which each monitor a JMS destination on behalf of a deployed message-driven bean.

This panel displays links to the Additional Properties pages for Listener Ports, Thread Pool, and Custom Properties for the message listener service.

To view this administrative console page, click **Servers** → **Application Servers** → *application_server* → **[Communications] Messaging** → **Message Listener Service**

Custom Properties:

An optional set of name and value pairs for custom properties of the message listener service.

You can use the Custom properties page to define the following properties for use by the message listener service.

- NON.ASF.RECEIVE.TIMEOUT
- MQJMS.POOLING.TIMEOUT
- MQJMS.POOLING.THRESHOLD
- MAX.RECOVERY.RETRIES
- RECOVERY.RETRY.INTERVAL

Message listener port collection:

The message listener ports configured in the administrative domain

This panel displays a list of the message listener ports configured in the administrative domain. Each listener port is used with a message-driven bean to automatically receive messages from an associated JMS destination. You can use this panel to add new listener ports or to change the properties of existing listener ports. For more information about the property fields for listener ports, see Listener port properties.

To view this administrative console page, click **Servers** → **Application Servers** → *application_server* → **[Messaging] Message Listener Service** → **Listener Ports**

Listener port settings:

A listener port is used to simplify administration of the association between a connection factory, destination, and deployed message-driven bean.

Use this panel to view or change the configuration properties of the selected listener port.

To view this administrative console page, click **Servers** → **Application Servers** → *application_server* → **[Communications] Messaging** → **Message Listener Service** → **Listener Ports** → *listener_port*

Name:

The name by which the listener port is known for administrative purposes.

Data type	String
Default	Null

Initial state:

The state that you want the listener port to have when the application server is next restarted

Data type	Enum
Units	Not applicable
Default	Started
Range	**Started** When the application server is next started, the listener port is started automatically. **Stopped** When the application server is next started, the listener port is not started automatically. If message-driven beans are to use this listener port on the application server, the system administrator must start the port manually or select the Started value of this property then restart the application server.

Description:

A description of the listener port, for administrative purposes within IBM WebSphere Application Server.

Data type	String
Default	Null

Connection factory JNDI name:

The JNDI name for the JMS connection factory to be used by the listener port; for example, `jms/connFactory1`.

Data type	String
Default	Null

Destination JNDI name:

The JNDI name for the destination to be used by the listener port; for example, `jms/destn1`.

You cannot use a temporary destination for late responses.

Data type	String
Default	Null

Maximum sessions:

Specifies the maximum number of concurrent sessions that a listener can have with the JMS server to process messages.

Each session corresponds to a separate listener thread and therefore controls the number of concurrently processed messages. Adjust this parameter when the server does not fully use the available capacity of the machine and if you do not need to process messages in a specific message order.

Data type	Integer
Units	Sessions
Default	1
Range	1 through 2147483647
Recommended	• If you want to process messages in a strict message order, set the value to 1, so only one thread is ever processing messages. • If you want to process multiple messages simultaneously (known as "message concurrency"), set this property to a value greater than 1. Keep this value as low as possible to prevent overloading client applications. A good starting point for a 100% JMS workload with short transaction times is 2 to 4 sessions per processor. If longer running transactions exist, you may need more sessions, which should be determined by experimentation.

Maximum retries:

The maximum number of times that the listener tries to deliver a message before the listener is stopped, in the range 0 through 2147483647.

The maximum number of times that the listener tries to deliver a message to a message-driven bean instance before the listener is stopped.

Data type	Integer
Units	Retry attempts
Default	0 (no retries)
Range	0 (no retries) through 2147483647

Maximum messages:

The maximum number of messages that the listener can process in one transaction.

If the queue is empty, the listener processes each message when it arrives. Each message is processed within a separate transaction.

For the WebSphere V5 default messaging provider or WebSphere MQ as the JMS provider, if messages start accumulating on the queue then the listener can start processing messages in batches. For generic JMS providers, this property value is passed to the JMS provider but the effect depends on the JMS provider.

Data type	Integer
Units	Number of messages
Default	1
Range	1 through 2147483647
Recommended	For the WebSphere default messaging providers or WebSphere MQ as the JMS provider, if you want to process multiple messages in a single transaction, then set this value to more than 1. If messages start accumulating on the queue, then a value greater than 1 enables multiple messages to be batch-processed into a single transaction, and eliminates much of the overhead of transactions on JMS messages. **Note:** • If one message in the batch fails processing with an exception, the entire batch of messages is put back on the queue for processing. • Any resource lock held by any of the interactions for the individual messages are held for the duration of the entire batch. • Depending on the amount of processing that messages need, and if XA transactions are being used, setting a value greater than 1 can cause the transaction to time out. If an XA transaction does time out routinely because processing multiple messages exceeds the transaction timeout, reduce this property to 1 (to limit processing to one message per transaction) or increase your transaction timeout.

Message listener service custom properties:

Use this panel to view or change an optional set of name and value pairs for custom properties of the message listener service.

To view this administrative console page, click **Servers** → **Application Servers** → *application_server* → **[Communications] Messaging** → **Message Listener Service** → **Custom Properties**

You can use the Custom properties page to define the following properties for use by the message listener service.

- NON.ASF.RECEIVE.TIMEOUT
- MQJMS.POOLING.TIMEOUT
- MQJMS.POOLING.THRESHOLD
- MAX.RECOVERY.RETRIES
- RECOVERY.RETRY.INTERVAL

NON.ASF.RECEIVE.TIMEOUT:

The timeout in milliseconds for synchronous message receives performed by message-driven bean listener sessions in the non-ASF mode of operation.

You should set this property to a non-zero value only if you want to enable the non-ASF mode of operation for all message-driven bean listeners on the application server.

The message listener service has two modes of operation, Application Server Facilities (ASF) and non-Application Server Facilities (non-ASF).

- The ASF mode is meant to provide concurrency and transactional support for applications. For publish/subscribe message-drive beans, the ASF mode provides better throughput and concurrency, because in the non-ASF mode the listener is single-threaded.
- The non-ASF mode is mainly for use with generic JMS providers that do not support JMS ASF, which is an optional extension to the JMS specification. The non-ASF mode is also transactional but, because the path length is shorter than the ASF mode, usually provides improved performance.

  Use non-ASF if:
  - Your generic JMS provider does not provide JMS ASF support
  - You are using message-driven beans with WebSphere topic connections with the DIRECT port, because the embedded publish/subscribe broker using that port does not support XA transactions or JMS ASF.
  - Message order is a strict requirement

Data type	Integer
Units	Milliseconds
Default	ASF mode (custom property not created)
Range	0 or greater milliseconds **0** non-ASF mode is disabled **1 or more** The timeout in milliseconds for non-ASF message-driven bean listener synchronous session receives
Recommended	If a transaction timeout occurs, the message must recycle causing extra work. If you want to use the non-ASF mode, set this property to lower than the transaction timeout, but leave spare at least the maximum duration of your message-driven bean's onMessage() method. For example, if your message-driven bean's onMessage() method typically takes a maximum of 10 seconds, and the transaction timeout is set to 120 seconds, you might set the NON.ASF.RECEIVE.TIMEOUT property to no more than 110000 (110000 milliseconds, that is 110 seconds).

MQJMS.POOLING.TIMEOUT:

The number of milliseconds after which a connection in the pool is destroyed if it has not been used.

An MQSimpleConnectionManager allocates connections on a most-recently-used basis, and destroys connections on a least-recently-used basis. By default, a connection is destroyed if it has not been used for five minutes.

Data type	Integer
Units	Milliseconds
Default	5 minutes
Range	

MQJMS.POOLING.THRESHOLD:

The maximum number of unused connections in the pool.

An MQSimpleConnectionManager allocates connections on a most-recently-used basis, and destroys connections on a least-recently-used basis. By default, a connection is destroyed if there are more than ten unused connections in the pool.

Data type	Integer
Units	Number of connections
Default	10
Range	

MAX.RECOVERY.RETRIES:

The maximum number of times that the listener service tries to get a message from a listener port before the associated listener is stopped, in the range 0 through 2147483647.

Data type	Integer
Units	Retry attempts
Default	0 (no retries)
Range	0 (no retries) through 2147483647

RECOVERY.RETRY.INTERVAL:

The time in seconds between retry attempts by the listener service to get a message from a listener port.

Data type	Integer
Units	Seconds
Default	10
Range	1 through 2147483647

Creating a new listener port:

Use this task to create a new listener port for the message listener service, so that message-driven beans can be associated with the port to retrieve messages.

Although you can continue to deploy an EJB 2.0 message-driven bean against a listener port (as in WebSphere Application Server version 5), you are recommended to deploy such beans as JCA 1.5-compliant resources and to upgrade them to be EJB 2.1 message-driven beans.

If you want to deploy an enterprise application to use EJB 2.0 message-driven beans with listener ports, use this task to create a new listener port for a message-driven bean to retrieve messages from.

To create a new listener port, use the administrative console to complete the following steps:

1. Display the collection list of listener ports:
   a. In the navigation pane, select **Servers** → **Application Servers**
   b. In the content pane, click the name of the application server.
   c. Under Additional Properties, click **Message Listener Service**
   d. Click **Listener Ports**.
2. Click **New**.

3. Specify the following required properties:

   Name The name by which the listener port is known for administrative purposes.

   Connection factory JNDI name
   The JNDI name for the JMS connection factory to be used by the listener port; for example, `jms/connFactory1`

   Destination JNDI name
   The JNDI name for the destination to be used by the listener port; for example, `jms/destn1`.
4. **Optional:** Change other properties for the listener port, according to your needs.
5. Click **OK**.
6. Save your changes to the master configuration.
7. To have the changed configuration take effect, stop then restart the application server.

If enabled, the listener port is started automatically when a message-driven bean associated with that port is installed.

Configuring a listener port:

Use this task to browse or change the properties of an existing listener port, used by message-driven beans associated with the port to retrieve messages.

Although you can continue to deploy an EJB 2.0 message-driven bean against a listener port (as in WebSphere Application Server version 5), you are recommended to deploy such beans as JCA 1.5-compliant resources and to upgrade them to be EJB 2.1 message-driven beans.

If you have deployed an enterprise application to use EJB 2.0 message-driven beans with listener ports, use this task to browse or change the configuration of a listener port that a message-driven bean retrieves messages from.

To configure the properties of a listener port, use the administrative console to complete the following steps:
1. Display the collection list of listener ports:
   a. In the navigation pane, select **Servers** → **Application Servers**
   b. In the content pane, click the name of the application server.
   c. Under Additional Properties, click **Message Listener Service**
   d. Click **Listener Ports**.
2. Click the name of the listener port that you want to work with. This displays the properties of the listener port in the content pane.
3. **Optional:** Change properties for the listener port, according to your needs.
4. Click **OK**.
5. Save any changes to the master configuration.
6. To have a changed configuration take effect, stop then restart the application server.

Deleting a listener port:

Use this task to delete a listener port from the message listener service, to prevent message-driven beans associated with the port from retrieving messages.

To delete a listener port, use the administrative console to complete the following steps:
1. In the navigation pane, select **Servers-> Application Servers** This displays a table of the application servers in the administrative domain.

2. In the content pane, click the name of the application server. This displays the properties of the application server in the content pane.
3. Under Communications, click **Messaging** → **Message Listener Service** This displays the Message Listener Service properties in the content pane.
4. In the content pane, click **Listener Ports**. This displays a list of the listener ports.
5. In the content pane, select the check box for the listener port that you want to delete.
6. Click **Delete**. This action stops the port (needed to allow the port to be deleted) then deletes the port.
7. To save your configuration, click **Save** on the task bar of the Administrative console window.
8. To have the changed configuration take effect, stop then restart the application server.

Configuring security for message-driven beans that use listener ports:

Use this task to configure resource security and security permissions for EJB 2.0 message-driven beans deployed to use listener ports.

Messages arriving at a listener port have no client credentials associated with them. The messages are anonymous.

To call secure enterprise beans from a message-driven bean, the message-driven bean needs to be configured with a RunAs Identity deployment descriptor. Security depends on the role specified by the RunAs Identity for the message-driven bean as an EJB component.

For more information about EJB security, see EJB component security. For more information about configuring security for your application, see Assembling secured applications.

JMS connections used by message-driven beans can benefit from the added security of using J2C container-managed authentication. To enable the use of J2C container authentication aliases and mapping, define a J2C container-managed alias on the JMS connection factory definition that the message-driven bean is using to listen upon (defined by the **Connection factory JNDI name** property of the listener port). If defined, the listener uses the container-managed authentication alias for its JMSConnection security credentials instead of any application-managed alias. To set the container-managed alias, use the administrative console to complete the following steps:

1. To display the listener port settings, click **Servers** → **Application Servers** → *application_server* → **[Communications] Messaging** → **Message Listener Service** → **Listener Ports** → *listener_port*
2. To get the name of the JMS connection factory, look at the **Connection factory JNDI name** property.
3. Display the JMS connection factory properties. For example, to display the properties of a WebSphere queue connection factory provided by the default messaging provider, click **Resources** → **JMS Providers** → **Default Messaging Provider** → → **[Content pane] WebSphere Queue Connection Factories** → *connection_factory*
4. Set the **Authentication alias** property.
5. Click **OK**

Administering listener ports:

Use the following tasks to administer listener ports, which each define the association between a connection factory, a destination, and a message-driven bean.

You can use the WebSphere administrative console to administer listener ports, as described in the following tasks.

- Adding a new listener port

  Use this task to create a new listener port, to specify a new association between a connection factory, a destination, and a message-driven bean. This enables deployed message-driven beans associated with the port to retrieve messages from the destination.

- Configuring a listener port

  Use this task to browse or change the configuration properties of a listener port.
- Starting a listener port

  Use this task to start a listener port manually.
- Stopping a listener port

  Use this task to stop a listener port manually.

Note: If configured as enabled, a listener port is started automatically when a message-driven bean associated with that port is installed. You do not normally need to start or stop a listener port manually.

Starting a listener port:

Use this task to start a listener port on an application server, to enable the listeners for message-driven beans associated with the port to retrieve messages.

A listener is active, that is able to receive messages from a destination, if the deployed message-driven bean, listener port, and message listener service are all started. Although you can start these components in any order, they must all be in a started state before the listener can retrieve messages.

If configured as enabled, a listener port is started automatically when a message-driven bean associated with that port is installed. However, you can start a listener port manually, as described in this topic.

When a listener port is started, the listener manager tries to start the listeners for each message-driven bean associated with the port. If a message-driven bean is stopped, the port is started but the listener is not started, and remains stopped. If you start a message-driven bean, the related listener is started.

To start a listener port on an application server, use the administrative console to complete the following steps:

1. If you want the listener for a deployed message-driven bean to be able to receive messages at the port, check that the message-driven bean has been started.
2. Display the collection list of listener ports:
   a. In the navigation pane, select **Servers** → **Application Servers**
   b. In the content pane, click the name of the application server.
   c. Under Additional Properties, click **Message Listener Service**
   d. Click **Listener Ports**.
3. Select the check box for the listener port that you want to start.
4. Click **Start**.
5. Save your changes to the master configuration.

Stopping a listener port:

Use this task to stop a listener port on an application server, to prevent the listeners for message-driven beans associated with the port from retrieving messages.

When you stop a listener port as described in this topic, the listener manager stops the listeners for all message-driven beans associated with the port.

To stop a listener port on an application server, use the administrative console to complete the following steps:

1. Display the collection list of listener ports:
   a. In the navigation pane, select **Servers** → **Application Servers**

   b. In the content pane, click the name of the application server.
   c. Under Additional Properties, click **Message Listener Service**
   d. Click **Listener Ports**.
2. Select the check box for the listener port that you want to stop.
3. Click **Stop**.
4. Save your changes to the master configuration.
5. To have the changed configuration take effect, stop then restart the application server.

Message-driven beans - listener port components: The WebSphere Application Server support for message-driven beans deployed against listener ports is based on JMS message listeners and the message listener service, and builds on the base support for JMS. The main components of WebSphere Application Server support for message-driven beans are described below:

The message listener service is an extension to the JMS functions of the JMS provider and provides a listener manager, which controls and monitors one or more JMS listeners.

Each listener monitors either a JMS queue destination (for point-to-point messaging) or a JMS topic destination (for publish/subscribe messaging).

A connection factory is used to create connections with the JMS provider for a specific JMS queue or topic destination. Each connection factory encapsulates the configuration parameters needed to create a connection to a JMS destination.

A listener port defines the association between a connection factory, a destination, and a deployed message-driven bean. Listener ports are used to simplify the administration of the associations between these resources.

When a deployed message-driven bean is installed, it is associated with a listener port and the listener for a destination. When a message arrives on the destination, the listener passes the message to a new instance of a message-driven bean for processing.

When an application server is started, it initializes the listener manager based on the configuration data. The listener manager creates a dynamic session thread pool for use by listeners, creates and starts listeners, and during server termination controls the cleanup of listener message service resources. Each listener completes several steps for the JMS destination that it is to monitor, including:

- Creating a JMS server session pool, and allocating JMS server sessions and session threads for incoming messages.
- Interfacing with JMS ASF to create JMS connection consumers to listen for incoming messages.
- If specified, starting a transaction and requesting that it is committed (or rolled back) when the EJB method has completed.
- Processing incoming messages by invoking the onMessage() method of the specified enterprise bean.

Important file for message-driven beans

The following file in the WAS_HOME/temp directory is important for the operation of the WebSphere Application Server messaging service, so should not be deleted. If you do need to delete the WAS_HOME/temp directory or other files in it, ensure that you preserve the following file:

server_name-**durableSubscriptions.ser**
   You should not delete this file, because the messaging service uses it to keep track of durable subscriptions for message-driven beans. If you uninstall an application that contains a message-driven bean, this file is used to unsubscribe the durable subscription.

Mail, URLs, and other J2EE resources

Using mail

Using the JavaMail API, a code segment can be embedded in any Java 2 Enterprise Edition (J2EE) application component, such as an EJB or a servlet, allowing the application to send a message and save a copy of the mail to the Sent folder.

The following is a code sample that you would embed in a J2EE application:

```
javax.naming.InitialContext ctx = new javax.naming.InitialContext();

   javax.mail.Session mail_session = (javax.mail.Session)
      ctx.lookup("java:comp/env/mail/MailSession3");
   MimeMessage msg = new MimeMessage(mail_session);

   msg.setRecipients(Message.RecipientType.TO,
      InternetAddress.parse("bob@coldmail.net"));

   msg.setFrom(new InternetAddress("alice@mail.eedge.com"));

   msg.setSubject("Important message from eEdge.com");

   msg.setText(msg_text);

   Transport.send(msg);

   Store store = mail_session.getStore();

   store.connect();

   Folder f = store.getFolder("Sent");

   if (!f.exists()) f.create(Folder.HOLDS_MESSAGES);

   f.appendMessages(new Message[] {msg});
```

J2EE applications can use JavaMail APIs by looking up references to logically named mail connection factories through the `java:comp/env/mail` subcontext that is declared in the application deployment descriptor and mapped to installation specific mail session resources. As in the case of other J2EE resources, this can be done in order to eliminate the need for the application to hard code references to external resources.

1. Locate a resource through Java Naming and Directory Interface (JNDI). The J2EE specification considers a mail session instance as a resource, or a factory from which mail transport and store connections can be obtained. Do not hard code mail sessions (namely, fill up a Properties object, then use it to create a javax.mai.Session object). Instead, you must follow the J2EE programming model of configuring resources through the system facilities and then locating them through JNDI lookups.

   In the previous sample code, the line `javax.mail.Session mail_session = (javax.mail.Session) ctx.lookup(″java:comp/env/mail/MailSession3″);` is an example of not hard coding a mail session and using a resource name located through JNDI. You can consider the lookup name, `mail/MailSession3`, as a *soft link* to the real resource.

2. Define resource references while assembling your application. See ″Assembling applications″ in the information center. You must define a resource reference for the mail resource in the deployment descriptor of the component, because a mail session is referenced in the JNDI lookup. Typically, you can use an assembly tool shipped with WebSphere Application Server.

   When you create this reference, be sure that the name of the reference matches the name used in the code. For example, the previous code uses `java:comp/env/mail/MailSession3` in its lookup. Therefore the name of this reference must be `mail/Session3`, and the type of the resource must be `javax.mail.Session`. After configuration, the deployment descriptor contains the following entry for the mail resource reference:

```
<resource-reference>
<description>description</description>
<res-ref-name>mail/MailSession3</res-ref-name>
<res-type>javax.mail.Session</res-type>
<res-auth>Container</res-auth>
```

3. Configure mail providers and sessions. The sample code references a mail resource, the deployment descriptor declares the reference, but the resource itself does not exist yet. Now you need to configure the mail resource that is referenced by your application component. Notice that the mail session you configure must have both its transport and mail access portions defined; the former required because the code is sending a message, the latter because it also saves a copy to the local mail store. When you configure the mail session, you need to specify a JNDI name. This is an important name for installing your application and linking up the resource references in your application with the real resources that you configure.
4. Install your application. You can install your application using either the administrative console or the scripting tool. During installation, WebSphere Application Server inspects all resource references and requires you to supply a JNDI name for each of them. This is not an arbitrary JNDI name, but the JNDI name given to a particular, configured resource that is the target of the reference.
5. Manage existing mail providers and sessions. You can update and remove mail providers and sessions.

   To update mail providers and sessions:
   a. Open the administrative console.
   b. Click **Resources** > **Mail Providers** in the console navigation tree. Then, click **Mail Provider** > *mail_provider* > **Mail Session**.
   c. Click the *mail_provider* or *mail_session* that you want to modify. To remove a mail provider or mail session, click **Remove** after making your selection.
   d. Click **Apply** or **OK**.
   e. Save the configuration.
6. Enable debugger for a mail session.

If your application has a client, you can update mail providers and mail sessions using the Application Client Resource Configuration Tool (ACRCT).

JavaMail API

The JavaMail APIs provide a platform and protocol-independent framework for building Java-based mail client applications.

WebSphere Application Server supports the JavaMail API, Version 1.2, and the JavaBeans Activation Framework (JAF) Version 1.0. In WebSphere Application Server, the JavaMail API is supported in all Web application components, namely:
- Servlets
- JavaServer Pages (JSP) files
- Enterprise beans
- Application clients

The JavaMail APIs are generic for sending and reading mail. They require service providers, known in WebSphere Application Server as protocol providers, to interact with mail servers that run on pertaining protocols.

For example, Simple Mail Transfer Protocol (SMTP) is a popular transport protocol for sending mail. JavaMail applications can connect to an SMTP server and send mail through it by using this SMTP protocol provider.

In addition to service providers, the JavaMail API requires the Java Application Framework (JAF) to handle mail content that is not plain text, including Multipurpose Internet Mail Extensions (MIME), URL pages, and file attachments.

The JavaMail APIs, the JAF, the service providers and the protocols are shipped as part of WebSphere Application Server using the following Sun licensed packages:

- `mail.jar` - Contains the JavaMail APIs, and the SMTP, IMAP, and POP3 service providers.
- `activation.jar` - Contains the JavaBeans Activation Framework.

Mail providers and mail sessions

A JavaMail service provider is a driver that supports JavaMail interaction with mail servers using a particular mail protocol. WebSphere Application Server includes service providers, also known as *protocol providers*, for mail protocols including Simple Mail Transfer Protocol (SMTP), Internet Message Access Protocol (IMAP), and Post Office Protocol 3 (POP3).

A mail provider encapsulates a collection of protocol providers. For example, WebSphere Application Server has a built-in mail provider that encompasses the three protocol providers: SMTP, IMAP and POP3. These protocol providers are installed as the default and suffice for most applications.

If you have a particular application that requires custom protocol providers, you must first follow the steps outlined in the ″JavaMail API Design Specification, V1.2, Chapter 5 - The Mail Session″ to install your own protocol providers. See the article, *Mail: Resources for learning*, for a link to this documentation.

Mail sessions are represented by the `javax.mail.Session` class. A mail `Session` object authenticates users, and controls users' access to messaging systems.

To create platform-independent applications, use a resource factory reference to create a JavaMail session. A resource factory is an object that provides access to resources in the deployed environment of a program using the naming conventions defined by the Java Naming and Directory Interface (JNDI).

Ensure that every mail session is defined under a parent mail provider. Select a mail provider first and then create your new mail session.

Mail migration tip

Parts of the JavaServer Page (JSP) 1.2 specification change the way the EmailBean class works with Email.jsp.

The specifications state that the JSP container creates a JSP page implementation class for each JSP page. The name of the JSP page implementation class is implementation-dependent. The JSP page implementation object belongs to an implementation-dependent named package which can vary between one JSP and another; therefore minimal assumptions should be made. The unnamed package should not be used without explicit import of the class.

Following these specifications, you should place EmailBean.class in a package referred to it by the fully qualified packageName in Email.jsp. Otherwise, Email.jsp is unable to find EmailBean.class.

JavaMail security permissions best practices

In many of its activities, the JavaMail API needs to access certain configuration files. The JavaMail and JavaBeans Activation Framework binary packages themselves already contain the necessary configuration files. However, the JavaMail API allows the user to define user-specific and installation-specific configuration files to meet special requirements.

The two locations where such configuration files can exist are `<user.home>`and `<java.home>/lib`. For example, if the JavaMail API needs to access a file named `mailcap` when sending a message, it first tries to access `<user.home>/.mailcap`. If that attempt fails, either due to lack of security permission or a nonexistent file, the API continues to try<java.home> /lib/mailcap. If that attempts also fails, it tries META-INF/mailcap in the class path, which actually leads to the configuration files contained in the mail.jar and activation.jar files. WebSphere Application Server uses the general-purpose JavaMail configuration files contained in the mail.jar and activation.jar files and does not put any mail configuration files in <user.home>and <java.home>/lib. File read permission for both the mail.jar and activation.jar files is granted to all applications to ensure proper functioning of the JavaMail API, as shown in the following segment of the app.policy file:

```
grant codeBase "file:${application}" {
 // The following are required by Java mail
permission java.io.FilePermission "${was.install.root}${/}java${/}jre${/}lib${/}ext${/}mail.jar", "read";
permission java.io.FilePermission "${was.install.root}${/}java${/}jre${/}lib${/}ext${/}activation.jar", "read";
};
```

JavaMail code attempts to access configuration files at <user.home>and <java.home>/lib causing AccessControlExceptions to be thrown, since there is no file read permission granted for those two locations by default. This activity does not affect the proper functioning of the JavaMail API, but you might see a large amount of JavaMail-related security exceptions reported in the system log, which might swamp harmful errors that you are looking for. If this situation is a problem, consider adding two more permission lines to the permission block above. This should eliminate most, if not all, JavaMail-related harmless security exceptions from the log file. The application permission block in the app.policy file now looks like:

```
 grant codeBase "file:${application}" {
// The following are required by Java mail
permission java.io.FilePermission "${was.install.root}${/}java${/}jre${/}lib${/}ext${/}mail.jar", "read";
permission java.io.FilePermission "${was.install.root}${/}java${/}jre${/}lib${/}ext${/}activation.jar", "read";
permission java.io.FilePermission "${user.home}${/}.mailcap", "read";
permission java.io.FilePermission "${java.home}${/}lib${/}mailcap", "read";
};
```

Mail: Resources for learning

Use the following links to find relevant supplemental information about the JavaMail API. The information resides on IBM and non-IBM Internet sites, whose sponsors control the technical accuracy of the information.

These links are provided for convenience. Often, the information is not specific to the IBM WebSphere Application Server product, but is useful all or in part for understanding the product. When possible, links are provided to technical papers and Redbooks that supplement the broad coverage of the release documentation with in-depth examinations of particular product areas.

Programming model and decisions

- JavaMail documentation

Programming specifications

- JavaMail 1.3 API documentation (Sun Java specifications)

JavaMail support for IPv6

WebSphere Application Server Version 6.0 and its JavaMail component support Internet Protocol Version 6.0 (IPv6), meaning that:

- Both can run on a pure IPv4 network, a pure IPv6 network, *or* a mixed IPv4 and IPv6 network.
- On either the pure IPv6 network or the mixed network, the JavaMail component works with mail servers (such as the SMTP mail transfer agent, and the IMAP and POP3 mail stores) that are also IPv6 compatible. Additionally, a JavaMail component that is run on the mixed IPv4 and IPv6 network can communicate with mail servers using IPv4.

Use of brackets with IPv6 addresses

When you configure a mail session, you can specify the mail server hosts (also known as mail transport and mail store hosts) with domain-qualified host names or numerical IP addresses. Using host names is generally the preferred method. If you use IP addresses, however, consider enclosing IPv6 addresses in square brackets to prevent parsing inaccuracies. See the following example:

```
[fe80::202:57ff:fec4:2334]
```

The JavaMail API requires a combination of many host names or IP addresses with a port number, using the `host:port number` syntax . This extra colon can cause the port number to be read as part of an IPv6 address. Using brackets prevents your JavaMail implementation from processing the extra characters erroneously.

Using URL resources within an application

Java 2 Enterprise Edition (J2EE) applications can use Uniform Resource Locators (URLs) by looking up references to logically named URL connection factories through the `java:comp/env/url` subcontext, which is declared in the application deployment descriptor and mapped to installation specific URL resources. As in the case of other J2EE resources, this can be done in order to eliminate the need for the application to hard code references to external resources. The process is the same used with other J2EE resources, such as JDBC objects and JavaMail sessions.

1. Develop an application that relies on naming features.
2. Define resource references while assembling your application. See ″Assembling applications″ in the information center. A URL resource that uses a built-in protocol, such as HTTP, FTP, or file, can use the default URL provider. URL resources that use other protocols need to use a custom URL provider.
3. Configure your URL resources within an application.
   a. Open the administrative console.
   b. Click **Resources**>**URL Providers** in the console navigation tree.
   c. Click *URL_provider*>**URLs**.
4. **Optional:** Configure URL providers and URLs within an application client using the Application Client Resource Configuration Tool (ACRCT).
5. Manage URL providers and URL resources used by the deployed application. To update or remove existing URL configurations:
   a. Open the administrative console.
   b. Click **Resources** > **URL Providers** in the console navigation tree.
   c. Click **URL Provider** > **URLs**.
   d. Select the URL to modify.
   e. Modify the URL properties.
   f. Click **Apply** or **OK**.

   To remove URL providers and URLs, after step 2, Click *URL_provider* > URLs. Select the URL you want to remove and click **Delete**. Then, click **Apply** or **OK**.

URLs

A Uniform Resource Locator (URL) is an identifier that points to an electronically accessible resource, such as a directory file on a machine in a network, or a document stored in a database.

URLs appear in the format *scheme*:*scheme_information*.

You can represent a *scheme* as HTTP, FTP, file, or another term that identifies the type of resource and the mechanism by which you can access the resource.

In a World Wide Web browser location or address box, a URL for a file available using HyperText Transfer Protocol (HTTP) starts with `http:`. An example is `http://www.ibm.com`. Files available using File Transfer Protocol (FTP) start with `ftp:`. Files available locally start with `file:`.

The *scheme_information* commonly identifies the Internet machine making a resource available, the path to that resource, and the resource name. The *scheme_information* for HTTP, FTP and file generally starts with two slashes (//), then provides the Internet address separated from the resource path name with one slash (/). For example,

```
http://www-4.ibm.com/software/webservers/appserv/library.html.
```

For HTTP and FTP, the path name ends in a slash when the URL points to a directory. In such cases, the server generally returns the default index for the directory.

URL provider collection

Use this page to create new URL providers to handle URL protocols that are not supported by the IBM Developer Kit For the Java™ Platform. You also have the option of selecting the default URL provider, which uses the URL support provided by the kit. Any URL resource with protocols based on Java 2 Standard Edition 1.3.1, such as HyperText Transfer Protocol (HTTP) or File Transfer Protocol (FTP), can use the default URL provider.

To view this administrative console page, click **Resources** > **URL Providers**.

Name:

Specifies the administrative name for the URL provider.

Description:

Describes the URL provider for your administrative records.

URL provider settings

Use this page create new URL providers.

To view this administrative console page, click **Resources** > **URL Providers** > *URL_provider*.

Name:

Specifies the administrative name for the URL provider.

Description:

Describes the URL provider, for your administrative records.

Class path:

Specifies paths or JAR file names which together form the location for the resource provider classes.

Stream handler class name:

Specifies fully qualified name of a user-defined Java class that extends the `java.net.URLStreamHandler` class for a particular URL protocol, such as FTP.

Protocol:

Specifies the protocol supported by this stream handler. For example, NNTP, SMTP, FTP.

URL configuration collection

Use this page to view existing Uniform Resource Locator (URL) configurations, as well as begin configuring new URLs that point to electronically accessible resources (such as directory files on a machine in a network, or a document stored in a database).

To view this administrative console page, click **Resources** > **URL Providers** > *URL_provider* > **URLs**.

Name:

Specifies the display name for the resource.

JNDI Name:

Specifies the JNDI name.

Description:

Specifies the description of the resource.

Category:

Specifies the category string, which you can use to classify or group the resource.

URL configuration settings

Use this page to configure Uniform Resource Locators (URLs) that point to electronically accessible resources, such as a directory file on a machine in a network, or a document stored in a database.

To view this administrative console page, click **Resources** > **URL Providers** > *URL_provider* > **URLs** > *URL*.

Name:

Specifies the display name for the resource.

JNDI Name:

Specifies the JNDI name.

Description:

Specifies the description of the resource.

Category:

Specifies the category string, which you can use to classify or group the resource.

Spec:

Specifies the string from which to form a URL.

URLs: Resources for learning

Resource environment entries

This topic provides instructions on configuring *new* resource environment entries, which define environment resources that are the binding targets for resource-environment-references in an application's deployment descriptor.

1. Configure a resource environment provider, which is a library that provides the implementation for a environment resource factory. Begin by clicking **Resources** >**Resource Environment Providers** > **New**. (See the New Resource Environment Provider topic for more information.)
2. After saving your resource environment provider, go to the Additional Properties heading and click **Resource environment entries**. Click **New** to define a new resource environment entry. Refer to the "Resource environment entry settings" on page 1387 topic for descriptions of the required fields.
3. You also might need to create a referenceable, which specifies the factory class name that converts information in the name space into a class instance for your resource. To view the appropriate administrative console page for referenceables, click **Resources** >**Resource Environment Providers** > *your_resource_environment_provider* > **Referenceables**. Click **New** to begin the configuration process. See the "Referenceables settings" on page 1388 topic for descriptions of the required fields.

Resource environment providers and resource environment entries

A resource environment reference maps a logical name used by the client application to the physical name of an object.

Not all objects bound into the server JNDI namespace are intended for use by an application client. For example, the WebSphere Application Server client run time does not support the use of Java 2 Connector (J2C) objects on the client. The object needs to be remotable, and the client-side implementations must be made available on the application client run-time classpath.

Resource environment references are different than resource references. Resource environment references allow your application client to use a logical name to look up a resource bound into the server JNDI namespace. A resource reference allows your application to use a logical name to look up a local J2EE resource. The J2EE specification does not specify a particular implementation of a resource.

Resource Environment Provider collection

Use this page to view the resource environment providers.

To view this administrative console page, click **Resources** >**Resource Environment Providers**.

Name:

Specifies a text identifier for the resource environment provider.

Data type	String

Description:

Specifies a text string describing the resource environment provider.

Data type	String

Resource environment provider settings:

Use this page to create settings for a resource environment provider.

To view this administrative console page, click **Resources** >**Resource Environment Providers** > *resource environment provider*

Name:

Specifies the name of the resource provider.

Data type	String

Description:

Specifies a text description for the resource provider.

Data type	String

New Resource Environment Provider:

Use this page to define the configuration for a library that provides the implementation for a environment resource factory.

To view this administrative console page, click **Resources** >**Resource Environment Providers** > **New**.

Name:

Specifies a text identifier for the resource environment provider.

Data type	String

Description:

Specifies a text string describing the resource environment provider.

Data type	String

Resource environment entries collection

Use this page to view resource environment entries.

An environment resource can be of any arbitrary type. See the latest EJB specification for more information about resource environment references and environment resources.

To view this administrative console page, click **Resources** >**Resource Environment Providers** > *resource_environment_provider* > **Resource Environment Entries**.

Name:

Specifies a text identifier that helps distinguish this resource environment entry from others.

For example, you can use *My Resource* for the name.

Data type	String

JNDI Name:

Specifies the string to be used when looking up this environment resource using JNDI.

This is the string to which you bind resource environment reference deployment descriptors.

Data type	String

Description:

Specifies text for information to help further identify and distinguish this resource

Data type	String

Category:

Specifies a category you can use to group environment resources according to some common feature.

It is strictly an organizational property and has no effect on the function of the environment resource.

Data type	String

Resource environment entry settings:

Use this page to set resource environment entries, which define configuration for an environment resource that is the binding target for a resource-environment-reference in some application's deployment descriptor.

To view this administrative console page, click **Resources** >**Resource Environment Providers** > *resource_environment_provider* > **Resource Environment Entries** > *resource_environment_entry*.

Name:

Specifies a display name for the resource.

Data type	String

JNDI name:

Specifies the JNDI name for the resource, including any naming subcontexts.

This name is used as the linkage between the platform's binding information for resources defined by a module's deployment descriptor and actual resources bound into JNDI by the platform.

Data type	String

Description:

Specifies a text description for the resource.

Data type	String

Category:

Specifies a category string that you can use to classify or group the resource.

Data type	String

Referenceables:

Specifies the referenceable that holds the factoryClass object name of the factory that converts information in the name space into a class instance for the type of resource desired, and for the class name of the type to be returned.

Data type	Drop-down menu

Referenceables collection

Use this page to specify the class name of the factory that will convert information in the name space into a class instance for the type of resource desired.

To view this administrative console page, click **Resources** >**Resource Environment Providers** > *resource_environment_provider* > **Referenceables**.

Factory Classname:

Specifies a javax.naming.ObjectFactory implementation class name

Data type	String

Classname:

Specifies the Java type to which a referenceable provides access, for binding validation and to create the reference.

Data type	String

Referenceables settings:

Use this page to set the class name of the factory that converts information in the name space into a class instance for the type of resource desired

To view this administrative console page, click **Resources** >**Resource Environment Providers** > *resource_environment_provider* > **Referenceables** > *referenceable*.

Factory Classname:

Specifies a javax.naming.ObjectFactory implementation class name

Data type	String

Classname:

Specifies the Java type to which a Referenceable provides access, for binding validation and to create the reference.

Data type	String

Configuring mail providers and sessions

WebSphere Application Server includes a default mail provider called the *built-in* provider. If you use the default mail provider you only have to configure the mail session, which is the last step in this task. To use the customized mail provider you must first create the mail provider and session:

1. Open the administrative console.
2. Click **Resources** > **Mail Providers**.
3. Create the mail provider.
   a. Click **New**.
   b. Type the name of the mail provider in the Name field.
   c. Click **Apply** or **OK**.
4. Define the protocol provider for the mail provider.
   a. Click *mail_provider*.
   b. Click **Protocol Providers**.
   c. Click **New**.
   d. Type the protocol name in the Protocol field.
   e. Type the class name in the Class name field.
   f. Click **Apply** or **OK**.

   Ensure that every mail session is defined under a parent mail provider. Select a mail provider first and then create your new mail session.
5. Create the mail session.
   a. Click *mail_provider*.
   b. Click **Mail Sessions**.
   c. Click **New**.
   d. Type the mail session name in the Name field.
   e. Type the JNDI name in the JNDI Name field.
   f. Click **Apply** or **OK**.
6. Configure the mail session.
   a. Click *mail_provider*.
   b. Click **Mail Sessions**.
   c. Click *mail_session*.
   d. Make changes to appropriate fields.
   e. Click **Apply** or **OK**.

If your application has a client you can configure JavaMail providers and sessions using the Application Client Resource Configuration Tool (ACRCT).

Mail provider collection

Use this page to begin implementing mail capabilities by selecting a JavaMail service provider, also known simply as a *mail provider*. The mail provider encapsulates a collection of protocol providers.

To view this administrative console page, click **Resources** > **Mail Providers**.

The **built-in mail provider** made available by WebSphere Application Server encompasses three protocol providers: Simple Mail Transfer Protocol (SMTP), Internet Message Access Protocol (IMAP) and Post Office Protocol (POP3). Select the built-in provider if these protocols provide the right support for your mail system. If you have installed or plan to install different protocol providers, you must assign them a mail provider by selecting **New** and typing values for the following settings:

Name:

Specifies the name of the JavaMail resource provider.

Description:

Specifies the resource provider description.

Mail provider settings

Use this page to establish and edit settings for your JavaMail service provider (also simply called a *mail provider*). The mail provider informs the application server of the protocols needed for your mail application.

To view this administrative console page, click **Resources** > **Mail Providers** > *mail_provider* (or **Resources** > **Mail Providers** >**New**).

Supply appropriate values for the following general mail provider settings. After clicking **Apply**, select **Protocol providers** to designate the protocols for your mail system, or select **Mail sessions** to begin configuring mail sessions.

Name:

Specifies the name of the JavaMail resource provider.

Description:

Specifies the resource provider description.

Protocol providers collection

Use this page to select or add a protocol provider that supports interaction between your JavaMail application and mail servers. For example, your application might require the Simple Mail Transfer Protocol (SMTP), which is a popular transport protocol for sending mail. Selecting that protocol provider allows your JavaMail application to connect to an SMTP server, and send mail through the server.

To view this administrative console page, click **Resources** > **Mail Providers** > *mail_provider* > **Protocol Providers**.

Protocol:

Specifies the configuration of the protocol provider for a given protocol.

Class name:

Specifies the implementation class for the specific protocol provider (also known as JavaMail service provider).

Class path:

Specifies the path to the implementation class for the specific protocol provider (also known as JavaMail service provider).

Type:

Specifies the type of protocol provider. Valid options are **STORE** or **TRANSPORT**.

Protocol providers settings

Use this page to configure protocol provider settings.

To view this administrative console page, click **Resources** > **Mail Providers** > *mail_provider* > **Protocol Providers** > *protocol_provider*.

Protocol:

Specifies the configuration of the protocol provider for a given protocol.

Class name:

Specifies the implementation class for the specific protocol provider (also known as JavaMail service provider).

Class path:

Specifies the path to the implementation class for the specific protocol provider (also known as JavaMail service provider).

Type:

Specifies the type of protocol provider. Valid options are **STORE** or **TRANSPORT**.

Mail session collection

Use this page to view mail sessions that are defined under the parent mail provider, or to configure new mail sessions.

To view this administrative console page, click **Resources** > **Mail Providers** > *mail_provider* > **Mail Sessions**.

Name:

Specifies the administrative name of the JavaMail session object.

JNDI Name:

Specifies the Java Naming and Directory Interface (JNDI) name for the resource, including any naming subcontexts.

This name provides the link between the platform binding information for resources defined in the client application deployment descriptor and the actual resources bound into JNDI by the platform.

Description:

Specifies an optional description for your administrative records.

Category:

Specifies an optional collection for classifying or grouping sessions.

Mail session settings

Use this page to configure mail sessions.

To view this administrative console page, click **Resources**> **Mail Providers** > *mail_provider* > **Mail Sessions** > *mail_session*.

Name:

Specifies the administrative name of the JavaMail session object.

JNDI name:

Specifies the Java Naming and Directory Interface (JNDI) name for the resource, including any naming subcontexts.

This name provides the link between the platform binding information for resources that are defined in the client application deployment descriptor and the actual resources bound into JNDI by the platform.

Description:

Specifies an optional description for your administrative records.

Category:

Specifies an optional collection for classifying or grouping sessions.

Mail transport host:

Specifies the server that is accessed when sending mail.

Mail transport protocol:

Specifies the transport protocol that is used when sending mail.

Mail transport user ID:

Specifies the user ID when the mail transport host requires authentication.

This setting is not generally used for most mail servers. Leave this field blank unless you use a mail server that requires a user ID and password.

Mail transport password:

Specifies the password when the mail transport host requires authentication.

This setting is not generally used for most mail servers. Leave this field blank unless you use a mail server that requires a user ID and password.

Enable strict Internet address parsing:

Specifies whether the recipient addresses must be parsed in strict compliance with RFC 822, which is a specifications document issued by the Internet Architecture Board.

This setting is not generally used for most mail applications. RFC 822 syntax for parsing addresses effectively enforces a strict definition of a valid e-mail address. If you select this setting, your JavaMail component adheres to RFC 822 syntax and rejects recipient addresses that do not parse into valid e-mail addresses (as defined by the specification). If you do not select this setting, your JavaMail component does not adhere to RFC 822 syntax and accepts recipient addresses that do not comply with the specification. By default, this setting is not selected. You can view the RFC 822 specification at the following Web address for the World Wide Web Consortium (W3C): http://www.w3.org/Protocols/rfc822/.

Mail from:

Specifies the mail originator.

This value represents the Internet e-mail address that, by default, displays in the received message, as either the `From` or the `Reply-To` address. The recipient's reply comes to this address.

Mail store host:

Specifies the server that is accessed when receiving the mail.

This setting, combined with the mail store user ID and password, represents a valid mail account. For example, if the mail account is *john_william@my.company.com*, then the mail store host is *my.company.com*.

Mail store protocol:

Specifies the protocol that is used when receiving mail; it can be Internet Message Access Protocol (IMAP), Post Office Protocol 3 (POP3), or any store protocol for which an administrator has installed a provider.

Mail store user ID:

Specifies the user ID for the given mail account.

For example, if the mail account is *john_william@my.company.com* then the user is *john_william*.

Mail store password:

Specifies the password for the given mail account .

For example, if the mail account is *john_william@my.company.com* then enter the password for ID *john_william*.

Enable debug mode:

Toggles debug mode on and off for this mail session.

Security

Securing applications and their environments

WebSphere Application Server supports the J2EE model for creating, assembling, securing, and deploying applications. This article provides a high-level description of what is involved in securing resources in a J2EE environment. Applications are often created, assembled and deployed in different phases and by different teams.

Consult the J2EE specifications for complete details.

1. Plan to secure your applications and environment. For more information, see “Planning to secure your environment” on page 1394. Complete this step before you install the WebSphere Application Server.
2. Consider pre-installation and post-installation requirements. For more information, see “Implementing security considerations at installation time” on page 1404. For example, during this step, you learn how to protect security configurations after you install the product.
3. Migrate your existing security systems. For more information, see ″Migrating security configurations from previous releases″ in the information center.
4. Develop secured applications. For more information, see Developing secured applications.
5. Assemble secured applications. For more information, see Assembling secured applications. Development tools, such as those included in the topic ″Assembling applications″ in the information center, are used to assemble J2EE modules and to set the attributes in the deployment descriptors.

   Most of the steps in assembling J2EE applications involve deployment descriptors; deployment descriptors play a central role in application security in a J2EE environment.

Application assemblers combine J2EE modules, resolve references between them, and create from them a single deployment unit, typically an Enterprise Archive (EAR) file. Component providers and application assemblers can be represented by the same person but do not have to be.

6. Deploy secured applications. For more information, see “Deploying secured applications” on page 1767.

   Deployer link entities referred to in an enterprise application are mapped to the runtime environment. The deployer:

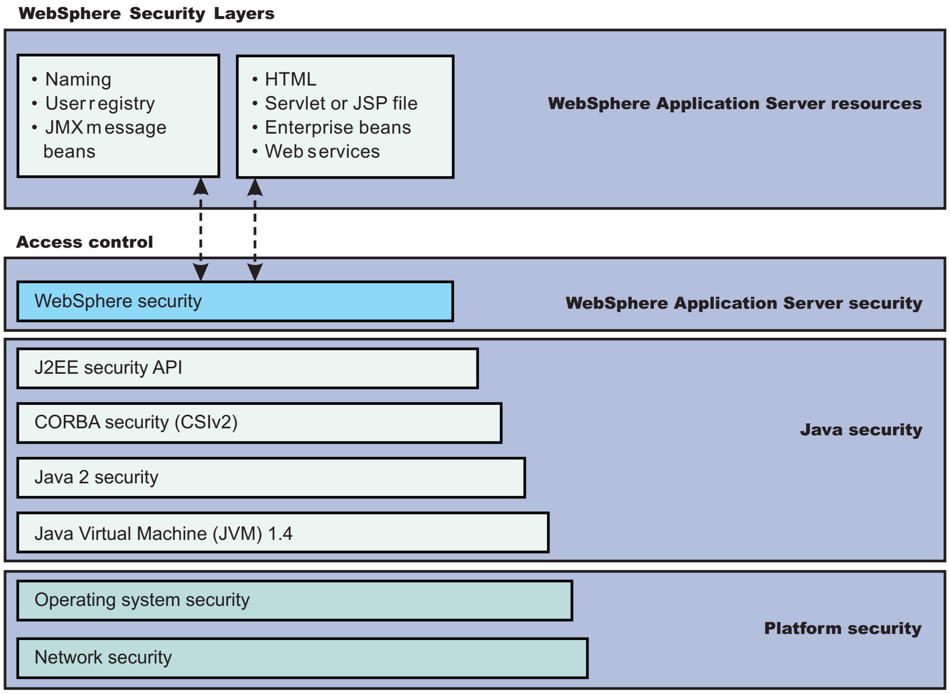
   - Maps actual users and groups to application roles
   - Installs the enterprise application into the environment
   - Makes the final adjustments needed to run the application
7. Test secured applications. For more information, see Testing security.
8. Manage security configurations. For more information, see ″Administering security″ in the information center.
9. Improve performance by tuning security configurations. For more information, see ″Tuning security configurations″ in the information center.
10. Troubleshoot security configurations. For more information, see ″Troubleshooting security configurations″ in the information center.

Your applications and production environment are secured.

See ″Security: Resources for learning″ in the information center for more information on the WebSphere Application Server security architecture.

Planning to secure your environment

There are several communication links from a browser on the Internet, through Web servers and product servers, to the enterprise data at the back-end. This section examines some typical configurations and common security practices. WebSphere Application Server security is built on a layered security architecture as showed in the following figure. This section also examines the security protection that is offered by each security layer and common security practice for good quality of protection in end-to-end security. The following figure illustrates the building blocks that comprise the operating environment for security within WebSphere Application Server:



- **Operating System Security** -

  The security infrastructure of the underlying operating system provides certain security services for WebSphere Application Server. These services include the file system security support that secure sensitive files in the product installation for WebSphere Application Server. The system administrator can configure the product to obtain authentication information directly from the operating system user registry.
- **Network Security** - The Network Security layers provide transport level authentication and message integrity and encryption. You can configure the communication between separate application servers to use Secure Sockets Layer (SSL) and HTTPS. Additionally, you can use IP Security and Virtual Private Network (VPN) for added message protection.
- **JVM 1.4** - The JVM security model provides a layer of security above the operating system layer.
- **Java 2 Security** - The Java 2 Security model offers fine-grained access control to system resources including file system, system property, socket connection, threading, class loading, and so on. Application code must explicitly grant the required permission to access a protected resource.
- **OMG CSIv2 Security** - Any calls made among secure Object Request Brokers (ORB) are invoked over the Common Security Interoperability Version 2 (CSIv2) security protocol that sets up the security context and the necessary quality of protection. After the session is established, the call is passed up to the enterprise bean layer. For backward compatibility, WebSphere Application Server supports the Secure Authentication Service (SAS) security protocol, which was used in prior releases of WebSphere Application Server and other IBM products.
- **J2EE Security** - The security collaborator enforces Java 2 Platform, Enterprise Edition (J2EE)-based security policies and supports J2EE security APIs.
- **WebSphere Security** - WebSphere Application Server security enforces security policies and services in a unified manner on access to Web resources, enterprise beans, and JMX administrative resources. It consists of WebSphere Application Server security technologies and features to support the needs of a secure enterprise environment.

WebSphere Application Server Network Deployment installation: The following figure shows a typical multiple-tier business computing environment for a WebSphere Application Server Network Deployment installation.

Important: There is a node agent instance on every computer node.

Each product application server consists of a Web container, an EJB container, and the administrative subsystem. The WebSphere Application Server deployment manager contains only WebSphere administrative code and the administrative console. The administrative console is a special J2EE Web application that provides the interface for performing administrative functions. WebSphere Application Server configuration data is stored in XML descriptor files, which must be protected by operating system security. Passwords and other sensitive configuration data can be modified using the administrative console. However, you must protect these passwords and sensitive data. For more information, see "Protecting plain text passwords" on page 1407.

The administrative console Web application has a setup data constraint that requires the administrative console servlets and JSP files to be accessed only through an SSL connection when global security is enabled.

After installation, the administrative console HTTPS port is configured to use **DummyServerKeyFile.jks** and **DummyServerTrustFile.jks** with the default self-signed certificate. Using the dummy key and trust file certificate is not safe and you need to generate your own certificate to replace dummy ones immediately. It is more secure if you first enable global security and complete other configuration tasks after global security is enforced.

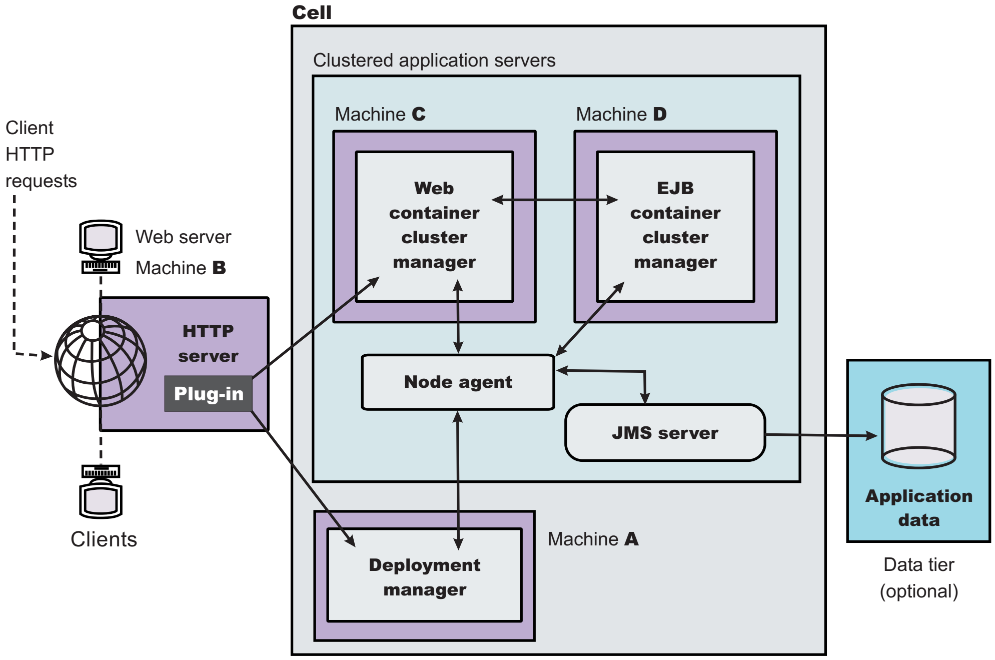


Figure 6. Multiple-tier business computing environment.

Global and administrative security:

WebSphere Application Servers interact with each other through CSIv2 and Secure Authentication Services (SAS) security protocols as well as HTTP and HTTPS protocols.

You can configure these protocols to use Secure Sockets Layer (SSL) when you enable WebSphere Application Server global security. The WebSphere Application Server administrative subsystem in every server uses Simple Object Access Protocol (SOAP) Java Management Extensions (JMX) connectors and Remote Method Invocation over the Internet Inter-ORB Protocol (RMI/IIOP) JMX connectors to pass administrative commands and configuration data. When global security is disabled, the SOAP JMX connector uses HTTP protocol and the RMI/IIOP connector uses the TCP/IP protocol. When global security is enabled, the SOAP JMX connector always uses HTTPS protocol. When global security is enabled, you can configure the RMI/IIOP JMX connector to either use SSL or to use TCP/IP. It is recommended that you enable global security and enable SSL to protect the sensitive configuration data.

Global security and administrative security configuration is at the cell level.

When global security is enabled, you can disable application security at each individual application server by clearing the **Enable global security** option on the global security panel. The Global security panel is accessed through the administrative console by clicking **Security > Global security**. Disabling application server security does not affect the administrative subsystem in that application server, which is controlled by the global security configuration only. Both administrative subsystem and application code in an application server share the optional per server security protocol configuration. For more information, see ″Configuring server security″ in the information center.

Security for J2EE resources: Security for J2EE resources is provided by the Web container and the EJB container. Each container provides two kinds of security: declarative security and programmatic security.

In declarative security, an application security structure includes data integrity and confidentiality, authentication requirements, security roles, and access control. Access control is expressed in a form that is external to the application. In particular, the deployment descriptor is the primary vehicle for declarative security in the J2EE platform. WebSphere Application Server maintains J2EE security policy, including information derived from the deployment descriptor and specified by deployers and administrators in a set of XML descriptor files. At run time, the container uses the security policy that is defined in the XML descriptor files to enforce data constraints and access control.

When declarative security alone is not sufficient to express the security model of an application, you might use Programmatic login to make access decisions. When global security is enabled and application server security is not disabled at the server level, J2EE applications security is enforced. When the security policy is specified for a Web resource, the Web container performs access control when the resource is requested by a Web client. The Web container challenges the Web client for authentication data if none is present according to the specified authentication method, ensures the data constraints are met, and determines whether the authenticated user has the required security role. The Web security collaborator enforces role-based access control by using an access manager implementation. An access manager makes authorization decisions that are based on security policy derived from the deployment descriptor. An authenticated user principal can access the requested servlet or JavaServer Pages (JSP) file if it has one of the required security roles. Servlets and JSP pages can use the `HttpServletRequest` methods `isUserInRole` and `getUserPrincipal`.

When global security is enabled and application server security is not disabled, the EJB container enforces access control on EJB method invocation.

The authentication takes place regardless of whether method permission is defined for the specific EJB method. The EJB security collaborator enforces role-based access control by using an access manager implementation. An access manager makes authorization decisions that are based on security policy derived from the deployment descriptor. An authenticated user principal can access the requested EJB method if it has one of the required security roles. EJB code can use the `EJBContext` methods `isCallerInRole` and `getCallerPrincipal`. Use the J2EE role-based access control to protect valuable business data from access by unauthorized users from both the Internet and the intranet. Refer to Securing Web applications using an assembly tool and Securing enterprise bean applications.

Role-based security: WebSphere Application Server extends the security, role-based access control to administrative resources including the JMX system management subsystem, user registries, and JNDI name space. WebSphere administrative subsystem defines four administrative security roles:

Monitor role

A monitor can view the configuration information and status, but cannot make any changes.

Operator role

An operator can trigger run-time state changes, such as start an application server or stop an application, but cannot make configuration changes.

Configurator role

A configurator can modify the configuration information, but cannot change the state of the run time.

Administrator role

An operator as well as a configurator, which additionally can modify sensitive security configuration and security policy such as setting server ID and password, enable or disable global security and Java 2 security, and map users and groups to the administrator role.

A user with the configurator role can perform most administrative work including installing new applications and application servers. There are certain configuration tasks a configurator does not have sufficient authority to do when global security is enabled, including modifying a WebSphere Application Server identity and password, LTPA password and keys, and assigning users to administrative security roles.

Those sensitive configuration tasks require the administrative role because the server ID is mapped to the administrator role.

WebSphere Application Server administrative security is enforced when global security is enabled. It is recommended that WebSphere Application Server global security be enabled to protect administrative subsystem integrity. Application server security can be selectively disabled if there is no sensitive information to protect. For securing administrative security, refer to ″Assigning users to administrator roles″ and “Assigning users and groups to roles” on page 1768.

Java 2 security permissions: WebSphere Application Server uses the Java 2 security model to create a secure environment to run application code. Java 2 security provides a fine-grained and policy-based access control to protect system resources such as files, system properties, opening socket connections, loading libraries, and so on. The J2EE Version 1.4 specification defines a typical set of Java 2 security permissions that Web and EJB components expect to have. These permissions are shown in the following table.

Table 9. J2EE security permissions set for Web components

Security Permission	Target	Action
java.lang.RuntimePermission	loadLibrary	
java.lang.RuntimePermission	queuePrintJob	
java.net.SocketPermission	*	connect
java.io.FilePermission	*	read, write
java.util.PropertyPermission	*	read

Table 10. J2EE security permissions set for EJB components

Security Permission	Target	Action
java.lang.RuntimePermission	queuePrintJob	
java.net.SocketPermission	*	connect
java.util.PropertyPermission	*	read

The WebSphere Application Server Java 2 security implementation is based on the J2EE Version 1.4 specification. The specification granted Web components read and write file access permission to any file in the file system, which might be too broad. The WebSphere Application Server default policy gives Web components read and write permission to the subdirectory and the subtree where the Web module is installed. The default Java 2 security policy for all Java virtual machines and WebSphere Application Server processes are contained in the following policy files:

`${java.home}/jre/lib/security/java.policy`
Used as the default policy for the Java virtual machine (JVM).

`${USER_INSTALL_ROOT}/properties/server.policy`
Used as the default policy for all product server processes

To simplify policy management, WebSphere Application Server policy is based on resource type rather than code base (location). The following files are the default policy files for WebSphere Application Server subsystem. These policy files, which are an extension of WebSphere Application Server run time and are referred to as *Service Provider Programming Interfaces (SPI)*, are shared by multiple J2EE applications:

${WAS_INSTALL_ROOT}/profiles/*profile_name***/config/cells/***cell_name***/nodes/***node_name***/spi.policy**
Used for embedded resources defined in the resources.xml file, such as the Java Message Service (JMS), JavaMail, and JDBC drivers.

${WAS_INSTALL_ROOT}/profiles/*profile_name***/config/cells/***cell_name***/nodes/***node_name***/library.policy**
Used by the shared library that is defined by the WebSphere Application Server administrative console.

${WAS_INSTALL_ROOT}/profiles/*profile_name***/config/cells/***cell_name***/nodes/***node_name***/app.policy**
Used as the default policy for J2EE applications.

In general, applications should not require more permissions to run than those recommended by the J2EE specification to be portable among various application servers. However, some applications might require more permissions. WebSphere Application Server supports a per application policy file, was.policy, to be packaged together with each application from granting extra permissions to that application.

Note: Grant extra permissions to an application after careful consideration because of the potential of compromising the system integrity.

WebSphere Application Server uses a permission filtering policy file to alert users when an application requires permissions that are on the filter list during application installation and causes the offended application installation to fail. For example, it is recommended that you not give the java.lang.RuntimePermission *exitVM* permission to an application so that application code cannot terminate WebSphere Application Server. The filtering policy is defined by the filterMask in ${WAS_INSTALL_ROOT}/profiles/*profile_name*/config/cells/*cell_name*/filter.policy. Moreover, WebSphere Application Server also performs run-time permission filtering that is based on the run-time filtering policy to ensure that application code is not granted a permission that is considered harmful to system integrity.

WebSphere Application Server Version 4 supported Java 2 Security, but enforced only three permissions checking against exitVM, create and set the security manager. Other permission checking is disabled by default.

Therefore, many applications developed for prior releases of WebSphere Application Server might not be Java 2 Security ready. To migrate those applications to WebSphere Application Server Version 6 quickly, you might temporarily give those applications java.security.AllPermission in the was.policy file. It is recommended to test or make those applications Java 2 Security ready; for example, identity what extra permissions, if any, are required and to grant only those permissions to a particular application. Not granting applications AllPermission can certainly reduce the risk of compromising system integrity. For more information on migrating applications to WebSphere Application Server Version 6, refer to ″Migrating Java 2 security policy″ in the information center.

The WebSphere Application Server run time uses Java 2 Security to protect sensitive run-time functions; therefore, it is recommended that you enforce Java 2 security. Applications that are granted with

AllPermission not only have access to sensitive system resources, but also WebSphere Application Server run-time resources and can potentially cause damage to both. In cases where an application can be trusted to be safe, WebSphere Application Server allows Java 2 Security to be disabled on a per application server basis. You can enforce Java 2 security by default in the security center and disable the per application server Java 2 Security flag to disable it at the particular application server.

When you specify the **Enable global security** and **Enable Java 2 Security** options on the Global security panel of the administrative console, the information, along with other sensitive configuration data, are stored in a set of XML configuration files. Both role-based access control and Java 2 Security permission-based access control are employed to protect the integrity of the configuration data. The example uses configuration data protection to illustrate how system integrity is maintained.

- When Java 2 security is enforced, the application code cannot access the WebSphere Application Server run-time classes that manage the configuration data unless it is granted the required WebSphere Application Server run-time permissions.
- When Java 2 security is enforced, application code cannot access the WebSphere Application Server configuration XML files unless it has been granted the required file read and write permission.
- The JMX administrative subsystem provides SOAP over HTTP or HTTPS and RMI/IIOP remote interface to enable application programs to extract and to modify configuration files and data. When global security is enabled, an application program can modify the WebSphere Application Server configuration if the application program has presented valid authentication data and the security identity has the required security roles.
- If a user can disable Java 2 security, then that user can modify the WebSphere Application Server configuration including the WebSphere Application Server security identity and authentication data along with other sensitive data. Only users with the administrator security role can disable Java 2 security.
- Because WebSphere Application Server security identity is given to the administrator role, only users with the administrator role can disable global security, to change server ID and password, and to map users and groups to administrative roles, and so on.

Other Runtime resources: Other WebSphere Application Server run time resources are protected by a similar mechanism as described previously. It is very important to enable WebSphere Application Server global security and to enforce Java 2 Security. J2EE Specification defines several authentication methods for Web components: HTTP Basic Authentication, Form-Based Authentication, and HTTPS Client Certificate Authentication. When you use client certificate login, it is more convenient for the browser client if the Web resources have integral or confidential data constraint. If a browser uses HTTP to access the Web resource, the Web container automatically redirects the browser to the HTTPS port. The CSIv2 security protocol also supports client certificate authentication. You can also use SSL client authentication to setup secure communication among a selected set of servers based on a trust relationship.

If you start from the WebSphere Application Server plug-in at the Web server, you can configure SSL mutual authentication between it and the WebSphere Application Server HTTPS server. When using a self-signed certificate, you can restrict the WebSphere Application Server plug-in to communicate with only the selected two WebSphere Application Server servers as shown in the following figure. Suppose you want to restrict the HTTPS server in WebSphere Application Server **A** and in WebSphere Application Server **B** to accept secure socket connections only from the WebSphere Application Server plug-in **W**. You can generate three self-signed certificates using the IKEYMAN and the certificate management utilities. For example, use certificate **W** and trust certificate **A** and **B**. The HTTPS server of WebSphere Application Server **A** is configured to use certificate **A** and to trust certificate **W**. The HTTPS server of WebSphere Application Server **B** is configured to use certificate **B** and to trust certificate **W**. For more information on IKEYMAN, refer to ″Starting the key management utility (iKeyman)″ in the information center.

Server	Key	Trust
WebSphere Application Server plug-in	W	A, B
WebSphere Application Server A	A	W
WebSphere Application Server B	B	W

When WebSphere Application Server is configured to use an Lightweight Directory Access Protocol (LDAP) user registry, you also can configure SSL with mutual authentication between every application server and the LDAP server with self-signed certificate so that a password is not passed in clear text from WebSphere Application Server to the LDAP server. In this example, the node agent processes are not discussed. Each node agent must communicate with application servers on the same node and with the Deployment Manager. Node agents also must communicate with LDAP servers when they are configured to use an LDAP user registry. It is reasonable to let the deployment manager and the node agents use the same certificate. Suppose application server **A** and **C** are on the same computer node. The Node agent on that node needs to have certificates **A** and **C** in its trust file. WebSphere Application Server does not provide a user registry configuration or management utility. In addition, it does not dictate the user registry password policy. It is recommended that you use the password policy recommended by your user registry, including the password length and expiration period.

1. Determine which versions of WebSphere Application Server you are using.
2. Review the WebSphere Application Server security architecture.
3. Review each of the following topics in the information center.
   - Authentication protocol for EJB security
     - Supported authentication protocols
     - Common Secure Interoperability Version 2 features
     - Identity assertion
   - Authentication mechanisms
     - Lightweight Third Party Authentication settings

  - Trust associations
  - Single signon (SSO)
- User registries
  - Local operating system user registries
  - Lightweight Directory Access Protocol
- Custom user registries
- Java 2 security
  - Java 2 security policy files
- Java Authentication and Authorization Service (JAAS)
  - Programmatic login
- J2EE Connector security
- Access control exception
  - Role-based authorization
  - Administrative console and naming service authorization
- Secure Socket Layer (SSL)
  - Authenticity
  - Confidentiality
  - Integrity

Security considerations when adding a Base Application Server node to Network Deployment

At some point, you might decide to centralize the configuration of your stand-alone base application servers by adding them into a Network Deployment cell. If your base application server is currently configured with security, there are some issues to consider. The major issue when adding a node to the cell is whether the user registries between the base application server and the Deployment Manager are the same.

When adding a node to the cell, you automatically inherit both the user registry and the authentication mechanism of the cell.

For distributed security, all servers in the cell must use the same user registry and authentication mechanism. To recover from a user registry change, you must modify your applications so that the user and group to role mappings are correct for the new user registry. To do this, see the article on “Assigning users and groups to roles” on page 1768.

Another major issue is the SSL public-key infrastructure. Prior to performing `addNode` with the Deployment Manager, verify that `addNode` can communicate as an SSL client with the Deployment Manager. This requires that the addNode truststore (configured in `sas.client.props`) contains the signer certificate of the Deployment Manager personal certificate as found in the keystore (specified in the administrative console).

See the article, ″Managing digital certificates″ in the information center.

The following are other issues to consider when running the `addNode` command with security:

1. When attempting to run system management commands such as `addNode`, you need to explicitly specify administrative credentials to perform the operation. The `addNode` command accepts `-username` and `-password` parameters to specify the userid and password, respectively. The user ID and password that are specified must be an administrative user; for example, a user that is a member of the console users with **Operator** or **Administrator** privileges or the administrative user ID configured in the User Registry. An example for `addNode`, `addNode CELL_HOST 8879 -includeapps -username user -password pass`. `-includeapps` is optional, but this option attempts to include the server applications into the Deployment Manager. The `addNode` command might fail if the user registries used by the WebSphere Application Server and the Deployment Manager are not the same. To correct this problem, either make the user registries the same or turn off security. If you change the user registries, remember to verify that the users to roles and groups to roles mappings are correct. See the addNode command for more information on the addNode syntax.

2. Adding a secured remote node through the administrative console is not supported. You can either disable security on the remote node before performing the operation or perform the operation from the command line using the addNode script.
3. Before running the `addNode` command, you must verify that the truststore files on the nodes can communicate with the keystore files from the Deployment Manager and vice versa. When using the default `DummyServerKeyFile` and `DummyServerTrustFile`, you should not see this problem as these are already able to communicate. However, never use these dummy files in a production environment or anytime sensitive data is being transmitted.
4. After running addNode, the application server is in a new SSL domain. It might contain SSL configurations that point to keystore and truststore files that are not prepared to interoperate with other servers in the same domain. Consider which servers will be intercommunicating and ensure that the servers are trusted within your truststore files.

Proper understanding of the security interactions between distributed servers greatly reduces problems encountered with secure communications. Security adds complexity because additional function needs to be managed. For security to function, it needs thorough consideration during the planning of your infrastructure. This document helps to reduce the problems that could occur due to inherent security interactions.

When you have security problems related to the WebSphere Application Server Network Deployment environment, check the ″Troubleshooting security configurations″ section in the information center to see if you can get information about the problem. When trace is needed to solve a problem, because servers are distributed, quite often it is required to gather trace on all servers simultaneously while recreating the problem. This trace can be enabled dynamically or statically, depending on the type problem occurring.

Creating login key files

1. Create a login key file. The authenticating user IDs, passwords, and target realms for each different target server are specified in the login key file, which is an ASCII file. When the security authentication service processes the login key file, the passwords in the file are encoded.
2. Add information to the login key file in the following format:

   Realm_name User_ID Password
3. Make sure that the data conforms to the following rules:
   - One realm name
   - One user ID, and one password defined in each entry
   - One entry per line
   - No blank lines between entries
   - Comments on separate lines only
   - Begin any comment with a pound sign (#):

     Example:

     ```
     # Sample key file
     #
     # First target realm
     #
     TargetRealm serverID serverPassword
     #
     # Second target realm
     #
     TargetRealm2 serverID2 serverPassword2
     #
     # End of key file
     ```

A sample file named `wsserver.key` also contains these instructions. After installation, you can locate this sample file in the *install_root*/`properties` directory. You can use or modify the sample file as needed for testing.

Note: You can place the login key file anywhere on a host machine running the application server. However, it is recommended that you place the login key file under a securable file system .

After creating the login key files, read the article entitled, “Preparing truststore files.”

Preparing truststore files

Secure Sockets Layer (SSL) protocol protects the communication between WebSphere Application Servers. To complete the SSL connection, establish a valid truststore file for the WebSphere Application Server. A truststore file is a key database file that contains the public keys (See “Creating login key files” on page 1403 for information about how to create a new keystore file.)

1. Extract the public key of the server by using the key management tool from WebSphere Application Server. For details, see ″Configuring the server for request decryption: choosing the decryption method″ in the information center.
2. Add the public key from the WebSphere Application Server as a signer certificate into the requesting WebSphere Application Server truststore file. For details, see the related information about how to import signer certificates.

The WebSphere Application Server truststore file is now ready to use for SSL connections with the WebSphere Application Server.

See “Configuring the application server for interoperability” for interoperability.

Configuring the application server for interoperability

After the truststore file is ready, complete the following steps to configure the WebSphere Application Server.

1. Configure the enterprise beans that access WebSphere Application Server. Before deploying the enterprise beans, configure the RunAs Identity.
2. Enable security.
3. Enable outbound SAS authentication protocol.
4. Specify the truststore file in an Secure Sockets Layer (SSL) configuration alias and configure the WebSphere Application Server with that alias.
5. Set the **Request timeout** and **Locate request timeout** values to zero for the Object Request Broker (ORB) service.
6. Specify a security property named com.ibm.CORBA.keyFileName for the absolute path of the login key file created earlier.
7. Restart the WebSphere Application Server.

Implementing security considerations at installation time

Complete the following tasks to implement security before, during, and after installing WebSphere Application Server.

1. “Securing your environment before installation” on page 1405. This step describes how to install WebSphere Application Server with the proper authority.
2. Install the WebSphere Application Server. This step describes how to install WebSphere Application Server as the root user on a UNIX platform or as an administrator on a Windows platform.

   During installation you are prompted to migrate security configurations from previous releases.

3. “Securing your environment after installation.” This step provides information on how to protect password information after you install WebSphere Application Server.

Securing your environment before installation

The following instructions explain how to perform a product installation with proper authority on UNIX platforms, Linux platforms, Solaris operating environments, and Windows platforms.

UNIX platforms

On UNIX platforms, log on as **root** and verify that the umask value is **022**.

To verify that the umask value is **022**, execute the **umask** command.

To set up the umask value as **022**, execute the **umask 022** command.

Linux platforms and Solaris operating environments

On Linux platforms or Solaris operating environments, make sure that the `/etc` directory contains a shadow password file. The shadow password file is named shadow and is in the `/etc` directory. If the shadow password file does not exist, an error occurs after enabling global security and configuring the user registry as local operating system.

To create the shadow file, run the pwconv command (with no parameters). This command creates an `/etc/shadow` file from the `/etc/passwd` file. After creating the shadow file, you can configure local operating system security.

Windows platforms

On Windows platforms, the logon user must be a member of the administrator group with the rights of **Act as part of the operating system** and **Log on as a service**.

To add the rights to a user on a Windows 2000 platform:

1. Click **Start** > **Programs** > **Administrative Tools** > **Local Security Policy** (for domain configuration, select **Domain Security Policies**, instead).
2. From the Local Security Settings Panel, click **Local Policies** > **User Rights Assignment** and add the following rights to the user ID:
   - Act as part of the operating system
   - Log on as a service

Securing your environment after installation

WebSphere Application Server depends on several configuration files created during installation. These files contain password information and need protection. Although the files are protected to a limited degree during installation, this basic level of protection is probably not sufficient for your site. Verify that these files are protected in compliance with the policies of your site.

The files in the *install_root*`\profiles\`*profile_name*`\config` and *install_root*`\profiles\`*profile_name*`\properties` , except for those in the following list, need protection. For example, give permission to the user who logs onto the system for WebSphere Application Server primary administrative tasks. Other users or groups, such as WebSphere Application Server console users and console groups, who perform partial WebSphere Application Server administrative tasks, like configuring, starting servers and stopping servers, need permissions as well.

The files in the *install_root*`\profiles\`*profile_name*`\properties` directory that should not be protected are:

- `TraceSettings.properties`
- `client.policy`
- `client_types.xml`
- `implfactory.properties`
- `sas.client.props`
- `sas.stdclient.properties`
- `sas.tools.properties`
- `soap.client.props`
- `wsadmin.properties`
- `wsjaas_client.conf`

1. Secure files on a Windows system:
   a. Open the browser for a view of the files and directories on the machine.
   b. Locate and right-click the file or the directory that you want to protect.
   c. Click **Properties**.
   d. Click the **Security** tab.
   e. Remove the `Everyone` entry and any other user or group that you do not want to have access to the file.
   f. Add the users who can access the files with the proper permission.
2. Secure files on UNIX systems. This procedure applies only to the ordinary UNIX file system. If your site uses access-control lists, secure the files by using that mechanism. Any site-specific requirements can affect the owner, group, and corresponding privileges. For example, on AIX,
   a. Go to the *`install_root`* directory and change the ownership of the directory configuration and properties to the user who logs onto the system for WebSphere Application Server primary administrative tasks. Run the following command: `chown -R` *`logon_name directory_name`*

      Where:

      - *login_name* is a specified user or group.
      - *directory_name* is the name of the directory that contains the files.

      It is recommended that you assign ownership of the files that contain password information to the user who runs the application server. If more than one user runs the application server, provide permission to the group in which the users are assigned in the user registry.
   b. Set up the permission by running the following command: `chmod -R 770` *`directory_name`*.
   c. Go to the *`install_root`*`\profiles\`*`profile_name`*`\properties` directory and set the following file permission to **everybody** by running the following command: `chmod 777` *`file_names`*. where *`file_names`* are the following files:
      - `TraceSettings.properties`
      - `client.policy`
      - `client_types.xml`
      - `implfactory.properties`
      - `sas.client.props`
      - `sas.stdclient.properties`
      - `sas.tools.properties`
      - `soap.client.props`
      - `wsadmin.properties`
      - `wsjaas_client.conf`
   d. Create a group for WebSphere Application Server and put the users who perform full or partial WebSphere Application Server administrative tasks in that group.
   e. If you want to use WebSphere MQ as a JMS provider, restrict access to the `/var/mqm` directories and log files used. Give write access to the user ID mqm or members of the mqm user group only.

After securing your environment, only the users given permission can access the files. Failure to adequately secure these files can lead to a breach of security in your WebSphere Application Server applications.

If failures occur that are caused by file accessing permissions, check the permission settings.

Protecting plain text passwords

The WebSphere Application Server has several plain text passwords. These passwords are not encrypted, but are encoded. The following is a list of files with encoded passwords:

Important: *WAS_INSTALL_ROOT* is a WebSphere Application Server Environment variable that you can configure through the administrative console by clicking **Environment > WebSphere variables**.

File name	Additional information
`WAS_INSTALL_ROOT \profiles \profile_name\config\cells \cell_name\security.xml`	The following fields contain encoded passwords: • **LTPA password** • **JAAS authentication data** • **User registry server password** • **LDAP user registry bind password** • **Key file password** • **Trust file password** • **Cryptographic token device password**
`WAS_INSTALL_ROOT \profiles \profile_name\properties \sas.client.props`	Specifies passwords for: • com.ibm.ssl.keyStorePassword • com.ibm.ssl.trustStorePassword • com.ibm.CORBA.loginPassword
`war/WEB-INF/ibm_web_bnd.xml`	Specify passwords for the default basic authentication for the ″resource-ref″ bindings within all descriptors (except in the Java cryptography architecture)
`ejb jar/META-INF/ibm_ejbjar_bnd.xml`	Specify passwords for the default basic authentication for the ″resource-ref″ bindings within all descriptors (except in the Java crytography architecture)
`client jar/META-INF/ibm-appclient_bnd.xml`	Specify passwords for the default basic authentication for the ″resource-ref″ bindings within all descriptors (except in the Java crytography architecture)
`ear/META-INF/ibm_application_bnd.xml`	Specify passwords for the default basic authentication for the ″run as″ bindings within all descriptors
`WAS_INSTALL_ROOT \profiles\profile_name\config\cells \cell_name\nodes\node_name\servers \server.xml`	The following fields contain encoded passwords: • **Key file password** • **Trust file password** • **Cryptographic token device password** • **Authentication target password** • **Session persistence password** • **DRS Client data replication password**

File name	Additional information
WAS_INSTALL_ROOT\profiles\profile_name\config\cells \cell_name\nodes\node_name \servers\server1\resources.xml	The following fields contain encoded passwords: • **WAS40Datasource password** • **mailTransport password** • **mailStore password** • **MQQueue queue mgr password**
For WebSphere Application Server and WebSphere Application Server Express: • *WAS_INSTALL_ROOT*\profiles\profile_name\config\cells \cell_name\ws-security.xml • *WAS_INSTALL_ROOT*\profiles\profile_name\config\cells \cell_name\nodes\node_name\servers\server1\ws-security For Network Deployment: *WAS_INSTALL_ROOT*\profiles\profile_name\config\cells \cell_name\ws-security.xml	
ibm-webservices-bnd.xmi	
ibm-webservicesclient-bnd.xmi	
WAS_INSTALL_ROOT \profiles\profile_name \properties\soap.client.props com.ibm.ssl.trustStorePassword	Specifies passwords for: • com.ibm.ssl.keyStorePassword • com.ibm.ssl.trustStorePassword • com.ibm.SOAP.loginPassword
WAS_INSTALL_ROOT \profiles\profile_name \properties\sas.tools.properties	Specifies passwords for: • com.ibm.ssl.keyStorePassword • com.ibm.ssl.trustStorePassword • com.ibm.CORBA.loginPassword
WAS_INSTALL_ROOT \profiles\profile_name\properties \sas.stdclient.propertiescom.ibm.ssl.keyStorePassword	Specifies passwords for: • com.ibm.ssl.keyStorePassword • com.ibm.ssl.trustStorePassword • com.ibm.CORBA.loginPassword
WAS_INSTALL_ROOT \profiles\profile_name \properties\wsserver.key	

To re-encode a password in one of the previous files, complete the following steps:

1. Access the file using a text editor and type over the encoded password in plain text. The new password is shown in plain text and must be encoded.
2. Use the PropFilePasswordEncoder.bat or PropFilePasswordEncode.sh file in the *WAS_INSTALL_ROOT*\profiles\profile_name\bin\ directory to re-encode the password.

   If you are re-encoding SAS properties files, type PropFilePasswordEncoder *file_name* -sas and the PropFilePasswordEncoder file encodes the known SAS properties.

   If you are encoding files that are not SAS properties files, type PropFilePasswordEncoder *file_name password_properties_list*

   file_name is the name of the z/SAS properties file. *password_properties_list* is the name of the properties to encode within the file.

   Use the PropFilePasswordEncoder utility to encode WebSphere Application Server password files only. The utility cannot encode passwords contained in XML files or other files that contain open and close tags.

If you reopen the affected file or files, the passwords do not display in plain text. Instead, the passwords appear encoded. WebSphere Application Server does not provide a utility for decoding the passwords.

PropFilePasswordEncoder command reference

Purpose

The **PropFilePasswordEncoder** command encodes passwords located in plain text property files. This command encodes both Secure Authentication Server (SAS) property files and non-SAS property files. After you have encoded the passwords, note that a decoding command does not exist. To encode passwords, you must run this command from the *install_dir*/bin directory of a WebSphere Application Server installation.

Syntax

The command syntax is as follows:

```
PropFilePasswordEncoder file_name
```

Parameters

The following option is available for the PropFilePasswordEncoder command:

-sas
Encodes SAS property files.

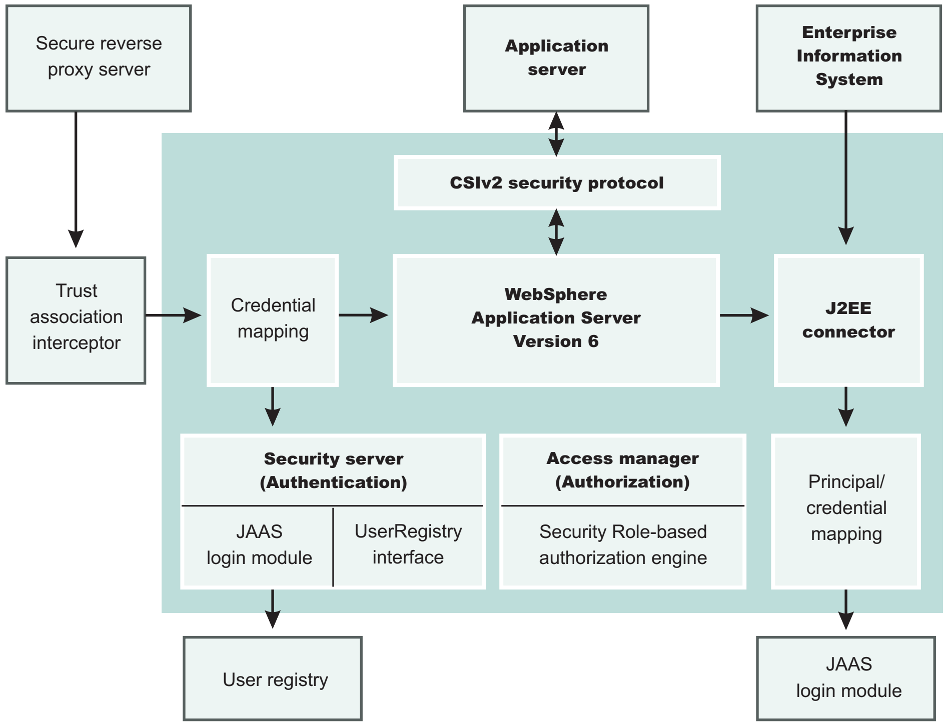
The following examples demonstrate the correct syntax.

```
PropFilePasswordEncoder file_name password_properties_list
PropFilePasswordEncoder file_name -SAS
```

Integrating IBM WebSphere Application Server security with existing security systems

WebSphere Application Server plays an integral part of the multiple-tier enterprise computing framework. WebSphere Application Server adopts the open architecture paradigm and provides many plug-in points to integrate with enterprise software components to provide end-to-end security. WebSphere Application Server plug-in points are based on standard J2EE specifications wherever applicable. WebSphere Application Server is actively involved in various standard bodies to externalize and to standardize plug-in interfaces.

In the following example, several typical multiple-tier enterprise network configurations are discussed. In each case, various WebSphere Application Server plug-in points are used to integrate with other business components. The discussion starts with a basic multiple-tier enterprise network configuration:



Secure reverse proxy server
Application server
Enterprise Information System
CSIv2 security protocol
Trust association interceptor
Credential mapping
WebSphere Application Server Version 6
J2EE connector
Security server (Authentication)
JAAS login module
UserRegistry interface
Access manager (Authorization)
Security Role-based authorization engine
Principal/ credential mapping
User registry
JAAS login module

A list of terms used in this discussion follows:

Protocol firewall
Prevents unauthorized access from the Internet to the demilitarized zone. The role of this node is to provide the Internet traffic access only on certain ports and to block other IP ports.

WebSphere Application Server plug-in
Redirects all the requests for servlets and JSP pages. Also referred to in WebSphere Application Server literature as *Web server redirector* was introduced to separate Web server from application server. The advantage of using Web server redirector is that you can move an application server and all the application business logic behind the domain firewall.

Domain firewall
Prevents unauthorized access from the demilitarized zone to an internal network. The role of this firewall is to allow the network traffic originating from the demilitarized zone and note from the Internet.

Directory
Provides information about the users and their rights in the Web application. The information can contain user IDs, passwords, certificates, access groups, and so forth. This node supplies the information to the security services like authentication and authorization service.

Enterprise information system
Represents existing enterprise applications and business data in back-end databases.

WebSphere Application Server provides the infrastructure to run application business logic and communicate with internal back-end systems and databases Web applications and enterprise beans can access. WebSphere Application Server has a built in HTTPS server that can accept client requests. A typical configuration, however, places WebSphere Application Server behind the domain firewall for better protection. A WebSphere Application Server plug-in to Web server configuration can redirect Web requests to WebSphere Application Server. WebSphere Application Server provides plug-ins for many popular Web servers.

You can configure WebSphere Application Server and the Web server plug-in to communicate through secure SSL channels. You can configure a WebSphere Application Server HTTP server to open communication channels only with a restricted set of Web server plug-ins. You can configure the HTTP server to require client certificate authentication with self-signed certificates and to trust only the signer certificate.

For more information, refer to Network communication using Secure Sockets Layer and the Channel Framework

For instructions on how to generate self-signed certificates and how to set up secure communications channels between an HTTP server and the WebSphere Application Server plug-in, refer to Configuring IHS plug-in and the Internal Web Server for SSL and Configuring IHS for SSL Mutual Authentication.

Protocol firewall
Web server
WebSphere Application Server plug-in
Domain firewall
WebSphere Application Server
Database (DB2 version 8.1 fix pack 6)
MQ CICS
IBM Directory (LDAP)

The WebSphere Application Server plug-in routes HTTP requests according to the virtual host and port configuration and the URL pattern matching. Client authentication and finer grained access control are handled by WebSphere Application Server behind the firewall.

In cases where the Web server can contain sensitive data and direct access is not desirable, the following configuration uses Tivoli WebSEAL to shield a Web server from unauthorized requests. WebSEAL is a Reverse Proxy Security Server (RPSS) that uses Tivoli Access Manager to perform coarse-grained access control to filter out unauthorized requests before they reach the domain firewall. WebSEAL uses Tivoli Access Manager to perform access control as illustrated in the picture. WebSphere Application Server supports various user registry implementations through the pluggable user registry interface.

WebSphere Application Server ships a Local OS user registry implementation for Windows, AIX, AS/400, and Lightweight Directory Access Protocol (LDAP).

WebSphere Application Server also supports users in developing their own custom registry and plug-in through the pluggable user registry interface. When integrated with a third party security provider, WebSphere Application Server can share the user registry with the third-party security provider. In the particular example of integrating with WebSEAL, you can configure WebSphere Application Server to use the LDAP user registry, which can be shared with WebSEAL and Tivoli Access Manager. Moreover, you can configure WebSphere Application Server to use the Light Weight Third Party (LTPA) authentication mechanism, which supports the Trust Association Interceptor plug-in point.

Basically, the RPSS performs authentication and adds proper authentication data into the request header and then redirects the request to Web server. A trust relationship is formed between an RPSS and WebSphere Application Server, and the RPSS can assert client identity to WebSphere Application Server to achieve single signon (SSO) between RPSS and WebSphere Application Server. When the request is forward to WebSphere Application Server, WebSphere Application Server uses the TAI plug-in for the particular RPSS server to evaluate the trust relationship and to extract the authenticated client identity. WebSphere Application Server then maps the client identity to a WebSphere Application Server security credential. For instructions on setting up a trust association interceptor, refer to Trust associations, Configuring trust association interceptors.

WebSphere Application Server plug-in
WebSphere Application Server
Trust Association Interceptor
Database (DB2 version 8.1 fix pack 6)
MQ CICS
IBM Directory (LDAP)
Third-party security provider (Tivoli Access Manager, and so on)

When configured to use the LDAP user registry, WebSphere Application Server uses LDAP to perform authentication. The client ID and password are passed from WebSphere Application Server to the LDAP server. You can configure WebSphere Application Server to set up an SSL connection to LDAP so that passwords are not passed in plain text. To set up an SSL connection from WebSphere Application Server to the LDAP server, refer to Configuring SSL for the LDAP client. WebSphere Application Server Version 5 supports the J2EE Connector Architecture (JCA). The connector architecture defines a standard interface for WebSphere Application Server to connect to heterogeneous enterprise information systems (EIS). Examples of EIS includes database systems, transaction processing such as CICS, and messaging such as Message Queue (MQ). The EIS implementation can perform authentication and access control to protect business data and resources. Resource Adapters authenticate EIS. The authentication data can be provided either by application code or by WebSphere Application Server. WebSphere Application Server provides a principal mapping plug-in point. A principal mapping module plug-in maps the authenticated client principal to a password credential, (that is, user ID and password, for the EIS security domain). WebSphere Application Server ships a default principal mapping module, which maps any authenticated client principal to a configured pair of user IDs and passwords.

Each connector can be configured to use a different set of IDs and passwords. For a description on how to configure JCA principal mapping user IDs and passwords, refer to Managing J2C Authentication Data Entries. A principal mapping module is a special purpose Java Authentication and Authorization Service (JAAS) login module. You can develop your own principal mapping module to fit your particular business application environment. For detailed steps on developing and configuring a custom principal mapping module, refer to the articles, Developing your own Java 2 security mapping module underneath JAAS Programmatic Login and ″Managing Java Authentication and Authorization Service (JAAS) Login Configuration.″

Security and WebSphere MQseries

It is important to note that security logging information on UNIX systems is not protected because of the world-writeable files in the `/var` file system of MQseries. MQseries ships the following files with its product:

- -rw-rw-rw- /var/mqm/errors/AMQERR01.LOG
- -rw-rw-rw- /var/mqm/errors/AMQERR02.LOG
- -rw-rw-rw- /var/mqm/errors/AMQERR03.LOG

The previously mentioned files are world-writeable and enable any users on the system to fill up the /var file system where all the security logging information is stored. This leaves the security information unprotected because anyone can access the logging information without being tracked.

To work around this problem, create a file system for the embedded messaging component working data on UNIX. Before you install the embedded messaging component of WebSphere Application Server on UNIX platforms, consider creating and mounting a journalized file system called /var/mqm. Use a partition strategy with a separate volume for the WebSphere MQ data. This means that other system activity is not affected if a large amount of WebSphere MQ work builds up.

To determine the size of the /var/mqm file system for a server installation, consider the following:
- Maximum number of messages in the system at one time
- Contingency for message buildups, if there is a system problem
- Average size of the message data, plus 500 bytes for the message header
- Number of queues
- Size of log files and error messages

Allow 50MB as a minimum for a WebSphere MQ server. You need less space in the /var/mqm file system for a WebSphere MQ client (typically 15MB).

Interoperability issues for security

To have interoperability of Security Authentication Service (SAS) between C++ and WebSphere Application Server, use the Common Secure Interoperability Version 2 (CSIv2) authentication protocol over Remote Method Invocation over the Internet Inter-ORB Protocol (RMI-IIOP).

Interoperating with a C++ common object request broker architecture client

You can achieve interoperability of Security Authentication Service between the C++ Common Object Request Broker Architecture (CORBA) client and WebSphere Application Server using Common Secure Interoperability Version 2 (CSIv2) authentication protocol over Remote Method Invocation over the Internet Inter-ORB Protocol (RMI-IIOP). The CSIv2 security service protocol has authentication, attribute and transport layers. Among the three layers, transport authentication is conceptually simple, however, cryptographically based transport authentication is the strongest. WebSphere Application Server Enterprise has implemented the transport authentication layer, so that C++ secure CORBA clients can use it effectively in making CORBA clients and protected enterprise bean resources work together.

Security authentication from non-Java based C++ client to enterprise beans. WebSphere Application Server supports security in the CORBA C++ client to access protected enterprise beans. If configured, C++ CORBA clients can access protected enterprise bean methods using client certificate to achieve mutual authentication on WebSphere Application Server Enterprise applications.

To support the C++ CORBA client in accessing protected enterprise beans:
- Create an environment file for the client, such as current.env. Set the variables listed below (security_sslKeyring, client_protocol_user, client_protocol_password) in the file.
- Point to the environment file using the fully qualified path name through the environment variable WAS_CONFIG_FILE. For example, in the test shell script test.sh, export WAS_CONFIG_FILE=/WebSphere/V5R0M0/AppServer/bin/current.env.

C++ security setting	Description
client_protocol_password	Specifies the password for the user ID.
client_protocol_user	Specifies the user ID to be authenticated at the target server.

C++ security setting	Description
security_sslKeyring	Specifies the name of the RACF keyring the client will use. The keyring must be defined under the user ID that is issuing the command to run the client.

To support the C++ CORBA client in accessing protected enterprise beans:

1. Obtain a valid certificate to represent the client and export its public key to the target enterprise bean server.

   A valid certificate is needed to represent the C++ client. Request a certificate from the certificate authority (CA) or create a self-signed certificate for testing purposes.

   Use the Key Management Utility from the Global Security Kit (GSKit) to extract the public key from the personal certificate and save it in the `.arm` format. For details, see the related information about how to extract the personal certificate of the public key.

2. Prepare a truststore file for WebSphere Application Server.

   Add the extracted client public key in the `.arm` file from the client to the server key truststore file. The server can now authenticate the client.

   Note: This is done by invoking the Key Management Utility through ikeyman.bat or ikeyman.sh from WebSphere Application Server installation.

   For details, see the article on Adding truststore files.

3. Configure WebSphere Application Server to support SSL as the authentication mechanism.

   a. Start the administrative console.

   b. Locate the application server that has the target enterprise bean deployed and configure it to use SSL client certificate authentication.

      If it is a base installation, complete the following steps:

      1) Click **Security > Global security**. Under Authentication, click **Authentication protocol > CSIv2 inbound authentication**. Select **Supported** for the Basic authentication and Client certificate authentication options. Leave the rest of the options as defaults.

      2) Click **Security > Global security**. Under Authentication, click **Authentication protocol > CSIv2 inbound transport** and verify that the **SSL-supported** option is selected.

      If it is a Network Deployment setting, complete the following steps:

      1) Click **Server > Application Server >***server_name_where_the_EJB_resides*. Under security, click **Server security**. Under Additional properties, click **CSI inbound authentication**. Select **Supported** for the Basic authentication and Client certificate authentication options. Leave the rest of the options as defaults.

      2) Click **Server > Application Server >***server_name_where_the_EJB_resides*. Under security, click **Server security**. Under Additional properties, click **CSI inbound transport**. Verify that the **SSL-Supported** option is selected.

      For details, see the security articles Configuring CSIv2 inbound authentication and Configuring CSIv2 inbound transport.

   c. Restart the application server.

      The WebSphere Application Server is ready to take a C++ CORBA security client and a mutually authenticated server and client by using SSL in the transport layer.

4. Configure the C++ CORBA client to use a certificate in performing the mutual authentication.

   Client users are accustomed to using property files in their applications because they are helpful in specifying configuration settings. The following list presents important C++ security settings:

C++ security setting	Description
com.ibm.CORBA.bootstrapHostName=ricebella.austin.ibm.com	Specifies the target host name.

com.ibm.CORBA.securityEnabled=yes	Enables security.
com.ibm.CSI.performTLClientAuthenticationSupported=yes	Ensures client is supporting mutual authentication by certificate
com.ibm.CSI.performTransportAssocSSLTLSSupported=yes	Ensures SSL is used, not TCP/IP
com.ibm.ssl.keyFile=C:/ricebella/etc/DummyKeyRingFile.KDB	Specifies which key database file to use.
com.ibm.ssl.keyPassword=WebAS	Specifies the password for opening the key database file. WebSphere Application Server supports a utility called `PasswordEncode4cpp` to encode the plain password.
com.ibm.CORBA.translationEnabled=1	Enables the valueType conversion.

To use the property files in running a C++ client, an environment variable WASPROPS, is used to indicate where a property file or a list of property files exist.

For the complete set of C++ client properties, see the sample property file `scclient.props`, which is shipped with the product located in the *install_root*`\profiles\`*profile_name*`\etc` directory.

Interoperating with previous product versions

IBM WebSphere Application Server, Version 5.x or later interoperates with the previous product versions (such as Version 4 and Version 3.5). Interoperability is achieved only when the Lightweight Third Party Authentication (LTPA) authentication mechanism and Lightweight Directory Access Protocol (LDAP) user registry are used. Credentials derived from Simple WebSphere Authentication Mechanisms (SWAM) are not forwardable.

1. Enable security with the LTPA authentication mechanism and the LDAP user registry. Make sure that the same LDAP user registry is shared by all the product versions.
2. Extract and add Version 5 server certificates into the server key ring file of the previous version.
   a. Open the Version 5 server key ring file using the key management utility (iKeyman) and extract the server certificate to a file.
   b. Open the server key ring of the previous product version, using the key management utility and add the certificate extracted from product Version 5.
3. Extract and add Version 5 server certificates into the server key ring file of the previous version.
   a. Open the Version 5 server key ring file using the key management utility (iKeyman) and extract the server certificate to a file.
   b. Open the server key ring of the previous product version, using the key management utility and add the certificate extracted from product Version 5.
4. Extract and add Version 5 trust certificates into the trust key ring file of the previous product version.
   a. Open the Version 5 trust key ring file using the key management utility and extract the trust certificate to a file.
   b. Open the trust key ring file of the previous product version using the key management utility and add the certificate extracted from Version 5.
5. If single signon (SSO) is enabled, export keys from the Version 5 product and import them into the previous product version. The Version 4 product requires the fix, PQ61779, and the Version 3.5 product requires the fix, PQ59667, for SSO to function.
6. Verify that the application uses the correct JNDI name. In Version 5, the enterprise beans are registered with long JNDI names like, `(top)/nodes/`*node_name*`/servers/`*server_name*`/HelloHome`. Whereas in previous releases, enterprise beans are registered under a root like, `(top)/HelloHome`. Therefore, EJB applications from previous versions perform a lookup on the Version 5 enterprise beans.

   You can also create EJB name bindings in Version 5 that are compatible with the previous version. To create an EJB name binding at the root Version 5, start the administrative console and click **Environment** > **Naming** > **Naming Space Bindings** > **New** > **EJB** > **Next**. Complete all the fields and enter a short name (for example, `-HelloHome`) as the JNDI Name. Click **Next** and **Finish**.

7. Stop and restart all the servers.
8. Make sure that the correct naming bootstrap port is used to perform naming lookup. In previous product versions, the naming bootstrap port is **900**. In Version 5, the bootstrap port is **2809**.

Security: Resources for learning

Use the following links to find relevant supplemental information about Securing applications and their environment. The information resides on IBM and non-IBM Internet sites, whose sponsors control the technical accuracy of the information.

These links are provided for convenience. Often, the information is not specific to the IBM WebSphere Application Server product, but is useful all or in part for understanding the product. When possible, links are provided to technical papers and Redbooks that supplement the broad coverage of the release documentation with in-depth examinations of particular product areas.

Administering security

Administering secure applications requires access to the WebSphere Application Server administrative console. Log in with a valid user ID and password that have administrative access. To administer security, complete these steps:

1. Configure global security. For more information, see “Configuring global security” on page 1418.
2. Assign users to administrator roles. For more information, see “Assigning users to administrator roles” on page 1430.
3. Assign users to naming roles. For more information, see “Assigning users to naming roles” on page 1432.
4. Configure authentication mechanisms. For more information, see “Configuring authentication mechanisms” on page 1436.
5. Configure Lightweight Third Party Authentication. For more information, see “Configuring Lightweight Third Party Authentication” on page 1437.
6. Configure trust association interceptors. For more information, see “Configuring trust association interceptors” on page 1445.
7. Configure single signon. For more information, see “Configuring single signon” on page 1448.
8. Configure user registries. For more information, see “Configuring user registries” on page 1466.
   a. Configure local operating system user registries. For more information, see “Configuring local operating system user registries” on page 1471.
   b. Configure Lightweight Directory Access Protocol user registries. For more information, see “Configuring Lightweight Directory Access Protocol user registries” on page 1474.
   c. Configure custom user registries. For more information, see “Configuring custom user registries” on page 1488.
9. Configure Java Authentication and Authorization Service login. For more information, see ″Configuring application logins for Java Authentication and Authorization Service″ in the information center.
10. Configure an authorization provider. For more information, see “Configuring a JACC provider” on page 1617. To configure the Tivoli Access Manager Java Authorization Contract for Containers

(JACC) provider, see either “Configuring the JACC provider for Tivoli Access Manager using the wsadmin utility” on page 1627 or “Configuring the JACC provider for Tivoli Access Manager using the administrative console” on page 1629.

11. Configure the Common Secure Interoperability Version 2 and Security Authentication Service authentication protocols. For more information, see “Configuring Common Secure Interoperability Version 2 and Security Authentication Service authentication protocols” on page 1657.
12. Configure Secure Sockets Layer. For more information, see ″Configuring Secure Sockets Layer″ in the information center.
13. Configure Java 2 Security Manager. For more information, see “Configuring Java 2 security” on page 1740.
14. **Optional:** Configure security attribute propagation. For more information, see “Security attribute propagation” on page 1551.

Global security

Global security applies to all applications running in the environment and determines whether security is used at all, the type of registry against which authentication takes place, and other values, many of which act as defaults.

The term *global security* represents the security configuration that is effective for the entire security domain. A *security domain* consists of all servers configured with the same user registry *realm* name. In some cases, the realm can be the machine name of a Local OS user registry. In this case, all application servers must reside on the same physical machine. In other cases, the realm can be the machine name of an Lightweight Directory Access Protocol (LDAP) user registry. Since LDAP is a distributed user registry, a multiple node configuration is supported, such as the case for a Network Deployment environment. The basic requirement for a security domain is that the access ID returned by the registry from one server within the security domain is the same access ID as that returned from the registry on any other server within the same security domain. The *access ID* is the unique identification of a user and is used during authorization to determine if access is permitted to the resource.

Configuration of global security for a security domain consists of configuring the common user registry, the authentication mechanism, and other security information that defines the behavior of a security domain. The other security information that you can configure includes Java 2 Security Manager, Java Authentication and Authorization Service (JAAS), Java 2 Connector authentication data entries, Common Secure Interoperability Version 2 (CSIv2)/Security Authentication Service (SAS) authentication protocol (Remote Method Invocation over the Internet Inter-ORB Protocol (RMI/IIOP) security), and other miscellaneous attributes. The global security configuration usually applies to every server within the security domain.

Configuring global security

It is helpful to understand security from an infrastructure standpoint so that you know the advantages of different authentication mechanisms, user registries, authentication protocols, and so on. Picking the right security components to meet your needs is a part of configuring global security. The following sections help you make these decisions. Read the following articles before continuing with the security configuration.

- “Global security”
- Introduction: Security

After you understand the security components, you can proceed to configure global security in WebSphere Application Server.

1. Start the WebSphere Application Server administrative console by clicking `http://yourhost.domain:9060/ibm/console` after starting the WebSphere Application Server. If security is currently disabled, log in with any user ID. If security is currently enabled, log in with a predefined administrative ID and password (this is typically the server user ID specified when you configured the user registry).

2. Click **Security > Global security** and configure the authentication mechanism, user registry, and so on. The configuration order is not important. However, when you select the **Enable global security** flag in the **Global security** panel, verify that all these tasks are completed. When you click **Apply** or **OK** and the **Enable global security** option is set, a verification occurs to see if the administrative user ID and password can be authenticated to the configured user registry. If you do not configure these, the validation fails.
3. Configure a user registry. For more information, see “Configuring user registries” on page 1466. You can configure a local OS, LDAP, or custom user registry through the links under User registry on the Global security panel.

   One of the details common to all user registries is the **server user ID**. This ID is a member of the chosen user registry, but also has special privileges in WebSphere Application Server. The privileges for this ID and the privileges associated with the administrative role ID are the same. The server user ID can access all protected administrative methods. On Windows systems, the ID must not be the same name as the machine name of your system, since the registry sometimes returns machine-specific information when querying a user of the same name. In LDAP user registries, verify that the server user ID is a member of the registry and not just the LDAP administrative role ID. The entry must be searchable.

   The server user ID does **not** run WebSphere Application Server processes. Rather, the process ID runs the WebSphere Application Server processes.The process ID runs the WebSphere Application Server processes.

   The process ID is determined by the way the process starts. For example, if you use a command line to start processes, the user ID that is logged into the system is the process ID. If running as a service, the user ID that is logged into the system is the user ID running the service. If you choose the LocalOS registry, the process ID requires special privileges to call the operating system APIs. Specifically, the process ID must have the **Act as Part of Operating System** privileges on Windows systems or **root** privileges on a UNIX system.
4. Configure the authentication mechanism. To get details about configuring authentication mechanisms, read the “Configuring authentication mechanisms” on page 1436 article. There are two authentication mechanisms to choose from in the Global Security panel: Simple WebSphere Authentication Mechanism (SWAM) and Lightweight Third-Party Authentication (LTPA). However, only LTPA requires any additional configuration parameters. Use the SWAM option for single server requirements. Use the LTPA option for multi-server distributed requirements. SWAM credentials are not forwardable to other machines and for that reason do not expire. Credentials for LTPA are forwardable to other machines and for security reasons do expire. This expiration time is configurable. If you choose to go with LTPA, then “Configuring single signon” on page 1448 support. This support permits browsers to visit different product servers without having to authenticate multiple times.
5. Configure the authentication protocol for special security requirements from Java clients, if needed. This task entails choosing a protocol, either Common Secure Interoperability Version 2 (CSIv2) or Security Authentication Service (SAS). The SAS protocol is still provided as a backwards compatibility to previous product releases, but is being deprecated. For details on configuring CSIv2 or SAS, see the article, “Configuring Common Secure Interoperability Version 2 and Security Authentication Service authentication protocols” on page 1657.
6. Modify the default Secure Sockets Layer (SSL) keystore and truststore files that are packaged with the product. This action protects the integrity of the messages sent across the Internet. The product provides a single location where you can specify SSL configurations that the various WebSphere Application Server features that use SSL can utilize, including the LDAP user registry, Web container and the authentication protocol (CSIv2 and SAS). Create a new keystore and truststore, by referring to the “Creating a keystore file” on page 1717 and “Creating truststore files” on page 1721 articles. You can create different keystore files and truststore files for different uses or you can create just one set for everything that the server uses Secure Sockets Layer (SSL) for. After you create these new keystore and truststore files, specify them in the **SSL Configuration Repertoires**. To get to the **SSL Configuration Repertoires**, click **Security > SSL**. See the article, ″Configuring Secure Sockets Layer″ in the information center. To get to the SSL Configuration Repertoire, click **Security > SSL**. You can either edit the DefaultSSLConfig file or create a new SSL configuration with a new alias name. If

you create a new alias name for your new keystore and truststore files, change every location that references the DefaultSSLConfig SSL configuration alias. The following list specifies the locations of where the SSL configuration repertoire aliases are used in the WebSphere Application Server configuration.

For any transports that use the new network input/output channel chains, including HTTP and Java Message Service (JMS), you can modify the SSL configuration repertoire aliases in the following locations for each server:

- Click **Server > Application server >** *server_name*. Under Communications, click **Ports**. Locate a transport chain where SSL is enabled and click **View associated transports**. Click *transport_channel_name*. Under Transport Channels, click **SSL Inbound Channel (SSL_2)**.

For the Object Request Broker (ORB) SSL transports, you can modify the SSL configuration repertoire aliases in the following locations. These configurations are for the server-level for WebSphere Application Server and WebSphere Application Server Express and the cell level for WebSphere Application Server Network Deployment.

- Click **Security > Global security**. Under Authentication, click **Authentication protocol > CSIv2 Inbound Transport**.
- Click **Security > Global security**. Under Authentication, click **Authentication protocol > CSIv2 Outbound Transport**.
- Click **Security > Global security**. Under Authentication, click **Authentication protocol > SAS Inbound Transport**.
- Click **Security > Global security**. Under Authentication, click **Authentication protocol > SAS Outbound Transport**.

For the Simple Object Access Protocol (SOAP) Java Management Extensions (JMX) administrative transports, you can modify the SSL configurations repertoire aliases by clicking **Servers > Application servers >***server_name*. Under Server infrastructure, click **Administration > Administration services**. Under Additional properties, click **JMX connectors > SOAPConnector**. Under Additional properties, click **Custom properties**. If you want to point the sslConfig property to a new alias, click **sslConfig** and select an alias in the Value field.

For the Lightweight Directory Access Protocol (LDAP) SSL transport, you can modify the SSL configuration repertoire aliases by clicking **Security > Global security**. Under User registries, click **LDAP**.

7. Click **Security** > **Global security** to configure the rest of the security settings and enable security. This panel performs a final validation of the security configuration. When you click **OK** or **Apply** from this panel, the security validation routine is performed and any problems are reported at the top of the page. See the “Global security settings” on page 1421 article for detailed information about these fields. When you complete all of the fields, click **OK** or **Apply** to accept the selected settings. Click **Save** to persist these settings out to a file. If you see any informational messages in red text color, then a problem has occurred with the security validation. Typically, the message indicates the problem; therefore, review your configuration to verify that the user registry settings are accurate and the correct registry is selected. In some cases the LTPA configuration might not be fully specified.
8. Store the configuration for the server to use after it restarts. Complete this action if you have clicked **OK** or **Apply** on the **Security > Global security** panel, and there are no validation problems. To save the configuration, click **Save** in the menu bar at the top. This action writes the settings out to the configuration repository. If you do not click **Apply** or **OK** in the **Global security** panel before clicking **Save** on the main menu, your changes are not written to the repository.
9. Start the WebSphere Application Server administrative console by typing `http://yourhost.domain:9060/ibm/console` after the WebSphere Application Server deployment manager has been started. If security is currently disabled, log in with any user ID. If security is currently enabled, log in with a predefined administrative ID and password, which is typically the server user ID specified when you configure the user registry.

Enabling global security:

You can decide whether to enable IBM WebSphere Application Server security. You must enable security for all other security settings to function.

Note: WebSphere Application Server uses cryptography to protect sensitive data and ensure confidentiallity and integrity of communications between WebSphere Application Server and other components in the network. Cryptography is also used by Web Services security when certain security constraints have been configured for the Web Services application.

WebSphere uses JSSE and JCE libraries in the JDK to enforce this cryptography. The JDK provides strong but limited jurisdiction policy files. Unrestricted policy files provide the ability to perform full strength cryptography and improve performance.

IBM's SDKs ship with strong but limited jurisdiction policy files. For Windows, Linux, HPUX Solaris, and AIX platforms, the unrestricted policy files can be downloaded from https://www6.software.ibm.com/dl/jcesdk/jcesdk-p (Use the link near the bottom of the page.) The ZIP file should be unpacked and the two JAR files placed in the `JRE's jre/lib/security/` directory.

1. Select the unrestricted JCE policy files for SDK 1.4.2.
2. Extract the unlimited jurisdiction policy files that are packaged in the ZIP file that contains two files:
   a. `US_export_policy.jar`
   b. `local_policy.jar`
3. Back up the original version of the policy files.
4. Replace the policy files in the `$JAVA_HOME/jre/lib/security` directory with the two files above.

Global security settings:

Use this page to configure security. When you enable security, you are enabling security settings on a global level.

To view this administrative console page, click **Security > Global security**.

When security is disabled, WebSphere Application Server performance is increased between 10-20%. Therefore, consider disabling security when it is not needed.

If you are configuring security for the first time, complete the steps in the ″Configuring server security″ article in the documentation to avoid problems. When security is configured, validate any changes to the registry or authentication mechanism panels. Click **Apply** to validate the user registry settings. An attempt is made to authenticate the server ID to the configured user registry. Validating the user registry settings after enabling global security can avoid problems when you restart the server for the first time.

Enable global security:

Specifies whether to enable global security for this WebSphere Application Server domain.

This flag is commonly referred to as the *global security flag* in WebSphere Application Server information. When enabling security, set the authentication mechanism configuration and specify a valid user ID and password in the selected user registry configuration.

Default:	Disable

Enforce Java 2 Security:

Specifies whether to enable or disable Java 2 security permission checking. By default, Java 2 security is disabled. However, enabling global security automatically enables Java 2 security. You can choose to disable Java 2 security, even when global security is enabled.

When the **Enforce Java 2 security** option is enabled and if an application requires more Java 2 security permissions than are granted in the default policy, then the application might fail to run properly until the required permissions are granted in either the `app.policy` file or the `was.policy` file of the application. AccessControl exceptions are generated by applications that do have all the required permissions. Consult the WebSphere Application Server documentation and review the Java 2 Security and Dynamic Policy sections if you are unfamiliar with Java 2 security.

If your server does not restart after you enable global security, you can disable security. Go to your `$install_root\bin` directory and execute the `wsadmin -conntype NONE` command. At the `wsadmin>` prompt, enter `securityoff` and then type `exit` to return to a command prompt. Restart the server with security disabled to check any incorrect settings through the administrative console.

Default:	Disabled

Enforce fine-grained JCA security:

Enable this option to restrict application access to sensitive Java Connector Architecture (JCA) mapping authentication data.

Consider enabling this option when both of the following conditions are true:
- Java 2 Security is enforced.
- The application code is granted the accessRuntimeClasses WebSphereRuntimePermission in the `was.policy` file found within the application enterprise archive (EAR) file. For example, the application code is granted the permission when the following line is found in your `was.policy` file:

```
permission com.ibm.websphere.security.WebSphereRuntimePermission ″accessRuntimeClasses″;
```

The **Enforce fine-grained JCA security** option adds fine-grained Java 2 Security permission checking to the default principal mapping of the WSPrincipalMappingLoginModule implementation. You must grant explicit permission to Java 2 Platform, Enterprise Edition (J2EE) applications that use the WSPrincipalMappingLoginModule implementation directly in the Java Authentication and Authorization Service (JAAS) login when Java 2 Security and the **Enforce fine-grained JCA security** option is enabled.

Default:	Disabled

Use domain-qualified user IDs:

Specifies that user names returned by methods are qualified with the security domain in which they reside.

Default:	Disabled

Cache timeout:

Specifies the timeout value in seconds for security cache. This value is a relative timeout.

If WebSphere Application Server security is enabled, the security cache timeout can influence performance. The timeout setting specifies how often to refresh the security-related caches. Security information pertaining to beans, permissions, and credentials is cached. When the cache timeout expires, all cached information becomes invalid. Subsequent requests for the information result in a database lookup. Sometimes, acquiring the information requires invoking a Lightweight Directory Access Protocol

(LDAP)-bind or native authentication. Both invocations are relatively costly operations for performance. Determine the best trade off for the application, by looking at usage patterns and security needs for the site.

In a 20-minute performance test, setting the cache timeout so that a timeout does not occur yields a 40% performance improvement.

Data type:	Integer
Units:	Seconds
Default:	600
Range:	Greater than 30 seconds

Issue permission warning:

Specifies that during application deployment and application start, the security run time issues a warning if applications are granted any custom permissions. Custom permissions are permissions defined by the user applications, not Java API permissions. Java API permissions are permissions in `package java.*` and `javax.*`.

WebSphere Application Server provides support for policy file management. A number of policy files are available in this product, some of them are static and some of them are dynamic. Dynamic policy is a template of permissions for a particular type of resource. There is no code base defined or relative code base used in the dynamic policy template. The real code base is dynamically created from the configuration and run-time data. The `filter.policy` file contains a list of permissions that an application should not have according to the J2EE 1.3 specification. For more information on permissions, see the ″Java 2 security policy files″ article in the documentation.

Default:	Disabled

Active protocol:

Specifies the active authentication protocol for Remote Method Invocation over the Internet Inter-ORB Protocol (RMI IIOP) requests when security is enabled.

In previous releases the Security Authentication Service (SAS) protocol was the only available protocol.

An Object Management Group (OMG) protocol called Common Secure Interoperability Version 2 (CSIv2) supports increased vendor interoperability and additional features. If all of the servers in your security domain are Version 5 servers, specify `CSI` as your protocol.

If some servers are version 3.x or version 4.x servers, specify `CSI and SAS`.

Default:	BOTH
Range:	CSI and SAS, CSI
Range:	

Active authentication mechanism:

Specifies the active authentication mechanism when security is enabled.

WebSphere Application Server and WebSphere Application Server Express, Version 6 support the following authentication mechanisms: Simple WebSphere Authentication Mechanism (SWAM) and Lightweight Third Party Authentication (LTPA).

Default:	SWAM (WebSphere Application Server)
Default:	
Range:	SWAM, LTPA

Default:	
Range:	

Active User Registry:

Specifies the active user registry, when security is enabled. LDAP or a custom user registry is required when running as a UNIX nonroot user or running in a multi-node environment.

You can configure settings for one of the following user registries:

- Local OS

  When you enable global security on a UNIX platform and the user registry is the local OS, you must run the server as root. The local OS user registry is not supported for nonroot users on a UNIX platform.
- LDAP user registry

  The LDAP user registry settings are used when users and groups reside in an external LDAP directory. When security is enabled and any of these properties change, go to the Global Security panel and click **Apply** or **OK** to validate the changes.
- Custom user registry

Default:	Local OS (single, stand-alone server or sysplex and root administrator only)
Range:	Local OS (single, stand-alone server or sysplex and root administrator only), LDAP user registry, Custom user registry

Use the Federal Information Processing Standard (FIPS):

Enables the use of Federal Information Processing Standard (FIPS)-approved cryptographic algorithms.

When **Use the Federal Information Processing Standard (FIPS)** is enabled, the Lightweight Third Party Authentication (LTPA) implementation uses IBMJCEFIPS. IBMJCEFIPS supports the Federal Information Processing Standard (FIPS)-approved cryptographic algorithms for DES, Triple DES, and AES. Although the LTPA keys are backwards compatible with prior releases of WebSphere Application Server, the LTPA token is not compatible with prior releases.

WebSphere Application Server provides a FIPS-approved Java Secure Socket Extension (JSSE) provider called IBMJSSEFIPS. A FIPS-approved JSSE requires the Transport Layer Security (TLS) protocol because it is not compatible with the Secure Sockets Layer (SSL) protocol. If you select the **Use the Federal Information Processing Standard (FIPS)** option prior to specifying a FIPS-approved JSSE provider and a TLS protocol, the following error message displays at the top of the **Global security** panel:

```
The security policy is set to use only FIPS approved cryptographic algorithms.
However at least one SSL configuration may not be using a FIPS approved JSSE provider.
FIPS approved cryptographic algorithms may not be used in those cases.
```

To correct this problem, configure your JSSE provider and security protocol on the **SSL configuration repertoires** panel by completing one of the following tasks:

- Clicking **Security > SSL** and modifying an existing configuration
- Clicking **New** and creating a new configuration

Note:

- The IBMJSSEFIPS provider is not supported on the HP-UX platform.
- In WebSphere Application Server Version 6, the HTTP transport does not support the FIPS-approved providers because it uses the new IBMJSSE2 provider to support channel framework. The channel framework supports asynchronous communication that might enhance performance. The IBMJSSE2 provider is specified for the Secure Sockets Layer (SSL) channel because it must use the IBMJCE provider for encryption. Currently, an IBMJCEFIPS provider that works with the IBMJSSE2 provider, is not available.

Default:	Disabled

Custom Properties: For an existing configuration, there are a number of profiles that you must modify. To modify the profiles, go into the administrative console and click **Security > Global security**. Under Additional Properties, click **Custom properties**.

Configuring server security

You can customize security to some extent at the application server level. You can disable user security on an application server (administrative security remains enabled when global security is enabled). You can also modify Java 2 Security Manager, CSIv2 or Secure Authentication Service (SAS), and some of the other security attributes that are found on the global security (also called *cell-level* security) panel. You cannot configure a different authentication mechanism or user registry on an individual server basis. This feature is limited to cell-level configuration only. Also, when global security is disabled, you cannot enable application server security.

By default, server security inherits all of the values that are configured in global security (cell-level security). To override the security configuration at the server level, click **Servers > Application Servers >** *server name*. Under Security, click **Server Security > Additional properties** and click any of the following panels:

- **CSIv2 Inbound Authentication**
- **CSIv2 Inbound Transport**
- **CSIv2 Outbound Authentication**
- **CSIv2 Outbound Transport**
- **SAS Inbound Transport**
- **SAS Outbound Transport**
- **Server-level Security**

After modifying the configuration in any of these panels and clicking **OK** or **Apply**, the security configuration for that panel or set of panels now overrides cell-level security. Other panels that are not overridden continue to be inherited at the cell-level. However, you can always revert back to the cell-level configuration at any time. On the Server Security panel, click to revert back to the global security configuration on these panels:

- **Use cell security**
- **Use cell CSI**
- **Use cell SAS**

1. Start the administrative console for the deployment manager. To get to the administrative console, go to `http://host.domain:9060/ibm/console`. If security is disabled, you can enter any ID. If security is enabled, you must enter a valid user ID and password, which is either the administrative ID (configured for the user registry) or a user ID entered as an administrative user. To add a user ID as an administrative user, click **System Administration > Console settings > Console Users**.
2. Configure global security if you have not already done so. Go to the “Configuring global security” on page 1418 article for detailed steps. After global security is configured, configure server-level security.

3. To configure server-level security, click **Servers > Application Servers >** *server name*. Under Security, click **Server Security**. The status of the security level that is in use for this application server is displayed.

   By default, you can see that global security, CSI, and SAS have not been overridden at the server level. CSI and SAS are authentication protocols for RMI/IIOP requests. The Server Level Security panel lists attributes that are on the Global Security panel and can be overridden at the server level. Not all of the attributes on the Global Security panel can be overridden at the server level, including Active Authentication Mechanism and Active User Registry.
4. To disable security for this application server, go to the Server Level Security panel, clear the **Enabled** flag and click **OK** or **Apply**. Click **Save**. By modifying the Server Level Security panel, you can see that this flag overrides the cell-level security.
5. To configure CSI at the server level, you can change any panel that starts with CSI. By doing so, all panels that start with CSI will override the CSI settings specified at the cell level. This change includes all authentication and transport panels for CSI. See the "Configuring Common Secure Interoperability Version 2 and Security Authentication Service authentication protocols" on page 1657 article for more detailed steps regarding configuring CSI authentication protocol.

Typically server-level security is used to disable user security for a specific application server. However, this can also be used to disable (or enable) the Java 2 Security Manager, and configure the authentication requirements for RMI/IIOP requests both incoming and outgoing from this application server.

After you modify the configuration for a particular application server, you must restart the application server for the changes to become effective. To restart the application server, go to **Servers > Application Servers** and click the server name that you recently modified. Then, click the **Stop** button and then the **Start** button.

If you disabled security for the application server, you can typically test a URL that is protected when security is enabled.

Server-level security settings:

Use this page to enable server level security and specify other server level security configurations.

To view this administrative console page, click **Servers > Application Servers >** *server_name*. Under Security, click **Server Security**. Under Additional properties, click **Server Level Security**.

Enable global security:

Use this flag to disable or enable security again for this application server while global security is enabled. Server security is enabled by default when global security is enabled. You cannot enable security on an application server while global security is disabled. Administrative (administrative console and wsadmin) and naming security remain enabled while global security is enabled, regardless of the status of this flag.

Default	Disable

Enforce Java 2 security:

Specifies that the server enforces Java 2 Security permission checking at the server level. When cleared, the Java 2 server-level security manager is not installed and all of the Java 2 Security permission checking is disabled at the server level.

If your application policy file is not set up correctly, see the documentation on configuring an application policy in a `was.policy` file.

Default	Disabled

Enforce fine-grained JCA security: Enable this option to restrict application access to sensitive Java Connector Architecture (JCA) mapping authentication data.

Default	Disabled

Use domain qualified user IDs:

Specifies whether user IDs returned by getUserPrincipal()-like calls are qualified with the server level security domain within which they reside.

Default	Disabled

Cache timeout:

Specifies the timeout value for server level security cache in seconds.

Data type	Integer
Units	Seconds
Default	600
Range	Greater than 30 seconds. Avoid setting cache timeout value to 30 seconds or less.

Issue permission warning:

Specifies whether a warning is issued during application installation when an application requires a Java 2 permission that is normally not granted to an application.

WebSphere Application Server provides support for policy file management. A number of policy files are included in WebSphere Application Server. Some of these policy files are static and some of them are dynamic. Dynamic policy is a template of permissions for a particular type of resource. In dynamic policy files, the code bases are evaluated at run time using configuration data. You can add or remove permissions, as needed, for each code base. However, do not add, remove, or modify the existing code bases. The real code base is dynamically created from the configuration and run-time data. The `filter.policy` file contains a list of permissions that an application does not have, according to the J2EE 1.3 Specification. For more information on permissions, see the documentation on the Java 2 security policy files.

Default	Enabled

Active protocol:

Specifies the active server level security authentication protocol when server level security is enabled.

You can use an Object Management Group (OMG) protocol called Common Secure Interoperability Version 2 (CSIv2) for more vendor interoperability and additional features. If all of the servers in your entire security domain are Version 5.0 servers, it is best to specify **CSI** as your protocol.

If some servers are Version 3.x or Version 4.x servers, it is best to specify **CSI and SAS**. However, by specifying **CSI and SAS**, you now have two interceptors invoking each request.

Data type	String
Default	CSI and SAS

Range	CSI, CSI and SAS

Administrative console and naming service authorization

WebSphere Application Server extends the Java 2 Platform, Enterprise Edition (J2EE) security role-based access control to protect the product administrative and naming subsystems.

Administrative console

Four administrative roles are defined to provide degrees of authority needed to perform certain WebSphere Application Server administrative functions from either the administrative console or the system management scripting interface. The authorization policy is only enforced when global security is enabled. The four administrative security roles are defined in the following table:

administrative roles

Role	Description
monitor	Least privileged where a user can view the WebSphere Application Server configuration and current state.
configurator	Monitor privilege plus the ability to change the WebSphere Application Server configuration.
operator	Monitor privilege plus the ability to change the run-time state, such as starting or stopping services.
administrator	Operator plus configuration privilege and the permission required to access sensitive data including the server password, LTPA password, LTPA, keys, and so on.

When global security is enabled, the administrative subsystem role-based access control is enforced. The administrative subsystem includes security server, user registry, and all the Java Management Extensions (JMX) MBeans. When security is enabled, both the administrative console and the administrative scripting tool require users to provide the required authentication data. Moreover, the administrative console is designed so the control functions that display on the pages are adjusted according to the security roles that a user has. For example, a user who has only the monitor role can see only the non-sensitive configuration data. A user with the operator role can change the system state.

The server identity specified when enabling global security is automatically mapped to the administrative role. You can add or remove users and groups to or from the administrative roles from the WebSphere Application Server administrative console. However, a server restart is required for the changes to take effect. A best practice is to map a group, rather than specific users, to administrative roles because it is more flexible and easier to administer. By mapping a group to an administrative role, adding or removing users to or from the group occurs outside of WebSphere Application Server and does not require a server restart for the change to take effect.

When global security is enabled, WebSphere Application Servers run under the server identity that is defined under the active user registry configuration. Although it is not shown on the administrative console and in other tools, a special Server subject is mapped to the administrator role. The WebSphere Application Server run-time code, which runs under the server identity, requires authorization to runtime operations. If no other user is assigned administrative roles, you can log into the administrative console or to the wsadmin scripting tool using the server identity to perform administrative operations and to assign other users or groups to administrative roles. Because the server identity is assigned to the administrative role by default, the administrative security policy requires the administrative role to perform the following operations:

- Change server ID and server password
- Enable or disable WebSphere Application Server global security
- Enforce or disable Java 2 Security

- Change the LTPA password or generate keys
- Assign users and groups to administrative roles

When enabling security, you can assign one or more users and groups to administrative roles. For more information, see Assigning users to naming roles. However, before assigning users to naming roles, configure the active user registry. User and group validation depends on the active user registry. For more information, see Configuring user registries.

Naming service authorization

CosNaming security offers increased granularity of security control over CosNaming functions. CosNaming functions are available on CosNaming servers such as the WebSphere Application Server. They affect the content of the WebSphere Application Server name space. There are generally two ways in which client programs result in CosNaming calls. The first is through the JNDI interfaces. The second is with CORBA clients invoking CosNaming methods directly.

Four security roles are introduced :

- CosNamingRead
- CosNamingWrite
- CosNamingCreate
- CosNamingDelete

The names of the four roles are the same with WebSphere Application Server Advanced Edition Version 4.0.2. The roles now have authority levels from low to high:

CosNamingRead
Users can query of the WebSphere Application Server name space, using, for example, the JNDI lookup method. The special-subject Everyone is the default policy for this role.

CosNamingWrite
Users can perform write operations such as JNDI **bind**, **rebind**, or **unbind**, and CosNamingRead operations. The special-subject AllAuthenticated is the default policy for this role.

CosNamingCreate
Users can create new objects in the name space through such operations as JNDI createSubcontext and CosNamingWrite operations. The special subject AllAuthenticated is the default policy for this role.

CosNamingDelete
Users can destroy objects in the name space, for example using the JNDI destroySubcontext method and CosNamingCreate operations. The special-subject AllAuthenticated is the default policy for this role.

Additionally, a Server special-subject is assigned to all the four CosNaming roles by default. The Server special-subject provides a WebSphere Application Server server process, which runs under the server identity, access to all the CosNaming operations. Note that the Server special-subject does not display and cannot be modified through the administrative console or other administrative tools.

No special configuration is required to enable the server identity (as specified) when enabling global security for administrative use because the server identity is automatically mapped to the administrator role (enabled with PQ81586) .

Users, groups, or the special subjects AllAuthenticated and Everyone can be added or removed to or from the naming roles from the WebSphere Application Server administrative console at any time. However, a server restart is required for the changes to take effect. A best practice is to map groups or one of the special-subjects, rather than specific users, to naming roles because it is more flexible and easier to administer in the long run. By mapping a group to a naming role, adding or removing users to or from the group occurs outside of WebSphere Application Server and does not require a server restart for the change to take effect.

The CosNaming authorization policy is only enforced when global security is enabled. When global security is enabled, attempts to do CosNaming operations without the proper role assignment result in an `org.omg.CORBA.NO_PERMISSION` exception from the CosNaming Server.

In WebSphere Application Server Version 4.0.2, each CosNaming function is assigned to only one role. Therefore, users who are assigned the CosNamingCreate role cannot query the name space unless they have also been assigned CosNamingRead. And in most cases a creator needs to be assigned three roles: CosNamingRead, CosNamingWrite, and CosNamingCreate. The CosNamingRead and CosNamingWrite roles assignment for the creator example are included in the CosNamingCreate role. In most of the cases, WebSphere Application Server administrators do not have to change the roles assignment for every user or group when they move to this release from a previous one.

Although the ability exists to greatly restrict access to the name space by changing the default policy, unexpected `org.omg.CORBA.NO_PERMISSION` exceptions can occur at run time. Typically, J2EE applications access the name space and the identity they use is that of the user that authenticated to WebSphere Application Server when they access the J2EE application. Unless the J2EE application provider clearly communicates the expected Naming roles, use caution when changing the default naming authorization policy.

Assigning users to administrator roles

The following steps are needed to assign users to administrative roles.

In the administrative console, click **System Administration** > **Console settings** . Click either **Console Users** or **Console Groups**.

1. To add a user or a group, click **Add** on the **Console users** or **Console groups** panel.
2. To add a new administrator user, enter a user identity in the User field, highlight **Administrator**, and click **OK**. If there is no validation error, the specified user is displayed with the assigned security role.
3. To add a new administrative group, either enter a group name in the **Specify group** field or select EVERYONE or ALL AUTHENTICATED from the Select from special subject menu, and click **OK**. If no validation error exists, the specified group or special subject displays with the assigned security role.
4. To remove a user or group assignment, click **Remove** on the Console Users or the Console Groups panel. On the Console Users or the Console Groups panel, select the check box of the user or group to remove and click **OK**.
5. To manage the set of users or groups to display, expand the **filter** folder on the right panel and modify the filter. For example, setting the filter to `user*` only displays users with the `user` prefix.
6. After the modifications are complete, click **Save** to save the mappings.
7. Restart the server for changes to take effect.

The task of assigning users and groups to administrative roles is performed to identify users for performing WebSphere Application Server administrative functions. Administrator roles are used to control access to WebSphere Application Server administrative functions. There are four roles: administrator, configurator, operator and monitor.

Administrator role

Users and groups assigned to the administrator role can perform all administrative operations and can set up both J2EE role-based and Java 2 security policy.

Configurator role

Users assigned to the configurator role can perform all of the day-to-day configuration tasks including installing and uninstalling applications, assigning users and groups to role mapping for applications, setting run-as configurations, setting up Java 2 security permissions for applications, and customizing Common Secure Interoperability Version 2 (CSIv2), Security Authentication Service (SAS), and Secure Sockets Layer (SSL) configurations.

Operator role
Users assigned to the operator role can view the WebSphere Application Server configuration and its current state, but also can change the run-time state such as stopping and starting services.

Monitor role
Users assigned the monitor state can view the WebSphere Application server configuration and its current state only.

Before you assign users to administrative roles (administrator, configurator, operator, and monitor), you must set up your user registry, which can be LDAP, local OS, or a custom registry. You can set up your user registries without enabling security.

Once you assign users to administrative roles, you must restart the server for the new roles to take effect. However, the administrative resources are not protected until you enable security.

Console groups and CORBA naming service groups:

Use the Console Groups page to give groups specific authority to administer the WebSphere Application Server using tools such as the administrative console or wsadmin scripting. The authority requirements are only effective when global security is enabled. Use the CORBA naming service groups page to manage CORBA Naming Service groups settings.

To view the Console Groups administrative console page, click **System Administration > Console Groups**.

To view the CORBA naming service groups administrative console page, click **Environment > Naming > CORBA Naming Service Groups**.

Group (Console groups):

Specifies groups.

The ALL_AUTHENTICATED and the EVERYONE groups can have the following role privileges: Administrator, Configurator, Operator, and Monitor.

Data type:	String
Range:	ALL_AUTHENTICATED, EVERYONE

Group (CORBA naming service groups):

Identifies CORBA naming service groups.

The ALL_AUTHENTICATED group has the following role privileges: CosNamingRead, CosNamingWrite, CosNamingCreate, and CosNamingDelete. The EVERYONE group indicates that the users in this group have CosNamingRead privileges only.

Data type:	String
Range:	ALL_AUTHENTICATED, EVERYONE

Role (Console group):

Specifies user roles.

The following administrative roles provide different degrees of authority needed to perform certain WebSphere Application Server administrative functions:

Administrator

The administrator role has operator permissions, configurator permissions, and the permission required to access sensitive data including server password, LTPA password and keys, and so on.

Configurator

The configurator role has monitor permissions and can change the WebSphere Application Server configuration.

Operator

The operator role has monitor permissions and can change the run-time state. For example, the operator can start or stop services.

Monitor

The monitor role has the least permissions. This role primarily confines the user to viewing the WebSphere Application Server configuration and current state.

Data type:	String
Range:	Administrator, Configurator, Operator, and Monitor

Role (CORBA naming service groups):

Identifies naming service group roles.

A number of naming roles are defined to provide degrees of authority needed to perform certain WebSphere naming service functions. The authorization policy is only enforced when global security is enabled.

Four name space security roles are available: CosNamingRead, CosNamingWrite, CosNamingCreate, and CosNamingDelete. The names of the four roles are the same with WebSphere Advanced Edition, Version 4.0.2. However, the roles now have authority levels from low to high:

CosNamingRead

Users can query the WebSphere name space using, for example, the Java Naming and Directory Interface (JNDI) lookup method. The special-subject EVERYONE is the default policy for this role.

CosNamingWrite

Users can perform write operations such as JNDI bind, rebind, or unbind, and CosNamingRead operations. The special-subject ALL_AUTHENTICATED is the default policy for this role.

CosNamingCreate

Users can create new objects in the name space through operations such as JNDI createSubcontext and CosNamingWrite operations. The special-subject ALL_AUTHENTICATED is the default policy for this role.

CosNamingDelete

Users can destroy objects in the name space, for example using the JNDI destroySubcontext method and CosNamingCreate operations. The special-subject ALL_AUTHENTICATED is the default policy for this role.

Data type:	String
Range:	CosNamingRead, CosNamingWrite, CosNamingCreate, and CosNamingDelete

Assigning users to naming roles

The following steps are needed to assign users to naming roles. In the administrative console, expand **Environment > Naming**, and click **CORBA Naming Service Users** or **CORBA Naming Service Groups**.

1. Click **Add** on the **CORBA Naming Service Users** or **CORBA Naming Service Groups** panel.

2. To add a new naming service user, enter a user identity in the **User** field, highlight one or more naming roles, and click **OK**. If no validation errors occur, the specified user is displayed with the assigned security role.
3. To add a new naming service group, either select **Specify group** and enter a group name or select **Select from special subject** and then select either **EVERYONE** or **ALL AUTHENTICATED**. Click **OK**. If no validation errors occur, the specified group or special subject is displayed with the assigned security role.
4. To remove a user or group assignment, go to the **CORBA Naming Service Users** or **CORBA Naming Service Groups** panel. Select the check box next to the user or group that you want to remove and click **Remove**.
5. To manage the set of users or groups to display, expand the **Filter** folder on the right panel, and modify the filter text box. For example, setting the filter to `user*` displays only users with the `user` prefix.
6. After modifications are complete, click **Save** to save the mappings. Restart the server for the changes to take effect.

The default naming security policy is to grant all users read access to the CosNaming space and to grant any valid user the privilege to modify the contents of the CosNaming space. You can perform the previously mentioned steps to restrict user access to the CosNaming space. However, use caution when changing the naming security policy. Unless a Java 2 Platform, Enterprise Edition (J2EE) application has clearly specified its naming space access requirements, changing the default policy can result in unexpected org.omg.CORBA.NO_PERMISSION exceptions at run time.

Console users settings and CORBA naming service user settings:

Use the Console users settings page to give users specific authority to administer WebSphere Application Server using tools such as the administrative console or wsadmin scripting. The authority requirements are only effective when global security is enabled. Use the common object request broker architecture (CORBA) naming service users settings page to manage CORBA naming service users settings.

To view the Console users administrative console page, click **System Administration > Console Users**.

To view the CORBA naming service users administrative console page, click **Environment > Naming > CORBA Naming Service users**.

User (Console users):

Specifies users.

The users entered must exist in the configured active user registry.

Data type:	String

User (CORBA naming service users):

Specifies CORBA naming service users.

The users entered must exist in the configured active user registry.

Data type:	String

Role (Console users):

Specifies user roles.

The following administrative roles provide different degrees of authority needed to perform certain WebSphere Application Server administrative functions:

Administrator
The administrator role has operator permissions, configurator permissions, and the permission required to access sensitive data including server password, Lightweight Third Party Authentication (LTPA) password and keys, and so on.

Configurator
The configurator role has monitor permissions and can change the WebSphere Application Server configuration.

Operator
The operator role has monitor permissions and can change the run-time state. For example, the operator can start or stop services.

Monitor
The monitor role has the least permissions. This role primarily confines the user to viewing the WebSphere Application Server configuration and current state.

Data type:	String
Range:	Administrator, Configurator, Operator, and Monitor

Role (CORBA naming service users):

Specifies naming service user roles.

A number of naming roles are defined to provide degrees of authority needed to perform certain WebSphere naming service functions. The authorization policy is only enforced when global security is enabled. The following roles are valid: CosNamingRead, CosNamingWrite, CosNamingCreate, and CosNamingDelete.

The names of the four roles are the same with WebSphere Application Server, Advanced Edition Version 4.0.2. However, the roles now have authority levels from low to high:

CosNamingRead
Users can query the WebSphere name space using, for example, the Java Naming and Directory Interface (JNDI) lookup method. The special-subject EVERYONE is the default policy for this role.

CosNamingWrite
Users can perform write operations such as JNDI bind, rebind, or unbind, plus CosNamingRead operations. The special-subject ALL AUTHENTICATED is the default policy for this role.

CosNamingCreate
Users can create new objects in the name space through operations such as JNDI createSubcontext and CosNamingWrite operations. The special-subject ALL AUTHENTICATED is the default policy for this role.

CosNamingDelete
Users can destroy objects in the name space, for example using the JNDI destroySubcontext method and CosNamingCreate operations. The special-subject ALL AUTHENTICATED is the default policy for this role.

Data type:	String
Range:	CosNamingRead, CosNamingWrite, CosNamingCreate and CosNamingDelete

Authentication mechanisms

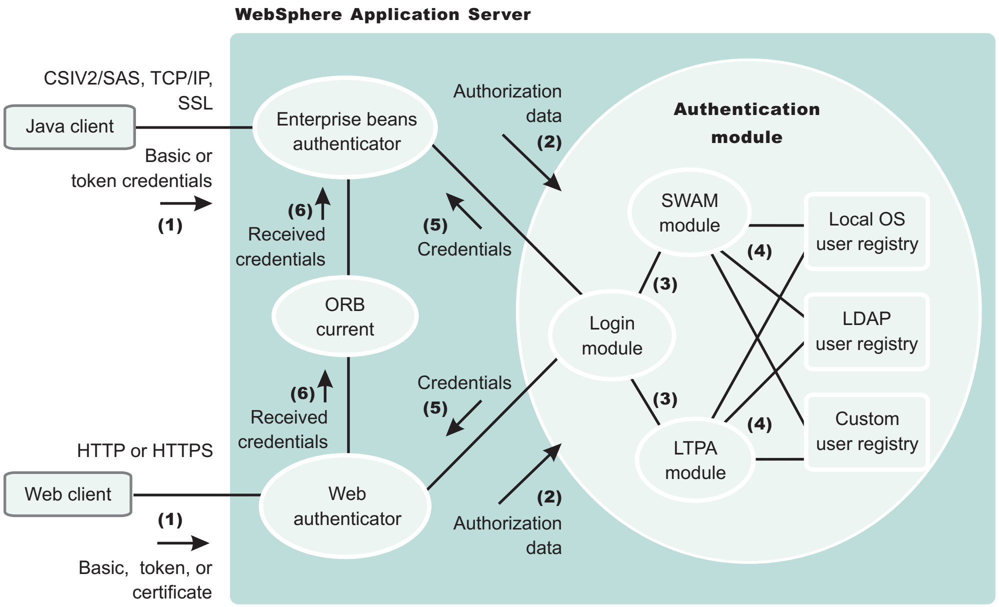
An *authentication mechanism* defines rules about security information (for example, whether a credential is forwardable to another Java process), and the format of how security information is stored in both credentials and tokens.

Authentication is the process of establishing whether a client is valid in a particular context. A client can be either an end user, a machine, or an application.

An authentication mechanism in WebSphere Application Server typically collaborates closely with a *user registry*. The user registry is the user and groups account repository that the authentication mechanism consults with when performing authentication. The authentication mechanism is responsible for creating a *credential*, which is an internal product representation of a successfully authenticated client user. Not all credentials are created equally. The abilities of the credential are determined by the configured authentication mechanism.

Although this product provides several authentication mechanisms, you can configure only a single *active* authentication mechanism at a time. The active authentication mechanism is selected when configuring WebSphere Application Server global security.

Authentication



Authentication Process

The figure demonstrates the authentication process. Basically, authentication is required for enterprise bean clients and Web clients when they access protected resources. Enterprise bean clients (a servlet or other enterprise beans or a pure client) send the authentication information to a Web application server using one of the following protocols:

- Common Secure Interoperability Version 2 (CSIv2)
- Secure Authentication Service (SAS)

Web clients use the HTTP or HTTPS protocol to send the authentication information as shown in the previous figure.

The authentication information can be BasicAuth (user ID and password), credential token (in case of Lightweight Third Party Authentication (LTPA) on all platforms), or client certificate. The Web authentication is performed by the Web Authentication module and the enterprise bean authentication is performed by the Enterprise JavaBean (EJB) authentication module, which resides in the CSIv2 and SAS layer. The authentication module is implemented using the Java Authentication and Authorization Service (JAAS) login module. The Web authenticator and the EJB authenticator pass the authentication data to the login module (2), which can use any of the following mechanisms to authenticate the data:

- Lightweight Third Party Authentication (LTPA).

- Simple WebSphere Authentication Mechanism (SWAM)

The authentication module uses the registry that is configured on the system to perform the authentication (4). Three types of registries are supported: LocalOS, Lightweight Directory Access Protocol (LDAP), and custom registry. External registry implementation following the registry interface specified by IBM can replace either the LocalOS or the LDAP user registry.

The login module creates a JAAS subject after authentication and stores the Common Object Request Broker Architecture (CORBA) credential derived from the authentication data in the public credentials list of the subject. The credential is returned to the Web authenticator or EJB authenticator (5).

The Web authenticator and the EJB authenticator store the received credentials in the Object Request Broker (ORB) current for the authorization service to use in performing further access control checks.

WebSphere Application Server provides two authentication mechanisms: SWAM and LTPA. These authentication mechanisms differ primarily in the distributed security features that each supports.

Configuring authentication mechanisms

Configure authentication mechanisms by clicking **Authentication Mechanisms** under **Security > Global security** in the administrative console.

For LTPA, follow the steps in “Configuring single signon” on page 1448 for most situations. If trust association is required, follow the steps in “Configuring trust association interceptors” on page 1445.

Simple WebSphere authentication mechanism:

The Simple WebSphere authentication mechanism (SWAM) is intended for simple, non-distributed, single application server run-time environments. The single application server restriction is due to the fact that SWAM does not support *forwardable* credentials. If a servlet or enterprise bean in application server process 1, invokes a remote method on an enterprise bean living in another application server process 2, the identity of the caller identity in process 1 is not transmitted to server process 2. What is transmitted is an unauthenticated credential, which, depending on the security permissions configured on the EJB methods, can cause authorization failures.

Since SWAM is intended for a single application server process, single signon (SSO) is not supported.

The SWAM authentication mechanism is suitable for simple environments, software development environments, or other environments that do not require a distributed security solution.

Lightweight Third Party Authentication:

Lightweight Third Party Authentication (LTPA) is intended for distributed, multiple application server and machine environments. It supports forwardable credentials and single signon (SSO). LTPA can support security in a distributed environment through cryptography. This support permits LTPA to encrypt, digitally sign, and securely transmit authentication-related data, and later decrypt and verify the signature.

The Lightweight Third Party Authentication (LTPA) protocol enables the WebSphere Application Server to provide security in a distributed environment using cryptography. Application servers distributed in multiple nodes and cells can securely communicate using this protocol. It also provides the single signon (SSO) feature wherein a user is required to authenticate only once in a domain name system (DNS) domain and can access resources in other WebSphere Application Server cells without getting prompted. The realm names on each system in the SSO domain are case sensitive and must match identically.

Windows For local OS on the Windows platform, the realm name is the domain name, if a domain is in use, or the machine name.

UNIX On the UNIX platform, the realm name is the same as the host name.

For the Lightweight Directory Access Protocol (LDAP), the realm name is the host:port of the LDAP server.

The LTPA protocol uses cryptographic keys (LTPA keys) to encrypt and decrypt user data that passes between the servers. These keys need to be shared between the different cells for the resources in one cell to access resources in other cells (assuming that all the cells involved use the same LDAP or custom registry).

When using LTPA, a token is created with the user information and an expiration time and is signed by the keys. The LTPA token is time sensitive. All product servers participating in a protection domain must have their time, date, and time zone synchronized. If not, LTPA tokens appear prematurely expired and cause authentication or validation failures.

This token passes to other servers, in the same cell or in a different cell through cookies (for Web resources when SSO is enabled) or through the authentication layer (Security Authentication Service (SAS) or Common Secure Interoperability Version 2 (CSIv2) for enterprise beans).

If the receiving servers share the same keys as the originating server, the token can be decrypted to obtain the user information, which then is validated to make sure it has not expired and the user information in the token is valid in its registry. On successful validation, the resources in the receiving servers are accessible after the authorization check.

All the WebSphere Application Server processes in a cell (cell, nodes, application servers) share the same set of keys. If key sharing is required between different cells, export them from one cell and import them to the other. For security purposes, the exported keys are encrypted with a user-defined password. This same password is needed when importing the keys into another cell.

In the base version of WebSphere Application Server, LTPA, ICSF, and the Simple WebSphere Authentication Mechanism (SWAM) protocols are supported.

When security is enabled for the first time with LTPA, configuring LTPA is normally the initial step performed.

LTPA requires that the configured user registry be a centrally shared repository such as LDAP or a Windows domain type registry so that users and groups are the same regardless of the machine.

The following table summarizes the authentication mechanism capabilities and user registries with which LTPA can work.

	Forwardable Credentials	SSO	LocalOS User Registry	LDAP User Registry	Custom User Registry
SWAM	No	No	Yes	Yes	Yes
LTPA	Yes	Yes	Yes	Yes	Yes
ICSF	Yes	Yes	Yes	Yes	Yes

Configuring Lightweight Third Party Authentication:

The following steps are needed to configure Lightweight Third Party Authentication (LTPA) when setting up security for the first time:

1. Access the administrative console by typing `http://localhost:`*`port_number`*`/ibm/console` in a Web browser. Port 9060 is the default port number for accessing the administrative console. During installation, however, you might have specified a different port number. Use the appropriate port number.

2. Click **Security > Global security**.
3. Under Authentication mechanisms, click **LTPA**.
4. Enter the password and confirm it in the password fields. This password is used to encrypt and decrypt the LTPA keys during export and import of the keys. Remember this password because you enter it again when the keys from this cell are exported to another cell.
5. Enter a positive integer value in the **Timeout** field. This timeout value refers to how long an LTPA token is valid in minutes. The token contains this expiration time so that any server that receives the token can verify that the token is valid before proceeding further.

   When the token expires, the user is prompted to log in.

   An optimal value for this field depends on your configuration. The default value is 30 minutes.
6. **Optional:** In the **Key file name** field, specify the name of the file that is used when you import or export keys. You can use this field in conjunction with the **Import keys** and **Export keys** buttons at the top of the panel.
7. Click **Apply** or **OK**. The LTPA configuration is now set. Do not generate the LTPA keys in this step because they are automatically generated later. Proceed with the rest of the steps required to enable security, starting with single signon (SSO) (if SSO is required).
8. Complete the information in the Global Security panel and click **OK**. The LTPA keys are generated automatically the first time. Do not generate the keys manually.

The previous steps configure LTPA by setting passwords that generate LTPA keys.

After configuring LTPA, complete the following steps to work with your key files:
1. Generate key files.
2. Export key files.
3. Import key files.
4. If you are enabling security, make sure that you complete the remaining steps starting with enabling SSO.
5. If you generated a new set of keys or imported a new set of keys, verify that the keys are saved by clicking **Save** at the top of the panel. Because LTPA authentication uses time sensitive tokens, verify that the time, date, and time zone are synchronized among all product servers that are participating in the protection domain. If the clock skew is too high between servers, the LTPA token appears prematurely expired and causes authentication or validation failures.

Configuring Lightweight Third Party Authentication keys:

Generating keys:

Lightweight Third Party Authentication (LTPA) keys are automatically generated when a password change is detected. The first time that you set the LTPA password, as part of enabling security, the LTPA keys are automatically generated after **OK** or **Apply** is clicked in the LTPA panel. You do not have to click **Generate Keys** in this situation. Complete the following steps in the administrative console to generate a new set of LTPA keys:
1. Access the administrative console by typing `http://localhost:9060/ibm/console` in a Web browser.
2. Verify that all the WebSphere Application Server processes are running (cell, nodes, and all of the application servers). If any of the servers are down at the time of key generation and then brought back up later, these servers might contain old keys. Copy the new set of keys to these servers to bring them back up.
3. Click **Security > Authentication mechanisms > LTPA** in the navigation panel on the left.
4. Click **Generate Keys** if you want to use the existing password. This action generates a new set of keys that are encrypted with the same password as the old set of keys. Regardless of the password change, a new set of keys is generated when you click **Generate Keys**. This new set of keys is not propagated to the run time unless saved; save the files immediately.

5. Enter the new password and confirm it, to use a new password to generate keys. Click **OK** or **Apply**. A new set of keys is generated. A message indicating that a new set of keys is generated displays on the console. Do not click **Generate Keys**. These new keys are propagated to the run time after you save them.
6. Click **Save** to save the keys. After a new set of keys is generated and saved, the key propagation is dynamic. All of the processes running at that time (cells, node agents, application servers) are updated with the new set of keys. The next sections describe the process of exporting and importing the keys.

Exporting keys:

To support single signon (SSO) in WebSphere Application Server across multiple WebSphere Application Server domains or cells, share the LTPA keys and the password among the domains. Make sure that the time on the domains is similar to prevent the tokens from appearing as expired between the cells. You can use **Export Keys** to export the LTPA keys to other domains or cells. Complete the following steps in the administrative console to export key files for LTPA:

1. Access the administrative console by typing `http://localhost:9060/ibm/console` in a Web browser.
2. Click **Security** > **Authentication mechanisms** > **LTPA** in the navigation panel on the left.
3. In the **Key File Name** field, enter the full path of a file for key storage. This file needs write permissions.
4. Click **Export Keys**. A file is created with the LTPA keys. Exporting keys fails if a new set of keys is generated or imported and not saved prior to exporting. To avoid failure, make sure that you save the new set of keys (if any) prior to exporting them.
5. Click **Save** to save the configuration.

Importing keys:

To support SSO in WebSphere Application Server across multiple WebSphere Application Server domains or cells, share the LTPA keys and the password among the domains. You can use **Import Keys** to import the LTPA keys from other domains. Verify that key files are exported from one of the cells involved, into a file. Complete the following steps in the administrative console to import key files for LTPA.

Importing keys is a dynamic operation. All of the servers that are running at this time are updated with the new set of keys. Any back-level tokens signed with the back-level keys fail validation and the user is prompted to log in again.

1. Access the administrative console by typing `http://localhost:9060/ibm/console` in a Web browser.
2. Click **Security** > **Authentication mechanisms** > **LTPA** in the navigation panel on the left.
3. Change the password in the **password** fields to match the password in the cell from which you are importing the keys.
4. Click **Save** to save the new set of keys in the repository. This step is important to complete before importing the keys. If the password and the keys do not match, the servers fail. If the servers fail, turn off security and redo these steps.
5. In the **Key File Name** field, enter the full path of a file for key storage. This file needs read permissions.
6. Click **Import Keys**. The keys are now imported into the system.
7. Click **Save** to save the new set of keys in the repository. It is important to save the new set of keys to match the new password so that no problems are encountered starting the servers later.

Lightweight Third Party Authentication settings:

Use this page to configure Lightweight Third Party Authentication (LTPA) settings.

To view this administrative console page, complete the following steps:

1. Click **Security > Global security**.

2. Under Authentication, click **Authentication mechanisms > LTPA**.

If you are configuring security for the first time, only the password is required. After the password is entered, click **Apply**. Under Additional Properties, click **Single signon (SSO)** and enter the domain name. Make sure that SSO is enabled. Click **Apply**.

To complete the security setup, make sure that the appropriate registry is set up and click **Apply** from the Global security panel. When security is enabled and any of these properties change, go to the Global security panel under **Security > Global security** and click **Apply** to validate the changes.

Generate Keys:

Specifies whether the server generates new Lightweight Third Party Authentication (LTPA) keys.

When security is turned on for the first time with LTPA as the authentication mechanism, the LTPA keys are automatically generated with the password entered in the panel. If you need a new set of keys to generate using the previously set password, click **Generate Keys**. If a new password is used, do not click this option. After the new password is entered and **OK** or **Apply** is clicked, a new set of keys is generated. *A new set of generated keys is not used until you save them.*

Import Keys:

Specifies whether the server imports new LTPA keys.

To support single signon (SSO) in the WebSphere product across multiple WebSphere domains (cells), share the LTPA keys and the password among the domains. You can use the **Import Keys** option to import the LTPA keys from other domains. The LTPA keys are exported from one of the cells to a file. To import a new set of LTPA keys, enter the appropriate password, click **OK** and click **Save**. Then, enter the directory location where the LTPA keys are located prior to clicking **Import keys**. Do not click **OK** or **Apply**, but save the settings.

Export Keys:

Specifies whether the server exports LTPA keys.

To support single signon (SSO) in the WebSphere product across multiple WebSphere Application Server domains (cells), share the LTPA keys and the password among the domains. Use the **Export Keys** option to export the LTPA keys to other domains.

To export the LTPA keys, make sure that the system is running with security enabled and is using LTPA. Enter the file name in the **Key file name** field and click **Export Keys**. The encrypted keys are stored in the specified file.

Password:

Specifies the password to encrypt and decrypt the LTPA keys. Use this password when importing these keys into other WebSphere Application Server administrative domain configurations (if any) and when configuring SSO for a Lotus Domino server.

After the keys are generated or imported, they are used to encrypt and decrypt the LTPA token. Whenever the password is changed, a new set of LTPA keys are automatically generated when you click **OK** or **Apply**. The new set of keys is used after the configuration changes are saved.

Data type	String

Confirm password:

Specifies the confirmed password used to encrypt and decrypt the LTPA keys.

Use this password when importing these keys into other WebSphere Application Server administrative domain configurations (if any) and when configuring SSO for a Lotus Domino server.

Data type	String

Timeout:

Specifies the time period in minutes at which an LTPA token expires. Verify that this time period is longer than the cache timeout configured in the Global security panel.

Data type	Integer
Units	Minutes
Default	120

Key file name:

Specifies the name of the file used when importing or exporting keys.

Enter a fully qualified key file name, and click **Import Keys** or **Export Keys**.

Data type	String

Trust associations:

Trust association enables the integration of IBM WebSphere Application Server security and third-party security servers. More specifically, a reverse proxy server can act as a front-end authentication server while the product applies its own authorization policy onto the resulting credentials passed by the proxy server.

Demand for such an integrated configuration has become more compelling, especially when a single product cannot meet all of the customer needs or when migration is not a viable solution. This article provides a conceptual background behind the approach.

The demand is growing to provide customers with a trust association solution between IBM WebSphere Application Server and other Web authentication servers that act as a reverse proxy security server (IBM Tivoli Access Manager for e-business - WebSEAL, Caching Proxy) as an entry point to all service requests (See the first figure). This implementation design intends to have the proxy server as the only exposed entry point. The proxy server authenticates all requests that come in and provides coarse, granularity junction point authorization.

In this setup, the WebSphere Application Server is used as a back-end server to further exploit its fine-grained access control. The reverse proxy server passes the HTTP request to the WebSphere Application Server that includes the credentials of the authenticated user. WebSphere Application Server then uses these credentials to authorize the request.

Trust association model

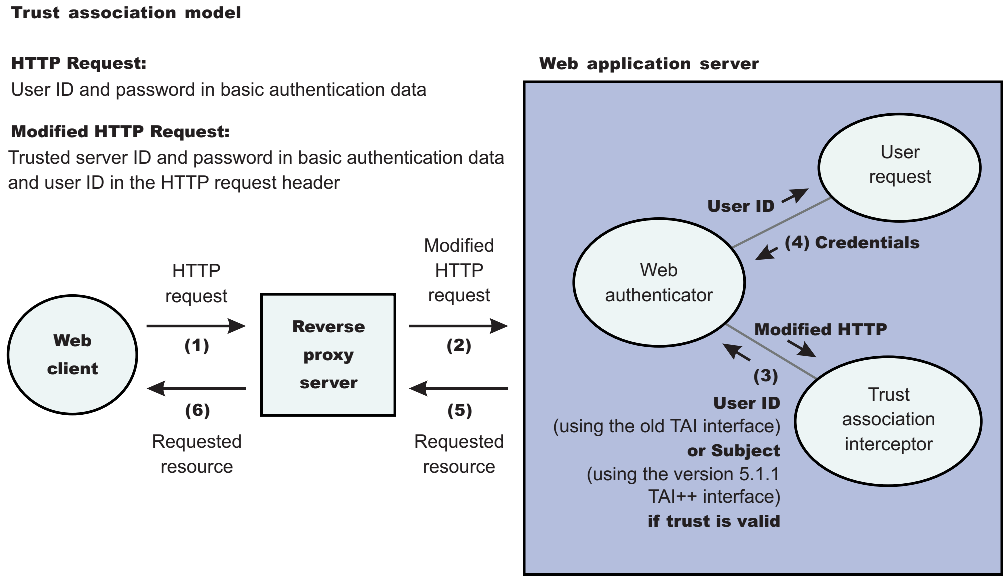
The idea that WebSphere Application Server can support trust association implies that the product application security recognizes and processes HTTP requests received from a reverse proxy server. WebSphere Application Server and the proxy server engage in a contract in which the product gives its full trust to the proxy server and the proxy server applies its authentication policies on every Web request that is dispatched to WebSphere Application Server. This trust is validated by the interceptors that reside in the product environment for every request received. The method of validation is agreed upon by the proxy server and the interceptor.

Running in trust association mode does not prohibit WebSphere Application Server from accepting requests that did not pass through the proxy server. In this case, no interceptor is needed for validating trust. It is possible, however, to configure WebSphere Application Server to strictly require that all HTTP requests go through a reverse proxy server. In this case, all requests that do not come from a proxy server are immediately denied by WebSphere Application Server.

WebSphere Application Server supports the following trust association interceptor (TAI) interfaces:

com.ibm.ws.security.web.WebSealTrustAssociationInterceptor
This Tivoli TAI interceptor that implements WebSphere Application Serve TAI interface is provided to support WebSEAL Version 4.1. If you plan to use WebSEAL 5.1, it is recommended that you migrate to use the new com.ibm.ws.security.web.TAMTrustAssociationInterceptorPlus interceptor which implements the new com.ibm.wsspi.security.tai.TrustAssociationInterceptor interface.

com.ibm.ws.security.web.TAMTrustAssociationInterceptorPlus
This TAI interceptor implementation that implements the new WebSphere Application Server interface supports WebSphere Application Server Version 5.1.1 and later. The interface supports WebSEAL Version 5.1, but does not support WebSEAL Version 4.1. For an explanation of security attribute propagation, see ″Security attribute propagation.″



IBM WebSphere Application Server: WebSEAL Integration

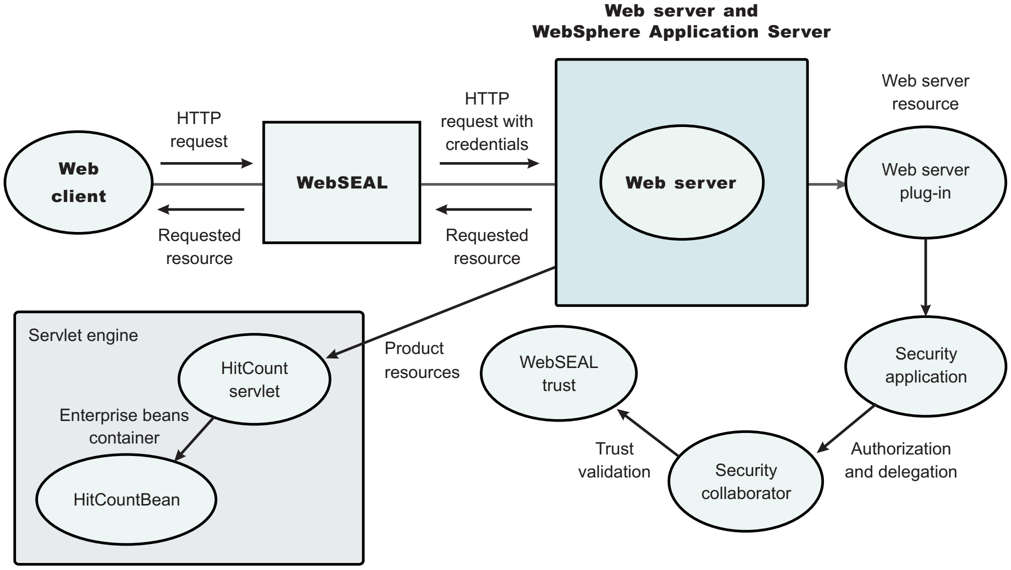
The integration of WebSEAL and WebSphere Application Server security is achieved by placing the WebSEAL server at the front-end as a reverse proxy server. See Figure 2. From a WebSEAL management perspective, a junction is created with WebSEAL on one end, and the product Web server on the other end. A junction is a logical connection created to establish a path from the WebSEAL server to another server.

In this setup, a request for Web resources stored in a protected domain of the product is submitted to the WebSEAL server where it is authenticated against the WebSEAL security realm. If the requesting user has access to the junction, the request is transmitted to the WebSphere Application Server HTTP server through the junction, and then to the application server.

Meanwhile, the WebSphere Application Server validates every request that comes through the junction to ensure that the source is a trusted party. This process is referenced as *validating the trust* and it is performed by a WebSEAL product-designated interceptor. If the validation is successful, the WebSphere Application Server authorizes the request by checking whether the client user has the required permissions to access the Web resource. If so, the Web resource is delivered to the WebSEAL server, through the Web server, which then gives it to the client user.

WebSEAL server

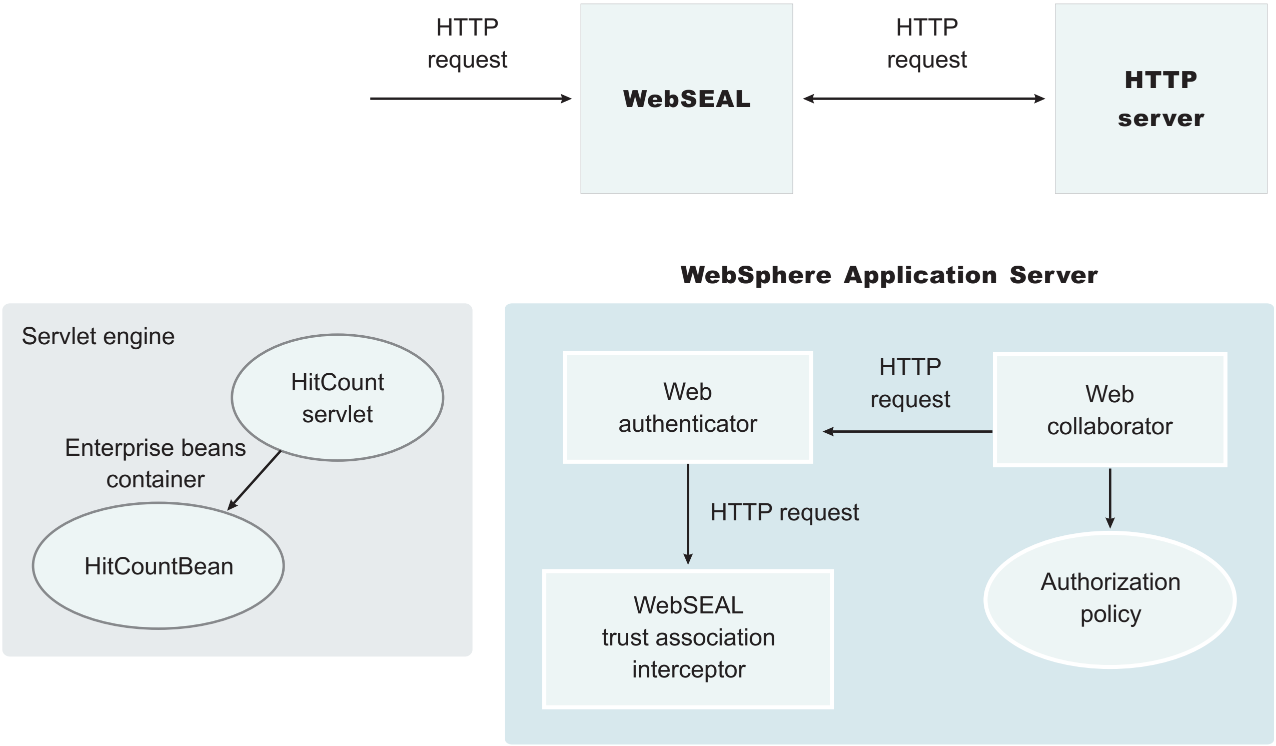
The policy director delegates all of the Web requests to its Web component, the WebSEAL server. One of the major functions of the server is to perform authentication of the requesting user. The WebSEAL server consults a Lightweight Directory Access Protocol (LDAP) directory. It can also map the original user ID to another user ID, such as when global single signon (GSO) is used.



For successful authentication, the server plays the role of a client to WebSphere Application Server when channeling the request. The server needs its own user ID and password to identify itself to WebSphere Application Server. This identity must be valid in the security realm of WebSphere Application Server. The WebSEAL server replaces the basic authentication information in the HTTP request with its own user ID and password. In addition, WebSphere Application Server must determine the credentials of the requesting client so that the application server has an identity to use as a basis for its authorization decisions. This information is transmitted through the HTTP request by creating a header called `iv-creds` with the Tivoli Access Manager user credentials as its value.

HTTP server

The junction created in the WebSEAL server must get to the HTTP server that serves as the product front end. However, the HTTP server is shielded from knowing that trust association is used. As far as it is concerned, the WebSEAL product is just another HTTP client, and as part of its normal routines, it sends the HTTP request to the product. The only requirement on the HTTP server is a Secure Sockets Layer (SSL) configuration using server authentication only. This requirement protects the requests that flow within the junction.



Web collaborator

When trust association is enabled, the Web collaborator manages the interceptors that are configured in the system. It loads and initializes these interceptors when you restart your servers. When a request is passed to WebSphere Application Server by the Web server, the Web collaborator eventually receives the request for a security check. Two actions must take place:
1. The request must be authenticated.
2. The request must be authorized.

The Web authenticator is called to authenticate the request by passing the HTTP request. If successful, a good credential record is returned by the authenticator, which the Web collaborator uses to base its authorization for the requested resource. If the authorization succeeds, the Web collaborator indicates to WebSphere Application Server that the security check has succeeded and that the requested resource can be served.

Web authenticator

The Web authenticator is asked by the Web collaborator to authenticate a given HTTP request. Knowing that trust association is enabled, the task of the Web authenticator is to find the appropriate trust association interceptor to direct the request for processing. The Web authenticator queries every available interceptor. If no target interceptor is found, the Web authenticator processes the request as though trust association is not enabled.

For an HTTP request sent by the WebSEAL server, the WebSEAL trust association interceptor replies with a positive response to the Web authenticator. Subsequently, the interceptor is asked to validate its trust association with the WebSEAL server and retrieve the Subject, using the new trust association interface (TAI) interface, or user ID, using the old TAI interface, of the original user client.

Note: The new Trust Association Interceptor (TAI) interface, `com.ibm.wsspi.security.tai.TrustAssociationInterceptor`, supports several new features and is different from the existing `com.ibm.websphere.security.TrustAssociationInterceptor` interface. Although the existing interface is still supported, it is being deprecated in a future release. Refer to X for more information.

WebSphere Application Server Version 4 through WebSphere Application Server Version 5.x support the `com.ibm.websphere.security.TrustAssociationInterceptor.java` interface. WebSphere Application Server Version 6 supports the `com.ibm.wsspi.security.tai.TrustAssociationInterceptor` interface

For more information, seeTrust association interceptor support for Subject creation .

Trust association interceptor interface

The intent of the trust association interceptor interface is to have reverse proxy security servers (RPSS) exist as the exposed entry points to perform authentication and coarse-grained authorization, while the WebSphere Application Server enforces further fine-grained access control. Trust associations improve security by reducing the scope and risk of exposure.

In a typical e-business infrastructure, the distributed environment of a company consists of Web application servers, Web servers, legacy systems, and one or more RPSS, such as the Tivoli WebSEAL product. Such reverse proxy servers, front-end security servers, or security plug-ins registered within Web servers, guard the HTTP access requests to the Web servers and the Web application servers. While protecting access to the Uniform Resource Identifiers (URIs), these RPSS perform authentication, coarse-grained authorization, and request routing to the target application server.

Using the trust association interceptor feature

The following points further describe the benefits of the trust association interceptor (TAI) feature:
- RPSS can authenticate WebSphere Application Server users up front and send credential information about the authenticated user to the product so that the product can trust the RPSS to perform authentication and not prompt the end user for authentication data later. The strength of the trust relationship between RPSS and the product is based on the criteria of trust association that is particular to a RPSS and enforced through the TAI implementation. This level of trust might need relaxing based on the environment. Be aware of the vulnerabilities in cases where the RPSS is not trusted, based on a security technology.
- The end user credentials most likely are sent in a special format as part of the Hypertext Transfer Protocol (HTTP) headers as in the case of RPSS authentication. The credentials can be a special header or a cookie. The data that passes is implementation specific, and the TAI feature considers this fact and accommodates the idea. The TAI implementation works with the credential data and returns a Subject, using the new TAI interface, or a user ID, using the old TAI interface, that represents the end user. WebSphere Application Server uses the information to enforce security policies.

Configuring trust association interceptors:

These steps are required to use either a WebSEAL trust association interceptor or your own trust association interceptor with a reverse proxy security server. WebSphere Application Server enables you to use multiple trust association interceptors. The Application Server uses the first interceptor that can handle the request.

1. Access the administrative console by typing `http://localhost:`*`port_number`*`/ibm/console` in a Web browser. Port 9060 is the default port number for accessing the administrative console. During installation, however, you might have specified a different port number. Use the appropriate port number.
2. Click **Security** > **Global security**.
3. Under Authentication mechanisms, click **LTPA**.
4. Under Additional properties, click **Trust Association**.

5. Select the **Enable trust association** option.
6. Under Additional properties, click **Interceptors**. The default value appears.
7. Verify that the appropriate trust association interceptors are listed. If you need to use a WebSEAL trust association interceptor, see “Configuring single signon using the trust association interceptor” on page 1457 or “Configuring single signon using trust association interceptor ++” on page 1458. If you are not using WebSEAL and need to use a different interceptor, complete the following steps:
   a. Select both the `com.ibm.ws.security.web.WebSealTrustAssociationInterceptor` and the `com.ibm.ws.security.web.TAMTrustAssociationInterceptorPlus` class name and click **Delete**.
   b. Click **New** and specify a trust association interceptor.

Enables trust association.
1. If you are enabling security, make sure that you complete the remaining steps for enabling security.
2. Save, stop and restart all of the product servers (deployment managers, nodes and Application Servers) for the changes to take effect.

Trust association settings:

Trust association enables the integration of IBM WebSphere Application Server security and third-party security servers. More specifically, a reverse proxy server can act as a front-end authentication server while the product applies its own authorization policy onto the resulting credentials passed by the proxy server. Use this page to configure trust association settings.

To view this administrative console page, complete the following steps:
1. Click **Security > Global security**.
2. Under Authentication, click **Authentication mechanisms > LTPA**.
3. Under Additional properties, click **Trust association**.

When security is enabled and any of these properties change, go to the **Global security** panel and click **Apply** to validate the changes.

Enable trust association:

Specifies whether trust association is enabled.

Data type:	Boolean
Default:	Disable
Range:	Enable or Disable

Trust association interceptor collection:

Use this page to specify trust information for reverse security proxy servers.

To view this administrative console page, complete the following steps:
1. Click **Security > Global security**.
2. Under Authentication, click **Authentication mechanisms > LTPA**.
3. Under Additional Properties, click **Trust association > Interceptors**.

When security is enabled and any of these properties are changed, go to the Global security panel and click **Apply** to validate the changes.

Interceptor class name:

Specifies the trust association interceptor class name.

Data type
String

Default
`com.ibm.ws.security.web.WebSealTrustAssociationInterceptor`

Single signon:

With single signon (SSO) support, Web users can authenticate once when accessing both WebSphere Application Server resources, such as HTML, JavaServer Pages (JSP) files, servlets, enterprise beans, and Lotus Domino resources, such as documents in a Domino database, or accessing resources in multiple WebSphere Application Server domains.

Web users can authenticate once to a WebSphere Application Server or to a Domino server. Without logging in again, Web users can access any other WebSphere Application Servers or Domino servers in the same Domain Name Service (DNS) domain that are enabled for SSO. This authentication is accomplished by configuring the WebSphere Application Servers and the Domino servers to share authentication information.

Enable SSO among WebSphere Application Servers by configuring SSO for WebSphere Application Server. To enable SSO between WebSphere Application Servers and Domino servers, you must configure SSO for both WebSphere Application Server and for Domino.

Prerequisites and conditions

To take advantage of support for single signon between WebSphere Application Servers or between WebSphere Application Server and a Domino server, applications must meet the following prerequisites and conditions:

- Verify that all servers are configured as part of the same DNS domain. For example, if the DNS domain is specified as `mycompany.com`, then SSO is effective with any Domino server or WebSphere Application Server on a host that is part of the mycompany.com domain, for example, a.mycompany.com and b.mycompany.com.
- Verify that all servers share the same user registry.

  This registry can be either a supported Lightweight Directory Access Protocol (LDAP) directory server or, if SSO is configured between two WebSphere Application Servers, a custom user registry.Domino servers do not support custom registries, but you can use a Domino-supported registry as a custom registry within WebSphere Application Server. For more information on custom registries, see *Introduction to custom registries*.

  You can use a Domino directory (configured for LDAP access) or other LDAP directory for the user registry. The LDAP directory product must have WebSphere Application Server support. Supported products include both Domino and IBM SecureWay LDAP directory servers. Regardless of the choice to use an LDAP or a custom registry, the SSO configuration is the same. The difference is in the configuration of the registry.
- Define all users in a single LDAP directory. Using LDAP referrals to connect more than one directory together is not supported. Using multiple Domino directory assistance documents to access multiple directories also is not supported.
- Enable HTTP cookies in browsers because the authentication information that is generated by the server is transported to the browser in a cookie. The cookie is then used to propagate the authentication information for the user to other servers, exempting the user from entering the authentication information for every request to a different server.
- For a Domino server:
  - Domino Release 5.0.6a for iSeries 400 or later and Domino Release 5.0.5 or later for other platforms are supported.
  - A Lotus Notes client Release 5.0.5 or later is required for configuring the Domino server for SSO.
  - You can share authentication information across multiple Domino domains.
- For WebSphere Application Server:

– WebSphere Application Server Version 3.5 or later for all platforms is supported.
– You can use any HTTP Web server supported by WebSphere Application Server.
– You can share authentication information across multiple product administrative domains.
– Basic authentication (user ID and password) using the basic and form-login mechanisms is supported.
– By default, WebSphere Application Server does a case-sensitive comparison for authorization. This comparison implies that a user who is authenticated by Domino matches the entry exactly (including the base distinguished name) in the WebSphere Application Server authorization table. If case sensitivity is not considered for the authorization, enable the **Ignore Case** property in the LDAP user registry settings.

Configuring single signon:

With single signon (SSO) support, Web users can authenticate once when accessing Web resources across multiple WebSphere Application Servers. Form login mechanisms for Web applications require that SSO is enabled.

SSO is supported only when Lightweight Third Party Authentication (LTPA) is the authentication mechanism.

When SSO is enabled, a cookie is created containing the LTPA token and inserted into the HTTP response. When the user accesses other Web resources in any other WebSphere Application Server process in the same domain name service (DNS) domain, the cookie is sent in the request. The LTPA token is then extracted from the cookie and validated. If the request is between different cells of WebSphere Application Servers, you must share the LTPA keys and the user registry between the cells for SSO to work. The realm names on each system in the SSO domain are case sensitive and must match identically.

Windows For local OS on the Windows platform, the realm name is the domain name if a domain is in use or the machine name.

UNIX On the Linux or UNIX platforms, the release name is the same as the host name.

For the Lightweight Directory Access Protocol (LDAP) the realm name is the host:port realm name of the LDAP server. The LTPA authentication mechanism requires that you enable SSO if any of the Web applications have form login as the authentication method.

Because single signon is a subset of LTPA, it is recommended that you read “Lightweight Third Party Authentication” on page 1436 for more information.

When you enable security attribute propagation, the following cookies are added to the response:

LtpaToken
The LtpaToken is used for interoperating with previous releases of WebSphere Application Server. This token contains the authentication identity attribute only.

LtpaToken2
LtpaToken2 contains stronger encryption and enables you to add multiple attributes to the token. This token contains the authentication identity and additional information such as the attributes used for contacting the original login server and the unique cache key for looking up the Subject when considering more than just the identity in determining uniqueness.

For more information, see ″Security attribute propagation″ in the information center.

Token type	Purpose	How to specify
LtpaToken only	This token type is used for the same SSO behavior existing in WebSphere Application Server Version 5.1 and previous releases. Also, this token type is interoperable with those previous releases.	Disable the **Web inbound security attribute propagation** option located in the SSO configuration panel in the administrative console. To access this panel, complete the following steps: 1. Click **Security > Global security**. 2. Under Authentication, click **Authentication mechanisms > LTPA**. 3. Under Additional properties, click **Single signon (SSO)**.
LtpaToken2 only	This token type is used for Web inbound security attribute propagation and uses the AES, CBC, PKCS5 padding encryption strength (128 bit key size). However, this token type is not interoperable with releases prior to WebSphere Application Server Version 5.1.1. The token type allows for multiple attributes specified in the token (mostly containing information to contact the original login server).	Enable the **Web inbound security attribute propagation** option in the SSO configuration panel within the administrative console. Disable the **Interoperability mode** option in the SSO configuration panel within the administrative console. To access this panel, complete the following steps: 1. Click **Security > Global security**. 2. Under Authentication, click **Authentication mechanisms > LTPA**. 3. Under Additional properties, click **Single signon (SSO)**.
LtpaToken and LtpaToken2	These tokens together support both of the previous two options. The token types are interoperable with releases prior to WebSphere Application Server Version 5.1.1 because LtpaToken is present. The security attribute propagation function is enabled because the LtpaToken2 is present.	Enable the **Web inbound security attribute propagation** option in the SSO configuration panel within the administrative console. Enable the **Interoperability mode** option in the SSO configuration panel within the administrative console. To access this panel, complete the following steps: 1. Click **Security > Global security**. 2. Under Authentication, click **Authentication mechanisms > LTPA**. 3. Under Additional properties, click **Single signon (SSO)**.

The following steps are required to configure SSO for the first time.

1. Access the administrative console by typing `http://localhost:`*`port_number`*`/ibm/console` in a Web browser. Port 9060 is the default port number for accessing the administrative console. During installation, however, you might have specified a different port number. Use the appropriate port number.
2. Click **Security > Global security** .
3. Under Authentication, click **Authentication mechanisms > LTPA**.
4. Under Additional properties, click **Single signon (SSO)**.
5. Click the **Enabled** option if SSO is disabled. After you click **Enabled**, make sure that you complete the remaining steps to enable security.
6. Click the **Requires SSL** option if all of the requests are expected to use HTTPS.

7. Enter the fully-qualified domain names in the **Domain name** field where SSO is effective. The cookie is sent for all of the servers that are contained within the domains that you specify in this field. If you specify domain names, they must be fully qualified. If the domain name is not fully qualified, WebSphere Application Server does not set a domain name value for the LtpaToken cookie and SSO is valid only for the server that created the cookie.

   You can configure the **Domain name** field using any of the following values:

Domain name value type	Example
Blank	
Single domain name	austin.ibm.com
UseDomainFromURL	UseDomainFromURL
Multiple domain names	austin.ibm.com;raleigh.ibm.com
Multiple domain names and UseDomainFromURL	• austin.ibm.com;raleigh.ibm.com • UseDomainFromURL

   If you specify the UseDomainFromURL, WebSphere Application Server sets the SSO domain name value to the domain of the host that makes the request. For example, if an HTTP request comes from server1.raleigh.ibm.com, WebSphere Application Server sets the SSO domain name value to raleigh.ibm.com.

   Tip: The value, `UseDomainFromURL`, is case insensitive. You can type `usedomainfromurl` to use this value.

   When you specify multiple domains, you can use the following delimiters: a semicolon (;), a space ( ), a comma (,), or a pipe (|). WebSphere Application Server searches the specified domains in order from left to right. Each domain is compared with the host name of the HTTP request until the first match is located. For example, if you specify ibm.com; austin.ibm.com and a match is found in the ibm.com domain first, WebSphere Application server does not continue to search for a match in the austin.ibm.com domain. However, if a match is not found in either the ibm.com or austin.ibm.com domains, then WebSphere Application Server does not set a domain for the LtpaToken cookie.

   For more information, see “Single signon settings” on page 1451.

8. **Optional:** Enable the **Interoperability mode** option if you want to allow SSO connections in WebSphere Application Server version 5.1.1 or later to interoperate with previous versions of the application server. This option sets the old-style LtpaToken into the response so it can be sent to other servers that work only with this token type. However, this option applies only when the **Web inbound security attribute propagation** option is enabled. In this case, both the LtpaToken and LtpaToken2 are added to the response. Otherwise, only the LtpaToken2 is added to the response. If the **Web inbound security attribute propagation** option is disabled, then only the LtpaToken is added to the response.

9. **Optional:** Enable the **Web inbound security attribute propagation** option if you want information added during the login at a specific front-end server to propagate to other front-end servers. The SSO token does not contain any sensitive attributes, but does understand where the original login server exists in cases where it needs to contact that server to retrieve serialized information. It also contains the cache look up value for finding the serialized information in DynaCache, if both front-end servers are configured in the same DRS replication domain. For more information, see ″Security attribute propagation.″

   Important: If the following statements are true, it is recommended that you disable the **Web inbound security attribute propagation** option for performance reasons:

   - You do not have any specific information added to the Subject during a login that cannot be obtained at a different front-end server.
   - You did not add custom attributes to the PropagationToken using WSSecurityHelper application programming interfaces (APIs).

If you find you are missing custom information in the Subject, re-enable the **Web inbound security attribute propagation** option to see if the information is propagated successfully to other front-end application servers. If you disable SSO, but use a trust association interceptor instead, you might still need to enable the **Web inbound security attribute propagation** option if you want to retrieve the same Subject generated at different front-end servers.

10. Click **OK**.

For the changes to take effect, save, stop, and restart all the product servers (deployment managers, nodes and Application Servers).

Single signon settings:

Use this page to set the configuration values for single signon (SSO).

To view this administrative console page, complete the following steps:

1. Click **Security** > **Global Security**.
2. Under Authentication mechanisms, click **LTPA**.
3. Under Additional properties, click **Single signon (SSO)**.

Enabled:

Specifies that the single signon function is enabled.

Web applications that use J2EE FormLogin style login pages (such as the WebSphere Application Server administrative console) require single signon (SSO) enablement. Only disable SSO for certain advanced configurations where LTPA SSO-type cookies are not required.

Data type:	Boolean
Default:	Enabled
Range:	Enabled or Disabled

Requires SSL:

Specifies that the single signon function is enabled only when requests are made over HTTPS Secure Sockets Layer (SSL) connections.

Data type:	Boolean
Default:	Disable
Range:	Enable or Disable

Domain name:

Specifies the domain name (.ibm.com, for example) for all single signon hosts.

WebSphere Application Server uses all the information after the first period, from left to right, for the domain names. If this field is not defined, the Web browser defaults the domain name to the host name where the Web application is running. Also, single signon is then restricted to the application server host name and does not work with other application server host names in the domain.

You can specify multiple domains separated by a semicolon (;), a space ( ), a comma (,), or a pipe (|). Each domain is compared with the host name of the HTTP request until the first match is located. For example, if you specify ibm.com;austin.ibm.com and a match is found in the ibm.com domain first, WebSphere Application server does not match the austin.ibm.com domain. However, if a match is not found in either ibm.com or austin.ibm.com, then WebSphere Application Server does not set a domain for the LtpaToken cookie.

If you specify `UseDomainFromURL`, WebSphere Application Server sets the SSO domain name value to the domain of the host used in the URL. For example, if an HTTP request comes from `server1.raleigh.ibm.com`, WebSphere Application Server sets the SSO domain name value to `raleigh.ibm.com`.

Tip: The UseDomainFromURL value is case insensitive. You can type `usedomainfromurl` to use this value.

Data type:	String

Interoperability mode:

Specifies that an interoperable cookie is sent to the browser to support back-level servers.

In WebSphere Application Server, Version 6 and later, a new cookie format is needed by the security attribute propagation functionality. When the interoperability mode flag is enabled, the server can send a maximum of two single signon (SSO) cookies back to the browser. In some cases, the server just sends the interoperable SSO cookie.

Web inbound security attribute propagation:

When Web inbound security attribution propagation is enabled, security attributes are propagated to front-end application servers. When this option is disabled, the single signon (SSO) token is used to log in and recreate the Subject from the user registry. If you disable this option, the Web inbound login module functions the same as it did in previous releases.

If the application server is a member of a cluster and the cluster is configured with a distributed replication service (DRS) domain, then propagation occurs. If DRS is not configured, then the SSO token contains the originating server information. With this information the receiving server can contact the originating server using an MBean call to get the original serialized security attributes.

Troubleshooting single signon configurations:

This article describes common problems in configuring single signon (SSO) between a WebSphere Application Server and a Domino server and suggests possible solutions.

- Failure to save the Domino Web SSO configuration document

  The client must find Domino server documents for the participating SSO Domino servers. The Web SSO configuration document is encrypted for the servers that you specify. The home server that is indicated by the client location record must point to a server in the Domino domain where the participating servers reside. This pointer ensures that lookups can find the public keys of the servers.

  If you receive a message stating that one or more of the participating Domino servers cannot be found, then those servers cannot decrypt the Web SSO configuration document or perform SSO.

  When the Web SSO configuration document is saved, the status bar indicates how many public keys are used to encrypt the document by finding the listed servers, authors, and administrators in the document.
- Failure of the Domino server console to load the Web SSO configuration document at Domino HTTP server startup

  During configuration of SSO, the server document is configured for **Multi-Server** in the **Session Authentication** field. The Domino HTTP server tries to find and load a Web SSO configuration document during startup. The Domino server console reports the following information if a valid document is found and decrypted: `HTTP: Successfully loaded Web SSO Configuration`.

If a server cannot load the Web SSO configuration document, SSO does not work. In this case, a server reports the following message: `HTTP: Error Loading Web SSO configuration`. Reverting to single-server session authentication.

Verify that only one Web SSO Configuration document is in the Web Configurations view of the Domino directory and in the $WebSSOConfigs hidden view. You cannot create more than one document, but you can insert additional documents during replication.

If you can verify only one Web SSO Configuration document, consider another condition. When the public key of the Server document does not match the public key in the ID file, this same error message can display. In this case, attempts to decrypt the Web SSO configuration document fail and the error message is generated.

This situation can occur when the ID file is created multiple times but the Server document is not updated correctly. Usually, an error message is displayed on the Domino server console stating that the public key does not match the server ID. If this situation occurs, then SSO does not work because the document is encrypted with a public key for which the server does not possess the corresponding private key.

To correct a key-mismatch problem:
1. Copy the public key from the server ID file and paste it into the Server document.
2. Create the Web SSO configuration document again.

- Authentication fails when accessing a protected resource.

  If a Web user is repeatedly prompted for a user ID and password, SSO is not working because either the Domino or the WebSphere Application Server security server cannot authenticate the user with the Lightweight Directory Access Protocol (LDAP) server. Check the following possibilities:
  - Verify that the LDAP server is accessible from the Domino server machine. Use the **TCP/IP ping** utility to check TCP/IP connectivity and to verify that the host machine is running.
  - Verify that the LDAP user is defined in the LDAP directory. Use the **ldapsearch** utility to confirm that the user ID exists and that the password is correct. For example, you can run the following command, entered as a single line:

    You can use the OS/400 Qshell, a UNIX shell, or a Windows DOS prompt

    ```
    % ldapsearch -D "cn=John Doe, ou=Rochester, o=IBM, c=US" -w mypassword
    -h myhost.mycompany.com -p 389
    -b "ou=Rochester, o=IBM, c=US" (objectclass=*)
    ```

    (The percent character (%) indicates the prompt and is not part of the command.) A list of directory entries is expected. Possible error conditions and causes are contained in the following list:
    - No such object: This error indicates that the directory entry referenced by either the user's distinguished name (DN) value, which is specified after the -D option, or the base DN value, which is specified after the -b option, does not exist.
    - Invalid credentials: This error indicates that the password is invalid.
    - Cannot contact the LDAP server: This error indicates that the host name or port specified for the server is invalid or that the LDAP server is not running.
    - An empty list means that the base directory specified by the -b option does not contain any directory entries.
  - If you are using the user's short name (or user ID) instead of the distinguished name, verify that the directory entry is configured with the short name. For a Domino directory, verify the **Short name/UserID** field of the Person document. For other LDAP directories, verify the userid property of the directory entry.
  - If Domino authentication fails when using an LDAP directory other than a Domino directory, verify the configuration settings of the LDAP server in the Directory assistance document in the Directory assistance database. Also verify that the Server document refers to the correct Directory assistance document. The following LDAP values specified in the Directory Assistance document must match the values specified for the user registry in the WebSphere administrative domain:
    - Domain name
    - LDAP host name
    - LDAP port

    - Base DN

  Additionally, the rules defined in the Directory assistance document must refer to the base distinguished name (DN) of the directory containing the directory entries of the users.

  You can trace Domino server requests to the LDAP server by adding the following line to the server `notes.ini` file:

  ```
  webauth_verbose_trace=1
  ```

  After restarting the Domino server, trace messages are displayed in the Domino server console as Web users attempt to authenticate to the Domino server.

- Authorization failure when accessing a protected resource.

  After authenticating successfully, if an authorization error message is displayed, security is not configured correctly. Check the following possibilities:
  - For Domino databases, verify that the user is defined in the access-control settings for the database. Refer to the Domino Administrative documentation for the correct way to specify the user's DN. For example, for the `DN cn=John Doe, ou=Rochester, o=IBM, c=US`, the value on the access-control list must be set as `John Doe/Rochester/IBM/US`.
  - For resources protected by WebSphere Application Server, verify that the security permissions are set correctly.
    - If granting permissions to selected groups, make sure that the user attempting to access the resource is a member of the group. For example, you can verify the members of the groups by using the following Web site to display the directory contents: `Ldap://myhost.mycompany.com:389/ou=Rochester, o=IBM, c=US??sub`
    - If you have changed the LDAP configuration information (host, port, and base DN) in a WebSphere Application Server administrative domain since the permissions were set, the existing permissions are probably invalid and need to be recreated.

- SSO failure when accessing protected resources.

  If a Web user is prompted to authenticate with each resource, SSO is not configured correctly. Check the following possibilities:
  1. Configure both the WebSphere Application Server and the Domino server to use the same LDAP directory. The HTTP cookie used for SSO stores the full DN of the user, for example, `cn=John Doe, ou=Rochester, o=IBM, c=US`, and the domain name service (DNS) domain.
  2. Define Web users by hierarchical names if the Domino Directory is used. For example, update the **User name** field in the Person document to include names of this format as the first value: `John Doe/Rochester/IBM/US`.
  3. Specify the full DNS server name, not just the host name or TCP/IP address for Web sites issued to Domino servers and WebSphere Application Servers configured for SSO. For browsers to send cookies to a group of servers, the DNS domain must be included in the cookie, and the DNS domain in the cookie must match the Web address. (This requirement is why you cannot use cookies across TCP/IP domains.)
  4. Configure both Domino and the WebSphere Application Server to use the same DNS domain. Verify that the DNS domain value is exactly the same, including capitalization. The DNS domain value is found on the Configure Global Security Settings panel of the WebSphere Application Server administrative console and in the Web SSO Configuration document of a Domino server. If you make a change to the Domino Web SSO Configuration document, replicate the modified document to all of the Domino servers participating in SSO.
  5. Verify that the clustered Domino servers have the host name populated with the full DNS server name in the Server document. By using the full DNS server name, Domino Internet Cluster Manager (ICM) can redirect to cluster members using SSO. If this field is not populated, by default, ICM redirects Web addresses to clustered Web servers by using the host name of the server only. It cannot send the SSO cookie because the DNS domain is not included in the Web address. To correct the problem:
     a. Edit the Server document.
     b. Click **Internet Protocols > HTTP** tab.
     c. Enter the full DNS name of the server in the **Host names** field.

6. If a port value for an LDAP server was specified for a WebSphere Application Server administrative domain, edit the Domino Web SSO configuration document and insert a backslash character (\) into the value of the **LDAP Realm** field before the colon character (:). For example, replace `myhost.mycompany.com:389` with `myhost.mycompany.com\:389`.

Single signon using WebSEAL or the Tivoli Access Manager plug-in for Web servers:

Either Tivoli Access Manager WebSEAL or Tivoli Access Manager plug-in for Web servers can be used as reverse proxy servers to provide access management and single signon (SSO) capability to WebSphere Application Server resources. With such an architecture, either WebSEAL or the plug-in authenticates users and forwards the collected credentials to WebSphere Application Server in the form of an IV Header. Two types of single signon are available, the TAI interface and the new TAI interface, so named as both use WebSphere Application Server trust association interceptors (TAIs). With TAI, the end-user name is extracted from the HTTP header and forwarded to embedded Tivoli Access Manager where it is used to construct the client credential information and authorize the user. The difference with the new TAI interface is that all user credential information is available in the HTTP header (not just user name). The new TAI is the more efficient of the two solutions as an Lightweight Directory Access Protocol (LDAP) call is not required as it is with TAI. TAI functionality is retained for backwards compatibility.

The following tasks need to be completed to enable single signon to WebSphere Application Server using either WebSEAL or the plug-in for Web servers. These tasks assume that embedded Tivoli Access Manager is configured for use.

1. "Creating a trusted user account in Tivoli Access Manager"
2. "Configuring WebSEAL for use with WebSphere Application Server" or "Configuring Tivoli Access Manager plug-in for Web servers for use with WebSphere Application Server" on page 1456
3. "Configuring single signon using the trust association interceptor" on page 1457 or "Configuring single signon using trust association interceptor ++" on page 1458

Creating a trusted user account in Tivoli Access Manager:

Tivoli Access Manager Trust Association Interceptors require the creation of a trusted user account in the shared LDAP user registry. This is the ID and password that WebSEAL uses to identify itself to WebSphere Application Server. To prevent potential vulnerabilities, do not use sec_master as the trusted user account and ensure the password you use is unique and generated randomly. The trusted user account should be used for the TAI or TAI++ only.

Use either the Tivoli Access Manager **pdadmin** command line utility or Web Portal Manager to create the trusted user. For example, from the **pdadmin** command line:

```
pdadmin> user create webseal_userid webseal_userid_DN firstname surname password
pdadmin> user modify webseal_userid account-valid yes
```

"Configuring WebSEAL for use with WebSphere Application Server" or "Configuring Tivoli Access Manager plug-in for Web servers for use with WebSphere Application Server" on page 1456

Configuring WebSEAL for use with WebSphere Application Server:

A junction must be created between WebSEAL and WebSphere Application Server. This junction will carry the iv-creds (for TAI++) or iv-user (for TAI) and the HTTP basic authentication headers with the request. While WebSEAL can be configured to pass the end user identity in other ways, the iv-creds header is the only one supported by the TAI++ and iv-user the only one supported by TAI.

We recommend that communications over the junction use SSL for increased security. Setting up SSL across this junction requires that you configure the HTTP Server used by WebSphere Application Server, and WebSphere Application Server itself, to accept inbound SSL traffic and route it correctly to WebSphere

Application Server. This requires importing the necessary signing certificates into the WebSEAL certificate keystore, and possibly also the HTTP Server certificate keystore.

Create the junction between WebSEAL and the WebSphere Application Server using the **-c iv-creds** option for TAI++ and **-c iv-user** for TAI. For example (commands are entered as one line):

TAI++

```
server task webseald-server create -t ssl -b supply -c iv-creds
 -h host_name -p websphere_app_port_number junction_name
```

TAI

```
server task webseald-server create -t ssl -b supply -c iv-user
 -h host_name -p websphere_app_port_number junction_name
```

Notes:

1. If warning messages are displayed about the incorrect setup of certificates and key databases, delete the junction, correct problems with the key databases and re-create the junction.
2. The junction can be created as `-t tcp` or `-t ssl` depending on your requirements.

For single signon to WebSphere Application Server the SSO password must be set in WebSEAL. To set the password, complete the following steps:

1. Edit the WebSEAL configuration file, `webseal_install_directory/etc/webseald-default.conf` and set the following parameter, **basicauth-dummy-passwd=*webseal_userid_passwd***. Where **webseal_userid_passwd** is the SSO password for the trusted user account set in “Creating a trusted user account in Tivoli Access Manager” on page 1455.
2. Restart WebSEAL.

For more details and options about how to configure junctions between WebSEAL and WebSphere Application Server, including other options for specifying the WebSEAL server identity, refer to the *Tivoli Access Manager WebSEAL Administration Guide* as well as to the documentation for the HTTP Server you are using with your WebSphere Application Server. Tivoli Access Manager documentation is available at http://publib.boulder.ibm.com/tividd/td/tdprodlist.html.

Configuring Tivoli Access Manager plug-in for Web servers for use with WebSphere Application Server:

Tivoli Access Manager plug-in for Web servers can be used as a security gateway for your protected WebSphere Application resources. With such an arrangement the plug-in authorizes all user requests before passing the authorized user’s credentials onto WebSphere Application Server in the form of an iv-creds header. Trust between the plug-in and WebSphere Application Server is established through use of basic authentication headers containing the single signon (SSO) user password.

In the following example Tivoli Access Manager plug-in for Web Servers Version 5.1 configuration shows IV headers configured for post-authorization processing and basic authentication configured as the authentication mechanism and for post-authorization processing. After a request has been authorized the basic authentication header is removed from the request (`strip-hdr = always`) and a new one added (`add-hdr = supply`). Included in this new header is the password set when the SSO user was created in “Creating a trusted user account in Tivoli Access Manager” on page 1455. This password needs to be specified in the **supply-password** parameter and is passed in the newly created header. This basic authentication header enables trust between WebSphere Application Server and the plug-in.

An iv-creds header is also added (`generate = iv-creds`) which contains the credential information of the user passed onto WebSphere Application Server. Note also that session cookies are used to maintain session state.

```
[common-modules]
authentication = BA
session = session-cookie
post-authzn = BA
post-authzn = iv-headers

[iv-headers]
accept = all
generate = iv-creds

[BA]
strip-hdr = always
add-hdr = supply
supply-password = sso_user_password
```

"Configuring single signon using the trust association interceptor" or "Configuring single signon using trust association interceptor ++" on page 1458

Configuring single signon using the trust association interceptor:

The following steps are required when setting up security for the first time. Ensure that Lightweight Third Party Authentication (LTPA) is the active authentication mechanism:

1. From the WebSphere Application Server console click **Security > Global security**.
2. Ensure that the **Active authentication mechanism** field is set to *Lightweight Third Party Authentication (LTPA)*. If not, set it and save your changes.

This task is performed to enable single signon using the trust association interceptor. The steps involve setting up trust association and creating the interceptor properties.

1. From the WebSphere Application Server console, click **Security > Global security**.
2. Under Authentication mechanisms, click **LTPA**.
3. Under Additional properties, click **Trust association**.
4. Select the **Enable trust association** option.
5. Under Additional properties, click the **Interceptors** link.
6. Click the **com.ibm.ws.security.web.WebSealTrustAssociationInterceptor** link to use the WebSEAL interceptor. This interceptor is the default.
7. Under Additional properties, click **Custom Properties** .
8. Click **New** to enter the property name and value pairs. Ensure the following parameters are set:

Option	Description
com.ibm.websphere.security.trustassociation.types	Ensure *webseal* is listed.
com.ibm.websphere.security.webseal.loginId	The WebSEAL trusted user as created in "Creating a trusted user account in Tivoli Access Manager" on page 1455 The format of the username is the short name representation. This is a mandatory property. If it is not set in WebSphere then TAI initialization will fail.

com.ibm.websphere.security.webseal.id	The *iv-user* header. That is;
	com.ibm.websphere.security.webseal.id=iv-user

Option	Description
com.ibm.websphere.security.webseal.hostnames	Do not set this property if using Tivoli Access Manager Plug-in for Web Servers. The host names (case sensitive) that are trusted and expected in the request header. For example: com.ibm.websphere.security.webseal.hostnames=host1 This should also include the proxy host names (if any) unless the com.ibm.websphere.security.webseal.ignoreProxy is set to *true*. A list of servers can be obtained using the server list **pdadmin** command.
com.ibm.websphere.security.webseal.ports	Do not set this property if using Tivoli Access Manager Plug-in for Web Servers. The corresponding port number of the host names that are expected in the request header. This should also include the proxy ports (if any) unless the com.ibm.websphere.security.webseal.ignoreProxy is set to *true*. For example: com.ibm.websphere.security.webseal.ports=80,443
com.ibm.websphere.security.webseal.ignoreProxy	An optional property that if set to *true* or *yes* ignores the proxy host names and ports in the IV header. By default this property is set to *false*.

9. Click **OK**.
10. Save configuration and logout.
11. Restart WebSphere Application Server.

Configuring single signon using trust association interceptor ++:

The following steps are required when setting up security for the first time. Ensure that LTPA is the active authentication mechanism:

1. From the WebSphere Application Server console, click **Security** > **Global Security**.
2. Ensure that the **Active Authentication Mechanism** field is set to Lightweight Third Party Authentication (LTPA). Save your changes.

This task is performed to enable single signon using trust association interceptor ++. The steps involve setting up trust association and creating the interceptor properties.

1. From the WebSphere Application Server console select, click **Security > Global security**.
2. Under Authentication, click **Authentication mechanisms > LTPA**
3. Under Additional properties, click **Trust association**.
4. Select the **Enable Trust Association** option.
5. Click the **Interceptors** link.
6. Click **com.ibm.ws.security.web.TAMTrustAssociationInterceptorPlus** to use the WebSEAL interceptor. This interceptor is the default.
7. Click the **Custom Properties** link.

8. Click **New** to enter the property name and value pairs. Ensure the following parameters are set:

Option	Description
com.ibm.websphere.security.webseal.checkViaHeader	The TAI can be configured so that the via header can be ignored when validating trust for a request. Set this property to *false* if none of the hosts in the via header need to be trusted. When set to *false* the trusted **hostnames** and host **ports** properties do not need to be set. Therefore the only mandatory property when check via header is *false* is com.ibm.websphere.security.webseal.loginId The default value of the check via header property is *false*. When using Tivoli Access Manager Plug-in for Web Servers this property should be set to *false*. **Note:** The via header is part of the standard HTTP header that records the server names the request has passed through.
com.ibm.websphere.security.webseal.loginId	The WebSEAL trusted user as created in "Creating a trusted user account in Tivoli Access Manager" on page 1455 The format of the username is the short name representation. This is a mandatory property. If it is not set in WebSphere Application Server, then the TAI initialization fails.
com.ibm.websphere.security.webseal.id	A comma-separated list of headers that should exist in the request. If not all of the configured headers exist in the request then trust can not be established. The default value for the id property is *iv-creds*. Any other values set in WebSphere Application Server are added to the list along with *iv-creds*, separated by commas.
com.ibm.websphere.security.webseal.hostnames	Do not set this property if using Tivoli Access Manager Plug-in for Web Servers. The property specifies the host names (case sensitive) that are trusted and expected in the request header. Requests arriving from un-listed hosts might not be trusted. If the checkViaHeader property is not set or is set to false then the trusted host names property has no influence. If the checkViaHeader property is set to true and the trusted host names property is not set then TAI initialization will fail.
com.ibm.websphere.security.webseal.ports	Do not set this property if using Tivoli Access Manager Plug-in for Web Servers. This property is a comma-separated list of trusted host ports. Requests arriving from unlisted ports might not be trusted. If the checkViaHeader property is not set or is set to false then this property has no influence. If the checkViaHeader property is set to true and the trusted host ports property is not set in WebSphere Application Server then the TAI initialization fails.

Option	Description

com.ibm.websphere.security.webseal.viaDepth	A positive integer specifying the number of source hosts in the via header to check for trust. By default, every host in the via header is checked and if any are not trusted then trust cannot be established. The via depth property is used when not all hosts in the via header are required to be trusted. The setting indicates the number of hosts that are required to be trusted.
	As an example, consider the following header:
	`Via: HTTP/1.1 webseal1:7002, 1.1 webseal2:7001`
	If the viaDepth property is not set, is set to 2 or is set to 0, and a request with the previous via header is received then both webseal1:7002 and webseal2:7001 need to be trusted. The following configuration applies:
	`com.ibm.websphere.security.webseal.hostnames =`
	`     webseal1,webseal2`
	`com.ibm.websphere.security.webseal.ports = 7002,7001`
	If the via depth property is set to 1 and the previous request is received then only the last host in the via header needs to be trusted. The following configuration applies:
	`com.ibm.websphere.security.webseal.hostnames =`
	`     webseal2`
	`com.ibm.websphere.security.webseal.ports = 7001`
	The viaDepth property is set to 0 by default which means all hosts in the via header are checked for trust.

com.ibm.websphere.security.webseal.ssoPwdExpiry	Once trust has been established for a request the single signon user password is cached saving the need to have the TAI re-authenticate the single signon user with Tivoli Access Manager for every request. The cache timeout period can be modified by setting the single signon password expiry property to the required time in seconds. If the password expiry property is set to 0, the cached password will never expire. The default value for the password expiry property is 600.
com.ibm.websphere.security.webseal.ignoreProxy	This property can be used to tell the TAI to ignore proxies as trusted hosts. If set to true the comments field of the hosts entry in the via header is checked to determine if a host is a proxy. It must be remembered that not all proxies insert comments in the via header indicating that they are proxies. The default value of the ignoreProxy property is false. If the checkViaHeader property is set to false then the ignoreProxy property has no influence in establishing trust.

Option	Description
com.ibm.websphere.security.webseal.configURL	For the TAI to be able to establish trust for a request it requires that SvrSslCfg has been run for the WebSphere Java Virtual Machine resulting in a properties file being created. If this properties file is not at the default URL file://java.home/PdPerm.properties then the correct URL of the properties file must be set in the config URL property. If this property is not set and the SvrSslCfg generated properties file is not in the default location, the TAI initialization fails. The default value for the config URL property is file://${WAS_INSTALL_ROOT}/java/jre/PdPerm.properties

9. Click **OK**.
10. Save configuration and logout.
11. Restart WebSphere Application Server.

Global signon principal mapping:

The Tivoli Access Manager JACC provider can be used to manage authentication to WebSphere Enterprise Information Systems (EIS) such as databases, transaction processing systems and message queue systems, located within the WebSphere Application Server security domain. Such authentication is achieved using the Global single signon (GSO) Principal Mapper JAAS login module for J2EE Connector Architecture (J2C) resources.

With GSO principal mapping, a special-purpose JAAS login module inserts a credential into the subject header. This is used by the resource adapter to authenticate to the Enterprise Information System (EIS). The JAAS login module used is configured on a per-connection factory basis. The default principal mapping module retrieves the user name and password information from XML configuration files. The Tivoli Access Manager JACC provider bypasses the credential stored in the XML configuration files and instead uses the Tivoli Access Manager GSO database to provide the EIS security domain authentication information.

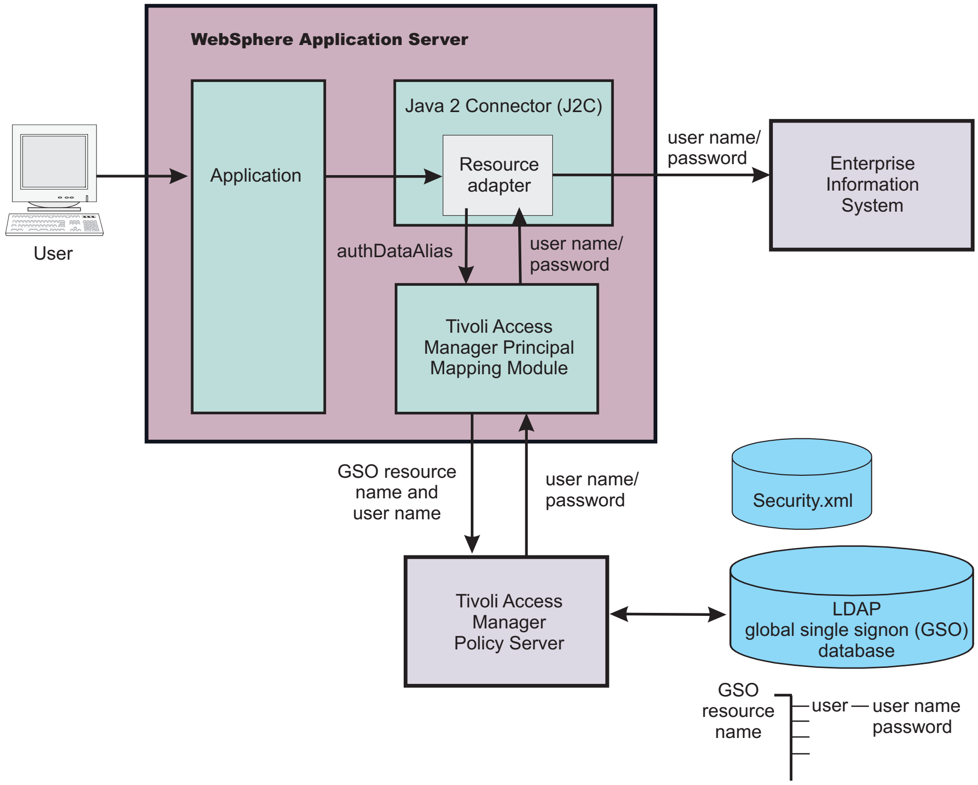
WebSphere Application Server provides a default principal mapping module that associates user credential information with EIS resources. The default mapping module is defined in the WebSphere Application Server administration console on the application login panel. To access the panel, click **Security** > **Global security**. Under JAAS configuration, click **Application logins**. The mapping module name is **DefaultPrincipalMapping**.

The EIS security domain user ID and password are defined under each connection factory by an authDataAlias attribute. The authDataAlias attribute does not contain the user name and password, it contains an alias that refers to a user name and password pair defined elsewhere.

The Tivoli Access Manager Principal Mapping module uses the authDataAlias to determine the GSO resource name and user name required to perform the lookup on the Tivoli Access Manager GSO database. It is the Tivoli Access Manager Policy Server which retrieves the GSO data from the registry.

Tivoli Access Manager stores authentication information on the Tivoli Access Manager GSO database against a resource/user name pair.

GSO principal mapping architecture



WebSphere Application Server
User
Application
Java 2 Connector (J2C)
Resource adapter
user name/ password
Enterprise Information System
authDataAlias
user name/ password
Tivoli Access Manager Principal Mapping Module
GSO resource name and user name
user name/ password
Security.xml
Tivoli Access Manager Policy Server
LDAP global single signon (GSO) database
GSO resource name
user
user name password

Configuring global signon principal mapping:

To create a new application login that uses the Tivoli Access Manager GSO database to store the login credentials:

1. Select **Security** > **Global security**.
2. Under Authentication, click **JAAS Configuration** > **Application logins**
3. Click **New** to create a new JAAS login configuration.
4. Enter the alias name of the new application login. Click **Apply**.
5. Under Additional properties, click **JAAS Login Modules** link to define the JAAS Login Modules.
6. Click **New** and enter the following:

   Module class name: com.tivoli.pd.as.gso.AMPrincipalMapper
   Use Login Module Proxy: enable
   Authentication strategy: REQUIRED

   Click **Apply**
7. In the *Additional Properties* section, click **Custom Properties** to define Login Module-specific values which are passed directly to the underlying Login Modules.
8. Click **New**.

   The Tivoli Access Manager principal mapping module uses the configuration string, authDataAlias, to retrieve the correct user name and password from the security configuration.

   The authDataAlias passed to the module is configured for the J2C ConnectionFactory. Since the authDataAlias is an arbitrary string entered at configuration time, the following scenarios are possible:

   - The authDataAlias contains both the GSO Resource name and the user name. The format of this string is ″Resource/User″
   - The authDataAlias contains only the GSO Resource name. The user name is determined using the Subject of the current session.

Which scenario to use is determined by a JAAS configuration option. The details of these options are:

Name: com.tivoli.pd.as.gso.AliasContainsUserName
Value: True if the alias contains the user name, false if the user name is retrieved from the security context.

When entering authDataAliases through the WebSphere Application Server console, the node name is automatically pre-pended to the alias. The JAAS configuration entry is to determine whether this node name should be removed or included as part of the resource name.

Name: com.tivoli.pd.as.gso.AliasContainsNodeName
Value: True if the alias contains the node name.

Enter each new parameter using the following scenario information as a guide.

Note: If the PdPerm.properties configuration file is not located in the default location, JAVA_HOME/PdPerm.properties, then you will also need to add the following property:

Name = com.tivoli.pd.as.gso.AMCfgURL
Value = file:///*path to PdPerm.properties*

Scenario 1
Auth Data Alias - BackendEIS/eisUser
Resource - BackEndEIS
User - eisUser
Principal Mapping Parameters

Name	Value
delegate	com.tivoli.pdwas.gso.AMPrincipalMapper
com.tivoli.pd.as.gso.AliasContainsUserName	true
com.tivoli.pd.as.gso.AliasContainsNodeName	false
com.tivoli.pd.as.gso.AMLoggingURL	file:///*jlog_props_path*
debug	false

Scenario 2
Auth Data Alias - BackendEIS
Resource - BackEndEIS
User - Currently authenticated WAS user
Principal Mapping Parameters

Name	Value
delegate	com.tivoli.pdwas.gso.AMPrincipalMapper
com.tivoli.pd.as.gso.AliasContainsUserName	false
com.tivoli.pd.as.gso.AliasContainsNodeName	false
com.tivoli.pd.as.gso.AMLoggingURL	file:///*jlog_props_path*
debug	false

Scenario 3
Auth Data Alias - nodename/BackendEIS/eisUser
Resource - BackEndEIS
User - eisUser
Principal Mapping Parameters

Name	Value
delegate	com.tivoli.pdwas.gso.AMPrincipalMapper
com.tivoli.pd.as.gso.AliasContainsUserName	true
com.tivoli.pd.as.gso.AliasContainsNodeName	true
com.tivoli.pd.as.gso.AMLoggingURL	file:///*jlog_props_path*
debug	false

Scenario 4
Auth Data Alias - nodename/BackendEIS/eisUser
Resource - nodename/BackEndEIS (notice that node name was not removed)
User - eisUser
Principal Mapping Parameters

Name	Value
delegate	com.tivoli.pdwas.gso.AMPrincipalMapper
com.tivoli.pd.as.gso.AliasContainsUserName	true
com.tivoli.pd.as.gso.AliasContainsNodeName	false
com.tivoli.pd.as.gso.AMLoggingURL	file:///*jlog_props_path*
debug	false

Scenario 5
Auth Data Alias - BackendEIS/eisUser
Resource - BackEndEIS
User - eisUser
Principal Mapping Parameters

Name	Value
delegate	com.tivoli.pdwas.gso.AMPrincipalMapper
com.tivoli.pd.as.gso.AliasContainsUserName	false
com.tivoli.pd.as.gso.AliasContainsNodeName	true
com.tivoli.pd.as.gso.AMLoggingURL	file:///*jlog_props_path*
debug	false

Scenario 6
Auth Data Alias - nodename/BackendEIS/eisUser
Resource - nodename/BackendEIS/eisUser (notice that the Resource is the same as Auth Data Alias).
User - Currently authenticated WAS user
Principal Mapping Parameters

Name	Value
delegate	com.tivoli.pdwas.gso.AMPrincipalMapper
com.tivoli.pd.as.gso.AliasContainsUserName	false
com.tivoli.pd.as.gso.AliasContainsNodeName	false
com.tivoli.pd.as.gso.AMLoggingURL	file:///*jlog_props_path*
debug	false

You now need to create the J2C authentication aliases. The user name and password assigned to these alias entries is irrelevant as Tivoli Access Manager is responsible for providing user names and passwords. However, the user name and password assigned to the J2C authentication aliases need to exist so they can be selected for the J2C connection factory in the console.

To create the J2C authentication aliases, from the WebSphere Application Server administrative console, click **Security** >**Global security**. Under **JAAS Configuration** > **J2C Authentication Data** and click **New** for each entry. Refer to the table above for scenario inputs.

The connection factories for each resource adapter that needs to use the GSO database must be configured to use the Tivoli Access Manager Principal Mapping module. To do this:

a. From the WebSphere Application Server console, select **Applications** > **Enterprise Applications** > *application_name*.

b. Under Related items, click the **Connector Modules** link.

c. Click the **.rar** link.

d. Under Additional properties, click the **Resource Adapter** link.

   Note: The resource adapter does not need to be packaged with the application. It can be standalone. For such a scenario the resource adapter is configured from **Resources** > **Resource Adapters**.

e. Under Additional properties, click the **J2C Connection Factories** link.

f. Click **New** and enter the connection factory properties.

Note: Configuring custom mapping on connection factory is deprecated in WebSphere Application Server Version 6. To configure the GSO credential mapping, it is recommended that you use the Map Resource References to Resources panel on the administrative console. For more information, refer to “J2EE Connector security” on page 1531.

User registries

Information about users and groups reside in a user registry.

With WebSphere Application Server, a user registry authenticates a user and retrieves information about users and groups to perform security-related functions, including authentication and authorization.

WebSphere Application Server provides several implementations to support multiple types of operating system base user registries. You can use the custom Lightweight Directory Access Protocol (LDAP) feature to support any LDAP server by setting up the correct configuration (user and group filters). However, support is not extended to these custom LDAP servers because many configuration possibilities exist.

In addition to Local operating system (OS) and LDAP registries, WebSphere Application Server also provides a plug-in that supports any user registry by using the custom registry feature (also referred to as a *custom user registry*). The custom registry feature supports any user registry that is not implemented by WebSphere Application Server. You can use any registry used in the product environment by implementing the *UserRegistry interface* interface.

The UserRegistry interface is very helpful in situations where the current user and group information exists in some other format (for example, a database) and cannot move to Local OS or LDAP. In such a case, implement the UserRegistry interface so that WebSphere Application Server can use the existing registry for all of the security-related operations. Using a custom registry is a software implementation effort; it is expected that the implementation does not depend on other WebSphere Application Server resources, for example, data sources, for its operation.

Although WebSphere Application Server supports different types of user registries, only one user registry can be active. This active registry is shared by all of the product server processes. If the product processes in one node or cell need to communicate with other product processes in other nodes or cells using Lightweight Third Party Authentication (LTPA) (or Integrated Cryptographic Service Facility (ICSF) on the z/OS platform), all of the nodes and cells share the same user registry.

Configuring user registries

Before configuring the user registry, decide which registry to use. Though different types of registries are supported, all of the processes in WebSphere Application Server can use one active registry. Configuring the correct registry is a prerequisite to assigning users and groups to roles for applications. When no registry is configured, the LocalOS registry is used by default. So, if your choice of registry is not Local OS you need to first configure the registry, which is normally done as part of enabling security, restart the servers, and then assign users and groups to roles for all your applications.

After the applications are assigned users and groups, and you need to change the registries (for example from Lightweight Directory Access Protocol (LDAP) to Custom), delete all the users and groups (including any RunAs role) from the applications, and reassign them after changing the registry through the administrative console or by using wsadmin scripting. The following wsadmin command removes all of the users and groups (including the RunAs role) from any application:

```
$AdminApp deleteUserAndGroupEntries yourAppName
```

where *yourAppName* is the name of the application. Backing up the old application is advised before performing this operation. However, if both of the following conditions are true, you might be able to switch the registries without having to delete the users and groups information:

- All of the user and group names (including the password for the RunAs role users) in all of the applications match in both registries.
- The application bindings file does not contain the `accessIDs`, which are unique for each registry even for the same user or group name.

By default, an application does not contain `accessIDs` in the bindings file (these IDs are generated when the applications start). However, if you migrated an existing application from an earlier release, or if you used the wsadmin script to add accessIDs for the applications to improve performance you have to remove the existing user and group information and add the information after configuring the new registry.

For more information on updating accessIDs, see updateAccessIDs in the AdminApp object for scripted administration article.

Complete one of the following steps to configure your user registry:

- Configure the local operating system user registry.
- Configure the LDAP user registry.
- Configure the custom user registries.

This step is required as part of enabling security in WebSphere Application Server.

1. If you are enabling security, make sure that you complete the remaining steps. Verify that the Active User Registry field in the **Global Security** panel is set to the appropriate registry. As the final step, validate the user ID and the password by clicking **OK** or **Apply** in the Global Security panel. Save, stop and start all WebSphere Application Servers.
2. For any changes in user registry panels to be effective, you must validate the changes by clicking **OK** or **Apply** in the Global Security panel. After validation, save the configuration, stop and start all WebSphere Application Servers (cells, nodes and all the application servers). To avoid inconsistencies between the WebSphere Application Server processes, make sure that any changes to the registry are done when all of the processes are running. If any of the processes are down, force synchronization to make sure that the process can start later.

   If the server or servers start without any problems, the setup is correct.

Local operating system user registries:

With the local operating system, or Local OS, user registry implementation, the WebSphere Application Server authentication mechanism can use the user accounts database of the local operating system.

WebSphere Application Server provides implementations for the Windows local accounts registry and domain registry, as well as implementations for the Linux, Solaris, and AIX user accounts registries. Windows Active Directory is supported through the Lightweight Directory Access Protocol (LDAP) user registry implementation discussed later.

Note: For an Active Directory (domain controller), the three group scopes are Domain Local Group, Global Group, and Universal Group. For an Active Directory (Domain Controller), the two group types are Security and Distribution.

When a group is created, the default value is Global (and the default type is Security). With Windows NT domain registry support for Windows 2000 and 20003 domain controllers, WebSphere Application Server only supports Global groups that are the Security type. It is recommended that you use the Active Directory registry support (rather than an NT domain registry) if you use Windows 2000 and 2003 domain controllers because the Active Directory supports all group scopes and types. The Active Directory also supports a nested group that is not support by NT domain registry. The Active Directory is a centralized control registry.

WebSphere Application Server does not have to install the member of the domain because it can be installed on any machine on any platform. Note that the NT domain native call only returns the support group (with no error).

A Local OS user registry is not a centralized user registry like LDAP

Do not use a Local OS user registry in a WebSphere Application Server environment, where application servers are dispersed across more than one machine because each machine has its own user registry. Exceptions include a Windows domain registry, which is a centralized registry and Network Information Services (NIS), which is not supported by WebSphere Application Server.

As mentioned previously, the access IDs taken from the user registry are used during authorization checks. Because these IDs are typically unique identifiers, they vary from machine to machine, even if the exact users and passwords exist on each machine.

Web client certificate authentication is not currently supported when using the local operating system user registry. However, Java client certificate authentication does function with a local operating user registry. Java client certificate authentication maps the first attribute of the certificate domain name to the user ID in the user registry.

Even though Java client certificates function correctly, the following error displays in the `SystemOut.log` file:

```
CWSCJ0337E: The mapCertificate method is not supported
```

The error is intended for Web client certificates; however, it also displays for Java client certificates. Ignore this error for Java client certificates.

Using Windows operating system registries

When enabling security on Windows operating systems, if the local operating system (LocalOS) is selected as the registry, consider the following points:

Required privileges

The user that is running the WebSphere Application Server process requires enough operating system privilege to call the Windows systems application programming interface (API) for authenticating and obtaining user and group information from the Windows operating system. This user logs into the machine, or if running as a service, is the Log On As user. Depending on the machine and whether the machine is a stand-alone machine or a machine that is part of a domain or is the domain controller, the access requirements vary.

- For a stand-alone machine, the user:
  - Is a member of the administrative group.
  - Has the Act as part of the operating system privilege.
  - Has the Log on as a service privilege, if the server is run as a service.
- For a machine that is a member of a domain, only a domain user can start the server process and:
  - Is a member of the domain administrative groups in the domain controller.
  - Has the Act as part of the operating system privilege in the Domain security policy on the domain controller.
  - Has the Act as part of the operating system privilege in the Local security policy on the local machine.
  - Has the Log on as a service privilege on the local machine, if the server is run as a service.

    The user is a domain user and not a local user, which implies that when a machine is part of a domain, only a domain user can start the server.
- For a domain controller machine, the user:
  - Is a member of the domain administrative groups in the domain controller.
  - Has the Act as part of the operating system privilege in the Domain security policy on the domain controller.
  - Has the Log on as a service privilege on the domain controller, if the server is run as a service.

To give a user the Act as part of the operating system or Log on as a service on Windows 2000 systems:

1. Click **Start** > **Settings** > **Control Panel** > **Administrative Tools** > **Local Security Policy** > **Local Policies** > **User Rights Assignments** > **Act as part of the operating system** (or **Log on as a service**) .

   Note: If the machine is a stand-alone machine and not a member of a domain, you must add a machineName\userID, where the *userID* is the owner of the process, such as WebSphere Application Server. If you run WebSphere Application Server as a service, you can log on with `localsystem` as the service.

   If the machine is a member of a domain, add domainName\userID, where the *userID* is the owner of process (such as WebSphere Application Server). Start WebSphere Application Server as a service with login ID domainName\userID. If WebSphere Application Server is already in service, go to the service and right-click **IBM WebSphere Application Server > properties >Logon to change the logon ID and password** to restart WebSphere Application Server.
2. Add the user name by clicking **Add**.
3. Restart the machine.

   Windows 2000 domain controller users: For a Windows 2000 domain controller, replace **Local Security Policy** with **Domain Security Policy** in the previous step.

   Note: In all of the previous configurations, the server can be run as a service using `LocalSystem` for the Log On As entry. The `LocalSystem` entry has the required privileges and there is no need to give special privileges to any user. However, because the `LocalSystem` entry has special privileges, make sure that it is appropriate to use in your environment.

If the user running the server does not have the required privilege, you might see one of the following exception messages in the log files:

- `A required privilege is not held by the client.`
- `Access is denied.`

Domain and local registries

When WebSphere Application Server is started, the security run-time initialization process dynamically attempts to determine if the local machine is a member of a Windows domain. If the machine is part of a domain then by default both the local registry users or groups and the domain registry users or groups can be used for authentication and authorization purposes with the domain registry taking precedence. The list of users and groups that is presented during the security role mapping includes users and groups from both the local user registry and the domain user registry. The users and groups can be distinguished by the associated host names.

WebSphere Application Server does not support trusted domains.

If the machine is not a member of a Windows system domain, the user registry local to that machine is used.

Using both the domain registry and the local registry

When the machine that hosts the WebSphere Application Server process is a member of a domain, both the local and the domain registries are used by default. The following section describes more on this topic and recommends some best practices to avoid unfavorable consequences.

- **Best practices**

  In general, if the local and the domain registries do not contain common users or groups, it is simpler to administer and it eliminates unfavorable side effects. If possible, give users and groups access to unique security roles, including the server ID and administrative roles). In this situation, select the users and groups from either the local registry or the domain registry to map to the roles.

  In cases where the same users or groups exist in both the local registry and the domain registry, it is recommended that at least the server ID and the users and groups that are mapped to the administrative roles be unique in the registries and exist only in the domain.

  If a common set of users exists, set a different password to make sure that the appropriate user is authenticated.
- **How it works**

  When a machine is part of a domain, the domain user registry takes precedence over the local user registry. For example, when a user logs into the system, the domain registry tries to authenticate the user first. If the authentication fails the local registry is used. When a user or a group is mapped to a role, the user and group information is first obtained from the domain registry. In case of failure, the local registry is tried. However, when a fully qualified user or a group name (one with an attached domain or host name) is mapped to a role, then only that registry is used to get the information. Use the administrative console or scripts to get the fully qualified user and group names, which is the recommended way to map users and groups to roles.

  Note: A user **Bob** on one machine (the local registry, for example) is not the same as the user **Bob** on another machine (say the domain registry) because the `uniqueID` of **Bob** (the security identifier [SID], in this case) is different in different registries.
- **Examples**

  The machine `MyMachine` is part of the domain `MyDomain`. `MyMachine` contains the following users and groups:
  - MyMachine\user2
  - MyMachine\user3
  - MyMachine\group2

  MyDomain contains the following users and groups:
  - MyDomain\user1
  - MyDomain\user2
  - MyDomain\group1
  - MyDomain\group2

Here are some scenarios that assume the previous set of users and groups.

1. When user2 logs into the system, the domain registry is used for authentication. If the authentication fails (the password is different) the local registry is used.
2. If the user MyMachine\user2 is mapped to a role, only the user2 in MyMachine has access. So if the user2 password is the same on both the local and the domain registries, user2 cannot access the resource, because user2 is always authenticated using the domain registry. Hence, if both registries have common users, it is recommended that the password be different.
3. If the group2 is mapped to a role, only the users who are members of the MyDomain\group2 can access the resource because group2 information is first obtained from the domain registry.
4. If the group MyMachine\group2 is mapped to a role, only the users who are members of the MyMachine\group2 can access the resource. A specific group is mapped to the role (MyMachine\group2 instead of just group2).
5. Use either user3 or MyMachine\user3 to map to a role, because user3 is unique; it exists in one registry only.

Authorizing with the domain user registry first can cause problems if a user exists in both the domain and local user registries with the same password. Role-based authorization can fail in this situation because the user is first authenticated within the domain user registry. This authentication produces a unique domain security ID that is used in WebSphere Application Server during the authorization check. However, the local user registry is used for role assignment. The domain security ID does not match the unique security ID that is associated with the role. To avoid this problem, map security roles to domain users instead of local users.

Using either the local or the domain registry. If you want to access users and groups from either the local registry or the domain registry, instead of both, set the com.ibm.websphere.registry.UseRegistry property. This property can be set to either localor domain. When this property is set to local(case insensitive) only the local registry is used. When this property is set to domain, (case insensitive) only the domain registry is used. Set this property by clicking **Custom Properties** in the **Security** > **User Registries** > **Local OS** panel in the administrative console or by using scripts. When the property is set, the privilege requirement for the user who is running the product process does not change. For example, if this property is set to local, the user that is running the process requires the same privilege, as if the property was not set.

Using UNIX system registries

When using UNIX system registries, the process ID that runs the WebSphere Application Server process needs the root authority to call the local operating system APIs for authentication and for obtaining user or group information.

Note: In UNIX systems, only the local machine registry is used. Network Information Service (NIS) (Yellow Pages) is not supported.

Using Linux and Solaris system registries

For WebSphere Application Server Local OS security registry to work on the Linux and Solaris platforms, a shadow password file must exist. The shadow password file is named shadow and is located in the /etc directory. If the shadow password file does not exist, an error occurs after enabling global security and configuring the user registry as Local OS.

To create the shadow file, run the **pwconv** command (with no parameters). This command creates an /etc/shadow file from the /etc/passwd file. After creating the shadow file, you can enable local operating system security successfully.

Remote registries

By default, the registry is local to all of the product processes. The performance is higher, (no need for remote calls) and the registry also increases availability. Any process failing does not effect other processes.

When using LocalOS as the registry, every product process must run with privilege access (`root` in UNIX, `Act as part of operating system` in Windows systems).

If this process is not practical in some situations, you can use a remote registry from the node (or in very rare situations from the cell). Using a remote registry affects performance and creates a single point of failure. **Use remote registries only in rare situations.**

The node and the cell processes are meant for manipulating configuration information and for hosting the registry for all the application servers that create traffic and cause problems.

Using a node agent (instead of the cell) to host the remote registry is preferable because the cell process is not designed to be highly available. Also, using a node to host the remote registry indicates that only the application servers in that node are using it. Because the node agent does not contain any application code, giving it the access required privilege is not a concern.

You can set up a remote registry by setting the WAS_UseRemoteRegistry property in the Global Security panel using the **Custom Properties** link at the bottom of the administrative console panel. Use either the`Cell` or the `Node`(case insensitive) value. If the value is `Cell`, the cell registry is used by all of the product processes including the node agent and all of the application servers. If the cell process is down for any reason, restart all of the processes after the cell is restarted. If the node agent registry is used for the remote registry, set the WAS_UseRemoteRegistry value to `node`. In this case, all the application server processes use the node agent registry. In this case, if the node agent fails and does not start automatically, you might need to restart all the application servers after the node agent is started.

Configuring local operating system user registries:

For security purposes, the WebSphere Application Server provides and supports the implementation for Windows operating system registries, AIX, Solaris and multiple versions of Linux operating systems. The respective operating system APIs are called by the product processes (servers) for authenticating a user and other security-related tasks (for example, getting user or group information). Access to these APIs are restricted to users who have special privileges. These privileges depend on the operating system and are described below.

Before configuring the LocalOS registry you need to know the user name (ID) and password to use here. This user can be any valid user in the registry. This user is referred to as either a product security server ID, a server ID or a server user ID in the documentation. Having a server ID means that a user has special privileges when calling protected internal methods. Normally, this ID and password are used to log into the administrative console after security is turned on. You can use other users to log in if those users are part of the administrative roles. When security is enabled in the product, this server ID and password are authenticated with the registry during product startup. If authentication fails, the server does not come up. So it is important to choose an ID and password that do not expire or change often. If the product server user ID or password need to change in the registry, ensure that the changes are performed when all the product servers are up and running. After the changes are completed in the registry, use the following steps to change the ID and the password information. Save, stop, and restart all the servers so that the product can use the new ID or password. If any problem arises after starting the product because of authentication problems (that cannot be fixed), disable security before the server can start up. To avoid this step, make sure that the changes are validated in the Global Security panel. After the server is up, change the ID and password information and enable security.

When using the Windows operating system, consider the following issues:

- The server ID needs to be different from the Windows machine name where the product is installed. For example, if the Windows machine name is *vicky* and the security server ID is vicky, the Windows system fails when getting the information (group information, for example) for user *vicky*.
- WebSphere Application Server dynamically determines whether the machine is a member of a Windows system domain.
- WebSphere Application Server does not support Windows trusted domains.
- If a machine is a member of a Windows domain, both the domain user registry and the local user registry of the machine participate in authentication and security role mapping.
- The domain user registry takes precedence over the local user registry of the machine and can have undesirable implications if users with the same password exist in both user registries.
- The user that the product processes run under requires the `Administrative` and `Act as part of the operating system` privileges to call the Windows operating system APIs that authenticate or collect user and group information. The process needs special authority, which is given by these privileges. The user in this example might not be the same as the security server ID (the requirement for which is a valid user in the registry). This user logs into the machine (if using the command line to start the product process) or the Log On User setting in the services panel if the product processes have started using the services. If the machine is also part of a domain, this user is a part of the Domain Admin group in the domain to call the operating system APIs in the domain in addition to having the Act as part of operating system privilege in the local machine.

When using the UNIX operating systems (AIX and Solaris) and Linux, consider the following points:

- The user that the product processes run under requires the `root` privilege. This privilege is needed to call the UNIX operating system APIs to authenticate or to collect user and group information. The process needs special authority, which is given by the `root` privilege. This user might not be the same as the security server ID (the requirement is that it should be a valid user in the registry). This user logs into the machine and is running the product processes.
- On a UNIX operating system, the user that enables global security must have the `root` privilege if you use the local OS user registry. Otherwise, a failed validation error is displayed.
- When using the Linux operating system, you might need to have the password shadow file in your system.

The following steps are needed to perform this task initially when setting up security for the first time.

1. Click **Security > Global security**.
2. Under User registries, click **Local OS**,
3. Enter a valid user name in the Server user ID field.
4. Enter the user password in the Server user password field.
5. Click **OK**. Validation of the user and password does not happen in this panel. Validation is only done when you click **OK** or **Apply** in the Global Security panel. If you are enabling security for the first time, complete the other steps and go to the Global Security panel. Make sure that LocalOS is the Active User Registry. If security was already enabled and you had changed either the user or the password information in this panel, make sure to go to the Global Security panel and click **OK** or **Apply** to validate your changes. If your changes are not validated, the server might not come up.

The Local OS user registry has been configured.

1. If you are enabling security, complete the remaining steps. As the final step, ensure that you validate the user and password by clicking **OK** or **Apply** in the Global Security panel. Save, stop, and start all the product servers.
2. For any changes in this panel to be effective, you need to save, stop and start all the product servers (deployment managers, nodes and Application Servers).
3. If the server comes up without any problems the setup is correct.

Local operating system user registry settings:

Use this page to configure local operating system user registry settings.

To view this administrative console page, click **Security** > **Global Security**. Under User registries, click **Local OS**.

Server user ID:

Specifies a valid user ID in the local OS registry.

This ID is the security server ID, which is only used for WebSphere Application Server security and is not associated with the system process that runs the server. The server calls the Local OS registry to authenticate and obtain privilege information about users by calling the native APIs in that particular registry. Access to native APIs is normally restricted to users having special privileges (for example, **root** in UNIX systems and **Act as part of operating system** in Windows systems). To use security in the application server, the process ID (not the security server ID) on which WebSphere Application Server runs requires enough privileges to call the system APIs. The special privilege means that the process running the WebSphere Application Server needs to be part of the **Administrators** group and have the **Act as part of operating system** privilege on Windows systems, and be **root**, or have root authority on UNIX systems.

Note: Windows If you are configuring Local OS security on Windows and you encounter the `A required privilege is not helped by the client` error message, you must follow the procedure documented to give the user those privileges. To set the privilege, click **Start > Settings > Control Panel > Administrative Tools > Local Security Policy > Local Policies > User Rights Assignments > Act as part of the operating system**.

When using a Windows system registry, this ID cannot match the name of the Windows machine. Windows systems treat the machine name bob as having an account similar to user bob.

Data type:	String
Units:	Alphanumeric characters

Server user password:

Specifies a valid user password that corresponds to a valid user ID in the local OS registry.

Data type	String

Lightweight Directory Access Protocol:

Lightweight Directory Access Protocol (LDAP) is a user registry in which authentication is performed using an LDAP binding.

WebSphere Application Server security provides and supports implementation of most major LDAP directory servers, which can act as the repository for user and group information. These LDAP servers are called by the product processes (servers) for authenticating a user and other security-related tasks (for example, getting user or group information). This support is provided by using different user and group filters to obtain the user and group information. These filters have default values that you can modify to fit your needs. The custom LDAP feature enables you to use any other LDAP server (which is not in the product supported list of LDAP servers) for its user registry by using the appropriate filters.

To use LDAP as the user registry, you need to know a valid user name (ID), the user password, the server host and port, the base distinguished name (DN) and if necessary the bind DN and the bind password. You can choose any valid user in the registry that is searchable. In some LDAP servers, the administrative users are not searchable and cannot be used (for example, `cn=root` in SecureWay). This user is referred to as WebSphere Application Server security server ID, server ID, or server user ID in the documentation. Being a server ID means a user has special privileges when calling some protected internal methods.

Normally, this ID and password are used to log into the administrative console after security is turned on. You can use other users to log in if those users are part of the administrative roles.

When security is enabled in the product, this server ID and password are authenticated with the registry during the product startup. If authentication fails, the server does not start. Choosing an ID and password that do not expire or change often is important. If the product server user ID or password need to change in the registry, make sure that the changes are performed when all the product servers are up and running.

When the changes are done in the registry, use the steps described in Configuring LDAP user registries. Change the ID, password, and other configuration information, save, stop, and restart all the servers so that the new ID or password is used by the product. If any problems occur starting the product when security is enabled, disable security before the server can start up (to avoid these problems, make sure that any changes in this panel are validated in the Global Security panel). When the server is up, you can change the ID, password and other configuration information and then enable security.

Configuring Lightweight Directory Access Protocol user registries:

Review the article on Lightweight Directory Access Protocol (LDAP) before beginning this task.

1. In the administrative console, click **Security > Global security**.
2. Under User registries, click **LDAP**.
3. Enter a valid user name in the Server user ID field. You can either enter the complete distinguished name (DN) of the user or the short name of the user as defined by the User Filter in the Advanced LDAP settings panel. For example, enter the user ID for Netscape.
4. Enter the password of the user in the Server user password field.
5. Select the type of LDAP server that is used from the Type list. The type of LDAP server determines the default filters that are used by the WebSphere Application Server. These default filters change the **Type** field to **Custom**, which indicates that custom filters are used. This action occurs after you click **OK** or **Apply** in the Advanced LDAP settings panel. Choose the **Custom** type from the list and modify the user and group filters to use other LDAP servers, if required. If either the IBM Directory Server or the iPlanet Directory Server is selected, also select the Ignore Case field.
6. Enter the fully qualified host name of the LDAP server in the Host field.
7. Enter the LDAP server port number in the Port field. The host name and the port number represent the realm for this LDAP server in the WebSphere Application Server cell. So, if servers in different cells are communicating with each other using Lightweight Third Party Authentication (LTPA) tokens, these realms must match exactly in all the cells.
8. Enter the Base distinguished name (DN) in the Base distinguished name field. The Base DN indicates the starting point for searches in this LDAP directory server. For example, for a user with a DN of `cn=John Doe, ou=Rochester, o=IBM, c=US`, specify the Base DN as any of the following options (assuming a suffix of `c=us`): `ou=Rochester, o=IBM, c=us or o=IBM c=us` or `c=us`. This field can be case sensitive. Match the case in your directory server. This field is required for all LDAP directories except the Domino Directory. The Base DN field is optional for the Domino server.
9. Enter the Bind DN name in the Bind distinguished name field, if necessary. The Bind DN is required if anonymous binds are not possible on the LDAP server to obtain user and group information. If the LDAP server is set up to use anonymous binds, leave this field blank.
10. Enter the password corresponding to the Bind DN in the Bind password field, if necessary.
11. Modify the Search time out value if required. This timeout value is the maximum amount of time that the LDAP server waits to send a response to the product client before aborting the request. The default is 120 seconds.
12. Deselect the **Reuse connection** option only if you use routers to send requests to multiple LDAP servers, and if the routers do not support affinity. Leave this field enabled for all other situations.
13. Select the **Ignore case for authorization** option, if required. When this flag is enabled, the authorization check is case insensitive. Normally, an authorization check involves checking the

complete DN of a user, which is unique in the LDAP server and is case sensitive. However, when using either the IBM Directory Server or the iPlanet Directory Server LDAP servers, this flag needs enabling because the group information obtained from the LDAP servers is not consistent in case. This inconsistency only effects the authorization check.

14. Enable Secure Sockets Layer (SSL) if the communication to the LDAP server is through SSL. For more information on setting up LDAP for SSL, refer to Configuring SSL for LDAP clients.
15. Select the **SSL enabled** option if you want to use secure sockets layer communications with the LDAP server. If you select the **SSL enabled** option, select the appropriate SSL alias configuration from the list in the SSL configuration field.
16. Click **OK**. The validation of the user, password, and the setup do not take place in this panel. Validation is only done when you click **OK** or **Apply** in the **Global Security** panel. If you are enabling security for the first time, complete the remaining steps and go to the **Global Security** panel. Select **LDAP** as the active user registry. If security is already enabled, but information on this panel changes, go to the **Global Security** panel and click **OK** or **Apply** to validate your changes. If your changes are not validated, the server might not come up.

Sets the LDAP registry configuration. This step is required to set up the LDAP registry. This step is required as part of enabling security in the WebSphere Application Server.

1. If you are enabling security, complete the remaining steps. As the final step, validate this setup by clicking **OK** or **Apply** in the Global Security panel.
2. Save, stop, and restart all the product servers (deployment managers, nodes and Application Servers) for changes in this panel to take effect.
3. If the server comes up without any problems the setup is correct.

Lightweight Directory Access Protocol settings:

Use this page to configure Lightweight Directory Access Protocol (LDAP) settings when users and groups reside in an external LDAP directory.

To view this administrative console page, click **Security > Global security**. Under User registries, click **LDAP**.

When security is enabled and any of these properties change, go to the Global security panel and click **Apply** to validate the changes.

Server user ID:

Specifies the user ID that is used to run the WebSphere Application Server for security purposes.

Although this ID is not the LDAP administrator user ID, specify a valid entry in the LDAP directory located under the Base Distinguished Name.

Server user password:

Specifies the password corresponding to the security server ID.

Type:

Specifies the type of LDAP server to which you connect.

IBM SecureWay Directory Server is not supported.

For a list of supported LDAP servers, see ″Supported directory services.″ in the documentation.

Host:

Specifies the host ID (IP address or domain name service (DNS) name) of the LDAP server.

Port:

Specifies the host port of the LDAP server.

If multiple WebSphere Application Servers are installed and configured to run in the same single signon domain, or if the WebSphere Application Server interoperates with a previous version of the WebSphere Application Server, then it is important that the port number match all configurations. For example, if the LDAP port is explicitly specified as `389` in a Version 4.0.x configuration, and a WebSphere Application Server at Version 5 is going to interoperate with the Version 4.0.x server, then verify that port `389` is specified explicitly for the Version 5 server.

Default:	389

Base distinguished name (DN):

Specifies the base distinguished name of the directory service, indicating the starting point for LDAP searches of the directory service.

For example, for a user with a distinguished name (DN) of `cn=John Doe, ou=Rochester, o=IBM, c=US`, you can specify the base DN as (assuming a suffix of `c=us`): `ou=Rochester, o=IBM, c=us`. For authorization purposes, this field is case sensitive. This specification implies that if a token is received (for example, from another cell or Domino) the base DN in the server must match the base DN from the other cell or Domino server exactly. If case sensitivity is not a consideration for authorization, enable the **Ignore case** field. This field is required for all Lightweight Directory Access Protocol (LDAP) directories except for the Domino Directory, where this field is optional.

If you need to interoperate between WebSphere Application Server Version 5 and a Version 5.0.1 or later server, you must enter a normalized base distinguished name. A normalized base distinguished name does not contain spaces before or after commas and equal symbols. An example of a non-normalized base distinguished name is `o = ibm, c = us` or `o=ibm, c=us`. An example of a normalized base distinguished name is `o=ibm,c=us`. In WebSphere Application Server, Version 5.0.1 or later, the normalization occurs automatically during run time

Bind distinguished name (DN):

Specifies the distinguished name for the application server to use when binding to the directory service.

If no name is specified, the application server binds anonymously. See the Base Distinguished Name field description for examples of distinguished names.

Bind password:

Specifies the password for the application server to use when binding to the directory service.

Search timeout:

Specifies the timeout value in seconds for an Lightweight Directory Access Protocol (LDAP) server to respond before aborting a request.

Default:	120

Reuse connection:

Specifies whether the server reuses the Lightweight Directory Access Protocol (LDAP) connection. Clear this option only in rare situations where a router is used to spray requests to multiple LDAP servers and when the router does not support affinity.

Default:	Enabled
Range:	Enabled or Disabled

Ignore case for authorization:

Specifies that a case insensitive authorization check is performed when using the default authorization.

This field is required when IBM Directory Server is selected as the LDAP directory server.

This field is required when Sun ONE Directory Server is selected as the LDAP directory server. For more information, see ″Using specific directory servers as the LDAP server″ in the documentation.

Otherwise, this field is optional and can be enabled when a case-sensitive authorization check is required. For example, use this field when the certificates and the certificate contents do not match the case used for the entry in the LDAP server. You can enable the **Ignore case** field when using single signon (SSO) between WebSphere Application Server and Lotus Domino.

Default:	Enabled
Range:	Enabled or Disabled

SSL enabled:

Specifies whether secure socket communication is enabled to the Lightweight Directory Access Protocol (LDAP) server. When enabled, the LDAP Secure Sockets Layer (SSL) settings are used, if specified.

SSL configuration:

Specifies the Secure Sockets Layer configuration to use for the Lightweight Directory Access Protocol (LDAP) connection. This configuration is used only when SSL is enabled for LDAP.

Default:	DefaultSSLSettings

Advanced Lightweight Directory Access Protocol user registry settings:

Use this page to configure the advanced Lightweight Directory Access Protocol (LDAP) user registry settings when users and groups reside in an external LDAP directory.

To view this administrative page, complete the following steps:

1. Click **Security > Global security**.
2. Under User registries, click **LDAP**.
3. Under Additional properties, click **Advanced Lightweight Directory Access Protocol (LDAP) user registry settings**.

Default values for all the user and group related filters are already completed in the appropriate fields. You can change these values depending on your requirements. These default values are based on the type of LDAP server selected in the **LDAP settings** panel. If this type changes (for example from Netscape to Secureway) the default filters automatically change. When the default filter values change, the LDAP server type changes to `Custom` to indicate that custom filters are used. When security is enabled and any of these properties change, go to the **Global security** panel and click **Apply** or **OK** to validate the changes.

User filter:

Specifies the LDAP user filter that searches the user registry for users.

This option is typically used for security role to user assignments. It specifies the property by which to look up users in the directory service. For example, to look up users based on their user IDs, specify `(%(uid=%v)(objectclass=inetOrgPerson))`. For more information about this syntax, see the LDAP directory service documentation.

Data type:	String

Group filter:

Specifies the LDAP group filter that searches the user registry for groups

This option is typically used for security role to group assignments. It specifies the property by which to look up groups in the directory service. For more information about this syntax, see the LDAP directory service documentation.

Data type:	String

User ID map:

Specifies the LDAP filter that maps the short name of a user to an LDAP entry.

Specifies the piece of information that represents users when users appear. For example, to display entries of the type `object class = inetOrgPerson` by their IDs, specify `inetOrgPerson:uid`. This field takes multiple objectclass:property pairs delimited by a semicolon (;).

Data type:	String

Group ID Map:

Specifies the LDAP filter that maps the short name of a group to an LDAP entry.

Specifies the piece of information that represents groups when groups appear. For example, to display groups by their names, specify `*:cn`. The asterisk (`*`) is a wildcard character that searches on any object class in this case. This field takes multiple `objectclass:property` pairs delimited by a semicolon (;).

Data type:	String

Group member ID map:

Specifies the LDAP filter that identifies user to group relationships.

For directory types SecureWay, Netscape, and Domino, this field takes multiple objectclass:property pairs, delimited by a semicolon (;). In an objectclass:property pair, the objectclass value is the same objectclass that is defined in the Group Filter, and the property is the member attribute. If the objectclass value does not match the objectclass in Group Filter, authorization might fail if groups are mapped to security roles. For more information about this syntax, see your LDAP directory service documentation.

For IBM Directory Server, iPlanet Directory Server and Active Directory, this field takes multiple (`group attribute:member attribute`) pairs delimited by a semicolon (;). They are used to find the group memberships of a user by enumerating all the group attributes possessed by a given user. For example, attribute pair (`memberof:member`) is used by Active Directory, and (ibm-allGroup:member) is used by IBM Directory Server . This field also specifies which property of an objectclass stores the list of members belonging to the group represented by the objectclass. For supported LDAP directory servers, see ″Supported directory services″.

Data type:	String

Perform a nested group search:

Specifies a recursive nested group search.

Select this option if the Lightweight Directory Access Protocol (LDAP) server does not support recursive server-side group member searches (and if recursive group member search is required). It is not recommended that you select this option to locate recursive group memberships for LDAP servers. WebSphere security leverages the LDAP server's recursive search functionality to search a user's group memberships, including recursive group memberships. For example:

- IBM Directory Server is pre-configured by WebSphere Application Server security to recursively calculate a user's group memberships using the `ibm-allGroup` attribute
- SunONE directory server is pre-configured to calculate nested group memberships using the `nsRole` attribute

Data type:	String

Certificate map mode:

Specifies whether to map X.509 certificates into an LDAP directory by EXACT_DN or CERTIFICATE_FILTER. Specify CERTIFICATE_FILTER to use the specified certificate filter for the mapping.

Data type:	String

Certificate filter:

Specifies the filter certificate mapping property for the LDAP filter. The filter is used to map attributes in the client certificate to entries in the LDAP registry.

If more than one LDAP entry matches the filter specification at run time, then authentication fails because it results in an ambiguous match. The syntax or structure of this filter is: `LDAP attribute=${Client certificate attribute}` (for example, `uid=${SubjectCN}`). The left side of the filter specification is an LDAP attribute that depends on the schema that your LDAP server is configured to use. The right side of the filter specification is one of the public attributes in your client certificate. The right side must begin with a dollar sign ($) and open bracket ({) and end with a close bracket (}). You can use the following certificate attribute values on the right side of the filter specification. The case of the strings is important:

- `${UniqueKey}`
- `${PublicKey}`
- `${PublicKey}`
- `${Issuer}`
- `${NotAfter}`
- `${NotBefore}`
- `${SerialNumber}`
- `${SigAlgName}`
- `${SigAlgOID}`
- `${SigAlgParams}`
- `${SubjectCN}`

- `${Version}`

Data type: String

Configuring Lightweight Directory Access Protocol search filters:

WebSphere Application Server uses Lightweight Directory Access Protocol (LDAP) filters to search and obtain information about users and groups from an LDAP directory server. A default set of filters is provided for each LDAP server that the product supports. You can modify these filters to fit your LDAP configuration. After the filters are modified (and you click **OK** or **Apply**) the directory type in the LDAP Registry panel changes to `custom`, which indicates that custom filters are used. Also, you can develop filters to support any additional type of LDAP server. The effort to support additional LDAP directories is optional and other LDAP directory types are not supported.

1. In the administrative console, click **Security > Global security.**.
2. Under User registries, click **LDAP**.
3. Under Additional properties, click **Advanced Lightweight Directory Access Protocol (LDAP) user registry settings**.
4. Modify the User filter, if necessary. The user filter is used for searching the registry for users and is typically used for the security role to user assignment. Also, the filter is used to authenticate a user using the attribute that is specified in the filter. The filter specifies the property that is used to look up users in the directory service.

   In the following example, the property that is assigned to `%v`, which is the short name of the user, must be a unique key. Two LDAP entries with the same object class cannot have the same short name. To look up users based on their user IDs (uid) and to use the inetOrgPerson object class, specify the following syntax:

   ```
   (&(uid=%v)(objectclass=inetOrgPerson)
   ```

   For more information about this syntax, see the LDAP directory service documentation.
5. Modify the Group filter, if necessary. The group filter is used in searching the registry for groups and is typically used for the security role to group assignment. Also, the filter is used to specify the property by which to look up groups in the directory service.

   In the following example, the property that is assigned to `%v`, which is the short name of the group, must be a unique key. Two LDAP entries with the same object class cannot have the same short name. To look up groups based on their common names (CN) and to use either the groupOfNames or the groupOfUniqueNames object class, specify the following syntax:

   ```
   (&(cn=%v)(|(objectclass=groupOfNames)(objectclass=groupOfUniqueNames)))
   ```

   For more information about this syntax, see the LDAP directory service documentation.
6. Modify the User ID map, if necessary. This filter maps the short name of a user to an LDAP entry. It specifies the piece of information that represents users when these users are displayed with their short names. For example, to display entries of the type object class = inetOrgPerson by their IDs, specify `inetOrgPerson:uid`. This field takes multiple objectclass:property pairs delimited by a semicolon (;). To provide a consistent value for methods like the getCallerPrincipal( ) method and the getUserPrincipal() method, the short name that is obtained by using this filter is used. For example, the user `CN=Bob Smith, ou=austin.ibm.com, o=IBM, c=US` can log in using any attributes that are defined (for example, e-mail address, social security number, and so on) but when these methods are called, the user ID `bob` is returned no matter how the user logs in.
7. Modify the Group ID map filter, if necessary. This filter maps the short name of a group to an LDAP entry. It specifies the piece of information that represents groups when groups display. For example, to display groups by their names, specify `*:cn`. The asterisk (*) is a wildcard character that searches on any object class in this case. This field takes multiple objectclass:property pairs delimited by a semicolon (;).

8. Modify the Group Member ID Map filter, if necessary. This filter identifies user to group memberships. For SecureWay, Netscape, and Domino directory types, this field is used to query all the groups that match the specified object classes to see if the user is contained in the specified attribute. For example, to get all the users belonging to groups with the groupOfNames object class and the users that are contained in the member attributes, specify `groupOfNames:member`. This syntax, which is a property of an objectclass, stores the list of members that belong to the group that is represented by the objectclass. This field takes multiple objectclass:property pairs that are delimited by a semicolon (;). For more information about this syntax, see the LDAP directory service documentation.

   For the IBM Directory Server, iPlanet Directory Server, and Active Directory, this field is used to query all users in a group by using the information that is stored in the user object (instead of querying all the groups individually to find if the user exists in that group). For example, the memberof:member filter (for Active Directory) is used to get the memberof attribute of the user object to obtain all the groups to which the user belongs. The member attribute is used to get all the users in a group that use the group object. Using the user object to obtain the group information improves performance.
9. Select the **Perform a nested group search** option if your LDAP server does not support recursive server-side searches.
10. Modify the Certificate map mode, if necessary. You can use the X.590 certificates for user authentication when LDAP is selected as the user registry. This field is used to indicate whether to map the X.509 certificates into an LDAP directory user by **EXACT_DN** or **CERTIFICATE_FILTER**. If **EXACT_DN** is selected, the DN in the certificate must exactly match the user entry in the LDAP server (including case and spaces).

    Select the Ignore case for authorization field on the LDAP settings to make the authorization case insensitive. To access the LDAP setting panel, complete the following steps:
    a. Click **Security > Global security.**.
    b. Under User registries, click **LDAP**.
11. If you select **CERTIFICATE_FILTER**, specify the LDAP filter for mapping attributes in the client certificate to entries in LDAP. If more than one LDAP entry matches the filter specification at run time, authentication fails because an ambiguous match results. The syntax or structure of this filter is: `LDAP attribute=${Client certificate attribute}` (for example, `uid=${SubjectCN}`).

    The left side of the filter specification is an LDAP attribute that depends on the schema that your LDAP server is configured to use. The right side of the filter specification is one of the public attributes in your client certificate. Note that the right side must begin with a dollar sign ($), open bracket ({), and end with a close bracket (}). Use the following certificate attribute values on the right side of the filter specification. The case of the strings is important.
    - ${UniqueKey}
    - ${PublicKey}
    - ${Issuer}
    - ${NotAfter}
    - ${NotBefore}
    - ${SerialNumber}
    - ${SigAlgName}
    - ${SigAlgOID}
    - ${SigAlgParams}
    - ${SubjectDN}
    - ${Version}

    To enable this field, select **CERTIFICATE_FILTER** for the certificate mapping.
12. Click **Apply**.

    When any LDAP user or group filter is modified in the Advanced LDAP Settings panel click **Apply**. Clicking **OK** navigates you to the LDAP User Registry panel, which contains the previous LDAP directory type, rather than the custom LDAP directory type. Clicking **OK** or **Apply** in the LDAP User Registry panel saves the back-level LDAP directory type and the default filters of that directory. This action overwrites any changes to the filters that you made. To avoid overwriting changes, you can take either of the following actions:

- Click **Apply** in the Advanced Lightweight Directory Access Protocol (LDAP) user registry settings panel. To proceed to another panel, use the left navigation. Using the navigation to access the LDAP User Registry panel changes the directory type to `Custom`.
- Choose **Custom** type from the LDAP User Registry panel. Click **Apply** and then change the filters by clicking the Advanced Lightweight Directory Access Protocol (LDAP) user registry settings panel. After you complete your changes, click **Apply** or **OK**.

The validation of the changes (if any) does not take place in this panel. Validation is done when you click **OK** or **Apply** in the Global Security panel. If you are in the process of enabling security for the first time, complete the remaining steps and go to the Global Security panel. Select **LDAP** as the Active User Registry. If security is already enabled and any information on this panel changes, go to the Global Security panel and click **OK** or **Apply** to validate your changes. If your changes are not validated, the server might not start.

Setting the LDAP search filters. This step is required to modify existing user and group filters for a particular LDAP directory type. It is also used to set up certificate filters to map certificates to entries in the LDAP server.

1. If you are enabling security, complete the remaining steps. As the final step make sure that you validate this setup by clicking **OK** or **Apply** in the Global Security panel.
2. Save, stop, and start all the product servers (cell, nodes and all the application servers) for any changes in this panel to become effective.
3. After the server starts, go through all the security-related tasks (getting users, getting groups, and so on) to verify that the changes to the filters function.

Using specific directory servers as the LDAP server:

For *Using MS Active Directory server as the LDAP server* below, note that to use Microsoft Active Directory as the LDAP server for authentication with WebSphere Application Server you must take specific steps. By default, Microsoft Active Directory does not permit anonymous LDAP queries. To create LDAP queries or to browse the directory, an LDAP client must bind to the LDAP server using the distinguished name (DN) of an account that belongs to the administrator group of the Windows system. A group membership search in the Active Directory is done by enumerating the memberof attribute possessed by a given user entry, rather than browsing through the member list in each group. If you change this default behavior to browse each group, you can change the **Group Member ID Map** field from `memberof:member` to `group:member`.

Using IBM Tivoli Directory Server as the LDAP server

To use IBM Tivoli Directory Server (formerly IBM Directory Server), choose **IBM Tivoli Directory Server** as the directory type.

For supported directory servers, refer to the article, Supported directory services. The difference between these two types is group membership lookup. It is recommended that you choose the IBM Tivoli Directory Server for optimum performance during run time. In the IBM Tivoli Directory Server, the group membership is an operational attribute. With this attribute, a group membership lookup is done by enumerating the ibm-allGroups attribute for the entry, All group memberships, including the static groups, dynamic groups, and nested groups, can be returned with the `ibm-allGroups` attribute. WebSphere Application Server supports dynamic groups, nested groups, and static groups in IBM Tivoli Directory Server using the `ibm-allGroups` attribute. To utilize this attribute in a security authorization application, use a case-insensitive match so that attribute values returned by the ibm-allGroups attribute are all in uppercase.

Important: It is recommended that you do not install IBM Tivoli Directory Server Version 5.2 on the same machine that you install WebSphere Application Server, Version 6.x. IBM Tivoli Directory Server, Version 5.2 includes WebSphere Application Server Express, Version 5.0.2, which the directory server uses for its administrative console. Install the Web Administration tool Version 5.2 and WebSphere Application Server Express, Version 5.0.2, which are both bundled with IBM Tivoli Directory Server, Version 5.2, on a different machine from WebSphere Application

Server, Version 6.x. You cannot use WebSphere Application Server, Version 6.x as the administrative console for IBM Tivoli Directory Server. If IBM Tivoli Directory Server, Version 5.2 and WebSphere Application Server, Version 6.x are installed on the same machine, you might encounter port conflicts.

If you must install IBM Tivoli Directory Server Version 5.2 and WebSphere Application Server Version 6.x on the same machine, consider the following information:

- During the IBM Tivoli Directory Server installation process, you must select both the **Web Administration tool** and **WebSphere Application Server Express, Version 5.0.2**.
- Install WebSphere Application Server, Version 6.x.
- When you install WebSphere Application Server, Version 6.x, change the port number for the application server.
- You might need to adjust the WebSphere Application Server environment variables on the version 6.x application server for *WAS_HOME* and *WAS_INSTALL_ROOT*. To change the variables using the administrative console, click **Environment > WebSphere Variables**.

Using a Lotus Domino Server as the LDAP server

If you choose the Lotus Domino LDAP server Version 6 and the attribute short name is not defined in the schema, you can take either of the following actions:

- Change the schema to add the short name attribute.
- Change the user ID map filter to replace the short name with any other defined attribute (preferably to UID). For example, change `person:shortname` to `person:uid`.

The userID map filter has been changed to use the **uid** attribute instead of the **shortname** attribute as the current version of Lotus Domino does not create the **shortname** attribute by default. If you want to use the **shortname** attribute, define the attribute in the schema and change the userID map filter to the following:

```
User ID Map :    person:shortname
```

Using Sun ONE Directory Server as the LDAP server

You can choose **Sun ONE Directory Server** for your Sun ONE Directory Server system. For supported directory servers, refer to the article, Supported directory services. In Sun ONE Directory Server, the default object class is `groupOfUniqueName` when you create a group. For better performance, WebSphere Application Server uses the user object to locate the user group membership from the *nsRole* attribute. Thus, create the group from the role. If you want to use `groupOfUniqueName` to search groups, specify your own filter setting. Roles unify entries. Roles are designed to be more efficient and easier to use for applications. For example, an application can locate the role of an entry by enumerating all the roles possessed by a given entry, rather than selecting a group and browsing through the members list. When using roles, you can create a group could be created using a:

- Managed role
- Filtered role
- Nested role

All of these roles are computable by `nsRole` attribute.

Using Microsoft Active Directory server as the LDAP server

To set up Microsoft Active Directory as your LDAP server, complete the following steps.

1. Determine the full distinguished name (DN) and password of an account in the **administrators** group.

   For example, if the Active Directory administrator creates an account in the Users folder of the Active Directory Users and Computers Windows control panel and the DNS domain is `ibm.com`, the resulting DN has the following structure:

```
cn=<adminUsername>, cn=users, dc=ibm,
dc=com
```

2. Determine the short name and password of any account in the Microsoft Active Directory. This password does not have to be the same account that is used in the previous step.
3. Use the WebSphere Application Server administrative console to set up the information needed to use Microsoft Active Directory
   a. Click **Security > Global security**.
   b. Under Authentication, click **Authentication mechanisms > LDAP**.
   c. Set up LDAP with Active Directory at the directory type. Based on the information determined in the previous steps, you can specify the following values on the LDAP settings panel:

      Server user ID
      Specify the short name of the account that was chosen in the second step.

      Server user password
      Specify the password of the account that was chosen in the second step.

      Type Specify Active Directory

      Host Specify the domain name service (DNS) name of the machine that is running Microsoft Active Directory.

      Base distinguished name (DN)
      Specify the domain components of the DN of the account that was chosen in the first step. For example: `dc=ibm, dc=com Bind`

      Bind distinguished name (DN)
      Specify the full distinguished name of the account that was chosen in the first step. For example: `cn=<adminUsername>, cn=users, dc=ibm, dc=com`

      Bind password
      Specify the password of the account that was chosen in the first step.
   d. Click **OK** to save the changes.
   e. Stop and restart the administrative server so that the changes take effect.
4. **Optional:** Set ObjectCategory as the filter in the Group member ID map field to improve LDAP performance.
   a. Under Additional properties, click **Advanced Lightweight Directory Access Protocol (LDAP) user registry settings** .
   b. Add `;objectCategory:group` to the end of the Group member ID map field.
   c. Click **OK** to save the changes
   d. Stop and restart the administrative server so that the changes take effect.

Supported directory services:

WebSphere Application Server security supports several different LDAP servers. For a list of supported LDAP servers, refer to the **Supported hardware, software and APIs** prerequisite Web site in the information center.

It is expected that other LDAP servers follow the LDAP specification function. Support is limited to these specific directory servers only. You can use any other directory server by using the custom directory type in the list and by filling in the filters required for that directory.

To improve performance for LDAP searches, the default filters for IBM Directory Server, iPlanet Directory Server, and Active Directory are defined such that when you search for a user, the result contains all the relevant information about the user (user ID, groups, and so on). As a result, the product does not call the LDAP server multiple times. This definition is possible only in these directory types, which support searches where the complete user information is obtained.

If you use the IBM Directory Server, enable the Ignore case flag. This flag is required because when the group information is obtained from the user object attributes, the case is not the same as when you get the group information directly. For the authorization to work in this case, perform a case insensitive check and verify the requirement for the Ignore case flag.

Locating a user's group memberships in Lightweight Directory Access Protocol: WebSphere Application Server security can be configured to search group memberships directly or indirectly. It can also be configured to search only a static group, or it can be configured to search static groups, recursive (or nested) groups, and dynamic groups for some Lightweight Directory Access Protocol (LDAP) servers.

Evaluate group memberships from user object directly

Several popular LDAP servers enable user objects to contain information about the groups to which they belong (such as Microsoft Active Directory Server, or eDirectory). Some user group memberships can be computable attributes from the user object (such as IBM Directory Server or Sun ONE directory server). In some LDAP servers, this attribute can be used to include a user's dynamic group memberships, nesting group memberships, and static group memberships to locate all group memberships from a single attribute.

For example, in IBM Directory Server all group memberships, including the static groups, dynamic groups, and nested groups, can be returned using the ibm-allGroups attribute. In Sun ONE, all roles, including managed roles, filtered roles, and nested roles, are calculated using the nsRole attribute. If an LDAP server has such an attribute in a user object to include dynamic groups, nested groups, and static groups, WebSphere Application Server security can be configured to use this attribute to support dynamic groups, nested groups, and static groups.

Evaluate group memberships from a group object indirectly

Some LDAP servers enable only group objects such as the Lotus Domino LDAP server to contain information about users. The LDAP server does not enable the user object to contain information about groups. For this type of LDAP server, group membership searches are performed by locating the user on the member list of groups. The member list evaluation is currently used in the static group membership search for all of the releases before WebSphere Application Server Version 5.

Use the direct method for searching group memberships if your LDAP server has such an attribute in user object to include group information. To use the direct method or the indirect method, enter the appropriate value in the Group Member ID Map field on the Advanced LDAP Settings panel using:

- objectclass:attribute pairs for the indirect method
- attribute:attribute pairs for the direct method

Sample entries of attribute:attribute pairs in Group Member ID Map fields include:

- ibm-allGroups:member for IBM Directory server
- nsRole:nsRole for Sun ONE directory if groups are created with Role inside Sun ONE
- memberOf:member in Microsoft Active Directory Server

Sample entries of objectClass:attribute pairs in the Group Member ID Map field include:

- dominoGroup:member for Domino
- groupOfNames:member for eDirectory

While using the direct method, dynamic groups, recursive groups, and static groups can be returned as multiple values of a single attribute. For example, in IBM Directory Server all group memberships, including the static groups, dynamic groups, and nested groups, can be returned using the ibm-allGroups attribute. In Sun ONE, all roles, including managed roles, filtered roles, and nested roles, are calculated using the nsRole attribute. If an LDAP server can use the nsRole attribute, dynamic groups, nested groups, and static groups are all supported by WebSphere Application Server.

Some LDAP servers do not have recursive computing functionality. For example, although Microsoft Active Directory server has direct group search capability using the memberOf attribute, memberOf lists the groups beneath which the group is directly nested only and does not contain the recursive list of nested predecessors. Another example is that the Lotus Domino LDAP server, which only supports the indirect method to locate the group memberships for a user (you cannot obtain recursive group memberships from a Domino server directly). For LDAP servers without recursive searching capability, WebSphere Application Server security provides a recursive function that is enabled by clicking **Perform a Nested Group Search** in the Advanced LDAP user registry settings. Select this option only if your LDAP server does not provide recursive searches and you want a recursive search.

Dynamic groups and nested group support: Dynamic groups contain a group name and membership criteria:

- The group membership information is as current as the information on the user object.
- There is no need to manually maintain members on the group object.
- Dynamic groups are designed such so an application does not need to pull a large amount of information from the directory to find out if someone is a member of a group.

Nested groups enable the creation of hierarchical relationships that are used to define inherited group membership. A nested group is defined as a child group entry whose distinguished name (DN) is referenced by a parent group entry attribute.

Dynamic and nested groups simplify WebSphere Application Server security management and increase its effectiveness and flexibility. You only need to assign a larger parent group if all nested groups share the same privilege. Assigning a role to a single parent group simplifies the runtime authorization table.

Dynamic and nested group support for the SunONE or iPlanet Directory Server: The SunONE or iPlanet Directory Server uses two grouping mechanisms:

Groups
Groups are entries that name other entries as a list of members or as a filter for members.

Roles
Roles are also entries that name other entries as a list of members or as a filter for members. Additional functionality is provided by generating the nsrole attribute on each role member.

Three types of roles are available:

Filtered roles
Entries are members if they match a specified Lightweight Directory Access Protocol (LDAP) filter. In this way, the role depends upon the attributes that are contained in each entry. This role is equivalent to a dynamic group.

Nested roles
Creates roles that contain other roles. This role is equivalent to a nested group.

Managed roles
Explicitly assigns a role to member entries. This role is equivalent to a static group.

Refer to “Configuring dynamic and nested group support for the SunONE or iPlanet Directory Server” for more information.

Configuring dynamic and nested group support for the SunONE or iPlanet Directory Server:

To use dynamic and nested groups with WebSphere Application Server security, you must be running WebSphere Application Server Version 5.1.1 or later. Refer to “Dynamic and nested group support for the SunONE or iPlanet Directory Server” for more information on this topic.

1. On the LDAP registry panel, select `SunONE` for the LDAP server.
2. Select the **Ignore case** option

3. On the LDAP settings panel, change the Group Filter setting to `&(cn=%v)(objectclass=ldapsubentry))`
4. On the LDAP settings panel, change the Group Member ID Map setting to `nsRole:nsRole`.

Dynamic groups and nested group support for the IBM Directory Server: WebSphere Application Server Version 5.x or later supports all Lightweight Directory Access Protocol (LDAP) dynamic and nested groups when using IBM Directory Server 4.x and later. This function is enabled by default by taking advantage of a new feature in IBM Directory Server. IBM Directory Server V4.1 uses the ibm-allGroups forward reference group attribute that automatically calculates all the group memberships (including dynamic and recursive memberships) for a user. Security directly locates a user group membership from a user object rather than indirectly search all the groups to match group members.

Refer to “Configuring dynamic and nested group support for the IBM Directory Server” for more information.

Configuring dynamic and nested group support for the IBM Directory Server:

When creating groups, ensure that nested and dynamic group memberships work correctly.

1. In the WebSphere Application Server security LDAP user registry configuration panel, select `IBM_Directory_Server` for the LDAP server.
2. On the LDAP settings panel change the Group Filter setting. Change the setting to the following value:

   ```
   (&(cn=%v)(|(objectclass=groupOfNames)(objectclass=groupOfUniqueNames)
   (objectclass=groupOfURLs))).
   ```
3. On the LDAP settings panel change the Group Member ID Map setting. Change the setting to the following value:

   ```
    ibm-allGroups:member;ibm-allGroups:uniqueMember
   ```
4. On the Add an LDAP entry panel the Auxiliary object class value is `ibm-nestedGroup` when creating a nested group. On the Add an LDAP entry panel, the Auxiliary object class value is `ibm-dynamicGroup` when creating a dynamic group.

Custom user registries:

A *custom user registry* is a customer-implemented user registry, that implements the UserRegistry Java interface, as provided by the product. A custom-implemented user registry can support virtually any type of an account repository from a relational database, flat file, and so on. The custom user registry provides considerable flexibility in adapting product security to various environments where some form of a user registry, other than Lightweight Directory Access Protocol (LDAP) or Local Operating System (LocalOS), already exists in the operational environment.

WebSphere Application Server security provides an implementation that uses various local operating system-based registries (Windows, AIX, Solaris, Linux) and various Lightweight Directory Access Protocol (LDAP)-based registries. However, situations can exist where your user and group data resides in other repositories or custom registries (a database, for example) and moving this information to either a LocalOS or an LDAP registry implementation might not be feasible. For these situations WebSphere Application Server security provides a service provider interface (SPI) that you can implement to interact with your current registry. The SPI is the UserRegistry interface. This interface has a set of methods to implement for the product security to interact with your registries for all security-related tasks. The LocalOS and LDAP registry implementations that are provided also implement this interface. Custom user registries are sometimes called the *pluggable user registries* or *custom registries* for short. Your custom user registry implementation is expected to be thread-safe.

The *UserRegistry interface* is a collection of methods that are required to authenticate individual users using either password or certificates and to collect information about the user (privilege attributes) for authorization purposes. This interface also includes methods that obtain user and group information so that they can be given access to resources. When implementing the methods in the interface, you must decide how to map the information that is manipulated by the UserRegistry interface to the information in your registry.

Make sure that your implementation of the custom registry does not depend on any WebSphere Application Server components such as data sources, enterprise beans, and so on. Do not have this dependency because security is initialized and enabled prior to most of the other WebSphere Application Server components during startup. If your previous implementation used these components, make a change that eliminates the dependency.

The methods in the UserRegistry interface operate on the following information for users:

User Security Name
: The user name, which is similar to the user name in the Windows, Linux and UNIX systems Local OS registries. This name is used to log in when prompted by a secured application. By default, the Enterprise JavaBeans (EJB) getCallerPrincipal method and the getRemoteUser and getUserPrincipal servlet methods return this name. The user security name is also referred to as *userSecurityName*, *userName*, or *user name*.

Unique ID
: This ID represents a unique identifier for the user. The UserRegistry interface requires this identifier to be unique. The unique ID similar to the system ID (SID) in Windows systems, the Unique ID (UID) in Linux and UNIX systems, and the distinguished name (DN) in Lightweight Directory Authentication Protocol (LDAP). This ID is also referred to as *uniqueUserId*. The unique ID is used to make the authorization decisions for protected resources.

Display name
: This name is an optional string that describes a user, and it is similar to the FullName attribute in Windows operating systems. The implementation can use display names for informational purposes only; these names are not required to exist or to be unique. The user interface can use the display name to present more information about the user.

Group Security name
: This name, which represents the security group, is also referred to as *groupSecurityName*, *groupName* and *group name*.

Unique ID
: The unique ID is the identifier for a group. This name is also referred to as *uniqueGroupId*.

Display name
: The display name is an optional string that describes a group.

The article on ″UserRegistry interface methods″, in the information center, describes each of the methods in the UserRegistry interface that need implementing. An explanation of each of the methods and their usage in the sample and any changes from the Version 4 interface are provided. The Related references section provides links to all other custom user registries documentation, including a file-based registry sample. The Sample provided is very simple and is intended to familiarize you with this feature. Do not use this sample in an actual production environment.

Configuring custom user registries:

Before you begin this task, implement and build the UserRegistry interface. For more information on developing custom user registries refer to the article, ″Developing custom user registries″ in the information center. The following steps are required to configure custom user registries through the administrative console.

1. Click **Security > Global security**
2. Under User registries, click **Custom**.
3. Enter a valid user name in the Server user ID field.
4. Enter the password of the user in the Server user password field.
5. Enter the full name of the location of the implementation class file in the Custom registry class name field as a dot-separated file name. For the sample, this file name is

com.ibm.websphere.security.FileRegistrySample. The file exists in the WebSphere Application Server class path (preferably in the *install_root*/lib/ext directory). This file exists in all the product processes. So, if you are operating in a Network Deployment environment, this file exists in the cell class path and in all of the node class paths.

6. Select the **Ignore case for authorization** option for the authorization to perform a case insensitive check. Enabling this option is necessary only when your registry is case insensitive and does not provide a consistent case when queried for users and groups.
7. Click **Apply** if you have any other additional properties to enter for the registry initialization. Otherwise click **OK** and complete the steps required to turn on security.
8. If you need to enter additional properties to initialize your implementation, click **Custom properties**. Click **New**. Enter the property name and value. Click **OK**. Repeat this step to add other additional properties. For the sample, enter the following two properties. It is assumed that the users.props and the groups.props file are in the *customer_sample* directory under the product installation directory. You can place these properties in any directory that you chose and reference their location through Custom properties. However, make sure that the directory has the appropriate access permissions.

Property name	Property value
usersFile	$*USER_INSTALL_ROOT*/*customer_sample*/users.props
groupsFile	$*USER_INSTALL_ROOT*/*customer_sample*/groups.props

Samples of these two properties are available in the “users.props file” on page 1515 and the “groups.props file” on page 1515 article.

The Description, Required, and Validation Expression fields are not used and you can leave them blank.

Note: In a Network Deployment environment where multiple WebSphere Application Server processes exist (cell and multiple nodes in different machines), these properties are available for each process. Use the relative name *USER_INSTALL_ROOT* to locate any files, as this name expands to the product installation directory. If this name is not used, ensure that the files exist in the same location in all the nodes. To change the value for the *USER_INSTALL_ROOT* variable

This step is required to set up the custom user registry and to enable security in WebSphere Application Server.

1. Complete the remaining steps, if you are enabling security.
2. After security is turned on, save, stop, and start all the product servers (cell, nodes and all the application servers) for any changes in this panel to take effect.
3. If the server comes up without any problems, the setup is correct.
4. Validate the user and password by clicking **OK** or **Apply** on the Global security panel. Save, synchronize (in the cell environment), stop and restart all the product servers.

UserRegistry.java files:

             RemoteException;  /**
   * Returns the realm of the registry.
   *
   * @return the realm. The realm is a registry-specific string indicating
   *            the realm or domain for which this registry
   *            applies.  For example, for OS400 or AIX this would be the
   *            host name of the system whose user registry this object
   *            represents.
   *            If null is returned by this method realm defaults to the
   *            value of "customRealm". It is recommended that you use
   *            your own value for realm.
   * @exception CustomRegistryException if there is any registry specific
   *            problem
   * @exception RemoteException as this extends java.rmi.Remote
   **/
   public String getRealm()
      throws CustomRegistryException,
             RemoteException;  /**
   * Gets a list of users that match a pattern in the registry.
   * The maximum number of users returned is defined by the limit
   * argument.
   * This method is called by administrative console and by scripting (command
   * line) to make available the users in the registry for adding them (users)
   * to roles.
   *
   * @parameter pattern the pattern to match. (For example., a* will match all
   *   userSecurityNames starting with a)
   * @parameter limit the maximum number of users that should be returned.
   *  This is very useful in situations where there are thousands of
   *            users in the registry and getting all of them at once is not
   *            practical. A value of 0 implies get all the users and hence
   *            must be used with care.
   * @return a Result object that contains the list of users
   *   requested and a flag to indicate if more users exist.
   * @exception CustomRegistryException if there is any registry specific
   *            problem
   * @exception RemoteException as this extends java.rmi.Remote
   **/
   public Result getUsers(String pattern, int limit)
      throws CustomRegistryException,
             RemoteException;  /**
   * Returns the display name for the user specified by userSecurityName.
   *
   * This method is called only when the user information displays
```

```
 * (information purposes only, for example, in the administrative console) and not used
 * in the actual authentication or authorization purposes. If there are no
 * display names in the registry return null or empty string.
 *
 * In WebSphere Application Server Version 4.0 custom registry, if you had a display
 * name for the user and  if it was different from the security name, the display name
 * was returned for the EJB methods getCallerPrincipal() and the servlet methods
 * getUserPrincipal() and  getRemoteUser().
 * In WebSphere Application Server Version 5.0 for the same methods the security
 * name is returned by default. This is the recommended way as the display name
 * is not unique and might create security holes.
 * However, for backward compatibility if one needs the display name to
 * be returned set the property WAS_UseDisplayName to true.
 *
 * See the documentation for more information.
 *
 * @parameter userSecurityName the name of the user.
 * @return the display name for the user. The display name
 *   is a registry-specific string that represents a descriptive, not
 *  necessarily unique, name for a user. If a display name does
 *            not exist return null or empty string.
 * @exception EntryNotFoundException if userSecurityName does not exist.
 * @exception CustomRegistryException if there is any registry specific
 *            problem
 * @exception RemoteException as this extends java.rmi.Remote

/**
 *  The main purpose of this sample is to demonstrate the use of the
 *  custom user registry feature available in WebSphere Application Server. This
 *  sample is a file-based registry sample where the users and the groups
 *  information is listed in files (users.props and groups.props). As such
 *  simplicity and not the performance was a major factor behind this. This
 *  sample should be used only to get familiarized with this feature. An
 *  actual implementation of a realistic registry should consider various
 *  factors like performance, scalability, thread safety, and so on.
 **/

* Returns the display name for the user specified by
*  userSecurityName.
*
* This method may be called only when the user information
* is displayed (information purposes only, for example, in
* the administrative console) and hence not used in the actual
* authentication or authorization purposes. If there are no
* display names in the registry return null or empty string.
*
* In WebSphere Application Server 4 custom registry, if you
* had a display name for the user and if it was different from the
* security name, the display name was returned for the EJB
* methods getCallerPrincipal() and the servlet methods
* getUserPrincipal() and  getRemoteUser().
* In WebSphere Application Server Version 5, for the same
* methods, the security name will be returned by default. This
* is the recommended way as the display name is not unique
* and might create security holes. However, for backward
* compatibility if one needs the display name to be returned
* set the property WAS_UseDisplayName to true.
*
*See the InfoCenter documentation for more information.
*
* @param     userSecurityName the name of the user.
* @return    the display name for the user. The display
*            name is a registry-specific string that
*            represents a descriptive, not necessarily
*            unique, name for a user. If a display name
*            does not exist return null or empty string.

/**
 * Gets a list of users in a group.
 *
 * The maximum number of users returned is defined by the
 * limit argument.
 *
 * In rare situations, if you are working with a registry where
 * getting all the users from any of your groups is not practical
 * (for example if there are a large number of users) you can throw
 * the NotImplementedException for that particular group. Make sure
 * that if the process choreographer is installed (or if installed later)
 * the staff assignments are not modeled using these particular groups.
 * If there is no concern about returning the users from groups
 * in the registry it is recommended that this method be implemented
 * without throwing the NotImplemented exception.
 * @param          groupSecurityName the name of the group
 * @param          Limits the maximum number of users that should be
 *                 returned. This is very useful in situations where there
 *                 are lot of users in the registry and getting all of
 *                 them at once is not practical. A value of 0 implies
 *                 get all the users and hence must be used with care.
 * @return         A result object that contains the list of users
 *                 requested and a flag to indicate if more users exist.
 * @deprecated     This method will be deprecated in future.
 * @exception      NotImplementedException throw this exception in rare
 *                 situations if it is not practical to get this information
 *                 for any of the group or groups from the registry.
 * @exception     EntryNotFoundException if the group does not exist in
 *                the registry
 * @exception     CustomRegistryException if there is any registry-specific
 *                problem

    /**
       Returns the list of users and groups
       @return the list of users and groups
    */
    public List getList() {
      return list;
    }

    /**
       indicates if there are more users and groups in the registry
    */
    public boolean hasMore() {
      return more;
    }
    /**
       Set the flag to indicate that there are more users and groups
       in the registry to true
    */
    public void setHasMore() {
      more = true;
    }
    /*
      Set the list of users and groups
      @param list   list of users/groups
    */
    public void setList(List list) {
      this.list = list;
    }

    private boolean more = false;
    private List list;
}
```

Custom user registry settings:

Use this page to configure the custom user registry.

To view this administrative console page, click **Security > Global security**. Under User registries, click **Custom**.

After the properties are set in this panel, click **Apply**. Under Additional Properties, click **Custom properties** to include additional properties that the custom registry requires. The following property is predefined by the product; set this property when required only:

WAS_UseDisplayName
When this property is set to `true`, the getCallerPrincipal(), getUserPrincipal(), and getRemoteUser() methods return the display name. By default, the securityName of the user is returned. This property is introduced to support backward compatibility with the version 4 custom registry.

When security is enabled and any of these custom user registry settings change, go to the Global security panel and click **Apply** to validate the changes.

Server user ID:

Specifies the user ID under which the server runs, for security purposes.

This server ID represents a valid user in the custom registry.

Data type:	String

Server user password:

Specifies the password corresponding to the security server ID.

Data type:	String

Custom registry class name:

Specifies a dot-separated class name that implements the com.ibm.websphere.security.UserRegistry interface.

Put the custom registry class name in the class path. A suggested location is the *%install_root%*`/lib/ext` directory. Although the custom registry implements the com.ibm.websphere.security.UserRegistry interface, for backward compatibility, a user registry can alternately implement the com.ibm.websphere.security.CustomRegistry interface.

Data type:	String

Default:	com.ibm.websphere.security.FileRegistrySample

Ignore case for authorization:

Specifies that a case insensitive authorization check is performed when you use the default authorization.

Default:	Disabled
Range:	Enabled or Disabled

users.props file: Following is the format for the `users.props` file:

```
# 5639-D57, 5630-A36, 5630-A37, 5724-D18
# (C) COPYRIGHT International Business Machines Corp. 1997, 2004
# All Rights Reserved * Licensed Materials - Property of IBM
#
# Format:
# name:passwd:uid:gids:display name
# where name   = userId/userName of the user
#       passwd = password of the user
#       uid    = uniqueId of the user
#       gid    = groupIds of the groups that the user belongs to
#       display name = a (optional) display name for the user.

Java Authentication and Authorization Service

The standard Java 2 security API helps enforce access control, based on the location of the code and the user. The current principal of the running thread is not considered in the Java 2 security authorization. Instances where authorization is based on the principal (as opposed to the code base) and the user exist. The Java Authentication and Authorization Service is a standard Java API that supports the Java 2 security authorization to extend the code base on the principal as well as the code base and users.

The Java Authentication and Authorization Service (JAAS) Version 1.0 extends the Java 2 security architecture of the Java 2 platform with additional support to authenticate and enforce access control with principals and users. It implements a Java version of the standard Pluggable Authentication Module (PAM) framework, and extends the access control architecture of the Java 2 platform in a compatible fashion to support user-based authorization or principal-based authorization. WebSphere Application Server fully supports the JAAS architecture and extends the access control architecture to support role-based authorization for Java 2 Platform, Enterprise Edition (J2EE) resources including servlets, JavaServer Pages (JSP) files, and Enterprise JavaBeans (EJB) components. Refer to Java 2 security for more information.

The following sections cover the JAAS implementation and programming model:
- Java Authentication and Authorization Service login configuration
- Programmatic Login
- Java Authentication and Authorization Service authorization

The JAAS documentation can be found at http://www.ibm.com/developerworks/java/jdk/security. Scroll down to find the JAAS documentation for your platform.

Java Authentication and Authorization Service authorization:

Java 2 security architecture uses a security policy to specify which access rights are granted to running code. This architecture is *code-centric*. That is, the permissions are granted based on code characteristics including where the code is coming from, whether it is digitally signed, and by whom. Authorization of the Java Authentication and Authorization Service (JAAS) augments the existing code-centric access controls with new user-centric access controls. Permissions are granted based on what code is running and who is running it.

When using JAAS authentication to authenticate a user, a *subject* is created to represent the authenticated user. A subject is comprised of a set of principals, where each principal represents an identity for that user. You can grant permissions in the policy to specific principals. After the user is authenticated, the application can associate the subject with the current access control context. For each subsequent security-checked operation, the Java run time automatically determines whether the policy grants the required permission to a specific principal only. If so, the operation is supported if the subject associated with the access control context contains the designated principal only.

Associate a subject with the current access control context by calling the static doAs method from the subject class, passing it an authenticated subject and java.security.PrivilegedAction or java.security.PrivilegedExceptionAction. The doAs method associates the provided subject with the current access control context and then invokes the run method from the action. The run method implementation contains all the code that ran as the specified subject. The action runs as the specified subject.

In the Java 2 Platform, Enterprise Edition (J2EE) programming model, when invoking the EJB method from an enterprise bean or servlet, the method runs under the user identity that is determined by the run-as setting. The J2EE Version 1.4 Specification does not indicate which user identity to use when invoking an enterprise bean from a Subject.doAs action block within either the EJB code or the servlet code. A logical extension is to use the proper identity specified in the subject when invoking the EJB method within the Subject doAs action block.

This simple rule of letting Subject.doAs overwrite the run-as identity setting is an ideal way to integrate the JAAS programming model with the J2EE run-time environment. However, a general JAAS design oversight was introduced into IBM Software Development Kit (SDK), Java Technology Edition Version 1.3 or later when integrating the JAAS Version 1.0 or later implementation with the Java 2 security architecture. A subject, which is associated with the access control context is cut off by a doPrivileged call when a doPrivileged call occurs within the Subject.doAs action block. Until this problem is corrected, no reliable and run-time efficient way is available to guarantee the correct behavior of Subject.doAs in a J2EE run-time environment.

The problem can be explained better with the following example:

```
Subject.doAs(subject, new java.security.PrivilegedAction() {
   Public Object run() {
       // Subject is associated with the current thread context
```

```
        java.security.AccessController.doPrivileged( new
            java.security.PrivilegedAction() {
                          public Object run() {
                          // Subject was cut off from the current
                          // thread context
   return null;
              }
         });
         // Subject is associated with the current thread context
         return null;
   }
});
```

At line three, the subject object is associated with the context of the current thread. As indicated on line 7 within the run method of a doPrivileged action block, the subject object is removed from the thread context. After leaving the doPrivileged block, the subject object is restored to the current thread context. Because doPrivileged blocks can be placed anywhere along the running path and instrumented quite often in a server environment, the run-time behavior of a doAs action block becomes difficult to manage.

To resolve this difficulty, WebSphere Application Server provides a WSSubject helper class to extend the JAAS authorization to a J2EE EJB method invocation as described previously. The WSSubject class provides static doAs and doAsPrivileged methods that have identical signatures to the subject class. The WSSubject.doAs method associates the Subject to the currently running thread. The WSSubject.doAs and WSSubject.doAsPrivileged methods then invoke the corresponding Subject.doAs and Subject.doAsPrivileged methods. The original credential is restored and associated with the running thread upon leaving the WSSubject.doAs and WSSubject.doAsPrivileged methods.

Note that the WSSubject class is not a replacement of the subject object, but rather a helper class to ensure consistent run-time behavior as long as an EJB method invocation is a concern.

The following example illustrates the run-time behavior of the WSSubject.doAs method:

```
WSSubject.doAs(subject, new java.security.PrivilegedAction() {
   Public Object run() {
       // Subject is associated with the current thread context
       java.security.AccessController.doPrivileged( new
           java.security.PrivilegedAction() {
                       public Object run() {
                          // Subject was cut off from the current thread
                          // context.
   return null;
              }
         });
         // Subject is associated with the current thread context
   return null;
   }
});
```

The Subject.doAs and Subject.doAsPrivileged methods are not integrated with the J2EE run-time environment. EJB methods that are invoked within the Subject.doAs and Subject.doAsPrivileged action blocks run under the identity specified by the run-as setting and not by the subject identity.

- The subject object generated by the WSLoginModuleImpl instance and the WSClientLoginModuleImpl instance contains a principal that implements the WSPrincipal interface. Using the getCredential() method for a WSPrincipal object returns an object that implements the WSCredential interface. You can also find the WSCredential object instance in the PublicCredentials list of the subject instance. Retrieve the WSCredential object from the PublicCredentials list instead of using the getCredential() method.

- The getCallerPrincipal() method for the WSSubject class returns a string representing the caller security identity. The return type differs from the getCallerPrincipal method of the EJBContext interface, which is java.security.Principal.
- The Subject object generated by the J2C DefaultPrincipalMapping module contains a resource principal and a PasswordCredentials list. The resource principal represents the RunAs identity.

Refer to “J2EE Connector security” on page 1531 for more information

Configuring application logins for Java Authentication and Authorization Service

Java Authentication and Authorization Service (JAAS) is a new feature in WebSphere Application Server. It is a collection of WebSphere Application Server strategic authentication APIs and replaces the Common Object Request Broker Architecture (CORBA) programmatic login APIs.

WebSphere Application Server provides some extensions to JAAS:

- **com.ibm.websphere.security.auth.WSSubject**. The com.ibm.websphere.security.auth.WSSubject API extends the JAAS authorization model to Java 2 Platform, Enterprise Edition (J2EE) resources.
- You can configure JAAS login in the administrative console and store this configuration in the WebSphere configuration application programming interface (API). However, WebSphere Application Server still supports the default JAAS login configuration format (plain text file) provided by the JAAS default implementation. If duplicate login configurations are defined in both the WebSphere configuration API and the plain text file format, the one in the WebSphere configuration API takes precedence. Advantages to defining the login configuration in the WebSphere configuration API include:
  - User interface support in defining JAAS login configuration
  - Central management of the JAAS login configuration
  - Distribution of the JAAS login configuration in a Network Deployment product installation

  Due to a design oversight in the JAAS V1.0, javax.security.auth.Subject.getSubject() method does not return the subject associated with the running thread inside a java.security.AccessController.doPrivileged() code block. This problem presents an inconsistent behavior that is problematic and causes undesirable effort. The com.ibm.websphere.security.auth.WSSubject API provides a workaround to associate the subject to a running thread.
- **Proxy LoginModule**. The Proxy LoginModule loads the actual LoginModule. The default JAAS implementation does not use the thread context class loader to load classes. The LoginModule module cannot load if the LoginModule class file is not in the application class loader or the Java extension class loader class path. Due to this class loader visibility problem, WebSphere Application Server provides a proxy LoginModule module to load the JAAS LoginModule using the thread context class loader. You do not need to place the LoginModule implementation on the application class loader or the Java extension class loader class path with this proxy LoginModule module.

  If you do not want to use the Proxy LoginModule, you can place the LoginModule in the `jre/lib/ext` directory. However, this is not recommended due to the security risks.

Two JAAS login configurations are defined in the WebSphere Configuration API security document for applications to use. In the left navigation pane, click **Security > Global Security > JAAS Configuration > Application Login >WSLogin** and **ClientContainer**. The following three JAAS login configurations are available:

WSLogin

Defines a login configuration and a LoginModule implementation that applications can use in general.

ClientContainer

Defines a login configuration and a LoginModule implementation that is similar to that of the WSLogin configuration, but enforces the requirements of the WebSphere Application Server client container. Refer to ″Configuration entry settings for Java Authentication and Authorization Service″ for more information.

DefaultPrincipalMapping,

Defines a special LoginModule module that is typically used by J2EE Connector to map an authenticated WebSphere user identity to a set of user authentication data (user ID and password) for the specified back-end enterprise information system (EIS). For more information about J2EE Connector and the DefaultMappingModule module, refer to the J2EE security section.

A new JAAS login configuration can be added and modified using the administrative console. The changes are saved in the cell-level security document and are available to all managed application servers. An application server restart is required for the changes to take effect at run time.

Attention: Do not remove or delete the predefined JAAS login configurations (ClientContainer, WSLogin and DefaultPrincipalMapping). Deleting or removing them can cause other enterprise applications to fail.

1. Delete a JAAS login configuration.
   a. Click **Security** in the navigation tree and expand the **Global Security** panel.
   b. Click **JAAS Configuration** > **Application Logins**. The Application Login Configuration panel appears.
   c. Select the check box for the login configurations to delete and click **Delete**.
2. Create a new JAAS login configuration.
   a. Click **Security** in the navigation tree and expand the **Global Security** panel.
   b. Click **JAAS Configuration** > **Application Logins**.
   c. Click **New**. The Application Login Configuration panel appears.
   d. Specify the alias name of the new JAAS login configuration and click **Apply**. This value is the name of the login configuration that you pass in the javax.security.auth.login.LoginContext implementation for creating a new LoginContext.

      Click **Apply** to save changes and to add the extra node name that precedes the original alias name. Clicking **OK** does not save the new changes in the `security.xml` file.
   e. Click **JAAS Login Modules**.
   f. Click **New**.
   g. Specify the Module Classname. Specify WebSphere Proxy LoginModule because of the limitation of the class loader visibility problem.
   h. Specify the LoginModule implementation as the delegate property of the Proxy LoginModule. The WebSphere Proxy LoginModule class name is com.ibm.ws.security.common.auth.module.proxy.WSLoginModuleProxy.
   i. Select **Authentication Strategy** from the list and click **Apply**.
   j. Click **Custom Properties**. The **Custom Properties** panel is displayed for the selected LoginModule.
   k. Create a new property with the name `delegate` and the value of the real LoginModule implementation. You can specify other properties like `debug` with the value `true`. These properties are passed to the LoginModule class as options to the initialize() method of the LoginModule instance.
   l. Click **Save**.

   There are several locations within the WebSphere Application Server directory structure where you can place a JAAS login module. The following list provides locations for the JAAS login module in order of recommendation:

   - Within an Enterprise Archive (EAR) file for a specific Java 2 Enterprise Edition (J2EE) application.

     If you place the login module within the EAR file, it is accessible to the specific application only.
   - In the WebSphere Application Server shared library.

     If you place the login module in the shared library, you must specify which applications can access the module. For more information on shared libraries, see ″Managing shared libraries.″
   - In the Java extensions directory (`*WAS_HOME*\jre\lib\ext`)

If you place the JAAS login module in the Java extensions directory, the login module is available to all applications.

Although the Java extensions directory provides the greatest availability for the login module, it is recommended that you place the login module in an application EAR file. If other applications need to access the same login module, consider using shared libraries.

3. Change the plain text file. WebSphere Application Server supports the default JAAS login configuration format (plain text file) provided by the JAAS default implementation. However, a tool is not provided that edits plain text files in this format. You can define the JAAS login configuration in the plain text file (`install_root/properties/wsjaas.conf`). Any syntax errors can cause the incorrect parsing of the plain JAAS login configuration text file. This problem can cause other applications to fail.

   Java client programs that use the Java Authentication and Authorization Service (JAAS) for authentication must invoke with the JAAS configuration file specified. This configuration file is set in the `/install_root/bin/launchClient.bat` file as `set JAAS_LOGIN_CONFIG=-Djava.security.auth.login.config=%install_root%\properties\wsjaas_client.conf`. If the `launchClient.bat` file is not used to invoke the Java client program, verify that the appropriate JAAS configuration file is passed to the Java virtual machine with the `-Djava.security.auth.login.config` flag.

A new JAAS login configuration is created or an old JAAS login configuration is removed. An enterprise application can use a newly created JAAS login configuration without restarting the application server process.

However, new JAAS login configurations defined in the `install_root/properties/wsjaas.conf` file, do not refresh automatically. Restart the application servers to validate changes. These JAAS login configurations are specific to a particular node and are not available for other application servers running on other nodes.

Create new JAAS login configurations used by enterprise applications to perform custom authentication. Use these newly defined JAAS login configurations to perform programmatic login.

Login configuration for Java Authentication and Authorization Service:

Java Authentication and Authorization Service (JAAS) is a new feature in WebSphere Application Server. JAAS is WebSphere strategic APIs for authentication and it will replace the CORBA programmatic login APIs. WebSphere Application Server provides some extensions to JAAS:

- **com.ibm.websphere.security.auth.WSSubject**: The com.ibm.websphere.security.auth.WSSubject API extends the JAAS authorization model to J2EE resources. You can configure JAAS login in the administrative console (or by using the scripting functions) and store this configuration in the WebSphere configuration application programming interface (API). However, WebSphere Application Server still supports the default JAAS login configuration format (plain text file) provided by the JAAS default implementation. If duplicate login configurations are defined in both the WebSphere configuration API and the plain text file format, the one in the WebSphere configuration API takes precedence. Advantages to defining the login configuration in the WebSphere configuration API include:
  - User interface support in defining JAAS login configuration
  - Central management of the JAAS login configuration
  - Distribution of the JAAS login configuration in a Network Deployment product installation

  Due to a design oversight in the JAAS 1.0, javax.security.auth.Subject.getSubject() does not return the Subject associated with the thread of execution inside a java.security.AccessController.doPrivileged() code block. This can present a inconsistent behavior that is problematic and causes undesirable effort. com.ibm.websphere.security.auth.WSSubject provides a work around to associate Subject to thread of execution. com.ibm.websphere.security.auth.WSSubject extends the JAAS authorization model to J2EE resources.

  Note: Why WebSphere Application Server has its own subject class: You can retrieve the subjects in a Subject.doAs() block with the Subject.getSubject() call. However, this procedure does not work if there is an AccessController.doPrivileged() call within the Subject.doAs() block. In the following example, s1 is equal to s, but s2 is null:

```
* AccessController.doPrivileged() not only truncates the Subject propagation,
* but also reduces the permissions. It does not include the JAAS security
* policy defined for the principals in the Subject.
Subject.doAs(s, new PrivilegedAction() {
  public Object run() {
    System.out.println("Within Subject.doAsPrivileged()");
    Subject s1 = Subject.getSubject(AccessController.getContext());
    AccessController.doPrivileged(new PrivilegedAction() {
      public Object run() {
      Subject s2 = Subject.getSubject(AccessController.getContext());
      return null;
    }
  });
  return null;
}
});
```

- JAAS Login Configuration can be configured in administrative console (or by using the scripting functions) and stored in WebSphere configuration application programming interface (API). An application can define new JAAS login configuration in the Admin Console and the the data is persisted in the configuration respository (stored in the WebSphere configuration API). However, WebSphere still support the default JAAS login configuration format (plan text file) provided by the JAAS default implementation. But if there are duplication login configurations defined in both the WebSphere configuration API and the plan text file format, the one in the WebSphere configuration API takes precedence. There are advantages to define the login configuration in the WebSphere configuration API:
  - UI support in defining JAAS login configuration.
  - The JAAS configuration login configuration can be managed centrally.
  - The JAAS configuration login configuration is distributed in a Network Deployment installation.
- **Proxy LoginModule**: The Proxy.LoginModule API stores login module .jar files. The default JAAS implementation does not use the thread context class loader to load classes, the LoginModule could not be loaded if the LoginModule class file is not in the application class loader or the Java extension class loader classpath. Due to this class loader visibility problem, WebSphere provides a proxy LoginModule to load JAAS LoginModule using the thread context class loader. The LoginModule implementation does not have to be placed on the application class loader or the Java extension class loader classpath with this proxy LoginModule.

Note: Do not remove or delete the pre-defined JAAS Login Configurations (ClientContainer, WSLogin and DefaultPrincipalMapping). Deleting or removing them could cause other enterprise applications to fail.

A system administrator determines the authentication technologies, or LoginModules, to be used for each application and configures them in a login configuration. The source of the configuration information (for example, a file or a database) is up to the current javax.security.auth.login.Configuration implementation. The WebSphere Application Server implementation permits the login configuration to be defined in both the WebSphere configuration API security document and in a JAAS configuration file where the former takes precedence.

Two JAAS login configurations are defined in the WebSphere configuration API security document for applications to use. To access the configurations, click **Security** > **JAAS Configuration** > **Application Login Config**: **WSLogin** and **ClientContainer**. The **WSLogin** defines a login configuration and LoginModule implementation that may be used by applications in general. The **ClientContainer** defines a login configuration and LoginModule implementation that is similar to that of WSLogin but enforces the requirements of the WebSphere Application Server Client Container. The third entry, **DefaultPrincipalMapping**, defines a special LoginModule that is typically used by Java 2 Connector to map an authenticated WebSphere user identity to a set of user authentication data (user ID and password) for the specified back end enterprise information system (EIS). For more information about Java 2 Connector and the DefaultMappingModule please refer to the Java 2 Security section.

New JAAS login configuration may be added and modified using Security Center. The changes are saved in the cell level security document and are available to all managed application servers. An application server restart is required for the changes to take effect at run time and for the client container login configuration to be made available.

WebSphere Application Server also reads JAAS Configuration information from the wsjaas.conf file under the properties sub directory of the root directory under which WebSphere Application Server is installed. Changes made to the wsjaas.conf file is used only by the local application server and will take effect after restarting the application server. Note that JAAS configuration in the WebSphere configuration API security document takes precedence over that defined in the `wsjaas.conf` file. In other words, a configuration entry in `wsjaas.conf` will be overridden by an entry of the same alias name in the WebSphere configuration API security document.

Note: The Java Authentication and Authorization Service (JAAS) login configuration entries in the Security Center are propagated to the server run time when they are created, not when the configuration is saved. However, the deleted JAAS login configuration entries are not removed from the server run time. To remove the entries, save the new configuration, then stop and restart the server.

The samples gallery provides a JAAS login sample that demonstrates how to use JAAS with WebSphere Application Server. The sample uses a server-side login with JAAS to authenticate a user with the security run time for WebSphere Application Server. The sample demonstrates the following technology:

- Java 2 Platform, Enterprise Edition (J2EE) Java Authentication and Authorization Service (JAAS)
- JAAS for WebSphere Application Server
- WebSphere Application Server security

The form login sample is component of the technology samples. For more information on how to access the form login sample, see ″Accessing the Samples (Samples Gallery)″ in the information center

Configuration entry settings for Java Authentication and Authorization Service:

Use this page to specify a list of Java Authentication and Authorization Service (JAAS) login configurations for the application code to use, including J2EE artifacts such as enterprise beans, JavaServer Pages (JSP) files, servlets, resource adapters, and message data blocks (MDBs).

To view this administrative console page, complete the following steps:

1. Click **Security > Global security**.
2. Under Authentication, click **JAAS configuration > Application logins**.

Read the JAAS documentation before you begin defining additional login modules for authenticating to the WebSphere Application Server security run time. You can define additional login configurations for your applications. However, if the WebSphere Application Server LoginModule (`com.ibm.ws.security.common.auth.module.WSLoginModuleImpl`) is not used or the LoginModule does not produce a credential that is recognized by WebSphere Application Server, then the WebSphere Application Server security run time cannot use the authenticated subject from these login configurations for an authorization check for resource access.

Note: You must invoke Java client programs that use Java Authentication and Authorization Service (JAAS) for authentication with a JAAS configuration file specified. The WebSphere product supplies the default JAAS configuration file, wsjaas_client.conf under the *install_root*/`properties` directory. This configuration file is set in the /*install_root*/`bin/launchClient.bat` file as: `set`

```
JAAS_LOGIN_CONFIG=-
Djava.security.auth.login.config=%WAS_HOME%\properties\wsjaas_client.conf
```

If `launchClient.bat` file is not used to invoke Java client programs, make sure that the appropriate JAAS configuration file is passed to the Java virtual machine with the *-Djava.security.auth.login.config* flag.

ClientContainer:

Specifies the login configuration used by the client container application, which uses the CallbackHandler API defined in the client container deployment descriptor.

The ClientContainer configuration is the default login configuration for the WebSphere Application Server. Do not remove this default, as other applications that use it fail.

Default:	ClientContainer

DefaultPrincipalMapping:

Specifies the login configuration used by Java 2 Connectors to map users to principals that are defined in the J2C Authentication Data Entries.

ClientContainer is the default login configuration for the WebSphere Application Server. Do not remove this default, as other applications that use it fail.

Default:	ClientContainer

WSLogin:

Specifies whether all applications can use the WSLogin configuration to perform authentication for the WebSphere Application Server security run time.

This login configuration does not honor the CallbackHandler defined in the client container deployment descriptor. To use this functionality, use the ClientContainer login configuration.

The WSLogin configuration is the default login configuration for the WebSphere Application Server. Do not remove this default because other administrative applications that use it will fail. This login configuration authenticates users for the WebSphere Application Server security run time. Use credentials from the authenticated subject returned from this login configurations as an authorization check for access to WebSphere Application Server resources.

Default:	ClientContainer

System login configuration entry settings for Java Authentication and Authorization Service:

Use this page to specify a list of Java Authentication and Authorization Service (JAAS) system login configurations.

To view this administrative console page, click **Security > Global security**. Under Authentication, click **JAAS configuration > System logins**.

Read the Java Authentication and Authorization Service documentation before you begin defining additional login modules for authenticating to the WebSphere Application Server security run time. Do not remove the following system login modules:

- RMI_INBOUND
- WEB_INBOUND
- DEFAULT
- RMI_OUTBOUND
- SWAM
- wssecurity.IDAssertion
- wssecurity.signature
- wssecurity.PKCS7
- wssecurity.PkiPath
- wssecurity.UsernameToken
- wssecurity.X509BST
- LTPA
- LTPA_WEB

RMI_INBOUND, WEB_INBOUND, DEFAULT:

Processes inbound login requests for Remote Method Invocation (RMI), Web applications, and most of the other login protocols. These login configurations are used by WebSphere Application Server Version 5.1.1 and later.

RMI_INBOUND

The RMI_INBOUND login configuration handles logins for inbound RMI requests. Typically, these logins are requests for authenticated access to Enterprise JavaBeans (EJB) files. Also, these logins might be Java Management Extensions (JMX) requests when using the RMI connector.

WEB_INBOUND

The WEB_INBOUND login configuration handles logins for Web application requests, which includes servlets and JavaServer Pages (JSP) files. This login configuration can interact with the output that is generated from a trust association interceptor (TAI), if configured. The Subject passed into the WEB_INBOUND login configuration might contain objects generated by the TAI.

DEFAULT

The DEFAULT login configuration handles the logins for inbound requests made by most of the other protocols and internal authentications.

These three login configurations can pass in the following callback information, which is handled by the login modules within these configurations. These callbacks are not passed in at the same time. However, the combination of these callbacks determines how WebSphere Application Server authenticates the user.

Callback

```
callbacks[0] = new javax.security.auth.callback.
NameCallback(″Username: ″);
```

Responsibility

Collects the user name that is provided during a login. This information can be the user name for the following types of logins:

- User name and password login, which is known as basic authentication.
- User name only for identity assertion.

Callback

```
callbacks[1] = new javax.security.auth.callback.
PasswordCallback(″Password: ″, false);
```

Responsibility

Collects the password that is provided during a login.

Callback

```
callbacks[2] = new com.ibm.websphere.security.auth.callback.
WSCredTokenCallbackImpl(″Credential Token: ″);
```

Responsibility

Collects the Lightweight Third Party Authentication (LTPA) token (or other token type) during a login. Typically, this information is present when a user name and a password are not present.

Callback

```
callbacks[3] = new com.ibm.wsspi.security.auth.callback.
WSTokenHolderCallback(″Authz Token List: ″);
```

Responsibility

Collects the ArrayList of the TokenHolder objects that are returned from the call to the WSOpaqueTokenHelper. createTokenHolderListFromOpaqueToken () method using the Common Secure Interoperability version 2 (CSIv2) authorization token as input.

Restriction: This callback is present only when the **Security Attribute Propagation** option is enabled and this login is a propagation login. In a propagation login, sufficient security attributes are propagated with the request to prevent having to access the user registry for additional attributes.

In system login configurations, WebSphere Application Server authenticates the user based upon the information collected by the callbacks. However, a custom login module does not need to act upon any of these callbacks. The following list explains the typical combinations of these callbacks:

- The `callbacks[0] = new javax.security.auth.callback.NameCallback(″Username: ″);` callback only

  This callback occurs for CSIv2 Identity Assertion; Web and CSIv2 X509 certificate logins; old-style trust association interceptor logins, and so on. In Web and CSIv2 X509 certificate logins, WebSphere Application Server maps the certificate to a user name. This callback is used by any login type that establishes trust using the user name only.
- Both the `callbacks[0] = new javax.security.auth.callback.NameCallback(″Username: ″);` callback and the `callbacks[1] = new javax.security.auth.callback.PasswordCallback(″Password: ″, false);` callbacks.

  This combination of callbacks is typical for basic authentication logins. Most user authentications occur using these two callbacks.
- The `callbacks[2] = new com.ibm.websphere.security.auth.callback.WSCredTokenCallbackImpl(″Credential Token: ″);` only

  This callback is used to validate a Lightweight Third Party Authentication (LTPA) token. This validation typically occurs during an single signon (SSO) or downstream login. Any time a request originates from a WebSphere Application Server, instead of a pure client, the LTPA token typically flows to the target server. For single signon (SSO), the LTPA token is received in the cookie and the token is used for login. If a custom login module needs the user name from an LTPA token, the module can use the following method to retrieve the unique ID from the token:

  ```
  com.ibm.wsspi.security.token.WSSecurityPropagationHelper.
  validateLTPAToken(byte[])
  ```

  After retrieving the unique ID, use the following method to get the user name:

  ```
  com.ibm.wsspi.security.token.WSSecurityPropagationHelper.
  getUserFromUniqueID(uniqueID)
  ```

  Important: Any time a custom login module is plugged in ahead of the WebSphere Application Server login modules and it changes the identity using the credential mapping services, it is important that this login module validates the LTPA token, if present. Calling the following method is sufficient to validate the trust in the LTPA token:

```
com.ibm.wsspi.security.token.WSSecurityPropagationHelper.
validateLTPAToken(byte[])
```

The receiving server must have the same LTPA keys as the sending server in order for this to be successful. There is a possible security exposure if you do not validate this LTPA token, when present.

- A combination of any of the previously mentioned callbacks plus the `callbacks[3] = new com.ibm.wsspi.security.auth.callback.WSTokenHolderCallback("Authz Token List: ");` callback.

  This callback indicates that some propagated attributes arrived at the server. The propagated attributes still require one of the following authentication methods:

  - `callbacks[0] = new javax.security.auth.callback. NameCallback("Username: ");`
  - `callbacks[1] = new javax.security.auth.callback. PasswordCallback("Password: ", false);`
  - `callbacks[2] = new com.ibm.websphere.security.auth.callback. WSCredTokenCallbackImpl("Credential Token: ");`

  If the attributes are added to the Subject from a pure client, then the NameCallback and PasswordCallback callbacks authenticate the information and the objects that are serialized in the token holder are added to the authenticated Subject.

  If both CSIv2 identity assertion and propagation are enabled, WebSphere Application Server uses the NameCallback and the token holder, which contains all of the propagated attributes, to deserialize most of the objects. WebSphere Application Server uses the NameCallback because trust is established with the servers that you indicate in the CSIv2 trusted server list. To specify trusted servers, complete the following steps:

  1. Click **Security > Global security**.
  2. Under Authentication, click **Authentication protocol > CSIv2 Inbound authentication**.

  Custom serialization needs to be handled by a custom login module. For more information, see "Security attribute propagation".

In addition to the callbacks defined previously, the WEB_INBOUND login configuration only can contain the following additional callbacks

Callback

```
callbacks[4] = new com.ibm.websphere.security.auth.callback.
WSServletRequestCallback("HttpServletRequest: ");
```

Responsibility

Collects the HTTP servlet request object, if presented. This callback enables login modules to retrieve information from the HTTP request to use during a login.

Callback

```
callbacks[5] = new com.ibm.websphere.security.auth.callback.
WSServletResponseCallback("HttpServletResponse: ");
```

Responsibility

Collects the HTTP servlet response object, if presented. This callback enables login modules to add information into the HTTP response as a result of the login. For example, login modules might add the SingleSignonCookie to the response.

Callback

```
callbacks[6] = new com.ibm.websphere.security.auth.callback.
WSAppContextCallback("ApplicationContextCallback: ");
```

Responsibility

Collects the Web application context used during the login. This callback consists of a Hashtable, which contains the application name and the redirect Web address, if present.

The following login modules are predefined for the RMI_INBOUND, WEB_INBOUND, and DEFAULT system login configurations. You can add custom login modules before, between, or after any of these login modules, but you cannot remove these predefined login modules.

- com.ibm.ws.security.server.lm.ltpaLoginModule

  This login module performs the primary login when attribute propagation is either enabled or disabled. A primary login uses normal authentication information such as a user ID and password; an LTPA token; or a trust association interceptor (TAI) and a certificate distinguished name (DN). If any of the following scenarios are true, this login module is not used and the com.ibm.ws.security.server.lm.wsMapDefaultInboundLoginModule module performs the primary login:

  – The java.util.Hashtable object with the required user attributes is contained in the Subject.

  – The java.util.Hashtable object with the required user attributes is present in the sharedState HashMap of the LoginContext.

  – The WSTokenHolderCallback callback is present without a specified password. If a user name and a password are present with a WSTokenHolderCallback, callback, which indicates propagated information, the request likely originates from either a pure client or a server from a different realm that mapped the existing identity to a user ID and password.

- com.ibm.ws.security.server.lm.wsMapDefaultInboundLoginModule

  This login module performs the primary login using the normal authentication information if any of the following conditions are true:

  – A java.util.Hashtable object with required user attributes is contained in the Subject

  – A java.util.Hashtable object with required user attributes is present in the sharedState HashMap of the LoginContext

  – The WSTokenHolderCallback callback is present without a PasswordCallback callback.

  When the java.util.Hashtable object is present, the login module maps the object attributes into a valid Subject. When the WSTokenHolderCallback is present, the login module deserializes the byte token objects and regenerates the serialized Subject contents. The java.util.Hashtable takes precedence over all of the other forms of login. Be careful to avoid duplicating or overriding what WebSphere Application Server might have propagated previously. By specifying a java.util.Hashtable to take precedence over other authentication information, the custom login module must have already verified the LTPA token, if present, to establish sufficient trust. The custom login module can use the com.ibm.wsspi.security.token.WSSecurityPropagationHelper.validationLTPAToken(byte[]) method to validate the LTPA token present in the WSCredTokenCallback. Failure to validate the LTPA token presents a security risk.

  For more information on adding a Hashtable containing well-known and well-formed attributes used by WebSphere Application Server as sufficient login information, see ″Configuring inbound identity mapping″.

RMI_OUTBOUND:

Processes Remote Method Invocation (RMI) requests that are sent outbound to another server when either the com.ibm.CSI.rmiOutboundLoginEnabled or the com.ibm.CSIOutboundPropagationEnabled properties are true.

These properties are set in the CSIv2 authentication panel. To access the panel, click **Security > Global security**. Under Authentication protocol, click **CSIv2 Outbound authentication**. To set the com.ibm.CSI.rmiOutboundLoginEnabled property, select **Custom outbound mapping**. To set the com.ibm.CSIOutboundPropagationEnabled property, select the **Security attribute propagation** option.

This login configuration determines the security capabilities of the target server and its security domain. For example, if WebSphere Application Server Version 5.1.1 or later communicates with a version 5.x Application Server, then the Version 5.1.1 Application Server sends the authentication information only, using an LTPA token, to the Version 5.x Application Server. However, if WebSphere Application Server Version 5.1.1 or later communicates with a version 5.1.x Application Server, the authentication and authorization information is sent to the receiving application server if propagation is enabled at both the sending and receiving servers. When the application server sends both the authentication and authorization information downstream, it removes the need to re-access the user registry and look up the security attributes of the user for authorization purposes. Additionally, any custom objects added at the sending server should be present in the Subject at the downstream server.

The following callback is available to in the RMI_OUTBOUND login configuration. You can use the com.ibm.wsspi.security.csiv2.CSIv2PerformPolicy object that is returned by this callback to query the security policy for this particular outbound request. This query can help determine if the target realm is different than the current realm and if WebSphere Application Server must map the realm. For more information, see ″Configuring outbound mapping to a different target realm″.

Callback

```
callbacks[0] = new WSProtocolPolicyCallback(″Protocol Policy Callback: ″);
```

Responsibility

Provides protocol-specific policy information for the login modules on this outbound invocation. This information is used to determine the level of security, including the target realm, target security requirements, and coalesced security requirements.

The following method obtains the CSIv2PerformPolicy from this specific login module:

```
csiv2PerformPolicy = (CSIv2PerformPolicy)
((WSProtocolPolicyCallback)callbacks[0]).getProtocolPolicy();
```

A different protocol other than RMI might have a different type of policy object.

The following login module is predefined in the RMI_OUTBOUND login configuration. You can add custom login modules before, between, or after any of these login modules, but you cannot remove these predefined login modules.

com.ibm.ws.security.lm.wsMapCSIv2OutboundLoginModule

Retrieves the following tokens and objects before creating an opaque byte that is sent to another server by using the Common Secure Interoperability version 2 (CSIv2) authorization token layer:

- Forwardable com.ibm.wsspi.security.token.Token implementations from the Subject
- Serializable custom objects from the Subject
- Propagation tokens from the thread

You can use a custom login module prior to this login module to perform credential mapping. However, it is recommended that the login module change the contents of the Subject that is passed in during the login phase. If this recommendation is followed, the login modules processed after this login module act on the new Subject contents.

For more information, see ″ Configuring outbound mapping to a different target realm″.

SWAM:

Processes login requests in a single server environment when Simple WebSphere Authentication Mechanism (SWAM) is used as the authentication method.

SWAM does not support forwardable credentials. When SWAM is the authentication method, WebSphere Application Server cannot send requests from server to server. In this case, you must use LTPA.

wssecurity.IDAssertion:

Processes login configuration requests for Web services security using identity assertion. This login configuration is for version 5.x systems.

wssecurity.PKCS7: This login configuration is for version 6.x systems.

wssecurity.PkiPath: This login configuration is for version 6.x systems.

wssecurity.signature:

Processes login configuration requests for Web services security using digital signature validation. This login configuration is for version 5.x systems.

wssecurity.UsernameToken: This login configuration is for version 6.x systems.

wssecurity.X509BST: This login configuration is for version 6.x systems.

LTPA_WEB:

Processes login requests used by the Web container such as servlets and JavaServer pages (JSP) files.

This login configuration is used by WebSphere Application Server Version 5.1. This login configuration was introduced in version 5.1 and is no longer used in version 5.1.1.

The com.ibm.ws.security.web.AuthenLoginModule login module is predefined in the LTPA login configuration. You can add custom login modules before or after this module in the LTPA_WEB login configuration.

The LTPA_WEB login configuration can process the HttpServletRequest object, the HttpServletResponse object, and the Web application name that are passed in using a callback handler. For more information, see ″Customizing a server-side Java Authentication and Authorization Service authentication and login configuration″ in the documentation.

LTPA:

Processes login requests that are not handled by the LTPA_WEB login configuration.

This login configuration is used by WebSphere Application Server Version 5.1 and previous versions.

The com.ibm.ws.security.server.lm.ltpaLoginModule login module is predefined in the LTPA login configuration. You can add custom login modules before or after this module in the LTPA login configuration. For more information, see ″Customizing a server-side Java Authentication and Authorization Service authentication and login configuration″ in the documentation.

Login module settings for Java Authentication and Authorization Service:

Use this page to define the login module for a Java Authentication and Authorization Service (JAAS) login configuration.

You can define the JAAS login modules for application and system logins. To define these login modules in the administrative console, use one of the following paths:

- To view this administrative console page, click **Security > Global security**. Under Authentication, click **JAAS configuration > Application logins** or **System logins** > *alias_name*. Under Additional properties, click **JAAS login modules**.

Module class name:

Specifies the class name of the given login module.

Data type:	String

Proxy class name:

Specifies the name of the proxy login module class.

The default login modules defined by the WebSphere product use the proxy LoginModule class, com.ibm.ws.security.common.auth.module.WSLoginModuleProxy. This proxy class loads the WebSphere Application Server login module with the thread context class loader and delegates all the operations to the *real* login module implementation. The real login module implementation is specified as the delegate option in the option configuration. The proxy class is needed because the Developer Kit application class loaders do not have visibility of the WebSphere Application Server product class loaders.

Data type:	String

Authentication Strategy:

Specifies the authentication behavior as authentication proceeds down the list of login modules.

A Java Authentication and Authorization Service (JAAS) authentication provider supplies the authentication strategy. In JAAS, an authentication strategy is implemented through the LoginModule interface.

Data type:	String
Default:	Required
Range:	Required, Requisite, Sufficient and Optional

Required
The LoginModule is required to succeed. If it succeeds or fails, authentication still continues to proceed down the LoginModule list for each realm.

Requisite
The LoginModule is required to succeed. If it succeeds, authentication continues down the LoginModule list in the realm entry. If it fails, control immediately returns to the application--that is, authentication does not proceed down the LoginModule list.

Sufficient
The LoginModule is not required to succeed. If it does succeed, control immediately returns to the application--again, authentication does not proceed down the LoginModule list. If it fails, authentication continues down the list.

Optional
The LoginModule is not required to succeed. If it succeeds or fails, authentication still continues to proceed down the LoginModule list.

Specify additional options by clicking **Custom Properties** under Additional Properties. These name and value pairs are passed to the login modules during initialization. This process is one of the mechanisms that is used to passed information to login modules.

Module order:

Specifies the order in which the Java Authentication and Authorization Service (JAAS) login modules are processed.

Click **Set Order** to change the processing order of the login modules.

Login module order settings for Java Authentication and Authorization Service:

Use this page to specify the order in which WebSphere Application Server processes the login configuration modules.

You can specify the order of the login modules for application and system logins. To define these login modules in the administrative console, complete the following steps:

1. Click **Security > Global security**.
2. Under Authentication, click **JAAS Configuration > Application logins** or **System logins** > *login_configuration*. You can create a new configuration by clicking **New**.
3. Under Additional properties, click **JAAS login modules**.
4. Click **Set order**.

When you select one of the JAAS login module class names, you can move that class name up and down the list. After you press **OK** and save the changes, the new order is reflected on either the Application login configuration or System login configuration panel.

Login configuration settings for Java Authentication and Authorization Service:

Use this page to configure application login configurations.

To view this administrative console page, click **Security > Global security**. Under Authentication, click **JAAS configuration > Application logins** or **System logins** > *alias_name*.

Click **Apply** to save changes and to add the extra node name that precedes the original alias name. Clicking **OK** does not save the new changes in the `security.xml` file.

Alias:

Specifies the alias name of the application login.

Do not use the forward slash character (/) in the alias name when defining JAAS login configuration entries. The JAAS login configuration parser cannot process the forward slash character.

Data type:	String

J2EE Connector security:

The J2EE connector architecture defines a standard architecture for connecting the Java 2 Platform, Enterprise Edition (J2EE) to heterogeneous enterprise information systems (EIS). Examples of EIS include Enterprise Resource Planning (ERP), mainframe transaction processing (TP) and database systems.

The connector architecture enables an EIS vendor to provide a standard *resource adapter* for its EIS. A *resource adapter* is a system-level software driver that is used by a Java application to connect to an EIS. The resource adapter plugs into an application server and provides connectivity between the EIS, the application server, and the enterprise application. Accessing information in EIS typically requires access control to prevent unauthorized accesses. J2EE applications must authenticate to the EIS to open a connection to it.

The J2EE Connector security architecture is designed to extend the end-to-end security model for J2EE-based applications to include integration with EISs. An application server and an EIS collaborate to ensure the proper authentication of a resource principal, which establishes a connection to an underlying EIS. The connector architecture identifies the following mechanisms as the commonly-supported authentication mechanisms although other mechanisms can be defined:

- BasicPassword: Basic user-password-based authentication mechanism that is specific to an EIS
- Kerbv5: Kerberos Version 5-based authentication mechanism

Applications define whether to use application-managed sign-on or container-managed sign-on in the resource-ref elements in the deployment descriptor. Each resource-ref element describes a single connection factory reference binding. The `res-auth` element in a resource-ref element, whose value is either Application or Container, indicates whether the enterprise bean code should perform sign-on or whether it should enable the WebSphere Application Server to sign-on to the resource manager using the principal mapping configuration. The resource-ref element is defined at application assembly time. Use the WebSphere Development Toolkit to configure the resource `-ref`.

Application managed sign-on

To access an EIS system, applications locate a connection factory from the JNDI namespace and invoke the getConnection method on that connection factory object. The getConnection method might require a user ID and password argument. A J2EE application can pass in a user ID and password to getConnection, which subsequently passes the information to the resource adapter. Specifying a user ID and password in the application code has some security implications, however.

The user ID and password, if coded into the Java source code, are available to developers and testers in the organization. Also, the user ID and password are visible to users if they de-compile the Java class.

The user ID and password cannot be changed without first requiring a synchronized code change. Alternatively, application code might retrieve sets of user IDs and passwords from persistent storage or from an external service. This approach requires that IT administrators configure and manage a user ID and password using the application-specific mechanism.

WebSphere Application Server allows a component-managed authentication alias to be specified on a resource. This authentication data is common to all references to the resource. On the **Resource Adapter**>**Connection Factory** configuration panel, select **component-managed authentication alias**.

With res-auth=Application, the authentication data is taken from, in order:

1. user id and password passed to getConnection(...)
2. component-managed auth alias on the Connection Factory or DataSource
3. Custom Properties UserName and Password on the DataSource

The username and password properties can be initially defined in the RAR file, and can also be defined in the admininstrative console or wsadmin scripting under custom properties. Do not use the custom properties, which enable users to connect to the resources.

Container-managed sign-on

The user ID and password for the target EIS can be supplied by the application server. WebSphere Application Server provides container-managed sign-on functionality. It locates the proper authentication data for the target EIS to enable the client to establish a connection. Application code does not have to provide a user ID and password in the getConnection call when it is configured to use container-managed sign-on, nor does authentication data have to be common to all references to a resource. WebSphere Application Server uses a Java Authentication and Authorization Service (JAAS) pluggable authentication mechanism to use a pre-configured JAAS login configuration, and LoginModule(s) to map a client security identity and credentials on the thread of execution to a pre-configured user ID and password.

WebSphere Application Server ships a default many-to-one credential mapping LoginModule that maps any client identity on the thread of execution to a pre-configured user ID and password for a specified target EIS. The default mapping module is a special purpose JAAS LoginModule that returns a PasswordCredential specified by the configured J2C authentication data entry. The default mapping LoginModule performs a table lookup, but does not perform actual authentication. The user ID and password are stored together with an alias in the J2C Authentication data list. The J2C Authentication data list is located on the Global Security panel under **Authentication** > **JAAS Configuration**. The default principal and credential mapping function is defined by the DefaultPrincipalMapping application JAAS login configuration.

The DefaultPrincipalMapping login configuration should not be modified since WebSphere Application Server added performance enhancements to this frequently used default mapping configuration. WebSphere Application Server does not support modifying the DefaultPrincipalMapping configuration, changing the default LoginModule, or stacking a custom LoginModule in the configuration.

For most systems, the default configuration with a many-to-one mapping is sufficient. However, WebSphere Application Server does support custom principal and credential mapping configurations. Custom mapping modules can be added to the application logins JAAS configuration by creating a new JAAS login configuration with a unique name. For example, a custom mapping module can provide one-to-one mapping or Kerberos functionality.

You also can use the WebSphere Application Server administrative console to bind the resource manager connection factory references to one of the configured resource factories. If the value of the res-auth element is Container, you must configure the mapping configuration using the **Map resource references to resources** link on an enterprise application panel.

Map resource references to references

To map resource references to resources, do the following:

1. Click **Applications** > **Enterprise Applications**.
2. Select an application.
3. Under Additional Properties, select **Map resource references to resources**.
4. Select a connection factory reference binding from the table that has a login configuration of Resource authorization: Container. You must specify an authentication method for the selected connection factory reference binding. Choose either **Use default method** or **Use custom login configuration**. If you choose the **Use default method** option, the WebSphere Application Server DefaultPrincipalMapping login configuration is selected. You must select an authentication data alias from the drop-down list.
5. After you make a selection, click **Apply** for the configuration to take effect.
6. If you choose **Use custom login configuration**, you must select a mapping JAAS login configuration from the drop-down list.
7. Click **Apply**. The selected login configuration name and an **Update** button appear in the login configuration field of the particular connection factory reference binding.
8. Click **Update** to define mapping properties that you might need to pass to the mapping LoginModule(s).

J2C mapping modules and mapping properties

Mapping modules are special JAAS login modules that provide principal and credential mapping functionality. You can define and configure custom mapping modules using the administrative console.

You also can define and pass context data to mapping modules by using login options in each JAAS login configuration. In WebSphere Application Server Version 6, you also can define context data using mapping properties on each connection factory reference binding.

Login options that are defined under each JAAS login configuration are shared among all resources that use the same JAAS login configuration and mapping modules. Mapping properties that are defined for each connection factory reference binding are used exclusively by that resource reference.

Consider a usage scenario where an external mapping service is used, (such the as Tivoli Access Manager Global Sign-On (GSO) service). You have two EIS servers: DB2 and MQ.

Use the Tivoli Access Manager GSO to locate authentication data for both backend servers. The authentication data for DB2 is different from that for MQ, however. Use the login option in a mapping JAAS login configuration to specify the parameters that are required to establish a connection to the TAM GSO service. Use the mapping properties in a connection factory reference binding to specify which EIS server the user ID and password are required for.

For more detailed information about developing a mapping module, see the ″Developing your own Java 2 security mapping module″ article in the information center.

Note:

- WebSphere Application Server Version 6 configures container-managed sign-on under each enterprise application. This is different than WebSphere Application Server Version 5, which configures container-managed sign-on for each connection factory.
- The deprecated way of configuration at the **Resource Adapter** > **Connection factory** panel still works in WebSphere Application Server Version 6. The advantage to configuring at the connection factory reference level is that the configuration has application scope and is not visible to other applications. However, the mapping configuration defined at the connection factory is visible to other applications.
- The mapping configuration at the connection factory has moved to the resource manager connection factory reference. The mapping LoginModules that were developed using WebSphere Application Server Version 5 JAAS Callback types can be used by the resource manager connection factory reference, but the mapping LoginModules cannot take advantage of the custom mapping properties feature.
- Connection factory reference binding supports mapping properties, and passes those properties to mapping LoginModules by way of a new WSMappingPropertiesCallback Callback type. In addition, WSMappingPropertiesCallback and the new WSManagedConnectionFactoryCallback are defined in the com.ibm.wsspi package. New mapping LoginModules should use the new Callback types.

Managing J2EE Connector Architecture authentication data entries:

Java 2 Platform, Enterprise Edition (J2EE) Connector authentication data entries are used by resource adapters and Java DataBase Connectivity (JDBC) data sources. A J2EE Connector authentication data entry contains authentication data, which includes the following information:

Alias An identifier that identifies the authenticated data entry. When configuring resource adapters or data sources, the administrator can specify which authentication data to choose using the corresponding alias.

User ID
A user identity of the intended security domain. For example, if a particular authentication data entry is used to open a new connection to DB2, this entry contains a DB2 user identity.

Password
The password of the user identity is encoded in the configuration respository.

Description
A short text description.

This task creates and deletes Java 2 Connector (J2C) authentication data entries.

1. Delete a J2C authentication data entry.
   a. Click **Security** in the navigation tree and select **Global Security**, and then click **JAAS Configuration** > **J2C Authentication Data**. The **J2C Authentication Data Entries** panel is displayed.
   b. Select the check boxes for the entries to delete and click **Delete**. Before deleting or removing an authentication data entry, make sure that it is not used or referenced by any resource adapter or data source. If the deleted authentication data entry is used or referenced by a resource, the application that uses the resource adapter or the data source fails to connect to the resources.
2. Create a new J2C authentication data entry.

a. Click **Security** in the navigation tree and select **Global Security**, and then click **JAAS Configuration** > **J2C Authentication Data**. The **J2C Authentication Data Entries** panel is displayed.
b. Click **New**.
c. Enter a unique alias, a valid user ID, a valid password, and a short description (optional).
d. Click **OK** or **Apply**. No validation for the user ID and password is required.
e. Click **Save**. For a Network Deployment installation, make sure that a file synchronized operation is performed to propagate the changes to other nodes.

A new J2C authentication data entry is created or an old entry is removed. The newly created entry is visible without restarting the application server process to use in the data source definition. But the entry is only in effect after the server is restarted. Specifically, the authentication data is loaded by an application server when starting an application and is shared among applications in the same application server.

If you create or update a data source that points to a newly created J2C authentication data alias, the test connection fails to connect until you restart the deployment manager. After you restart the deployment manager, the J2C authentication data is reflected in the run-time configuration. Any changes to the J2C authentication data fields require a deployment manager restart for the changes to take effect.

This step defines authentication data that you can share among resource adapters and data sources. Use the authentication data entry that is defined in the resource adapters or the data sources.

Java 2 Connector authentication data entry settings:

Use this page as a central place for administrators to define authentication data, which includes user identities and passwords. These values can reference authentication data entries by resource adapters, data sources, and other configurations that require authentication data using an alias.

You can display this page directly from the JAAS configuration page or from other pages for resources that use J2EE Connector (J2C) authentication data entries. For example, to view this administrative page, you can click either **Security > Global security**. Under Authentication, click **JAAS configuration > J2C authentication data**.

Deleting authentication data entries: Be careful when deleting authentication data entries. If the deleted authentication data is used by other configurations, the initializing resources process fails.

Define a new authentication data entry by clicking **New**.

Alias:

Specifies the name of the authentication data entry.

Data type:	String
Units:	String
Default:	None

User ID:

Specifies the user identity.

Data type:	String

Description:

Specifies an optional description of the authentication data entry. For example, this authentication data entry is used to connect to DB2.

Data type:	String

Identity mapping

Identity mapping is a one-to-one mapping of a user identity between two servers so that the proper authorization decisions are made by downstream servers. Identity mapping is necessary when the integration of servers is needed, but the user registries are different and not shared between the systems.

In most cases, requests flow downstream between two servers that are part of the same security domain. In WebSphere Application Server, two servers that are members of the same cell are also members of the same security domain. In the same cell, the two servers have the same user registry and the same Lightweight Third Party Authentication (LTPA) keys for token encryption. These two commonalities ensure that the LTPA token (among other user attributes), which flows between the two servers, not only can be decrypted and validated, but also the user identity in the token can be mapped to attributes that are recognized by the authorization engine.

The most reliable and recommended configuration involves two servers within the same cell. However, sometimes you need to integrate multiple systems that cannot use the same user registry. When the user registries are different between two servers, the security domain or realm of the target server does not match the security domain of the sending server.

WebSphere Application Server enables mapping to occur either before sending the request outbound or before enabling the existing security credentials to flow to the target server as-is. The credentials are mapped inbound with the specification that the target realm is trusted.

An alternative to mapping is to send the user identity without the token or the password to a target server without actually mapping the identity. The use of the user identity is based on trust between the two servers. Use Common Secure Interoperability version 2 (CSIv2) identity assertion. When enabled, it sends just the X.509 certificate, principal name, or distinguished name (DN) based upon what was used by the original client to perform the initial authentication. During CSIv2 identity assertion, trust is established between the WebSphere Application Servers.

The user identity must exist in the target user registry for identity assertion to work. This process can also enable interoperability between other Java 2 Platform, Enterprise Edition (J2EE) Version 1.3 and higher compliant application servers. When using identity assertion, if both the sending server and target servers have identity assertion configured, WebSphere Application Server always uses this method of authentication, even when both servers are in the same security domain. For more information on CSIv2 identity assertion, see ″Identity assertion.″

When the user identity is not present in the user registry of the target server, identity mapping must occur either before the request is sent outbound or when the request comes inbound. This decision depends upon your environment and requirements. However, it is typically easier to map the user identity before the request is sent outbound for the following reasons:

- You know the user identity of the existing credential as it comes from the user registry of the sending server.
- You do not have to worry about sharing Lightweight Third Party Authentication (LTPA) keys with the other target realm because you are not mapping the identity to LTPA credentials. Typically, you are mapping the identity to a user ID and password that are present in the user registry of the target realm.

When you do perform outbound mapping, in most cases, it is recommended that you use Secure Sockets Layer (SSL) to protect the integrity and confidentiality of the security information sent across the network. If LTPA keys are not shared between servers, an LTPA token cannot be validated at the inbound server. In this case, outbound mapping is necessary because the user identity can not be determined at the inbound server to do inbound mapping. For more information, see ″Configuring outbound mapping to a different target realm.″

When you need inbound mapping, potentially due to the mapping capabilities of the inbound server, you must ensure that both servers have the same LTPA keys so that you can get access to the user identity. Typically, in secure communications between servers, an LTPA token is passed into the WSCredTokenCallback of the inbound JAAS login configuration for the purposes of client authentication. A method is available that enables you to open the LTPA token, if valid, and get access to the user unique ID so that mapping can be performed. For more information, see ″Configuring inbound identity mapping″ in the information center. In other cases, such as identity assertion, you might receive a user name in the NameCallback of the inbound login configuration that enables you to map the identity.

Configuring inbound identity mapping

For inbound identity mapping, it is recommend that you write a custom login module and configure WebSphere Application Server to run the login module first within the system login configurations. Consider the following steps when you write your custom login module:

1. Get the inbound user identity from the callbacks and map the identity, if necessary This step occurs in the login() method of the login module. A valid authentication has either or both of the following callbacks present: NameCallback and the WSCredTokenCallback. The following code sample shows you how to determine the user identity:

```
javax.security.auth.callback.Callback callbacks[] =
   new javax.security.auth.callback.Callback[3];
 callbacks[0] = new javax.security.auth.callback.NameCallback(″″);
 callbacks[1] = new javax.security.auth.callback.PasswordCallback
     (″Password: ″, false);
 callbacks[2] = new com.ibm.websphere.security.auth.callback.
     WSCredTokenCallbackImpl(″″);
 callbacks[3] = new com.ibm.wsspi.security.auth.callback.
     WSTokenHolderCallback(″″);

 try
 {
  callbackHandler.handle(callbacks);
 }
 catch (Exception e)
 {
  // Handles exceptions
  throw new WSLoginFailedException (e.getMessage(), e);
 }

 // Shows which callbacks contain information
 boolean identitySwitched = false;
 String uid = ((NameCallback) callbacks[0]).getName();
 char password[] = ((PasswordCallback) callbacks[1]).getPassword();
 byte[] credToken = ((WSCredTokenCallbackImpl) callbacks[2]).getCredToken();
 java.util.List authzTokenList = ((WSTokenHolderCallback)
     callbacks[3]).getTokenHolderList();

 if (credToken != null)
 {
  try
  {
   String uniqueID = WSSecurityPropagationHelper.validateLTPAToken(credToken);
   String realm = WSSecurityPropagationHelper.getRealmFromUniqueID (uniqueID);
       // Now set the string to the UID so that you can use the result for either
       // mapping or logging in.
   uid = WSSecurityPropagationHelper.getUserFromUniqueID (uniqueID);
  }
  catch (Exception e)
  {
   // Handles the exception
  }
 }
 else if (uid == null)
 {
     // Throws an except if invalid authentication data exists.
     // You must have either UID or CredToken
  throw new WSLoginFailedException("invalid authentication data.");
 }
 else if (uid != null && password != null)
 {
     // This is a typical authentication. You can choose to map this ID to
     // another ID or you can skip it and allow WebSphere Application Server
     // to login for you. When passwords are presented, be very careful to not
     // validate the password because this is the initial authentication.

  return true;
 }

    // If desired, map this uid to something else and set the identitySwitched
    // boolean. If the identity was changed, clear the propagated attributes
    // below so they are not used incorrectly.
 uid = myCustomMappingRoutine (uid);

    // Clear the propagated attributes because they no longer applicable to the
    // new identity
 if (identitySwitched)
 {
  ((WSTokenHolderCallback) callbacks[3]).setTokenHolderList(null);
 }
```

2. Check to see if attribute propagation occurred and if the attributes for the user are already present when the identity remains the same. Check to see if the user attributes are already present from the sending server to avoid duplicate calls to the user registry lookup. To check for the user attributes, use a method on the WSTokenHolderCallback that analyzes the information present in the callback to determine if the information is sufficient for WebSphere Application Server to create a Subject. The following code sample checks for the user attributes:

   ```
   boolean requiresLogin =
   ((com.ibm.wsspi.security.auth.callback.WSTokenHolderCallback)
   callbacks[2]).requiresLogin();
   ```

   If sufficient attributes are not present to form the WSCredential and WSPrincipal objects needed to perform authorization, the previous code sample returns a true result. When the result is false, you can choose to discontinue processing as the necessary information exists to create the Subject without performing additional remote user registry calls.
3. **Optional:** Look up the required attributes from the user registry, put the attributes in hashtable, and add the hashtable to the shared state. If the identity is switched in this login module, you must complete the following steps:

a. Create the hashtable of attributes as shown in the following example.

b. Add the hashtable to shared state.

If the identity is not switched, but the value of the requiresLogin code sample shown previously is true, you can create the hashtable of attributes. However, you are not required to create a hashtable in this situation as WebSphere Application Server handles the login for you. However, you might consider creating a hashtable to gather attributes in special cases where you are using your own special user registry. Creating a UserRegistry implementation, using a hashtable, and letting WebSphere Application Server gather the user attributes for you might be the easiest solution. The following table shows how to create a hashtable of user attributes:

```
if (requiresLogin || identitySwitched)
 {
  // Retrives the default InitialContext for this server.
  javax.naming.InitialContext ctx = new javax.naming.InitialContext();

  // Retrieves the local UserRegistry implementation.
  com.ibm.websphere.security.UserRegistry reg = (com.ibm.websphere.
        security.UserRegistry)
  ctx.lookup("UserRegistry");

     // Retrieves the user registry uniqueID based on the uid specified
     // in the NameCallback.
  String uniqueid = reg.getUniqueUserId(uid);
   uid = WSSecurityPropagationHelper.getUserFromUniqueID (uniqueID);

     // Retrieves the display name from the user registry based on the uniqueID.
  String securityName = reg.getUserSecurityName(uid);

     // Retrieves the groups associated with the uniqueID.
  java.util.List groupList = reg.getUniqueGroupIds(uid);

     // Creates the java.util.Hashtable with the information that you gathered
     // from the UserRegistry implementation.
  java.util.Hashtable hashtable = new java.util.Hashtable();
  hashtable.put(com.ibm.wsspi.security.token.AttributeNameConstants.
       WSCREDENTIAL_UNIQUEID, uniqueid);
     hashtable.put(com.ibm.wsspi.security.token.AttributeNameConstants.
       WSCREDENTIAL_SECURITYNAME, securityName);
  hashtable.put(com.ibm.wsspi.security.token.AttributeNameConstants.
       WSCREDENTIAL_GROUPS, groupList);

     // Adds a cache key that is used as part of the look up mechanism for
     // the created Subject. The cache key can be an object, but should have
     // an implemented toString() method. Make sure that the cacheKey contains
     // enough information to scope it to the user and any additional attributes
     // that you are using. If you do not specify this property the Subject is
     // scoped to the returned WSCREDENTIAL_UNIQUEID, by default.
  hashtable.put(com.ibm.wsspi.security.token.AttributeNameConstants.
        WSCREDENTIAL_CACHE_KEY, "myCustomAttribute" + uniqueid);
  // Adds the hashtable to the sharedState of the Subject.
  _sharedState.put(com.ibm.wsspi.security.token.AttributeNameConstants.
        WSCREDENTIAL_PROPERTIES_KEY, hashtable);
 }
```

The following rules define in more detail how a hashtable login is performed. You must use a java.util.Hashtable object in either the Subject (public or private credential set) or shared state

HashMap. The com.ibm.wsspi.security.token.AttributeNameConstants class defines the keys that contain the user information. If the hashtable object is put into the shared state of the login context using a custom login module that is listed prior to the Lightweight Third Party Authentication (LTPA) login module, the value of the java.util.Hashtable object is searched using the following key within the shared state hashMap:

Property
com.ibm.wsspi.security.cred.propertiesObject

Reference to the property
AttributeNameConstants.WSCREDENTIAL_PROPERTIES_KEY

Explanation
This key searches for the hashtable object that contains the required properties in sharedState of the login context.

Expected result
A java.util.Hashtable object.

If a java.util.Hashtable object is found either inside the Subject or within the sharedState area, verify that the following properties are present in the hashtable:

Property
com.ibm.wsspi.security.cred.uniqueId

Reference to the property
AttributeNameConstants.WSCREDENTIAL_UNIQUEID

Returns
java.util.String

Explanation
The value of the property must be a unique representation of the user. For the WebSphere Application Server default implementation, this property represents the information that is stored in the application authorization table. The information is located in the application deployment descriptor after it is deployed and user-to-role mapping is performed. See the expected format examples if the user to role mapping is performed using a lookup to a WebSphere Application Server user registry implementation. If a third-party authorization provider overrides the user to role mapping, then the third-party authorization provider defines the format. To ensure compatibility with the WebSphere Application Server default implementation for the unique ID value, call the WebSphere Application Server `public String getUniqueUserId(String userSecurityName)` UserRegistry method.

Expected format examples

Realm	Format (uniqueUserId)
Lightweight Directory Access Protocol (LDAP)	`ldaphost.austin.ibm.com:389/cn=user,o=ibm,c=us`
Windows	`MYWINHOST/S-1-5-21-963918322-163748893-4247568029-500`
UNIX	`MYUNIXHOST/32`

The com.ibm.wsspi.security.cred.uniqueId property is required.

Property
com.ibm.wsspi.security.cred.securityName

Reference to the property
AttributeNameConstants. WSCREDENTIAL_ SECURITYNAME

Returns
java.util.String

Explanation
This property searches for the securityName of the authentication user. This name is commonly called the display name or short name. WebSphere Application Server uses the securityName attribute for the getRemoteUser(), getUserPrincipal() and getCallerPrincipal() application programming interfaces (APIs). To ensure compatibility with the WebSphere Application Server default implementation for the securityName value, call the WebSphere Application Server `public String getUserSecurityName(String uniqueUserId)` UserRegistry method.

Expected format examples

Realm	Format (uniqueUserId)
LDAP	user (*LDAP UID*)
Windows	user (*Windows username*)
UNIX	user (*UNIX username*)

The com.ibm.wsspi.security.cred.securityName property is required.

Property
com.ibm.wsspi.security.cred.groups

Reference to the property
AttributeNameConstants. WSCREDENTIAL_GROUPS

Returns
java.util.ArrayList

Explanation
This key searches for the ArrayList of groups to which the user belongs. The groups are specified in the `realm_name/user_name format`. The format of these groups is important as the groups are used by the WebSphere Application Server authorization engine for group-to-role mappings in the deployment descriptor. The format provided must match the format expected by the WebSphere Application Server default implementation. When you use a third-party authorization provider, you must use the format expected by the third-party provider. To ensure compatibility with the WebSphere Application Server default implementation for the unique group IDs value, call the WebSphere Application Server `public List getUniqueGroupIds(String uniqueUserId)` UserRegistry method.

Expected format examples for each group in the ArrayList

Realm	Format
LDAP	`ldap1.austin.ibm.com:389/cn=group1,o=ibm,c=us`
Windows	`MYWINREALM/S-1-5-32-544`
UNIX	`MY/S-1-5-32-544`

The com.ibm.wsspi.security.cred.groups property is not required. A user is not required to have associated groups.

Property
com.ibm.wsspi.security.cred.cacheKey

Reference to the property
AttributeNameConstants. WSCREDENTIAL_CACHE_KEY

Returns
java.lang.Object

Explanation
This key property can specify an Object that represents the unique properties of the login

including the user-specific information and the user dynamic attributes that might affect uniqueness. For example, when the user logs in from location A, which might affect their access control, the cacheKey needs to include location A so that the Subject received is the correct Subject for the current location.

This com.ibm.wsspi.security.cred.cacheKey property is not required. When this property is not specified, the cache lookup is the value specified for WSCREDENTIAL_UNIQUEID. When this information is found in the java.util.Hashtable object, WebSphere Application Server creates a Subject similar to the Subject that goes through the normal login process (at least for LTPA). The new Subject contains a WSCredential object and a WSPrincipal object that is fully populated with the information found in the Hashtable object.

4. Add your custom login module into the RMI_INBOUND, WEB_INBOUND, and DEFAULT Java Authentication and Authorization Service (JAAS) system login configurations. Configure the RMI_INBOUND login configuration so that WebSphere Application Server loads your new custom login module first.
   a. Click **Security > Global security**.
   b. Under Authentication, click **JAAS configuration > System logins > RMI_INBOUND**
   c. Under Additional Properties, click **JAAS login modules > New** to add your login module to the RMI_INBOUND configuration.
   d. Return to the JAAS login modules panel for RMI_INBOUND and click **Set order** to change the order that the login modules are loaded so that WebSphere Application Server loads your custom login module first.
   e. Repeat the previous three steps for the WEB_INBOUND and DEFAULT login configurations.

This process configures identity mapping for an inbound request.

The “Example: Custom login module for inbound mapping” article shows a custom login module that creates a java.util.Hashtable based on the specified NameCallback. The java.util.Hashtable is added to the sharedState java.util.Map so that the WebSphere Application Server login modules can locate the information in the Hashtable.

Example: Custom login module for inbound mapping:

This sample shows a custom login module that creates a java.util.Hashtable hastable that is based on the specified NameCallback callback. The java.util.Hashtable hash table is added to the sharedState java.util.Map so that the WebSphere Application Server login modules can locate the information in the Hashtable.

```
public customLoginModule()
{

public void initialize(Subject subject, CallbackHandler callbackHandler,
   Map sharedState, Map options)
{
 // (For more information on initialization, see
  //  ″Custom login module development for a system login configuration″
 //  in the information center.

 _sharedState = sharedState;
}

public boolean login() throws LoginException
{
 // (For more information on what to do during login, see
  //  ″Custom login module development for a system login configuration″
 //  in the information center.
   // Handles the WSTokenHolderCallback to see if this is an initial or
   // propagation login.
 javax.security.auth.callback.Callback callbacks[] =
     new javax.security.auth.callback.Callback[3];
 callbacks[0] = new javax.security.auth.callback.NameCallback("");
 callbacks[1] = new javax.security.auth.callback.PasswordCallback(
     "Password: ", false);
 callbacks[2] = new com.ibm.websphere.security.auth.callback.
     WSCredTokenCallbackImpl("");
 callbacks[3] = new com.ibm.wsspi.security.auth.callback.
     WSTokenHolderCallback("");

 try
 {
  callbackHandler.handle(callbacks);
 }
 catch (Exception e)
 {
  // Handles the exception
 }

 // Determines which callbacks contain information
 boolean identitySwitched = false;
 String uid = ((NameCallback) callbacks[0]).getName();
 char password[] = ((PasswordCallback) callbacks[1]).getPassword();
 byte[] credToken = ((WSCredTokenCallbackImpl) callbacks[2]).getCredToken();
 java.util.List authzTokenList = ((WSTokenHolderCallback) callbacks[3]).
     getTokenHolderList();

 if (credToken != null)
 {
  try
  {
   String uniqueID = WSSecurityPropagationHelper.validateLTPAToken(credToken);
   String realm = WSSecurityPropagationHelper.getRealmFromUniqueID (uniqueID);
       // Set the string to the UID so you can use the information to either
       // map or login.
   uid = WSSecurityPropagationHelper.getUserFromUniqueID (uniqueID);
  }
  catch (Exception e)
  {
   // handle exception
  }
 }
 else if (uid == null)

Configuring outbound mapping to a different target realm

By default, when WebSphere Application Server makes an outbound request from one server to another server in a different security realm, the request is rejected. This request is rejected to protect against a rogue server reading potentially sensitive information if successfully impersonating the home of the object. The following alternatives are available to enable one server to send outbound requests to a target server in a different realm:

- Do not perform mapping, instead, allow the existing security information to flow to a trusted target server even if the target server resides in a different realm. To allow information to flow to a server in a different realm, complete the following steps in the administrative console:
  1. Click **Security > Global security**.
  2.

3. Specify the target realms in the **Trusted target realms** field. You can specify each trusted target realm that is separated by a pipe (|) character. For example, specify *server_name.domain:port_number* for a Lightweight Directory Access Protocol (LDAP) server or the machine name for Local OS. If you want to propagate security attributes to a different target realm, you must specify that target realm in the **Trusted target realms** field.

- Use the Java Authentication and Authorization Service (JAAS) WSLogin application login configuration to create a basic authentication Subject that contains the credentials of the new target realm. This configuration enables you to log in with a realm, user ID, and password that are specific to the user registry of the target realm. You can provide the login information from within the Java 2 Platform, Enterprise Edition (J2EE) application that is making the outbound request or from within the RMI_OUTBOUND system login configuration. These two login options are described in the following information:
  1. Use the WSLogin application login configuration from within the J2EE application to log in and get a Subject that contains the user ID and the password of the target realm. The application then can wrap the remote call with a WSSubject.doAs call. For an example, see "Example: Using the WSLogin configuration to create a basic authentication subject" on page 1547.
  2. Use the code sample in "Example: Using the WSLogin configuration to create a basic authentication subject" on page 1547 from this plug point within the RMI_OUTBOUND login configuration. Every outbound Remote Method Invocation (RMI) request passes through this login configuration when it is enabled. Complete the following steps to enable and plug in this login configuration:
     a. Click **Security > Global security**.
     b. Under Authentication, click **Authentication protocol > CSIv2 outbound authentication**.
     c. Select the **Custom outbound mapping** option. If the **Security Attribute Propagation** option is selected, then WebSphere Application Server is already using this login configuration and you do not need to enable custom outbound mapping.
     d. Write a custom login module. For more information, see ″Custom login module development for a system login configuration″ in the information center.

        The "Example: Sample login configuration for RMI_OUTBOUND" on page 1548 article shows a custom login module that determines whether the realm names match. In this example, the realm names do not match so the WSLogin is used to create a basic authentication Subject based on custom mapping rules. The custom mapping rules are specific to the customer environment and must be implemented using a realm to user ID and password mapping utility.
     e. Configure the RMI_OUTBOUND login configuration so that your new custom login module is first in the list.
        1) Click **Security > Global security**.
        2) Under Authentication, click **JAAS configuration > System logins > RMI_OUTBOUND**.
        3) Under Additional Properties, click **JAAS login modules > New** to add your login module to the RMI_OUTBOUND configuration.
        4) Return to the JAAS login modules panel for RMI_OUTBOUND and click **Set order** to change the order that the login modules are loaded so that your custom login is loaded first.
- Add the use_realm_callback and use_appcontext_callback options to the outbound mapping module for WSLogin. To add these options, complete the following steps:
  1. Click **Security > Global security**.
  2. Under Authentication, click **JAAS Configuration > Application logins > WSLogin**.
  3. Under Additional Properties, click **JAAS Login Modules > com.ibm.ws.security.common.auth.module.WSLoginModuleImpl**.
  4. Under Additional Properties, click **Custom Properties > New**.
  5. On the Custom Properties panel, enter `use_realm_callback` in the **Name** field and `true` in the **Value** field.
  6. Click **OK**.
  7. Click **New** to enter the second custom property.

8. On the Custom Properties panel, enter `use_appcontext_callback` in the **Name** field and `true` in the **Value** field.
9. Click **OK**.

The following changes are made to the `security.xml` file:

```
<entries xmi:id="JAASConfigurationEntry_2" alias="WSLogin">
 <loginModules xmi:id="JAASLoginModule_2"
  moduleClassName="com.ibm.ws.security.common.auth.module.proxy.WSLoginModuleProxy"
  authenticationStrategy="REQUIRED">
  <options xmi:id="Property_2" name="delegate"
   value="com.ibm.ws.security.common.auth.module.WSLoginModuleImpl"/>
  <options xmi:id="Property_3" name="use_realm_callback" value="true"/>
  <options xmi:id="Property_4" name="use_appcontext_callback" value="true"/>
 </loginModules>
</entries>
```

Example: Using the WSLogin configuration to create a basic authentication subject:

This example shows how to use the WSLogin application login configuration from within a Java 2 Platform, Enterprise Edition (J2EE) application to login and get a Subject that contains the user ID and the password of the target realm

```
 javax.security.auth.Subject subject = null;

try
{
  // Create a login context using the WSLogin login configuration and specify a
  // user ID, target realm, and password. Note: If the target_realm_name is the
  // same as the current realm, an authenticated Subject is created. However, if
  // the target_realm_name is different from the current realm, a basic
  // authentication Subject is created that is not validated. This unvalidated
  // Subject is created so that you can send a request to the different target
  // realm with valid security credentials for that realm.
  javax.security.auth.login.LoginContext ctx = new LoginContext("WSLogin",
   new WSCallbackHandlerImpl("userid", "target_realm_name", "password"));

  // Note: The following is an alternative that  validates the user ID and
  // password specified against the target realm. It will perform a remote call
  // to the target server and will return  true if the user ID and password are
  // valid and false if the user ID and password are invalid. If false is
  // returned, a WSLoginFailedException is thrown. You can catch that exception and
  // perform a retry or stop the request from flowing by allowing that exception to
  // surface out of this login.

  // ALTERNATIVE LOGIN CONTEXT THAT VALIDATES THE USER ID AND PASSWORD TO THE
  // TARGET REALM

  javax.security.auth.Subject basic_auth_subject = null;
}
```

Security attribute propagation

Security attribute propagation enables WebSphere Application Server to transport security attributes (authenticated Subject contents and security context information) from one server to another in your configuration. WebSphere Application Server might obtain these security attributes from either an enterprise user registry, which queries static attributes, or a custom login module, which can query static or dynamic attributes. Dynamic security attributes, which are custom in nature, might include the authentication strength used for the connection, the identity of the original caller, the location of the original caller, the IP address of the original caller, and so on.

Security attribute propagation provides propagation services using Java serialization for any objects that are contained in the Subject. However, Java code must be able to serialize and de-serialize these objects. The Java programming language specifies the rules for how Java code can serialize an object. Because problems can occur when dealing with different platforms and versions of software, WebSphere Application Server also offers a token framework that enables custom serialization functionality. The token framework has other benefits that include the ability to identify the uniqueness of the token. This uniqueness determines how the Subject gets cached and the purpose of the token. The token framework defines four marker token interfaces that enable the WebSphere Application Server run time to determine how to propagate the token.

Important: Any custom tokens that are used in this framework are not used by WebSphere Application Server for authorization or authentication. The framework serves as a way to notify WebSphere Application Server that you want these tokens propagated in a particular way. WebSphere Application Server handles the propagation details, but does not handle serialization or deserialization of custom tokens. Serialization and deserialization of these custom tokens are carried out by the implementation and handled by a custom login module.

With WebSphere Application Server 6.0 and later, a custom Java Authorization Contract for Container (JACC) provider can be configured to enforce access control for Java 2 Platform, Enterprise Edition (J2EE) applications. A custom JACC provider can explore the custom security attributes in the caller JAAS subject in making access control decisions.

When a request is being authenticated, a determination is made by the login modules whether this is an *initial login* or a *propagation login*. An initial login is the process of authenticating the user information, typically a user ID and password, and then calling the application programming interfaces (APIs) for the remote user registry to look up secure attributes that represent the user access rights. A propagation login is the process of validating the user information, typically an Lightweight Third Party Authentication (LTPA) token, and then deserializing a series of tokens that constitute both custom objects and token framework objects known to the WebSphere Application Server.

The following marker tokens are introduced in the framework:

Authorization token

The authorization token contains most of the authorization-related security attributes that are propagated. The default authorization token is used by the WebSphere Application Server authorization engine to make Java 2 Platform, Enterprise Edition (J2EE) authorization decisions. Service providers can use custom authorization token implementations to isolate their data in a different token; perform custom serialization and de-serialization; and make custom authorization decisions using the information in their token at the appropriate time. For information on how to use and implement this token type, see “Default PropagationToken” on page 1557 and “Implementing a custom PropagationToken” on page 1563.

Single signon (SSO) token

A custom SingleSignonToken token that is added to the Subject is automatically added to the response as an HTTP cookie and contains the attributes sent back to Web browsers. The token interface getName() method together with the getVersion method defines the cookie name. WebSphere Application Server defines a default SingleSignonToken with the LtpaToken name and version 2. The cookie name added is LtpaToken2. Do not add sensitive information, confidential information, or unencrypted data to the response cookie.

It is also recommended that any time that you use cookies, use the Secure Sockets Layer (SSL) protocol to protect the request. Using an SSO token, Web users can authenticate once when accessing Web resources across multiple WebSphere Application Servers. A custom SSO token extends this functionality by adding custom processing to the single signon scenario. For more information on SSO tokens, see “Configuring single signon” on page 1448. For information on how to use and implement this token type, see “Default SingleSignonToken” on page 1585 and “Implementing a custom SingleSignonToken” on page 1586.

Propagation token

The propagation token is not associated with the authenticated user so it is not stored in the Subject. Instead, the propagation token is stored on the thread and follows the invocation wherever it goes. When a request is sent outbound to another server, the propagation tokens on that thread are sent with the request and the tokens are executed by the target server. The attributes stored on the thread are propagated regardless of the Java 2 Platform, Enterprise Edition (J2EE) RunAs user switches.

The default propagation token monitors and logs all user switches and host switches. You can add additional information to the default propagation token using the WSSecurityHelper application programming interfaces (APIs). To retrieve and set custom implementations of a propagation token, you can use the WSSecurityPropagationHelper class. For information on how to use and implement this token type, see “Default PropagationToken” on page 1557 and “Implementing a custom PropagationToken” on page 1563.

Authentication token

The authentication token flows to downstream servers and contains the identity of the user. This token type serves the same function as the Lightweight Third Party Authentication (LTPA) token in previous versions. Although this token type is typically reserved for internal WebSphere Application Server purposes, you can add this token to the Subject and the token is propagated using the getBytes method of the token interface.

A custom authentication token is used solely for the purpose of the service provider that adds it to the Subject. WebSphere Application Server do not use it for authentication purposes, because a default authentication token exists that is used for WebSphere Application Server authentication. This token type is available for the service provider to identify the purpose of the custom data to use the token to perform custom authentication decisions. For information on how to use and implement this token type, see “Default AuthenticationToken” on page 1597 and “Implementing a custom AuthenticationToken” on page 1598.

Horizontal propagation versus downstream propagation

In WebSphere Application Server, both horizontal propagation, which is uses single signon for Web requests, and downstream propagation, which uses Remote Method Invocation over the Internet Inter-ORB Protocol (RMI/IIOP) to access enterprise beans, are available.

Horizontal propagation

In horizontal propagation, security attributes are propagated amongst front-end servers. The serialized security attributes, which are the Subject contents and the propagation tokens, can contain both static and dynamic attributes. The single signon (SSO) token stores additional system-specific information that is needed for horizontal propagation. The information contained in the SSO token tells the receiving server where the originating server is located and how to communicate with that server. Additionally, the SSO token also contains the key to look up the serialized attributes. In order to enable horizontal propagation, you must configure the single signon token and the Web inbound security attribute propagation features. You can configure both of these features using the administrative console by completing the following steps:

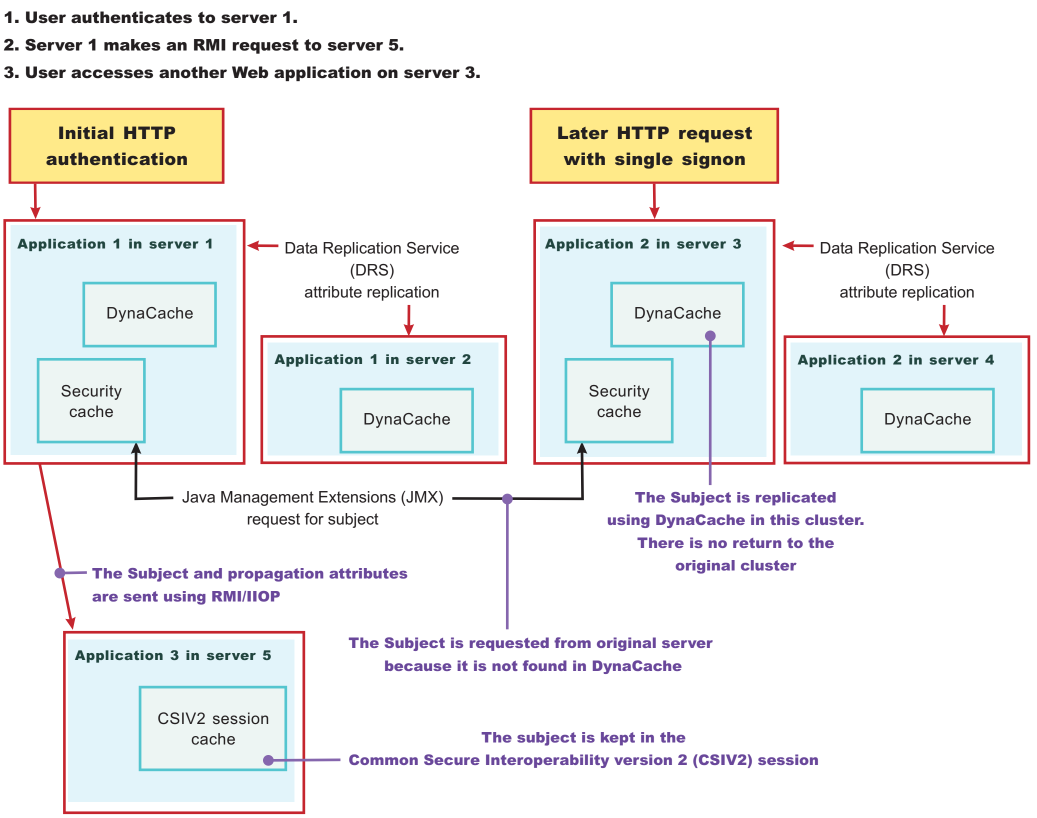
1. Click **Security > Global security**.
2. Under Authentication, click **Authentication Mechanisms > LTPA**.
3. Under Additional properties, click **Single signon (SSO)**

For more information, see “Enabling security attribute propagation” on page 1555.

When front-end servers are configured and in the same distributed replication service (DRS) replication domain, the application server automatically propagates the serialized information to all of the servers within the same domain. In figure 1, application 1 is deployed on server 1 and server 2, and both servers are members of the same DRS replication domain. If a request originates from application 1 on server 1 and then gets redirected to application 1 on server 2, the original login attributes are found on server 2 without additional remote requests. However, if the request originates from application 1 on either server 1 or server 2, but the request is redirected to application 2 on either server 1 or server 2, the serialized information is not found in the DRS cache because the servers are not configured in the same replication domain. As a result, a remote Java Management Extensions (JMX) request is sent back to the originating server that hosts application 1 to obtain the serialized information so that original login information is available to the application. By getting the serialized information using a single JMX remote call back to the originating server, the following benefits are realized:

- You gain the function of retrieving login information from the original server.
- You do not need to perform any remote user registry calls because the application server can regenerate the Subject from the serialized information. Without this ability, the application server might make 5 to 6 separate remote calls.

Figure 1



1. User authenticates to server 1.
2. Server 1 makes an RMI request to server 5.
3. User accesses another Web application on server 3.
Initial HTTP authentication
Later HTTP request with single signon
Application 1 in server 1
DynaCache
Security cache
Data Replication Service (DRS) attribute replication
Application 1 in server 2
DynaCache
Application 2 in server 3
DynaCache
Security cache
Data Replication Service (DRS) attribute replication
Application 2 in server 4
DynaCache
Java Management Extensions (JMX) request for subject
The Subject is replicated using DynaCache in this cluster. There is no return to the original cluster
The Subject and propagation attributes are sent using RMI/IIOP
Application 3 in server 5
CSIV2 session cache
The Subject is requested from original server because it is not found in DynaCache
The subject is kept in the Common Secure Interoperability version 2 (CSIV2) session

Performance implications for horizontal propagation

The performance implications of either the DRS or JMX remote call depends upon your environment. THE DRS or JMX remote call is used for obtaining the original login attributes. Horizontal propagation reduces many of the remote user registry calls in cases where these calls cause the most performance problems for an application. However, the de-serialization of these objects also might cause performance degradation, but this degradation might be less than the remote user registry calls. It is recommended that you test your environment with horizontal propagation enabled and disabled. In cases where you must use horizontal propagation for preserving original login attributes, test whether DRS or JMX provides better performance in your environment. Typically, it is recommended that you configure DRS both for failover and performance reasons. However, because DRS propagates the information to all of the servers in the same replication domain (whether the servers are accessed or not), there might be a performance degradation if too many servers are in the same replication domain. In this case, either reduce the number of servers in the replication domain or do not configure the servers in a DRS replication domain. The later suggestion causes a JMX remote call to retrieve the attributes, when needed, which might be quicker overall.

Downstream propagation

In *downstream propagation*, a Subject is generated at the Web front-end server, either by a propagation login or a user registry login. WebSphere Application Server propagates the security information downstream for enterprise bean invocations when both Remote Method Invocation (RMI) outbound and inbound propagation are enabled.

Benefits of propagating security attributes

The security attribute propagation feature of WebSphere Application Server has the following benefits:

- Enables WebSphere Application Server to use the security attribute information for authentication and authorization purposes. The propagation of security attributes can eliminate the need for user registry calls at each remote hop along an invocation. Previous versions of WebSphere Application Server propagated only the user name of the authenticated user, but ignored other security attribute information that needed to be regenerated downstream using remote user registry calls. To accentuate the benefits of this new functionality, consider the following example:

  In previous releases, you might use a reverse proxy server (RPSS), such as WebSEAL, to authenticate the user, gather group information, and gather other security attributes. As stated previously, WebSphere Application Server accepted the identity of the authenticated user, but disregarded the additional security attribute information. To create a Java Authentication and Authorization Service (JAAS) Subject containing the needed WSCredential and WSPrincipal objects, WebSphere Application Server made 5 to 6 calls to the user registry. The WSCredential object contains various security information that is required to authorize a J2EE resource. The WSPrincipal object contains the realm name and the user that represents the principal for the Subject.

  In the current release of the Application Server, information that is obtained from the reverse proxy server can be used by WebSphere Application Server and propagated downstream to other server resources without additional calls to the user registry. The retaining of the security attribute information enables you to protect server resources properly by making appropriate authorization and trust-based decisions User switches that occur because of J2EE RunAs configurations do not cause the application server to lose the original caller information. This information is stored in the PropagationToken located on the running thread.
- Enables third-party providers to plug in custom tokens. The token interface contains a getBytes method that enables the token implementation to define custom serialization, encryption methods, or both.
- Provides the ability to have multiple tokens of the same type within a Subject created by different providers. WebSphere Application Server can handle multiple tokens for the same purpose. For example, you might have multiple authorization tokens in the Subject and each token might have distinct authorization attributes that are generated by different providers.
- Provides the ability to have a unique ID for each token type that is used to formulate a more unique subject identifier than just the user name in cases where dynamic attributes might change the context of a user login. The token type has a getUniqueId() method that is used for returning a unique string for caching purposes. For example, you might need to propagate a location ID, which indicates the location from which the user logs into the system. This location ID can be generated during the original login using either an reverse proxy server or the WEB_INBOUND login configuration and added to the Subject prior to serialization. Other attributes might be added to the Subject as well and use a unique ID. All of the unique IDs must be considered for the uniqueness of the entire Subject. WebSphere Application Server has the ability to specify what is unique about the information in the Subject, which might affect how the user accesses the Subject later.

Enabling security attribute propagation

The security attribute propagation feature of WebSphere Application Server enables you to send security attribute information regarding the original login to other servers using a token. To fully enable security attribute propagation, you must configure the single signon (SSO), CSIv2 inbound, and CSIv2 outbound panels in the WebSphere Application Server Administrative Console. You can enable just the portions of security attribute propagation relevant to your configuration. For example, you can enable Web propagation, which is propagation amongst front-end application servers, using either the push technique (DynaCache) or the pull technique (remote method to originating server). You also can choose whether to enable Remote Method Invocation (RMI) outbound and inbound propagation, which is commonly called downstream propagation. Typically both types of propagation are enabled for any given cell. In some cases, you might want to choose a different option for a specific application server using the server security panel within the specific application server settings. To access the server security panel in the administrative console, click **Servers > Application Servers > *server_name***. Under Security, click **Server security**. Under Additional properties, click **Server-level security**.

Complete the following steps to configure WebSphere Application Server for security attribute propagation:

1. Access the WebSphere Application Server administrative console by typing http://*server_name*:9060/ibm/console The administrative console address might differ if you have previously changed the port number.
2. Click **Security > Global security**. Under Authentication, click **Authentication mechanisms > LTPA**. Under Additional Properties, click **Single Signon (SSO)**.
3. **Optional:** Select the **Interoperability Mode** option if you need to interoperate with servers that do not support security attribute propagation. Servers that do not support security attribute propagation receive the Lightweight Third Party Authentication (LTPA) token and the PropagationToken, but ignore the security attribute information that it does not understand.
4. Select the **Web inbound security attribute propagation** option. The **Web inbound security attribute propagation** option enables horizontal propagation, which allows the receiving SSO token to retrieve the login information from the original login server. If you do not enable this option, downstream propagation can occur if you enable the **Security Attribute Propagation** option on both the CSIv2 Inbound authentication and CSIv2 outbound authentication panels.

   Typically, you enable the **Web inbound security attribute propagation** option if you need to gather dynamic security attributes set at the original login server that cannot be regenerated at the new front-end server. This attributes include any custom attributes that might be set in the PropagationToken using the com.ibm.websphere.security.WSSecurityHelper application programming interfaces (APIs). You must determine whether enabling this option improves or degrades the performance of your system. While the option prevents some remote user registry calls, the deserialization and decryption of some tokens might impact performance. In some cases, propagation is faster especially if your user registry is the bottleneck of your topology. It is recommended that you measurement the performance of your environment using and not using this option. When you test the performance, it is recommended that you test in the operating environment of the typical production environment with the typical number of unique users accessing the system simultaneously.
5. Click **Security > Global security**. Under Authentication, click **Authentication protocol > CSIv2 inbound authentication**. The Login configuration field specifies `RMI_INBOUND` as the system login configuration used for inbound requests. To add custom Java Authentication and Authorization Service (JAAS) login modules, complete the following steps:
   a. Click **Security > Global security**. Under Authentication, click **JAAS Configuration > System logins**. A list of the system login configurations is displayed. WebSphere Application Server provides the following pre-configured system login configurations: DEFAULT, LTPA, LTPA_WEB, RMI_INBOUND, RMI_OUTBOUND, SWAM, WEB_INBOUND, wssecurity.IDAssertion, and wssecurity.Signature. Do not delete these predefined configurations.
   b. Click the name of the login configuration that you want to modify.
   c. Under Additional Properties, click **JAAS Login Modules**. The JAAS Login Modules panel is displayed, which lists all of the login modules processed in the login configuration. Do not delete the required JAAS login modules. Instead, you can add custom login modules before or after the required login modules. If you add custom login modules, do not begin their names with com.ibm.ws.security.server because this prefix is reserved for WebSphere Application Server internal use.

      You can specify the order in which the login modules are processed by clicking **Set Order**.
6. Select the **Security attribute propagation** option on the CSIv2 Inbound authentication panel. When you select **Security Attribute Propagation**, the server advertises to other application servers that it can receive propagated security attributes from another server in the same realm over the Common Secure Interoperability version 2 (CSIv2) protocol.
7. Click **Security**. Under Authentication, click **Authentication protocol > CSIv2 Outbound authentication**. The CSIv2 outbound authentication panel is displayed. The **Login configuration** field specifies `RMI_OUTBOUND` as JAAS login configuration that is used for outbound configuration. You cannot change this login configuration. Instead, you can customize this login configuration by completing the substeps listed previously for CSIv2 Inbound authentication.
8. **Optional:** Verify that the **Security Attribute Propagation** option is selected if you want to enable outbound Subject and security context token propagation for the Remote Method Invocation (RMI)

protocol. When you select this option, WebSphere Application Server serializes the Subject contents and the PropagationToken contents. After the contents are serialized, the server uses the Common Secure Interoperability version 2 (CSIv2) protocol to send the Subject and PropagationToken to the target servers that support security attribute propagation. If the receiving server does not support security attribute tokens, WebSphere Application Server sends the Lightweight Third Party Authentication (LTPA) token only.

Important: WebSphere Application Server propagates only the objects within the Subject that it can serialize. The server propagates custom objects on a best-effort basis.

When **Security Attribute Propagation** is enabled, WebSphere Application Server adds marker tokens to the Subject to enable the target server to add additional attributes during the inbound login. During the commit phase of the login, the marker tokens and the Subject are marked as read-only and cannot be modified thereafter.

9. **Optional:** Select the **Custom Outbound Mapping** option if you deselect the **Security Attribute Propagation** option and you want to use the RMI_OUTBOUND login configuration. If the **Custom Outbound Mapping** option nor the **Security Attribute Propagation** option is selected, WebSphere Application Server does not call the RMI_OUTBOUND login configuration. If you need to plug in a credential mapping login module, you must select the **Custom Outbound Mapping** option.
10. **Optional:** Specify trusted target realm names in the **Trusted Target Realms** field. By specifying these realm names, information can be sent to servers that reside outside the realm of the sending server to allow for inbound mapping to occur at these downstream servers. To perform outbound mapping to a realm different from the current realm, you must specify the realm in this field so that you can get to this point without the request being rejected due to a realm mismatch. If you need WebSphere Application Server to propagate security attributes to another realm when a request is sent, you must specify the realm name in the **Trusted Target Realms** field. Otherwise, the security attributes are not propagated to the unspecified realm. You can add multiple target realms by adding a pipe (|) delimiter between each entry.
11. **Optional:** Enable propagation for a pure client. For a pure client to propagate attributes added to the invocation Subject, you must add the following property to the `sas.client.props` file:

```
com.ibm.CSI.rmiOutboundPropagationEnabled=true
```

After completing these steps, you have configured WebSphere Application Server to propagate security attributes to other servers. After you have configured WebSphere Application Server for security attribute propagation and need to disable this functionality, you can disable propagation for either the server level or the cell level. To disable security attribute propagation on the server level, click **Server > Application Servers >***server_name*. Under Security, click **Server security**. You can disable security attribute propagation for inbound requests by clicking **CSI inbound authentication** under Additional Properties and deselecting **Security attribute propagation**. You can disable security attribute propagation for outbound requests by clicking **CSI outbound authentication** under Additional Properties and deselecting **Security attribute propagation**. To disable security attribute propagation on the cell level, undo each of the steps that you completed to enable security attribute propagation in this task.

Default PropagationToken

A default PropagationToken is located on the thread of execution for applications and the security infrastructure to use. WebSphere Application Server propagates this default PropagationToken downstream and the token stays on the thread where the invocation lands at each hop. The data should be available from within the container of any resource where the PropagationToken lands. Remember that you must enable the propagation feature at each server where a request is sent in order for propagation to work. Make sure that you have enabled security attribute propagation for all of the cells in your environment where you want propagation

There is a WSSecurityHelper class that has application programming interfaces (APIs) for accessing the PropagationToken attributes. This article documents the usage scenarios and includes examples. A close relationship exists between PropagationToken and the WorkArea feature. The main difference between these features is that after you add attributes to the PropagationToken, you cannot change the attributes. You cannot change these attributes so that the security run time can add auditable information and have that information remain there for the life of the invocation. Any time that you add an attribute to a specific key, an ArrayList is stored to hold that attribute. Any new attribute added with the same key is added to the ArrayList. When you call getAttributes, the ArrayList is converted to a String[] and the order is preserved. The first element in the String[] is the first attribute added for that specific key.

In the default PropagationToken, a change flag is kept that logs any data changes to the token. These changes are tracked to enable WebSphere Application Server to know when to re-send the authentication information downstream so that the downstream server has those changes. Normally, Common Secure Interoperability Version 2 (CSIv2) maintains a session between servers for an authenticated client. If the PropagationToken changes, a new session is generated and subsequently a new authentication occurs. Frequent changes to the PropagationToken during a method causes frequent downstream calls. If you change the token prior to making many downstream calls, but you change the token between each downstream call, you might impact security performance.

Getting the server list from the default PropagationToken

Every time the PropagationToken is propagated and used to create the authenticated Subject, either horizontally or downstream, the name of the receiving application server is logged into the PropagationToken. The format of the host is ″Cell:Node:Server″, which provides you access to the cell name, node name, and server name of each application server that receives the invocation. The following code provides you with this list of names and can be called from a Java 2 Platform, Enterprise Edition (J2EE) application:

```
String[] server_list = null;

// If security is disabled on this application server, do not bother checking
if (com.ibm.websphere.security.WSSecurityHelper.isServerSecurityEnabled())
{
 try
 {
  // Gets the server_list string array
  server_list = com.ibm.websphere.security.WSSecurityHelper.getServerList();
 }
 catch (Exception e)
 {
  // Performs normal exception handling for your application
 }

 if (server_list != null)
 {
  // print out each server in the list, server_list[0] is the first server
  for (int i=0; i<server_list.length; i++)
  {
   System.out.println(″Server[″ + i + ″] = ″ + server_list[i]);
  }
 }
}
```

The format of each server in the list is: *cell*:*node*:*server*. The output, for example, is:

```
myManager:node1:server1
```

Getting the caller list from the default PropagationToken

A default PropagationToken is generated any time an authenticated user is set on the thread of execution or any one tries to add attributes to the PropagationToken. Whenever an authenticated user is set on the thread, the user is logged in the default PropagationToken. There may be some pushing and popping of Subjects by the authorization code. At times, the same user might be logged in multiple times if the RunAs user is different from the caller. The following list provides the rules that are used to determine if a user added to the thread gets logged into the PropagationToken:

- The current Subject must be authenticated. For example, an unauthenticated Subject is not logged.
- The current authenticated Subject is logged if a Subject has not been previously logged.
- The current authenticated Subject is logged if the last authenticated Subject logged does not contain the same user.
- The current authenticated Subject is logged on each unique application server involved in the propagation process.

The following code sample shows how to use the getCallerList() API:

```
String[] caller_list = null;

// If security is disabled on this application server, do not check the caller list
if (com.ibm.websphere.security.WSSecurityHelper.isServerSecurityEnabled())
{
 try
 {
  // Gets the caller_list string array
  caller_list = com.ibm.websphere.security.WSSecurityHelper.getCallerList();
 }
 catch (Exception e)
 {
  // Performs normal exception handling for your application
 }

 if (caller_list != null)
 {
  // Prints out each caller in the list, caller_list[0] is the first caller
  for (int i=0; i<caller_list.length;i++)
  {
   System.out.println("Caller[" + i + "] = " + caller_list[i]);
  }
 }
}
```

The format of each caller in the list is: *cell*:*node*:*server*:*realm*/*securityName*. The output, for example, is: `myManager:node1:server1:ldap.austin.ibm.com:389/jsmith`.

Getting the first caller from the default PropagationToken

Whenever you want to know which authenticated caller started the request, you can call the getFirstCaller method and the caller list is parsed. However, this method returns the securityName of the caller only. If you need to know more than the securityName, call the getCallerList() method and retrieve the first entry in the String[]. This entry provides the entire caller information. The following code sample retrieves the securityName of the first authenticated caller using the getFirstCaller() API:

```
String first_caller = null;
```

```
// If security is disabled on this application server, do not bother checking
if (com.ibm.websphere.security.WSSecurityHelper.isServerSecurityEnabled())
{
 try
 {
  // Gets the first caller
  first_caller = com.ibm.websphere.security.WSSecurityHelper.getFirstCaller();

  // Prints out the caller name
  System.out.println("First caller: " + first_caller);
 }
 catch (Exception e)
 {
  // Performs normal exception handling for your application
 }
}
```

The output, for example, is: `jsmith`.

Getting the first host from the default PropagationToken

Whenever you want to know what the first application server is for this request, you can call the getFirstServer() method directly. The following code sample retrieves the name of the first application server using the getFirstServer() API:

```
String first_server = null;

// If security is disabled on this application server, do not bother checking
if (com.ibm.websphere.security.WSSecurityHelper.isServerSecurityEnabled())
{
 try
 {
  // Gets the first server
  first_server = com.ibm.websphere.security.WSSecurityHelper.getFirstServer();

  // Prints out the server name
  System.out.println("First server: " + first_server);
 }
 catch (Exception e)
 {
  // Performs normal exception handling for your application
 }
}
```

The output, for example, is: `myManager:node1:server1`.

Adding custom attributes to the default PropagationToken

You can add custom attributes to the default PropagationToken for application usage. This token follows the request downstream so that the attributes are available when they are needed. When you use the default PropagationToken to add attributes, you must understand the following issues:

- When you add information to the PropagationToken, it affects CSIv2 session caching. Add information sparingly between remote requests.
- After you add information with a specific key, the information cannot be removed.

- You can add as many values to a specific key as your need. However, all of the values must be available from a returned String[] in the order they were added.
- The PropagationToken is available only on servers where propagation and security are enabled.
- The Java 2 Security javax.security.auth.AuthPermission wssecurity.addPropagationAttribute is needed to add attributes to the default PropagationToken.
- An application cannot use keys that begin with either com.ibm.websphere.security or com.ibm.wsspi.security. These prefixes are reserved for system usage.

The following code sample shows how to use the addPropagationAttribute API:

```
// If security is disabled on this application server,
    // do not check the status of server security
if (com.ibm.websphere.security.WSSecurityHelper.isServerSecurityEnabled())
{
 try
 {
  // Specifies the key and values
  String key = "mykey";
  String value1 = "value1";
  String value2 = "value2";

  // Sets key, value1
      com.ibm.websphere.security.WSSecurityHelper.
      addPropagationAttribute (key, value1);

  // Sets key, value2
  String[] previous_values = com.ibm.websphere.security.WSSecurityHelper.
         addPropagationAttribute (key, value2);

  // Note: previous_values should contain value1
 }
 catch (Exception e)
 {
  // Performs normal exception handling for your application
 }
}
```

See “Getting custom attributes from the default PropagationToken” to retrieve attributes using the getPropagationAttributes application programming interface (API).

Getting custom attributes from the default PropagationToken

Custom attributes are added to the default PropagationToken using the addPropagationAttribute API. These attributes can be retrieved using the getPropagationAttributes API. This token follows the request downstream so the attributes are available when they are needed. When you use the default PropagationToken to retrieve attributes, you must understand the following issues.

- The PropagationToken is available only on servers where propagation and security are enabled.
- The Java 2 Security javax.security.auth.AuthPermission wssecurity.getPropagationAttributes is needed to retrieve attributes from the default PropagationToken.

The following code sample shows how to use the getPropagationAttributes API:

```
// If security is disabled on this application server, do not bother checking
if (com.ibm.websphere.security.WSSecurityHelper.isServerSecurityEnabled())
{
 try
 {
  String key = "mykey";
  String[] values = null;

  // Sets key, value1
      values = com.ibm.websphere.security.WSSecurityHelper.
      getPropagationAttributes (key);

  // Prints the values
  for (int i=0; i<values.length; i++)
  {
   System.out.println("Value[" + i + "] = " + values[i]);
  }
 }
 catch (Exception e)
 {
  // Performs normal exception handling for your application
 }
}
```

The output, for example, is:

```
Value[0] = value1
Value[1] = value2
```

See Adding custom attributes to the default PropagationToken to add attributes using the addPropagationAttributes API.

Changing the TokenFactory associated with the default PropagationToken

When WebSphere Application Server generates a default PropagationToken, the application server utilizes the TokenFactory class that is specified using the com.ibm.wsspi.security.token.propagationTokenFactory property. To modify this property using the administrative console, complete the following steps:

1. Click **Security > Global Security**.
2. Under Additional properties, click **Custom properties**.

The default TokenFactory specified for this property is called com.ibm.ws.security.ltpa.AuthzPropTokenFactory. This token factory encodes the data in the PropagationToken and does not encrypt the data. Because the PropagationToken typically flows over Common Secure Interoperability version 2 (CSIv2) using Secure Sockets Layer (SSL), there is no need to encrypt the token itself. However, if you need additional security for the PropagationToken, you can associate a different TokenFactory implementation with this property to get encryption. For example, if you choose to associate com.ibm.ws.security.ltpa.LTPAToken2Factory with this property, the token is AES encrypted. However, you need to weigh the performance impacts against your security needs. Adding sensitive information to the PropagationToken is a good reason to change the TokenFactory implementation to something that encrypts rather than just encodes.

If you want to perform your own signing and encryption of the default PropagationToken, you must implement the following classes:

- com.ibm.wsspi.security.ltpa.Token
- com.ibm.wsspi.security.ltpa.TokenFactory

Your TokenFactory implementation instantiates and validates your token implementation. You can choose to use the Lightweight Third Party Authentication (LTPA) keys passed into the initialize method of the

TokenFactory or you can use your own keys. If you use your own keys, they must be the same everywhere in order to validate the tokens that are generated using those keys. See the Javadoc, available through a link on the front page of the information center, for more information on implementing your own custom TokenFactory. To associate your TokenFactory with the default PropagationToken, using the administrative console, complete the following steps:

1. Click **Security > Global Security**.
2. Under Additional properties, click **Custom properties**.
3. Locate the com.ibm.wsspi.security.token.propagationTokenFactory property and verify that the value of this property matches your custom TokenFactory implementation.
4. Verify that your implementation classes are put into the `install directory/classes` directory so that the WebSphere class loader can load the classes.

Implementing a custom PropagationToken

This task explains how you might create your own PropagationToken implementation, which is set on the thread of execution and propagated downstream. The default PropagationToken usually is sufficient for propagating attributes that are not user-specific. Consider writing your own implementation if you want to accomplish one of the following tasks:

- Isolate your attributes within your own implementation.
- Serialize the information using custom serialization. You must deserialize the bytes at the target and add that information back on the thread by plugging in a custom login module into the inbound system login configurations. This task also might include encryption and decryption.

To implement a custom Propagation token, you must complete the following steps:

1. Write a custom implementation of the PropagationToken interface. There are many different methods for implementing the PropagationToken interface. However, make sure that the methods required by the PropagationToken interface and the token interface are fully implemented. After you implement this interface, you can place it in the `install_dir/classes` directory. Alternatively, you can place the class in any private directory. However, make sure that the WebSphere Application Server class loader can locate the class and that it is granted the appropriate permissions. You can add the Java archive (JAR) file or directory that contains this class into the `server.policy` file so that it has the necessary permissions that are needed by the server code.

   Tip: All of the token types defined by the propagation framework have similar interfaces. Basically, the token types are marker interfaces that implement the com.ibm.wsspi.security.token.Token interface. This interface defines most of the methods. If you plan to implement more than one token type, consider creating an abstract class that implements the com.ibm.wsspi.security.token.Token interface. All of your token implementations, including the PropagationToken, might extend the abstract class and then most of the work is completed.

   To see an implementation of PropagationToken, see “Example: com.ibm.wsspi.security.token.PropagationToken implementation” on page 1564
2. Add and receive the custom PropagationToken during WebSphere Application Server logins This task is typically accomplished by adding a custom login module to the various application and system login configurations. You also can add the implementation from an application. However, in order to deserialize the information, you will need to plug in a custom login module, which is discussed in “Propagating a custom Java serializable object” on page 1602. The WSSecurityPropagationHelper class has APIs that are used to set a PropagationToken on the thread and to retrieve it from the thread to make updates.

   The code sample in “Example: custom PropagationToken login module” on page 1570 shows how to determine if the login is an initial login or a propagation login. The difference between these login types is whether the WSTokenHolderCallback contains propagation data. If the callback does not contain propagation data, initialize a new custom PropagationToken implementation and set it on the thread. If the callback contains propagation data, look for your specific custom PropagationToken TokenHolder instance, convert the byte[] back into your customer PropagationToken object, and set it back on the thread. The code sample shows both instances.

You can add attributes any time your custom PropagationToken is added to the thread. If you add attributes between requests and the getUniqueId method changes, then the CSIv2 client session is invalidated so that it can send the new information downstream. Keep in mind that adding attributes between requests can affect performance. In many cases, this is the desired behavior so that downstream requests receive the new PropagationToken information.

To add the custom PropagationToken to the thread, call WSSecurityPropagationHelper.addPropagationToken. This call requires the following Java 2 Security permission: WebSphereRuntimePerMission ″setPropagationToken″

3. Add your custom login module to WebSphere Application Server system login configurations that already contain the com.ibm.ws.security.server.lm.wsMapDefaultInboundLoginModule for receiving serialized versions of your custom propagation token Also, you can add this login module to any of the application logins where you might want to generate your custom PropagationToken on the thread during the login. Alternatively, you can generate the custom PropagationToken implementation from within your application. However, to deserialize it, you need to add the implementation to the system login modules.

   For information on how to add your custom login module to the existing login configurations, see ″Custom login module development for a system login configuration″ in the information center.

After completing these steps, you have implemented a custom PropagationToken.

Example: com.ibm.wsspi.security.token.PropagationToken implementation:

Use this file to see an example of a PropagationToken implementation. The following sample code does not extend an abstract class, but rather implements the com.ibm.wsspi.security.token.PropagationToken interface directly. You can implement the interface directly, but it might cause you to write duplicate code. However, you might choose to implement the interface directly if there are considerable differences between how you handle the various token implementations.

For information on how to implement a custom PropagationToken, see “Implementing a custom PropagationToken” on page 1563.

Example: custom PropagationToken login module:

This file shows how to determine if the login is an initial login or a propagation login

```
public customLoginModule()
{
 public void initialize(Subject subject, CallbackHandler callbackHandler,
         Map sharedState, Map options)
 {
  // (For more information on what to do during initialization, see
     // "Custom login module development for a system login configuration"
  // in the information center.
 }

 public boolean login() throws LoginException
 {
  // (For more information on what to do during login, see
     // "Custom login module development for a system login configuration"
  // in the information center.

  // Handles the WSTokenHolderCallback to see if this is an initial
     // or propagation login.
  Callback callbacks[] = new Callback[1];
  callbacks[0] = new WSTokenHolderCallback("Authz Token List: ");

  try
  {
   callbackHandler.handle(callbacks);
  }
  catch (Exception e)
  {
   // handle exception
  }

  // Receives the ArrayList of TokenHolder objects (the serialized tokens)
  List authzTokenList = ((WSTokenHolderCallback) callbacks[0]).getTokenHolderList();

  if (authzTokenList != null)
  {
   // Iterates through the list looking for your custom token
   for (int i=0; i<authzTokenList.size(); i++)
   {
    TokenHolder tokenHolder = (TokenHolder)authzTokenList.get(i);

    // Looks for the name and version of your custom PropagationToken implementation
    if (tokenHolder.getName().equals(″
              com.ibm.websphere.security.token.CustomPropagationTokenImpl″) &&
        tokenHolder.getVersion() == 1)
    {
     // Passes the bytes into your custom PropagationToken constructor
            //  to deserialize
     customPropToken = new
      com.ibm.websphere.security.token.CustomPropagationTokenImpl(tokenHolder.
                  getBytes());

    }
   }
  }
  else // This is not a propagation login. Create a new instance of
          // your PropagationToken implementation
  {
   // Adds a new custom propagation token. This is an initial login
   customPropToken = new com.ibm.websphere.security.token.CustomPropagationTokenImpl();

   // Adds any initial attributes
   if (customPropToken != null)
   {
    customPropToken.addAttribute(″key1″, ″value1″);
    customPropToken.addAttribute(″key1″, ″value2″);
    customPropToken.addAttribute(″key2″, ″value1″);
    customPropToken.addAttribute(″key3″, ″something different″);
   }
  }

  // Note: You can add the token to the thread during commit in case
     // something happens during the login.
 }

 public boolean commit() throws LoginException
 {
  // For more information on what to do during commit, see
     // ″Custom login module development for a system login configuration″
  // in the information center.
  if (customPropToken != null)
  {
   // Sets the propagation token on the thread
   try
   {

    System.out.println(tc, ″*** ADDED MY CUSTOM PROPAGATION TOKEN TO THE THREAD ***″);
    // Prints out the values in the deserialized propagation token
```

```
    java.util.Enumeration keys = customPropToken.getAttributeNames();
    while (keys.hasMoreElements())
    {
     String key = (String) keys.nextElement();
     String[] list = (String[]) customPropToken.getAttributes(key);
     for (int k=0; k<list.length; k++)
     System.out.println("Key/Value: " + key + "/" + list[k]);
    }

    // This sets it on the thread using getName() + getVersion() as the key
    com.ibm.wsspi.security.token.WSSecurityPropagationHelper.addPropagationToken(
              customPropToken);
   }
   catch (Exception e)
   {
    // Handles exception
   }

   // Now you can verify that you have set it properly by trying to get
       // it back from the thread and print the values.
   try
   {
    // This gets the PropagationToken from the thread using getName()
          // and getVersion() parameters.
    com.ibm.wsspi.security.token.PropagationToken tempPropagationToken =
     com.ibm.wsspi.security.token.WSSecurityPropagationHelper.getPropagationToken
      ("com.ibm.websphere.security.token.CustomPropagationTokenImpl", 1);

    if  (tempPropagationToken != null)
    {
     System.out.println(tc, "*** RECEIVED MY CUSTOM PROPAGATION

Default AuthorizationToken

This article explains how WebSphere Application Server uses the default AuthorizationToken. Consider using the default AuthorizationToken when you are looking for a place to add string attributes that will get propagated downstream. However, make sure that the attributes that you add to the AuthorizationToken are specific to the user associated with the authenticated Subject. If they are not specific to a user, the attributes probably belong in the PropagationToken, which is also propagated with the request. For more information on the PropagationToken, see "Default PropagationToken" on page 1557. To add attributes into the AuthorizationToken, you must plug in a custom login module into the various system login modules that are configured. Any login module configuration that has the com.ibm.ws.security.server.lm.wsMapDefaultInboundLoginModule implementation configured can receive propagated information and can generate propagation information that can be sent outbound to another server.

If propagated attributes are not presented to the login configuration during an initial login, a default AuthorizationToken is created in the wsMapDefaultInboundLoginModule after the login occurs in the ltpaLoginModule. A reference to the default AuthorizationToken can be obtained from the login() method using the sharedState hashmap. You must plug in the custom login module after the wsMapDefaultInboundLoginModule implementation for WebSphere Application Server to see the default AuthorizationToken..

For more information on the Java Authentication and Authorization Service (JAAS) programming model, see ″Security: Resources for learning″ in the information center.

Important: Whenever you plug in a custom login module into the WebSphere Application Server login infrastructure, you must ensure that the code is trusted. When you add the login module into the *install_dir*/classes directory, it has Java 2 Security AllPermissions. It is recommended that you add your login module and other infrastructure classes into a private directory. However, if you use a private directory, modify the $(WAS_INSTALL_ROOT)/properties/server.policy file so that the private directory, Java archive (JAR) file, or both have the permissions needed to execute the application programming interfaces (API) called from the login module. Because the login module might run after the application code on the call stack, you might consider adding a doPrivileged code block so that you do not need to add additional permissions to your applications.

The following sample code shows you how to obtain a reference to the default AuthorizationToken from the login() method, how to add attributes to the token, and how to read from the existing attributes that are used for authorization.

```
public customLoginModule()
{
 public void initialize(Subject subject, CallbackHandler callbackHandler,
          Map sharedState, Map options)
 {
     // (For more information on initialization, see
     // ″Custom login module development for a system login configuration″
  // in the information center.

  // Get a reference to the sharedState map that is passed in during initialization.
  _sharedState = sharedState;
 }

 public boolean login() throws LoginException
 {
     // (For more information on what to during login, see
     // ″Custom login module development for a system login configuration″
  // in the information center.

  // Look for the default AuthorizationToken in the shared state
  defaultAuthzToken  = (com.ibm.wsspi.security.token.AuthorizationToken)
       sharedState.get
     (com.ibm.wsspi.security.auth.callback.Constants.WSAUTHZTOKEN_KEY);

  // Might not always have one of these generated. It depends on the login
     // configuration setup.
  if (defaultAuthzToken != null)
  {
   try
   {
    // Add a custom attribute
    defaultAuthzToken.addAttribute(″key1″, ″value1″);

    // Determine all of the attributes and values that exist in the token.
    java.util.Enumeration listOfAttributes = defaultAuthorizationToken.
              getAttributeNames();

    while (listOfAttributes.hasMoreElements())
    {
     String key = (String) listOfAttributes.nextElement();

     String[] values = (String[]) defaultAuthorizationToken.getAttributes (key);

     for (int i=0;  i<values.length; i++)
     {
      System.out.println (″Key: ″ + key + ″, Value[″ + i + ″]: ″
                  + values[i]);
     }
    }

    // Read the existing uniqueID attribute.
    String[]  uniqueID = defaultAuthzToken.getAttributes
      (com.ibm.wsspi.security.token.AttributeNameConstants.
               WSCREDENTIAL_UNIQUEID);

     // Getthe uniqueID from the String[]
     String unique_id = (uniqueID != null &&
                uniqueID[0] != null) ? uniqueID[0] : ″″;

    // Read the existing expiration attribute.
    String[]  expiration = defaultAuthzToken.getAttributes
      (com.ibm.wsspi.security.token.AttributeNameConstants.
               WSCREDENTIAL_EXPIRATION);

     // An example of getting a long expiration value from the string array.
     long expire_time = 0;
     if (expiration != null && expiration[0] != null)
      expire_time = Long.parseLong(expiration[0]);

    // Read the existing display name attribute.
    String[]  securityName = defaultAuthzToken.getAttributes
      (com.ibm.wsspi.security.token.AttributeNameConstants.
               WSCREDENTIAL_SECURITYNAME);
     // Get the display name from the String[]
     String display_name = (securityName != null &&
                securityName[0] != null) ? securityName[0] : "";

    // Read the existing long securityName attribute.

Changing the TokenFactory associated with the default AuthorizationToken

When WebSphere Application Server generates a default AuthorizationToken, the application server utilizes the TokenFactory class that is specified using the com.ibm.wsspi.security.token.authorizationTokenFactory property. To modify this property using the administrative console, complete the following steps:

1. Click **Security > Global Security**.
2. Under Additional properties, click **Custom properties**.

The default TokenFactory that used is called com.ibm.ws.security.ltpa.AuthzPropTokenFactory. This token factory encodes the data, but does not encrypt the data in the AuthorizationToken. Because the AuthorizationToken typically flows over Common Secure Interoperability version 2 (CSIv2) using Secure Sockets Layer (SSL), there is no need to encrypt the token itself. However, if you need addition security for the AuthorizationToken, you can associate a different TokenFactory implementation with this property to get encryption. For example, if you associate com.ibm.ws.security.ltpa.LTPAToken2Factory with this property, the token uses AES encryption. However, you need to weigh the performance impacts against your security needs. Adding sensitive information to the AuthorizationToken is one reason to change the TokenFactory implementation to something that encrypts rather than just encodes.

If you want to perform your own signing and encryption of the default AuthorizationToken you must implement the following classes:

- com.ibm.wsspi.security.ltpa.Token
- com.ibm.wsspi.security.ltpa.TokenFactory

Your TokenFactory implementation instantiates and validates your token implementation. You can use the Lightweight Third Party Authentication (LTPA) keys that are passed into the initialize method of the TokenFactory or you can use your own keys. If you use your own keys, they must be the same everywhere in order to validate the tokens that are generated using those keys. See the Javadoc, available through a link on the front page of the information center, for more information on implementing your own custom TokenFactory. To associate your TokenFactory with the default AuthorizationToken, using the administrative console, complete the following steps:

1. Click **Security > Global Security**.
2. Under Additional properties, click **Custom properties**.
3. Locate the com.ibm.wsspi.security.token.authorizationTokenFactory property and verify that the value of this property matches your custom TokenFactory implementation.
4. Verify that your implementation classes are put into the *install directory*/`classes` directory so that the WebSphere class loader can load the classes.

Implementing a custom AuthorizationToken

This task explains how you might create your own AuthorizationToken implementation, which is set in the login Subject and propagated downstream. The default AuthorizationToken usually is sufficient for propagating attributes that are user-specific. Consider writing your own implementation if you want to accomplish one of the following tasks:

- Isolate your attributes within your own implementation.
- Serialize the information using custom serialization. You must deserialize the bytes at the target and add that information back on the thread. This task also might include encryption and decryption.
- Affect the overall uniqueness of the Subject using the getUniqueID() API.

To implement a custom authorization token, you must complete the following steps:

1. Write a custom implementation of the AuthorizationToken interface. There are many different methods for implementing the AuthorizationToken interface. However, make sure that the methods required by the AuthorizationToken interface and the token interface are fully implemented. After you implement

this interface, you can place it in the *install_dir*/classes directory. Alternatively, you can place the class in any private directory. However, make sure that the WebSphere Application Server class loader can locate the class and that it is granted the appropriate permissions. You can add the Java archive (JAR) file or directory that contains this class into the server.policy file so that it has the necessary permissions that are needed by the server code.

Tip: All of the token types defined by the propagation framework have similar interfaces. Basically, the token types are marker interfaces that implement the com.ibm.wsspi.security.token.Token interface. This interface defines most of the methods. If you plan to implement more than one token type, consider creating an abstract class that implements the com.ibm.wsspi.security.token.Token interface. All of your token implementations, including the AuthorizationToken, might extend the abstract class and then most of the work is completed.

To see an implementation of AuthorizationToken, see "Example: com.ibm.wsspi.security.token.AuthorizationToken implementation"

2. Add and receive the custom AuthorizationToken during WebSphere Application Server logins This task is typically accomplished by adding a custom login module to the various application and system login configurations. However, in order to deserialize the information, you must plug in a custom login module, which is discussed in "Propagating a custom Java serializable object" on page 1602. After the object is instantiated in the login module, you can the object to the Subject during the commit() method.

   If you only want to add information to the Subject to get propagated, see "Propagating a custom Java serializable object" on page 1602. If you want to ensure that the information is propagated, want to do you own custom serialization, or want to specify the uniqueness for Subject caching purposes, then consider writing your own AuthorizationToken implementation.

   The code sample in "Example: custom AuthorizationToken login module" on page 1582 shows how to determine if the login is an initial login or a propagation login. The difference between these login types is whether the WSTokenHolderCallback contains propagation data. If the callback does not contain propagation data, initialize a new custom AuthorizationToken implementation and set it into the Subject. If the callback contains propagation data, look for your specific custom AuthorizationToken TokenHolder instance, convert the byte[] back into your custom AuthorizationToken object, and set it back into the Subject. The code sample shows both instances.

   You can make your AuthorizationToken read-only in the commit phase of the login module. If you do not make the token read-only, then attributes can be added within your applications.

3. Add your custom login module to WebSphere Application Server system login configurations that already contain the com.ibm.ws.security.server.lm.wsMapDefaultInboundLoginModule for receiving serialized versions of your custom authorization token

   Because this login module relies on information in the sharedState added by the com.ibm.ws.security.server.lm.wsMapDefaultInboundLoginModule, add this login module after com.ibm.ws.security.server.lm.wsMapDefaultInboundLoginModule. For information on how to add your custom login module to the existing login configurations, see ″Custom login module development for a system login configuration″ in the information center.

After completing these steps, you have implemented a custom AuthorizationToken.

Example: com.ibm.wsspi.security.token.AuthorizationToken implementation:

Use this file to see an example of a AuthorizationToken implementation. The following sample code does not extend an abstract class, but rather implements the com.ibm.wsspi.security.token.AuthorizationToken interface directly. You can implement the interface directly, but it might cause you to write duplicate code. However, you might choose to implement the interface directly if there are considerable differences between how you handle the various token implementations.

For information on how to implement a custom AuthorizationToken, see "Implementing a custom AuthorizationToken" on page 1576.

Default SingleSignonToken

Do not use the default SingleSignonToken in service provider code. This default token is used by the WebSphere Application Server run-time code only. There are size limitations for this token when it is added as an HTTP cookie. If you need to create an HTTP cookie using this token framework, you can implement a custom SingleSignonToken. To implement a custom SingleSignonToken, see “Implementing a custom SingleSignonToken” on page 1586 for more information.

Changing the TokenFactory associated with the default SingleSignonToken

When default SingleSignonToken is generated, the application server utilizes the TokenFactory class that is specified using the com.ibm.wsspi.security.token.singleSignonTokenFactory property. To modify this property using the administrative console, complete the following steps:

1. Click **Security > Global Security**.
2. Under Additional properties, click **Custom properties**.

The default TokenFactory specified for this property is called com.ibm.ws.security.ltpa.LTPAToken2Factory. This token factory creates an SSO token called LtpaToken2, which WebSphere Application Server uses for propagation. This TokenFactory uses the AES/CBC/PKCS5Padding cipher. If you change this TokenFactory, you lose the interoperability with any servers running a version of WebSphere Application Server prior to version 5.1.1 that use the default TokenFactory. Only servers running WebSphere Application Server Version 5.1.1 or later with propagation enabled are aware of the LtpaToken2 cookie. However, this is not a problem if all of your application servers use WebSphere Application Server Version 5.1.1 or later and all of your servers use your new TokenFactory.

If you need to perform your own signing and encryption of the default SingleSignonToken, you must implement the following classes:

- com.ibm.wsspi.security.ltpa.Token
- com.ibm.wsspi.security.ltpa.TokenFactory

Your TokenFactory implementation instantiates (createToken) and validates (validateTokenBytes) your token implementation. You can use the LTPA keys passed into the initialize method of the TokenFactory or you can use your own keys. If you use your own keys, they must be the same everywhere in order to validate the tokens that are generated using those keys. See the Javadoc, available through a link on the front page of the information center, for more information on implementing your own custom TokenFactory. To associate your TokenFactory with the default SingleSignonToken using the administrative console, complete the following steps:

1. Click **Security > Global Security**.
2. Under Additional properties, click **Custom properties**.
3. Locate the com.ibm.wsspi.security.token.singleSignonTokenFactory property and verify that the value of this property matches your custom TokenFactory implementation.
4. Verify that your implementation classes are put into the *install directory*/classes directory so that the WebSphere class loader can load the classes.

Implementing a custom SingleSignonToken

This task explains how to create your own SingleSignonToken implementation, which is set in the login Subject and added to the HTTP response as an HTTP cookie. The cookie name is the concatenation of the SingleSignonToken.getName() application programming interface (API) and the SingleSignonToken.getVersion() API. There is no delimiter. When you add a SingleSignonToken to the Subject, it also gets propagated horizontally and downstream in case the Subject is used for other Web requests. You must deserialize your custom SingleSignonToken when you receive it from a propagation login. Consider writing your own implementation if you want to accomplish one of the following:

- Isolate your attributes within your own implementation.
- Serialize the information using custom serialization. It is recommended that you encrypt the information because it is out to the HTTP response and is available on the Internet. You must deserialize or decrypt the bytes at the target and add that information back into the Subject.
- Affect the overall uniqueness of the Subject using the getUniqueID() API

To implement a custom SingleSignonToken, you must complete the following steps:

1. Write a custom implementation of the SingleSignonToken interface.

   There are many different methods for implementing the SingleSignonToken interface. However, make sure that the methods required by the SingleSignonToken interface and the token interface are fully implemented. After you implement this interface, you can place it in the *install_dir*/classes directory. Alternatively, you can place the class in any private directory. However, make sure that the WebSphere Application Server class loader can locate the class and that it is granted the appropriate permissions. You can add the Java archive (JAR) file or directory that contains this class into the server.policy file so that it has the necessary permissions that are needed by the server code.

   Tip: All of the token types defined by the propagation framework have similar interfaces. Basically, the token types are marker interfaces that implement the com.ibm.wsspi.security.token.Token interface. This interface defines most of the methods. If you plan to implement more than one token type, consider creating an abstract class that implements the com.ibm.wsspi.security.token.Token interface. All of your token implementations, including the SingleSignonToken, might extend the abstract class and then most of the work is completed.

   To see an implementation of the SingleSignonToken, see "Example: com.ibm.wsspi.security.token.SingleSignonToken implementation" on page 1587

2. Add and receive the custom SingleSignonToken during WebSphere Application Server logins. This task is typically accomplished by adding a custom login module to the various application and system login configurations. However, in order to deserialize the information, you will need to plug in a custom login module, which is discussed in a subsequent step. After the object is instantiated in the login module, you can add it to the Subject during the commit() method.
