Target mapping collection 734
Exporting applications 736
Exporting DDL files 736
Updating applications 736
Ways to update application files. 739
Preparing for application update settings 740
Hot deployment and dynamic reloading 744
Uninstalling applications 752
Removing a file. 752
Deploying and administering applications: Resources for learning 753

Chapter 8. Developing WebSphere applications. 755
Web applications 755
Task overview: Developing and deploying Web applications 755
Task overview: Managing HTTP sessions 792
Modifying the default Web container configuration 803
Configuring session management by level 808
Configuring session tracking 809
Configuring session tracking for Wireless Application Protocol (WAP) devices 813
Configuring for database session persistence. 814
EJB applications 817
Task overview: Using enterprise beans in applications 817
Using access intent policies 822
Managing EJB containers 831
Deploying EJB modules 837
Client applications. 839
Using application clients 839
Running application clients 852
Installing Application Client for WebSphere Application Server 869
Deploying J2EE application clients on workstation platforms 874
Web services 952
Implementing Web services applications 952
Deploying Web services 964
Configuring Web service client bindings 966
Configuring the scope of a Web service port 969
Web Services Invocation Framework (WSIF): Enabling Web services 971
Getting started with UDDI Registry. 975
Planning to use Web services 977
Setting up and deploying a new UDDI Registry 981
Publishing WSDL files 992
Configuring endpoint URL information for JMS bindings 995
Configuring Web services applications with the wsadmin tool 997
WSIF system management and administration 997
Using the UDDI Registry 1004
Removing and reinstalling UDDI Registry 1108
Configuring the UDDI Registry Application 1110

Managing the UDDI Registry . . . 1114
Data access resources . . . 1126
Task overview: Accessing data from applications . . . 1126
Deploying data access applications . . . 1156
Messaging resources . . . 1242
Learning about messaging with WebSphere Application Server . . . 1242
Installing and configuring a JMS provider . . . 1252
Using asynchronous messaging . . . 1253
Maintaining Version 5 default messaging resources . . . 1253
Using JMS resources of WebSphere MQ . . . 1286
Using JMS resources of a generic provider . . . 1353
Administering support for message-driven beans . . . 1361
Mail, URLs, and other J2EE resources. . . . 1378
Using mail . . . 1378
Using URL resources within an application . . . 1382
Resource environment entries . . . 1385
Configuring mail providers and sessions . . . 1389
Security . . . 1393
Securing applications and their environments . . . 1393
Planning to secure your environment . . . 1394
Implementing security considerations at installation time . . . 1404
Integrating IBM WebSphere Application Server security with existing security systems . . . 1409
Administering security . . . 1417
Deploying secured applications . . . 1767
Naming and directory . . . 1779
Using naming . . . 1779
Configuring name servers . . . 1789
Configuring and viewing name space bindings . . . 1790
Developing applications that use JNDI . . . 1794
Developing applications that use CosNaming (CORBA Naming interface) . . . 1809
Object Request Broker . . . 1813
Managing Object Request Brokers . . . 1813
Transactions . . . 1831
Configuring transaction properties for an application server . . . 1831
Using the transaction service . . . 1840
Managing active and prepared transactions . . . 1850
Managing transaction logging for optimum server availability. . . . 1851
Interoperating transactionally between application servers. . . . 1854
Using one-phase and two-phase commit resources in the same transaction . . . 1854
WebSphere programming extensions . . . 1858
ActivitySessions . . . 1858
Application profiling . . . 1872
Asynchronous beans . . . 1884
Dynamic cache . . . 1901
Dynamic query . . . 1949
Internationalization . . . 1978
Object pools . . . 1988
Scheduler . . . 1994
Startup beans . . . 2019
Work area . . . 2020

Chapter 9. Troubleshooting deployment . . . 2047
Errors or problems deploying, installing, or promoting applications . . . 2047
Troubleshooting testing and first time run problems . . . 2051
Errors starting an application . . . 2052
The application does not start or starts with errors . . . 2056

A web resource does not display 2057
Cannot uninstall an application or remove a node or application server 2059

Chapter 10. Troubleshooting administration 2061
Administration and administrative console troubleshooting tips 2061
Installation completes but the administrative console does not start 2063
Errors connecting to the administrative console from a browser 2064
When a single user that uses multiple instances of the Mozilla browser logs into the administrative console, the first user ID that logs into the administrative console is the current user. 2064
A user on Mozilla browser Version 1.4 selects a check box on a collection table, presses Enter, and receives an error. 2064
A user on Mozilla browser Version 1.4 enters an invalid ID or password, presses Enter, and receives an error message 2065
Web server plug-in troubleshooting tips 2065
The server process does not start or starts with errors 2067
The stopServer.sh hangs and creates a Java core dump (Red Hat Linux) 2068
Problems starting or using the wsadmin command 2068
Problems using tracing, logging or other troubleshooting features 2071

How to send your comments

Your feedback is important in helping to provide the most accurate and highest quality information.

- To send comments on articles in the WebSphere Application Server Information Center
  1. Display the article in your Web browser and scroll to the end of the article.
  2. Click on the **Feedback** link at the bottom of the article, and a separate window containing an e-mail form appears.
  3. Fill out the e-mail form as instructed, and click on **Submit feedback** .
- To send comments on PDF books, you can e-mail your comments to: **wasdoc@us.ibm.com** or fax them to 919-254-0206.

  Be sure to include the document name and number, the WebSphere Application Server version you are using, and, if applicable, the specific page, table, or figure number on which you are commenting.

When you send information to IBM, you grant IBM a nonexclusive right to use or distribute the information in any way it believes appropriate without incurring any obligation to you.

Chapter 1. Overview and new features for administering applications and their environments

This topic summarizes the contents and organization of the administration documentation, including links to conceptual overviews and descriptions of new features.

- Overview of administering applications and their environments
- What is new for administrators

Sections in the administration documentation:

Chapter 3, “Setting up the application serving environment,” on page 15
This section is for the administrator who is responsible for integrating application serving capabilities into an existing network environment. It looks at the product as part of a larger system, typically a production environment or realistic test environment. This section reiterates some installation and customization activities, including topology planning and creating product configurations. It carries the focus into the administrative realm, discussing port configuration and other network concerns. See also ″Overview and new features for installing an application serving environment″ in the information center.

This information expands the topology planning discussion by describing how to set up and maintain logical administrative domains of cells and nodes, and how to balance workload through clustering and high availability configurations.

Chapter 4, “Using the administrative clients,” on page 171
This section describes the many options available for administering your applications and the servers to which the applications are deployed. Options include the graphical administrative console; scripting with the wsadmin tool; programmatic administration using Java Management Extensions (JMX) and MBeans; and a wide array of command-line tools, including ANT.

Chapter 5, “Starting and stopping quick reference,” on page 691
This section summarizes what can be started and stopped, including applications and the application servers on which these applications are deployed.

Chapter 6, “Class loading,” on page 693
This section describes how to configure class loaders. It includes both configuration that is performed during application assembly (packaging) and configuration performed at the server. The product run-time environment uses class loaders to find and load new classes for an application. Class loaders are part of the Java virtual machine (JVM) code and are responsible for finding and loading class files.

Chapter 7, “Deploying and administering applications,” on page 705
This section describes how to deploy applications onto application servers, and then how to administer the deployed applications. It includes installing applications, starting applications, exporting application files, updating applications, removing applications, and other common tasks.

Administer WebSphere applications
This section provides administrative instructions that are specific to the various types of applications. For example, you can focus on administering your Web applications in their Web container; or aspects of Web services support; or the messaging or security subsystems.

Chapter 9, “Troubleshooting deployment,” on page 2047
This section describes how to identify and handle a variety of problems encountered during development, assembly, and deployment activities.

Chapter 10, “Troubleshooting administration,” on page 2061
This section describes how to identify and handle a variety of problems encountered during administrative activities.

Overview of administering applications and their environments

This topic provides links to conceptual overviews of administering your applications and application serving environment.

What is new for administrators

This topic provides an overview of new and changed features of system administration.

“Introduction: System administration” on page 3

This topic describes the administration of WebSphere Application Server, Version 6 products and the applications that run on them.

Presentations from Education on Demand

The following presentations provide a quick overview:

- System management architecture
- Administrative security
- Administrative clients overview
  - Start, stop, and monitor processes
  - Other commands
  - Browser-based administrative console
  - Scripting - wsadmin
  - Custom Java administrative client (JMX)
- Topologies and logical administrative domains
  - Resource scoping
- Applications and application resources
  - Application management overview
  - JDBC
  - Installing and uninstalling applications
  - Managed application resources - Enhanced EAR files
  - Fine grained application updates
- Servers
  - Server templates
  - Custom services
  - Manage Web server nodes
- Configuration management
  - Configuration repository
  - Configuration archives
  - File synchronization

Getting started with WebSphere Application Server

Note: If you prefer to browse PDF versions of this documentation using Adobe Reader, see the **Getting Started** PDF files that are available from www.ibm.com/software/webservers/appserv/infocenter.html.

IBM WebSphere Application Server products provide a next-generation application server on an industry-standard foundation. Each product addresses a distinct set of scenarios and needs. WebSphere Application Server, Version 6 product offerings are described in ″Packaging″ in the information center.

Planning

See ″Task overview: Installing″ in the information center for a description of typical scenarios for each WebSphere Application Server product.

Installing

See ″Task overview: Installing″ for a description of installing the WebSphere Application Server product and other installable components on the product disc.

Configuring

See ″Using the Profile creation wizard″ in the information center for a description of installing other stand-alone Application Servers on your machine.

Migrating

See ″Migration and coexistence overview″ and ″Migrating and coexisting″ in the information center for a description of how to migrate applications and configuration data from a previous version of WebSphere Application Server.

Using the Samples Gallery

See ″Accessing the Samples (Samples Gallery)″ in the information center for a description of the set of Samples that ship with each product. The Samples demonstrate common Web application tasks.

Deploying applications

The information center describes a way to sample WebSphere Application Server functionality by quickly deploying Web components, such as servlets and JSP files. The method is not recommended as an official development method. See ″Fast paths for WebSphere Application Server″ in the information center to get started.

Introduction: System administration

A variety of tools are provided for administering the WebSphere Application Server product:

- **Console**

  The administrative console is a graphical interface that provides many features to guide you through deployment and systems administration tasks. Use it to explore available management options.

  For more information, refer to “Introduction: Administrative console” on page 4.
- **Scripting**

  The WebSphere administrative (wsadmin) scripting program is a powerful, non-graphical command interpreter environment enabling you to run administrative operations in a scripting language. You can also submit scripting language programs to run. The wsadmin tool is intended for production environments and unattended operations.

  For more information, refer to “Introduction: Administrative scripting (wsadmin)” on page 4.
- **Commands**

  Command-line tools are simple programs that you run from an operating system command-line prompt to perform specific tasks, as opposed to general purpose administration. Using the tools, you can start and stop application servers, check server status, add or remove nodes, and complete similar tasks.

For more information, refer to “Introduction: Administrative commands” on page 5.

- **Programming**

  The product supports a Java programming interface for developing administrative programs. All of the administrative tools supplied with the product are written according to the API, which is based on the industry standard Java Management Extensions (JMX) specification.

  For more information, refer to “Introduction: Administrative programs” on page 5.
- **Data**

  Product configuration data resides in XML files that are manipulated by the previously-mentioned administrative tools.

  For more information, refer to “Introduction: Administrative configuration data” on page 5.

Introduction: Administrative console

The administrative console is a graphical interface for performing deployment and system administration tasks. It runs in your Web browser. Your actions in the console modify a set of XML configuration files.

You can use the console to perform tasks such as:

- Add, delete, start, and stop application servers
- Deploy new applications to a server
- Start and stop existing applications, and modify certain configurations
- Add and delete Java 2 Platform, Enterprise Edition (J2EE) resource providers for applications that require data access, mail, URLs, and so on
- Manage variables, shared libraries, and other configurations that can span multiple application servers
- Configure product security, including access to the administrative console
- Collect data for performance and troubleshooting purposes
- Find the product version information. It is located on the front page of the console.

See the *Using the administrative clients* PDF for information on how you begin using the console. See also the **Reference > Administrator > Settings** section of the Information Center navigation. It lists the settings or properties you can configure.

Introduction: Administrative scripting (wsadmin)

The WebSphere administrative (wsadmin) scripting program is a powerful, non-graphical command interpreter environment enabling you to run administrative operations in a scripting language. The wsadmin tool is intended for production environments and unattended operations. You can use the wsadmin tool to perform the same tasks that you can perform using the administrative console.

The following list highlights the topics and tasks available with scripting. See the *Administering applications and their environment* PDF for more information on how to perform these tasks.

- Getting started with scripting Provides an introduction to WebSphere Application Server scripting and information about using the wsadmin tool. Topics include information about the scripting languages and the scripting objects, and instructions for starting the wsadmin tool.
- Deploying applications Provides instructions for deploying and uninstalling applications. For example, stand-alone Java archive files and Web archive files, the administrative console, remote enterprise archive (EAR) files, file transfer applications, and so on.
- Managing deployed applications Includes tasks that you perform after the application is deployed. For example, starting and stopping applications, checking status, modifying listener address ports, querying application state, configuring a shared library, and so on.
- Configuring servers Provides instructions for configuring servers, such as creating a server, modifying and restarting the server, configuring the Java virtual machine, disabling a component, disabling a service, and so on.

- Configuring connections to Web servers Includes topics such as regenerating the plug-in, creating new virtual host templates, modifying virtual hosts, and so on.
- Managing servers Includes tasks that you use to manage servers. For example, stopping nodes, starting and stopping servers, querying a server state, starting a listener port, and so on.
- Configuring security Includes security tasks, for example, enabling and disabling global security, enabling and disabling Java 2 security, and so on.
- Configuring data access Includes topics such as configuring a Java DataBase Connectivity (JDBC) provider, defining a data source, configuring connection pools, and so on.
- Configuring messaging Includes topics about messaging, such as Java Message Service (JMS) connection, JMS provider, WebSphere queue connection factory, MQ topics, and so on.
- Configuring mail, URLs, and resource environment entries Includes topics such as mail providers, mail sessions, protocols, resource environment providers, reference tables, URL providers, URLs, and so on.
- Dynamic caching Includes caching topics, for example, creating, viewing and modifying a cache instance.
- Troubleshooting Provides information about how to troubleshoot using scripting. For example, tracing, thread dumps, profiles, and so on.
- Obtaining product information Includes tasks such as querying the product identification.
- Scripting reference material Includes all of the reference material related to scripting. Topics include the syntax for the wsadmin tool and for the administrative command framework, explanations and examples for all of the scripting object commands, the scripting properties, and so on.

Introduction: Administrative commands

Command-line tools are simple programs that you run from an operating system command-line prompt to perform specific tasks, as opposed to general purpose administration. Using the tools, you can start and stop application servers, check server status, add or remove nodes, and complete similar tasks.

See **Reference > Commands** in the information center navigation for the names and syntax of all the commands that are available with the product. A subset of these commands are particular to system administration purposes.

Introduction: Administrative programs

The product supports a Java programming interface for developing administrative programs. All of the administrative tools supplied with the product are written according to the API, which is based on the industry standard Java Management Extensions (JMX) specification. You can write a Java program that performs any of the administrative features of the WebSphere Application Server administrative tools. You can also extend the basic WebSphere Application Server administrative system to include your own managed resources.

Introduction: Administrative configuration data

The WebSphere Application Server product includes an implementation of the Java Management Extension (JMX) specification. All operations on managed resources in the product go through JMX functions. This setup means a more standard framework underlying your administrative operations as well as the ability to tap into the systems management infrastructure programmatically.

Introduction: Servers

Application servers

Application servers provide the core functionality of the WebSphere Application Server product family. They extend the ability of a Web server to handle Web application requests, and much more. An application server enables a server to generate a dynamic, customized response to a client request.

For additional overview, refer to “Introduction: Application servers.”

Introduction: Application servers

Overview

An application server is a Java Virtual Machine (JVM) that is running user applications. The application server collaborates with the Web server to return a dynamic, customized response to a client request. Application code, including servlets, JavaServer Pages (JSP) files, enterprise beans and their supporting classes, runs in an application server. Conforming to the Java 2 platform, Enterprise Edition (J2EE) component architecture, servlets and JSP files run in a Web container, and enterprise beans run in an Enterprise JavaBeans (EJB) container.

To begin creating and managing an application server, see “Administering application servers” on page 111.

You can define multiple application servers, each running its own JVM. Enhance the operation of an application server by using the following options:

- Configure transport chains to provide networking services to such functions as the service integration bus component of IBM service integration technologies, WebSphere Secure Caching Proxy, and the high availability manager core group bridge service. See “Configuring transport chains” on page 126 for more information.
- Plug into an application server to define a hook point that runs when the server starts and shuts down. See “Custom services” on page 142 for more information.
- Define command-line information that passes to a server when it starts or initializes. See the *Using the administrative clients* PDF for more information.
- “Tuning application servers” on page 167
- Enhance the performance of the application server JVM. See “Using the JVM” on page 155 for more information.
- Use an Object Request Broker (ORB) for RMI/IIOP communication. See the *Developing and deploying applications* PDF for more information.

Asynchronous messaging

The product supports asynchronous messaging based on the Java Messaging Service (JMS) of a JMS provider that conforms to the JMS specification version 1.1.

The JMS functions of the default messaging provider in WebSphere Application Server are served by one or more messaging engines (in a service integration bus) that runs within application servers.

Generic Servers

In distributed platforms, the Generic Servers feature allows you create a generic server as an application server instance within the WebSphere Application Server administration, and associate it with a non-WebSphere server or process. The generic server can be associated with any server or process necessary to support the application server environment, including:

- A Java server
- A C or C++ server or process
- A CORBA server
- A Remote Method Invocation (RMI) server

After you define a generic server, you can use the Application Server administrative console to start, stop, and monitor the associated non-WebSphere server or process when stopping or starting the applications that rely on them.

For more information, refer to “Creating generic servers” on page 124.

Introduction: Web servers

In the WebSphere Application Server product, an application server works with a Web server to handle requests for dynamic content, such as servlets, from Web applications. Go to http://www.ibm.com/software/webservers/appserv/doc/latest/prereq.html for the most current information about supported Web servers.

The application server and Web server communicate using “Web server plug-ins” on page 72. “Communicating with Web servers” on page 57 describes how to set up your Web server and Web server plug-in environment and how to create a Web server definition. The Web server definition associates a Web server with an application server. After you create a Web server definition, you can use the administrative console to perform the following functions for that Web server:

- Check the status of the Web server
- Generate a plug-in configuration file for that Web server.

If the Web server is an IBM HTTP Server (IHS) and the IHS Administration server is installed and properly configured, you can also:

- Display the IBM HTTP Server Error log (error.log) and Access log (access.log) files.
- Start and stop the server.
- Display and edit the IBM HTTP Server configuration file (httpd.conf).
- Propagate the plug-in configuration file after it is generated.

You can not propagate a plug-in configuration file for a non-IHS Web server. You must manually install an updated plug-in configuration file on that Web server.

After you set up your Web server and Web server plug-in, whenever you deploy a Web application, you must specify a Web server as the deployment target that serves as a router for requests to the Web application. The configuration settings in the plug-in configuration file (plugin-cfg.xml) for each Web server are based on the applications that are routed through that Web server. If the Web server plug-in configuration service is enabled, a Web server plug-in’s configuration file is automatically regenerated whenever a new application is associated with that Web server.

Note: Before starting the Web server, make sure you are authorized to run any Application Response Measurement (ARM) agent associated with that Web server.

Refer to your Web server documentation for information on how to administer that Web server. For tips on tuning your Web server plug-in, see “Web server plug-in tuning tips” on page 77.

Introduction: Environment

The environment of the product applies to the configuring of Web server plug-ins, variables, and objects that you want consistent throughout a cell.

Web servers

In the WebSphere Application Server product, an application server works with a Web server to handle requests for Web applications. The application Server and Web server communicate using a WebSphere HTTP plug-in for the Web server.

For more information, refer to “Introduction: Web servers.”

Variables

A variable is a configuration property that can be used to provide a parameter for any value in the system. A variable has a name and a value to use in place of that name wherever the variable name is located within the system.

For more information, refer to “Configuring WebSphere variables” on page 94.

Chapter 2. How do I administer applications and their environments?

- Establish the application serving environment
- Secure the application serving environment - see Security
- Set up Web access for applications
- Set up resources for applications to use
- Configure class loaders - see development and deployment
- Deploy and administer applications
- Use the administrative clients
- Troubleshoot deployment and administration

Documentation	Show me	Tell me	Guide me	Teach me
Refer to the detailed steps and reference	Watch a brief multimedia demonstration	View the presentation for an overview	Be led through the console pages	Perform the tutorial with sample code
Approximate time: Varies	**Approximate time:** 3 to 5 minutes	**Approximate time:** 10 minutes+	**Approximate time:** 1/2 hour+	**Approximate time:** 1 hour+

Establish the application serving environment

The following tasks involve establishing application serving capability in your network environment, whether you use single or clustered application servers. Servers can be grouped into administrative domains known as nodes and cells.

See also the overview:

- Version 6 topology and terminology

Create WebSphere profiles

Profiles are the files that define a stand-alone Application Server node, a managed node, or a deployment manager node. A profile also includes all of the files that the node can change.

Documentation	Show me:	Tell me
	- Standalone node	

Administer configurations

Application server configuration files define the available application servers, their configurations, and their contents. You should periodically save changes to your administrative configuration. You can change the default locations of configuration files, as needed.

Documentation	Tell me:
	• Repository • Archives

Administer application servers

Create, configure, and operate application server processes. An application server configuration provides settings that control how an application server provides services for running enterprise applications and their components.

Documentation:	Show me	Tell me
• Console • Scripting - configure • Scripting - administer		

Administer other server types

One step in the process of creating an application server is to specify a template. A server template is used to define the configuration settings of the new server. You have the option of specifying the default server template or choosing a template that is based on a server that already exists. The default template will be used if you do not specify a different template when you create the server.

You can create other types of servers, to represent Web servers in your topology, or for other purposes. There are two types of *generic* servers: (1) Non-Java applications or processes, or (2) Java applications or processes. A *custom service* provides the ability to plug into a WebSphere application server to define a hook point that runs when the server starts and shuts down.

Documentation:	Tell me:	Guide me (Web servers)
• Generic servers • Custom services	• Generic servers • Templates • Custom services	

Administer the UDDI registry

The UDDI Registry is supplied as a J2EE application file, uddi.ear. Change its configuration properties using the assembly tools. You can use either the WebSphere Application Server administrative console or the Java Management Extensions (JMX) management interface to manage UDDI Registries.

Documentation:	Show me	Tell me	Teach me
• Configure • Administer			

Set up Web access for applications

These tasks involve enabling HTTP requests for applications on the application server.

Administer communication with Web servers (plug-ins)

The product provides plug-ins for supported Web servers, to enable the Web servers to pass requests to the application server, for applications running on the application server. See also the Web server related tasks in How do I install an application serving environment?.

Documentation: Show me Tell me Guide me

- Console
- Scripting

Administer HTTP sessions

Configure the service that the product provides for managing HTTP sessions: Session Manager.

Documentation: Show me

- Console
- Scripting

Administer IBM HTTP Server Version 6.x

The product provides a complementary Web server with its own documentation that can be installed into the information center.

Set up resources for applications to use

Make a variety of resources available to your applications that are deployed on the application server.

Provide access to naming and directory resources (JNDI)

Configure naming. Naming is used by clients of WebSphere Application Server applications to obtain references to objects related to those applications, such as Enterprise JavaBeans (EJB) homes. These objects are bound into a mostly hierarchical structure, referred to as a name space. The name space structure consists of a set of name bindings, each consisting of a name relative to a specific context and the object bound with that name.

Documentation: Show me Tell me

- Name server
- Bindings

Provide access to relational databases (JDBC resources)

Configure data sources that applications use to access the data from databases.

Documentation:	Show me:	Tell me	Guide me
• Console • Scripting	• Cloudscape • DB2 • Oracle		

Provide access to messaging resources (default messaging provider)

Use one of various ways to implement a messaging provider for use with WebSphere Application Server. A messaging provider enables use of the Java Messaging Service (JMS) and other message resources in the product.

		• Service integration bus resources • JMS resources for service integration bus

----

Deploy and administer applications

These tasks involve deploying applications onto the application server, then administering the applications.

Install applications

Installable modules include enterprise archive (EAR), enterprise bean (EJB), Web archive (WAR), resource adapter (connector or RAR), and application client files.

Documentation	Show me	Tell me
• Console • Scripting		

Start and stop applications

You can start an application that is not running (has a status of Stopped) or stop an application that is running (has a status of Started).

Documentation:	Show me	Tell me	

- Console
- Scripting

Update applications

Update deployed applications or modules using the administrative console or **wsadmin** scripting. Learn which changes are candidates for hot deployment and dynamic reloading, in which you can make various changes to applications and their modules without having to stop the server and start it again.

Documentation:		Tell me	Teach me

- Console
- Scripting

Deploy applications rapidly (WebSphere Rapid Deployment)

Take advantage of new rapid deployment capabilities. WebSphere rapid deployment offers the following advantages: You do not need to assemble your J2EE application files prior to deployment. You do not need to use other installation tools mentioned in this table to deploy the files. Refer to the **Rapid deployment tools** documentation in the information center.

Enhanced EAR files

		Tell me	Teach me

Deploy and administer Web services applications

To deploy Web services that are based on the Web Services for Java 2 platform, Enterprise Edition (J2EE) specification, you need an enterprise application, also known as an enterprise archive (EAR) file that has been configured and enabled for Web services. You can use either the administrative console or the wsadmin scripting interface to deploy an EAR file.

Documentation	Show me	Tell me	Teach me

Use the administrative clients

A variety of tools are provided for administering the product.

Choose an administrative client

Learn about and decide among the available administrative clients, including a graphical console, scripting (wsadmin), command line tools, and Java Management Extensions (JMX) programs.

Documentation Tell me

Use the administrative console

The administrative console is a Web-based tool that you use to administer the product. The administrative console supports a full range of product administrative activities.

Documentation Show me Tell me

Use scripting (wsadmin)

Scripting is a non-graphical alternative that you can use to configure and manage WebSphere Application Server. The WebSphere Application Server **wsadmin** tool provides the ability to run scripts. The tool supports a full range of product administrative activities.

Documentation Tell me

See also:

- Start, stop, monitor processes
- Other administrative commands
- Custom Java administrative clients (JMX)

Troubleshoot deployment and administration

Troubleshoot problems that occur when you are deploying applications onto the application server, or when you are administering an established application serving environment.

Troubleshoot deployment

Troubleshoot problems that occur either during deployment or shortly afterwards, when you try to access an application that you just deployed for the first time.

Documentation

Troubleshoot administration

Review some possible causes, based on the error you are seeing.

Documentation

Chapter 3. Setting up the application serving environment

This topic summarizes the contents of the documentation that helps you set up your application serving environment. This information is for administrators, particularly those performing installation, customization, and maintenance of topologies.

“Planning the installation (diagrams)”

In preparation for installation, this topic describes common product topologies that you can install with WebSphere Application Server, Version 6 products.

“Configuring the product after installation” on page 32

This topic describes what to do after installing the product.

You can display the First Steps tool, an easy way to get started with the product.

“Configuring ports” on page 55

This topic provides information about port number settings for Version 6 and previous versions, for use in coexistence and interoperability situations.

“Communicating with Web servers” on page 57

This topic describes how to install and configure WebSphere plug-ins for Web servers, enabling communication between Web servers and application servers.

“Setting up the administrative architecture” on page 79

This topic describes how to configure administrative services.

“Configuring the environment” on page 86

This topic describes how to configure settings for virtual hosts, variables, and shared libraries to assist in handling requests among Web applications, Web containers, and application servers.

“Working with server configuration files” on page 104

This topic describes how to change the default locations of configuration files, as needed. Application server configuration files define the available application servers, their configurations, and their contents.

“Administering application servers” on page 111

This topic describes how to configure individual application servers to provides services for running enterprise applications and their components.

Planning the installation (diagrams)

This topic describes common product topologies that you can install with the product.

Use this topic to understand the capabilities of your product package. Knowing what you can do with the product might influence how you install the product and other installable components on the product disc.

This topic describes topology diagrams and shows you how to create the topologies by showing what components to install for each topology.

Phased installation roadmap

To install a Version 6 production environment, you install the following components:

- The WebSphere Application Server product on your product CD
- A supported Web server, such as the IBM HTTP Server V6 on the product CD
- A binary plug-in module for your Web server from the product CD

You can also use the product CD to install an application client environment on a client machine. Running Java 2 Platform, Enterprise Edition (J2EE) and thin application clients that communicate with WebSphere Application Server requires that elements of the Application Server are installed on the machine on which the client runs. However, if the machine does not have the Application Server installed, you can install Application Server clients to provide a stand-alone client run-time environment for your client applications.

You can use the Rational Web Developer CD in the primary packet of discs to install a fully integrated development environment that includes an exact replica of the Application Server for development testing.

Installation features

Installation features in V6 include:

Feature	Description
The Express product includes Application Server nodes.	You can use the Profile creation wizard to create stand-alone application server nodes after installing the Express product. You do not have to reinstall the product to create additional application servers. All application servers on a machine share the same core product files.
The product CD includes all of the installable components that are required to create an e-business environment.	You can use the product CD to install the IBM HTTP Server, the Web server plug-ins, and the WebSphere Application Server Clients. You do not have to use separate CDs. Separate installation programs exist within component directories on the product CD.
Each installable component has its own installation program.	You can use the V6 launchpad to install any installable component on the product CD. Or you can install each component directly using the **install** command in each component directory.
The launchpad can install any installable product in the primary packet of compact discs.	The launchpad for the Express product can also install the Rational Web Developer on Windows and Linux (Intel) systems. Rational Web Developer is on separate CDs, which requires you to change discs to launch the installation.

Review topology diagrams for each of the following installable components to determine which topology best fits your needs. The diagrams and their accompanying procedures can serve as a roadmap for installing a similar topology.

This topic describes installation scenarios for the following installable components:

- WebSphere Application Server - Express
- Web server plug-ins
- Application clients

In addition to product installation diagrams for the installable components, this topic also links to a roadmap for using the Profile creation wizard, which is new for Version 6. The Profile creation wizard lets you create run-time environments for application server processes.

Each of the following installation scenarios includes topology diagrams and associated installation steps. Each step links to a specific procedure for installing a component or to a description of a command or tool.

1. Review the installation scenarios for the Express product, as described in “Planning to install WebSphere Application Server - Express” on page 17.
2. Review the installation scenarios for the WebSphere Application Server plug-ins, as described in “Planning to install Web server plug-ins” on page 22.
3. Review the installation scenarios for the application clients, as described in “Planning to install WebSphere Application Server Clients” on page 25.
4. Review the installation scenarios for the Profile creation wizard, as described in “Planning to create application server environments” on page 26.
5. **Optional:** Review interoperability and coexistence diagrams to know what is possible with Version 6.

WebSphere Application Server V6 can interoperate with your other e-business systems, including other versions of WebSphere Application Server. *Interoperability* provides a communication mechanism for WebSphere Application Server nodes that are at different versions. *Coexistence* describes multiple versions or instances running on the same machine, at the same time.

Interoperability support enhances migration scenarios with more configuration options. It often is convenient or practical to interoperate during the migration of a configuration from an earlier WebSphere Application Server version to a later one when some machines are at the earlier version and some machines are at the later version. The mixed environment of machines and application components at different software version levels requires interoperability and coexistence.

It is often impractical, or even physically impossible, to migrate all the machines and applications within an enterprise at the same time. Understanding multiversion interoperability and coexistence is therefore an essential part of a migration between version levels.

See the following topics for more information:

a. Interoperating

b. Setting up Version 4.0.x and Version 6 coexistence

c. Setting up Version 5 and Version 6 coexistence

d. Setting up Version 6 coexistence

6. **Optional:** Consider performance when designing your network, as described in "Queuing network" on page 27.

You can review installation scenarios to identify the specific steps to follow when installing more than one component on a single machine or on separate machines.

After determining an appropriate installation scenario, you are ready to install the necessary components and to configure the products for the system that you selected.

Planning to install WebSphere Application Server - Express

This topic describes common installation scenarios and links to component installation procedures for each scenario.

IBM WebSphere Application Server - Express, Version 6 is an integrated platform that contains an Application Server, Web development tools, a Web server, and additional supporting software and documentation.

The following information describes scenarios for installing the product in various topologies on one or more machines:

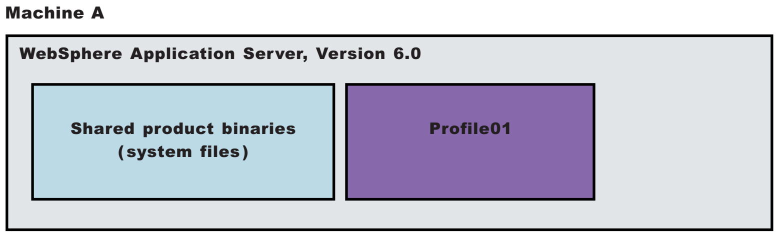
- **Scenario 1:** Single-machine installation of WebSphere Application Server - Express
- **Scenario 2:** Single-machine installation of WebSphere Application Server - Express and a Web server
- **Scenario 3:** Two-machine installation of WebSphere Application Server - Express and a Web server
- **Scenario 4:** Creating multiple profiles that use one installation of WebSphere Application Server - Express
- **Scenario 5:** Single-machine installation of Rational Web Developer
- **Scenario 6:** Multiple-machine installation of WebSphere Application Server - Express, Rational Web Developer, and a Web server

Each scenario includes a diagram and a list of detailed installation steps.

- **Scenario 1:** Install WebSphere Application Server - Express on a single machine.

  Installing WebSphere Application Server - Express by itself on a single machine creates a stand-alone application server, which is server1. Installing Express creates a set of system files and a *profile* for the application server. The profile is a separate set of files that define the application server environment.

In this scenario, the application server uses its internal HTTP transport chain for communication, which is suitable for handling an application with a relatively low request work load. For example, this type of installation can support a simple test environment or a departmental intranet environment.

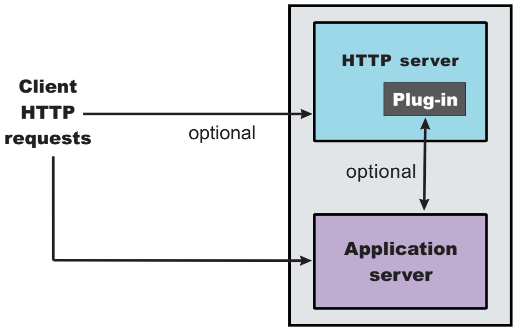


Machine A
WebSphere Application Server, Version 6.0
Shared product binaries (system files)
Profile01

1. Install WebSphere Application Server - Express. See the *Installing your application serving environment* PDF.

- **Scenario 2:** Install WebSphere Application Server - Express and a Web server on a single machine.

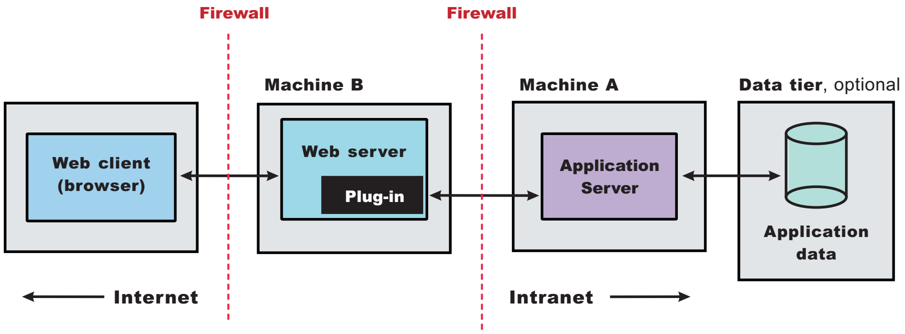
  Installing a Web server, such as IBM HTTP Server, on the same machine as the application server provides a more robust Web server environment. Installing a Web server plug-in is a requirement for the Web server to communicate with the application server. This type of installation supports rigorous testing environments or production environments that do not require a firewall. However, this is not a typical production environment.



1. Install WebSphere Application Server - Express See the *Installing your application serving environment* PDF.
2. Install IBM HTTP Server or another supported Web server. See your Web server documentation.
3. Install the Web server plug-ins and configure the Web server using the Plug-ins installation wizard. See the *Installing your application serving environment* PDF.

- **Scenario 3:** Install WebSphere Application Server - Express and a Web server on separate machines.

  In the typical production environment, the application server on one machine communicates with a Web server on a separate (remote) machine through the Web server plug-in. Optional firewalls can provide additional security for the application server machine.



1. Install WebSphere Application Server - Express on Machine A. See the *Installing your application serving environment* PDF.
2. Install IBM HTTP Server or another supported Web server on Machine B. See your Web server documentation.
3. Install the Web server plug-ins and configure the Web server using the Plug-ins installation wizard on Machine B. See the *Installing your application serving environment* PDF.
4. The Plug-ins installation wizard creates a script named `configure`*`Web_server_name`* in the *plugins_install_root*/`bin` directory on Machine B. Copy the script to the *install_root*/`bin` directory on Machine A.
5. Run the `configure`*`Web_server_name`* script to create a Web server definition in the administrative console. You can then use the administrative console to manage the Web server.
6. Propagate the `plugin-cfg.xml` file from the application server to the Web server using the administrative console. Click **Servers > Web server > Propagate Plug-in**. (Web servers other than IBM HTTP Server require manual propagation.)

- **Scenario 4:** Install multiple stand-alone application servers on one machine and a Web server on a separate machine.

  A profile is a separate data partition containing the files that define the run-time environment for an application server. A default profile is created during the installation of the Express product. Create additional profiles using the Profile creation wizard. Each profile defines a separate stand-alone application server that has its own administrative interface.

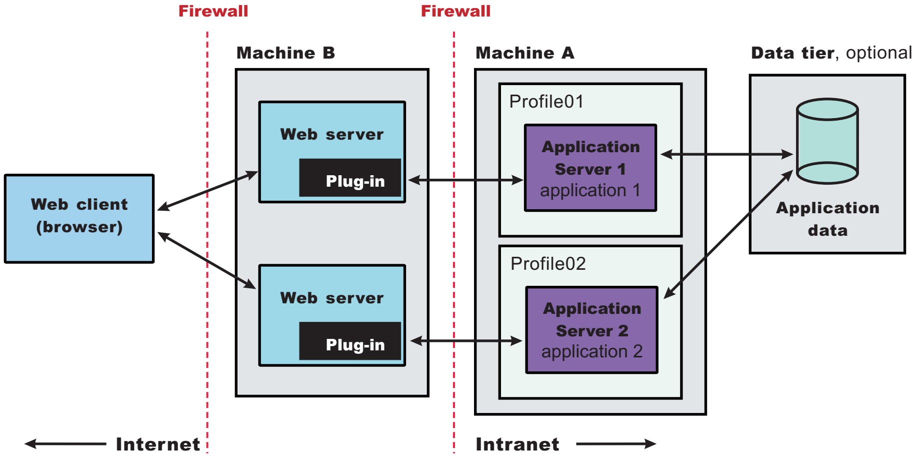
  After creating a profile and installing a dedicated Web server, use the Plug-ins installation wizard to install a Web server plug-in and to update the Web server configuration file. The Web server can then communicate with the application server.

  This topology lets each profile have unique applications, configuration settings, data, and log files, while sharing the same set of core product files. Creating multiple profiles creates multiple application server environments that you can dedicate to different purposes.

  For example, each application server on a Web site can serve a different application. In another example, each application server can be a separate test environment that you assign to a programmer or a development team.

  Updating the core product files

  Another feature of having multiple profiles is enhanced serviceability. When a refresh pack or fix pack updates the core product files on a machine, all of the application server profiles that were created from the core product files begin using the updated files. In some situations, you might prefer to not update all of the application servers on a machine. In such situations, simply install the product a second time to create a second set of core product files. Create application server profiles from both installations to manage the product updates incrementally.

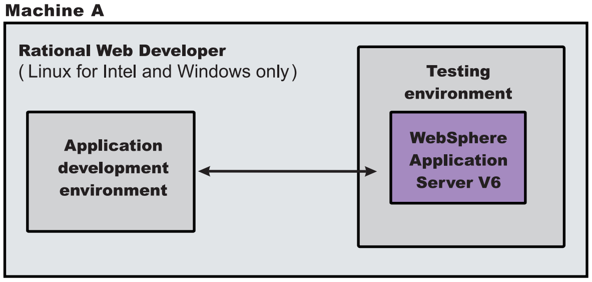


1. Install WebSphere Application Server - Express on Machine A. See the *Installing your application serving environment* PDF.
2. Install IBM HTTP Server or another supported Web server on Machine B. See your Web server documentation.
3. Install the Web server plug-ins and configure the Web server using the Plug-ins installation wizard on Machine B. See the *Installing your application serving environment* PDF.
4. The Plug-ins installation wizard creates a script named `configure`*`Web_server_name`* in the *plugins_install_root*/`bin` directory on Machine B. Copy the script to the *install_root*/`bin` directory on Machine A.
5. Run the `configure`*`Web_server_name`* script to create a Web server definition in the administrative console. You can then use the administrative console to manage the Web server.
6. Propagate the `plugin-cfg.xml` file from the application server to the Web server using the administrative console. Click **Servers > Web server > Propagate Plug-in**. (Web servers other than IBM HTTP Server require manual propagation.)
7. Create the second Application Server profile using the Profile creation wizard on Machine A. Make the profile the default profile during the profile creation by selecting the check box on the appropriate panel.

   The script that the Plug-ins installation wizard creates works on the default profile only. So, this script can only create a Web server definition on the profile that is the default profile at the time that the script runs.
8. Install a second IBM HTTP Server or another supported Web server on Machine B. See your Web server documentation.
9. On Machine B, install the Web server plug-ins to configure the second Web server using the Plug-ins installation wizard. Both Web servers share a single installation of the plug-in binaries but must be configured individually. See the *Installing your application serving environment* PDF.
10. The Plug-ins installation wizard creates a script named `configure`*`Web_server_name`* for the second Web server. The script is in the *plugins_install_root*/`bin` directory on Machine B. Copy the script to the *install_root*/`bin` directory on Machine A.
11. Run the `configure`*`Web_server_name`* script to create a Web server definition in the administrative console. You can then use the administrative console to manage the Web server.
12. Propagate the `plugin-cfg.xml` file from the second application server to the Web server using the administrative console. Click **Servers > Web server > Propagate Plug-in**. (Web servers other than IBM HTTP Server require manual propagation.)

- **Scenario 5:** Install Rational Web Developer on a single machine.

  Install Rational Web Developer by itself to create an integrated development environment. Developers can test applications in the test environment for V6 that is included in the Rational Web Developer product.

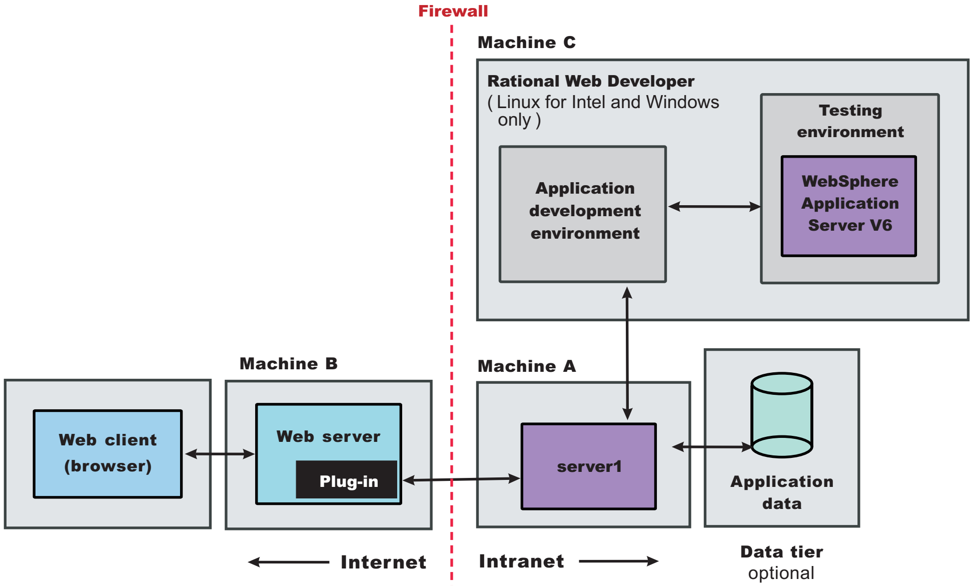


Machine A
Rational Web Developer
(Linux for Intel and Windows only)
Application development environment
Testing environment
WebSphere Application Server V6

1. Install Rational Web Developer.

- **Scenario 6:** Install WebSphere Application Server - Express, Rational Web Developer, and a Web server on multiple machines.

  In this integrated testing environment, install the application server behind an optional firewall on one machine and the Web server on a separate (remote) machine. The Web server plug-in lets the application server and Web server communicate with each other. Install Rational Web Developer on a separate Linux (Intel) or Windows machine. This type of installation is useful for quality assurance because the test environment closely mirrors the typical production environment.



1. Install WebSphere Application Server - Express on Machine A. See the *Installing your application serving environment* PDF.
2. Install IBM HTTP Server or another supported Web server on Machine B. See your Web server documentation.
3. Install the Web server plug-ins and configure the Web server using the Plug-ins installation wizard on Machine B. See the *Installing your application serving environment* PDF.
4. The Plug-ins installation wizard creates a script named `configure`*`Web_server_name`* in the *plugins_install_root*/`bin` directory on Machine B. Copy the script to the *install_root*/`bin` directory on Machine A.
5. Run the `configure`*`Web_server_name`* script to create a Web server definition in the administrative console. You can then use the administrative console to manage the Web server.
6. Propagate the `plugin-cfg.xml` file from the application server to the Web server using the administrative console. Click **Servers > Web server > Propagate Plug-in**. (Web servers other than IBM HTTP Server require manual propagation.)
7. Install Rational Web Developer on Machine C.

You can review common installation scenarios to find a possible match for the topology that you intend to install. Each product installation diagram provides a high-level procedure for installing the components that comprise the topology.

After determining a possible topology, you are ready to follow the detailed installation instructions for each product that you plan to install.

Planning to install Web server plug-ins

This topic describes common installation scenarios and links to component installation procedures for each scenario.

The primary production configuration is an application server on one machine and a Web server on a separate machine. This configuration is referred to as a *remote* configuration. Contrast the remote configuration to the local configuration, where the application server and the Web server are on the same machine.

The Plug-ins installation wizard has four main tasks:

- Installs the binary plug-in module on the Web server machine.
- Configures the Web server configuration file on the Web server machine to point to the binary plug-in module and to the XML configuration file for the binary module.
- Installs a temporary XML configuration file for the binary module (`plugin-cfg.xml`) on the Web server machine in remote scenarios.
- Creates the configuration for a Web server definition on the application server machine. The wizard processes the creation of the Web server definition differently depending on the scenario:
  - Recommended remote stand-alone Application Server installation:

    Creates a configuration script that you run on the application server machine. Install the Web server and its plug-in on a different machine than the application server. This configuration is recommended for a production environment.
  - Local stand-alone Application Server installation:

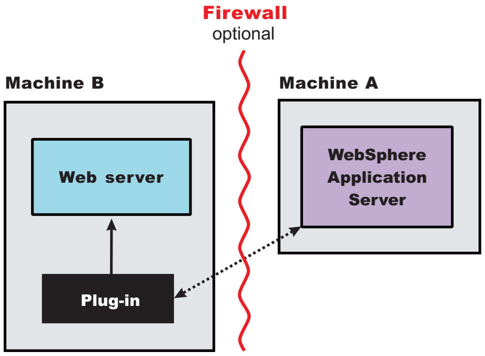
    Detects the default profile on a local application server machine and creates the Web server definition for it directly. Install the Web server and its plug-in on the same machine with the application server. This configuration is for development and test environments.

Select a link to go to the appropriate steps in the following procedure.

- **Set up a remote Web server installation.**

  The remote Web server configuration is recommended for production environments.

  The remote installation installs the Web server plug-in on the Web server machine when the application server is on a separate machine, such as shown in the following graphic:



Remote installation scenario

Table 1. Installation and configuration

Step	Machine	Task
1	A	Install your WebSphere Application Server product. See ″Installing the product and additional software″ in the information center.
2	B	Install IBM HTTP Server or another supported Web server. See ″Installing IBM HTTP Server″ in the information center.
3	B	Install the binary plug-in module using the Plug-ins installation wizard. See ″Configuring a Web server and an application server on separate machines (remote)″ in the information center. The script for creating and configuring the Web server is created under the *`plug-ins_install_root`*`/ bin` directory.
4	B	Copy the `configure`*`Web_server_name`* script to Machine A. If one machine is running under Linux or UNIX and the other machine is running under Windows, copy the script from the *`plug-ins_install_root`*`/ bin/ crossPlatformScripts` directory.
5	A	Paste the `configure`*`Web_server_name`* script from Machine B to the *`was_install_root`*`/ bin` directory on Machine A.
6	A	Run the script from a command line.
7	A	Verify that the application server is running. Open the administrative console and save the changed configuration.
8	B	Linux UNIX Run the *plug-ins_install_root*`/setupPluginCfg.sh` script for a Domino Web Server before starting a Domino Web server.Otherwise, start the Web server.
9	B	Run the snoop servlet. See ″Troubleshooting installation″ in the information center. To verify with your own application, regenerate and propagate the `plugin-cfg.xml` file after installing the application.

Regeneration of the `plugin-cfg.xml` file

During the installation of the plug-ins, the temporary `plugin-cfg.xml` file is installed on Machine B in the *`plug-ins_install_root`*`/ config/ web_server_name` directory.

The Web server plug-in configuration service regenerates the `plugin-cfg.xml` file automatically.

To use the real `plugin-cfg.xml` file from the application server, propagate the `plugin-cfg.xml` file as described in the next section.

Propagation of the `plugin-cfg.xml` file

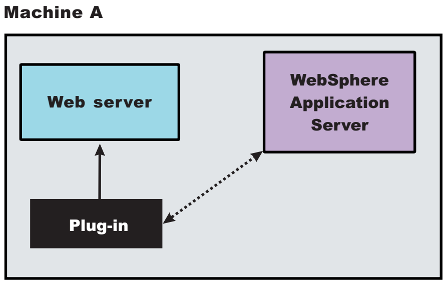
The Web server plug-in configuration service propagates the `plugin-cfg.xml` file automatically for IBM HTTP Server 6.0 only.

For all other Web servers, propagate the plug-in configuration file manually. Copy the `plugin-cfg.xml` file from the *`profiles_install_root`*`/ config/ cells/` *`cell_name`*`/ nodes/` *`Web_server_name`*`_node/ servers/` *`web_server_name`* directory on Machine A. Paste the file into the *`plug-ins_install_root`*`/ config/` *`web_server_name`* directory on Machine B.

- **Set up a local Web server configuration.**

  The local Web server configuration is recommended for a development or test environment.

  A local installation includes the Web server plug-in, the Web server, and the application server on the same machine:



Local installation scenario

Table 2. Installation and configuration

Step	Machine	Task
1	A	Install your WebSphere Application Server product. See ″Installing the product and additional software″ in the information center.
2	A	Install IBM HTTP Server or another supported Web server. See ″Installing IBM HTTP Server″ in the information center.
3	A	Install the binary plug-in module using the Plug-ins installation wizard. See ″Configuring a Web server and an application server on separate machines (remote)″ in the information center. The Web server definition is automatically created and configured during the installation of the plug-ins.
4	A	Verify that the application server is running. Open the administrative console and save the changed configuration.
5	B	Linux UNIX Run the *plug-ins_install_root*/`setupPluginCfg.sh` script for a Domino Web Server before starting a Domino Web server.Otherwise, start the Web server.
6	B	Run the snoop servlet. To verify with your own application, regenerate and propagate the `plugin-cfg.xml` file after installing the application.

Regeneration of the `plugin-cfg.xml` file

The Web server plug-in configuration service regenerates the `plugin-cfg.xml` file automatically.

The `plugin-cfg.xml` file is generated in the *profiles_install_root*/ *profile_name*/ config/ cells/ *cell_name*/ nodes/ *Web_server_name*_node/ servers/ *web_server_name* directory. The generation occurs when the Web server definition is created.

Propagation of the plugin-cfg.xml file

The local file does not require propagation.

You can set up a remote or local Web server by installing Application Server, the Web server, and then the Web server plug-ins.

See Web server configuration for more information about the files involved in configuring a Web server.

See ″Editing Web server configuration files″ in the information center for details for information about the logic behind the processing scenarios for the Plug-ins installation wizard.

See Editing Web server configuration files for information about how the Plug-ins installation wizard configures supported Web servers.

See Installing Web server plug-ins for information about other installation scenarios for installing Web server plug-ins.

Planning to install WebSphere Application Server Clients

This topic helps you examine typical topologies and uses for WebSphere Application Server Clients.

This topic is one in a series of topics described in "Planning the installation (diagrams)" on page 15. Consider all of the planning scenarios that are mentioned in the parent article to determine the best approach to installing your e-business network. This topic describes installing and using the WebSphere Application Server Clients.

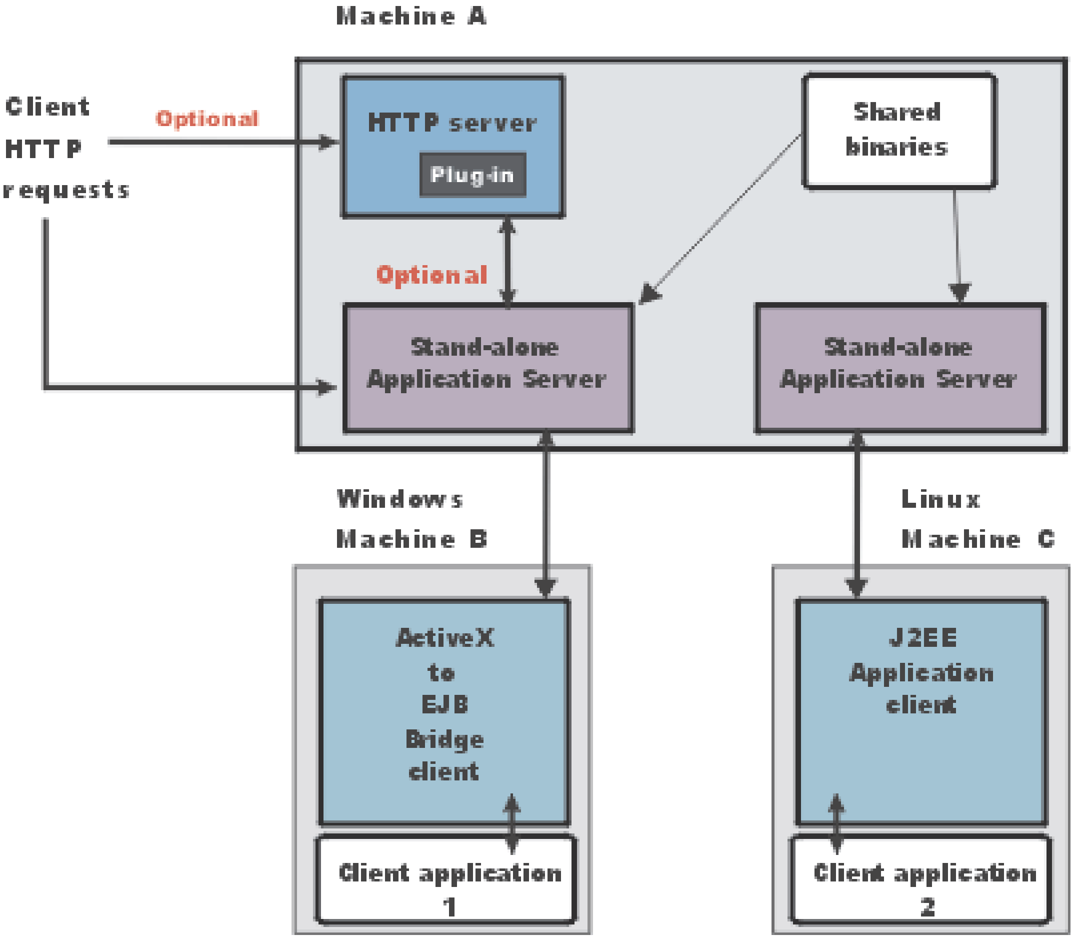
In a traditional client server environment, the client requests a service and the server fulfills the request. Multiple clients use a single server. Clients can also access several different servers. This model persists for Java clients except that now these requests use a client run-time environment.

In this model, the client application requires a servlet to communicate with the enterprise bean, and the servlet must reside on the same machine as the WebSphere Application Server.

The Application Client for WebSphere Application Server, Version 6 now consists of the following models:

- ActiveX application client
- Applet client
- J2EE application client
- Pluggable and thin application clients

The following graphic shows a topology for installing the Application Client and using client applications:



The example shows two types of application clients installed in a topology that uses client applications to access applications and data on Machine A:

- The ActiveX application client on Machine B is a Windows only client that uses the Java Native Interface (JNI) architecture to programmatically access the Java virtual machine (JVM) API. The JVM code exists in the same process space as the ActiveX application (Visual Basic, VBScript, or Active Server Pages (ASP) files) and remains attached to the process until that process terminates.
- The J2EE application client on Machine C is a Java application program that accesses enterprise beans, Java Database Connectivity (JDBC) APIs, and Java Message Service message queues. The application program must configure the execution environment of the J2EE application client and use the Java Naming and Directory Interface (JNDI) name space to access resources.

Use the following procedure as a roadmap for installing the Application Client.

1. Install the WebSphere Application Server product from your product CD on Machine A to establish the core product files.
2. Use the Profile creation wizard to create the additional stand-alone application server profile.
3. Use the administrative console of each application server to deploy any user applications.
4. Use the administrative console of each application server to create a Web server configuration for the Web server.
5. Use the administrative console of each application server to regenerate each `plugin-cfg.xml` file in the local Web server configuration.
6. Install the IBM HTTP Server from the product CD on Machine A.
7. Use the Plug-ins installation wizard to install the plug-in for IBM HTTP Server on Machine A.

   The wizard automatically configures the HTTP Server to communicate with the first application server.
8. Install the Application Client from your product CD on Machine B.
   a. Select the Custom install type.
   b. Select the ActiveX to EJB Bridge feature.
   c. Select to add the Java run time to the system path.
   d. Select the Java run time as the default JRE, which adds the Java run time path to the beginning of the system path.
9. Install the Application Client from your product CD on Machine C.
   a. Select the Custom install type.
   b. Select the J2EE application client feature.

This topic can help you plan run-time environments for client applications.

See “Application Client for WebSphere Application Server” on page 839 for information about creating client applications.

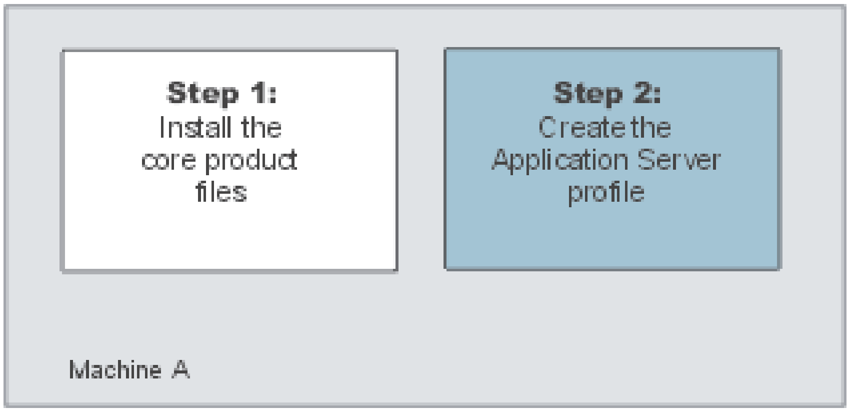
Planning to create application server environments

Application server profiles are the run-time environments for application server processes. This topic describes common scenarios for creating application server profiles and provides links to profile creation procedures for each scenario.

Install the core product files for a WebSphere Application Server product before using the Profile creation wizard to create additional application server run-time environments.

This topic describes how to use the Profile creation wizard to create application server profiles. Each profile is a run-time environment for the application server that it defines, with data files, configuration files, applications, and an administrative console.

Create a stand-alone application server, as described in “Using the Profile creation wizard to create an application server” on page 38.



The installation procedure creates an application server during installation named server1. However, you can use the Profile creation wizard to create more stand-alone application servers on a machine where server1 or another application server already exists.

You can create additional application server processes using the Profile creation wizard.

After installing the product and optionally adding more application servers with the Profile creation wizard, you are ready to deploy applications to test the environment.

Queuing network

WebSphere Application Server contains interrelated components that must be harmoniously tuned to support the custom needs of your end-to-end e-business application. These adjustments help the system achieve maximum throughput while maintaining the overall stability of the system. This group of interconnected components is known as a queuing network. These queues or components include the network, Web server, Web container, EJB container, data source, and possibly a connection manager to a custom back-end system. Each of these resources represents a queue of requests waiting to use that resource. Various queue settings include:

- IBM HTTP Server: MaxClients for UNIX and ThreadsPerChild for Windows NT and Windows 2000 systems described in “Web server tuning parameters” on page 73.
- Web container: **Maximum size** described in “Thread pool settings” on page 120, **MaxKeepAliveConnections** and **MaxKeepAliveRequests** described in “HTTP transport custom properties” on page 132.
- **Tuning Object Request Brokers** explained in “Tuning application servers” on page 167.
- Data source **connection pooling** and **statement cache size** are explained in the *Developing and deploying applications* PDF.

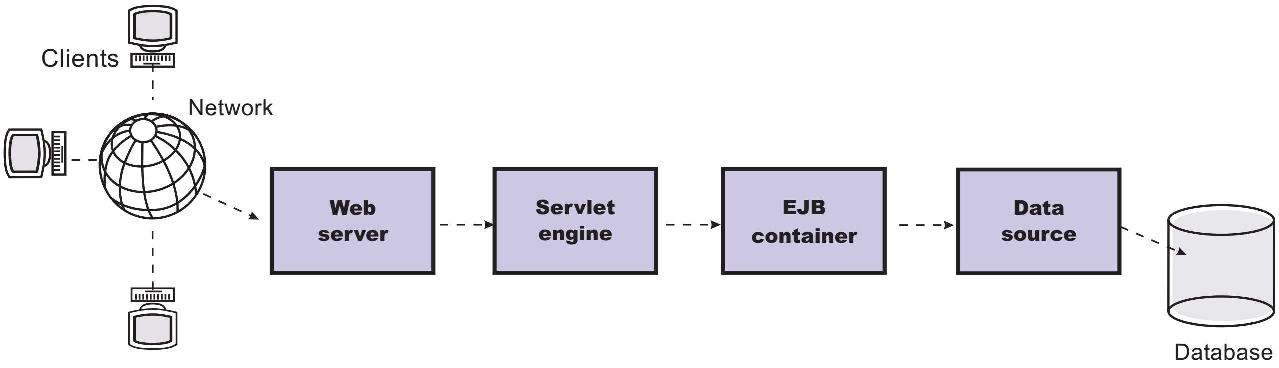


Figure Reference 1: WebSphere queuing network

Most of the queues that make up the queuing network are closed queues. A closed queue places a limit on the maximum number of requests present in the queue, while an open queue has no limit. A closed queue supports tight management of system resources. For example, the Web container thread pool setting controls the size of the Web container queue. If the average servlet running in a Web container creates 10MB of objects during each request, a value of 100 for thread pools limits the memory consumed by the Web container to 1GB.

In a closed queue, requests can be active or waiting. An active request is doing work or waiting for a response from a downstream queue. For example, an active request in the Web server is doing work, such as retrieving static HTML, or waiting for a request to complete in the Web container. A waiting request is waiting to become active. The request remains in the waiting state until one of the active requests leaves the queue.

All Web servers supported by WebSphere Application Server are closed queues, as are WebSphere Application Server data sources. You can configure Web containers as open or closed queues. In general, it is best to make them closed queues. EJB containers are open queues. If there are no threads available in the pool, a new one is created for the duration of the request.

If enterprise beans are called by servlets, the Web container limits the number of total concurrent requests into an EJB container, because the Web container also has a limit. The Web container limits the number of total concurrent requests only if enterprise beans are called from the servlet thread of execution. Nothing prevents you from creating threads and bombarding the EJB container with requests. Therefore, servlets should not create their own work threads.

Queuing and clustering

Cloning application servers can be a valuable asset in configuring highly-scalable production environments, especially when the application is experiencing bottlenecks that are preventing full CPU utilization of symmetric multiprocessing (SMP) servers. When adjusting the WebSphere Application Server system queues in clustered configurations, remember that when a server is added to a cluster, the server downstream receives twice the load.

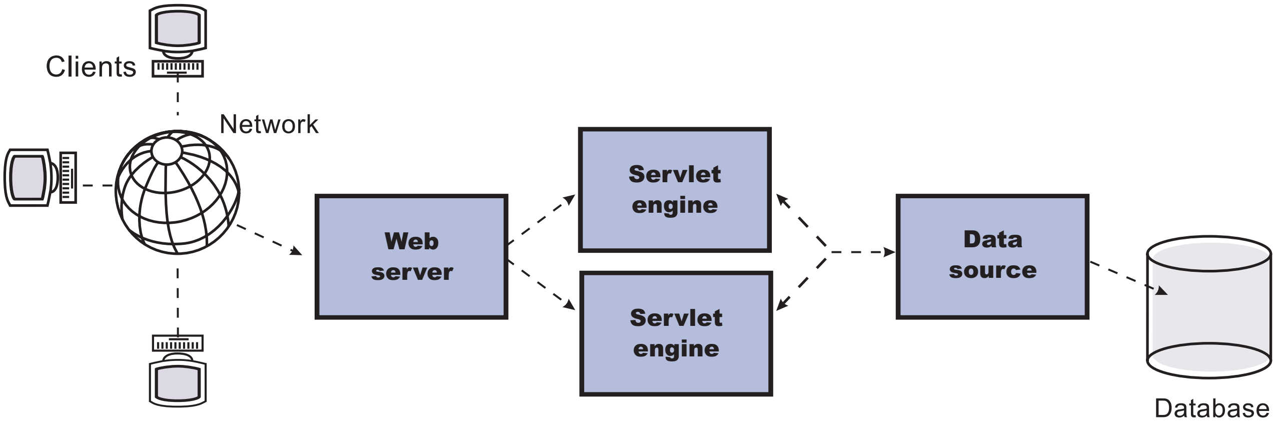

Figure Reference 1: Clustering and queuing

Two servlet engines are located between a Web server and a data source. It is assumed that the Web server, servlet engines and data source, but not the database, are all running on a single SMP server. Given these constraints, the following queue considerations must be made:

- Double the Web server queue settings to ensure ample work is distributed to each Web container.
- Reduce the Web container thread pools to avoid saturating a system resource like CPU or another resource that the servlets are using.
- Reduce the data source to avoid saturating the database server.
- Reduce Java heap parameters for each instance of the application server. For versions of the Java virtual machine (JVM) shipped with WebSphere Application Server, it is crucial that the heap from all JVMs remain in physical memory. For example, if a cluster of four JVMs is running on a system, enough physical memory must be available for all four heaps.

Queue configuration tips

The following section outlines a methodology for configuring the WebSphere Application Server queues. Moving the database server onto another machine or providing more powerful resources, for example a faster set of CPUs with more memory, can dramatically change the dynamics of your system.

There are four tips for queuing:

- **Minimize the number of requests in WebSphere Application Server queues**.

  In general, requests wait in the network in front of the Web server, rather than waiting in WebSphere Application Server. This configuration only supports those requests that are ready for processing to enter the queuing network. Specify that the queues furthest upstream or closest to the client are slightly larger, and queues further downstream or furthest from the client are progressively smaller.

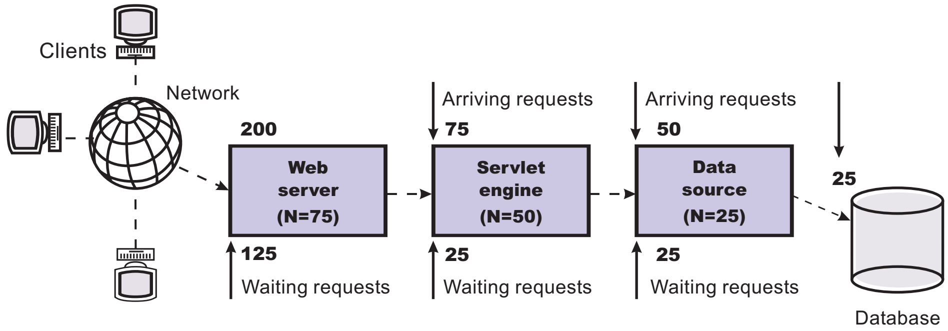

Figure Reference 1: Upstream queuing network

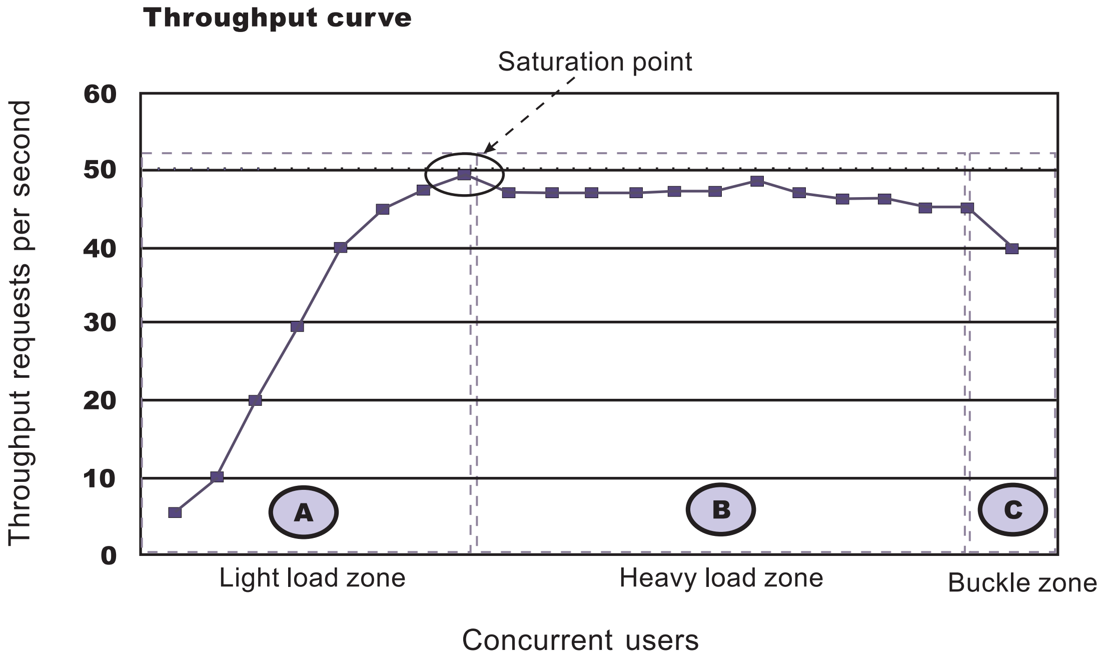
Queues in the queuing network become progressively smaller as work flows downstream. When 200 client requests arrive at the Web server, 125 requests remain queued in the network because the Web server is set to handle 75 concurrent clients. As the 75 requests pass from the Web server to the Web container, 25 requests remain queued in the Web server and the remaining 50 are handled by the Web container. This process progresses through the data source until 25 user requests arrive at the final destination, the database server. Because there is work waiting to enter a component at each point upstream, no component in this system must wait for work to arrive. The bulk of the requests wait in the network, outside of WebSphere Application Server. This type of configuration adds stability, because no component is overloaded.

- **Draw throughput curves to determine when the system capabilities are maximized**.

  You can use a test case that represents the full spirit of the production application by either exercising all meaningful code paths or using the production application. Run a set of experiments to determine when the system capabilities are fully stressed or when it has reached the saturation point. Conduct these tests after most of the bottlenecks are removed from the application. The goal of these tests is to drive CPUs to near 100% utilization. For maximum concurrency through the system, start the initial baseline experiment with large queues. For example, start the first experiment with a queue size of 100 at each of the servers in the queuing network: Web server, Web container and data source. Begin a series of experiments to plot a throughput curve, increasing the concurrent user load after each experiment. For example, perform experiments with one user, two users, five, 10, 25, 50, 100, 150 and 200 users. After each run, record the throughput requests per second, and response times in seconds per request. The curve resulting from the baseline experiments resembles the following typical throughput curve shown as follows:



The WebSphere Application Server throughput is a function of the number of concurrent requests present in the total system. Section A, the light load zone, shows that the number of concurrent user requests increases, the throughput increases almost linearly with the number of requests. At light loads, concurrent requests face very little congestion within the WebSphere Application Server system queues. At some point, congestion starts to develop and throughput increases at a much lower rate until it reaches a saturation point that represents the maximum throughput value, as determined by some bottleneck in the WebSphere Application Server system. The most manageable type of bottleneck occurs when the WebSphere Application Server machine CPUs become fully utilized because adding CPUs or more powerful CPUs fixes the bottleneck.

In the heavy load zone or Section B, as the concurrent client load increases, throughput remains relatively constant. However, the response time increases proportionally to the user load. That is, if the user load is doubled in the heavy load zone, the response time doubles. At some point, represented by Section C, the buckle zone, one of the system components becomes exhausted. At this point, throughput starts to degrade. For example, the system might enter the buckle zone when the network connections at the Web server exhaust the limits of the network adapter or if the requests exceed operating system limits for file handles.

If the saturation point is reached by driving CPU utilization close to 100%, you can move on to the next step. If the saturation CPU occurs before system utilization reaches 100%, it is likely that another bottleneck is being aggravated by the application. For example, the application might be creating Java objects causing excessive garbage collection bottlenecks in the Java code.

There are two ways to manage application bottlenecks: remove the bottleneck or clone the bottleneck. The best way to manage a bottleneck is to remove it. You can use a Java-based application profiler, such as Rational Application Developer, Performance Trace Data Visualizer (PTDV), Borland's Optimizeit, JProbe or Jinsight to examine overall object utilization.

- **Decrease queue sizes while moving downstream from the client**.

  The number of concurrent users at the throughput saturation point represents the maximum concurrency of the application. For example, if the application saturates WebSphere Application Server at 50 users, using 48 users might produce the best combination of throughput and response time. This value is called the Max Application Concurrency value. Max Application Concurrency becomes the preferred value for adjusting the WebSphere Application Server system queues. Remember, it is desirable for most users to wait in the network; therefore, queue sizes should increase when moving downstream farther from the client. For example, given a Max Application Concurrency value of 48, start with system queues at the following values: Web server 75, Web container 50, data source 45. Perform a set of additional experiments adjusting these values slightly higher and lower to find the best settings.

To help determine the number of concurrent users, view the Servlet Engine Thread Pool and Concurrently Active Threads metric in the Tivoli Performance Viewer.

- **Adjust queue settings to correspond to access patterns**.

  In many cases, only a fraction of the requests passing through one queue enters the next queue downstream. In a site with many static pages, a number of requests are fulfilled at the Web server and are not passed to the Web container. In this circumstance, the Web server queue can be significantly larger than the Web container queue. In the previous example, the Web server queue was set to 75, rather than closer to the value of Max Application Concurrency. You can make similar adjustments when different components have different execution times.

  For example, in an application that spends 90% of its time in a complex servlet and only 10% of its time making a short JDBC query, on average 10% of the servlets are using database connections at any time, so the database connection queue can be significantly smaller than the Web container queue. Conversely, if the majority of servlet execution time is spent making a complex query to a database, consider increasing the queue values at both the Web container and the data source. Always monitor the CPU and memory utilization for both the WebSphere Application Server and the database servers to verify that the CPU or memory are not saturating.

Configuring the product after installation

This topic summarizes how to configure the application serving environment.

Use the First steps console to configure and test the WebSphere Application Server environment after installation.

This procedure uses the First steps console to launch the installation verification test (IVT) that tests and verifies your WebSphere Application Server - Express environment. This procedure also uses the First steps console to launch the Profile creation wizard to create an additional Application Server.

1. Start the First steps console by selecting the check box on the last panel of the wizard.

   The First steps console can start automatically at the end of the installation. Select the check box on the last panel of the Installation wizard.

   The First steps console is an easy way to start using the product. The console provides one-stop access to the administrative console, Samples Gallery, Profile creation wizard, installation verification test, Migration wizard, and other activities.

   See the description of the “firststeps command” on page 33 for more information.
2. Click **Installation verification** on the First steps console.

   The installation verification test starts the Application Server process named server1 and runs several tests to verify that the server1 process can start without errors.

   See “Using the installation verification test” on page 53 for more information.
3. Click **Profile creation wizard** on the First steps console to create an Application Server profile.

   You can create multiple Application Servers on your system without installing the product again.

   See “Using the Profile creation wizard to create an application server” on page 38.
4. Start the First steps console by selecting the check box on the last panel of the Profile creation wizard.

   This First steps console belongs to the Application Server profile that you just created. Each profile has its own First steps console.
5. Click **Installation verification** on the First steps console.

   The installation verification test starts the new Application Server process named server1 and runs several tests to verify that the server1 process can start without error.

This procedure results in configuring and testing the Application Server environment.

See “Planning to install WebSphere Application Server - Express” on page 17 for diagrams of topologies that you can create using the First steps console and the Profile creation wizard.

firststeps command

The **firststeps** command starts the First steps console.

The First steps console

The First steps console is a post-installation ease-of-use tool for directing WebSphere Application Server elements from one place. Options display dynamically on the First steps console, depending on features you install. With all of the options present, you can use the First steps console to start or stop the application server, verify the installation, access the information center, access the administrative console, launch the Migration wizard, or access the Samples gallery.

Select the check box to start the First steps console at the end of the product installation.

You can also start the First steps console from the command line as described later.

Installation verification

This option starts the installation verification test (IVT). The test consists of starting and monitoring the application server during its start up.

If this is the first time that you have used the First steps console since creating an application server profile, click **Installation verification** to verify that all is well with your installation. The verification process starts the application server.

If you select the **Installation verification** option, the **Start the server** option is grayed out while the IVT is running.

The IVT provides the following useful information about the application server:

- The server name: server1
- The name of the profile
- The profile file path
- The type of profile: default
- The cell name
- The node name
- The current encoding
- The port number for the administrative console
- Various informational messages that include the location of the `SystemOut.log` file and how many errors are listed within the file
- A completion message

Start the server

This option toggles to **Stop the server** when the application server is running.

After selecting the **Start the server** option, an output screen displays with status messages. The success message informs you that the server is open for e-business. Then the menu item changes to **Stop the server**.

If you select the **Start the server** option, the **Installation verification** option is grayed out while the application server is running.

Administrative console

This option is grayed out until the application server is running.

The administrative console is a configuration editor that runs in a Web browser. The administrative console lets you work with XML configuration files for the application server. To launch the administrative console, click **Administrative console**. You can also point your browser to http://localhost:9060/ibm/console to start the administrative console. Substitute your own host name in the address if the localhost variable does not resolve correctly. As the administrative console opens, it prompts you for a login name. This is not a security item, but merely a tag to identify configuration changes that you make during the session. Secure signon is also available.

Profile creation wizard

This option starts the Profile creation wizard. The wizard lets you create additional application servers. A *profile* consists of files that define the run-time environment for the application server. Each environment has its own administrative interface. This means that the new application server has its own administrative console.

Each application server has its own First steps console. The location of the command is within the set of files in the profile. A prompt to launch the First steps console displays on the last panel of the Profile creation wizard.

Samples gallery

This option starts the Samples gallery. The option is grayed out until you start the application server. The option displays when you have installed the Samples during installation. The typical installation includes the Samples by default.

From the First steps console, click **Samples gallery** to explore the application Samples. Alternatively you can point your browser directly to http://localhost:9080/WSsamples. Substitute your own host name in the address if the localhost variable does not resolve correctly. The Web address is case sensitive. Substitute your own host name in the address.

Information center for WebSphere Application Server

This option links you to the online information center at the http://publib.boulder.ibm.com/infocenter/ws60help/index.jsp IBM Web address.

Migration wizard

This option starts the Migration wizard. The Migration wizard is a new graphical interface to the migration tools. The migration tools are described in ″WASPreUpgrade command″ and ″WASPostUpgrade command″ in the information center.

Exit This option closes the First steps console.

Location of the command file

Installing the product creates a default profile for the server1 application server. The location of the First steps console for the default profile is:

- Linux UNIX *install_root*`/profiles/default/firststeps/firststeps.sh`
- Windows *install_root*`\profiles\default\firststeps\firststeps.bat`

The location of the `firststeps.sh` or `firststeps.bat` script for any profile is:

- Linux UNIX *install_root*`/profiles/`*profile_name*`/firststeps/firststeps.sh`
- Windows *install_root*`\profiles\`*profile_name*`\firststeps\firststeps.bat`

Parameters

No parameters are associated with this command.

Syntax for the firststeps command

Use the following syntax for the command:

- Linux UNIX `./firststeps.sh`

- Windows `firststeps.bat`

Usage tips

The following links exist on the First steps console for the WebSphere Application Server - Express product:

Option	Link
Installation verification	Calls the **ivt** command. The location of the installation verification test varies per platform: • Linux UNIX *install_root*/profiles/*profile_name*/bin/ivt.sh • Windows *install_root*\profiles\profile_name\bin\ivt.bat
Start the server	Calls the **startServer** command. The location of the **startServer** command varies per platform: • Linux server1 UNIX *install_root*/profiles/*profile_name*/bin/startServer.sh • Windows *install_root*\profiles\profile_name\bin\startServer.bat server1 When you have more than one application server on the same machine, the command starts the same application server that is associated with the First steps console.
Stop the server	Calls the **stopServer** command. The location of the **stopServer** command varies per platform: • Linux server1 UNIX *install_root*/profiles/*profile_name*/bin/stopServer.sh • Windows *install_root*\profiles\profile_name\bin\stopServer.bat server1
Administrative console	Opens the default browser to the http://localhost:9060/ibm/console Web address. When you have more than one application server on the same machine, the port varies. The First steps console starts the administrative console that is associated with the First steps console.

Option	Link
Profile creation wizard	Calls the **pct*platform*** command. The command is in the *install_root*/bin/ProfileCreator directory. The name of the command varies per platform: • AIX pctAIX.bin • HP-UX pctHPUX.bin • HP-UX 64-bit platforms: pctHPUXIA64.bin • Linux pctLinux.bin • Linux 64-bit platforms: pct.bin • Linux Power platforms: pctLinuxPPC.bin • Solaris pctSolaris.bin • Windows pctWindows.exe • Windows 64-bit platforms: pctWindowsIA64.exe
Samples Gallery	Opens the default browser to the http://localhost:9080/WSsamples Web address. If you do not install Samples, the option does not appear on the First steps console. If you do not install the Samples during the initial installation of the product, the option does not display on the First steps console. You can perform an incremental installation to add the Samples feature. After adding the Samples, the options displays on the First steps console. When you have more than one profile on the same machine, the port varies. The First steps console starts the Samples gallery that is associated with the First steps console.
Information center for WebSphere Application Server products	Opens the default browser to the online information center at the http://publib.boulder.ibm.com/infocenter/ws60help/index.jsp Web address.
Migration wizard	Calls the **migration** command. The location of the **migration** command is: • Linux UNIX *install_root*/bin/migration.sh • Windows *install_root*\bin\migration.bat The migration tools are also in the /migration folder on the product disc.

Using the Profile creation wizard

This topic describes how to create run-time environments for WebSphere Application Server. Each run-time environment is created within a *profile*. A profile is the set of files that define the run-time environment. The Profile creation wizard creates the profile for each run-time environment.

Before using the Profile creation wizard, install the core product files.

The Profile creation wizard is the wizard interface to the profile creation tool, wasprofile. See the description of the "wasprofile command" on page 43 for more information.

An error can occur when you have not provided enough system temporary space to create a profile. Verify that you have a minimum of 40 MB of temp space available before creating a profile.

You must have 200 MB of available disk space in the directory where you create an Application Server profile.

AIX Manually verify that the required space for creating a profile is available on AIX. A known problem in the underlying InstallShield for Multiplatforms (ISMP) code prevents proper space checking on AIX systems at the time that the product disc was created.

Important: Concurrent profile creation is not supported at this time for one set of core product files. Concurrent attempts to create profiles result in a warning about a profile creation already in progress.

The installation procedure creates one profile named `default` for an application server named `server1`. You can use the Profile creation wizard to create more application server processes. For example, a second profile can allow two different teams in a department to test independently of one another using the same machine.

Each use of the Profile creation wizard or the **wasprofile** command line tool creates one profile.

1. Install the product to create the core product files.
2. Start the Profile creation wizard to create a new run-time environment.

   Several ways exist to start the wizard.

   One way to start the wizard is to issue the command directly from a command line.

   The command is in the *install_root*`/bin/ProfileCreator` directory. The name of the command varies per platform:

   - AIX `pctAIX.bin`
   - HP-UX `pctHPUX.bin`
   - HP-UX 64-bit platforms: `pctHPUXIA64.bin`
   - Linux `pctLinux.bin`
   - Linux 64-bit platforms: `pct.bin`
   - Linux Power platforms: `pctLinuxPPC.bin`
   - Solaris `pctSolaris.bin`
   - Windows `pctWindows.exe`
   - Windows 64-bit platforms: `pctWindowsIA64.exe`

   Another way to start the Profile creation wizard is to select the wizard from the First steps console.

   a. Open a command window.

   b. Change directories to the `firststeps` directory in the installation root directory:

      The installation root varies by platform:

      - AIX `/usr/IBM/WebSphere/AppServer/firststeps`
      - HP-UX Linux Solaris `/opt/IBM/WebSphere/AppServer/firststeps`
      - Windows `C:\Program Files\IBM\WebSphere\AppServer\firststeps`

   c. Issue the **firststeps** command to start the console:

        - Linux UNIX `./firststeps.sh`
        - Windows `firststeps.bat`
    d. Select the Profile creation wizard option on the console.

       The Profile creation wizard is an InstallShield for Multiplatforms application. The wizard loads the Java 2 SDK and then displays its Welcome panel.

    See the description of the “firststeps command” on page 33 for more information.
3. Create another stand-alone application server.

   See “Using the Profile creation wizard to create an application server.”

   The installation procedure creates a stand-alone application server during installation. However, you can use the Profile creation wizard to create additional stand-alone application servers.

See the description of the “wasprofile command” on page 43 to learn more about the command-line alternative method of creating a profile, and to see examples of using the command.

See “Planning the installation (diagrams)” on page 15 for examples of configurations that you can create by creating profiles.

Using the Profile creation wizard to create an application server

The Profile creation wizard can create an application server profile on any machine where the core product files exist.

Before using the Profile creation wizard, install the core product files.

The Profile creation wizard is the wizard interface to the profile creation tool, wasprofile. See the description of the “wasprofile command” on page 43 for more information.

An error can occur when you have not provided enough system temporary space to create a profile. Verify that you have a minimum of 40 MB of temp space available before creating a profile.

You must have 200 MB of available disk space in the directory where you create an Application Server profile.

AIX Manually verify that the required space for creating a profile is available on AIX. A known problem in the underlying InstallShield for Multiplatforms (ISMP) code prevents proper space checking on AIX systems at the time that the product disc was created.

The Installation wizard creates an application server profile with a server named server1. You can create additional profiles. Each additional profile is an application server named server1.

This procedure describes creating an application server profile using the graphical user interface provided by the Profile creation wizard.

You can also use the **wasprofile** command to create an application server profile. See the description of the “wasprofile command” on page 43 for more information.

1. Start the Profile creation wizard to create a new run-time environment.

   Several ways exist to start the wizard.

   One way to start the wizard is to issue the command directly from a command line.

   The command is in the *install_root*/`bin/ProfileCreator` directory. The name of the command varies per platform:

   - AIX `pctAIX.bin`

- HP-UX `pctHPUX.bin`
- HP-UX 64-bit platforms: `pctHPUXIA64.bin`
- Linux `pctLinux.bin`
- Linux 64-bit platforms: `pct.bin`
- Linux Power platforms: `pctLinuxPPC.bin`
- Solaris `pctSolaris.bin`
- Windows `pctWindows.exe`
- Windows 64-bit platforms: `pctWindowsIA64.exe`

Another way to start the Profile creation wizard is to select the wizard from the First steps console.

a. Open a command window.

b. Change directories to the `firststeps` directory in the installation root directory:

   The installation root varies by platform:

   - AIX `/usr/IBM/WebSphere/AppServer/firststeps`
   - HP-UX Linux Solaris `/opt/IBM/WebSphere/AppServer/firststeps`
   - Windows `C:\Program Files\IBM\WebSphere\AppServer\firststeps`

c. Issue the **firststeps** command to start the console:

   - Linux UNIX `./firststeps.sh`
   - Windows `firststeps.bat`

d. Select the Profile creation wizard option on the console.

   The Profile creation wizard is an InstallShield for Multiplatforms application. The wizard loads the Java 2 SDK and then displays its Welcome panel.

See the description of the "firststeps command" on page 33 for more information.

2. Click **Next** on the Welcome panel.

   The wizard displays the Profile type selection panel.

3. Click **Next**.

   The wizard displays the Profile name panel.

   Each profile that you create must have a name. The name is the name of the folder that contains all of the files that define the run-time environment for the profile. When you have more than one profile, you can tell them apart at their highest level by this name.

4. Specify a name for the profile, then click **Next**.

   Profile naming guidelines: The profile name can be any unique name with the following restrictions. Do not use any of the following characters when naming your profile:

   - Spaces
   - Illegal special characters that are not allowed within the name of a directory on your operating system, such as *&?
   - Slashes (/) or (\)

   Double-byte characters are allowed.

   The default profile

   The first profile that you create on a machine is the default profile. The default profile is the default target for commands issued from the `bin` directory in the product installation root. When only one profile exists on a machine, every command works on the only server process in the configuration.

Addressing a profile in a multi-profile environment

When two or more profiles exist on a machine, certain commands require that you specify the profile to which the command applies. These commands use the -profileName parameter to identify which profile to address. You might find it easier to use the commands that in the `bin` directory of each profile.

A command in the `profiles/`*`profile_name`*`/bin` directory has two lines. The first line sets the WAS_USER_SCRIPT environment variable for the command window. The variable sets up the command environment to address the profile. The second line calls the actual command in the *install_root*/`bin` directory.

The actual command queries the command shell to determine the calling profile and to autonomically address the command to the calling profile.

The wizard then displays the Profile directory panel.

5. Accept the default directory or specify a non-default location, then click **Next**. Or click **Browse** to select a different location.

   If you click **Back** and change the name of the profile, you must manually change the name on this panel when it displays again.

   The wizard displays the Node and host name panel.

6. Specify the characteristics for the application server, then click **Next**.

   Use unique names for each application server that you create.

   Reserved names: Avoid using reserved folder names as field values. The use of reserved folder names can cause unpredictable results. The following words are reserved:

   - cells
   - nodes
   - servers
   - clusters
   - applications
   - deployments

Field name	Default value	Constraints	Description
Node name	Name of your machine	Avoid using the reserved words.	Pick any name you want. To help organize your installation, use a unique name if you plan to create more than one application server on the machine.
Host name	DNS name of your machine	Addressable through your network.	Use the actual DNS name or IP address of your machine to enable communication with your machine. See additional information about the host name following this table.

Node name considerations:

Windows The installation directory path must be no longer than 60 characters.

Host name considerations:

The host name is the network name for the physical machine on which the node is installed. The host name must resolve to a physical network node on the server. When multiple network cards exist in the server, the host name or IP address must resolve to one of the network cards. Remote nodes use the host name to connect to and to communicate with this node. Selecting a host name that other machines can reach within your network is extremely important. Do not use the generic localhost identifier for this value.

If you define coexisting nodes on the same computer with unique IP addresses, define each IP address in a domain name server (DNS) look-up table. Configuration files for stand-alone Application Servers do not provide domain name resolution for multiple IP addresses on a machine with a single network address.

The value that you specify for the host name is used as the value of the hostName property in configuration documents for the stand-alone Application Server. Specify the host name value in one of the following formats:

- Fully qualified domain name servers (DNS) host name string, such as xmachine.manhattan.ibm.com
- The default short DNS host name string, such as xmachine
- Numeric IP address, such as 127.1.255.3

The fully qualified DNS host name has the advantage of being totally unambiguous and also flexible. You have the flexibility of changing the actual IP address for the host system without having to change the Application Server configuration. This value for host name is particularly useful if you plan to change the IP address frequently when using Dynamic Host Configuration Protocol (DHCP) to assign IP addresses. A format disadvantage is being dependent on DNS. If DNS is not available, then connectivity is compromised.

The short host name is also dynamically resolvable. A short name format has the added ability of being redefined in the local hosts file so that the system can run the Application Server even when disconnected from the network. Define the short name to 127.0.0.1 (local loopback) in the hosts file to run disconnected. A format disadvantage is being dependent on DNS for remote access. If DNS is not available, then connectivity is compromised.

A numeric IP address has the advantage of not requiring name resolution through DNS. A remote node can connect to the node you name with a numeric IP address without DNS being available. A format disadvantage is that the numeric IP address is fixed. You must change the setting of the hostName property in Express configuration documents whenever you change the machine IP address. Therefore, do not use a numeric IP address if you use DHCP, or if you change IP addresses regularly. Another format disadvantage is that you cannot use the node if the host is disconnected from the network.

After specifying application server characteristics, the wizard displays the Port value assignment panel.

7. Verify that the ports specified for the stand-alone application server are unique, then click **Next**.

   Windows After specifying port assignments, the wizard displays the Windows service definition panel, if you are installing on a Windows platform.

8. Windows Choose whether to run the application server as a Windows service on a Windows platform and click **Next**.

   Version 6 attempts to start Windows services for application server processes started by a **startServer** command. For example, if you configure an application server as a Windows service and issue the **startServer** command, the **wasservice** command attempts to start the defined service.

   If you chose to install a local system service, you do not have to specify your user ID or password. If you create a specified user type of service, you must specify the user ID and the password for the user who is to run the service. The user must have *Log on as a service* authority for the service to run properly.

   To perform this installation task, the user ID must not have spaces in its name. The ID must also belong to the administrator group and must have the advanced user rights *Act as part of the operating system* and *Log on as a service*. The Installation wizard grants the user ID the advanced user rights if it does not already have them, if the user ID belongs to the administrator group.

   You can also create other Windows services after the installation is complete, to start other server processes. See “Automatically restarting server processes” on page 149 for more information.

   The installation wizard shows which components are selected for installation in a pre-installation summary panel.

9. Click **Next** to create the application server or click **Back** to change the characteristics of the application server.

   The wizard displays the Installation status panel that shows which components are installing.

   When the installation is complete, the wizard displays the Profile creation is complete panel.
10. Click **Finish** to exit, then click **Profile creation wizard** on the First steps console to start the wizard again to create other application servers.

You can create an application server profile. The node within the profile has an application server named server1.

Refer to the description of the "wasprofile command" on page 43 to learn about creating this type of profile using a command instead of a wizard.

Deploy an application to get started!

See Fast paths for WebSphere Application Server to get started deploying applications.

Deleting a profile

This topic describes how to manually delete a profile.

Before using the manual procedure to remove a profile, try the **wasprofile** command with the -delete option. For example, issue one of the following commands:

Linux UNIX

```
./wasprofile.sh -delete
                -profileName profile_name | -profilePath profile_path
```

Windows

```
wasprofile.bat -delete
               -profileName profile_name | -profilePath profile_path
```

See "wasprofile command" on page 43.

If the command does not work, use this procedure to delete the profile.

This procedure describes how to manually delete a profile when the **wasprofile -delete** command results in the following message:

```
INSTCONFFAILED: Cannot delete profile
```

1. Delete the *profiles_install_root*/*profile_name* directory.
2. If the *install_root*/`properties/profileRegistry.xml` file exists, edit the file in a flat-file editor to delete the entry for the profile, if the entry is present.

   The entry resembles the following example:

   ```
   <profile isDefault="true"
            name="BadProfile"
            path="E:\IBM\WebSphere\AppServer\profiles\BadProfile"
            template="E:\IBM\WebSphere\AppServer\profileTemplates\default"/>
   ```
3. Linux UNIX Compare the two batch files, *install_root*/ `properties/ fsdb/ _was_profile_default/ default.sh` and *install_root*/ `properties/ fsdb/` *`bad_profile_name`*`.sh`.

   If the files are identical, delete the *install_root*/ `properties/ fsdb/ _was_profile_default` directory and the *install_root*/ `properties/ fsdb/` *`bad_profile_name`*`.sh` file.

   If the files are not identical, delete only the *install_root*/ `properties/ fsdb/` *`bad_profile_name`*`.sh` file.

4. Windows Compare the two batch files, *install_root*\ `properties\ fsdb\ _was_profile_default\ default.bat` and *install_root*\ `properties\ fsdb\` *`bad_profile_name`*`.bat`.

   If the files are identical, delete the *install_root*\ `properties\ fsdb\ _was_profile_default` directory and the *install_root*\ `properties\ fsdb\` *`bad_profile_name`*`.bat` file.

   If the files are not identical, delete only the *install_root*\ `properties\ fsdb\` *`bad_profile_name`*`.bat` file.

See the description of the “wasprofile command” to learn more about the command-line method of working with profiles.

See “Using the Profile creation wizard” on page 36 for more information about creating profiles with the Profile creation wizard.

wasprofile command

The **wasprofile** command line tool creates all Application Server run-time environments in Version 6. The command creates a profile, which is the set of files that define the run-time environment for a stand-alone Application Server.

The **wasprofile** command is also referred to as the *profile creation tool*.

Introduction to terms that describe Version 6 profiles

The **wasprofile** command creates the run-time environment for a WebSphere Application Server process in a set of files called a *profile*. The profile defines the run-time environment and includes all of the files that the server processes in the run-time environment can change. The *profile creation tool* and its graphical user interface, the *Profile creation wizard*, are the only ways to create run-time environments in V6.

The *Profile creation wizard* is an InstallShield for Multiplatforms (ISMP) application. You can use the wizard to enter most of the parameters that are described in this topic. Some parameters, however, require you to use the **wasprofile** command. You must use the **wasprofile** command to delete a profile, for instance, because the Profile creation wizard does not provide a deletion function.

However, the Profile creation wizard also performs tasks that the wasprofile command does not. For instance, the wizard can create a Windows service for each profile that it creates. It can also assign non-conflicting ports based on previous Version 6 port assignments.

Core product files: The core product files are the shared product binaries. The binary files are shared by all profiles.

The directory structure for V6 has two major divisions of files in the installation root directory for the product:

- The core product files are shared product binary files that do not change unless you install a refresh pack, a fix pack, or an interim fix. Some log information is also updated.
- The `profiles` directory is the default directory for creating profiles. The configuration for every defined Application Server process is within the `profiles` directory unless you specify a new directory when you create a profile. These files change as often as you create a new profile, reconfigure an existing profile, or delete a profile.

All of the folders except for the `profiles` directory and a few others such as the `logs` directory and the `properties` directory do not change unless you install service fixes. The `profiles` directory, however, changes each time you add, change, or delete a profile. The profiles directory is the default repository for profiles. However, you can put a profile anywhere on the machine provided there is enough available disk space.

If you put a profile in another existing folder in the installation root directory, a risk exists that the profile might be affected by the installation of a service fix that applies maintenance to the folder. Use a directory outside of the installation root directory when using a directory other than the `profiles` directory for creating profiles.

WebSphere Application Server profile: The **wasprofile** command line tool defines each Application Server instance of a Version 6 product.

You must run the wizard or the command line tool each time that you want to create a stand-alone Application Server. A need for more than one stand-alone Application Server on a machine is common.

Administration is greatly enhanced when using V6 profiles instead of multiple product installs. Not only is disk space saved, but updating the product is simplified when you only maintain a single set of product core files. Also, creating new profiles is faster and less prone to error than full product installs, allowing a developer to create new disposable profiles of the product for development and testing.

You can run the Profile creation wizard or the profile creation tool to create a new Application Server environment on the same machine as an existing one. Simply define unique characteristics (such as profile name and node name) for the new profile. Each profile has its own administrative console and administrative scripting interface. Each Application Server process shares all run-time scripts, libraries, the Software Development Kit, and other core product files.

The installation program for WebSphere Application Server - Express uses the profile creation tool to create an Application Server profile named `default`.

Installed file set: You decide where to install the files that define a profile. The default location is in the `profiles` directory in the installation root directory. But you can change the location on the Profile creation wizard or in a parameter when using the command line tool. For example, assume that you create two profiles on a Linux platform with host name devhost1. The profile directories resemble the following example if you do not relocate them:

```
/opt/IBM/WebSphere/AppServer/profiles/devhost1Profile01
/opt/IBM/WebSphere/AppServer/profiles/devhost1Profile02
```

Suppose that you specify a different directory, such as `/opt/profiles`, for the profile directory field in the wizard. The profile directories resemble the following example:

```
/opt/profiles/devhost1Profile01
/opt/profiles/devhost1Profile02
```

The following directories exist within a profile. This example assumes that a profile named devhost1Profile01 exists:

/opt/IBM/WebSphere/AppServer/profiles/devhost1Profile01/bin

/opt/IBM/WebSphere/AppServer/profiles/devhost1Profile01/config

/opt/IBM/WebSphere/AppServer/profiles/devhost1Profile01/etc

/opt/IBM/WebSphere/AppServer/profiles/devhost1Profile01/firststeps

/opt/IBM/WebSphere/AppServer/profiles/devhost1Profile01/installableApps

/opt/IBM/WebSphere/AppServer/profiles/devhost1Profile01/installedApps

/opt/IBM/WebSphere/AppServer/profiles/devhost1Profile01/installedConnectors

/opt/IBM/WebSphere/AppServer/profiles/devhost1Profile01/installedFilters

/opt/IBM/WebSphere/AppServer/profiles/devhost1Profile01/logs

/opt/IBM/WebSphere/AppServer/profiles/devhost1Profile01/properties

/opt/IBM/WebSphere/AppServer/profiles/devhost1Profile01/samples

/opt/IBM/WebSphere/AppServer/profiles/devhost1Profile01/temp

/opt/IBM/WebSphere/AppServer/profiles/devhost1Profile01/tranlog

```
/opt/IBM/WebSphere/AppServer/profiles/devhost1Profile01/wstemp
```

The profile repository: The profile repository is the default location of profile-related metadata. The repository is the default location for new profiles, which is often referred to as the profiles installation root directory.

However, you can decide where to install a profile. The default location of the profile repository is the *install_root*/`profiles` directory. In the earlier example, creating two profiles on a Linux platform with host name devhost1 results in the following example directories in the profile repository:

```
/opt/IBM/WebSphere/AppServer/profiles/devhost1Profile01
/opt/IBM/WebSphere/AppServer/profiles/devhost1Profile02
```

When you specify a directory, such as `/opt/profiles`, the profiles are no longer in the default repository, which is not a problem. For example, the following locations are valid:

```
/opt/profiles/devhost1Profile01
/opt/profiles/devhost1Profile02
```

Location of the command file

The command file is located in the `*install_root*/bin` directory. The command file is a script named `wasprofile.sh` for Linux and UNIX platforms or `wasprofile.bat` for Windows platforms.

The Profile creation wizard is the graphical user interface to the command line tool. The file name of the command that calls the Profile creation wizard varies per operating system platform. See “Using the Profile creation wizard” on page 36 for more information.

Logging

The **wasprofile** command creates a log for every profile that it creates. The logs are in the *install_root*/`logs/wasprofile` directory. The files are named in this pattern: `wasprofile_create_`*`profile_name`*`.log`.

The command also creates a log for every profile that it deletes. The logs are in the *install_root*/`logs/wasprofile` directory. The files are named in this pattern: `wasprofile_delete_`*`profile_name`*`.log`.

Required disk space

AIX Manually verify that the required space for creating a profile is available on AIX. A known problem in the underlying InstallShield for Multiplatforms (ISMP) code prevents proper space checking on AIX systems at the time that the product disc was created.

An error can occur when you have not provided enough system temporary space to create a profile. Verify that you have a minimum of 40 MB of temp space available before creating a profile.

You must have 200 MB of available disk space in the directory where you create an Application Server profile.

Concurrent profile creation

Important: Concurrent profile creation is not supported at this time for one set of core product files. Concurrent attempts to create profiles result in a warning about a profile creation already in progress.

Entering lengthy commands on more than one line

The length of the **wasprofile** command can exceed the normal shell window limit for one line of 256 characters. If your command is longer than the limit, issue the command on multiple lines by ending a line with a backward slash, pressing **Enter**, and continuing the command on the next line.

For example, on a Solaris system, the following command requires input on multiple lines:

```
./wasprofile.sh \
-create -profileName bladetcb6profile \
-profilePath /usr/IBM/WebSphere/AppServer/profiles/bladetcb6profile \
-templatePath /usr/WebSphere/AppServer/profileTemplates/default \
-nodeName bladetcb6node \
-cellName bladetcb6Cell \
-hostName bladetcb6.rtp.raleigh.ibm.com
```

Omit the line continuation character from the last line to signal the end of the command to the operating system.

wasprofile.sh command syntax

List existing profiles:

```
# ./wasprofile.sh -listProfiles
                 [-debug]
```

Delete profiles:

```
# ./wasprofile.sh -delete
                -profileName profile_name | -profilePath profile_path
               [-debug]
```

Create new profiles:

```
wasprofile.sh -create
              -profileName profile_name
              -profilePath fully_qualified_profile_path
              -templatePath template_path
              -nodeName node_name
              -cellName cell_name
              -hostName host_name
              -server  iSeries_server_name
             [-startingPort starting_port | -portsFile filepath]
              -winserviceCheck true | false
              -winserviceAccountType specifieduser | localsystem
              -winserviceUserName yourusername
              -winservicePassword yourpassword
              -winserviceStartupType manual | automatic | disabled
             [-debug]
```

Get name of existing profile from path:

```
# ./wasprofile.sh -getName
                 -profilePath profile_path
                [-debug]
```

Get path of existing profile from name:

```
# ./wasprofile.sh -getPath
                 -profileName profile_name
                [-debug]
```

Check the integrity of the profile registry:

```
# ./wasprofile.sh -validateRegistry
                [-debug]
```

Check the integrity of the profile registry, removing profiles that are not found:

```
# ./wasprofile.sh -validateAndUpdateRegistry
                 [-backup file_name]
                 [-debug]
```

wasprofile.bat command syntax

List existing profiles:

```
wasprofile.bat -listProfiles
             [-debug]
```

Delete profiles:

```
wasprofile.bat -delete
              -profileName profile_name | -profilePath profile_path
             [-debug]
```

Create new profiles:

```
wasprofile.bat -create
              -profileName profile_name
              -profilePath fully_qualified_profile_path
              -templatePath template_path
              -nodeName node_name
             [-cellName cell_name]
              -hostName host_name
              -server  iSeries_server_name
             [-startingPort starting_port | -portsFile filepath]
              -winserviceCheck true | false
              -winserviceAccountType specifieduser | localsystem
              -winserviceUserName yourusername
              -winservicePassword yourpassword
              -winserviceStartupType manual | automatic | disabled
             [-debug]
```

When the -startingPort parameter is not used, the profile creation tool uses the default port settings specified in the `serverindex.xml` file.

Get name of existing profile from path:

```
wasprofile.bat -getName
              -profilePath fully_qualified_profile_path
             [-debug]
```

Get path of existing profile from name:

```
wasprofile.bat -getPath
              -profileName profile_name
             [-debug]
```

Check integrity of profile registry:

```
wasprofile.bat -validateRegistry
             [-debug]
```

Check integrity of profile registry, removing unfound profiles:

```
wasprofile.bat -validateAndUpdateRegistry
             [-backup file_name]
             [-debug]
```

Parameters

Supported arguments include:

-augment
Refreshes or augments the given profile using the template in the templatePath parameter.

-backup *file_name*
Backs up the profile registry file to a file with the file name specified.

-cellname *file_name*
Specifies the cell name of the profile.

This is an optional parameter. If you omit the parameter, a default cell name is assigned.

-create
Creates the profile.

-debug
Turns on the debug function of the Ant utility, which the **wasprofile** command uses.

-delete
Deletes the profile.

-getName
Gets the name for a profile registered at a given file system path. Requires the –profilePath parameter.

-getPath
Gets the file system location for a profile of a given name. Requires the –profileName parameter.

-hostName *host_name*
Specifies the host name where you are creating the profile. This should match the host name that you specified during installation of the initial product.

-listProfiles
Llists all defined profiles.

-nodeName *node_name*
Specifies the node name for the node that is created with the new profile. Use a unique value or on the machine. Each profile that shares the same set of product binaries must have a unique node name.

-portsFile *file_path*
An optional parameter that specifies the path to a file that defines port settings for the new profile. When omitted, the wasprofile tool looks for the *install_root* `/profileTemplates/`*`profile_type`* `/actions/portsUpdate/bin/portdef.props` file.

Do not use this parameter when using the startingPort parameter.

-profileName *profile_name*
Specifies the name of the profile. Use a unique value when creating a profile. Each profile that shares the same set of product binaries must have a unique name.

-profilePath *profile_path*
Specifies the fully qualified path to the profile.

Windows If the fully qualified path contains spaces, enclose the value in quotation marks.

Specifies the name of the server on an iSeries platform.

-startingPort *startingPort*
Specifies the starting port number for generating all ports for the profile. If not specified, the **wasprofile** command uses default ports specified in the `serverindex.xml` file.

-templatePath *template_path*
Specifies the path to the templates in the shared binaries.

-validateAndUpdateRegistry *registry_file backup_file*
Checks all of the profiles that are listed in the profile registry to see if the profiles are present on the file system. Removes any missing profiles from the registry. Returns a list of the missing profiles that were deleted from the profile.

-validateRegistry *registry_file*
Checks all of the profiles that are listed in the profile registry to see if the profiles are present on the file system. Returns a list of missing profiles.

Windows **-winserviceAccountType** *type_of_owner_account*

The type of the owner account of the Windows service created for the profile can be either specifieduser or localsystem. The Windows service can run under the local account of the user who is creating the profile.

Windows **winserviceCheck** *value*

The value can be either true or false. Specify `true` to create a Windows service for the server process that is created within the profile. Specify `false` to not create the Windows service.

Windows **-winservicePassword** *yourpassword*

Specify the password for the specified user or the local account that is to own the Windows service.

Windows **-winserviceStartupType** *startup_type*

Possible startup_type values are:

- manual
- automatic
- disabled

See ″WASService command″ in the Installation PDF for more information about Windows services.

Windows **-winserviceUserName** *user_ID*

Specify your user ID so that Windows can verify you as an ID that is capable of creating a Windows service. Your user ID must belong to the administrator group and have the following advanced user rights, *Act as part of the operating system* and *Log on as a service*

Use case scenarios

Use cases are a description of common tasks for which the tool is used.

Scenario: Deleting a profile: The following command is on more than one line for clarity. Enter the command on one line to delete the profile named `shasti`:

```
wasprofile.sh -delete
              -profileName shasti
```

Scenario: Using predefined port numbers: When you use the wasprofile tool without the -startingPort parameter, the tool uses the `/profileTemplates/`*`profile_type`* `/actions/portsUpdate/bin/portdef.props` file to set the initial ports.

Example of using the -portsFile parameter

Copy the file, edit the port settings, and use your copy by using the -portsFile parameter as shown in the following example:

```
wasprofile.bat
   -create
   -profileName Wow_Profile
   -profilePath
       C:\ExpressV6\IBM\WebSphere\AppServer\profiles\Wow_Profile
   -templatePath
       C:\ExpressV6\IBM\WebSphere\AppServer\profileTemplates\default
   -nodeName Wow_node
   -cellName Wow_cell
   -hostName loyAllen
   -portsFile C:\temp\ports\portdef.props
```

Suppose that the `portdef.props` file has the following values:

```
WC_defaulthost=39080
WC_adminhost=39060
WC_defaulthost_secure=39443
```

```
WC_adminhost_secure=39043
BOOTSTRAP_ADDRESS=32809
SOAP_CONNECTOR_ADDRESS=38880
SAS_SSL_SERVERAUTH_LISTENER_ADDRESS=39401
CSIV2_SSL_SERVERAUTH_LISTENER_ADDRESS=39403
CSIV2_SSL_MUTUALAUTH_LISTENER_ADDRESS=39402
ORB_LISTENER_ADDRESS=39100
DCS_UNICAST_ADDRESS=39353
SIB_ENDPOINT_ADDRESS=37276
SIB_ENDPOINT_SECURE_ADDRESS=37286
SIB_MQ_ENDPOINT_ADDRESS=35558
SIB_MQ_ENDPOINT_SECURE_ADDRESS=35578
```

As you run the command, messages similar to the following appear in the output stream:

```
replaceRegExpAllInstancesOfGivenTokenWithGivenValueForTheGivenFile:
  [echo] File C:\ExpressV6\IBM\WebSphere\AppServer\profiles\
  Wow_Profile/config/templates/default/serverentry-template.xml:
  setting CSIV2_SSL_SERVERAUTH_LISTENER_ADDRESS to 39403

...
replaceRegExpAllInstancesOfGivenTokenWithGivenValueForTheGivenFile:
   [echo] File C:\ExpressV6\IBM\WebSphere\AppServer\profiles\
   Wow_Profile/config/templates/default/serverentry-template.xml:
   setting CSIV2_SSL_MUTUALAUTH_LISTENER_ADDRESS to 39402
...
```

The resulting serverindex.xml file looks similar to the following example:

```
<?xml version="1.0" encoding="UTF-8"?>
<serverindex:ServerIndex xmi:version="2.0" xmlns:xmi="http://www.omg.org/XMI"
...
   <specialEndpoints xmi:id="NamedEndPoint_..."
                                         endPointName="BOOTSTRAP_ADDRESS">
      <endPoint xmi:id="EndPoint_..." host="IBMmachine" port="32809"/>
    </specialEndpoints>
    <specialEndpoints xmi:id="NamedEndPoint_..."
                                   endPointName="SOAP_CONNECTOR_ADDRESS">
      <endPoint xmi:id="EndPoint_..." host="IBMmachine" port="38880"/>
    </specialEndpoints>
    <specialEndpoints xmi:id="NamedEndPoint_..."
                   endPointName="SAS_SSL_SERVERAUTH_LISTENER_ADDRESS">
      <endPoint xmi:id="EndPoint_..." host="IBMmachine" port="39401"/>
    </specialEndpoints>
    <specialEndpoints xmi:id="NamedEndPoint_..."
                  endPointName="CSIV2_SSL_SERVERAUTH_LISTENER_ADDRESS">
      <endPoint xmi:id="EndPoint_..." host="IBMmachine" port="39403"/>
    </specialEndpoints>
    <specialEndpoints xmi:id="NamedEndPoint_..."
                 endPointName="CSIV2_SSL_MUTUALAUTH_LISTENER_ADDRESS">
      <endPoint xmi:id="EndPoint_..." host="IBMmachine" port="39402"/>
    </specialEndpoints>
    <specialEndpoints xmi:id="NamedEndPoint_..."
                                      endPointName="WC_adminhost">
      <endPoint xmi:id="EndPoint_..." host="*" port="39060"/>
    </specialEndpoints>
    <specialEndpoints xmi:id="NamedEndPoint_..."
                                    endPointName="WC_defaulthost">
      <endPoint xmi:id="EndPoint_..." host="*" port="39080"/>
    </specialEndpoints>
    <specialEndpoints xmi:id="NamedEndPoint_..."
                                  endPointName="DCS_UNICAST_ADDRESS">
      <endPoint xmi:id="EndPoint_..." host="IBMmachine" port="39353"/>
    </specialEndpoints>
    <specialEndpoints xmi:id="NamedEndPoint_..."
                                endPointName="WC_adminhost_secure">
      <endPoint xmi:id="EndPoint_..." host="*" port="39043"/>
    </specialEndpoints>
    <specialEndpoints xmi:id="NamedEndPoint_..."
                                endPointName="WC_defaulthost_secure">
      <endPoint xmi:id="EndPoint_..." host="*" port="39443"/>
    </specialEndpoints>
    <specialEndpoints xmi:id="NamedEndPoint_..."
                               endPointName="SIB_ENDPOINT_ADDRESS">
      <endPoint xmi:id="EndPoint_..." host="*" port="37276"/>
    </specialEndpoints>
    <specialEndpoints xmi:id="NamedEndPoint_..."
                         endPointName="SIB_ENDPOINT_SECURE_ADDRESS">
      <endPoint xmi:id="EndPoint_..." host="*" port="37286"/>
    </specialEndpoints>
    <specialEndpoints xmi:id="NamedEndPoint_..."
                              endPointName="SIB_MQ_ENDPOINT_ADDRESS">
      <endPoint xmi:id="EndPoint_..." host="*" port="35558"/>
    </specialEndpoints>
    <specialEndpoints xmi:id="NamedEndPoint_..."
                       endPointName="SIB_MQ_ENDPOINT_SECURE_ADDRESS">
      <endPoint xmi:id="EndPoint_..." host="*" port="35578"/>
    </specialEndpoints>
    <specialEndpoints xmi:id="NamedEndPoint_..."
                                endPointName="ORB_LISTENER_ADDRESS">
      <endPoint xmi:id="EndPoint_..." host="IBMmachine" port="39100"/>
    </specialEndpoints>
  </serverEntries>
</serverindex:ServerIndex>
```

The **wasprofile** command creates a copy of the current `portdefs.props` file in the *install_root*`\profiles\`*`profile_name`*`\logs` directory.

Do not use the portsFile parameter when using the startingPort parameter. The two parameters are mutually exclusive.

Scenario: Incrementing default port numbers from a starting point: The **wasprofile** command can assign port numbers based on a starting port value that you give on the command line, using the `-startingPort` parameter. The tool assigns port numbers sequentially from the starting port number value.

The order of port assignments is arbitrary. Predicting assignments is not possible.

For example, ports created with -startingPort 20002 would appear similar to the following example:

Assigned ports for an Application Server profile

```
WC_defaulthost=20002
WC_adminhost=20003
WC_defaulthost_secure=20004
WC_adminhost_secure=20005
BOOTSTRAP_ADDRESS=20006
SOAP_CONNECTOR_ADDRESS=20007
SAS_SSL_SERVERAUTH_LISTENER_ADDRESS=20008
CSIV2_SSL_SERVERAUTH_LISTENER_ADDRESS=20009
CSIV2_SSL_MUTUALAUTH_LISTENER_ADDRESS=20010
ORB_LISTENER_ADDRESS=20011
DCS_UNICAST_ADDRESS=20012
SIB_ENDPOINT_ADDRESS=20013
SIB_ENDPOINT_SECURE_ADDRESS=20014
SIB_MQ_ENDPOINT_ADDRESS=20015
SIB_MQ_ENDPOINT_SECURE_ADDRESS=20016
```

Example of startingPort parameter use

The following example of using the **wasprofile** command creates ports from an initial value of 20002, with the content shown in the previous example:

```
wasprofile.bat -create
               -profileName shasti
               -profilePath G:\shasti\WebSphere
               -templatePath template_path
               -nodeName W2K03
               -cellName W2K03_Cell01
               -hostName planetnt
               -startingPort 20002
```

Scenario: Setting up and using the profile environment: Most tasks that you perform in a profile are done using the -profileName attribute on the command line tools that you use. Such a scenario might be:

1. Create the server process using the *install_root*/bin/wasprofile.sh (or wasprofile.bat) script from the original installation. Assume that you create the Profile02 profile.
2. In that command window or in another, change directories to the /bin directory of the new server process.
3. Establish a temporary override for the normal WebSphere Application Server environment by using the -profileName attribute on a command you issue. In the same window, start server1 by changing directories to the install_root/bin directory of the original installation and issuing the command. There is no such command in the /bin directory of the server process:

   ```
   startServer.sh server1 -profileName Profile02
   ```
4. Notice the changes in the environment. Display all of the ports for the machine to see the ports that you set for the server process. For example, in a Linux bash shell or in the command window on a Windows platform, type:

   ```
   netstat -a
   ```
5. Open a browser window and point it at the port defined for the HTTP_TRANSPORT_ADMIN port of the new process. For example, suppose the setting is HTTP_TRANSPORT_ADMIN=20003. Open the administrative console for server1 by pointing your browser at:

   ```
   http://hostname_orIP_address:20003/ibm/console/
   ```

Scenario: Profile creation for a non-root user: Two methods exist for a non-root user to create a profile:

- The root user creates the profile and assigns ownership to the non-root user.
- A non-root user creates a profile after getting write permission to the appropriate directories.

Remember: An ease-of-use limitation exists for non-root users who create profiles. Mechanisms within the Profile creation wizard that suggest unique names and port values are disabled for non-root users. The non-root user must change the default field values in the Profile creation wizard for the profile name, node name, and port assignments. Consider assigning non-root users a range of values for each of the fields. You can assign responsibility to the non-root profilers for adhering to their proper value ranges and for maintaining the integrity of their own definitions.

Root creates the profile and assigns ownership to a non-root user: The root user can create a profile and assigns ownership of the profile directory to a non-root user.

1. The root user creates the profile with the following command:

   ```
   ./wasprofile.sh -create -profileName profile01 -profilePath install_root/profiles/profile01
   ```
2. The root user changes ownership of the directory for the profile to the non-root user with the following command:

   ```
   chown -R user1 install_root/profiles/profile01
   ```

A non-root user creates the profile (advanced option): The root user can grant write permission to the appropriate files and directories to a non-root user. The non-root user can then create the profile. You can create a group for users who are authorized to create profiles. Or you can give everyone the ability to create profiles. The following example shows how to create a group that is authorized to create profiles.

1. Log on to the Application Server system as root.
2. Create the `profilers` group that you can use to create profiles.
3. Create a user named `user1` to create profiles.
4. Add users root and `user1` to the `profilers` group.
5. Log off and back on as root to pick up the new group.
6. As root, use operating system tools to change file permissions.

   The following example assumes that the installation root directory is `/opt/IBM/WebSphere/AppServer`:

   ```
   mkdir /opt/IBM/WebSphere/AppServer/logs/wasprofile
   chgrp profilers /opt/IBM/WebSphere/AppServer/logs/wasprofile
   chmod g+wr  /opt/IBM/WebSphere/AppServer/logs/wasprofile
   chgrp profilers /opt/IBM/WebSphere/AppServer/properties
   chmod g+wr  /opt/IBM/WebSphere/AppServer/properties
   chmod g+wr  /opt/IBM/WebSphere/AppServer/properties/profileRegistry.xml
   ```

   You might have to change the permissions on additional `/opt/IBM/WebSphere/AppServer` directories if you encounter permission problems.
7. The non-root user who belongs to the profilers group can then create a profile in any directory to which the non-root user has write permission.

   If the non-root user does not have write access to any directories, it is up to the root user to change that situation. If the non-root user does not have write access to the /tmp directory, it is up to the root user to change that as well.

   The commands listed in step 6 give users assigned to the profilers group the ability to write to the `/opt/IBM/WebSphere/AppServer/logs/wasprofile` directory and to the `/opt/IBM/WebSphere/AppServer/properties` directory. It is not necessary to write to any other directories in the installation root of your WebSphere Application Server product.

   Have non-root users create a `profiles` directory in their own area, not in the installation root directory of the product.

Using the installation verification test

This topic describes how to use the installation verification test (IVT). The IVT verifies that the installation of the application server profile was successful. A *profile* consists of files that define the run-time environment for an application server. Each profile has its own IVT command.

After installing the product, you are ready to use the installation verification test (IVT).

The IVT program scans product log files for errors and verifies core functionality of the product installation.

After installing the product, the Installation wizard displays a prompt for starting the First steps console.

Installation verification is the first option on the First steps console.

The test consists of starting and monitoring the application server during its start up.

1. Select **Installation verification** on the First steps console after installing the product.

   You can also start the First steps console from the command line, as described in “firststeps command” on page 33.

   You can also start the “ivt command” on page 54 directly from the `bin` directory of the profile:

   - Linux UNIX *install_root*`/profiles/default/bin/ivt.sh`
   - Windows *install_root*`\profiles\default\bin\ivt.bat`

   If you create additional profiles, the `ivt` script location is within the *profile_home*`/bin` directory.
2. Observe the results in the First steps status window.

   The log file for installation verification is the *install_root*`/profiles/default/logs/ivtClient.log` file. If you create additional profiles, the file path is *profile_home*`/logs/ivtClient.log`.

The IVT provides the following useful information about the application server:

- The application server name
- The name of the profile
- The profile file path
- The type of profile
- The node name
- The current encoding
- The port number for the administrative console
- Various informational messages that include the location of the `SystemOut.log` file and how many errors are listed within the file
- A completion message

As the IVT starts the application server on a Windows platform, the IVT attempts to start the Windows service for the application server, if a Windows service exists. This is true even though the Windows service might have a manual startup type.

See “Automatically restarting server processes” on page 149 for more information.

3. If the log shows that errors occurred during the installation verification, correct the errors and run the IVT again. If necessary, create a new profile after correcting the error, and run the IVT on the new profile.

The IVT program starts the server process automatically if the server is not running. Once the server initializes, the IVT runs a series of verification tests. The tool displays pass or fail status in a console window. The tool also logs results to the *profile_home*`/logs/ivtClient.log` file. As the IVT verifies your system, the tool reports any detectable errors in the `SystemOut.log` file.

Return to the ″Task overview: Installing″ topic in the information center to continue.

ivt command

The **ivt** command starts the installation verification test (IVT) program. The IVT verifies that the installation of the application server profile was successful. A *profile* consists of files that define the run-time environment for an application server. Each profile has its own IVT command.

The IVT program starts the application server automatically if the server process is not already running. After the server process initializes, the IVT runs a series of verification tests and displays pass or fail status in a console window.

The IVT program scans the `SystemOut.log` file for errors and verifies core functionality of the profile.

You can start the IVT program from the command line or from the First steps console.

Location of the command file

Installing the product creates a default profile for the server1 application server. The location of the installation verification test program for the default profile is:

- Linux UNIX *install_root*`/profiles/default/bin/ivt.sh`
- Windows *install_root*`\profiles\default\bin\ivt.bat`

The location of the `ivt.sh` or `ivt.bat` script for any profile is:

- Linux UNIX *install_root*`/profiles/`*profile_name*`/bin/ivt.sh`
- Windows *install_root*`\profiles\`*profile_name*`\bin\ivt.bat`

Parameters

The following parameters are associated with this command.

server_name
Required parameter that identifies the name of the server process, such as server1.

profile_name
Required parameter that identifies the name of the profile that contains the server definition.

-p *server_port_number*
Optional parameter that identifies the default_host port when the port is not 9080, which is the default.

-host *machine_host_name*
Optional parameter that identifies the host machine of the profile to test. The default is localhost.

Syntax for the ivt command

Use the following syntax for the command:

- Linux UNIX *install_root*/profiles/*profile_name*/bin/ivt.sh
- Windows *install_root*\profiles\profile_name\bin\ivt.bat

Logging

The **ivt** command logs results to the *install_root*/profiles/*profile name*/logs/ivtClient.log file.

Example

The following examples test the server1 process in the profile01 profile on the myhost machine using the default_host on port 9081.

Windows

```
ivt.bat server1 profile01 -p 9081 -host myhost
```

Linux UNIX

```
ivt.sh server1 profile01 -p 9081 -host myhost
```

Configuring ports

This topic discusses configuring ports, particularly in coexistence scenarios.

1. Review “Port number settings in WebSphere Application Server versions” on page 56.

   This topic provides reference information about identifying port numbers in versions of WebSphere Application Server, as a means of determining port conflicts that might occur when you intend for an earlier version to coexist with Version 6.
2. You can change port settings on the port assignment panel while using the Installation wizard orthe Profile creation wizard.

   See “Using the Profile creation wizard” on page 36 and the *Installing your application serving environment* PDF for more information.
3. After installation, edit the *profiles_install_root*/*profile_name*/config/cells/*cell_name*/nodes/*node_name*/serverindex.xml file to change the port settings, or use scripting to change the values.

   See the *Administering applications and their environment* PDF for more information.

Port number settings in WebSphere Application Server versions

This topic provides reference information about identifying port numbers in versions of WebSphere Application Server, as a means of determining port conflicts that might occur when you intend for an earlier version to coexist or interoperate with Version 6.

Version 6 port numbers

Table 3. Port definitions for WebSphere Application Server Version 6

Port name	WebSphere Application Server	File
	Value	
HTTP_TRANSPORT	9080	serverindex.xml and virtualhosts.xml
HTTP Admin Console Port (HTTP_TRANSPORT_ADMIN)	9060	
HTTPS Transport Port (HTTPS_TRANSPORT)	9443	
HTTPS Admin Console Secure Port (HTTPS_TRANSPORT_ADMIN)	9043	
BOOTSTRAP_ADDRESS	2809	serverindex.xml
SOAP_CONNECTOR_ADDRESS	8880	
SAS_SSL_SERVERAUTH_LISTENER_ADDRESS	9401	
CSIV2_SSL_SERVERAUTH_LISTENER_ADDRESS	9403	
CSIV2_SSL_MUTUALAUTH_LISTENER_ADDRESS	9402	
ORB_LISTENER_ADDRESS	9100	
DCS_UNICAST_ADDRESS	9353	
SIB_ENDPOINT_ADDRESS	7276	
SIB_ENDPOINT_SECURE_ADDRESS	7286	
SIB_MQ_ENDPOINT_ADDRESS	5558	
SIB_MQ_ENDPOINT_SECURE_ADDRESS	5578	
Internal JMS Server (JMSSERVER_SECURITY_PORT)	5557	
IBM HTTP Server Port	80	virtualhosts.xml,
IBM HTTP Server Admin Port	8008	*IHSinstall_root*/`conf/ admin.conf`
NODE_MULTICAST_IPV6_DISCOVERY_ADDRESS	5001	serverindex.xml

Version 5.x port numbers

Version 4.0.x port numbers

For WebSphere Application Server Advanced Single Server Edition, Version 4.0.x: Inspect the `server-cfg.xml` file to find the Web container HTTP transports port values for the configuration.

For WebSphere Application Server Advanced Edition, Version 4.0.x: When the administrative server is running, use this command to extract the configuration from the database:

```
xmlConfig -export config.xml -nodeName theNodeName
```

Look for the Web container HTTP transports port assignments.

Table 4. Port definitions for WebSphere Application Server V4.0.x

Port name	Value	Advanced Edition	IBM WebSphere Business Integration Server Foundation Edition	Advanced Single Server Edition
			File	
bootstrapPort	900	admin.config	admin.config	server-cfg.xml
lsdPort	9000			
LSDSSLPort	9001			
HTTP transport port	9080	database	database	
HTTPS transport port	9443			
Admin Console HTTP transport port	9090			
ObjectLevelTrace	2102			
diagThreadPort	7000			

Communicating with Web servers

The WebSphere Application Server works with a Web server to route requests for dynamic content, such as servlets, from Web applications. The Web servers are necessary for directing traffic from browsers to the applications that run in WebSphere Application Server. The Web server plug-in uses the XML configuration file to determine whether a request is from the Web server or the Application Server.

The Web server plug-ins for distributed platform Web servers are provided on a separate CD from the WebSphere Application Server products. A Web Server Plug-in Installation Wizard is also provided on that CD. Installing Web server plug-ins describes how to install a Web server plug-in and create a Web server definition.

1. Install your Web server if it is not already installed. If you want to use an IBM HTTP Server, see Installing IBM HTTP Server. Otherwise, see the installation information provided with your Web server.
2. Ensure that your Web server is configured to perform operations required by Web applications, such as GET and POST. Typically, this involves setting a directive in the Web server configuration file (such as the httpd.conf file for an IBM HTTP Server). Refer to the Web server documentation for instructions. If an operation is not enabled when a servlet or JSP file requiring the operation is accessed, an error message displays, such as this one from the IBM HTTP Server:

   ```
   HTTP method POST is not supported by this URL.
   ```
3. Use the Plug-in Installation wizard to install the appropriate plug-in file to your Web server and run the script configureWeb_server_name created by the wizard to create and configure the Web server definition in the WebSphere configuration repository. The following substeps are performed during the plug-in installation process. See the Plug-in Installation Roadmap for additional information.
   a. A Web server definitions is created. You can also use either use the administrative console or use the ConfigureWebServerDefintion.jacl script to create a Web server definition.

      If you use the administrative console:

      1) Select the node that was created in the preceding step, and in the Server name field, enter the local name of the Web server for which you are creating a Web server definition.
      2) Use the wizard to complete the Web server definition.

   b. An application or modules are mapped to a Web server. If an application that you want to use with this Web server is already installed, the application is automatically mapped to the Web server. If the application is not installed, select this Web server during the Map modules to servers step of the application installation process.

   c. Master repository is updated and saved.

4. **Optional:** Configure the plug-in. Use either the administrative console, or issue the “GenPluginCfg command” on page 688 to create your `plugin-cfg.xml` file.

   When setting up your Web server plug-in, you must decide whether or not to have the configuration automatically generated in response to a configuration change. When the Web server plug-in configuration service is enabled and any of the following conditions occur, the plug-in configuration file is automatically generated:

   - When the Web server is created or saved.
   - When an application is installed.
   - When an application is uninstalled.
   - When the virtual host definition is updated

   Generating or regenerating the configuration file might take a while to complete. After it finishes, all objects in the administrative cell use their newest settings, which the Web server can access. If the Application Server is on the same physical machine as the Web server, the regeneration usually takes about 30 to 60 seconds to complete. The regeneration takes longer if they are not both on the same machine.

   Important: When the plug-in configuration file is first generated, it does not include admin_host on the list of virtual hosts. ″Allowing Web servers to access the administrative console″ in the information center describes how to add it to the list.

   To use the administrative console:

   a. Select **Servers > Web Servers >** *webserver* **> plug-in properties**.
   b. Select **Automatically generate plug-in configuration file** or click on one or more of the following topics to manually configure the `plugin-cfg.xml` file:
      - Caching
      - Request and response
      - Request routing
      - Service

      Web server plug-in configuration properties maps each property to one of these topics.
   c. Click **OK**.
   d. You might need to stop the application server and then start the application server again to enable the Web server to locate the `plugin-cfg.xml` file.

5. If you want to use Secure-socket layer (SSL) with this configuration, use the plug-in’s installation wizard to install the appropriate GSKIT installation image file on your workstation. See “Configuring the Web server plug-in for Secure Sockets Layer” on page 1693 for information on how to configure GSKIT.

6. If you want to enable the Web server plug-in to use private headers, define an SSL configuration repertoire that defines a trust file. Then in the administrative console, select **Application servers > server1 > Web Container Settings > Web Container Transport Chains >** *transport_chain* > **SSL Inbound Channel (SSL_2)** and specify this repertoire for that transport chain. If you try to use private headers without setting up an SSL configuration repertoire that does not include a trust file definition, the private headers will be ignored. If the private headers are ignored, the application server might not locate the requested application.

   After you enable the use of private headers, the transport chain’s SSL inbound channel trusts all private headers it receives. Therefore, you must ensure that all paths to the transport chain’s SSL inbound channel are trusted.

7. Tune your Web server with Web server tuning parameters.

8. Propagate the plug-in configuration. The plug-in configuration file (plugin-cfg.xml) is automatically propagated to the Web server if the Web server plug-in configuration service is enabled, and one of the following is true:

- The Web server is a local Web server. (It are located on the same machine as an application server.)
- The Web server is a remote IBM HTTP Server (IHS) Version 6.0 that has a running IHS Administrative server.

If neither of these conditions is true, the plugin-cfg.xml file must be manually copied to the remote Web server's installation location.

The configuration is complete. To activate the configuration, stop and restart the Web server. If you encounter problems restarting your Web server, check the http_plugin.log file for information on what portion of the plugin-cfg.xml file contains an error. The log file states the line number on which the error occurred along with other details that might help you diagnose why the Web server did not start. You can then use the administrative console to update the plugin-cfg.xml file.

If applications are infrequently installed or uninstalled, which is usually the situation in a production environment, or if you can tolerate the performance impact of generating and distributing the plug-in configuration file each time any of the previously listed actions occur, you should consider enabling this service.

If you are making a series of simultaneous changes, like installing numerous applications, you might want the configuration service disabled until after you make the last change. The Web server plug-in configuration service is enabled by default. To disable this service, in the administrative console click elect **Servers** > **Application Servers** > *server_name* > **Administration Services** >**Web server plug-in configuration service** and then unselect the Enable automated Web server configuration processing option.

Tip: If your installation uses a firewall, make sure you configure the Web server plug-in to use a port that has been opened. (See your security administrator for information on how to obtain an open port.

Web server plug-in properties settings

Use this page to view or change the settings of a Web server plug-in configuration file. The plug-in configuration file, `plugin_cfg.xml`, provides properties for establishing communication between the Web server and the Application Server.

To view this administrative console page, click **Servers > Web Servers >***Web_server_name* **Plug-in Properties**.

On the **Configuration** tab, you can edit fields. On the **Runtime** tab, you can look at read-only information.

The **Runtime** tab is available only when this Web server has accessed applications running on application servers and there is an `http_plugin.log` file.

Plug-in log file name

Specifies the fully qualified path to the log file to which the plug-in will write error messages. The default file path is *plugin_install_root*/`logs`/*web_server_name*/`http_plugin.log` .

If the file does not exist then it will be created. If the file already exists, it will be opened in append mode and the previous plug-in log messages will remain.

This field corresponds to the RequestMetrics loggingEnabled element in the plugin-cfg.xml file.

Data type	String
Default for Linux and UNIX platforms	*plugin_install_root*/`logs`/*web_server_name*/`http_plugin.log`
Default for Windows platforms	*plugin_install_root*/`logs`/*web_server_name*/`http_plugin.log`

Plug-in installation location

Specifies the fully qualified path to where the plug-in configuration file is installed.

Data type	String
Default	The default value is the installation root directory.

If you select a Web server plug-in during installation, the installer program configures the Web server to identify the location of the `plugin-cfg.xml` file, if possible. The Web server is considered installed on a local machine if it is on the same machine as the application server. It is considered installed on a remote machine if the Web server and the application server are on different machines.

- If the Web server is installed on a remote machine, the plug-in configuration file, by default, will be installed in the *plugin_install_root*/config/*web_server_name* directory.
- If the Web server is installed on a local standalone machine, the plug-in configuration file, by default will be installed in the *profile_install_root*/config/cells/*cell_name*/nodes/*web_server_name _node*/servers/*web_server_name* directory.

The installer program adds a directive to the Web server configuration that specifies the location of the `plugin-cfg.xml` file.

For remote Web servers, you must copy the file from the local directory where the Application Server is installed to the remote machine. This is known as propagating the plug-in configuration file. If you are using an IBM HTTP Server (IHS) V6 for your Web server, WebSphere Application Server can automatically propagate the plug-in configuration file for you to remote machines provided there is a working HTTP transport mechanism to propagate the file.

Plug-in configuration file name

Specifies the file name of the configuration file for the plug-in. The Application Server generates the `plugin-cfg.xml` file by default. The configuration file identifies applications, Application Servers, clusters, and HTTP ports for the Web server. The Web server uses the file to access deployed applications on various Application Servers.

Data type	String
Default	`plugin-cfg.xml`

If you select a plug-in during installation, the installer program configures the Web server to identify the location and name of the `plugin-cfg.xml` file, if possible.

You can change the name of the plug-in configuration file. However, if you do change the file name, you must also change the Web server configuration to point to the new plug-in configuration file.

Automatically generate plug-in configuration file

To automatically generate a plug-in configuration file to a remote Web server:

- This field must be checked.
- The plug-in configuration service must be enabled

When the plug-in configuration service is enabled, a plug-in configuration file is automatically generated for a Web server whenever:

- The WebSphere Application Server administrator defines new Web server.
- An application is deployed to an Application Server.
- An application is uninstalled.
- A virtual host definition is updated and saved.

Clear the check box if you want to manually generate a plug-in configuration file for this Web server.

Important: When the plug-in configuration file is generated, it does not include admin_host on the list of virtual hosts. ″Allowing Web servers to access the administrative console″ in the information center describes how to add it to the list.

Automatically propagate plug-in configuration file

To automatically propagate a copy of a changed plug-in configuration file to a Web server:

- This field must be checked.
- The plug-in configuration service must be enabled
- A WebSphere Application Server node agent must be on the node that hosts the Web server associated with the changed plug-in configuration file.

Note: The plug-in configuration file can only be automatically propagated to a remote Web server if that Web server is an IHS V6.0 Web server and its administration server is running.

Ignore DNS failures during Web server startup

Specifies whether the plug-in ignores DNS failures within a configuration when starting.

This field corresponds to the IgnoreDNSFuilures element in the plugin-cfg.xml file.

When set to **true**, the plug-in ignores DNS failures within a configuration and starts successfully if at least one server in each ServerCluster is able to resolve the host name. Any server for which the host name can not be resolved is marked **unavailable** for the life of the configuration. No attempts to resolve the host name are made later on during the routing of requests. If a DNS failure occurs, a log message is written to the plug-in log file and the plug-in initialization continues rather than causing the Web server not to start. When **false** is specified, DNS failures cause the Web server not to start.

Data type	String
Default	false

Refresh configuration interval

Specifies the time interval, in seconds, at which the plug-in should check the configuration file to see if updates or changes have occurred. The plug-in checks the file for any modifications that have occurred since the last time the plug-in configuration was loaded.

In a development environment in which changes are frequent, a lower setting than the default setting of 60 seconds is preferable. In production, a higher value than the default is preferable because updates to the configuration will not occur so often. If the plug-in reload fails for some reason, a message is written to the plug-in log file and the previous configuration is used until the plug-in configuration file successfully reloads. If you are not seeing the changes you made to your plug-in configuration, check the plug-in log file for indications of the problem.

Data type	Integer
Default	60 seconds.

Plug-in logging

Specifies the location and name of the `http_plugin.log` file. Also specifies the scope of messages in the log.

This field corresponds to the RequestMetrics traceLevel element in the plugin-cfg.xml file.

The log describes the location and level of log messages that are written by the plug-in. If a log is not specified within the configuration file, then, in some cases, log messages are written to the Web server error log.

On a distributed platform, if the log file does not exist then it will be created. If the log file already exists, it will be opened in append mode and the previous plug-in log messages will remain.

Log file name - The fully qualified path to the log file to which the plug-in will write error messages.

Data type	String
Default	*plugin_install_root*/logs/*web_server_name*/http_plugin.log Specify the file path of the http_plugin.log file.

Log level- The level of detail of the log messages that the plug-in should write to the log. You can specify one of the following values for this attribute:

- Trace. All of the steps in the request process are logged in detail.
- Stats. The server selected for each request and other load balancing information relating to request handling is logged.
- Warn. All warning and error messages resulting from abnormal request processing are logged.
- Error. Only error messages resulting from abnormal request processing are logged.

If a Log level is not specified, the default value **Error** is used.

Be careful when setting the level to **Trace**. A lot of messages are logged at this level which can cause the disk space/file system to fill up very quickly. A **Trace** setting should never be used in a normally functioning environment as it adversely affects performance.

Data type	String
Default	Error

Web server plug-in request and response optimization properties settings

Use this page to view or change the request and response optimization properties for a Web server plug-in.

To view this administrative console page, click **Servers > Web Servers >***web_server_name* **Plug-in Properties > Request and Response**.

On the **Configuration** tab, you can edit fields. On the **Runtime** tab, you can look at read-only information.

The **Runtime** tab is available only when this Web server has accessed applications running on application servers and there is an http_plugin.log file.

Maximum chunk size used when reading the response body:

Specifies the maximum chunk size the plug-in can use when reading the response body.

This field corresponds to the ResponseChunkSize element in the plugin-cfg.xml file.

The plug-in reads the response body in 64K chunks until all of the response data is read. This approach causes a performance problem for requests whose response body contains large amounts of data.

If the content length of the response body is unknown, the values specified for this property is used as the size of the buffer that is allocated. The response body is then read in this size chunks, until the entire body is read. If the content length is known, then a buffer size of either the content length or the specified size (whichever is less) is used to read the response body.

Data type	Integer

Default	64 kilobytes Specify the size in kilobytes (1024 byte blocks).

Enable Nagle algorithm for connections to the Application Server:

When checked, the Nagle algorithm is enabled for connections between the plug-in and the Application Server.

This field corresponds to the ASDisableNagle element in the plugin-cfg.xml file.

The Nagle algorithm is named after engineer John Nagle, who invented this standard part of the transmission control protocol/internet protocol (TCP/IP). The algorithm reduces network overhead by adding a transmission delay (usually 20 milliseconds) to a small packet, which lets other small packets arrive and be included in the transmission. Because communications has an associated cost that is not as dependent on packet size as it is on frequency of transmission, this algorithm potentially reduces overhead with a more efficient number of transmissions.

Clear the check box to disable the Nagle algorithm.

Enable Nagle Algorithm for the IIS Web Server:

When checked, the Nagle algorithm is used for connections from the Microsoft Internet Informations Services (IIS) Web Server to the Application Server.

This field corresponds to the IHSDisableNagle element in the plugin-cfg.xml file. It only appears if you are using the Microsoft Internet Informations Services (IIS) Web server. Clear the check box to disable the Nagle algorithm for this connection.

Chunk response to the client:

When checked, responses to the client are broken into chunks if a `Transfer-Encoding : Chunked` response header is present in the response.

This field corresponds to the ChunkedResponse element in the plugin-cfg.xml file. It only appears if you are using a Microsoft Internet Informations Services (IIS) Web Server, a Java System Web server, or a Domino Web server. The IHS Web server automatically handles breaking the response into chunks to send to the client.

Clear the check box to if you do not want responses broken into chunks.

Accept content for all requests: This field corresponds to the AcceptAllContent element in the plugin-cfg.xml file.

When selected, users can include content in POST, PUT, GET, and HEAD requests when a Content-Length or Transfer-encoding header is contained in the request header.

Virtual host matching:

When selected, virtual host mapping is performed by physically using the port number for which the request was received.

This field corresponds to the VHostMatchingCompat element in the plugin-cfg.xml file.

If this field is not selected, matching is done logically using the port number contained in the host header.

Use the radio buttons to make your physical or logical port selection.

Application server port preference:

Specifies which port number the Application Server should use to build URI's for a sendRedirect.

This field corresponds to the AppServerPortPreference element in the plugin-cfg.xml file.

Specify:
- `webserverPort` if the port number from the host header of the HTTP request coming in is to be used.
- `hostHeader` if the port number on which the Web server received the request is to be used.

The default is `webserverPort`.

Priority used by the IIS Web server when loading the plug-in configuration file:

Specifies the priority in which the Microsoft Internet Informations Services (IIS) Web server loads the WebSphere Web server plug-in.

This field corresponds to the IISPluginPriority element in the plugin-cfg.xml file. It only appears if you are using the IIS Web server. Because the IIS Web server uses this value during startup, the Web server must be restarted before a change to this field takes effect.

Select one of the following priorities:
- High
- Medium
- Low

The default value of **High** ensures that all requests are handled by the Web server plug-in before they are handled by any other filter/extensions. If problems occur while using a priority of **Medium** or **Low**, you will have to rearrange the order or change the priority of the interfering filter/extension.

Web server plug-in caching properties settings

Use this page to view or change the caching properties for a Web server plug-in.

To view this administrative console page, click **Servers > Web Servers >***Web_server_name* **Plug-in Properties > Caching Properties**.

On the **Configuration** tab, you can edit fields. On the **Runtime** tab, you can look at read-only information.

The **Runtime** tab is available only when this Web server has accessed applications running on application servers and there is an `http_plugin.log` file.

Enable Edge Side Include (ESI) processing to cache the responses:

Specifies whether to enable Edge Side Include processing to cache the responses.

This field corresponds to the esiEnable element in the plugin-cfg.xml file.

When selected, Edge Side Include (ESI) processing is used to cache responses. If ESI processing is disabled for the plug-in, the other ESI plug-in properties are ignored. Clear the checkbox to disable Edge Side Include processing.

Enable invalidation monitor to receive notifications:

When checked, the ESI processor receives invalidations from the Application Server.

This field corresponds to the ESIInvalidationMonitor element in the plugin-cfg.xml file. It is ignored if Edge Side Include (ESI) processing is not enabled for the plug-in.

Maximum cache size:

Specifies, in 1K byte units, the maximum size of the cache. The default maximum size of the cache is 1024K bytes (1 megabyte). If the cache is full, the first entry to be evicted from the cache is the entry that is closest its expiration time.

This field corresponds to the esiMaxCacheSize element in the plugin-cfg.xml file.

Data type	Integer
Default	1024 kilobytes Specify the size in kilobytes (1024 byte blocks).

Web server plug-in request routing properties settings

Use this page to view or change the request routing properties for a Web server plug-in.

To view this administrative console page, click **Servers > Web Servers >***Web_server_name* **Plug-in Properties > Plug-in** *server_cluster_name* **Properties**.

On the **Configuration** tab, you can edit fields. On the **Runtime** tab, you can look at read-only information.

The **Runtime** tab is available only when this Web server has accessed applications running on application servers and there is an `http_plugin.log` file.

Load balancing option:

Specifies the load balancing option that the plug-in uses in sending requests to the various application servers associated with that Web server.

This field corresponds to the LoadBalanceWeight element in the plugin-cfg.xml file.

Select the appropriate load balancing option:

- Round robin
- Random

The Round Robin implementation has a random starting point. The first application server is picked randomly. Round Robin is then used to pick application servers from that point forward. This implementation ensures that in multiple process based Web servers, all of the processes don't start up by sending the first request to the same Application Server.

The default load balancing type is Round Robin.

Retry interval:

Specifies the length of time, in seconds, that should elapse from the time an application server is marked down to the time that the plug-in retries a connection.

This field corresponds to the ServerWaitforContinue element in the plugin-cfg.xml file.

Data type	Integer
Default	60 seconds

Maximum size of request content:

Select whether there is a limit on the size of request content. If limited, this field also specifies the maximum number of bytes of request content allowed in order for the plug-in to attempt to send the request to an application server.

This field corresponds to the PostSizeLimit element in the plugin-cfg.xml file.

When a limit is set, the plug-in fails any request that is received that is greater than the specified limit.

Select whether to limit the size of request content:
- No limit
- Set limit

If **Set limit** is selected, specify a limit size.

Data type	Integer
Default	-1, which indicates there is no limit for the post size. Specify the size in kilobytes (1024 byte blocks).

Remove special headers:

When checked, the plug-in will remove any headers from incoming requests before adding the headers the plug-in is supposed to add before forwarding the request to an application server.

This field corresponds to the RemoveSpecialHeaders element in the plugin-cfg.xml file.

The plug-in adds special headers to the request before it is forwarded to the application server. These headers store information about the request that will need to be used by the application. Not removing the headers from incoming requests introduces a potential security exposure.

Clear the check box to retain special headers.

Clone separator change:

When checked, the plug-in expects the plus character (+) as the clone separator.

This field corresponds to the ServerCloneID element in the plugin-cfg.xml file.

Some pervasive devices cannot handle the colon character (:) used to separate clone IDs in conjunction with session affinity. If this field is checked, you must also change the configurations of the associated application servers such that the application servers separates clone IDs with the plus character as well.

Clear the checkbox to use the colon character to separate clone IDs.

Web server plug-in custom properties

If you are using a Web server plug-in, you can add the following custom property to the configuration settings for that plug-in.

To add a custom property:
1. In the administrative console, click In the administrative console, click **Servers > Web Servers >** *Web_server_name* **> Plug-in properties > Custom properties > New**

2. Under **General Properties** specify the name of the custom property in the Name field and a value for this property in the Value field. You can also specify a description of this property in the Description field.
3. Click **Apply** or **OK**.
4. Click **Save** to save your configuration changes.
5. Restart the server.

Following is a list of Web server plug-in custom properties that are provided with the Application Server. These properties are not shown on the properties settings pages for the plug-in.

StashfileLocation

Use this element to set a value for the stashfile initialization parameter.

Data type	String

KeyringLocation

Use this element to set a value for the keyring initialization parameter.

Data type	String

Web server plug-in configuration service properties settings

Use this page to view or change the configuration settings for the Web server plug-in configuration service.

To view this administrative console page, click **Application Servers >***server_name* > **Administration Services** > **Web server plug-in configuration service**.

On the **Configuration** tab, you can edit fields. On the **Runtime** tab, you can look at read-only information.

Enable automated Web server configuration processing

When selected, the Web server plug-in configuration service automatically generates the plug-in configuration file whenever the Web server environment changes. For example, the plug-in configuration file is regenerated whenever one of the following activities occurs:

- A new application is deployed on an associated application server.
- The Web server definition is saved.
- An application is removed from an associated application server.
- A new virtual host is defined.

Whenever a virtual host definition is updated, the plug-in configuration file is automatically regenerated for all of the Web servers.

Application Server property settings for a Web server plug-in

Use this page to view or change application server settings for a Web server plug-in.

To view this administrative console page, click **Application Servers >***server_name* **> Web Server Plug-in**.

On the **Configuration** tab, you can edit fields. On the **Runtime** tab, you can look at read-only information.

The **Runtime** tab is available only when this Web server has accessed applications running on application servers and there is an `http_plugin.log` file.

Server role

Specifies the role this application server is assigned.

Select `Primary` to add this application server to the list of primary application servers. The plug-in initially attempts to route requests to the application servers on this list.

Select `Backup` to add this application server to the list of backup application servers. The plug-in does not load balance across the backup application servers. A backup server is only used if a primary server is not available. When the plug-in determines that a backup application server is required, it goes through the list of backup servers, in order, until no servers are left in the list or until a request is successfully sent and a response received from one of the servers on this list.

Connect timeout

Specifies whether or not there is a limited amount of time the Application Server will maintain a connection with the Web server.

You can select either **No timeout** or **Set timeout**. If you select **Set timeout** you, must specify, in seconds, the length of time a connection with the Web server is to be maintained.

This property enables the plug-in to perform non-blocking connections with the application server. Non-blocking connections are beneficial when the plug-in is unable to contact the destination to determine whether or not the port is available. If no value is specified for this property, the plug-in performs a blocking connect in which the plug-in sits until an operating system times out (which could be as long as 2 minutes depending on the platform) and allows the plug-in to mark the server `unavailable`.

A value of 0 causes the plug-in to perform a blocking connect. A value greater than 0 specifies the number of seconds you want the plug-in to wait for a successful connection. If a connection does not occur after that time interval, the plug-in marks the server unavailable and fails over to another application server defined for the requested application.

Data type	Integer

Maximum number of connections that can be handled by the Application Server

Specifies the maximum number of pending connections to an Application Server that can be flowing through a Web server process at any point in time.

This field corresponds to the ServerMaxConnections element in the plugin-cfg.xml file.

You can select either **No limit** or **Set limit**. If you select **Set limit** you, must specify the maximum number of connections that can exist between the Web server and the Application Server at any given point in time.

If this attribute is set to either zero or -1, there is no limit to the number of pending connections to the Application Servers.

Data type	Integer
Default	-1

Use extended handshake to check whether Application Server is running

When selected, the Web server plug-in will use an extended handshake to check whether or not the Application Server is running.

This field corresponds to the ServerExtendedHandshake element in the plugin-cfg.xml file.

Select this property if a proxy firewall is between the plug-in and the application server.

The plug-in marks a server as down when the connect() fails. However, when a proxy firewall is in between the plug-in and the application server, the connect() will succeed, even though the back end application server is down. This causes the plug-in to not failover correctly to other application servers.

If the plug-in performs some handshaking with the application server to ensure that it is started before it sends a request it can failover to another application server if it detects that the application server with which it is attempting to perform a handshake is down.

Send the header ″100 Continue″ before sending the request content

This field corresponds to the WaitForContinue element in the plugin-cfg.xml file.

When selected, the Web server plug-in will send the header ″100 Continue″ to the Application Server before it sends the request content.

Web server plug-in configuration properties

The following table indicates which panel in the administrative console you need to use to manually configure a Web server plug-in property.

Table 5. Web server plug-in configuration properties

Administrative console panel	Field name	Configuration property name
In the administrative console, click **Servers** > **Web Servers** >*Web_server_name* > **Plug-in properties**	Refresh configuration interval	RefreshInterval
In the administrative console, click **Servers** > **Web Servers** > *Web_server_name* > **Plug-in properties**	Plug-in log file name	Log->name
In the administrative console, click **Servers** > **Web Servers** > *Web_server_name* > **Plug-in properties**	Plug-in logging	Log->LogLevel
In the administrative console, click **Servers** > **Web Servers** > *Web_server_name* > **Plug-in properties**	Ignore DNS failures during Web server startup	IgnoreDNSFailures
In the administrative console, click **Servers** > **Web Servers** > *Web_server_name* > **Plug-in properties** > **Custom properties** > **New**	KeyringLocation	Keyring
In the administrative console, click **Servers** > **Web Servers** > *Web_server_name* > **Plug-in properties** > **Custom properties** > **New**	StashfileLocation	Stashfile
In the administrative console, click **Servers** > **Web Servers** > *Web_server_name* > **Plug-in properties** > **Request routing**	Load balancing option	LoadBalance
In the administrative console, click **Servers** > **Web Servers** > *Web_server_name* > **Plug-in properties** > **Request Routing**	Clone separator change	CloneSeparatorChange

Table 5. Web server plug-in configuration properties (continued)

In the administrative console, click **Servers > Web Servers >** *Web_server_name* **> Plug-in properties > Request Routing**	Retry interval	RetryInterval
In the administrative console, click **Servers >***Web server_name* **> Plug-in properties > Request routing**	Maximum size of request content	PostSizeLimit
In the administrative console, click **Servers > Web Servers >** *Web_server_name* **> Plug-in properties > Request routing**	Remove special headers	RemoveSpecialHeaders
In the administrative console, click **Application Servers >***server_name* **> Web server plug-in properties**	Server role	PrimaryServers and BackupServers list
In the administrative console, click **Application Servers >***server_name* **> Web server plug-in properties**	Connect timeout	Server ConnectTimeout
In the administrative console, click **Application Servers >***server_name* **> Web server plug-in properties**	Use extended handshake to check whether Application Server is running	Server Extended Handshake
In the administrative console, click **Application Servers >***server_name* **> Web server plug-in properties**	Send the header ″100 Continue″ before sending the request content	WaitForContinue
In the administrative console, click **Application Servers >***server_name* **> Web server plug-in properties**	Maximum number of connections that can be handled by the Application Server	Server MaxConnections
In the administrative console, click **Servers > Web Servers >** *Web_server_name* **> Plug-in properties > Request and Response**	Application server port preference	AppServerPortPreference
In the administrative console, click **Servers > Web Servers >** *Web_server_name* **> Plug-in properties > Request and Response**	Enable Nagle algorithm for connections to the Application Server	ASDisableNagle
In the administrative console, click **Servers > Web Servers >** *Web_server_name* **> Plug-in properties > Request and Response**	Enable Nagle Algorithm for the IIS Web Server	IISDisableNagle
In the administrative console, click **Servers > Web Servers >** *Web_server_name* **> Plug-in properties > Request and Response**	Virtual host matching	VHostMatchingCompat
In the administrative console, click **Servers > Web Servers >** *Web_server_name* **> Plug-in properties > Request and Response**	Maximum chunk size used when reading the response body	ResponseChunkSize

Table 5. Web server plug-in configuration properties (continued)

In the administrative console, click **Servers** > **Web Servers** > *Web_server_name* > **Plug-in properties** > **Request and Response**	Accept content for all requests	AcceptAllContent
In the administrative console, click **Servers** > **Web Servers** > *Web_server_name* > **Plug-in properties** > **Request and Response**	Chunk response to the client	ChunkedResponse
In the administrative console, click **Servers** > **Web Servers** > *Web_server_name* > **Plug-in properties** > **Request and Response**	Priority used by the IIS Web server when loading the plug-in configuration file	IISPluginPriority
In the administrative console, click **Servers** > **Web Servers** > *Web_server_name* > **Plug-in properties** > **Caching**	Enable Edge Side Include (ESI) processing to cache the responses	ESIEnable
In the administrative console, click **Servers** > **Web Servers** > *Web_server_name* > **Plug-in properties** > **Caching**	Maximum cache size	ESIMaxCacheSize
In the administrative console, click **Servers** > **Web Servers** > *Web_server_name* > **Plug-in properties** > **Caching**	Enable invalidation monitor to receive notifications	ESIInvalidationMonitor

Web server plug-in connections

The WebSphere Application Server Web server plug-ins are used to establish and maintain persistent HTTP and HTTPS connections to Application Servers .

When the plug-in is ready to send a request to the application server, it first checks its connection pool for existing connections. If an existing connection is available the plug-in checks its connection status. If the status is still good, the plug-in uses that connection to send the request. If a connection does not exist, the plug-in creates one. If a connection exists but has been closed by the application server, the plug-in closes that connection and opens a new one.

After a connection is established between a plug-in and an application server, it will not be closed unless the application server closes it for one of the following reasons:

- If the **Use Keep-Alive** property is selected and the time limit specified on the **Read timeout** or **Write timeout** property for the HTTP inbound channel has expired.
- The maximum number of persistent requests which can be processed on an HTTP inbound channel has been exceeded. (This number is set using the HTTP inbound channel’s **Maximum persistent requests** property.)
- The Application Server is shutting down.

Even if the application server closes a connection, the plug-in will not know that it has been closed until it tries to use it again. The connection will be closed if one of the following events occur:

- The plug-in receives a new HTTP request and tries to reuse the existing connection.

- The number of **httpd** processes drop because the Web server is not receiving any new HTTP requests. (For the IHS Web server, the number of **httpd** processes that are kept alive depends on the value specified on the Web server's MinSpareServers directive.)
- The Web server is stopped and all **httpd** processes are terminated, and their corresponding sockets are closed.

Note: Sometimes, if a heavy request load is stopped or decreased abruptly on a particular application server, a lot of the plug-in's connections to that application server will be in CLOSE_WAIT state. Because these connections will be closed the first time the plug-in tries to reuse them, having a large number of connections in CLOSE-WAIT state should not affect performance

Web server plug-in remote user information processing

You can configure your Web server with a third-party authentication module and then configure the Web server plug-in to route requests to the Application Server. If an application calls the getRemoteUser() method, it relies on a private HTTP header that contains the remote user information and is parsed by the plug-in. The plug-in sets the private HTTP header value whenever a Web server authentication module populates the remote user in the Web server data structure. If the private HTTP header value is not set, the application's call to getRemoteUser() returns a null value.

- In the case of an Apache and IBM HTTP Server (IHS) Web server, the plug-in builds the private header from the information contained in the associated request record.
- In the case of a Sun One Web server, the plug-in builds the private header from the information contained in the **auth_user** property associated with the request. The private header is usually set to the name of the local HTTP user of the Web browser, if HTTP access authorization is activated for the URL.
- In the case of a Domino Web server, the plug-in builds the private header from the information contained in the **REMOTE_USER** environment variable. The plug-in sets this variable to **anonymous** for users who have not logged in and to the *username* for users who are logged into the application.
- In the case of an Internet Information Services (IIS) Web server, the plug-in builds the private header from the information contained in the **REMOTE_USER** environment variable. The plug-in sets this variable to the name of the user as it is derived from the authorization header sent by the client.

If the private header is not being set in the Sun One, IIS, or Domino Web server plug-in, make sure the request record includes information about the user requesting the data.

Note: If an application's call to getRemoteUser() returns a null value, or if the correct remote user information is not being added to the Web server plug-in's data structure, make sure the remote user parameter within the WebAgent is still set to **YES**. (Sometimes this parameter gets set to **NO** when service is applied.)

Web server plug-ins

Web server plug-ins enable the Web server to communicate requests for dynamic content, such as servlets, to the application server. A Web server plug-in is associated with each Web server definition. The configuration file (plugin-cfg.xml) that is generated for each plug-in is based on the applications that are routed through the associated Web server.

A Web server plug-in is used to forward HTTP requests from a supported Web server to an application server. Using a Web server plug-in to provide communication between a Web server and an application server has the following advantages:

- XML-based configuration file
- Standard protocol recognized by firewall products
- Security using HTTPS, replacing proprietary Open Servlet Engine (OSE) over Secure Sockets Layer (SSL)

Each of the supported distributed platform Web server plug-ins run on a number of operating systems. See Supported Hardware and Software at `http://www.ibm.com/software/webservers/appserv/doc/latest/prereq.html`for the product for the most current information about supported Web servers.

Checking your IBM HTTP Server version

At times, you might need to determine the version of your IBM HTTP Server installation.

1. Change directory to the installation root of the Web server. For example, this is /opt/IBMIHS on a Solaris machine.
2. Find the subdirectory that contains apache.exe (on a Windows platforms) or apachectl (on a UNIX-based platforms, such as z/OS, Solaris, Linux, and HP-UX)
3. On a Windows platform, issue:

   ```
   apache.exe -V
   ```
4. On a UNIX-based platforms issue:

   ```
   ./apachectl -V 4
   ```

The version is shown in the ″Server version:″ field and will looks something like the following:

```
Server version: IBM_HTTP_Server/2.0.47 Apache/2.0.47
Server built: July 2 2004 20:38:36
Server's Module Magic Number: 20020903:4.
```

Web server tuning parameters

WebSphere Application Server provides plug-ins for several Web server brands and versions. Each Web server operating system combination has specific tuning parameters that affect the application performance.

- **IBM HTTP Server**

  The IBM HTTP Server V6.0 is a multi-process, multi-threaded server.

  - **Access logs**
    - **Description:** Collects all incoming HTTP requests. Logging degrades performance because IO operation overhead causes logs to grow significantly in a short time.
    - **How to view or set:**
      1. Open the IBM HTTP Server `httpd.conf` file, located in the directory *IBM_HTTP_Server_root_directory*/conf.
      2. Search for a line with the text **CustomLog**.
      3. Comment out this line by placing # in front of the line.
      4. Save and close the `httpd.conf` file.
      5. Stop and restart the IBM HTTP Server.
    - **Default value:** Logging of every incoming HTTP request is enabled.
    - **Recommended value:** Disable the access logs.
  - **MaxClients**
    - **Description:** The MaxClients directive controls the maximum number of simultaneous connections or users that the web server can service at any one time. If, at peak usage, your web server needs to support 200 active users at once, you should set MaxClients to 220 (200 plus an extra 10% for load growth). Setting MaxClients too low could cause some users to believe the web server is not responding. You should have sufficient RAM in your web server machines to support each connected client. For IBM HTTP Server V6.0 on UNIX, you should allocate around 1.5MB MaxClients of RAM for use by the IBM HTTP Server. For IBM HTTP Server V6.0 on Windows, you should allocate around 300KB MaxClients of RAM for use by the IBM HTTP Server. Some third party modules can significantly increase the amount of RAM used per connected client.
    - **How to view or set:** Edit the MaxClients directive in the IBM HTTP Server `httpd.conf` file, located in the directory *IBM_HTTP_Server_root_directory*/conf.
    - **Default value:** 150

    - **Recommended value:** The maximum number of users normally simultaneously connected to your web server, plus an additional 10% for buffer. Note: The KeepAliveTimeout setting can affect how long a user is connected to the webserver.
  - **MinSpareServers, MaxSpareServers, and StartServers**
    - **Description:** Pre-allocates and maintains the specified number of processes so that few processes are created and destroyed as the load approaches the specified number of processes. Specifying similar values reduces the CPU usage for creating and destroying HTTPD processes. Adjust this parameter if the time waiting for IBM HTTP Server to start more servers, so that it can handle HTTP requests, is not acceptable.
    - **How to view or set:** Edit the MinSpareServers, MaxSpareServers and StartServers directives in the `httpd.conf` file located in the *IBM_HTTP_Server_root_directory*/conf directory.
    - **Default value:** MinSpareServers 5, MaxSpareServers 10, StartServers 5
    - **Recommended value:** For optimum performance, specify the same value for the MinSpareServers and the StartServers parameters. If MaxSpareServers is set to less than MinSpareServers, IBM HTTP Server resets MaxSpareServer=MinSpareServer+1. Setting the StartServers too high can cause swapping if memory is not sufficient, degrading performance.
  - **ListenBackLog**
    - **Description:** Sets the length of a pending connections queue. When several clients request connections to the IBM HTTP Server, and all threads used, a queue exists to hold additional client requests. However, if you use the default Fast Response Cache Accelerator (FRCA) feature of IBM HTTP Server V6.0 on Windows, the ListenBackLog directive is not used since FRCA has its own internal queue.
    - **How to view or set:** For non-FRCA: Edit the IBM HTTP Server `httpd.conf` file. Then, add or view the ListenBackLog directive.
    - **Default value:** For HTTP Server V6.0: 1024 with FRCA enabled, 511 with FRCA disabled
    - **Recommended value:** Use the defaults.
- **IBM HTTP Server - Linux**
  - **MaxRequestsPerChild**
    - **Description:** Sets the limit on the number of requests that an individual child server process handles. After the number of requests reaches the value set for the MaxRequestsPerChild parameter, the child process dies. Adjust this parameter if destroying and creating child processes is degrading your Web server performance.
    - **How to view or set:**
      1. Edit the IBM HTTP server `httpd.conf` file located in the *IBM_HTTP_Server_root_directory*/conf directory.
      2. Change the value of the parameter.
      3. Save the changes and restart the IBM HTTP server.
    - **Default value:** 500
    - **Recommended value:** Should normally be set to 0. Non-zero settings can be useful if child memory usage is observed to steadily increase over time. Memory leaks have occasionally been observed in third party modules and various OS runtime libraries used by the IBM HTTP Server.
- **IBM HTTP Server - Windows 2000 and Windows 2003**
  - **ThreadsPerChild**
    - **Description:** Sets the number of concurrent threads running at any one time within the IBM HTTP Server.
    - **How to view or set:** Edit the IBM HTTP Server file `httpd.conf` file located in the directory *IBM_HTTP_Server_root_directory*/conf. Change the value of the parameter. Save the changes and restart the IBM HTTP Server.

      There are two ways to find how many threads are used under load:
      1. Use the Windows 2000 and Windows 2003 Performance Monitor under the desktop Start menu:
         a. Right-click the status bar on your desktop. Click **Task Manager**.
         b. Select the **Processes** tab.
         c. Click **View** > **Select Columns**.
         d. Select **Thread Count**.
         e. Click **OK**.

The **Processes** tab shows the number threads for each process under the column name **Threads**, including Apache.

2. Use the IBM HTTP Server server-status (this choice works on all platforms, not just Windows):
   a. Edit the IBM HTTP Server `httpd.conf` file as follows: Remove the comment character # from the following lines: `#LoadModule status_module`, `modules/ApacheModuleStatus.dll`, `#<Location/server-status>`, `#SetHandler server-status`, and `#</Location>`.
   b. Save the changes and restart the IBM HTTP Server.
   c. In a Web browser, go to the URL: `http://`*`yourhost`*`/server-status`. Alternatively,
   d. Click **Reload** to update status.
   e. (Optional) If the browser supports refresh, go to `http://`*`your_host`*`/server-status?refresh=5` to refresh every five seconds. You will see five requests currently processing 45 idle servers.

- **Default value:** 250 for IBM HTTP Server V6.0.
- **Recommended value:** Set this value to prevent bottlenecks, allowing just enough traffic through to the application server.

– **Web server configuration reload interval**

- **Description:** Tracks a variety of configuration information about WebSphere Application Server resources. The Web server needs to understand some of this information, such as Uniform Resource Identifiers (URIs) pointing to WebSphere Application Server resources. This configuration data is pushed to the Web server through the WebSphere Application Server plug-in at intervals specified by this parameter. Periodic updates add new servlet definitions without having to restart any of the WebSphere Application Server servers. However, the dynamic regeneration of this configuration information is costly in terms of performance. Adjust this parameter in a stable production environment.
- **How to view or set:**Use the Refresh configuration interval Web server plug-in property to change the current setting for this parameter. In the administrative console, click **Servers > Web Servers >***Web_server_name* **> Plug-in properties**.
- **Default value:** The default reload interval is 60 seconds.
- **Recommended value:** Increase the reload interval to a value that represents an acceptable wait time between the servlet update and the Web server update.

For more information about the `plugin-cfg.xml` file see the topic "Web server plug-ins" on page 72.

- **Sun Java System Web server, Enterprise Edition (formerly Sun ONE) - Solaris operating environment**

  The default configuration of the Sun ONE Web server, Enterprise Edition provides a single-process, multi-threaded server.

  – **Active threads**

  - **Description:** Specifies the current number of threads active in the server. After the server reaches the limit set with this parameter, the server stops servicing new connections until it finishes old connections. If this setting is too low, the server can become throttled, resulting in degraded response times. To tell if the Web server is being throttled, consult its perfdump statistics. Look at the following data:
    - **WaitingThreads count:** If WaitingThreads count is getting close to zero, or is zero, the server is not accepting new connections.
    - **BusyThreads count:** If the WaitingThreads count is close to zero, or is zero, BusyThreads is probably very close to its limit.
    - **ActiveThreads count:** If ActiveThreads count is close to its limit, the server is probably limiting itself.
  - **How to view or set:** Use the Maximum number of simultaneous requests parameter in the Enterprise Server Manager interface to control the number of active threads within Sun ONE Web server, Enterprise Edition. This setting corresponds to the RqThrottle parameter in the `magnus.conf` file.
  - **Default value:** 512
  - **Recommended value:** Increase the thread count until the active threads parameters show optimum behavior.

- **Microsoft Internet Information Server (IIS) - Windows NT and Windows 2000**
  - **IIS permission properties**
    - **Description:** The Web server has several properties that dramatically affect the performance of the application server. The default settings are usually acceptable. However, because other products can change the default settings without user knowledge, make sure to check the IIS settings for the Home Directory permissions of the Web server. The permissions should be set to Script and not to Execute. If the permissions are set to Execute, no error messages are returned, but the performance of WebSphere Application Server is decreased.
    - **How to view or set:** To check or change these permissions, perform the following procedure in the Microsoft management console:
      1. Select the Web site (usually default Web site).
      2. Right-click and select the **Properties** option.
      3. Click the **Home Directory** tab. To set the permissions of the Home Directory:
         a. In the **Application** settings, select the **Script** check box in the **Permissions** list and clear the **Execute** check box.
         b. (Optional) Check the permissions of the sePlugin:
            1) Expand the Web server.
            2) Right-click the sePlugin and select **Properties**.
            3) Confirm that the **Execute** permissions are set to **Execute**.
    - **Default value:** Script
    - **Recommended value:** Script
  - **Number of expected hits per day**
    - **Description:** Controls the memory that IIS allocates for connections.
    - **How to view or set:** Using the performance window, set the parameter to More than 100000 in the Web site properties panel of the Microsoft management console.
    - **Default value:** Fewer than 100000
    - **Recommended value:** More than 100000
  - **ListenBackLog parameter**
    - **Description:** Alleviates failed connections under heavy load conditions, if you are using IIS on Windows NT and Windows 2000. Failure typically occurs when you are using more than 100 clients. ListenBackLog increases the number of requests that IIS keeps in its queue. Consider raising this value if you see intermittent `Unable to locate server errors` in the Netscape browser.
    - **How to view or set:**
      1. Use a command prompt to issue the **regedit** command to access the operating system registry.
      2. In the registry window, locate the parameter in the HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\InetInfo\Parameters\ListenBackLog directory.
      3. Right-click the parameter to adjust the setting according to the server load.
    - **Default value:** 25 (decimal)
    - **Recommended value:** You can set the ListenBackLog parameter can be set as high as 200, without negative impact on performance and with an improvement in load handling.

Modifying the WebSphere plug-in to improve performance

You can improve the performance of IBM HTTP Server V6.0 (with the WebSphere Web server plug-in) by modifying the plug-in's RetryInterval configuration. The RetryInterval is the length of time to wait before trying to connect to a server that has been marked temporarily unavailable. Making this change can help the IBM HTTP Server V6.0 to scale higher than 400 users.

The plug-in marks a server temporarily unavailable if the connection to the server fails. Although a default value is 60 seconds, it is recommended that you lower this value in order to increase throughput under heavy load conditions. Lowering the RetryInterval is important for IBM HTTP Server V6.0 on UNIX operating systems that have a single thread per process, or for IBM HTTP Server 2.0 if it is configured to have fewer than 10 threads per process.

How can lowering the RetryInterval affect throughput? If the plug-in attempts to connect to a particular application server while the application server threads are busy handling other connections, which happens under heavy load conditions, the connection times out and the plug-in marks the server temporarily unavailable. If the same plug-in process has other connections open to the same server and a response is received on one of these connections, the server is marked again. However, when you use the IBM HTTP Server V6.0 on a UNIX operating system, there is no other connection since there is only one thread and one concurrent request per plug-in process. Therefore, the plug-in waits for the RetryInterval before attempting to connect to the server again.

Since the application server is not really down, but is busy, requests are typically completed in a small amount of time. The application server threads become available to accept more connections. A large RetryInterval causes application servers that are marked temporarily unavailable, resulting in more consistent application server CPU utilization and a higher sustained throughput.

Note: Although lowering the RetryInterval can improve performance, if all the application servers are running, a low value can have an adverse affect when one of the application servers is down. In this case, each IBM HTTP Server V6.0 process attempts to connect and fail more frequently, resulting in increased latency and decreased overall throughput.

Gskit install images files

The Global Security Kit (GSKit) installation image files for the WebSphere Web server plug-ins are packaged on the CD with the Web server plug-in files. You can download the appropriate GSKIT file to the workstation on which your Web server is running. Use the following table to assist you in selecting the correct GSKIT installation image file.

Operating system	GSKit 7 Installation image file
Windows	No image name
AIX	gskta.rte
HP-UX	gsk7bas
Solaris Operating Environment	gsk7bas
Linux	gsk7bas_7.0.3.1.i386.rpm
Linux390	gsk7bas-7.0.3.1.s390.rpm
LinuxPPC	gsk7bas-7.0.3.1.ppc.rpm

Plug-ins: Resources for learning

See this topic in the V6 Information Center to find links links to relevant supplemental information about Web server plug-ins. The information resides on IBM and non-IBM Internet sites, whose sponsors control the technical accuracy of the information.

These links are provided for convenience. Often, the information is not specific to the IBM WebSphere Application Server product, but is useful all or in part for understanding the product. When possible, links are provided to technical papers and Redbooks that supplement the broad coverage of the release documentation with in-depth examinations of particular product areas.

Web server plug-in tuning tips

Balancing workloads:

In a distributed environment, you can limit the number of connections that can be handled by an applications server. To do this, go to the **Servers > Web Servers >** *webserver* **> Plug-in properties** page in the administrative console and select **Set limit** for the **Minimum number of connections that can be handled by the Application Server** field. Then specify in the **Connections** field the maximum number of connections you want to allow. When this maximum number of connections is reached, the plug-in returns an HTTP 503 response code to the client. This code indicates that the server is currently unable to handle the request because it is experiencing a temporary overloading or because maintenance is being performed.

When this maximum number of connections is reached, the plug-in, when establishing connections, automatically skips that application server, and tries the next available application server. If no application servers are available, an HTTP 503 response code will be returned to the client. This code indicates that the server is currently unable to handle the request because it is experiencing a temporary overloading or because maintenance is being performed.

Limiting the number of connections that can be established with an application server works best for Web servers that follow the threading model instead of the process model, and only one process is started.

The IBM HTTP Server V6.0.x follows the threading model. To prevent the IBM HTTP Server from starting more than one process, change the following properties in the Web server configuration file (`httpd.conf`) to the indicated values:

```
ServerLimit          1
ThreadLimit          4000
StartServers         1
MaxClients           1024
MinSpareThreads      1
MaxSpareThreads      1024
ThreadsPerChild      1024
MaxRequestsPerChild  0
```

Windows **Improving performance in a high stress environment:**

If you use the default settings for a Microsoft Windows operating system, you might encounter Web server plug-in performance problems if you are running in a high stress environment. To avoid these problems, consider tuning the the TCP/IP setting for this operating system. Two of the keys setting to tune are TcpTimedWaitDelay and MaxUserPort.

To tune the TcpTimedWaitDelay setting, change the value of the tcp_time_wait_interval parameter from the default value of 240 seconds, to 30 seconds:

1. Locate in the Windows Registry:

   ```
   HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\tcpip\Parameters\TcpTimedWaitDelay
   ```

   If this entry does not exist in your Windows Registry, create it by editing this entry as a new DWORD item.
2. Specify, in seconds, a value between 30 and 300 inclusive for this entry. (It is recommended that you specify a value of 30.)

To tune the MaxUserPort setting:

1. Locate in the Windows Registry:

   ```
   HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\tcpip\Parameters\MaxUserPort
   ```

   If this entry does not exist in your Windows Registry, create it by editing this entry as a new DWORD item.
2. Set the maximum number of ports to a value between 5000 and 65534 ports, inclusive. (It is recommended that you specify a value of 65534,)

See the Microsoft Web site for more information about these settings.

Tuning Web servers

“Web server tuning parameters” on page 73 lists tuning parameters specific to Web servers. The listed parameters may not apply to all of the supported Web servers. Check your Web server documentation before using any of these parameters.

Setting up the administrative architecture

If your system uses administrative services, you can specify settings for the service.

Use the settings page for an administrative service to configure administrative services.

Administration service settings

Use this page to view and change the configuration for an administration service.

To view this administrative console page, click **Servers > Application Servers >***server_name* **> Administration > Administration Services**

Standalone

Specifies whether the server process is a participant in a Network Deployment cell or not. If the box is checked (true), the server does not participate in distributed administration. If the box is unchecked (false), the server participates in the Network Deployment system.

The default value for base WebSphere Application Server installations is true. When addNode runs to incorporate the server into a Network Deployment cell, the value switches to false.

Data type	Boolean
Default	true

Preferred Connector

Specifies the preferred JMX Connector type. Available options, such as SOAPConnector or RMIConnector, are defined using the JMX Connectors page.

Data type	String
Default	SOAP

Extension MBean Providers collection

Use this page to view and change the configuration for JMX extension MBean providers.

You can configure JMX extension MBean providers to be used to extend the existing WebSphere managed resources in the core administrative system. Each MBean provider is a library containing an implementation of a JMX MBean and its MBean XML Descriptor file.

To view this administrative console page, click **Servers > Application Servers >***server_name* **> Administration > Administration Services > Extension MBean Providers**

Name The name used to identify the Extension MBean provider library.

Description
An arbitrary descriptive text for the Extension MBean Provider configuration.

Classpath
The path to the Java archive (JAR) file that contains the Extension MBean provider library. This class path is automatically added to the Application Server class path.

Extension MBean Provider settings:

Use this page to view and change the configuration for a JMX extension MBean provider.

You can configure a library containing an implementation of a JMX MBean, and its MBean XML Descriptor file, to be used to extend the existing WebSphere managed resources in the core administrative system

To view this administrative console page, click **Servers > Application Servers >***server_name* **> Administration > Administration Services > Extension MBean Providers >***provider_library_name*

Classpath: The path to the Java archive (JAR) file that contains the Extension MBean provider library. This class path is automatically added to the Application Server class path. The class loader needs this information to load and parse the Extension MBean XML Descriptor file.

Description: An arbitrary descriptive text for the Extension MBean Provider configuration. Use this field for any text that helps identify or differentiate the provider configuration.

Name: The name used to identify the Extension MBean provider library.

Extension MBean collection

You can configure Java Management Extension (JMX) MBeans to extend the existing WebSphere Application Server managed resources in the administrative console. Use this page to register JMX MBeans. Any MBeans that are listed have already been registered.

To view this administrative console page, click **Servers > Application Servers >***server name* **> Administration > Administration Services > Extension MBean Providers >** *provider library name***> Extension MBean**

DescriptorURI
Specifies the location, relative to the provider class path, where the MBean XML descriptor file is located.

Type Specifies the type to use for registering this MBean. The type must match the type that is declared in the MBean descriptor file.

Extension MBean settings:

Use this page to view and configure Java Management Extension (JMX) MBeans.

To view this administrative console page, click **Servers > Application Servers >***server name***> Administration > Administration Services > Extension MBean Providers >** *provider library name***> Extension MBean >***Extension MBean name*

descriptorURI: Specifies the location, relative to the provider class path, where the MBean XML descriptor file is located.

type: Specifies the type to use for registering this MBean. The type must match the type that is declared in the MBean descriptor file.

Java Management Extensions connector properties

A Java Management Extensions (JMX) connector can either be a Remote Method Invocation (RMI) connector or a Simple Object Access Protocol (SOAP) connector.

Depending on the property, you can specify or set a property in the administrative console, the wsadmin tool, Application Server commands, scripts run from a command line interface, or a custom Java administrative client program that you write. You can also set SOAP connector properties in the `soap.client.props` file.

For specific information on how to code the JMX connector properties for the wsadmin tool, the Application Server commands, or scripts, see the particular tool or command. For specific information on how to code the JMX connector properties for a custom Java administrative client program, see the ″Java API documentation for Application Server″ topic in the Information Center.

For the administrative console, this article specifies the coding of the particular setting or property. Coding of properties in the `soap.client.props` file that are specific to JMX connectors is specified. These properties begin with com.ibm.SOAP. Other properties in the `soap.client.props` file that contain information that can be set elsewhere in the Application Server are not documented here. The coding for the com.ibm.ssl.contextProvider property, which can be set only in the `soap.client.props` file, is specified.

Each profile has a property file at *installation root*/profiles/*profile name*/properties/soap.client.props. These property files allow you to set different properties, including security and timeout properties. These properties are the default for all administrative connections that use the SOAP JMX connector between processes executing in a particular profile. For instance, the wsadmin program executing under a particular profile uses the property values from that file for the SOAP connector behavior unless the properties are overridden by some other programmatic means.

To view the JMX connector custom properties administrative console panel that goes with this article, click one of the following paths:

- **Servers -> Application servers ->***server name* **-> Server Infrastructure -> Administration -> Administration Services -> Additional properties -> JMX Connectors->***connector type* **-> Additional Properties -> Custom properties**
- **System administration -> Deployment manager ->Additional Properties -> Administration Services -> Additional Properties -> JMX Connectors->***connector type***-> Additional Properties -> Custom properties**
- **System administration -> Node agents ->***node agent name* **-> Additional Properties -> Administration Services -> Additional Properties -> JMX Connectors->***connector type***-> Additional Properties -> Custom properties**

SOAP connector properties

This section discusses JMX connector properties that pertain to SOAP connectors.

SOAP Request timeout

Specifies the SOAP client request timeout. The value that you choose depends on a number of factors such as the size and the number of the applications that are installed on the server, the speed of your machine, and the level of usage of your machine.

The program default value for the request timeout is 600 seconds. However, other components that connect to the SOAP client can override the default. Components that use the `soap.client.props` file have a default value of 180 seconds.

You can set the property by using one of the following options:

- Scripts run from a command line interface.
- The `soap.client.props` file.

Property	com.ibm.SOAP.requestTimeout
Data type	Integer
Range in seconds	0 to n If the property is zero (0), the request never times out.
Default	180

- The administrative console. Specify the property and the value as a name-value pair on the JMX connector custom properties panel of the administrative console.

Property	requestTimeout
Data type	Integer
Range in seconds	0 to n If the property is zero (0), the request never times out.
Default	600

- A Java administrative client. The property is AdminClient.CONNECTOR_SOAP_REQUEST_TIMEOUT.

Configuration URL

Specifies the Universal Resource Locator (URL) of the `soap.client.props` file. Specify the configuration URL property if you want a program to read SOAP properties from this file. You can set the property by using one of the following options:

- Scripts run from a command line interface. Scripts can pass the Configuration URL property to the Application Server on the com.ibm.SOAP.ConfigURL system property.
- The administrative console. Specify the property and the value as a name-value pair on the JMX connector custom properties panel of the administrative console.

Property	ConfigURL
Data type	String
Valid Value	http://*Path*/soap.client.props
Default	None

- A Java administrative client. The property is AdminClient.CONNECTOR_SOAP_CONFIG.

Security context provider

Specifies the Secure Sockets Layer (SSL) implementation to use between the Application Server and the SOAP client. You can specify either IBM Java Secure Sockets Extension (IBMJSSE) or IBM Java Secure Sockets Extension that has undergone Federal Information Processing Standards certification (IBMJSSEFIPS).

You can set the property by using the `soap.client.props` file.

Property	com.ibm.ssl.contextProvider
Data type	String

Valid Values	`IBMJSSE`
	`IBMJSSEFIPS`
	`IBMJSSE2`

Default	IBMJSSE2

Secure Sockets Layer (SSL) security

Use this property to enable SSL security between Application Server and the SOAP client. You can set the property by using one of the following options:

- Scripts run from a command line interface.
- The `soap.client.props` file.

Property	com.ibm.SOAP.securityEnabled
Data type	Boolean
Default	False

- The administrative console. Specify the property and the value as a name-value pair on the JMX connector custom properties panel of the administrative console.

Property	securityEnabled
Data type	Boolean
Default	False

- A Java administrative client. The property is AdminClient.CONNECTOR_SECURITY_ENABLED.

SOAP and RMI connector properties

This section discusses JMX connector properties that pertain to both SOAP connectors and RMI connectors.

Connector type

Specify a connector type of SOAP or RMI, depending on whether Application Server connects to a SOAP server or an RMI server. You can set the property by using one of the following options:

- The wsadmin tool.
- Scripts run from a command line interface.
- The administrative console. Specify the property and the value as a name-value pair on the JMX connector custom properties panel of the administrative console.

Property	Type
Data type	String
Valid values	`SOAPConnector` `RMIConnector`
Default	SOAP

- A Java administrative client. The property is AdminClient.CONNECTOR_TYPE. Specify by using the AdminClient.CONNECTOR_TYPE_RMI or the AdminClient.CONNECTOR_TYPE_SOAP constants.

Host

Use the host property to specify the host name or the IP address of the server to which Application Server connects. The server can be a SOAP server or an RMI server. You can set the property by using one of the following options:

- The wsadmin tool.
- Scripts run from a command line interface.
- The administrative console. Specify the property and the value as a name-value pair on the JMX connector custom properties panel of the administrative console.

Property	host
Data type	String
Valid values	Host name or IP address
Default	None

- A Java administrative client. The property is AdminClient.CONNECTOR_HOST.

Port

Use the port property to specify the port number of the server to which Application Server connects. The server can be a SOAP server or an RMI server. You can set the property by using one of the following options:

- The wsadmin tool.
- Scripts run from a command line interface.

- The administrative console. Specify the property and the value as a name-value pair on the JMX connector custom properties panel of the administrative console.

Property	port
Data type	Integer
Valid value	Port number
Default	None

- A Java administrative client. The property is AdminClient.CONNECTOR_PORT.

User name

Specifies the user name that Application Server uses to access the SOAP server or the RMI server. You can set the property by using one of the following options:

- The wsadmin tool.
- Scripts run from a command line interface.
- The `soap.client.props` file.

Property	com.ibm.SOAP.loginUserid
Data type	String
Valid value	The value must match the global SSL settings for SOAP or RMI.
Default	None

- The administrative console. Specify the property and the value as a name-value pair on the JMX connector custom properties panel of the administrative console.

Property	username
Data type	String
Valid value	The value must match the global SSL settings for SOAP or RMI.
Default	None

- A Java administrative client. The property is AdminClient.USERNAME.

Password

Specifies the password that Application Server uses to access the SOAP server or the RMI server. You can set the property by using one of the following options:

- The wsadmin tool.
- Scripts run from a command line interface.
- The `soap.client.props` file.

Property	com.ibm.SOAP.loginPassword
Data type	String
Valid values	The value must match the global SSL settings for SOAP or RMI.
Default	None

- The administrative console. Specify the property and the value as a name-value pair on the JMX connector custom properties panel of the administrative console.

Property	password
Data type	String

Valid values	The value must match the global SSL settings for SOAP or RMI.
Default	None

- A Java administrative client. The property is AdminClient.PASSWORD.

Java Management Extensions connectors

Use this page to view and change the configuration for Java Management Extensions (JMX) connectors.

To view this administrative console page, click **Servers > Application Servers >***server_name* **> Administration > Administration Services > JMX Connectors**

Java Management Extensions (JMX) connectors communicate with WebSphere Application Server when you invoke a scripting process. There is no default for the type and parameters of a connector. The `wsadmin.properties` file specifies the Simple Object Access Protocol (SOAP) connector and an appropriate port number. You can also use the Remote Method Invocation (RMI) connector.

Use one of the following methods to select the connector type and attributes:
- Specify properties in a properties file.
- Indicate options on the command line.

Type:

Specifies the type of the JMX connector.

Data type	Enum
Default	SOAPConnector
Range	**SOAPConnector** For JMX connections using Simple Object Access Protocol (SOAP). **RMIConnector** For JMX connections using Remote Method Invocation (RMI).

JMX connector settings:

Use this page to view the configuration for a Java Management Extensions (JMX) connector.

To view this administrative console page, click **Servers > Application Servers >***server_name* **> Administration Services > JMX Connectors >***connector_type*

Type:

Specifies the type of the JMX connector.

Data type	Enum
Default	SOAPConnector
Range	**SOAPConnector** For JMX connections using Simple Object Access Protocol (SOAP). **RMIConnector** For JMX connections using Remote Method Invocation (RMI).

Repository service settings

Use this page to view and change the configuration for an administrative service repository.

To view this administrative console page, click **Servers > Application Servers >***server_name* **> Administration Services > Repository Service**.

Audit Enabled:

Specifies whether to audit repository updates in the log file. The default is to audit repository updates.

Data type	Boolean
Default	true

Administrative agents: Resources for learning

Use the following links to find relevant supplemental information about WebSphere Application Server administrative agents and distributed administration. The information resides on IBM and non-IBM Internet sites, whose sponsors control the technical accuracy of the information.

These links are provided for convenience. Often, the information is not specific to the IBM WebSphere Application Server product, but is useful all or in part for understanding the product. When possible, links are provided to technical papers and Redbooks that supplement the broad coverage of the release documentation with in-depth examinations of particular product areas.

View links to additional information:

Administration

- IBM WebSphere Application Server Redbooks at `http://publib-b.boulder.ibm.com/Redbooks.nsf/portals/WebSphere`.

  This site contains a listing of all WebSphere Application Server Redbooks.
- IBM developerWorks WebSphere at `http://www.software.ibm.com/wsdd/`.

  This site is the home of technical information for developers working with WebSphere products. You can download WebSphere software, take a fast path to developerWorks zones, such as VisualAge Java or WebSphere Application Server, learn about WebSphere products through a newcomers page, tutorials, technology previews, training, and Redbooks, get answers to questions about WebSphere products, and join the WebSphere community, where you can keep up with the latest developments and technical papers.
- WebSphere Application Server Support page at `http://www.ibm.com/software/webservers/appserv/support.html`.

  Take advantage of the Web-based Support and Service resources from IBM to quickly find answers to your technical questions. You can easily access this extensive Web-based support through the IBM Software Support portal and search by product category, or by product name. For example, if you are experiencing problems specific to WebSphere Application Server, click **WebSphere Application Server** in the product list. The WebSphere Application Server Support page appears.

Configuring the environment

To assist in handling requests among Web applications, Web containers, and application servers, you can configure settings for virtual hosts, variables and shared libraries.

1. Configure virtual hosts.
2. Configure variables.
3. If your deployed applications use shared library files, define the shared library files needed.

   See “Managing shared libraries” on page 97.

Virtual hosts

A virtual host is a configuration that enables a single host machine to resemble multiple host machines. Resources associated with one virtual host cannot share data with resources associated with another virtual host, even if the virtual hosts share the same physical machine.

Each virtual host has a logical name and a list of one or more DNS aliases by which it is known. A DNS alias is the TCP/IP hostname and port number that is used to request the servlet, for example yourHostName:80. When no port number is specified, 80 is assumed.

When a servlet request is made, the server name and port number entered into the browser are compared to a list of all known aliases in an effort to locate the correct virtual host and serve the servlet. If no match is found, an error is returned to the browser.

An application server provides a default virtual host with some common aliases, such as the machine's IP address, short host name, and fully qualified host name. The alias comprises the first part of the path for accessing a resource such as a servlet. For example, it is localhost:80 in the request http://localhost:80/myServlet.

A virtual host is not associated with a particular machine. It is a configuration, rather than a ″live object,″ explaining why you can create it, but cannot start or stop it. For many users, creating virtual hosts is unnecessary because the default_host is provided.

Adding a localhost to the virtual hosts adds the host name and IP address of the localhost machine to the alias table. This allows a remote user to access the administrative console.

Why you would use virtual hosting

Virtual hosts let you manage a single application server on a single machine as if the application server were multiple application servers each on their own host machine. Resources associated with one virtual host cannot share data with resources associated with another virtual host. This is true even though the virtual hosts share the same application server on the same physical machine.

Virtual hosts allow the administrator to isolate and independently manage multiple sets of resources on the same physical machine.

Suppose an Internet service provider (ISP) has two customers with Internet sites hosted on the same machine. The ISP keeps the two sites isolated from one another, despite their sharing a machine, by using virtual hosts. The ISP associates the resources of the first company with VirtualHost1 and the resources of the second company with VirtualHost2. Both virtual hosts map to the same application server.

Further suppose that both company sites offer the same servlet. Each site has its own instance of the servlet, and is unaware of the same servlet on the other site. If the company whose site is organized on VirtualHost2 is past due in paying its account with the ISP, the ISP can refuse all servlet requests that are routed to VirtualHost2. Even though the same servlet is available on VirtualHost1, the requests directed at VirtualHost2 do not go to the other virtual host.

The servlets on one virtual host do not share their context with the servlets on the other virtual host. Requests for the servlet on VirtualHost1 can continue as usual. This is true even though VirtualHost2 is refusing to fill requests for the servlet with the same name.

You associate a servlet or other application with a virtual host instead of the actual DNS address.

The default virtual host (default_host)

The product provides a default virtual host (named default_host).

The virtual host configuration uses wildcard entries with the ports for its virtual host entries.

- The default alias is *:80, using an internal port that is not secure.
- Aliases of the form *:9080 use the secure internal port.
- Aliases of the form *:9443 use the external port that is not secure.
- Aliases of the form *:443 use the secure external port.

Unless you specifically want to isolate resources from one another on the same physical machine, you probably do not need any virtual hosts in addition to the default host.

How requests map to virtual host aliases

Virtual hosts let you manage a single application server on a single machine as if the application server were multiple application servers that are each on their own host machine. Resources associated with one virtual host cannot share data with resources associated with another virtual host, even though the virtual hosts share the same application server on the same physical machine.

When you request a resource, WebSphere Application Server tries to map the request to an alias of a defined virtual host.

Mappings are both case sensitive and insensitive. For example, the portion ″http://host:port/″ is case insensitive, but the URL that follows is case sensitive. The match must be alphanumerically exact. Also, different port numbers are treated as different aliases.

For example, the request `http://www.myhost.com/myservlet` maps successfully to `http://WWW.MYHOST.COM/myservlet` but not to `http://WWW.MYHOST.COM/MYSERVLET or Www.Myhost.Com/Myservlet`. In the latter two cases, these mappings fail due to case sensitivity. The request `http://www.myhost.com/myservlet` does not map successfully to `http://myhost/myservlet` or to `http://myhost:9876/myservlet`. These mappings fail because they are not alphanumerically correct.

You can use wildcard entries for aliases by port and specify that all valid host name and address combinations on a particular port map to a particular virtual host.

If you request a resource using an alias that cannot be mapped to an alias of a defined virtual host, you receive a 404 error in the browser that was used to issue the request. A message states that the virtual host could not be found.

Two sets of associations occur for virtual hosts. Application deployment associates an application with a virtual host. Virtual host definitions associate the network address of the machine and the HTTP transport or Web server port assignment of the application server with the virtual host. Looking at the flow from the Web client request for the snoop servlet, for example, the following actions occur:

1. The Web client asks for the snoop servlet: at Web address http://www.some_host.some_company.com:9080/snoop
2. The some_host machine has the 9080 port assigned to the stand-alone WebSphere Application Server, *server1*.
3. The server1 Application Server looks at the virtual host assignments to determine the virtual host that is assigned to the alias some_host.some_company.com:9080.
4. The application server finds that no explicit alias for that DNS string exists. However, a wild card assignment for host name * at port 9080 does exist. This is a match. The virtual host that defines the match is default_host.
5. The application server looks at the applications deployed on the default_host and finds the snoop servlet.
6. The application server serves the application to the Web client and the requester is able to use the snoop servlet.

You can have any number of aliases for a virtual host. You can even have overlapping aliases, such as:

Virtual host	Alias	Port
default_host	*	9080
	localhost	9080
	my_machine	9080
	my_machine.my_company.com	9080
	localhost	80

The Application Server looks for a match using the explicit address specified on the Web client address. However, it might resolve the match to any other alias that matches the pattern before matching the explicit address. Simply defining an alias first in the list of aliases does not guarantee the search order when WebSphere Application Server is looking for a matching alias.

A problem can occur if you use the same alias for two different virtual hosts. For example, assume that you installed the default application and the snoop servlet on the default_host. You also have another virtual host called the admin_host. However, you have not installed the default application or the snoop servlet on the admin_host.

Assume that you define overlapping aliases for both virtual hosts because you accidentally defined port 9080 for the admin_host instead of port 9060:

Virtual host	Alias	Port
default_host	*	9080
	localhost	9080
admin_host	*	9060
	my_machine.com	9080

Assume that a Web client request comes in for http://my_machine.com:9080/snoop.

If the application server matches the request against *:9080, the application is served from the default_host. If the application server matches the request to my.machine.com:9080, the application cannot be found. A 404 error occurs in the browser that issues the request. A message states that the virtual host could not be found.

This problem is the result of not finding the requested application in the first virtual host that has a matching alias. The correct way to code aliases is for the alias name on an incoming request to match only one virtual host in all of your virtual host definitions. If the URL can match more than one virtual host, you can see the problem just described.

Configuring virtual hosts

Virtual hosts enable you to isolate and independently manage multiple sets of resources on the same physical machine.

1. Create a virtual host using the “Virtual host collection” on page 90 of the administrative console. Click **Environment > Virtual Hosts** from the navigation tree of the console. Click **New**. On the “Virtual host settings” on page 91 page that displays, specify an administrative name for the virtual host. When you create a virtual host, a default set of 90 MIME entries is created for the virtual host.
2. There must be a virtual host alias corresponding to each port used by an HTTP transport. There is one HTTP transport in each Web container, usually assigned to the virtual host named default_host. You can change the default assignment to any valid virtual host.

You must create a virtual host for each HTTP port in the following cases:

- You are using the internal HTTP transport with a port other than the default of 9080. You must define the port that you are using.
- You are using the default port 9080, but the port is no longer defined. You must define port 9080.
- You have created multiple Application Servers (either stand-alone servers or cluster members) that use the same virtual host. Because each server must be listening on a different HTTP transport port, you must define a virtual host alias for the transport port of each server.

If you define new virtual host aliases, identify the port values that the aliases use on the “HTTP transport collection” on page 130 page.

3. If necessary, create a virtual host alias for each HTTP transport port.

   From the “Virtual host collection” page, click your virtual host. On the “Virtual host settings” on page 91 page for the virtual host, click **Host aliases**. To define a virtual host alias on the “Host alias collection” on page 91 page, click **New**. On the “Host alias settings” on page 92 page for the virtual host alias, specify a host name and a port. Configure the virtual host to contain an alias for the port number. For example, specify an alias of `*:9082` if 9082 is the port number in use by the transport.

4. When you enter the URL for the application into a Web browser, include the port number in the URL.

   For example, if 9082 is the port number, specify a URL such as `http://localhost:9082/wlm/SimpleServlet`

5. If MIME entries are not specified at the Web module level, define MIME object types and their file name extensions. For each needed MIME entry on the “MIME type collection” on page 92 page, click **New**. On the “MIME type settings” on page 93 page, specify a MIME type and extension.

6. After you configure a virtual host alias or change a configuration, you must regenerate the Web server plug-in configuration and restart WebSphere Application Server.

Virtual host collection

Use this page to create and manage configurations that each let a single host machine resemble multiple host machines. Such configurations are known as *virtual hosts.*

To view this administrative console page, click **Environment > Virtual Hosts**.

Each virtual host has a logical name (which you define on this panel) and is known by its list of one or more domain name system (DNS) aliases. A DNS alias is the TCP/IP host name and port number used to request the servlet, for example yourHostName:80. (Port 80 is the default.)

You define one or more alias associations by clicking an existing virtual host or by adding a new virtual host.

When a servlet request is made, the server name and port number entered into the browser are compared to a list of all known aliases in an effort to locate the correct virtual host to serve the servlet. No match returns an error to the browser.

An application server profile provides a default virtual host with some common aliases, such as the internet protocol (IP) address, the DNS short host name, and the DNS fully qualified host name. The alias comprises the first part of the path for accessing a resource such as a servlet.

For example, the alias is localhost:80 in the request http://localhost:80/myServlet.

A virtual host is not associated with a particular profile or node (machine), but is associated with a particular server instead. It is a configuration, rather than a ″live object.″ You can create a virtual host, but you cannot start or stop it.

For many users, creating virtual hosts is unnecessary because the default_host that is provided is sufficient.

Adding the host name and IP address of the localhost machine to the alias table lets a remote user access the administrative console.

Resources associated with one virtual host cannot share data with resources associated with another virtual host, even if the virtual hosts share the same physical machine.

Name:

Specifies a logical name for configuring Web applications to a particular host name. The default virtual host is suitable for most simple configurations.

Virtual hosts enable you to isolate, and independently manage, multiple sets of resources on the same physical machine. Determine whether you need a virtual host alias for each port associated with an HTTP transport channel or an HTTP transport. There must be a virtual host alias corresponding to each port used by an HTTP transport channel or an HTTP transport. There is one HTTP transport channel or HTTP transport associated with each Web container, and there is one Web container in each application server.

When you create a virtual host, a default set of 90 MIME entries is created for the virtual host.

You must create a virtual host for each HTTP port in the following cases:
- You use the internal HTTP transport with a port other than the default value of 9080, or for some reason the virtual host does not contain the usual entry for port 9080.
- You create multiple application servers (stand-alone servers, managed servers, or cluster members) that are using the same virtual host. Because each server must be listening on a different HTTP port, you need a virtual host alias for the HTTP port of each server.

Virtual host settings:

Use this page to configure a virtual host instance.

To view this administrative console page, click **Environment** > **Virtual Hosts** >*virtual_host_name*.

Name:

Specifies a logical name for configuring Web applications to a particular host name. The default virtual host is suitable for most simple configurations.

Data type	String
Default	default_host

Host alias collection:

Use this page to manage host name aliases defined for a virtual host. An alias is the DNS host name and port number that a client uses to form the URL request for a Web application resource.

To view this administrative console page, click **Environment** > **Virtual Hosts** >*virtual_host_name* > **Host Aliases**.

Host Name:

Specifies the IP address, DNS host name with domain name suffix, or just the DNS host name, used by a client to request a Web application resource (such as a servlet, JavaServer Pages (JSP) file, or HTML page). For example, the host alias name is `myhost` in a DNS name of `myhost:8080`.

The product provides a default virtual host (named default_host). The virtual host configuration uses the wildcard character * (asterisk) along with the port number for its virtual host entries. Unless you specifically want to isolate resources from one another on the same node (physical machine), you probably do not need any virtual hosts in addition to the default host.

Port:

Specifies the port for which the Web server has been configured to accept client requests. For example, the port assignment is *8080* in a DNS name of `myhost:8080`. A URL refers to this DNS as: http://*myhost:8080*/servlet/snoop.

Host alias settings:

Use this page to view and configure a host alias.

To view this administrative console page, click **Environment > Virtual Hosts >***virtual_host_name* **> Host Aliases >***host_alias_name*.

Host name:

Specifies the IP address, domain name system (DNS) host name with domain name suffix, or the DNS host name that clients use to request a Web application resource, such as a servlet, JSP file, or HTML page.

For example, when the DNS name is `myhost`, the host alias is `myhost:8080`, where *8080* is the port. A URL request can refer to the snoop servlet on the host alias as: http://*myhost:8080*/servlet/snoop.

When there is no port number specified for a host alias, the default port is 80. For existing virtual hosts, the default host name and port reflect the values specified at product installation or configuration. For new virtual hosts, the default can be `*` to allow any value or no specification.

Data type	String
Default	* You can also use the IP address or the long or short DNS name.

Port:

Specifies the port where the Web server accepts client requests. Specify a port value in conjunction with the host name.

The default reflects the value specified at product setup. The default might be `80`, `81`, `9060` or a similar value.

Data type	Integer
Default	9060

MIME type collection:

Use this page to view and configure multi-purpose internet mail extensions (MIME) object types and their file name extensions.

The list shows a collection of MIME type extension mappings defined for the virtual host. Virtual host MIME entries apply when you do not specify MIME entries at the Web module level.

To view a list of current virtual host Mime types in the administrative console, click **Environment > Virtual Hosts >***virtual_host_name* **> MIME Types**.

MIME Type:

Specifies a MIME type, which can be application, audio, image, text, video, www, or x-world. An example value for MIME type is `text/html`.

Extensions:

Specifies file extensions of files that map the MIME type. Do not specify the period before the extension. Example extensions for a `text/html` MIME type are `htm` and `html`.

MIME type settings:

Use this page to configure a multi-purpose internet mail extensions (MIME) object type.

To view this administrative console page, click **Environment > Virtual Hosts >***virtual_host_name* **> MIME Types >***MIME_type*.

MIME Type:

Specifies a MIME type, which can be application, audio, image, text, video, www, or x-world. An example value for MIME type is `text/html`.

An example value for MIME type is `text/html`. A default value appears only if you are viewing the configuration for an existing instance.

Data type	String

Extensions:

Specifies file extensions of files that map the MIME type. Do not specify the period before the extension. Example extensions for a `text/html` MIME type are `htm` and `html`.

File extensions for a `text/html` MIME type are `.htm` and `.html`. A default value appears only if you are viewing the configuration for an existing MIME type.

Data type	String

Variables

A variable is a configuration property that can be used to provide a parameter for some values in the system. A variable has a name and a value.

WebSphere variables are used for:

- Configuring WebSphere Application Server path names, such as JAVA_HOME, and APP_INSTALL_ROOT.
- Configuring certain customization values.

Each variable has a scope. A scope is the range of locations in the WebSphere Application Server network where the variable is applicable.

- A variable with a node-level scope is available only on the node and the servers on that node. If a node-level variable has the same name as a cell-wide variable, the node-level variable value takes precedence.

- A server variable is available only on the one server process. A server variable takes precedence over a variable with the same name that is defined at a higher level.

You can use variables in configuration values such as file system path settings. Use the following syntax to refer to a variable:

```
${variable_name}
```

The value of a variable can contain a reference to another variable. The value of the variable is computed by substituting the value of the referenced variable recursively.

Variables are useful when concatenating two path variables when the specification does not accept the *AND* operator. For example, suppose that the following variables exist:

Variable name	Variable value
ROOT_DIR	`/`
HOME_DIR	`${ROOT_DIR}home`
USER_DIR	`${HOME_DIR}/myuserdir`

The variable reference `${USER_DIR}` resolves to the value `/home/myuserdir`.

Configuring WebSphere variables

This topic describes how to create a WebSphere Application Server variable.

You can define a WebSphere Application Server variable to provide a parameter for some values in the system. After you define the name and value for a variable, the value is used in place of the variable name. Variables most often specify file paths. However, some system components also support the use of variables.

WebSphere variables are used for:

- Configuring WebSphere Application Server path names, such as JAVA_HOME, and APP_INSTALL_ROOT.
- Configuring certain customization values.

The scope of a variable can be cell-wide, node-wide, or applicable to only one server process.

Define variables on the **Environment > WebSphere Variables** console page.

Define the scope to apply a variable node-wide or to only one server process. A variable resolves to its new value when used in a component that supports the use of variables.

1. Click **Environment > WebSphere Variables** in the administrative console to define a new variable.
2. Specify the scope of the variable. Declare the new variable for the **Node** or **Server** and click **Apply**.

   The variable exists at the level you specify. Define a variable at multiple levels to use multiple values. The more granular definition overrides the higher level setting.

   For instance, if you specify the same variable on a node and a server, the server setting overrides the node setting.

   Scoping variables is particularly important when testing data source objects. Variable scoping can cause a data source to fail the test connection, but to succeed at run time, or to pass the test connection, but fail at run time.

   See the *Developing and deploying applications* PDF for more information.
3. Click **New** on the WebSphere Variables page.
4. Specify a name, a value, and a description on the Variable page. Click **OK**.

5. Verify that the variable is displayed in the list of variables. The administrative console does not pick up typing errors. The variable is ignored if it is referred to incorrectly.
6. Save your configuration.
7. Stop the server and start the server again to put the variable configuration into effect.

WebSphere variables collection

Use this page to view and change a list of substitution variables with their values and scope.

To view this administrative console page, click **Environment > WebSphere Variables**.

For information on a variable, click the variable and read the value in the **Description** field.

Name:

Specifies the symbolic name for a WebSphere Application Server variable. For example, a variable name might represent a physical path or URL root used by WebSphere Application Server.

Value:

Specifies the value that the symbolic name represents. For example, the value might be an absolute path value for a file or URL root.

Scope:

Specifies the level at which a WebSphere Application Server variable is visible on the administrative console panel.

A resource can be visible in the administrative console collection table at the node or server scope.

Variable settings:

Use this page to define the name and value of a WebSphere Application Server substitution variable.

To view this administrative console page, click **Environment > WebSphere Variables >***WebSphere_variable_name*.

Name:

Specifies the symbolic name for a WebSphere Application Server variable. For example, a variable name might represent a physical path or URL root that is used by WebSphere Application Server.

WebSphere variables are used for:

- Configuring WebSphere Application Server path names, such as JAVA_HOME, and APP_INSTALL_ROOT.
- Configuring certain customization values.

WebSphere Application Server substitutes the symbolic name wherever its value displays in the system.

For example, ″JAVA_HOME″ is the symbolic name representing the file system path to the installation directory for the Java Virtual Machine (JVM). For example, the value is `/opt/IBM/WebSphere/AppServer/java` for the WebSphere Application Server product on a Linux machine.

You can create new variables for use in WebSphere Application Server components that support the use of variables.

Data type	String

Value:

Specifies the value that the symbolic name represents. For example, the value might be an absolute path value for a file or URL root.

For example, `/opt/IBM/WebSphere/AppServer/java` is the value on a Linux machine for a variable named JAVA_HOME.

Data type	String

Description:

Documents the purpose of a variable.

Data type	String

IBM Toolbox for Java JDBC driver

WebSphere Application Server supports the **IBM Toolbox for Java** JDBC driver. The IBM Toolbox for Java JDBC driver is included with the IBM Toolbox for Java product.

IBM Toolbox for Java is a library of Java classes that are optimized for accessing iSeries and AS/400 data and resources. You can use the IBM Toolbox for Java JDBC driver to access local or remote **DB2 UDB for iSeries 400** databases from server-side and client Java applications that run on any platform that supports Java.

IBM Toolbox for Java is available in these versions:

IBM Toolbox for Java licensed program

The licensed program is available with every OS/400 release, starting with Version 4 Release 2 (V4R2). You can install the licensed program on your iSeries 400 system, and then either copy the IBM Toolbox for Java JAR file (*jt400.jar*) to your system or update your system *classpath* to locate the server installation. Product documentation for IBM Toolbox for Java is available from the iSeries information center: `http://publib.boulder.ibm.com/iseries/v5r1/ic2924/index.htm` Locate the documentation by traversing the following path in the left-hand navigation window of the iSeries information center: **Programming** > **Java** > **IBM Toolbox for Java**.

JTOpen

JTOpen is the open source version of IBM Toolbox for Java, and is more frequently updated than the licensed program version. You can download JTOpen from `http://www-1.ibm.com/servers/eserver/iseries/toolbox/downloads.htm`. You can also download the *JTOpen Programming Guide*. The guide includes instructions for installing JTOpen and information about the JDBC driver.

The JDBC driver for both versions supports JDBC 2.0. For more information about IBM Toolbox for Java and JTOpen, see the product Web site at `http://www-1.ibm.com/servers/eserver/iseries/toolbox/index.html`.

Note: If you are using WebSphere Application Server on platforms other than iSeries, use the **JTOpen** version of the Toolbox JDBC driver.

Configure and use the jt400.jar file

1. Download the *jt400.jar* file from the **JTOpen** URL at `http://www-1.ibm.com/servers/eserver/iseries/toolbox/downloads.htm`. Place it in a directory on your workstation such as *C:\JDBC_Drivers\Toolbox*.
2. Open the administrative console.
3. Select **Environment**.
4. Select **Managed WebSphere Variables**.
5. Set the managed variable *OS400_TOOLBOX_JDBC_DRIVER_PATH* at the **Node** level.
6. Double click **OS400_TOOLBOX_JDBC_DRIVER_PATH**.
7. Set the value to the full directory path to the `jt400.jar` file downloaded in step one. Do not include *jt400.jar* in this value. For example,

   ```
   OS400_TOOLBOX_JDBC_DRIVER_PATH == "C:\JDBC_Drivers\Toolbox"
   ```

   When you choose a Toolbox driver from the list of possible resource providers the **Classpath** field looks like:

   ```
   Classpath == ${OS400_TOOLBOX_JDBC_DRIVER_PATH}/jt400.jar
   ```

Shared library files

Shared library files in WebSphere Application Server consist of a symbolic name, a Java class path, and a native path for loading Java Native Interface (JNI) libraries.

You can define a shared library at the cell, node, or server level. Defining a library at one of the three levels does not cause the library to be placed into the application server's class loader. You must associate the library to an application or server in order for the classes represented by the shared library to be loaded in either a server-wide or application-specific class loader.

A separate class loader is used for shared libraries that are associated with an application server. This class loader is the parent of the application class loader, and the WebSphere Application Server extensions class loader is its parent. Shared libraries that are associated with an application are loaded by the application class loader.

Managing shared libraries

Shared libraries are files used by multiple applications. Using the administrative console, you can define a shared library at the cell, node, or server level. You can then associate the library to an application or server to load the classes represented by the shared library in either a server-wide or application-specific class loader. Using an installed optional package, you can associate a shared library to an application by declaring the dependent library `.jar` file in the `MANIFEST.MF` file of the application. Refer to the Java 2 Platform, Enterprise Edition (J2EE) 1.4 specification, section 8.2 for an example.

If your deployed applications use shared library files, define shared libraries for the library files and associate the libraries with specific applications or with an application server. Associating a shared library file with a server associates the file with all applications on the server. Use the Shared Libraries page to define new shared library files to the system and remove them.

- Use the administrative console to define a shared library.
  1. Create a shared library for each library file that your applications need.
  2. Associate each shared library with an application or a server.
     - Associate a shared library with an application that uses the shared library file.
     - Associate a shared library with an application server so every application on the server can use the shared library file.
- Use an installed optional package to declare a shared library for an application.
- Remove a shared library.

1. Click **Environment > Shared Libraries** in the console navigation tree to access the Shared Libraries page.
2. Select the library to be removed.
3. Click **Delete**.

The list of shared libraries is refreshed. The library file no longer displays in the list.

Creating shared libraries

Shared libraries are files used by multiple applications.

The first step for making a library file available to multiple applications deployed on a server is to create a shared library for each library file that your applications need. When you create the shared libraries, set variables for the library files.

Use the Shared Libraries page to create and configure shared libraries.

1. Go to the Shared Libraries page. Click **Environment > Shared Libraries** in the console navigation tree.
2. Change the scope of the collection table to see what shared libraries are in a cell, node, or server.
   a. Select the cell, a node, or a server.
   b. Click **Apply**.
3. Click **New**.
4. Configure the shared library.
   a. On the settings page for a shared library, specify the name, class path, and any other variables for the library file that are needed.
   b. Click **Apply**.
5. Repeat steps 1 through 4 until you define a shared library instance for each library file that your applications need.

Using the administrative console, associate your shared libraries with specific applications or with the class loader of an application server. Associating a shared library file with a server class loader associates the file with all applications on the server.

Alternatively, you can use an installed optional package to associate your shared libraries with an application.

Shared library collection

Use this page to define a list of shared library files that deployed applications can use.

To view this administrative console page, click **Environment > Shared Libraries**.

By default, a shared library is accessible to applications deployed (or installed) on the same node as the shared library file. Use the **Scope** field to change the scope to a different node or to a specific server.

Name:

Specifies a name for the shared library.

Description:

Describes the shared library file.

Shared library settings:

Use this page to make a library file available to deployed applications.

To view this administrative console page, click **Environment > Shared Libraries >***shared_library_name*.

Name:

Specifies a name for the shared library.

Data type	String

Description:

Describes the shared library file.

Data type	String

Classpath:

Specifies the class path used to locate the JAR files for the shared library support.

Data type	String
Units	Class path

Native Library Path:

Specifies the class path for locating platform-specific library files for shared library support; for example, .dll, .so, or *SRVPGM objects.

Data type	String
Units	Class path

Associating shared libraries with applications

You can associate a shared library with an application. Classes represented by the shared library are then loaded in the application's class loader, making the classes available to the application.

This article assumes that you have defined a shared library at the cell, node, or server level. The shared library represents a library file used by multiple deployed applications.

This article also assumes that you want to use the administrative console, and not an installed optional package, to associate a shared library with an application.

To associate a shared library with an application, create and configure a library reference using the administrative console. A library reference specifies the name of the shared library file.

If you associate a shared library with an application, do not associate the same shared library with a server class loader.

1. Click **Applications > Enterprise Applications >***application_name* **> Libraries** in the console navigation tree to access the Library Ref page.
2. Click **Add**.
3. On the settings page for a library reference, specify variables for the library reference as needed. The variables identify the shared library file that your application uses.
4. Click **Apply**.

The name of the library reference is shown in the list on the Library Ref page.

Repeat steps 2 through 4 until you define a library reference instance for each shared library that your application requires.

Associating shared libraries with servers

You can associate shared libraries with the class loader of a server. Classes represented by the shared library are then loaded in a server-wide class loader, making the classes available to all applications deployed on the server.

This article assumes that you have defined a shared library at the cell, node, or server level. The shared library represents a library file used by multiple deployed applications.

To associate a shared library with the class loader of a server, create and configure a library reference using the administrative console. A library reference specifies the name of the shared library file.

If you associate a shared library with a server class loader, do not associate the same shared library with an application.

1. Configure class loaders for applications deployed on the server.
   a. Click **Servers > Application Servers > *server_name*** to access the settings page for the application server.
   b. Set values for the application **Class loader policy** and **Class loading mode** of the server. For information on these settings, see "Application server settings" on page 115 and class loaders.
2. Create a library reference for each shared library file that your application needs.
   a. Go to the settings page for a class loader.
   b. Click **Libraries** to access the Library Ref page.
   c. Click **Add**.
   d. On the settings page for a library reference, specify variables for the library reference as needed. The variables identify the shared library file that your application uses.
   e. Click **Apply**. The name of the library reference is shown in the list on the Library Ref page.

   Repeat the previous steps until you define a library reference for each shared library that your application needs.

Installed optional packages

Installed optional packages enable applications to use the classes in Java archive (`.jar`) files without having to include them explicitly in a class path. An installed optional package is a `.jar` file containing specialized tags in its manifest file that enable the application server to identify it. An installed optional package declares one or more shared library `.jar` files in the manifest file of an application. When the application is installed on a server, the classes represented by the shared libraries are loaded in the class loader of the application, making the classes available to the application.

When a Java 2 Platform, Enterprise Edition (J2EE) application is installed on a server, dependency information is specified in its manifest file. WebSphere Application Server reads the dependency information of the application (`.ear` file) to automatically associate the application with an installed optional package `.jar` file. WebSphere Application Server adds the `.jar` files in associated optional packages to the application class path. Classes in the installed optional packages are then available to application classes.

Installed optional packages used by WebSphere Application Server are described in section 8.2 of the J2EE specification, Version 1.4 at `http://java.sun.com/j2ee/j2ee-1_4-fr-spec.pdf`.

WebSphere Application Server supports using the manifest file (`manifest.mf`) in shared library `.jar` files and application `.ear` files. WebSphere Application Server does not support the Java 2 Platform Standard Edition (J2SE) Installed Optional Package semantics used in the J2SE specification (http://java.sun.com/j2se/1.3/docs/guide/extensions/spec.html), which primarily serve the applet environment. WebSphere Application Server ignores applet-specific tags within manifest files.

Sample manifest.mf file

A sample manifest file follows for an application app1.ear that refers to a single shared library file util.jar:

```
app1.ear:
    META-INF/application.xml
    ejb1.jar:
         META-INF/MANIFEST.MF:
             Extension-List: util
             util-Extension-Name: com/example/util
             util-Specification-Version: 1.4
         META-INF/ejb-jar.xml

util.jar:
    META-INF/MANIFEST.MF:
        Extension-Name: com/example/util
        Specification-Title: example.com's util package
        Specification-Version: 1.4
        Specification-Vendor: example.com
        Implementation-Version: build96
```

The syntax of a manifest entry depends on whether the entry applies to a member with a defining role (the shared library) or a member with a referencing role (a J2EE application or a module within a J2EE application).

Manifest entry tagging

Main tags used for manifest entries include the following:

Extension-List
A required tag with variable syntax. Within the context of the referencing role (application's manifest), this is a space delimited list that identifies and constructs unique Extension-Name, Extension-Specification tags for each element in the list. Within the context of the defining role (shared library), this tag is not valid.

Extension-Name
A required tag that provides a name and links the defining and referencing members. The syntax of the element within the referencing role is to prefix the element with the <ListElement> string. For each element in the Extension-List, there is a corresponding <ListElement>-Extension-Name tag. The defining string literal value for this tag (in the above sample com/example/util1) is used to match (in an equality test) the corresponding tags between the defining and referencing roles.

Specification-Version
A required tag that identifies the specification version and links the defining and referencing members.

Implementation-Version
An optional tag that identifies the implementation version and links the defining and referencing members.

Further information on these tags is in the .jar file specification at http://java.sun.com/j2se/1.4.2/docs/guide/jar/jar.html#Manifest%20Specification.

Using installed optional packages

You can associate one or more shared libraries with an application using an installed optional package that declares the shared libraries in the application's manifest file. Classes represented by the shared libraries are then loaded in the application's class loader, making the classes available to the application.

Read about installed optional packages in “Installed optional packages” on page 100 and in section 8.2 of the Java 2 Platform, Enterprise Edition (J2EE) specification, Version 1.4 at `http://java.sun.com/j2ee/j2ee-1_4-fr-spec.pdf`.

WebSphere Application Server does not support the Java 2 Platform Standard Edition (J2SE) Installed Optional Package semantics used in the J2SE specification (`http://java.sun.com/j2se/1.3/docs/guide/extensions/spec.html`), which primarily serve the applet environment. WebSphere Application Server ignores applet-specific tags within manifest files.

Installed optional packages expand the existing shared library capabilities of an application server. Prior to Version 6, an administrator was required to associate a shared library to an application or server. Installed optional packages enable an administrator to declare a dependency in an application’s manifest file to a shared library, with installed optional package elements listed in the manifest file, and automatically associate the application to the shared library. During application installation, the shared library `.jar` file is added to the class path of the application class loader.

If you use an installed optional package to associate a shared library with an application, do not associate the same shared library with an application class loader or a server class loader using the administrative console.

1. Assemble the library file, including the manifest information that identifies it as an extension. Two sample manifest files follow. The first sample manifest file has application `app1.ear` refer to a single shared library file `util.jar`:

   ```
   app1.ear:
       META-INF/application.xml
       ejb1.jar:
            META-INF/MANIFEST.MF:
                Extension-List: util
                util-Extension-Name: com/example/util
                util-Specification-Version: 1.4
            META-INF/ejb-jar.xml

   util.jar:
       META-INF/MANIFEST.MF:
           Extension-Name: com/example/util
           Specification-Title: example.com's util package
           Specification-Version: 1.4
           Specification-Vendor: example.com
           Implementation-Version: build96
   ```

   The second sample manifest file has application `app1.ear` refer to multiple shared library `.jar` files:

   ```
   app1.ear:
       META-INF/application.xml
       ejb1.jar:
            META-INF/MANIFEST.MF:
                Extension-List: util1 util2 util3
                Util1-Extension-Name: com/example/util1
                Util1-Specification-Version: 1.4
                Util2-Extension-Name: com/example/util2
                Util2-Specification-Version: 1.4
                Util3-Extension-Name: com/example/util3
                Util3-Specification-Version: 1.4
            META-INF/ejb-jar.xml

   util1.jar:
       META-INF/MANIFEST.MF:
           Extension-Name: com/example/util1
           Specification-Title: example.com's util package
           Specification-Version: 1.4
           Specification-Vendor: example.com
           Implementation-Version: build96
   ```

```
util2.jar:
    META-INF/MANIFEST.MF:
        Extension-Name: com/example/util2
        Specification-Title: example.com's util package
        Specification-Version: 1.4
        Specification-Vendor: example.com
        Implementation-Version: build96

util3.jar:
    META-INF/MANIFEST.MF:
        Extension-Name: com/example/util3
        Specification-Title: example.com's util package
        Specification-Version: 1.4
        Specification-Vendor: example.com
        Implementation-Version: build96
```

2. Create a shared library that represents the library file assembled in step 1. This installs the library file as a WebSphere Application Server shared library.
3. Assemble the application, declaring in the application manifest file dependencies to the library files named the manifest created for step 1.
4. Install the application on the server.

During application installation, the shared library `.jar` files are added to the class path of the application class loader.

Library reference collection

Use this page to view and manage library references that define how to use global libraries. For example, you can use this page to associate shared library files with a deployed application.

To view this administrative console page, click **Applications > Enterprise Applications >***application_name* **> Libraries**.

If no shared libraries are defined, after you click **Add** a message is displayed stating that you must define a shared library before you can create a library reference. A shared library is a container-wide library file that can be used by deployed applications. To define a shared library, click **Environment > Shared Libraries** and specify the scope of the container. Then, click **New** and specify a name and one or more paths for the shared library. After you define a shared library, return to this page, click **Add**, and create a library reference.

Library name:

Specifies a name for the library reference.

Library reference settings:

Use this page to define library references, which specify how to use global libraries.

To view this administrative console page, click **Applications > Enterprise Applications >***application_name* **> Libraries >***library_reference_name*. A shared library must be defined to view this page.

A shared library is a container-wide library file that can be used by deployed applications. To define a shared library, click **Environment > Shared Libraries** and specify the scope of the container. Then, click **New** and specify a name and one or more paths for the shared library.

Library name:

Specifies the name of the shared library to use for the library reference.

Data type	String

Environment: Resources for learning

Use the following links to find relevant supplemental information about configuring the WebSphere Application Server environment. The information resides on IBM and non-IBM Internet sites, whose sponsors control the technical accuracy of the information.

These links are provided for convenience. Often, the information is not specific to the IBM WebSphere Application Server product, but is useful all or in part for understanding the product. When possible, links are provided to technical papers and Redbooks that supplement the broad coverage of the release documentation with in-depth examinations of particular product areas.

Programming instructions and examples

Administration

- Listing of all IBM WebSphere Application Server Redbooks at `http://publib-b.boulder.ibm.com/Redbooks.nsf/Portals/WebSphere`.

Working with server configuration files

Application server configuration documents define the available application servers, their configurations, and their contents.

You should periodically save changes to your administrative configuration. You can change the default locations of configuration files, as needed.

1. Edit configuration files. The master repository is comprised of .xml configuration files. You can edit configuration files using the administrative console, scripting, wsadmin commands, programming, or by editing a configuration file directly.
2. Save changes made to configuration files. Using the console, you can save changes as follows:
   a. Click **Save** on the taskbar of the administrative console.
   b. On the Save page, click **Save**.
3. Handle temporary configuration files resulting from a session timing out.
4. Change the location of temporary configuration files.
5. Change the location of backed-up configuration files.
6. Change the location of temporary workspace files.
7. Back up and restore configurations.

Configuration documents

WebSphere Application Server stores configuration data for servers in several documents in a cascading hierarchy of directories. The configuration documents describe the available application servers, their configurations, and their contents. Most configuration documents have XML content.

Hierarchy of directories of documents

The cascading hierarchy of directories and the documents' structure support multinode replication to synchronize the activities of all servers in a cell. In a Network Deployment environment, changes made to configuration documents in the cell repository, are automatically replicated to the same configuration documents that are stored on nodes throughout the cell.

At the top of the hierarchy is the **cells** directory. It holds a subdirectory for each cell. The names of the cell subdirectories match the names of the cells. For example, a cell named *cell1* has its configuration documents in the subdirectory *cell1*.

On the Network Deployment node, the subdirectories under the cell contain the entire set of documents for every node and server throughout the cell. On other nodes, the set of documents is limited to what applies to that specific node. If a configuration document only applies to *node1*, then that document exists in the configuration on *node1* and in the Network Deployment configuration, but not on any other node in the cell.

Each cell subdirectory has the following files and subdirectories:

- The `cell.xml` file, which provides configuration data for the cell
- Files such as `security.xml`, `virtualhosts.xml`, `resources.xml`, and `variables.xml`, which provide configuration data that applies across every node in the cell
- The **clusters** subdirectory, which holds a subdirectory for each cluster defined in the cell. The names of the subdirectories under clusters match the names of the clusters.

  Each cluster subdirectory holds a cluster.xml file, which provides configuration data specifically for that cluster.
- The **nodes** subdirectory, which holds a subdirectory for each node in the cell. The names of the nodes subdirectories match the names of the nodes.

  Each node subdirectory holds files such as `variables.xml` and `resources.xml`, which provide configuration data that applies across the node. Note that these files have the same name as those in the containing cell's directory. The configurations specified in these node documents override the configurations specified in cell documents having the same name. For example, if a particular variable is in both cell- and node-level `variables.xml` files, all servers on the node use the variable definition in the node document and ignore the definition in the cell document.

  Each node subdirectory holds a subdirectory for each server defined on the node. The names of the subdirectories match the names of the servers. Each server subdirectory holds a `server.xml` file, which provides configuration data specific to that server. Server subdirectories might hold files such as `security.xml`, `resources.xml` and `variables.xml`, which provide configuration data that applies only to the server. The configurations specified in these server documents override the configurations specified in containing cell and node documents having the same name.
- The **applications** subdirectory, which holds a subdirectory for each application deployed in the cell. The names of the applications subdirectories match the names of the deployed applications.

  Each deployed application subdirectory holds a `deployment.xml` file that contains configuration data on the application deployment. Each subdirectory also holds a **META-INF** subdirectory that holds a J2EE application deployment descriptor file as well as IBM deployment extensions files and bindings files. Deployed application subdirectories also hold subdirectories for all .war and entity bean .jar files in the application. Binary files such as .jar files are also part of the configuration structure.

An example file structure is as follows:

```
cells
  cell1
     cell.xml resources.xml virtualhosts.xml variables.xml security.xml
     nodes
        nodeX
           node.xml variables.xml resources.xml serverindex.xml
           serverA
              server.xml variables.xml
           nodeAgent
              server.xml variables.xml
        nodeY
           node.xml variables.xml resources.xml serverindex.xml
     applications
        sampleApp1
           deployment.xml
           META-INF
```

```
          application.xml ibm-application-ext.xml ibm-application-bnd.xml
    sampleApp2
       deployment.xml
       META-INF
          application.xml ibm-application-ext.xml ibm-application-bnd.xml
```

Changing configuration documents

You can use one of the administrative tools (console, wsadmin, Java APIs) to modify configuration documents or edit them directly. It is preferable to use the administrative console because it validates changes made to configurations. ″“Configuration document descriptions”″ states whether you can edit a document using the administrative tools or must edit it directly.

Configuration document descriptions

Most configuration documents have XML content. The table below describes the documents and states whether you can edit them using an administrative tool or must edit them directly.

If possible, edit a configuration document using the administrative console because it validates any changes that you make to configurations. You can also use one of the other administrative tools (wsadmin or Java APIs) to modify configuration documents. Using the administrative console or wsadmin scripting to update configurations is less error prone and likely quicker and easier than other methods.

However, you cannot edit some files using the administrative tools. Configuration files that you must edit manually have an X in the **Manual editing required** column in the table below.

Document descriptions

(Locations split for publishing)

Configuration file	Locations	Purpose	Manual editing required
`admin-authz.xml`	`config/cells/` *`cell_name/`*	Define a role for administrative operation authorization.	X

`app.policy`	`config/cells/`
	`cell_name/`
	`nodes/`*`node_name/`*
		Define security permissions for application code.	X

`cell.xml`	`config/cells/` *`cell_name/`*	Identify a cell.	

`cluster.xml`	`config/cells/`
	`cell_name/`
	`clusters/`
	`cluster_name/`
		Identify a cluster and its members and weights.
		This file is only available with the Network Deployment product.	

`deployment.xml`	`config/cells/`
	`cell_name/`
	`applications/`
	`application_name/`
		Configure application deployment settings such as target servers and application-specific server configuration.	

`filter.policy`	`config/cells/` *`cell_name/`*	Specify security permissions to be filtered out of other policy files.	X
`integral-jms-authorizations.xml`	`config/cells/` *`cell_name/`*	Provide security configuration data for the integrated messaging system.	X

library.policy	config/cells/ *cell_name*/ nodes/*node_name*/	Define security permissions for shared library code.	X
multibroker.xml	config/cells/ *cell_name*/	Configure a data replication message broker.	
namestore.xml	config/cells/ *cell_name*/	Provide persistent name binding data.	X
naming-authz.xml	config/cells/ *cell_name*/	Define roles for a naming operation authorization.	X
node.xml	config/cells/ *cell_name*/ nodes/*node_name*/	Identify a node.	
pmirm.xml	config/cells/ *cell_name*/	Configure PMI request metrics.	X
resources.xml	config/cells/ *cell_name*/ config/cells/ *cell_name*/ nodes/*node_name*/ config/cells/ *cell_name*/ nodes/*node_name*/ servers/ *server_name*/	Define operating environment resources, including JDBC, JMS, JavaMail, URL, JCA resource providers and factories.	
security.xml	config/cells/ *cell_name*/	Configure security, including all user ID and password data.	
server.xml	config/cells/ *cell_name*/ nodes/ *node_name*/ servers/ *server_name*/	Identify a server and its components.	
serverindex.xml	config/cells/ *cell_name*/ nodes/ *node_name*/	Specify communication ports used on a specific node.	
spi.policy	config/cells/ *cell_name*/ nodes/ *node_name*/	Define security permissions for service provider libraries such as resource providers.	X
variables.xml	config/cells/ *cell_name*/ config/cells/ *cell_name*/ nodes/ *node_name*/ config/cells/ *cell_name*/ nodes/*node_name*/ servers/ *server_name*/	Configure variables used to parameterize any part of the configuration settings.	

`virtualhosts.xml`	`config/cells/`
	`cell_name``/`
		Configure a virtual host and its MIME types.	

Object names

When you create a new object using the administrative console or a wsadmin command, you often must specify a string for a name attribute. Most characters are allowed in the name string. However, the name string cannot contain the following characters. The name string also cannot contain leading and trailing spaces.

/	forward slash
\	backslash
*****	asterisk
,	comma
:	colon
;	semi-colon
=	equal sign
+	plus sign
?	question mark
|	vertical bar
<	left angle bracket
>	right angle bracket
&	ampersand (and sign)
%	percent sign
’	single quote mark
″	double quote mark
]]>	No specific name exists for this character combination.
.	period (not valid if first character; valid if a later character)

Configuration repositories

A configuration repository stores configuration data. By default, configuration repositories reside in the *config* subdirectory of the product installation root directory.

Handling temporary configuration files resulting from session timeout

If the console is not used for 15 minutes or more, the session times out. The same thing happens if you close the browser window without saving the configuration file. Changes to the file are saved to a temporary file when the session times out, after 15 minutes.

When a session times out, the configuration file in use is saved under the userid/timeout directory under the ServletContext’s temp area. This is the value of the javax.servlet.context.tempdir attribute of the ServletContext. By default, it is: *`install_root`*`/temp/hostname/Administration/admin/admin.war`

You can change the temp area by specifying it as a value for the tempDir init-param of the action servlet in the deployment descriptor (web.xml) of the administrative application.

The next time you log on to the console, you are prompted to load the saved configuration file. If you decide to load the saved file:

1. If a file with the same name exists in the *install_root*/config directory, that file is moved to the userid/backup directory in the temp area.
2. The saved file is moved to the *install_root*/config directory.
3. The file is then loaded.

If you decide not to load the saved file, it is deleted from the userid/timeout directory in the temp area.

The configuration file is also saved automatically when the same user ID logs into the non-secured console again, effectively starting a different session. This process is equivalent to forcing the existing user ID out of session, similar to a session timing out.

Changing the location of temporary configuration files

The configuration repository uses copies of configuration files and temporary files while processing repository requests. It also uses a backup directory while managing the configuration. You can change the default locations of these files from the configuration directory to a directory of your choice using system variables or the administrative console.

The default location for the configuration temporary directory is CONFIG_ROOT/temp. Change the location by doing either of the following:

- Set the system variable *was.repository.temp* to the location you want for the repository temporary directory. Set the system variable when launching a Java process using the -D option. For example, to set the default location of the repository temporary directory, use the following option:

  ```
  -Dwas.repository.temp=%CONFIG_ROOT%/temp
  ```
- Use the administrative console to change the location of the temporary repository file location for each server configuration. For example, on the Network Deployment product, to change the setting for a deployment manager, do the following:
  1. Click **System Administration > Deployment Manager** in the navigation tree of the administrative console. Then, click **Administration Services**, **Repository Service**, and **Custom Properties**.
  2. On the Properties page, click **New**.
  3. On the settings page for a property, define a property for the temporary file location. The key for this property is `was.repository.temp`. The value can include WebSphere Application Server variables such as `${WAS_TEMP_DIR}/config`. Then, click **OK**.

The system property set using the first option takes precedence over the configuration property set using the second option.

Changing the location of backed-up configuration files

During administrative processes like adding a node to a cell or updating a file, configuration files are backed up to a backup location. The default location for the backup configuration directory is CONFIG_ROOT/backup. Change the location by doing either of the following:

- Set the system variable *was.repository.backup* to the location you want as the repository backup directory. Set the system variable when launching a Java process using the -D option. For example, to set the default location of the repository backup directory, use the following option:

  ```
  -Dwas.repository.backup=%CONFIG_ROOT%/backup
  ```
- Use the administrative console to change the location of the repository backup directory for each server configuration. For example, on the Network Deployment product, do the following to change the setting for a deployment manager:
  1. Click **System Administration > Deployment Manager** in the navigation tree of the administrative console. Then, click **Administration Services**, **Repository Service**, and **Custom Properties**.
  2. On the Properties page, click **New**.
  3. On the settings page for a property, define a property for the backup file location. The key for this property is `was.repository.backup`. The value can include WebSphere Application Server variables such as `${WAS_TEMP_DIR}/backup`. Then, click **OK**.

The system property set using the first option takes precedence over the configuration property set using the second option.

Changing the location of temporary workspace files

The administrative console workspace allows client applications to navigate the configuration. Each workspace has its own repository location defined either in the system property or the property passed to a workspace manager when creating the workspace: workspace.user.root or workspace.root, which is calculated as %workspace.root%/*user_ID*/workspace/wstemp.

The default workspace root is calculated based on the user installation root: %user.install.root%/wstemp. You can change the default location of temporary workspace files by doing the following:

- Distributed platforms: Change the setting for the system variable *workspace.user.root* or *workspace.root* so its value is no longer set to the default location. Set the system variable when launching a Java process using the -D option. For example, to set the default location the full path of the root of all users' directories, use the following option:

  ```
  -Dworkspace.user.root=full_path_for_root_of_all_user_directories
  ```

Backing up and restoring administrative configurations

WebSphere Application Server represents its administrative configurations as XML files. You should back up configuration files on a regular basis.

1. Run the backupConfig command to back up configuration files.
2. Run the restoreConfig command to restore configuration files. Specify backup files that do not contain invalid or inconsistent configurations.

Transformation of configuration files

The WebSphere Application Server master configuration repository stores configuration files for all the nodes in the cell. When you upgrade the deployment manager from one release of WebSphere Application Server to another, the configuration files that are stored in the master repository for the nodes on the old release are converted into the format of the new release.

With this conversion, the deployment manager can process the configuration files uniformly. However, nodes on an old release cannot readily use configuration files that are in the format of the new release. WebSphere Application Server addresses the problem when it synchronizes the configuration files from the master repository to a node on an old release. The configuration files are first transformed into the old release format before they ship to the node. WebSphere Application Server performs the following transformations on configuration documents:

- Changes the XML name space from the format of the new release to the format of the old release
- Strips out attributes of cell-level documents that are applicable to the new release only
- Strips out new resource definitions that are not understood by old release nodes

Server configuration files: Resources for learning

Use the following links to find relevant supplemental information about administering WebSphere Application Server configuration files. The information resides on IBM and non-IBM Internet sites, whose sponsors control the technical accuracy of the information.

These links are provided for convenience. Often, the information is not specific to the IBM WebSphere Application Server product, but is useful all or in part for understanding the product. When possible, links are provided to technical papers and Redbooks that supplement the broad coverage of the release documentation with in-depth examinations of particular product areas.

View links to additional information:

Administration

- IBM WebSphere Application Server Redbooks at `http://publib-b.boulder.ibm.com/Redbooks.nsf/Portals/WebSphere`.

  This site contains a listing of all WebSphere Application Server Redbooks.
- IBM developerWorks WebSphere at `http://www.software.ibm.com/wsdd`.

  This site is the home of technical information for developers working with WebSphere products. You can download WebSphere software, take a fast path to developerWorks zones, such as VisualAge Java or WebSphere Application Server, learn about WebSphere products through a newcomers page, tutorials, technology previews, training, and Redbooks, get answers to questions about WebSphere products, and join the WebSphere community, where you can keep up with the latest developments and technical papers.
- WebSphere Application Server Support page at `http://www.ibm.com/software/webservers/appserv/support.html`.

  Take advantage of the Web-based Support and Service resources from IBM to quickly find answers to your technical questions. You can easily access this extensive Web-based support through the IBM Software Support portal at URL `http://www-3.ibm.com/software/support/` and search by product category, or by product name. For example, if you are experiencing problems specific to WebSphere Application Server, click **WebSphere Application Server** in the product list. The WebSphere Application Server Support page appears.

Administering application servers

An application server configuration provides settings that control how an application server provides services for running enterprise applications and their components.

This section describes how to create and configure application servers in an existing application server environment.

A WebSphere Application Server administrator can configure one or more application servers and perform tasks such as the following:

1. Create application servers.
2. Manage application servers.
3. Configure transport chains.
4. Develop custom services.
5. Define processes for the application server. As part of defining processes, you can define:
6. Use the Java virtual machine.

After preparing a server, deploy an application or component on the server. See “Preparing to host applications” on page 162 for a sample procedure that you might follow in configuring the application server runtime and resources.

Application servers

Application servers extend a Web server’s capabilities to handle Web application requests, typically using Java technology. An application server makes it possible for a server to generate a dynamic, customized response to a client request.

For example, suppose--

1. A user at a Web browser on the public Internet visits a company Web site. The user requests to use an application that provides access to data in a database.
2. The user request flows to the Web server.
3. The Web server determines that the request involves an application containing resources not handled directly by the Web server (such as servlets). It forwards the request to a WebSphere Application Server product.

4. The WebSphere Application Server product forwards the request to one of its application servers on which the application is running.
5. The invoked application then processes the user request. For example:
   - An application servlet prepares the user request for processing by an enterprise bean that performs the database access.
   - The application produces a dynamic Web page containing the results of the user query.
6. The application server collaborates with the Web server to return the results to the user at the Web browser.

The WebSphere Application Server product provides multiple application servers that can be either separately configured processes or nearly identical clones.

Creating application servers

For the Express and Base products, you must use scripting to create a new application server (see the *Administering applications and their environment* PDF). The server you create cannot be managed using the administrative console. Also note that the only server you can manage using the administrative console is the default server (server1).

With WebSphere Application Server Version 6.0, you can now upgrade a portion of the nodes in a cell, while leaving others at the older release level. This means that, for a period of time, you may be managing servers that are at the current release and servers that are running the newer release in the same cell. In this mixed environment, there are restrictions on what you can do with servers at the older release level. They are:

- You can only create new server definitions on nodes that are running WebSphere Application Server Version 6.0.
- When you create a new server definition, you must use a server configuration template, and that template must be created from a WebSphere Application Server Version 6.0 server instance. You cannot create (or use) a template from a WebSphere Application Server Version 5.x server instance.

There are no restrictions on what you can do with the servers running on the newer release level.

The steps below describe how to use the Create New Application Server page.

1. Create the new application server using the wsadmin **createApplicationServer** command. For information, see the *Administering applications and their environment* PDF.
2. To use multiple language encoding support in the administrative console, configure an application server with UTF-8 encoding enabled.

The new application server appears in the list of servers on the Application Servers page.

Note that the application server created has many default values specified for it. An application server has many properties that can be set and creating an application server on the Create New Application Server page specifies values for only a few of the important properties. To view all of the properties of your application server and to customize your application server further, click on the name of your application server on the Application Servers page and change the settings for your application server as needed.

Configuring application servers for UTF-8 encoding

To use multiple language encoding support in the administrative console, you must configure an application server with UTF-8 encoding enabled.

1. Create an application server or use an existing application server.
2. On the Application Server page, click on the name of the server you want enabled for UTF-8.
3. On the settings page for the selected application server, under Server Infrastructure, click **Java and Process Management > Process Definition**.

4. On the Process Definition page, click **Java Virtual Machine**.
5. On the Java Virtual Machine page, specify `-Dclient.encoding.override=UTF-8` for **Generic JVM Arguments** and click **OK**.
6. Click **Save** on the console task bar.
7. Restart the application server.

Note that the autoRequestEncoding option does not work with UTF-8 encoding enabled. The default behavior for WebSphere Application Server is, first, to check if charset is set on content type header. If it is, then the product uses content type header for character encoding; if it is not, then the product uses character encoding set on server using the system property default.client.encoding. If charset is not present and the system property is not set, then the product uses ISO-8859-1. Enabling autoRequestEncoding on a Web module changes the default behavior: if charset it not present on an incoming request header, the product checks the Accept-Language header of the incoming request and does encoding using the first language found in that header. If there is no charset on content type header and no Accept language header, then the product uses character encoding set on server using the system property default.client.encoding. As with the default behavior, if charset is not present and the system property is not set, then the product uses ISO-8859-1.

Managing application servers

To view information about an application server, use the Application Servers panel on the administrative console.

You must use the “Getting started with scripting” on page 186 to create a new application server. The server you create cannot be managed using the administrative console. Also note that the only server you can manage using the administrative console is the default server (server1).

1. Access the Application Servers page. Click **Servers > Application Servers** in the console navigation tree.
2. View information about application servers.

   The Application Servers page lists application servers in the cells holding the application servers.

   To view additional information about a particular application server or to further configure an application server, click on the application server name under **Name**. This accesses the settings page for an application server.

   To view product information for an application server:

   a. Verify that the application server is running.
   b. Display the **Runtime** tab on the settings page for an application server.
   c. Click **Product Information**.

   The Product Information page displayed lists the WebSphere Application Server products installed for the application server, the version and build levels for the products, the build dates, and any interim fixes applied to the application server.

   Note: You can also get this information by using the **versionInfo** command. For more information, see ″versionInfo command″ in the information center.
3. Create an application server using the wsadmin **createApplicationServer** command. For information, see “Commands for the AdminTask object” on page 489.
4. Monitor the running of application servers.

Server collection

Use this page to view information about and manage application servers, generic servers, Java Message Service (JMS) servers, and Web servers.

Application Servers

The Application Servers page lists the application servers in the cell. You can use this page to create new application servers, create application server templates, or delete existing application servers. You can also use this page to start and stop these application servers.

To view this administrative console page, click **Application Servers**.

Generic Servers

The Generic Servers page lists the generic servers in the cell. You can use this page to create new generic servers, create generic server templates, or delete existing generic servers. You can also use this page to start and stop these generic servers.

The Network Deployment product also shows the status of the generic servers. The status indicates whether a server is running, stopped, or encountering problems.

You can use this page to add or delete application servers.

To view this administrative console page, click **Generic Servers**.

Java Message Service (JMS) Servers

The JMS Servers page lists the JMS servers in the cell. You can use this page to start and stop these JMS servers.

Each JMS server provides the functions of the JMS provider for a node in your administrative domain. There can be at most one JMS server on each node in the administration domain, and any application server within the domain can access JMS resources served by any JMS server on any node in the domain.

Note: JMS servers apply only to WebSphere Application Server Version 5.x nodes. You cannot create a JMS server on a node that is running WebSphere Application Server 6.0, but the existing Version 5.x JMS servers will continue to be displayed, and you can modify their properties. You can also delete Version 5.x JMS servers.

To view this administrative console page, click **JMS Servers**.

Web Servers

The Web Servers page lists the Web servers in your administrative domain. You can use this page to generate and propagate a Web server plug-in configuration file, create new Web servers, create new Web server templates, or delete existing Web servers. You can also use this page to start and stop these Web servers.

To view this administrative console page, click **Web Servers**.

Name:

Specifies a logical name for the server. For WebSphere Application Server, server names must be unique within a node.

Node:

Specifies the name of the node holding the server.

Version:

Specifies the version of the WebSphere Application Server product on which the server runs.

Status:

Indicates whether the server is started or stopped. (Network Deployment only)

Note that if the status is *Unavailable*, the node agent is not running in that node and you must restart the node agent before you can start the server.

Application server settings:

An application server is a server which provides services required to run enterprise applications. Use this page to view or change the settings of an application server instance.

To view this administrative console page, click **Servers > Application Servers >***server_name*.

On the **Configuration** tab, you can edit fields. On the **Runtime** tab, you can look at read-only information. The **Runtime** tab is available only when the server is running.

Name:

Specifies a logical name for the server. Server names must be unique within a node. However, for multiple nodes within a cluster, you may have different servers with the same server name as long as the server and node pair are unique.

For example, a server named *server1* in a node named *node1* in the same cluster with a server named *server1* in a node named *node2* is allowed. Configuring two servers named *server1* in the same node is not allowed. WebSphere Application Server uses the server name for administrative actions, such as referencing the server in scripting.

Data type	String
Default	server1

Run in development mode:

Enabling this option may reduce the startup time of an application server. This may include JVM settings such as disabling bytecode verification and reducing JIT compilation costs. Do not enable this setting on production servers. This setting is only available on application servers running WebSphere Application Server Version 6.0 and later.

Specifies that you want to use the JVM settings **-Xverify** and **-Xquickstart** on startup. After selecting this option, save the configuration and restart the server to activate development mode.

The default setting for this option is `false`, which indicates that the server will not be started in development mode. Setting this option to `true` specifies that the server will be started in development mode (with settings that will speed server startup time).

Data type	Boolean
Default	false

Parallel start:

Select this field to start the server on multiple threads. This might shorten the startup time.

Specifies that you want the server components, services, and applications to start in parallel rather than sequentially.

The default setting for this option is `true`, which indicates that the server be started using multiple threads. Setting this option to `false` specifies that the server will not be started in using multiple threads (which may lengthen startup time).

Note that the order in which the applications start depends on the weights you assigned to each them. Applications that have the same weight are started in parallel. You set an application's weight with the *Starting weight* option on the **Applications > Enterprise Applications >** *application_name* page of the Administrative Console. For more information about the *Starting weight* option, see the *Installing your application serving environment* PDF.

Data type	Boolean
Default	true

Class loader policy:

Select whether there is a single class loader to load all applications or a different class loader for each application.

Class loading mode:

Specifies whether the class loader should search in the parent class loader or in the application class loader first to load a class. The standard for Developer Kit class loaders and WebSphere Application Server class loaders is `Parent first`.

If you select `Parent last`, your application can override classes contained in the parent class loader, but this action can potentially result in ClassCastException or linkage errors if you have mixed use of overridden classes and non-overridden classes.

Process Id:

The native operating system's process ID for this server.

The process ID property is read only. The system automatically generates the value.

Cell name:

The name of the cell in which this server is running.

The Cell name property is read only.

Node name:

The name of the node in which this server is running.

The Node name property is read only.

State:

The run-time execution state for this server.

The State property is read only.

Ports collection:

Use this page to view and manage communication ports used by run-time components running within a process. Communication ports provide host and port specifications for a server.

To view this administrative console page, click **Servers > Application Servers >***server_name* **Communications > Ports**.

Note that this page displays only when you are working with ports for application servers.

Port Name:

Specifies the name of a port. Each name must be unique within the server.

Host:

Specifies the IP address, domain name server (DNS) host name with domain name suffix, or just the DNS host name, used by a client to request a resource (such as the naming service, or administrative service).

Port:

Specifies the port for which the service is configured to accept client requests. The port value is used in conjunction with the host name.

Transport Details:

Provides a link to the transport chains associated with this port. If no transport chains are associated with this port, the string ″No associated transports″ appears in this column.

Ports settings:

Use this to view and change the configuration for a communication port used by run-time components running within a process. A communication port provides host and port specifications for a server.

For base WebSphere Application Server, you can view this administrative console page, by clicking **Servers > Application Servers >***server_name* **> Ports >***port_name*

Port Name:

Specifies the name of the port. The name must be unique within the server.

Note that this field displays only when you are defining a port for an application server. You can select a radio button to:

Well-known Port
: select a previously defined port from the drop down list

User-defined Port
: create a port with a new name by entering the name in the text box

Data type	String

Host:

Specifies the IP address, domain name server (DNS) host name with domain name suffix, or just the DNS host name, used by a client to request a resource (such as the naming service, administrative service, or JMS broker).

For example, if the host name is `myhost`, the fully qualified DNS name can be `myhost.myco.com` and the IP address can be `155.123.88.201`.

Host names on the ports can be resolvable names or IP addresses. The server will bind to the specific host name or IP address that is supplied. That port will only be accessible through the IP address that is resolved from the given host name or IP address. The IP address may be of the IPv4 (Internet Protocol Version 4) format for all platforms, and IPv6 (Internet Protocol Version 6) format on specific operating systems where the server supports IPv6.

Data type	String
Default	* (asterisk)

Port:

Specifies the port for which the service is configured to accept client requests. The port value is used in conjunction with the host name.

Port numbers in the server can be reused among multiple ports as long as they have host names that resolve to unique IP addresses and there is not a port with the same port number and a wildcard (*) host name. A port number is valid in the range of 0 and 65535. 0 specifies that the server should bind to any ephemeral port available.

Data type	Integer
Default	None
Range	1-65536

Custom property collection:

Use this page to view and manage arbitrary name-value pairs of data, where the name is a property key and the value is a string value that can be used to set internal system configuration properties.

The administrative console contains several Custom Properties pages that work similarly. To view one of these administrative pages, click a **Custom Properties** link.

Name:

Specifies the name (or key) for the property.

Do not start your property names with `was.` because this prefix is reserved for properties that are predefined in WebSphere Application Server.

Value:

Specifies the value paired with the specified name.

Description:

Provides information about the name-value pair.

Custom property settings:

Use this page to configure arbitrary name-value pairs of data, where the name is a property key and the value is a string value that can be used to set internal system configuration properties. Defining a new property enables you to configure a setting beyond that which is available in the administrative console.

For base WebSphere Application Server you can view this administrative console page by, clicking **Servers > Application Servers >***server_name*. Then, under Server Infrastructure, click **Administration** > **Custom Properties**

Name:

Specifies the name (or key) for the property.

Do not start your property names with `was.` because this prefix is reserved for properties that are predefined in WebSphere Application Server.

Data type	String

Value:

Specifies the value paired with the specified name.

Data type	String

Description:

Provides information about the name and value pair.

Data type	String

Server component collection:

Use this page to view information about and manage server component types such as application servers, messaging servers, or name servers.

To view this administrative console page, click **Servers > Application Servers >***server_name*. Then, under Server Infrastructure, click **Administration > Server Components**.

Type:

Specifies the type of internal server.

Server component settings:

Use this page to view or configure a server component instance.

To view this administrative console, click **Servers > Application Servers >***server_name*. Then, under Server Infrastructure, click **Administration > Server Components >***server_component_name*.

Name:

Specifies the name of the component.

Data type	String

Initial State:

Specifies the desired state of the component when the server process starts. The options are: *Started* and *Stopped*. The default is *Started*.

Data type	String
Default	Started

Thread pool collection:

Use this page to select or create a group of threads that an application server uses. Requests are sent to the server through any of the HTTP transports. A thread pool enables components of the server to reuse threads to eliminate the need to create new threads at run time. Creating new threads expends time and resources.

To view this administrative console page, click **Servers > Application Servers >***server_name* **> Thread Pools**. (You can reach this page through more than one navigational route.)

Thread pool settings:

Use this page to configure a group of threads that an application server uses. Requests are sent to the server through any of the HTTP transport channels or HTTP transports. A thread pool enables components of the server to reuse threads to eliminate the need to create new threads at run time. Creating new threads expends time and resources.

To view this administrative console page, click **Servers > Application Servers >***server_name* **> Thread Pools**, then select the thread pool. (You can reach this page through more than one navigational route.)

Minimum size:

Specifies the minimum number of threads to allow in the pool.

Data type	Integer
Default	10

Maximum size:

Specifies the maximum number of threads to allow in the pool.

If your Tivoli Performance Viewer shows the Percent Maxed metric to remain consistently in the double digits, consider increasing the Maximum size. The Percent Maxed metric indicates the amount of time that the configured threads are used. If there are several simultaneous clients connecting to the server-side ORB, increase the size to support up to 1000 clients.

Data type	Integer
Default	50
Recommended	50 (25 on Linux systems)

Thread inactivity timeout:

Specifies the number of milliseconds of inactivity that should elapse before a thread is reclaimed. A value of 0 indicates not to wait and a negative value (less than 0) means to wait forever.

Note: The administrative console does not allow you to set the inactivity timeout to a negative number. To do this you must modify the value directly in the *server.xml* file.

Data type	Integer
Units	Milliseconds
Default	3500

Allow thread allocation beyond maximum thread size:

Specifies whether the number of threads can increase beyond the maximum size configured for the thread pool.

Data type	Boolean
Default	Not enabled (false)

Generic server settings:

Use this page to view or change the settings of a generic server.

A generic server is a server that is managed in the WebSphere Application Server administrative domain, although it is not a server that is supplied by the WebSphere Application Server product. The generic server can be any server or process that is necessary to support the Application Server environment, including a Java server, a C or C++ server or process, or a Remote Method Invocation (RMI) server.

To view this administrative console page, click **Servers > Generic Servers >***server_name*.

On the **Configuration** tab, you can edit fields. On the **Runtime** tab, you can look at read-only information. The **Runtime** tab is available only when the server is running.

Name:

Specifies a logical name for the generic server.

It is highly recommended that you use a naming scheme that makes it easy to distinguish your generic application servers from regular WebSphere Application Servers. This will enable you to quickly determine whether to use the Terminate or Stop button in the administrative console to stop a specific application server.

You must use the Terminate button to stop a generic application server.

Data type	String
Default	

Starting servers

Starting a server starts a new server process based on the process definition settings of the current server configuration.

If you need to restart a server, follow the directions in this article for starting servers. The procedure that applies to starting servers also applies to restarting servers.

Note: If you created a new server definition using a base WebSphere Application Server, you cannot start, stop, or manage the new server using the original base Application Server.

There are several options for starting an Application Server:

- Windows If you are using Windows, you can use the **Start** menu to start the Application Server. If you are using the Express version of the product, click **Start > Programs > IBM WebSphere > Express v6.0 > Start the server**. You can check that the server has successfully started by checking the `startServer.log` file. If the server has successfully started, the last two lines of the `startServer.log` file reads:

  ```
  Server launched.  Waiting for initialization status.
  Server server1 open for e-business; process id is 1932.
  ```

The `startServer.log` file is located in the `<drive>:\Program Files\IBM\WebSphere\AppServer\profiles\`*`profile_name`*`\logs\server1` directory if you have installed your server with the default settings. The server name and process id vary depending on your settings.

- On distributed platforms, use the **startServer** command to start an Application Server from the command line.
- AIX On AIX, you can use the command line to start the server. Use the **startServer** command from the `/usr/WebSphere/AppServer/bin` directory, as shown below. To start a server that is associated with a non-default profile, issue the **startServer** command from the `/opt/WebSphere/AppServer/profiles/profile_name/bin` directory.

  ```
  #  ./startServer.sh server1
  ```

  You can check that the server has successfully started by checking the `startServer.log` file. If the server has successfully started, the last two lines of the `startServer.log` file reads:

  ```
  Server launched.  Waiting for initialization status.
  Server server1 open for e-business; process id is 1932.
  ```

  On AIX, the startServer.log file is located in the `/usr/IBM/WebSphere/AppServer/profiles/`*`profile_name`*`/logs/server1/` directory.
- Start an Application Server for tracing and debugging.

  To start the Application Server with standard Java debugging enabled:

  1. Click **Servers > Application Servers** from the administrative console navigation tree. Then, click the Application Server whose processes you want to trace and debug, then **Java and Process Management > Process Definition > Java Virtual Machine**.
  2. On the Java Virtual Machine page, place a checkmark in the check box for the **Debug Mode** setting to enable the standard Java debugger. If needed, set debug arguments. Then, click **OK**.
  3. Save the changes to a configuration file.
  4. Stop the Application Server.
  5. Start the Application Server again as described previously.

Once the server is started, you can install your applications.

Running application servers from a non-root user

By default, each base WebSphere Application Server server on a Linux and UNIX platform uses the root user ID to run all application server processes. However, you can run all application server processes under the same non-root user and user group. This task describes how to run an application server process from a non-root user.

If global security is enabled, the user registry must not be Local OS. Using the Local OS user registry requires the application server to run as root. Refer to the *Securing applications and their environment* PDF for details.

Run your application servers as non-root when you no longer want to use root authority. For security or administrative reasons, you may want to change to non-root user IDs. Perform this task at any time to change the permissions of an application server. You must restart the application server in order for the changes to take effect. .

Note: If you are using the Tivoli Access Manager (TAM) to perform authentication or authorization for WebSphere Application Server, it is important to be aware of potential permissions problems. For more information, see the *Securing applications and their environment* PDF.

For the following steps, assume that:

- `was1` is the user to run the application server
- `wasgroup` is the primary user group for user was1

- `wasnode` is the node name
- `server1` is the application server
- `/opt/WebSphere/AppServer` is the installation root
- `nodeProfile1` is the profile name.

Note: For information about creating a profile, see the *Administering applications and their environment* PDF.

To configure an application server to run as non-root, complete the following steps.

1. Log on to the application server system as the root user.
2. Create the user ID `was1` with a primary user group of `wasgroup`. The user ID, `was1`, is an example. You can name the user something else.
3. Log off and back on as root.
4. Start server1 as root. Run the `startServer.sh` script from the `/bin` directory of the installation root:

   ```
   startServer.sh server1
   ```
5. Specify user and group ID values for the **Run As User** and **Run As Group** settings for a server:
   a. Start the administrative console.
   b. Go to the Process execution page of the administrative console. You must define all three properties in the following table. Click **Servers > Application Servers > server1 > Server Infrastructure > Java and Process Management > Process Execution** and change all of the following values:

Property	Value
Run As User	was1
Run As Group	wasgroup
UMASK	022

   c. Click **OK**.
   d. Save the configuration.
6. Stop the application server. Use the `stopServer.sh` script from the `/bin` directory of the installation root:

   ```
   stopServer.sh server1
   ```
7. Change file permissions as the root user. The following example assumes that the installation root directory for WebSphere Application Server is `/opt/WebSphere/AppServer`:

   ```
   chgrp wasgroup /opt/WebSphere
   chgrp wasgroup /opt/WebSphere/AppServer
   chgrp -R wasgroup /opt/WebSphere/AppServer/cloudscape
   chgrp -R wasgroup /opt/WebSphere/AppServer/profiles/nodeProfile1
   chmod g+wr /opt/WebSphere
   chmod g+wr /opt/WebSphere/AppServer
   chmod -R g+wr /opt/WebSphere/AppServer/cloudscape
   chmod -R g+wr /opt/WebSphere/AppServer/profiles/nodeProfile1
   ```
8. Log on to the application server system as `was1`.
9. Start server1 as `was1`. Run the `startServer.sh` script from the `/bin` directory of the installation root:

   ```
   startServer.sh server1
   ```
10. If creating another server with a different user ID, follow this procedure again for the new user ID and server name.

    The two user IDs must share the same group, `wasgroup`.

You can start an application server from a non-root user.

Detecting and handling problems with run-time components

You must monitor the status of run-time components to ensure that, once started, they remain operational as needed.

1. Regularly examine the status of run-time components. Browse messages displayed under **Websphere Runtime Messages** in the status area at the bottom of the console. The run-time event messages marked with a red **X** provide detailed information on event processing. You can also use the Logging and Tracing page of the administrative console to monitor the status of run-time components. Click **Troubleshooting > Logs and Trace** in the console navigation tree to access the page.
2. If an application stops running when it should be operational, examine the application's status on an Applications page and try restarting the application.
3. If the run-time components do not restart, reexamine the messages and read information on problem determination to help you to restart the components.

Stopping servers

Stopping an application server stops a server process based on the process definition settings in the current application server configuration.

- Windows In Windows, you can use the Start menu to stop your application server. Click **Start > Programs > IBM WebSphere > Express v6.0 > Stop the server**. When the server stops successfully, the stopServer.log file contains the following in the last two lines:

  ```
  Server stop request issued.  Waiting for stop status.
  Server server1 stop completed.
  ```

  The server name varies depending on your settings.
- Use the **stopServer** command to stop an application server from the command line.

  A warning message appears if you are stopping the application server that is running the administrative console application.
- Stop the application server from the command line. In distributed environments, you can use the **stopServer** command to stop a single server. In AIX, use the **stopServer** or the **stopManager** command from the `/usr/WebSphere/AppServer/bin` directory:

  ```
  #  ./stopServer.sh server1
  ```

  ```
  #   ./stopManager.sh
  ```

Creating generic servers

There are two types of generic application servers:
- Non-Java applications or processes.
- Java applications or processes

You can use the wsadmin tool or the **Generic servers** panel of the administrative console to create either type.

Note: For the Base WebSphere Application Server product, although you can use the administrative console to create a generic application server definition, you cannot use it to start, stop or, in any way, control or manage that application server. The Base product administrative console can only be used to create server definitions and, if necessary, adjust the server definitions that it creates. To manage Base generic application servers, use the wsadmin tool.

- **Create a non-Java application as a generic server.** The following steps describe how to use the administrative console to create a non-Java application as a generic application server.
  1. Select **Servers** > **Generic servers**
  2. Click **New**. You can then specify the name of the generic server you are creating.

3. Type in a name for the generic server. The name must be unique within the application server. It is highly recommended that you use a naming scheme that makes it easy to distinguish your generic application servers from regular Websphere Application Servers. This will enable you to quickly determine whether to use the **Terminate** or **Stop** button in the administrative console to stop specific application server. You must use the **Terminate** button to stop a generic application server.
4. Select a template to use in creating the new server. You can use a default application server template for your new server or use an existing application server as a template. The new application server will inherit all properties of the template server. If you create the new server using an existing application server do not enable the option to map applications from the existing server to the new server. This option does not apply for a generic server.
5. Click **Next**
6. Click **Finish**. The generic server now appears as an option on the **Generic servers** panel in the administrative console.
7. On the **Generic servers** panel, click on the name of the generic server.
8. Under **Additional Properties** click **Process Definition**.
9. In the **Executable name** field under **General Properties**, enter the name of the non-WebSphere Application Server program that is to be launched when you start this generic server. Executable target type and Executable target properties are not used for non-Java applications. Executable target type and Executable target properties are only used for Java applications
10. Click **OK**.

- **Create a Java application as a generic server:** The following steps describe how to use the administrative console to create a Java application as a generic application server.
  1. Select **Servers** > **Generic servers**
  2. Click **New**. You can then specify the name of the generic server you are creating.
  3. Type in a name for the generic server. The name must be unique within the application server. It is highly recommended that you use a naming scheme that makes it easy to distinguish your generic application servers from regular Websphere Application Servers. This will enable you to quickly determine whether to use the **Terminate** or **Stop** button in the administrative console to stop specific application server. You must use the **Terminate** button to stop a generic application server.
  4. Click **Next**
  5. Click **Finish**. The generic server now appears as an option on the **Applications Server** panel in the administrative console.
  6. Click **Finish**. The generic server now appears as an option on the **Generic servers** panel in the administrative console.
  7. On the **Generic servers** panel, click on the name of the generic server.
  8. Under **Additional Properties** click **Process Definition**.
  9. In the **Executable name** field under **General Properties**, enter the path for Websphere Application Server's default JVM (${JAVA_HOME}/bin/java), which will be used to run the Java application when you start this generic server.
  10. In the **Executable target type** field under **General Properties**, select whether a Java class name, **JAVA_CLASS**, or the name of an executable JAR file, **EXECUTABLE_JAR**, will be used as the executable target of this Java process. The default for Websphere Application Server is **JAVA_CLASS**.
  11. In the **Executable target** field under **General Properties**, enter the name of the executable target. (Depending on the executable target type, this will be either a Java class containing a main() method, or the name of an executable JAR file.) The default for Websphere Application Server is **com.ibm.ws.runtime.WsServer**.
  12. Click **OK**.

Note: If the generic server is to run an application server other than the WebSphere Application Server, leave the **Executable name** field set to the default value and specify the Java class containing the main function for your application serve in the **Executable target** field.

You can now start and terminate the generic server whenever you want to start or terminate the non-WebSphere Application Server server or process associated with this server.

Starting and terminating generic servers

This topic describes how to start and terminate generic servers.

If you created a generic server on a Base WebSphere Application Server, you cannot start, terminate, or monitor this server with the Base Application Server administrative console. You must use the wsadmin tool to manage Base generic servers.

Starting generic servers

There are two ways to start a generic server in a Network Deployment environment:

- Use the administrative console:
  1. From the administrative console navigation tree, select **Servers > Application Servers**.
  2. Select the check box beside the name of the generic server, and then click **Start**.
  3. View the **Status** value and any messages or logs to see whether the generic server starts.
- Use the MBean NodeAgent launchProcess operation of the wsadmin tool.

Terminating generic servers

There are two ways to terminate a generic server in a Network Deployment environment:

- Use the administrative console:
  1. From the administrative console navigation tree, select **Servers > Application Servers**.
  2. Select the check box beside the name of the generic server, and then click **Terminate**.
  3. View the **Status** value and any messages or logs to see whether the generic server terminates.

  Note: The **Stop** and **Stop Immediate** buttons on the administrative console do not work for generic servers.
- Use the MBean terminate launchProcess operation of the wsadmin tool.

Configuring transport chains

You need to configure transport chains to provide networking services to such functions as the service integration bus component of IBM service integration technologies, WebSphere Secure Caching Proxy, and the high availability manager core group bridge service.

A transport chain consists of one or more types of channels, each of which supports a different type of I/O protocol, such as TCP or HTTP. Network ports can be shared among all of the channels within a chain. The channel framework function automatically distributes a request arriving on that port to the correct I/O protocol channel for processing. To define these channels:

1. Create a transport chain: You can either use the administrative console or wsadmin commands to create a transport chain. If you want to use the administrative console:
   a. Ensure that a port is available for the new transport chain.
   b. In the administrative console, click **Servers > Application servers >***server_name*, and then click on one of the following:
      - Under **Web container settings**, click **Web container transport chains**.

- Under **Server messaging**, click either **Messaging engine inbound transports** or **WebSphere MQ link inbound transports**.

c. Click **New**. The Create New Transport Chain wizard initializes. During the transport chain creation process, you are asked to:

- Specify a name for the new chain.
- Select a transport chain template
- Select a port, if one is available to which the new transport chain will be bound. If a port is not available or you want to define a new port, specify a port name, the host name or IP address for that port, and a valid port number.

When you click **Finish**, the new transport chain is added to the list of defined transport chains on the **Transport chain** panel.

2. Click on the transport chain's name to view the configuration settings that are in effect for the transport channels contained in this chain. To change any of these settings:
   a. Click on the channel that requires changes to its settings.
   b. Make your changes to the configuration settings. Some of the settings, such as the port number are determined by what is specified for the transport chain when it is created and cannot be changed.
   c. Click on **Custom properties** to set any custom properties that have been defined for your system.
3. When you have made all of your changes, click **OK**.
4. Stop the application server and start it again. You must stop the application server and start it again before the configuration changes you made take affect.

Transport chains

Transport chains represent a network protocol stack that is used for I/O operations within an application server environment. Transport chains are part of the channel framework function that provides a common networking service for all components, including the service integration bus component of IBM service integration technologies, WebSphere Secure Caching Proxy, and the high availability manager core group bridge service.

A transport chain consists of one or more types of channels, each of which supports a different type of I/O protocol, such as TCP, DCS or HTTP. Network ports can be shared among all of the channels within a chain. The channel framework function automatically distributes a request arriving on that port to the correct I/O protocol channel for processing.

The transport chain configuration settings determine which I/O protocols are supported for that chain. Following are some of the more common types of channels. Custom channels that support requirements unique to a particular customer or environment can also be added to a transport chain.

TCP channel

Used to provide client applications with persistent connections within a Local Area Network (LAN). When configuring a TCP channel, you can specify a list of IP addresses that are allowed to make inbound connections and a list of IP addresses that are not allowed to make inbound connections. You can also specify the thread pool that this channel uses, which allows you to segregate work by the port that the application server is listening on.

HTTP channel

Used to enable communication with remote servers. It implements the HTTP 1.0 and 1.1 standards and is used by other channels, such as the Web container channel, to server HTTP requests and to send HTTP specific information to servlets expecting this type of information.

HTTP Tunnel channel

Used to provide client applications with persistent HTTP connections to remote hosts that are either blocked by firewalls or require an HTTP proxy server (including authentication) or both. An HTTP Tunnel channel enables the exchange of application data in the body of an HTTP request or response that is sent to or received from a remote server. An HTTP Tunnel channel also enables client-side applications to poll the remote host and to use HTTP requests to either send data from the client or to receive data from an application server. In either case, neither the client nor the application server is aware that HTTP is being used to exchange the data.

Web container channel
Used to create a bridge in the transport chain between an HTTP inbound channel and a servlet and JavaServer Pages (JSP) engine.

DCS channel
Used by the core group bridge service, the data replication service (DRS), and the high availability manger to transfer data, objects, or events among application servers.

MQ channel
Used in combination with other channels, such as a TCP channel, within the confines of WebSphere MQ support to facilitate communications between a WebSphere System Integration Bus and a WebSphere MQ client or queue manager.

JFAP channel
Used by the Java Message Service (JMS) server to create connections to JMS resources on a service integration bus.

SSL channel
Used to associate an SSL configuration repertoire with the transport chain. This channel is only available when Secure Sockets Layer (SSL) support is enabled for the transport chain. An SSL configuration repertoire is defined in the administrative console, under security, on the **SSL configuration repertoires > SSL configuration repertoires** page.

HTTP transport channel custom property

If you are using an HTTP transport channel, you can add the following custom property to the configuration settings for that HTTP transport channel.

To add a custom property:

1. In the administrative console, click **Application servers >** *server_name* **Web container settings > Web container transport chains** >*chain_name* **> HTTP Inbound Channel > Custom Properties > New**
2. Under **General Properties** specify the name of the custom property in the Name field and a value for this property in the Value field. You can also specify a description of this property in the Description field.
3. Click **Apply** or **OK**.
4. Click **Save** to save your configuration changes.
5. Restart the server.

Following is a list of custom properties provided with the application server. These properties are not shown on the settings page for an HTTP transport channel.

inProcessLogFilenamePrefix

Use to specify a prefix for the filename of the network log file. Normally, when inprocess optimization is enabled, requests through the inprocess path are logged based on the logging attributes set up for the Web container's network channel chain. You can use this property to add a prefix to the filename of the network log file. This new filename is then used as the filename for the log file for inprocess requests. Requests sent through the inprocess path are logged to this file instead of to the network log file. For example, if the log file for a network transport chain is named `.../httpaccess.log`, and this property is set to `local` for the HTTP channel in that chain, the filename of the log file for inprocess requests to the host associated with that chain is `.../localhttpaccess.log`.

Data type	String

HTTP Tunnel transport channel custom property

If you are using an HTTP Tunnel transport channel, you can add the following custom property to the configuration settings for that HTTP Tunnel transport channel.

To add a custom property:

1. In the administrative console, click **Servers > Application servers >***server_name* **> Ports**. Click on **View associated transports** for the HTTP Tunnel port to whose configuration settings you want to add this custom property.
2. Click **New**.
3. Under **General Properties** specify the name of the custom property in the Name field and a value for this property in the Value field. You can also specify a description of this property in the Description field.
4. Click **Apply** or **OK**.
5. Click **Save** to save your configuration changes.
6. Restart the server.

Following is a description of the custom property that is provided with the application server. This property is not shown on the settings page for an HTTP Tunnel transport channel.

pluginConfigurable

Indicates whether or not the configuration settings for the HTTP Tunnel transport channel are included in the plugin-cfg.xml file for the Web server associated with the application server that is using this channel. Configuration settings for each of the Web container transport channels defined for an application server are automatically included in the plugin-cfg.xml file for the Web server associated with that application server.

Data type	Boolean
Default	False

Troubleshooting transport chain problems

TCP transport channel fails to bind to a specific host/port combination

If a TCP transport channel fails to bind to a specific port, one of the following situations might have occurred:

- You are trying to bind the channel to a port that is already bound to another application, such as another instance of a WebSphere Application Server.
- You are trying to bind to a port that is in a transitional state waiting for closure. This socket must transition to closed before you restart the server. The port might be in TIME_WAIT, FIN_WAIT_2, or CLOSE_WAIT state. Issue the `netstat -a` command from a command prompt window to display the state of the port to which you are trying to bind. If you need to change the amount of elapse time that must occur before TCP/IP can release a closed connection and reuse its resources, see the *Troubleshooting and support* PDF.

Configuring HTTP transports

Important: On a distributed platform, HTTP transport support is deprecated. Therefore, the administrative console page used to configure an HTTP transport is not available unless your migrated an HTTP transport from your V5 environment. You must define an HTTP transport channel instead of an HTTP transport to handle your HTTP requests.

An HTTP transport is the request queue between a WebSphere Application Server plug-in for Web servers and a Web container in which the Web modules of an application reside. To define the characteristics of the connections between that plug-in and the Web container, you must specify:

- How the transport is to handle a set of connections. For example, you must specify the number of concurrent requests that is to be allowed.
- Whether to secure the connections with SSL.
- The Host and IP information for the transport participants.

1. Change the configuration for an existing HTTP transport.
   a. Ensure that virtual host aliases include port values for the transport your are changing.
   b. Go to the HTTP Transports page and click on the transport under **Host** whose configuration you want to change.

      Remember, on a distributed platform, HTTP transport support is deprecated. Therefore you cannot view this administrative console page unless you are a V5.x user who, during the V6 migration process, indicated that you want to continue using the HTTP transports that are defined for your V5 environment.
   c. On the settings page for an HTTP transport, which might have the page title DefaultSSLSettings, change the specified values as needed, then click **OK**.
   d. Custom properties page, add and set any custom properties you want to use.
2. Stop the WebSphere Application Server and start it again. You must stop the WebSphere Application Server and start it again before the configuration changes you made take affect.

If the Web server is located on a machine remote from the Application Server, copy the `plugin-cfg.xml` file to the remote Web server and replace the file that is there. See ″Editing Web server configuration files″ in the information center for information about copying the `plugin-cfg.xml` and binary plug-in module to a remote Web server and configuring the Web server to use the files.

HTTP transport collection:

Use this page to view or manage HTTP transports. Transports provide request queues between WebSphere Application Server plug-ins for Web servers and Web containers in which the Web modules of applications reside. When you request an application in a Web browser, the request is passed to the Web server, then along the transport to the Web container.

On a distributed platform, if, when migrating from WebSphere Application Server Version 5.x, you indicate that you want to continue using an HTTP transport to handle your HTTP requests, your Version 5.x transports are migrated for you. If you are not migrating from Version 5.x, you must set up an HTTP transport channel to handle your HTTP requests.

To view the HTTP Transport administrative console page, click **Servers > Application Servers >***server_name* **> Web Container Settings > Web Container > HTTP Transports**.

the HTTP Transport panel on the administrative console

Host:

Specifies the host IP address to bind for transport. If the application server is on a local machine, the host name might be `localhost`.

Port:

Specifies the port to bind for transport. The port number can be any port that currently is not in use on the system. The port number must be unique for each application server instance on a given machine.

For distributed platforms, there is no limit to the number of HTTP ports that are allowed per process.

SSL Enabled:

Specifies whether to protect connections between the WebSphere plug-in and application server with Secure Sockets Layer (SSL). The default is not to use SSL.

HTTP transport settings:

Use this page to view and configure an HTTP transport. The name of the page might be that of an SSL setting such as DefaultSSLSettings.

On a distributed platform, if, when migrating from Version 5, you indicate that you want to continue using an HTTP transport to handle your HTTP requests, your Version 5 transports are migrated for you. If you are not migrating from WebSphere Application Server Version 5.x, you must set up an HTTP transport channel to handle your HTTP requests.

To view the HTTP Transport panel on the administrative console, click **Servers** > **Application Servers** >*server_name* > **Web Container Settings** > **Web Container** > **HTTP Transports** >*host_name*.

Host:

Specifies the host IP address to bind for transport.

If the application server is on a local machine, the host name might be `localhost`.

Data type	String

Port:

Specifies the port to bind for transport. Specify a port number between 1 and 65535. The port number must be unique for each application server on a given machine.

Data type	Integer
Range	1 to 65535

SSL Enabled:

Specifies whether to protect connections between the WebSphere Application Server plug-in and application server with Secure Sockets Layer (SSL). The default is not to use SSL.

Data type	Boolean
Default	false

SSL:

Specifies the Secure Sockets Layer (SSL) settings type for connections between the WebSphere Application Server plug-in and application server. The options include one or more SSL settings defined in the Security Center; for example, DefaultSSLSettings, ORBSSLSettings, or LDAPSSLSettings.

Data type	String
Default	An SSL setting defined in the Security Center

Transports:

A transport is the request queue between a WebSphere Application Server plug-in for Web servers and a Web container in which the Web modules of an application reside. When a user at a Web browser requests an application, the request is passed to the Web server, then along the transport to the Web container.

Transports define the characteristics of the connections between a Web server and an application server, across which requests for applications are routed. Specifically, they define the connection between the Web server plug-in and the Web container of the application server.

Administering transports is closely related to administering WebSphere Application Server plug-ins for Web servers. Indeed, without a plug-in configuration, a transport configuration is of little use.

On a distributed platform, when migrating from WebSphere Application Server Version 5.x, you indicate that you want to continue using an HTTP transport to handle your HTTP requests, your Version 5.x transports are migrated for you. If you are not migrating from Version 5.x, you must set up an HTTP transport channel to handle your HTTP requests.

The internal transport

The internal HTTP transport allows HTTP requests to be routed to the application server directly through a Web server plug-in. Logging is provided for debug purposes.

Prior to WebSphere Application Server Version 5.0.2, the HTTP transport functionality existed only as a means of accepting HTTP requests forwarded by an HTTP plug-in that was connected to a Web server. In WebSphere Application Server Version 5.0.2, HTTP transport functionality is now a supported internal Web server. By default, the internal HTTP transport listens for HTTP requests on port 9080 and for HTTPS requests on port 9443.

For example, use the URL `http://localhost:9080/snoop` to send requests to the snoop servlet on the local machine over HTTP and `https://localhost:9443/snoop` to send requests to the snoop servlet on the local machine over HTTPS.

The transport configuration is a part of the Web container configuration. You can configure the internal transport to use ports other than 9080 and 9443. However, you must also adjust your virtual host alias and what you type into the Web browser.

HTTP transport custom properties:

Use this page to set custom properties for an HTTP transport.

On a distributed platform, HTTP transport support is deprecated. Therefore you cannot create a new HTTP transport. Instead you must create an HTTP transport channel to handle your HTTP requests. If you are a WebSphere Application Server Version 5.x user who has migrated to Version 6, and during the migration process you indicated that you want to continue using an HTTP transport to handle your HTTP requests, your Version 5.x transports are still available for your use.

If you are using HTTP transports, you can set the following custom properties on either the Web Container or HTTP Transport **Custom Properties** panel on the administrative console. When set on the Web container **Custom Properties** page, all transports inherit the properties. Setting the same properties on a transport overrides like settings defined for a Web container.

To specify values for these custom properties for a specific transport on the HTTP Transport **Custom Properties** page:

1. In the console navigation tree, click **Servers > Application Servers >***server_name* **> Web Container settings > Web Container >HTTP Transport**

To specify a custom property:

1. Click on the **HOST** whose properties you want to set.
2. Under **Additional Properties** select **Custom Properties**.
3. On the Custom Properties page, click **New**.
4. On the settings page, enter the property you want to configure in the **Name** field and the value you want to set it to in the **Value** field.
5. Click **Apply** or **OK**.
6. Click **Save** on the console task bar to save your configuration changes.
7. Restart the server.

Following is a list of custom properties provided with the Application Server. These properties are not shown on the settings page for an HTTP transport.

ConnectionIOTimeOut:

Use the `ConnectionIOTimeOut` property to specify the maximum number of seconds to wait when trying to read or process data during a request.

Data type	Integer
Default	For distributed platforms: 5 seconds

ConnectionKeepAliveTimeout:

Use the `ConnectionKeepAliveTimeout` property to specify the maximum number of seconds to wait for the next request on a keep alive connection.

Data type	Integer

MaxConnectBacklog:

Use the `MaxConnectBacklog` property to specify the maximum number of outstanding connect requests that the operating system will buffer while it waits for the application server to accept the connections. If a client attempts to connect when this operating system buffer is full, the connect request will be rejected.

Set this value to the number of concurrent connections that you would like to allow. Keep in mind that a single client browser might need to open multiple concurrent connections (perhaps 4 or 5); however, also keep in mind that increasing this value consumes more kernel resources. The value of this property is specific to each transport.

Data type	Integer
Default	511

MaxKeepAliveRequests:

Use the `MaxKeepAliveRequests` property to specify the maximum number of requests which can be processed on a single keep alive connection. This parameter can help prevent denial of service attacks when a client tries to hold on to a keep-alive connection. The Web server plug-in keeps connections open to the application server as long as it can, providing optimum performance.

Data type	Integer
Default	For distributed platforms: 100 requests

KeepAliveEnabled:

This property is only valid in a distributed environment. Use the `KeepAliveEnabled` property to specify whether or not to keep connections alive

Data type	String
Default	true

Trusted:

This property is only valid in a distributed environment. Use the `Trusted` property to indicate that the application server can use the private headers that the Web server plug-in adds to requests.

Data type	String
Default	false

Configuring error logging for internal Web server HTTP transport:

To debug potential problems with using the HTTP transport as an internal Web server, you can use the following error logging capabilities.

1. Turn error logging on. To turn error logging on, add the following custom property to the HTTP Transport's configuration settings, and set the value to **false**:

   ```
   Property name: ErrorLogDisable
   Value: True/False
   Default: Error log is disabled by default
   ```

   When you are ready to turn error logging off, set the value of the **ErrorLogDisable** property back to **true**.
2. To specify your own error log file, add the following property to the transport section of the `server.xml` file:

   ```
   Property name: ErrorLog
   Value: <filename>
   Default: logs/<server instance>/http.log
   ```

   The error log property is used to specify where to place the error log. For example:<properties xmi:id=″WebContainer_Property_6″ name=″ErrorLog″ value=″logs/<server instance>/http.log″/>

   Note: The error log should appear in each instance of the server.

   If you are going to be using error logging for multiple HTTP transports in a single HTTP server, make sure you specify a unique filename for the error log file associated with each HTTP transport.
3. Add the LogLevel property to the transport section of the `server.xml` file to specify the level of messages to log in the error log file.

   ```
   Property name: LogLevel
   Value:  <level> (Levels include: debug, info, warn, error, crit)
   Default:  warn (warn includes error and crit; debug includes all levels)
   Scope:  Virtual/Global
   ```

   Log levels specify the type of message that appears in the error log. The *warn*, *error*, and *crit* messages are logged by default.
4. Restart the server.

If you have enabled error logging and encounter an error, there should be an error log message in the error log file you specified.

Configuring access logging for internal Web server HTTP transport:

To debug potential problems with using the HTTP transport as an internal Web server, you can use the following access logging capabilities.

1. Turn access logging on. To turn access logging on, add the following custom property to the HTTP Transport's configuration settings, and set the value to **false**:

   ```
   Property name: AccessLogDisable
   Values: True/False
   Default: Access log is disabled by default
   ```

   When you are ready to turn access logging off, set the value of the **AccessLogDisable** property back to **true**.
2. To specify your own access log file, add the following property to the transport section of the `server.xml` file:

   ```
   Property name: AccessLog
   Value: <filename>
   Default Value: logs/<server instance>/http_access.log
   ```

   The default access log file is `logs/<server_instance>/http_access.log`. Access log entries should have the format:

   ```
   <hostname or IP> <user agent> [<local time> -<status code>] <thread id> <http request> <status code> <bytecount>
   ```

   Note: If you are going to be using access logging for multiple HTTP transports in a single HTTP server, make sure you specify a unique filename for the access log file associated with each HTTP transport.
3. Restart the server.

If you have enabled access logging, there will be an access log in the location you specified.

Transport chains collection

Use this page to view or manage transport chains. Transport chains enable communication through transports, or protocol stacks, which are usually socket based.

A transport chain consists of one or more types of channels, each of which supports a different type of I/O protocol, such as TCP or HTTP. Network ports can be shared among all of the channels within a chain. The Channel Framework function automatically distributes a request arriving on that port to the correct I/O protocol channel for processing.

The **Transport chains** page lists the transport chains defined for the selected application server. Transport chains represent network protocol stacks operating within this application server.

To view this administrative console page, click **Servers > Application servers >** *server_name* **> Ports**. Click on **View associated transports** for the port whose transport chains you want to view.

Name: Specifies a unique identifier for the transport chain. For WebSphere Application Server, transport name must be unique within a WebSphere Application Server configuration. Click on the name of a transport chain to change its configuration settings.

Enabled: When set to true, the transport chain is activated at application server startup.

Host: Specifies the host IP address to bind for transport. If the application server is on a local machine, the host name might be localhost.

Port: Specifies the port to bind for transport. The port number can be any port that currently is not in use on the system, might be localhost or the wildcard character * (an asterisk). The port number must be unique for each application server instance on a given machine

SSL Enabled: When set to true, users are notified if there is a channel that enables Secure Sockets Layer (SSL) in the listed chain. When SSL is enabled, all traffic going through this transport is encrypted and digitally secured.

Transport chain settings

This page lists the types of transport channels configured for the selected transport chain. A transport chain consists of one or more types of channels, each of which supports a different type of I/O protocol, such as TCP, HTTP, or DCS.

To view this administrative console page, click **Servers > Application servers >** *server_name* **> Ports**. Click on **View associated transports** for the port whose transport chains you want view and then click on the name of a specific chain.

Name:

Specifies the name of the selected transport chain.

You can edit this field to rename this transport chain. However, remember that the name must be unique within a WebSphere Application Server configuration.

Enabled: When checked, this transport chain is activated at application server startup.

Transport channels: Lists the transport channels configured for this transport chain and their configuration settings. To change a transport channel's configuration settings, click on the name of that transport channel.

HTTP tunnel transport channel settings

Use this page to view and configure an HTTP tunnel transport channels. Inbound connections sent through this channel are tunneled over HTTP, allowing intermediates to view this data as the body of an HTTP message instead of in its natural format. This type of channel is often used to circumvent firewalls with protocol restrictions.

To view this administrative console page, click **Servers > Application servers >***server_name* **> Ports** . Click on **View associated transports** for the port associated with the HTTP Tunnel transport channel whose settings you want to look at.

Transport channel name:

Specifies the name of the HTTP tunnel transport channel.

This name must be unique across all channels in a WebSphere Application Server environment. For example DCS and TCP transport channels cannot have the same name if they reside within the same system.

Discrimination weight:

Specifies the priority this channel has in relation to the other channels in this transport chain. This property is only used when port sharing is enabled and the channel chain includes multiple channels to which it might forward data. The channel in the chain with the lowest discrimination weight is the first one given the opportunity to look at incoming data and determine whether or not it owns that data.

Data type	Positive integer
Default	10

HTTP transport channel settings

Use this page to view and configure an HTTP transport channel. This type of transport channel handles HTTP requests from a remote client.

An HTTP transport channel parses HTTP requests and then finds an appropriate application channel to handle the request and send a response.

To view this administrative console page, click **Servers > Application servers >***server_name* **> Ports** . Click on **View associated transports** for the port associated with the HTTP transport channel whose settings you want to look at.

Transport channel name:

Specifies the name of the HTTP transport channel.

This name must be unique across all channels in a WebSphere Application Server environment. For example, an HTTP transport channel and a TCP transport channel cannot have the same name if they reside within the same system.

Discrimination weight:

Specifies the priority this channel has in relation to the other channels in this transport chain. This property is only used when port sharing is enabled and the channel chain includes multiple channels to which it might forward data. The channel in the chain with the lowest discrimination weight is the first one given the opportunity to look at incoming data and determine whether or not it owns that data.

Data type	Positive integer
Default	10

Maximum persistent requests:

Specifies the maximum number of persistent (keep-alive) requests that are allowed on a single HTTP connection. If a value of 0 (zero) is specified, only one request is allowed per connection. If a value of -1 is specified, an unlimited number of requests is allowed per connection.

Data type	Integer
Default	100

Use Keep-Alive: When selected, the HTTP transport channel, when sending an outgoing HTTP message, uses a persistent connection (keep-alive connection) instead of a connection that closes after one request or response exchange occurs.

Note: If a value other than 0 is specified for the `maximum persistent requests` property, the `Use Keep-Alive property` setting is ignored.

The default for this property is selected.

Read timeout:

Specifies the amount of time, in seconds, the HTTP transport channel waits for a read request to complete on a socket after the first read request occurs. The read being waited for could be an HTTP body (such as a POST) or part of the headers if they were not all read as part of the first read request on the socket.

Data type	Integer
Default	60 seconds

Write timeout:

Specifies the amount of time, in seconds, that the HTTP transport channel waits on a socket for each portion of response data to be transmitted. This timeout usually only occurs in situations where the writes are lagging behind new requests. This can occur when a client has a low data rate or the server's network interface card (NIC) is saturated with I/O.

Data type	Integer
Default	60 seconds

Persistent timeout:

Specifies the amount of time, in seconds, that the HTTP transport channel allows a socket to remain idle between requests.

Data type	Integer
Default	30 seconds

Enable NCSA access logging:

When selected, the HTTP transport channel performs NCSA access and error logging. Enabling NCSA access and error logging slows server performance.

To configure NCSA access and error logging, click **HTTP error and NCSA access logging** under **Related Items**. Even if HTTP error and NCSA access logging is configured, it is not enabled unless the Enable NCSA access logging property is selected.

The default value for the Enable NCSA access logging property is not selected.

TCP transport channel settings

Use this page to view and configure an TCP transport channels. This type of transport channel handles inbound TCP/IP requests from a remote client.

To view this administrative console page, click **Servers > Application servers >***server_name* **> Ports >** . Click on **View associated transports** for the port associated with the TCP transport channel whose settings you want to view.

Transport channel name:

Specifies the name of the TCP transport channel.

This name must be unique across all channels in a WebSphere Application Server environment. For example, a TCP transport channel and an HTTP transport channel cannot have the same name if they reside within the same system.

Port: Specifies the TCP/IP port this transport channel uses to establish connections between a client and an application server. The TCP transport channel binds to the hostnames and ports listed for the Port property. You can specify the wildcard * (an asterisk), for the hostname if you want this channel to listen to all hosts that are available on this system. However, before specifying the wildcard value, make sure this TCP transport channel does not have to bind to a specific hostname.

Thread pool: Select from the drop-down list of available thread pools the thread pool you want the TCP transport channel to use when dispatching work.

Maximum open connections:

Specifies the maximum number of connections that can be open at one time.

Data type	Integer between 1 and 20,000 inclusive
Default	20,000

Inactivity timeout: Specifies the amount of time, in seconds, that the TCP transport channel waits for a read or write request to complete on a socket.

Note: The value specified for this property might be overridden by the wait times established for channels above this channel. For example, the wait time established for an HTTP transport channel overrides the value specified for this property for every operation except the initial read on a new socket.

Data type	Integer
Default	60 seconds

Address exclude list:

Lists the IP addresses that are not allowed to make inbound connections. Use a comma to separate the IPv4 or IPv6 or both addresses to which you want to deny access on inbound TCP connection requests.

All four numeric values in an IPv4 address must be represented by a number or the wildcard character * (an asterisk).

Following are examples of valid IPv4 addresses that can be included in an **Address exclude list**:

```
*.1.255.0
254.*.*.9
1.*.*.*
```

All eight numeric values of an IPv6 address must be represented by a number or the wildcard character * (an asterisk). No shortened version of the IPv6 address should be used. Even though a shortened version is processed with no error given, it does not function correctly in this list. Each numeric entry should be a 1- 4 digit hexadecimal number.

Following are examples of valid IPv6 addresses that can be included in an **Address exclude list**:

```
0:*:*:0:007F:0:0001:0001
F:FF:FFF:FFFF:1:01:001:0001
1234:*:4321:*:9F9f:*:*:0000
```

Note: The **Address include list** and **Host name include list** are processed before the **Address exclude list** and the **Host name exclude list**. If all four lists are defined:

- An address that is defined on either inclusion list will be allowed access provided it is not included on either of the exclusion lists.
- If an address is included in both an inclusion list and in an exclusion list, it will not be allowed access.

Address include list:

Lists the IP addresses that are allowed to make inbound connections. Use a comma to separate the IPv4 or IPv6 or both addresses to which you want to grant access on inbound TCP connection requests.

All four numeric values in an IPv4 address must be represented by a number or the wildcard character * (an asterisk).

Following are examples of valid IP addresses that can be included in an **Address include list**:

```
 *.1.255.0
 254.*.*.9
 1.*.*.*
```

All eight numeric values of an IPv6 address must be represented by a number or the wildcard character * (an asterisk). No shortened version of the IPv6 address should be used. Even though a shortened version is processed with no error given, it does not function correctly in this list. Each numeric entry should be a 1- 4 digit hexadecimal number.

Following are examples of valid IPv6 addresses that can be included in an **Address include list**:

```
0:*:*:0:007F:0:0001:0001
F:FF:FFF:FFFF:1:01:001:0001
1234:*:4321:*:9F9f:*:*:0000
```

Note: The **Address include list** and **Host name include list** are processed before the **Address exclude list** and the **Host name exclude list**. If all four lists are defined:

- An address that is defined on either inclusion list will be allowed access provided it is not included on either of the exclusion lists.
- If an address is included in both an inclusion list and in an exclusion list, it will not be allowed access.

Host name exclude list:

List the host names that are not allowed to make connections. Use a comma to separate the URL addresses to which you want to deny access on inbound TCP connection requests.

A URL address can start with the wildcard character * (an asterisk) followed by a period; for example, `*.Rest.Of.Address`. If a period does not follow the wildcard character, the asterisk will be treated as a normal non-wildcard character. The wildcard character can not appear any where else in the address. For example, ibm.*.com is not a valid hostname.

Following are examples of valid URL addresses that can be included in a **Host name exclude list**:

```
*.ibm.com
www.ibm.com
*.com
```

Note: The **Address include list** and **Host name include list** are processed before the **Address exclude list** and the **Host name exclude list**. If all four lists are defined:

- An address that is defined on either inclusion list will be allowed access provided it is not included on either of the exclusion lists.
- If an address is included in both an inclusion list and in an exclusion list, it is not allowed access.

Host name include list:

Lists the host names that are allowed to make inbound connections. Use a comma to separate the URL addresses to which you want to grant access on inbound TCP connection requests.

A URL address can start with the wildcard character * (an asterisk) followed by a period; for example, `*.Rest.Of.Address`. If a period does not follow the wildcard character, the asterisk will be treated as a normal non-wildcard character. The wildcard character can not appear any where else in the address. For example, ibm.*.com is not a valid hostname.

Following are examples of valid URL addresses that can be included in a **Host name include list**:

```
*.ibm.com
www.ibm.com
*.com
```

Note: The **Address include list** and **Host name include list** are processed before the **Address exclude list** and the **Host name exclude list**. If all four lists are defined:

- An address that is defined on either inclusion list will be allowed access provided it is not included on either of the exclusion lists.
- If an address is included in both an inclusion list and in an exclusion list, it is not allowed access.

DCS transport channel settings

Use this page to view and configure an DCS transport channels. This type of transport channel handles inbound Distribution and Consistency Services (DCS) messages.

By default, two channel transport chains are defined for an application server that contains a DCS channel:

- The chain named DCS contains a TCP and a DCS channel.
- The chain named DCS-Secure contains a TCP, an SSL, and a DCS channel.

Both of these chains terminate in, or use the same TCP channel instance. This TCP channel is associated with the DCS_UNICAST_ADDRESS port and is not used in any other transport chains. One instance of an SSL channel is reserved for use in the DCS-Secure chain. It also is not used in any other transport chains.

To view this administrative console page, click **Servers > Application servers >***server_name* **> Ports >** . Click on **View associated transports** for the port associated with the DCS transport channel whose settings you want to look at.

Transport channel name:

Specifies the name of the DCS transport channel.

This name must be unique across all channels in a WebSphere Application Server environment. For example DCS and TCP transport channels cannot have the same name if they reside within the same system.

Discrimination weight:

Specifies the priority this channel has in relation to the other channels in this transport chain. This property is only used when port sharing is enabled and the channel chain includes multiple channels to which it might forward data. The channel in the chain with the lowest discrimination weight is the first one given the opportunity to look at incoming data and determine whether or not it owns that data.

The discrimination weight of the DCS channel in a DCS-Secure transport chain should always be less than the discrimination weight of the SSL channel that is in that chain. Other SSL channels in other chains might have different discrimination values.

Data type	Positive integer	
Default	1 for the DCS channel	2 for the SSL channel

Web container transport channel settings

Use this page to view and configure a Web container inbound channel transport. This type of channel transport handles inbound Web container requests from a remote client.

To view this administrative console page, click **Servers** > **Application servers** > *server_instance* > **Web container settings** > **Web container transport chains** > *transport_chain* > **Web Container Inbound Channel** .

Transport Channel Name:

This name must be unique across all channels in a WebSphere Application Server environment. This means that TCP transport channels and HTTP transport channels cannot have the same name if they reside within the same system.

Discrimination weight:

Specifies the priority that this transport chain has in relation to other transport chains if this transport channel is shared amongst several transport chains.

Write buffer size:

Specifies the amount of content in bytes to buffer unless the servlet explicitly calls flush/close on the response/writer output stream.

Data type	bytes
Default	9192 bytes

Custom services

A custom service provides the ability to plug into a WebSphere Application Server application server to define a hook point that runs when the server starts and shuts down.

A developer implements a custom service containing a class that implements a particular interface. The administrator configures the custom service in the administrative console, identifying the class created by the developer. When an application server starts, any custom services defined for the application server are loaded and the server runtime calls their initialize methods.

Developing custom services

The following restrictions apply to the WebSphere Application Server custom services implementation:

- The init and shutdown methods must return control to the runtime.
- No work is dispatched into the server instance until all custom service initialize methods return.
- The init and shutdown methods are called only once on each service, and once for each operating system process that makes up the server instance. File I/O is supported.
- Initialization of process level static data, without leaving the process, is supported.
- Only JDBC RMLT (resource manager local transaction) operations are supported. Every unit of work (UOW) must be completed before the methods return.
- Creation of threads is not supported.
- Creation of sockets and I/O, other than file I/O, is not supported. Running standard J2EE code (client code, servlets, enterprise beans) is not supported.
- The JTA interface is not available. This feature is available in J2EE server processes and distributed generic server processes only.
- While the runtime makes an effort to call shutdown, there is no guarantee that shutdown will be called prior to process termination.

Note that these restrictions apply to the shutdown and init methods equally. Some JNDI operations are available.

Develop a custom service class that implements the com.ibm.websphere.runtime.CustomService interface. The properties passed by the application server runtime to the initialize method can include one for an external file containing configuration information for the service (retrieved with externalConfigURLKey). In addition, the properties can contain any name-value pairs that are stored for the service, along with the other system administration configuration data for the service. The properties are passed to the initialize method of the service as a Properties object.

There is a shutdown method for the interface as well. Both methods of the interface declare that they may create an exception, although no specific exception subclass is defined. If an exception is created, the runtime logs it, disables the custom service, and proceeds with starting the server.

As mentioned above, your custom services class must implement the CustomService interface. In addition, your class must implement the initialize and shutdown methods. Suppose the name of the class that implements your custom service is *ServerInit*, your code would declare this class as shown below. The code below assumes that your custom services class needs a configuration file. It shows how to process the input parameter in order to get the configuration file. If your class does not require a configuration file, the code that processes configProperties is not needed.

```
public class ServerInit implements CustomService
{
/**
* The initialize method is called by the application server run-time when the
* server starts. The Properties object passed to this method must contain all
* configuration information necessary for this service to initialize properly.
*
* @param configProperties java.util.Properties
*/
    static final java.lang.String externalConfigURLKey =
       "com.ibm.websphere.runtime.CustomService.externalConfigURLKey";

    static String ConfigFileName="";

    public void initialize(java.util.Properties configProperties) throws Exception
    {
        if (configProperties.getProperty(externalConfigURLKey) != null)
        {
           ConfigFileName = configProperties.getProperty(externalConfigURLKey);
        }

       // Implement rest of initialize method
    }
/**
* The shutdown method is called by the application server run-time when the
* server begins its shutdown processing.
*
* @param configProperties java.util.Properties
*/
    public void shutdown() throws Exception
    {
        // Implement shutdown method
    }
```

Custom service collection

Use this page to view a list of services available to the application server and to see whether the services are enabled. A custom service provides the ability to plug into a WebSphere application server and define code that runs when the server starts or shuts down.

To view this administrative console page, click **Servers > Application servers >***server_name*. Then, under Server Infrastructure, click **Administration > Custom Services**.

External Configuration URL:

Specifies the URL for a custom service configuration file.

If your custom services class requires a configuration file, the value provides a fully-qualified path name to that configuration file. This file name is passed into your custom service class.

Classname:

Specifies the class name of the service implementation. This class must implement the Custom Service interface.

Display Name:

Specifies the name of the service.

Enable service at server startup:

Specifies whether the server attempts to start and initialize the service when its containing process (the server) starts. By default, the service is not enabled when its containing process starts.

Custom service settings:

Use this page to configure a service that runs in an application server.

To view this administrative console page, click **Servers > Application servers >***server_name*. Then, under Server Infrastructure, click **Administration > Custom services >***custom_service_name*.

Enable service at server startup:

Specifies whether the server attempts to start and initialize the service when its containing process (the server) starts. By default, the service is not enabled when its containing process starts.

Data type	Boolean
Default	false

External Configuration URL:

Specifies the URL for a custom service configuration file.

If your custom services class requires a configuration file, specify the fully-qualified path name to that configuration file for the value. This file name is passed into your custom service class.

Data type	String
Units	URL

Classname:

Specifies the class name of the service implementation. This class must implement the Custom Service interface.

Data type	String
Units	Java class name

Display Name:

Specifies the name of the service.

Data type	String

Description:

Describes the custom service.

Data type	String

Classpath:

Specifies the class path used to locate the classes and JAR files for this service.

Data type	String
Units	Class path

Process definition

A process definition specifies the run-time characteristics of an application server process.

A process definition can include characteristics such as JVM settings, standard in, error and output paths, and the user ID and password under which a server runs.

Defining application server processes

To enhance the operation of an application server, you can define command-line information for starting or initializing an application server process. Such settings define run-time properties such as the program to run, arguments to run the program, and the working directory.

1. Go to the settings page for a process definition in the administrative console. Click **Servers > Application Servers** in the console navigation tree, click on an application server name and then **Java and Process Management > Process Definition**. Note that you can also define application server processes using the wsadmin tool. For more information, see the *Administering applications and their environment* PDF.
2. On the settings page for a process definition, specify the name of the executable to run, any arguments to pass when the process starts running, and the working directory in which the process will run. Then click **OK**.
3. Specify process execution statements for starting or initializing a UNIX process.
4. Specify monitoring policies to track the performance of a process.
5. Specify process logs to which standard out and standard error streams write. Complete this step if you do not want to use the default file names.
6. Specify name-value pairs for properties needed by the process definition.
7. Stop the application server and then restart the server.
8. Check the application server to ensure that the process definition runs and operates as intended.

Process definition settings

Use this page to view or change settings for a process definition. For WebSphere Application Server, this page provides command-line information for starting or initializing a process.

To view this administrative console page, click **Servers > Application Servers >***server_name*. Then under Server Infrastructure click **Java Process Management > Process Definition**.

Related concepts

"Process definition"
A process definition specifies the run-time characteristics of an application server process.

Related tasks

"Administrative console page features" on page 178
This topic provides information about the basic elements of an administrative console page, such as the various tabs.

"Java virtual machine settings" on page 155
Use this page to view and change the Java virtual machine (JVM) configuration for the application server's process.

"Custom property collection" on page 118
Use this page to view and manage arbitrary name-value pairs of data, where the name is a property key and the value is a string value that can be used to set internal system configuration properties.

Executable Name:

This command applies to base WebSphere Application Server only. It specifies the executable name that is invoked to start the process.

Data type	String

Executable Arguments:

This command applies to base WebSphere Application Server only. It specifies the arguments that are passed to the executable when starting the process.

For example, the executable target program might expect three arguments: *arg1 arg2 arg3*.

Data type	String
Units	Java command-line arguments

Working Directory:

Specifies the file system directory that the process uses as its current working directory.

The process uses this directory to determine the locations of input and output files with relative path names.

Passivated enterprise beans are placed in the current working directory of the application server on which the beans are running. Make sure the working directory is a known directory under the root directory of the WebSphere Application Server product.

Data type	String

Process execution settings:

Use this page to view or change the process execution settings for a server process that applies to either an application server, a node agent or a deployment manager.

To view this administrative console page for an application server, click **Servers > Application Servers >***server_name*. Then, under Server Infrastructure , click **Java and Process Management > Process Execution**.

To view this administrative console page for a node agent, click **System Administration > Node agents >***node_agent_name*. Then, under Server Infrastructure , click **Java and Process Management > Process Definition > Process Execution**.

To view this administrative console page for a deployment manager, click **System Administration > Deployment manager**. Then, under Server Infrastructure , click **Java and Process Management > Process Definition > Process Execution**.

Process Priority:

Specifies the operating system priority for the process. The administrative process that launches the server must have root operating system authority in order to honor this setting.

Data type	Integer
Default	20 for WebSphere Application Server on all operating systems.

UMASK:

Specifies the user mask under which the process runs (the file-mode permission mask).

Data type	Integer

Run As User:

Specifies the user that the process runs as.

Data type	String

Run As Group:

Specifies the group that the process is a member of and runs as.

On OS/400, the Run As Group setting is ignored.

Data type	String

Run In Process Group:

Specifies a specific process group for the process. This process group is useful for such things as processor partitioning. A system administrator can assign a process group to run on, for example, 6 of 12 processors. The default (0) is not to assign the process to any specific group.

On OS/400, the Run In Process Group setting is ignored.

Data type	Integer
Default	0

Process logs settings:

Use this page to view or change settings for specifying the files to which standard out and standard error streams write.

To view this administrative console page, click **Servers > Application Servers >***server_name*. Then, under Troubleshooting, click **Logging and Tracing > Process Logs**.

Stdout File Name:

Specifies the file to which the standard output stream is directed. The file name can include a symbolic path name defined in the variable entries.

Use the field on the configuration tab to specify the file name. Use the field on the Runtime tab to select a file for viewing. View the file by clicking **View**.

Direct server output to the administrative console or to the process that launched the server, by either deleting the file name or specifying `console` on the configuration tab.

Data type	String
Units	File path name

Stderr File Name:

Specifies the file to which the standard error stream is directed. The file name can include a symbolic path name defined in the variable entries.

Use the field on the configuration tab to specify the file name. Use the field on the runtime tab to select a file for viewing. View the file by clicking **View**.

Data type	String
Units	File path name

Monitoring policy settings:

Use this page to view or change settings that control how the node agent monitors and restarts a process.

To view this administrative console page, click **Servers > Application Servers >***server_name*. Then, under Server Infrastructure, click **Java and Process Management > Process Definition > Monitoring Policy**.

Maximum Startup Attempts:

Specifies the maximum number of times to attempt to start the application server before giving up.

Data type	Integer

Ping Interval:

Specifies the frequency of communication attempts between the parent process, such as the node agent, and the process it has spawned, such as an application server. Adjust this value based on your requirements for restarting failed servers. Decreasing the value detects failures sooner; increasing the value reduces the frequency of pings, reducing system overhead.

Data type	Integer
Range	Set the value greater than or equal to 0 (zero) and less than 2147483.

Ping Timeout:

When a parent process is spawning a child process, such as when a process manager spawns a server, the parent process pings the child process to see whether the child was spawned successfully. This value specifies the number of seconds that the parent process should wait (after pinging the child process) before assuming that the child process failed.

Data type	Integer
Units	Seconds
Range	Set the value greater than or equal to 0 (zero) and less than 2147483.

Automatic Restart:

Specifies whether the process should restart automatically if it fails. The default is to restart the process automatically.

Data type	Boolean
Default	true

Node Restart State:

Specifies the desired state for the process after the node completely shuts down and restarts.

Data type	String
Default	STOPPED
Range	Valid values are STOPPED, RUNNING, or PREVIOUS. If you want the process to return to its current state after the node restarts, use PREVIOUS.

Automatically restarting server processes

There are several server processes related to WebSphere Application Server products that the operating system can monitor and automatically restart when the server processes stop abnormally. This task describes how to set up these *monitored* processes.

To set up this function on a Linux or UNIX-based operating system, you must have root authority to edit the inittab file.

On a Windows operating system, you must belong to the Administrator group and have the following advanced user rights:

- Act as part of the operating system
- Log on as a service

The Installation wizard grants you the user rights if your user ID is part of the administrator group. If you are running on a Microsoft Windows 2000 Operating System, the Installation wizard displays a message that states that although the advanced user rights are now effective, they do not display as effective until the next time you log on to the Windows machine.

You can also add the advanced user rights manually if you are performing a silent installation on a Windows platform. For example, to grant the user rights to your administrator group user ID on a Windows 2000 Server platform, perform the following procedure:

1. Click **Administrative Tools** in the Control Panel.
2. Click **Local Security Policy**.
3. Click **Local Policies**.
4. Click **User Rights Assignments**.
5. Right click **Act as part of the operating system**.
6. Click **Security**.
7. Click **Add**.
8. Click your user ID.

9. Click **Add**.
10. Click **OK**.
11. Click **OK**.
12. Right click **Log on as a service**.
13. Click **Security**.
14. Click **Add**.
15. Click **OK**.
16. Click **OK**.
17. Reboot your machine to make the settings effective.

Consult your Windows help system for more information.

You can use this function to automatically restart Express servers. You can restart the ***server1*** process, for example.

You must manually create a shell script that automatically starts any of the processes previously mentioned, on a Linux and UNIX-based operating system. Each Windows service or UNIX shell script controls a single process, such as a stand-alone WebSphere Application Server instance. Multiple stand-alone Application Server processes require multiple Windows service or UNIX scripts, which you can define.

If you do not install the WebSphere Application Server base product as a Windows service during installation, you can use the **WASService** command in the *install_root*/bin directory to do so at a later time. You can use the tool to add any WebSphere Application Server process as a Windows service. The operating system can then monitor each server process and restart the process if it stops.

1. **Use the installation wizard** to set up a Windows service to automatically monitor and restart processes related to the WebSphere Application Server product.
   - Perform the following procedure from the installation wizard to select services that the installation wizard can set up:
     a. Click **Run WebSphere Application Server as a service**.

        If you select this option, the installation wizard creates the following service during the installation:

        IBMWAS6Service - *node_name*

        The **IBMWAS6Service -***node_name* service controls the *node_name* process.

        After you complete and verify the installation, use the Windows Services panel to change the **IBMWAS6Service -***node_name* service to an automatic startup type.
        1) Right click **IBMWAS6Service -***node_name* and click **Properties**.
        2) Click **Automatic** from the **Startup type** list box and click **OK**.

     b. Click **Run IBM HTTP Server as a service**.

        Select this option on the machine where you are installing the IBM HTTP Server.

        If you select this option, the installation wizard creates the following services during the installation:
        – **IBM HTTP Server 2.0.*x***
        – **IBM HTTP Administration 2.0.*x***

        The installation wizard defines the startup type of these services as **automatic**. It is not necessary for you to change the type from manual to automatic.

     c. Enter your user ID and password and click **Next**.

     In a coexistence environment, you can change the default service names to make them unique. In a same version coexistence scenario for IBM HTTP Server 2.0.x on a Windows platform, you cannot use the default service names created by the installer because they are common.

     To work around this problem:

a. Install the first copy of IBM HTTP Server, either by itself or with WebSphere Application Server and select to install the services.
b. Customize the service names for the first install by running the following commands from the first install location:

```
apache -k install -n "IHS 2.0(1)"
apache -k install -f conf\admin.conf -n "IHS 2.0 Administration (1)"
```

c. Edit the AdminAlias directive in the *installLocation 1*`\conf\admin.conf` file to point to the new service name, such as **IHS 2.0(1)**.
d. Remove the default service names installed by the first install by running the following commands:

```
apache -k uninstall -n "IBM HTTP Server 2.0"
apache -k uninstall -n "IBM HTTP Administration 2.0"
```

e. Install the second copy of IBM HTTP Server, either by itself or with WebSphere Application Server. The default service names correspond to the second install.

Note: Customized service names must be unique on your system.

2. **After installing**, you can use the WASService.exe utility in the *install_root*`\bin` directory to manually define a Windows service for another installation instance or for another configuration instance of the server1 process.

You can use the **net start** and **net stop** commands to control the IBM HTTP Server services on a Windows system. For more information about these commands, see the Windows help file. Access these commands from the Start menu, clicking **Start > Programs > IBM HTTP Server**.

You can also use the **Start the Server** and **Stop the Server** commands to control the IBM WebSphere Application Server process on a Windows system. Access these commands from the Start menu, clicking **Start > Programs > IBM WebSphere > Application Server V6**.

Processes started by a **startServer**command are not running as monitored processes, regardless of how you have configured them.

For example, you can configure a server1 process as a monitored process. However, if you start the server1 process using the **startServer** command, the operating system does not monitor or restart the server1 process because the operating system did not originally start the process as a monitored process.

Return to Defining application server processes to continue.

WASService command:

The **WASService** command line tool lets you create a Windows service for any WebSphere Application Server Java process.

You can create Windows services for WebSphere Application Server Java processes. Potential Windows services include the following server processes:

- The default server1 process on an application server node
- Application server processes that you create on an application server node

When the installation wizard creates a Windows service, the uninstaller program can remove the Windows service. If you use the **WASService** command to create a service yourself, it is your responsibility to remove the service when it is no longer valid. The uninstaller program does not remove Windows services that you create with the **WASService** command.

Location of the command file: The `WASService.exe` command file is located in the *install_root*`\bin` directory.

Command syntax:

WASService.exe command syntax for starting an existing service

The command syntax is as follows:

```
WASService.exe [-start] "service_name" [optional startServer.bat parameters]
```

WASService.exe command syntax for creating a service or updating an existing service

The command syntax is as follows:

```
WASService.exe -add "service_name"
                 -serverName server
                 -profilePath server_profile_directory

                [-wasHome  install_root]
             [-configRoot configuration_repository_directory]
               [-startArgs additional_start_arguments]
               [-stopArgs additional_stop_arguments]
               [-userid user_id -password password]
               [-logFile service_log_file]
               [-logRoot server_log_directory]
               [-restart true | -restart false]
               [-startType automatic | manual | disabled]
```

WASService.exe command syntax for deleting a service

The command syntax is as follows:

```
WASService.exe -remove "service_name"
```

WASService.exe command syntax for stopping a running service

The command syntax is as follows:

```
WASService.exe -stop "service_name" [optional stopServer.bat parameters]
```

WASService.exe command syntax for retrieving service status

The command syntax is as follows:

```
WASService.exe -status "service_name"
```

WASService.exe command syntax for encoding parameters

The command syntax is as follows:

```
WASService.exe -encodeParams "service_name"
```

Parameters: Supported arguments include:

-add *"service_name"*
Creates a service named *service_name* or updates an existing Windows service. The syntax is the same for both cases.

-configRoot *configuration_repository_directory*
Optional parameter that identifies the configuration directory of the installation root directory of a WebSphere Application Server product.

-encodeParams *service_name*
Optional parameter that forces the service to encode the -startArgs and -stopArgs so that the arguments cannot be determined by editing the registry. Use the parameter when creating a service with the -add parameter by adding -encodeParams to the command line with no arguments. Or encode the parameters of an existing service:

```
WASService -encodeParams service_name
```

-logFile *service_log_file*
Optional parameter that identifies a log file that the **WASService** command uses to record its activity.

-logRoot *server_log_directory*
Required parameter that identifies the server log directory for the profile. The **WASService** command looks for a file named `server_name.pid` to determine if the server is running.

-profilePath *server_profile_directory*
Specifies the directory path of the profile that defines the server process.

-remove *service_name*
Deletes the specified service.

-restart true | false
Restarts the existing service automatically if the service fails when set to true.

-serverName *Server_name*
Identifies the server that the service controls.

-start *"service_name"* **[optional startServer.bat parameters]**
Starts the existing service.

-startArgs *additional_start_arguments*
Optional parameter that identifies additional parameters.

-startType automatic | manual | disabled
Defines the startup type of the new service. An automatic startup type starts automatically when the system starts or when the service is called for the first time. You must start a manual service before the operating system can load it and make it available. You cannot start a disabled service before changing the startup type.

-status *service_name*
Returns the current status of the service, which includes whether the service is running or stopped.

-stop *service_name* **[optional stopServer.bat parameters]**
Stops the specified service.

-stopArgs *additional_stop_arguments*
Optional parameter that identifies additional parameters.

-userid *user_ID* **-password** *password*
Optional parameters that identify a privileged user ID and password that the Windows service will run as.

-wasHome *install_root*
Optional parameter that identifies the installation root directory of the WebSphere Application Server product.

Default names for Windows services that are created by the wizard: The name of the Windows service that is created by the Installation wizard is `IBM WebSphere Application Server V6 - DefaultNode`.

Viewing the Windows services panel: To view Windows services, open the Control panel and click **Administrative Tools > Services**. Select a service to view information about it. Right click the service and click **Properties**. Four tabs provide information and functionality. For example, select the **Setup type** field on the **General** tab to change the setup type.

Examples:
Creating an Application Server service

This example creates a service called *IBM WebSphere Application Server V6 - server2* that starts an Application Server process:

```
WASService -add server2
           -servername server2
           -profilePath "C:\Program Files\IBM\WebSphere\AppServer\
                     profiles\CustomProfile"
           -wasHome "C:\Program Files\IBM\WebSphere\AppServer"
           -logfile "C:\Program Files\IBM\WebSphere\AppServer\
                        profiles\CustomProfile\logs\startNode.log"
           -logRoot "C:\Program Files\IBM\WebSphere\AppServer\
                        profiles\CustomProfile\logs"
           -restart true
```

After entering the command, messages that are similar to those in the following example display in the command window:

```
Adding Service: server2
        Config Root: C:\Program Files\IBM\WebSphere\AppServer\
                        profiles\CustomProfile\config
        Server Name: server2
        Profile Path: C:\Program Files\IBM\WebSphere\AppServer\
                        profiles\CustomProfile
        Was Home: C:\Program Files\IBM\WebSphere\AppServer\
        Start Args:
        Restart: 1
IBM WebSphere Application Server V6 - server2 service successfully added.
```

Updating an existing Application Server service

This example updates an existing service called IBM WebSphere Application Server V6 - server2 with additional stop arguments, username and password. The user name and password are required by the **stopServer** command to stop the application server with security enabled.

```
WASService -add server2
           -servername server2
           -profilePath "C:\Program Files\IBM\WebSphere\AppServer\
                     profiles\CustomProfile"
           -stopArgs "-username user_name  -password password"
           -encodeParams server2
```

Starting and stopping a server process after creating a Windows service: If you issue the **startServer server1** command or the **stopServer server1** after creating a Windows service for server1, a message that is similar to the following example displays:

```
Because server1 is registered to run as a Windows Service, the
request to start this server will be completed by starting the
associated Windows Service.
```

Stopping a server after enabling security

If you enable security while a Windows service is running, you cannot stop the server from the command line, even when using the username and password parameters on the **stopServer** command. A message similar to the following example is displayed:

```
Could not stop the IBM WebSphere Application Server V6 -
server_name service on Local Computer. The service
did not return an error. This could be an internal Windows
error or an internal service error. If the problem persists,
contact your system administrator.
```

The problem is due to the service control of the process. You must change the service to use the proper stop-server arguments for a secure server.

Use the -stopArgs parameter and the -encodeParams parameter to update the service as described in the ″Updating an existing application server service″ example.

Java virtual machines (JVMs)

The Java virtual machine (JVM) is an interpretive computing engine responsible for running the byte codes in a compiled Java program. The JVM translates the Java byte codes into the native instructions of the host machine. The application server, being a Java process, requires a JVM in order to run, and to support the Java applications running on it. JVM settings are part of an application server configuration.

Using the JVM

As part of configuring an application server, you might define settings that enhance your system's use of the Java virtual machine (JVM).

To view and change the JVM configuration for an application server's process, use the Java Virtual Machine page of the administrative console or use the wsadmin tool to change the configuration through scripting.

1. Access the Java Virtual Machine page.
   a. Click **Servers > Application Servers** in the console navigation tree.
   b. On the Application Server page, click on the name of the server whose JVM settings you want to configure.
   c. On the settings page for the selected application server, click **Java and Process Management > Process Definition**.
   d. On the Process Definition page, click **Java Virtual Machine**.
2. On the Java Virtual Machine page, specify values for the JVM settings as needed and click **OK**.
3. Click **Save** on the console task bar.
4. Restart the application server.

″"Configuring application servers for UTF-8 encoding" on page 112″ provides an example that involves specifying a value for the **Generic JVM Arguments** property on the Java Virtual Machine page to enable UTF-8 encoding on an application server. Enabling UTF-8 allows multiple language encoding support to be used in the administrative console.

″"Configuring JVM sendRedirect calls to use context root" on page 159″ provides an example that involves defining a property for the JVM.

Java virtual machine settings

Use this page to view and change the Java virtual machine (JVM) configuration for the application server's process.

To view this administrative console page, click **Servers > Application Servers >***server_name* **> Process Definition > Java Virtual Machine**.

Classpath:

Specifies the standard class path in which the Java virtual machine code looks for classes.

Enter each classpath entry into a table row. You do not need to add the colon or semicolon at the end of each entry.

Data type	String
Units	Class path

Boot Classpath:

Specifies bootstrap classes and resources for JVM code. This option is only available for JVM instructions that support bootstrap classes and resources. You can separate multiple paths by a colon (:) or semi-colon (;), depending on operating system of the node.

Data type	String

Verbose Class Loading:

Specifies whether to use verbose debug output for class loading. The default is not to enable verbose class loading.

Data type	Boolean
Default	false

Verbose Garbage Collection:

Specifies whether to use verbose debug output for garbage collection. The default is not to enable verbose garbage collection.

Data type	Boolean
Default	false

Verbose JNI:

Specifies whether to use verbose debug output for native method invocation. The default is not to enable verbose Java Native Interface (JNI) activity.

Data type	Boolean
Default	false

Initial Heap Size:

Specifies the initial heap size available to the JVM code, in megabytes.

Increasing the minimum heap size can improve startup. The number of garbage collection occurrences are reduced and a 10% gain in performance is realized.

Increasing the size of the Java heap improves throughput until the heap no longer resides in physical memory, in general. After the heap begins swapping to disk, Java performance suffers drastically.

Data type	Integer
Default	The default is 50.

Maximum Heap Size:

Specifies the maximum heap size available to the JVM code, in megabytes.

Increasing the heap size can improve startup. By increasing heap size, you can reduce the number of garbage collection occurrences with a 10% gain in performance.

Increasing the size of the Java heap improves throughput until the heap no longer resides in physical memory, in general. After the heap begins swapping to disk, Java performance suffers drastically. Set the maximum heap size low enough to contain the heap within physical memory.

Data type	Integer
Default	0 for iSeries, 256 for all other platforms. Keep the value low enough to avoid paging or swapping-out-memory-to-disk.

Run HProf:

This setting applies to base WebSphere Application Server only. It specifies whether to use HProf profiler support. To use another profiler, specify the custom profiler settings using the HProf Arguments setting. The default is not to enable HProf profiler support.

If you set the Run HProf property to true, then you must specify command-line profiler arguments as values for the HProf Arguments property.

Data type	Boolean
Default	false

HProf Arguments:

This setting applies to base WebSphere Application Server only. It specifies command-line profiler arguments to pass to the JVM code that starts the application server process. You can specify arguments when HProf profiler support is enabled.

HProf arguments are only required if the Run HProf property is set to true.

Data type	String

Debug Mode:

Specifies whether to run the JVM in debug mode. The default is not to enable debug mode support.

If you set the Debug Mode property to true, then you must specify command-line debug arguments as values for the Debug Arguments property.

Data type	Boolean
Default	false

Debug Arguments:

Specifies command-line debug arguments to pass to the JVM code that starts the application server process. You can specify arguments when Debug Mode is enabled.

Debug arguments are only required if the Debug Mode property is set to true. If you enable debugging on multiple application servers on the same server, make sure that the servers are using different `address` arguments, which define the port for debugging. For example, if you enable debugging on two servers and leave the default debug port for each server as `address=7777`, the servers could fail to start properly.

Data type	String
Units	Java command-line arguments

Generic JVM Arguments:

Specifies command line arguments to pass to the Java virtual machine code that starts the application server process.

The following are optional command line arguments that you can use by entering them into the **General JVM Arguments** field. If you enter more than one argument, separate each argument by a space.

Note: If the argument says it is for the IBM Developer Kit only, you cannot use the argument with another JVM, such as the Sun JDK or the HP JDK.

- **-Xquickstart:** You can use **-Xquickstart** for initial compilation at a lower optimization level than in default mode. Later, depending on sampling results, you can recompile to the level of the initial compile in default mode. Use **-Xquickstart** for applications where early moderate speed is more important than long run throughput. In some debug scenarios, test harnesses and short-running tools, you can improve startup time between 15-20%.

  The **-Xquickstart** option is not supported on OS/400.
- **-Xverify:none:** When using this value, the class verification stage is skipped during class loading . By using **-Xverify:none** with the just in time (JIT) compiler enabled, startup time is improved by 10-15%.

  The **-Xverify:none** option is not supported on OS/400.
- **-Xnoclassgc:** You can use this value to disable class garbage collection, which leads to more class reuse and slightly improved performance. The trade-off is that you won't be collecting the resources owned by these classes. You can monitor garbage collection using the verbose:gc configuration setting, which will output class garbage collection statistics. Examining these statistics will help you understand the trade-off between the reclaimed resources and the amount of garbage collection required to reclaim the resources. However, if the same set of classes are garbage collected repeatedly in your workload, you should disable garbage collection. Class garbage collection is enabled by default.
- **-Xgcthreads:** You can use several garbage collection threads at one time, also known as *parallel garbage collection*. When entering this value in the **Generic JVM Arguments** field, also enter the number of processors that your machine has, for example, `-Xgcthreads=`*number_of_processors*. On a node with *n* processors, the default number of threads is *n*. You should use parallel garbage collection if your machine has more than one processor. This argument is valid only for the IBM Developer Kit.

  The **-Xgcthreads** option is not supported on OS/400.
- **-Xnocompactgc:** This value disables heap compaction which is the most expensive garbage collection operation. Avoid compaction in the IBM Developer Kit. If you disable heap compaction, you eliminate all associated overhead.
- **-Xinitsh:** You can use this value to set the initial heap size where class objects are stored. The method definitions and static fields are also stored with the class objects. Although the system heap size has no upper bound, set the initial size so that you do not incur the cost of expanding the system heap size, which involves calls to the operating system memory manager. You can compute a good initial system heap size by knowing the number of classes loaded in the WebSphere Application Server product, which is about 8,000 classes, and their average size. Having knowledge of the applications helps you include them in the calculation. You can use this argument only with the IBM Developer Kit.
- **-Xgpolicy:** You can use this value to set the garbage collection policy. If the garbage collection policy (gcpolicy) is set to `optavgpause`, concurrent marking is used to track application threads starting from the stack before the heap becomes full. The garbage collector pauses become uniform and long pauses are not apparent. The trade-off is reduced throughput because threads might have to do extra work. The default, recommended value is `optthruput`. Enter the value as `-Xgcpolicy:[optthruput|optavgpause]`. You can use this argument only with the IBM Developer Kit.
- **-XX:** The Sun-based Java Development Kit (JDK) Version 1.4.2 has generation garbage collection, which allows separate memory pools to contain objects with different ages. The garbage collection cycle collects the objects independently from one another depending on age. With additional parameters, you can set the size of the memory pools individually. To achieve better performance, set the size of the pool containing short lived objects so that objects in the pool do not live through more then one garbage collection cycle. The size of new generation pool is determined by the `NewSize` and `MaxNewSize` parameters. Objects that survive the first garbage collection cycle are transferred to another pool. The size of the survivor pool is determined by parameter `SurvivorRatio`. If garbage collection becomes a bottleneck, you can try customizing the generation pool settings. To monitor garbage collection statistics,

use the object statistics in Tivoli Performance Viewer or the verbose:gc configuration setting. Enter the following values: `-XX:NewSize (lower bound)` , `-XX:MaxNewSize (upper bound)`, and `-XX:SurvivorRatio=NewRatioSize`. The default values are:`NewSize=2m MaxNewSize=32m SurvivorRatio=2` However, if you have a JVM with more than 1 GB heap size, you should use the values: `-XX:newSize=640m -XX:MaxNewSize=640m -XX:SurvivorRatio=16`, or set 50 to 60% of total heap size to a new generation pool.

  The **-XX** option is not supported on OS/400.
- **-Xminf:** You can use this value to specify the minimum free heap size percentage. The heap grows if the free space is below the specified amount. In reset enabled mode, this option specifies the minimum percentage of free space for the middleware and transient heaps. This is a floating point number, 0 through 1. The default is .3 (30%).
- **-server | -client:** Java HotSpot Technology in the Sun-based Java Development Kit (JDK) Version 1.4.2 introduces an adaptive JVM containing algorithms for optimizing byte code execution over time. The JVM runs in two modes, **-server** and **-client**. If you use the default **-client** mode, there will be a faster startup time and a smaller memory footprint, but lower extended performance. You can enhance performance by using **-server** mode if a sufficient amount of time is allowed for the HotSpot JVM to warm up by performing continuous execution of byte code. In most cases, use **-server** mode, which produces more efficient run-time execution over extended periods. You can monitor the process size and the server startup time to check the difference between **-client** and**-server**.

  The **-server | -client** option is not supported on OS/400.

Data type	String
Units	Java command line arguments

Executable JAR File Name:

Specifies a full path name for an executable JAR file that the JVM code uses.

Data type	String
Units	Path name

Disable JIT:

Specifies whether to disable the just in time (JIT) compiler option of the JVM code.

If you disable the JIT compiler, throughput decreases noticeably. Therefore, for performance reasons, keep JIT enabled.

Data type	Boolean
Default	false (JIT enabled)
Recommended	JIT enabled

Operating System Name:

Specifies JVM settings for a given operating system. When started, the process uses the JVM settings for the operating system of the server.

Data type	String

Configuring JVM sendRedirect calls to use context root

If the com.ibm.websphere.sendredirect.compatibility property is not set and your application servlet code has statements such as *sendRedirect("/home.html")*, your Web browser might display messages such as *Error 404: No target servlet configured for uri: /home.html*. To instruct the server not to use the Web server's document root and to use instead the Web application's context root for sendRedirect() calls, configure the JVM by setting the com.ibm.websphere.sendredirect.compatibility property to a `true` or `false` value.

1. Access the settings page for a property of the JVM.
   a. Click **Servers > Application Servers** in the console navigation tree.
   b. On the Application Server page, click on the name of the server whose JVM settings you want to configure.
   c. On the settings page for the selected application server, under Server Infrastructure, click **Java and Process Management > Process Definition**.
   d. On the Process Definition page, click **Java Virtual Machine**.
   e. On the Java Virtual Machine page, click **Custom Properties**.
   f. On the Custom Properties page, click **New**.
2. On the settings page for a property, specify a name of `com.ibm.websphere.sendredirect.compatibility` and either `true` or `false` for the value, then click **OK**.
3. Click **Save** on the console task bar.
4. Stop the application server and then restart the application server.

Setting custom JVM properties

In the WebSphere Application Server administrative console, you can change the values of the following custom JVM properties:

com.ibm.websphere.network.useMultiHome

For a distributed platform:

Set this property in a multihomed environment where WebSphere Application Server is restricted to listen only on a specific IP address for Discovery and SOAP messages.

The settings for the **com.ibm.websphere.network.useMultiHome** property are as follows:

- Setting this property to `false` specifies that WebSphere Application Server will listen on all IP addresses on the host for Discovery and SOAP messages.
- Setting this property to `true` specifies that WebSphere Application Server will only listen on the configured host name for Discovery and SOAP messages. If you set this property to `true`, you should have a host name configured on WebSphere Application Server that resolves to a specific IP address.
- Setting this property to `null` specifies that WebSphere Application Server will only listen on the default IP address only.

If you cannot contact the server, check the setting for **com.ibm.websphere.network.useMultihome** to ensure it is correct.

You can change the value through the administrative console. Modify the defaults by setting the value for the server, deployment manager, and node agent. In order for these changes to take place, you must restart the server.

Steps for this task

1. To set this property, connect to the administrative console and navigate to the indicated page.

Application server	**Servers > Application Servers >***server1***> Process Definition >***Control* **> Java Virtual Machine > Custom Properties**
Deployment manager	**System Administration > Deployment Manager > Process definition >** *Control* **> Java Virtual Machine > Custom Properties**

Node agent	**System Administration >Node Agent >** *nodeagent* **> Process definition >***Control* **> Java Virtual Machine > Custom Properties**

2. If the **com.ibm.websphere.network.useMultiHome** property is not present in the list, create a new property name and indicate its value.
3. Restart the server.

com.ibm.websphere.deletejspclasses

Deletes JavaServer Pages classes for all applications after those applications have been deleted or updated. By default, the value of this property is `true`.

Steps for this task

1. Connect to the administrative console and navigate to the Java Virtual Machine Custom Properties panel.

   For a distributed platform:

Base configuration	**Servers > Application Servers >***server1*. Then, under Server Infrastructure, click **Java and Process Management > Process definition > Java Virtual Machine > Custom Properties**
ND configuration	**System Administration > Node Agents >***nodeagent*. Then, under Server Infrastructure, click **Java and Process Management > Process definition > Java Virtual Machine > Custom Properties**

2. If the **com.ibm.websphere.deletejspclasses** property is not present in the list, create a new property name.
3. Enter the name and value.

com.ibm.websphere.deletejspclasses.delete

Deletes JavaServer Pages classes for all applications after those applications have been deleted, but not after they have been updated. By default, the value of this property is `true`.

Steps for this task

1. Connect to the administrative console and navigate to the Java Virtual Machine Custom Properties panel.

   For a distributed platform:

Base configuration	**Servers > Application Servers >***server1* **> Process definition > Java Virtual Machine > Custom Properties**
ND configuration	**System Administration > Node Agents >***nodeagent*. Then, under Server Infrastructure, click **Java and Process Management > Process definition > Java Virtual Machine > Custom Properties**

2. If the **com.ibm.websphere.deletejspclasses.delete** property is not present in the list, create a new property name.
3. Enter the name and value.

com.ibm.websphere.deletejspclasses.update

Deletes JavaServer Pages classes for all applications after those applications have been updated, but not after they have been deleted. By default, the value of this property is `true`.

Steps for this task

1. Connect to the administrative console and navigate to the Java Virtual Machine Custom Properties panel.

For a distributed platform:

Base configuration	**Servers > Application Servers >***server1*. Then, under Server Infrastructure, click **Java and Process Management > Process definition > Java Virtual Machine > Custom Properties**
ND configuration	**System Administration > Node Agents >***nodeagent*. Then, under Server Infrastructure, click **Java and Process Management > Process definition > Java Virtual Machine> Custom Properties**

2. If the **com.ibm.websphere.deletejspclasses.update** property is not present in the list, create a new property name.
3. Enter the name and value.

Tuning Java virtual machines

The application server, being a Java process, requires a Java virtual machine (JVM) to run, and to support the Java applications running on it. As part of configuring an application server, you can fine-tune settings that enhance system use of the JVM. In addition to the following tuning parameters, see also “Java memory tuning tips” on page 163.

Use the following JVM parameters, including garbage collection options for IBM Developer Kit 1.4.2, to tune the Java virtual machine. For instructions on view and change the JVM configuration , go to “Using the JVM” on page 155. For information on specifying any of the following settings, go to “Java virtual machine settings” on page 155.

- **Specify any or all of the following generic JVM arguments.** These optional command line arguments are passed to the Java virtual machine code that starts the application server process.
  - Quickstart (-Xquickstart)
  - Avoiding class verification (-Xverify:none)
  - Class garbage collection (-Xnoclassgc)
  - Garbage collection threads (-Xgcthreads)
  - Garbage collection policy (-Xgcpolicy)
  - Sun JDK 1.4.2 Generational Garbage Collection (-XX)

    You can find more information about generational garbage collection at http://java.sun.com/docs/hotspot/gc/index.html.
  - Sun Java Development Kit 1.4.2 HotSpot JVM warm-up (-server)
  - Heap compaction (-Xnocompactgc)
  - Initial system heap size (-Xinitsh)
- **Set the initial heap size.**
- **Set the maximum heap size.**

Preparing to host applications

Rather than use the default application server provided with the product, you can configure a new server and set of resources.

The default application server and a set of default resources are available to help you begin quickly. You can choose instead to configure a new server and set of resources. Here is what you need to do in order to set up a run-time environment to support applications.

1. Create an application server.
2. Create a virtual host.
3. Configure a Web container.
4. Configure an EJB container.

5. Create resources for data access.
6. Create a JDBC provider and data source.
7. Create a URL and URL provider.
8. Create a JavaMail session.
9. Create resources for session support.
10. Configure a Session Manager.

Java memory tuning tips

Enterprise applications written in the Java language involve complex object relationships and utilize large numbers of objects. Although, the Java language automatically manages memory associated with object life cycles, understanding the application usage patterns for objects is important. In particular, verify the following:

- The application is not over-utilizing objects
- The application is not leaking objects
- The Java heap parameters are set properly to handle a given object usage pattern

Understanding the effect of garbage collection is necessary to apply these management techniques.

The garbage collection bottleneck

Examining Java garbage collection gives insight to how the application is utilizing memory. Garbage collection is a Java strength. By taking the burden of memory management away from the application writer, Java applications are more robust than applications written in languages that do not provide garbage collection. This robustness applies as long as the application is not abusing objects. Garbage collection normally consumes from 5% to 20% of total execution time of a properly functioning application. If not managed, garbage collection is one of the biggest bottlenecks for an application, especially when running on symmetric multiprocessing (SMP) server machines. The Java virtual machine (JVM) uses a parallel garbage collector to fully exploit an SMP during most garbage collection cycles where the Sun HotSpot 1.3.1 JVM has a single-threaded garbage collector. For more information about garbage collection in a Solaris operating environment see ″Performance: Resources for learning″ in the information center.

The garbage collection gauge

You can use garbage collection to evaluate application performance health. By monitoring garbage collection during the execution of a fixed workload, you gain insight as to whether the application is over-utilizing objects. Garbage collection can even detect the presence of memory leaks.

You can monitor garbage collection statistics using object statistics in the Tivoli Performance Viewer, or using the **verbose:gc** JVM configuration setting. The **verbose:gc** format is not standardized between different JVMs or release levels. For a description of the IBM verbose:gc output and more information about the IBM garbage collector, see ″Performance: Resources for learning″ in the information center.

For this type of investigation, set the minimum and maximum heap sizes to the same value. Choose a representative, repetitive workload that matches production usage as closely as possible, user errors included.

To ensure meaningful statistics, run the fixed workload until the application state is steady. It usually takes several minutes to reach a steady state.

Detecting over-utilization of objects

You can use the Tivoli Performance Viewer to check if the application is overusing objects, by observing the counters for the JVM runtime. You have to set the **-XrunpmiJvmpiProfiler** command line option, as well as the JVM module maximum level in order to enable the Java virtual machine profiler interface

(JVMPI) counters. The best result for the average time between garbage collections is at least 5-6 times the average duration of a single garbage collection. If you do not achieve this number, the application is spending more than 15% of its time in garbage collection.

If the information indicates a garbage collection bottleneck, there are two ways to clear the bottleneck. The most cost-effective way to optimize the application is to implement object caches and pools. Use a Java profiler to determine which objects to target. If you can not optimize the application, adding memory, processors and clones might help. Additional memory allows each clone to maintain a reasonable heap size. Additional processors allow the clones to run in parallel.

Detecting memory leaks

Memory leaks in the Java language are a dangerous contributor to garbage collection bottlenecks. Memory leaks are more damaging than memory overuse, because a memory leak ultimately leads to system instability. Over time, garbage collection occurs more frequently until the heap is exhausted and the Java code fails with a fatal `Out of Memory` exception. Memory leaks occur when an unused object has references that are never freed. Memory leaks most commonly occur in collection classes, such as Hashtable because the table always has a reference to the object, even after real references are deleted.

High workload often causes applications to crash immediately after deployment in the production environment. This is especially true for leaking applications where the high workload accelerates the magnification of the leakage and a memory allocation failure occurs.

The goal of memory leak testing is to magnify numbers. Memory leaks are measured in terms of the amount of bytes or kilobytes that cannot be garbage collected. The delicate task is to differentiate these amounts between expected sizes of useful and unusable memory. This task is achieved more easily if the numbers are magnified, resulting in larger gaps and easier identification of inconsistencies. The following list contains important conclusions about memory leaks:

- **Long-running test**

  Memory leak problems can manifest only after a period of time, therefore, memory leaks are found easily during long-running tests. Short running tests can lead to false alarms. It is sometimes difficult to know when a memory leak is occurring in the Java language, especially when memory usage has seemingly increased either abruptly or monotonically in a given period of time. The reason it is hard to detect a memory leak is that these kinds of increases can be valid or might be the intention of the developer. You can learn how to differentiate the delayed use of objects from completely unused objects by running applications for a longer period of time. Long-running application testing gives you higher confidence for whether the delayed use of objects is actually occurring.
- **Repetitive test**

  In many cases, memory leak problems occur by successive repetitions of the same test case. The goal of memory leak testing is to establish a big gap between unusable memory and used memory in terms of their relative sizes. By repeating the same scenario over and over again, the gap is multiplied in a very progressive way. This testing helps if the number of leaks caused by the execution of a test case is so minimal that it is hardly noticeable in one run.

  You can use repetitive tests at the system level or module level. The advantage with modular testing is better control. When a module is designed to keep the private module without creating external side effects such as memory usage, testing for memory leaks is easier. First, the memory usage before running the module is recorded. Then, a fixed set of test cases are run repeatedly. At the end of the test run, the current memory usage is recorded and checked for significant changes. Remember, garbage collection must be suggested when recording the actual memory usage by inserting System.gc() in the module where you want garbage collection to occur, or using a profiling tool, to force the event to occur.
- **Concurrency test**

  Some memory leak problems can occur only when there are several threads running in the application. Unfortunately, synchronization points are very susceptible to memory leaks because of the added complication in the program logic. Careless programming can lead to kept or unreleased references.

The incident of memory leaks is often facilitated or accelerated by increased concurrency in the system. The most common way to increase concurrency is to increase the number of clients in the test driver.

Consider the following points when choosing which test cases to use for memory leak testing:

- A good test case exercises areas of the application where objects are created. Most of the time, knowledge of the application is required. A description of the scenario can suggest creation of data spaces, such as adding a new record, creating an HTTP session, performing a transaction and searching a record.
- Look at areas where collections of objects are used. Typically, memory leaks are composed of objects within the same class. Also, collection classes such as Vector and Hashtable are common places where references to objects are implicitly stored by calling corresponding insertion methods. For example, the get method of a Hashtable object does not remove its reference to the retrieved object.

Tivoli Performance Viewer can help find memory leaks. For best results, repeat experiments with increasing duration, like 1000, 2000, and 4000-page requests. The Tivoli Performance Viewer graph of used memory should have a sawtooth shape. Each drop on the graph corresponds to a garbage collection. There is a memory leak if one of the following occurs:

- The amount of memory used immediately after each garbage collection increases significantly. The sawtooth pattern looks more like a staircase.
- The sawtooth pattern has an irregular shape.

Also, look at the difference between the number of objects allocated and the number of objects freed. If the gap between the two increases over time, there is a memory leak.

Heap consumption indicating a possible leak during a heavy workload (the application server is consistently near 100% CPU utilization), yet appearing to recover during a subsequent lighter or near-idle workload, is an indication of heap fragmentation. Heap fragmentation can occur when the JVM can free sufficient objects to satisfy memory allocation requests during garbage collection cycles, but the JVM does not have the time to compact small free memory areas in the heap to larger contiguous spaces.

Another form of heap fragmentation occurs when small objects (less than 512 bytes) are freed. The objects are freed, but the storage is not recovered, resulting in memory fragmentation until a heap compaction has been run.

To avoid heap fragmentation, turn on the -Xcompactgc flag in the JVM advanced settings command line arguments. The -Xcompactgc function verifies that each garbage collection cycle eliminates fragmentation. However, compaction is a relatively expensive operation. See the heap compaction command line argument (-Xnocompactgc) in “Java virtual machine settings” on page 155 for more information.

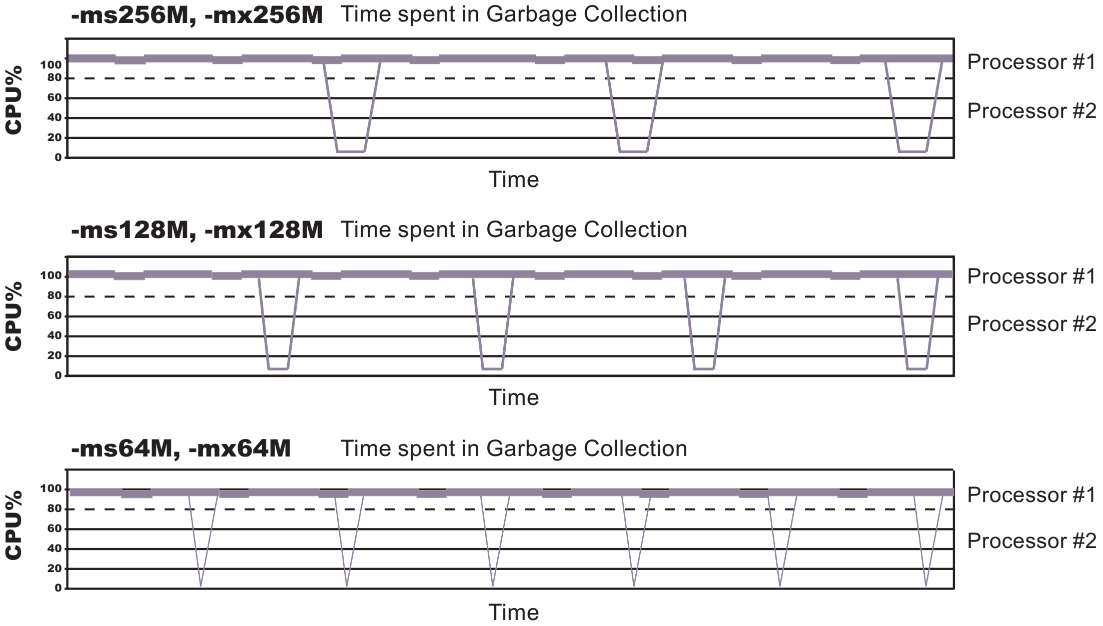
Java heap parameters

The Java heap parameters also influence the behavior of garbage collection. Increasing the heap size supports more object creation. Because a large heap takes longer to fill, the application runs longer before a garbage collection occurs. However, a larger heap also takes longer to compact and causes garbage collection to take longer. Refer to the sections on Java Heap sizes in “Java virtual machine settings” on page 155 for more information.

For performance analysis, the initial and maximum heap sizes should be equal.

When tuning a production system where the working set size of the Java application is not understood, a good starting value for the initial heap size is 25% of the maximum heap size. The JVM then tries to adapt the size of the heap to the working set size of the application.

Varying Java Heap Settings



The illustration represents three CPU profiles, each running a fixed workload with varying Java heap settings. In the middle profile, the initial and maximum heap sizes are set to 128MB. Four garbage collections occur. The total time in garbage collection is about 15% of the total run. When the heap parameters are doubled to 256MB, as in the top profile, the length of the work time increases between garbage collections. Only three garbage collections occur, but the length of each garbage collection is also increased. In the third profile, the heap size is reduced to 64MB and exhibits the opposite effect. With a smaller heap size, both the time between garbage collections and the time for each garbage collection are shorter. For all three configurations, the total time in garbage collection is approximately 15%. This example illustrates an important concept about the Java heap and its relationship to object utilization. There is always a cost for garbage collection in Java applications.

Run a series of test experiments that vary the Java heap settings. For example, run experiments with 128MB, 192MB, 256MB, and 320MB. During each experiment, monitor the total memory usage. If you expand the heap too aggressively, paging can occur. Use the **vmstat** command or the Windows NT or Windows 2000 Performance Monitor to check for paging. If paging occurs, reduce the size of the heap or add more memory to the system. When all the runs are finished, compare the following statistics:

- Number of garbage collection calls
- Average duration of a single garbage collection call
- Ratio between the length of a single garbage collection call and the average time between calls

If the application is not over-utilizing objects and has no memory leaks, the state of steady memory utilization is reached. Garbage collection also occurs less frequently and for short duration.

If the heap free space settles at 85% or more, consider decreasing the maximum heap size values because the application server and the application are under-utilizing the memory allocated for heap.

For more information about garbage collection see ″Performance: Resources for learning″ in the information center.

For current information available from IBM Support on known problems and their resolution, see the IBM Support page.

IBM Support has documents that can save you time gathering information needed to resolve this problem. Before opening a PMR, see the IBM Support page.

Tuning application servers

The WebSphere Application Server contains interrelated components that must be harmoniously tuned to support the custom needs of your end-to-end e-business application.

This group of interrelated components is known as the “Queuing network” on page 27. The queuing network helps the system achieve maximum throughput while maintaining the overall stability of the system.

The follow steps describe various tuning tasks that may improve your application server performance. You can choose to implement any of these application server settings.

- **Tune the object request broker.** An Object Request Broker (ORB) manages the interaction between clients and servers, using the Internet InterORB Protocol (IIOP). It supports client requests and responses received from servers in a network-distributed environment. You can tune the ORB with the following parameters:
  - Set **Pass by reference (com.ibm.CORBA.iiop.noLocalCopies)** as described in “Object Request Broker service settings” on page 1816.
  - Set the **Connection cache minimum (com.ibm.CORBA.MaxOpenConnections)** as described in “Object Request Broker service settings” on page 1816.
  - Set **Maximum size** as described in “Thread pool settings” on page 120
  - Set **com.ibm.CORBA.ServerSocketQueueDepth** as described in “Object Request Broker custom properties” on page 1819.
  - Set the **com.ibm.CORBA.FragmentSize** as described in “Object Request Broker custom properties” on page 1819.

  The “Object Request Broker tuning guidelines” on page 1815 offer tips on using these parameters to tune the ORB.
- **Tune the XML parser definitions.**
  - **Description:** Facilitates server startup by adding XML parser definitions to the `jaxp.properties` and `xerxes.properties` files in the ${*install_root*}/jre/lib directory. The XMLParserConfiguration value might change as new versions of Xerces are provided.
  - **How to view or set:** Insert the following lines in both files:

    ```
    javax.xml.parsers.SAXParserFactory=org.apache.xerces.jaxp.SAXParserFactoryImpl
    javax.xml.parsers.DocumentBuildFactory=org.apache.xerces.jaxp.
              DocumentBuilderFactoryImpl
    org.apache.xerces.xni.parser.XMLParserConfiguration=org.apache.xerces.parsers.
             StandardParserConfiguration
    ```
  - **Default value:** None
  - **Recommended value:** None
- **Tune the dynamic cache service.** Using the dynamic cache service can improve performance. See “Task overview: Using the dynamic cache service to improve performance” on page 1901 for information about using the dynamic cache service and how it can affect your application server performance.
- **Tune the Web container.** The WebSphere Application Server Web container manages all HTTP requests to servlets, JSPs and Web services. Requests flow through a transport chain to the Web container. The transport chain defines the important tuning parameters for performance for the Web container. There is a transport chain for each TCP port that WebSphere Application Server is listening on for HTTP requests. For example, the default HTTP port 9080 is defined in Web container inbound channel chain. Use the following parameters to tune the Web container:
  - HTTP requests are processed by a pool of server threads. The minimum and maximum thread pool size for the Web container can be configured for optimal performance. Generally, 5 to 10 threads per server CPU will provide the best throughput. The number of threads configured does not represent the number of requests WebSphere can process concurrently. Requests are queued in the transport chain when all threads are busy. To specify the thread pool settings:

    1. Click **Servers > Application Servers >***server_name* **Web Container Settings> Web Container > Web container transport chains**.
    2. Select the normal inbound chain for serving requests. This will usually be named WCInboundDefault, on port 9080.
    3. Click **TCP Inbound Channel (TCP_2)**.
    4. Set **Thread Pools** under Related Items.
    5. Select **WebContainer**.
    6. Enter values for **Minimum Size** and **Maximum Size**.
  - The HTTP 1.1 protocol provides a ″keep-alive″ feature to enable the TCP connection between HTTP clients and the server to remain open between requests. By default WebSphere Application Server will close a given client connection after a number of requests or a timeout period. After a connection is closed, it will be recreated if the client issues another request. Early closure of connections can reduce performance. Enter a value for the maximum number of persistent requests to (keep-alive) to specify the number of requests that are allowed on a single HTTP connection. Enter a value for persistent timeouts to specify the amount of time, in seconds, that the HTTP transport channel allows a socket to remain idle between requests. To specify values for Maximum persistent requests and Persistent timeout:
    1. Click **Servers > Application Servers >***server_name* **Web Container Settings> Web Container > Web container transport chains**.
    2. Select the normal inbound chain for serving requests. This will usually be named WCInboundDefault, on port 9080.
    3. Click **HTTP Inbound Channel (HTTP_2)**.
    4. Enter values for **Maximum persistent requests** and **Persistent timeout**.

- **Tune the EJB container.** An EJB container is automatically created when you create an application server. After the EJB container is deployed, you can use the following parameters to make adjustments that improve performance.
  - Set the **Cleanup interval** and the **Cache size** as described in “EJB cache settings” on page 834.
  - **Break CMP enterprise beans into several enterprise bean modules** while assembling EJB modules. See ″Assembling EJB modules″ in the information center for more information.

  See also “EJB method Invocation Queuing” on page 820.

- **Tune the session management.** The installed default settings for session management are optimal for performance. See “Tuning session management” on page 797 and “Tuning parameter settings” on page 798 for more information about tuning session management.

- **Tune the data sources.** A data source is used to access data from the database. The following parameters reveal how the number of physical connections within a connection pool can change performance.
  - Review information on “Connection pooling” on page 1137.
  - Set the **Maximum connection pool** and **Minimum connection pool** as described in “Connection pool settings” on page 1199.
  - Set the **Statement cache size** as described in “Data source settings” on page 1173.

Web services client to Web container optimized communication

To improve performance, there is an optimized communication path between a Web services client application and a Web container that are located in the same application server process. Requests from the Web services client that are normally sent to the Web container using a network connection are delivered directly to the Web container using an optimized local path. The local path is available because the Web services client application and the Web container are running in the same process.

This direct communication eliminates the need for clients and web containers that are in the same process to communicate over the network. For example, a Web services client might be running in an application server. Instead of accessing the network to communicate with the Web container, the Web services client can communicate with the Web container using the optimized local path. This optimized local path improves the performance of the application server by allowing Web services clients and Web containers to communicate without using network transports.

In a clustered environment, there is typically an HTTP server (such as IBM HTTP server) that handles incoming client requests, distributing them to the correct application server in the cluster. The HTTP server uses information about the requested application and the defined virtual hosts to determine which application server receives the request. The Web services client also uses the defined virtual host information to determine whether the request can be served by the local Web container. You must define unique values for the host and port on each application server. You cannot define the values of host and port as wild cards denoted by the asterisk symbol (*) when you enable the optimized communication between the Web services application and the Web container. Using wild cards indicate that the local Web container can handle Web services requests for all destinations.

The optimized local communication path is disabled by default. You can enable the local communication path with the `enableInProcessConnections` custom property. Before configuring this custom property, make sure that you are not using wild cards for host names in your Web container end points. Set this property to **true** in the Web container to enabled the optimized local communication path. When disabled, the Web services client and the Web container communicate using network transports.

For information about how to configure the `enableInProcessConnections` custom property, see the *Developing and deploying applications* PDF.

When the optimized local communication path is enabled, logging of requests through the local path uses the same log attributes as the network channel chain for the Web container. To use a different log file for in process requests than the log file for network requests, use a custom property on the HTTP Inbound Channel in the transport chain. Use the `inProcessLogFilenamePrefix` custom property to specify a string that is added to the beginning of the network log file name to create a file name that is unique. Requests through the local process path are logged to this specified file. For example, if the log filename is `../httpaccess.log` for a network chain, and the `inProcesslLogFilenamePrefix` custom property is set to “local” on the HTTP channel in that transport chain, the local log file name for requests to the host associated with that chain is `/localhttpaccess.log`.

Application servers: Resources for learning

Use the following links to find relevant supplemental information about configuring application servers. The information resides on IBM and non-IBM Internet sites, whose sponsors control the technical accuracy of the information.

These links are provided for convenience. Often, the information is not specific to the IBM WebSphere Application Server product, but is useful all or in part for understanding the product. When possible, links are provided to technical papers and Redbooks that supplement the broad coverage of the release documentation with in-depth examinations of particular product areas.

View links to additional information about:
- Programming instructions and examples
- Programming specifications
- Administration

Programming instructions and examples

Chapter 4. Using the administrative clients

The product provides a variety of administrative clients for deploying and administering your applications and application serving environment, including configurations and logical administrative domains.

- "Using the administrative console"

  The administrative console is a graphical, browser-based tool.
- "Getting started with scripting" on page 186

  Scripting is a non-graphical alternative that you can use to configure and administer your applications and application serving environment. The WebSphere Application Server **wsadmin** tool provides the ability to run scripts. The wsadmin tool supports a full range of product administrative activities.
- "Using Ant to automate tasks" on page 626

  To support using Apache Ant with Java 2 Platform, Enterprise Edition (J2EE) applications running on IBM WebSphere Application Server, the product provides a copy of the Ant tool and a set of Ant tasks that extend the capabilities of Ant to include product-specific functions.
- "Using administrative programs (JMX)" on page 627

  The product supports access to the administrative functions through a set of Java classes and methods, under the Java Management Extensions (JMX) specification. You can write a Java program that performs any of the administrative features of the other administrative clients. You also can extend the basic product administrative system to include your own managed resources.
- "Using command line tools" on page 668

  Several command-line tools are available that you can use to start, stop, and monitor WebSphere server processes and nodes. These tools work on local servers and nodes only. They cannot operate on a remote server or node.

Using the administrative console

The administrative console is a Web-based tool that you use to manage the IBM WebSphere Application Server product as well as the Network Deployment product. The administrative console supports a full range of product administrative activities.

1. Distributed platforms: Start the server for the administrative console.
2. Access the administrative console.
3. Change the session timeout for the administrative console. (Optional)
4. Browse the administrative console.
5. Specify console preferences.
6. Access help.

Starting and stopping the administrative console

This topic describes how to set up the administrative console environment, to access the administrative console, and to log out of the administrative console.

To access the administrative console, you must start it and then log in. After you finish working in the console, save your work and log out.

1. Start the administrative console.
   a. Distributed platforms: Verify that the administrative console runs on the `server1` application server for the WebSphere base product.
   b. Enable cookies in the Web browser that you use to access the administrative console for the administrative console to work correctly.
   c. Distributed platforms: In the same Web browser, type `http://`*`your_fully_qualified_server_name`*`:9060/ibm/console`, where

your_fully_qualified_server_name is the fully qualified host name for the machine that contains the administrative server. When the administrative console is on the local machine, *your_fully_qualified_server_name* can be `localhost` unless security is enabled. On Windows platforms, use the actual host name if `localhost` is not recognized. If security is enabled, your request is redirected to `https://`*`your_fully_qualified_server_name`*`:9043/ibm/console`, where *your_fully_qualified_server_name* is the fully qualified host name for the machine that contains the administrative server.

For a listing of supported Web browsers, see WebSphere Application Server system requirements at

```
http://www.ibm.com/software/webservers/
appserv/doc/latest/prereq.html
```

The Web address appears on two lines for printing purposes. Enter the Web address on one line in your browser.

d. Wait for the console to load into the browser. A Login page is displayed after the console starts.

If you cannot start the administrative console because the console port conflicts with an application that is already running on the machine, change the port number in the *`install_root`*`/profiles/`*`profile name`*`/config/cells/`*`cell_name`*`/ nodes/`*`node_name`*`/servers/`*`server_name`*`/server.xml` file and the *`install_root`*`/profiles/`*`profile name`*`/config/cells/`*`cell_name`*`/virtualhosts.xml` files. Change all the occurrences of port 9060 (or the port that is selected during profile creation for WebSphere Application Server) to the port for the console. Alternatively, shut down the other application that uses the conflicting port before starting the WebSphere Application Server product.

2. Log into the console.

   a. Enter your user name or user ID.

      The user ID lasts only for the duration of the session for which it was used to log in.

      Changes made to server configurations are saved to the user ID. Server configurations also are saved to the user ID if a session timeout occurs.

      If you enter an ID that is already in use (and in session), you are prompted to do one of the following actions:

      - Force the existing user ID out of session. The configuration file that is used by the existing user ID is saved in the temporary area.
      - Wait for the existing user ID to log out or time out of the session.
      - Specify a different user ID.

   b. If the console is secure, you must also enter a password for the user name. The console is secure if someone has taken the following actions for the console:

      - Specified security user IDs and passwords
      - Enabled global security

   c. Click **OK**.

3. Stop the administrative console. Click **System administration > Save changes to Master Repository > Save** to save work. Then click **Logout** to exit the console.

   If you close the browser before saving your work, when you next log in under the same user ID, you can recover any unsaved changes.

Login settings

Use this page to specify the user for the WebSphere Application Server administrative console. If you are using global security, then you must also specify a password.

When you specify a user, you can resume work done previously with the product. After you type in a user ID, and password if you are using global security, click **OK** to proceed to the next page and access the administrative console.

To view this page, start the administrative console.

Logging into the administrative console: When you log into the administrative console, you can optionally specify a user ID if the console is not secure. If the administrative console is secure, you must specify a user ID and password.

User ID

Specifies a string that identifies the user. The user ID must be unique to the administrative server. Concurrent administrative console sessions must use unique user IDs.

Work that you do with the product and then save before exiting the product is saved to a configuration that is identified by the user ID that you enter. To later access work done under that user ID, specify the same user ID in the Login page.

Data type	String

Password

If you use global security, specify a password.

Resolving conflicts during login: Conflicts can result if you log into the administrative console with a user ID that is already in use.

Another user is currently logged in with the same user name

Specifies whether to log out the user and to continue work with the user ID that is specified, or to return to the Login page and specify a different user ID, or wait for the user to log out.

This field is displayed if:

- The user closed a Web browser while browsing the administrative console and did not first log out, then opened a new browser and tried to access the administrative console with the same user ID.
- The user opened a Web browser to access the administrative console while accessing the administrative console in another open Web browser with the same user ID.
- The user opens a Web browser and attempts to log into the console with the same user ID that is already in use by another user who logged into the console from another Web browser on another computer.

Recovering prior changes: You can either recover changes that you made to the configuration from a prior session or use the master configuration. The default is to recover changes from a prior session.

Recover changes made in a prior session

When enabled, this setting specifies that you want to use the same administrative configuration used for the last user's session. This option recovers changes made by the user since the last saving of the administrative configuration for the user's session.

This field is displayed only if the user changed the administrative configuration and then logged out without saving the changes.

Work with the master configuration

When enabled, this setting specifies to use the default administrative configuration instead of the configuration that was last used for the user's session. Changes that are made to the user's session since the last saving of the administrative configuration are lost.

This field is displayed only if the user changed the administrative configuration and then logged out without saving the changes.

Resolving login failures: When the administrative console is enabled with global security, you must type in a valid user ID and password. If the user ID, password, or both are not valid, you receive the following message:

```
Unable to process login. Please check User ID and password and try again.
```

Resolve the problem by entering a valid user ID and password as defined in the WebSphere Application Server security documentation.

Save changes to the master configuration

Use this page to update the master repository with your administrative console changes, to discard your administrative console changes and continue working with the master repository, or to continue working with your administrative console changes that are not saved to the master repository.

Until you save changes to the master repository, the administrative console uses a local workspace to track your changes.

Total changed documents: Specifies the total number of documents that you changed for your session, but that are not saved to the master repository. By clicking the +/- toggle key, you can see additional information about the changed documents:

- **Changed items**

  When you change your local configuration, each path and configuration file that you can apply the update to in the master repository is displayed in the list.
- **Status**

  Can contain the following options:
  - **Added:** If you save your changes to the master repository, a new configuration file is created on the indicated path.
  - **Updated:** If you save your changes to the master repository, an existing configuration file is updated on the indicated path.
  - **Deleted:** If you save your changes to the master repository, an existing configuration file is deleted on the indicated path.

Synchronize changes with nodes: Specifies whether you want to force node synchronization at the time that you save your changes to the master repository rather than when node synchronization normally occurs.

Setting the session timeout for the administrative console

This topic describes how to change the session timeout from the default value for the administrative console.

Ensure that you have the proper permissions to change the `${WAS_HOME}/systemApps/adminconsole.ear/deployment.xml` file.

Determine whether the default session timeout value of 30 minutes is acceptable. Some reasons that you might change the default value are:

- Users in secure environments might need shorter session timeout periods to ensure security, encase they leave their machine and forget to log off the console.
- Users might need longer session timeout periods if they respond slower than typical users for accessibility reasons.
- Users in secure environments might not want the administrative console timeout value to conflict with Lightweight Third-Party Authentication (LTPA) cookie timeouts

Do the following actions to change the timeout value:

1. Edit the `${WAS_HOME}/systemApps/adminconsole.ear/deployment.xml` file in a text editor.
2. Locate the xml statement `<tuningParams xmi:id="TuningParams_1088453565469" maxInMemorySessionCount="1000" allowOverflow="true" writeFrequency="TIME_BASED_WRITE" writeInterval="10" writeContents="ONLY_UPDATED_ATTRIBUTES" invalidationTimeout="30">`
3. Change the invalidationTimeout value to the desired session timeout. The default is 30.
4. Save the `${WAS_HOME}/systemApps/adminconsole.ear/deployment.xml` file.
5. Restart the console.

Once you restart the console, the change takes effect.

Manage WebSphere Application Server through the administrative console.

Administrative console areas

Use the administrative console to create and manage objects in the WebSphere Application Server configuration such as resources, applications, and servers. Additionally, use the administrative console to view product messages. This topic describes the main areas that display on the administrative console.

To view the administrative console, ensure that the application server for the administrative console is running. Point a Web browser at the Web address for the administrative console, enter your user ID and, if needed, a password on the Login page.

You can resize the width of the navigation tree and workspace simultaneously by dragging the border between them to the left or the right. The change in width does not persist between administrative console user sessions.

The console has the following main areas.

Taskbar

The taskbar offers options for logging out of the console, accessing product information, and accessing support.

Navigation tree

The navigation tree on the left side of the console offers links to console pages that you use to create and manage components in a WebSphere Application Server administrative cell.

Click a plus sign (**+**) beside a tree folder or item to expand the tree for the folder or item. Click a minus sign (**-**) to collapse the tree for the folder or item. Click an item in the tree view to toggle its state between expanded and collapsed.

Workspace

The workspace on the right side of the console contains pages that you use to create and manage configuration objects such as servers and resources. Click links in the navigation tree to view the different types of configured objects. Within the workspace, click configured objects to view their configurations, run-time status, and options. Click **Welcome** in the navigation tree to display the workspace Home page, which contains links to information on using the WebSphere Application Server product.

Administrative console buttons

This page describes the button choices that are available on various pages of the administrative console, depending on which product features you enable.

- **Check all.** Selects each resource that is listed on the administrative console panel, in preparation for performing an action against the selected resources.
- **Uncheck all.** Removes all the listed resources from each selection so that no action is performed against any of the resources.

- **Filter the view.** Produces a dialog box for specifying the resources to view in the table on this administrative console page.

  Hide the filter view. Hides the dialog box for specifying the resources to view in the table on this administrative console page.

  When you produce the dialog box, select the column to filter and enter the filter criteria.

  Column to filter

  Select the column to filter from the drop-down list. When you apply the filter, only those items in the selected column that meet the filter criteria are displayed.

  For example, select **Names** to enter criteria by which to filter application server names.

  Filter criteria

  Enter a string that must be found in the name of a collection entry to qualify the entry to display in the collection table. The string can contain percent sign (%), asterisk (*), or question mark (?) symbols as wildcard characters. For example, enter `*App*` to find any application server whose name contains the string `App`.

  Prefix each of the following characters `( ) ^ * % { } \ + $` with a backslash (\) so that the regular expression engine performing the search correctly matches the search criteria. For example, to search for all Java DataBase Connectivity (JDBC) providers containing `(XA)` in the provider name, specify the following string:

  ```
  *\(XA\)
  ```
- **Clear filter criteria.** Clears your filter changes and restores the most recently saved values.
- **Abort.** Stops a transaction that is not yet in the prepared state. All operations that the transaction completed are undone.
- **Activate.** Activates a group member.
- **Add.** Adds the selected or typed item to a list, or produces a dialog for adding an item to a list.
- **Apply.** Saves your changes to a page without exiting the page.
- **Back.** Displays the previous page or item in a sequence. The administrative console does not support using the Back and Forward options of a browser, which can cause intermittent problems. Use Back or Cancel on the administrative console panels instead.
- **Balance.** Balances active members in high availability groups across servers that host the high availability groups. The administrator must first determine which groups have active members and select those groups before selecting Balance.
- **Browse.** Opens a dialog that enables you to look for a file on your system.
- **Calculate groups.** Calculates the number of high availability groups that are returned based on the match set.
- **Cancel.** Exits the current page or dialog, discarding unsaved changes. The administrative console does not support using the Back and Forward options of a browser, which can cause intermittent problems. Use Cancel on the administrative console panels instead.
- **Change.** In the context of security, you can search the user registry for a user ID for an application to run under. In the context of container properties, you can change the data source that the container is using.
- **Clear.** Clears your changes and restores the most recently saved values.
- **Clear selections.** Clears any selected cells in the tables on this tabbed page.
- **Close.** Exits the dialog.
- **Commit.** Releases all locks that are held by a prepared transaction and forces the transaction to commit.
- **Copy.** Creates copies of the selected application servers.
- **Create.** Saves your changes to all the tabbed pages in a dialog and exits the dialog.
- **Create tables.** Develops scheduler database tables.
- **Deactivate.** Deactivates a group member. The group member must be in the active state to be deactivated. The deactivate option causes the group member to move to the idle state. The group policy overrides which members are activated and deactivated for a group. The policy is enforced for every member state change. If the deactivate option conflicts with the group policy, the policy resets who is the active member of the group.
- **Delete.** Removes the selected instance.

- **Details.** Shows the details about a transaction.
- **Disable.** Disables a group or group member. When you disable a group or group member, the active group or group member is first deactivated. If the deactivate option is successful, the group or group member moves to the disable state. A disabled group or group member cannot be activated.
- **Done.** Saves your changes to all the tabbed pages in a dialog and exits the dialog.
- **Down.** Moves through a list.
- **Drop tables.** Removes scheduler database tables.
- **Dump.** Activates a dump of a traced application server.
- **Edit.** Lets you edit the selected item in a list, or produces a dialog box for editing the item.
- **Enable.** Enables a group or a group member.
- **Export.** Accesses a page for exporting enterprise archive (EAR) files for an enterprise application.
- **Export DDL.** Accesses a page for exporting data definition language (DDL) files for an enterprise application.
- **Export Keys.** Exports Lightweight Third-Party Authentication (LTPA) keys to other domains.
- **Export route table.** Exports the route table information for a selected cluster to a binary file in the configuration.
- **Filter.** Produces a dialog box for specifying the resources to view in the tables on this tabbed page.
- **Finish.** Forces a transaction to finish, regardless of whether its outcome has been reported to all participating applications.
- **First.** Displays the first record in a series of records.
- **Generate keys.** Generates new LTPA keys. When security is turned on for the first time with LTPA as the authentication mechanism, LTPA keys are automatically generated with the password entered in the panel. To generated new keys, use this option after the server is up with security turned on. Clicking this option generates the keys and propagates them to all active servers (cell, node, and application servers). The new keys can be used to encrypt and decrypt the LTPA tokens. Click **Save** on the console taskbar to save the new keys and the password in the repository.
- **Immediate stop.** Stops the server, but bypasses the normal server quiesce process that supports in-flight requests to complete before shutting down the entire server process. This shutdown mode is faster than the normal server stop processing, but some application clients can receive exceptions.
- **Import keys.** Imports new LTPA keys from other domains. To support single signon (SSO) in WebSphere Application Server across multiple WebSphere domains (cells), share LTPA keys and a password among the domains. After exporting the keys from one of the cells into a file, click this option to import the keys into all the active servers (cell, node, and application servers). The new keys can be used to encrypt and decrypt the LTPA token. Click **Save** on the console taskbar to save the new keys and the password in the repository.
- **Install.** Displays the Preparing for application installation page, which you use to deploy an application, an enterprise bean, or a Web component onto an application server.
- **Install RAR.** Opens a dialog that is used to install a Java 2 Platform, Enterprise Edition Connector Architecture (JCA) connector and to create a resource adapter.
- **Manage transactions.** Displays a list of active transactions running on a server. You can forcibly finish any transaction that has stopped processing because a transactional resource is not available.
- **Modify.** Opens a dialog that is used to change a specification.
- **Move.** Moves the selected application servers to a different location in the administrative cell. When prompted, specify the target location.
- **Move down.** Moves downward through a list.
- **Move up.** Moves upward through a list.
- **New.** Displays a page that you use to define a new instance. For example, clicking **New** on the Application Servers page displays a page on which you can configure a new application server.
- **Next.** Displays the next page, frame, or item in a sequence.
- **OK.** Saves your changes and exits the page.
- **Ping.** Attempts to contact selected application servers.
- **Previous.** Displays the previous page, frame, or item in a sequence.
- **Quit.** Exits a dialog box and discards any unsaved changes.
- **Refresh.** Refreshes the view of data for instances that are currently listed on this tabbed page.
- **Remove.** Deletes the selected item.
- **Remove file.** Removes the specified file from the selected application or module.

- **Reset.** Clears your changes on the tab or page and restores the most recently saved values.
- **Restart.** Stops the selected objects and starts them again.
- **Retrieve new.** Retrieves a new record.
- **Rollout update.** Sequentially updates an application that is installed on multiple cluster members across a cluster. After you update application files or a configuration, click **Rollout update** to install the configuration or the updated files for an application on all the cluster members of a cluster on which the application is installed. The Rollout update option applies the following steps to each cluster member in sequence:
  1. Saves an updated configuration.
  2. Stops the cluster member.
  3. Updates the application on the node by synchronizing the configuration.
  4. Restarts the cluster member.

  This action enables you to update an application on multiple cluster members while providing continuous availability of the application.
- **Save.** Saves the changes in your local configuration to the master configuration.
- **Select.** For resource analysis, lets you select a scope in which to monitor resources.
- **Set.** Saves your changes to settings in a dialog.
- **Settings.** Displays a dialog for editing servlet-related resource settings.
- **Settings in use.** Displays a dialog showing the settings in use.
- **Show groups.** Displays a collection of high availability groups, based on the match set.
- **Show servers.** Displays a collection of servers that are contained in the high availability groups that match the match set.
- **Start.** In the context of application servers, starts selected application servers. In the context of data collection, starts collecting data for the tables on this tabbed page.
- **Stop.** In the context of server components such as application servers, stops the selected server components. In the context of a data collection, stops collecting data for the tables on a tabbed page.
- **Terminate.** Deletes the Application Server process or another process that cannot be stopped by the **Stop** or **Immediate Stop** commands. Some application clients can receive exceptions. Always attempt an immediate stop before using this option.
- **Uninstall.** Deletes a deployed application from the WebSphere Application Server configuration repository. Also deletes application binary files from the file system.
- **Update.** Replaces an application that is deployed on a server with an updated application. As part of the updating, you might need to complete steps on the Preparing for application installation and Update application pages.
- **Update resource list.** Updates the data on a table. Discovers and adds new instances to the table.
- **Verify tables.** Validates the mapping between the table names, scheduler resource, and data sources.
- **View.** Opens a dialog on a file.

Administrative console page features

This topic provides information about the basic elements of an administrative console page, such as the various tabs.

Administrative console pages are arranged in a few basic patterns. Understanding their layout and behavior will help you use them more easily.

Collection pages

Use collection pages to manage a collection of existing administrative objects. A collection page typically contains one or more of the following elements:

Scope and Preferences

These are described in “Administrative console scope settings” on page 182 and “Administrative console preference settings” on page 182.

Table of existing objects

The table displays existing administrative objects of the type specified by the collection page. The table columns summarize the values of the key settings for these objects. If no objects exist yet, an empty table is displayed. Use the available buttons to create a new object.

Buttons for performing actions
The available buttons are described on the Administrative console buttons help panel. In most cases, you need to select one or more of the objects in the table, then click a button. The action will be applied to the selected objects.

Sort toggle buttons
Following column headings in the table are icons for sort ascending (^) and sort descending (v). By default, items such as names are sorted in descending order (alphabetically). To enable another sorting order, click on the icons for the column whose items you want sorted.

Detail pages

Use detail pages to configure specific administrative objects, such as an application server. A detail page typically contains one or more of the following elements:

Configuration tabbed page
This tabbed page is for modifying the configuration of an administrative object. Each configuration page has a set of general properties specific to the administrative object. Other sets of properties display on the page, but vary depending on the administrative object.

Runtime tabbed page
This tabbed page displays the configuration that is currently in use for the administrative object. It is read-only in most cases. Some detail pages do not have runtime tabs.

Local Topology tabbed page
This tabbed page displays the topology that is currently in use for the administrative object. View the topology by expanding and collapsing the different levels of the topology. Some detail pages do not have local topology tabs.

Buttons for performing actions
Buttons to perform specific actions display on the configuration tabbed page and the runtime tabbed page. The displayed buttons vary based on the administrative object. The available buttons are described on the Administrative console buttons help panel.

Wizard pages

Use wizard pages to complete a configuration process comprised of several steps. Be aware that wizards show or hide certain steps depending on the characteristics of the specific object you are configuring.

Administrative console navigation tree actions

Use the navigation tree of the administrative console to access pages for creating and managing servers, applications, resources, and other components.

To view the navigation tree, go to the WebSphere Application Server administrative console and look at the tree on the left side of the console. The tree provides navigation to configuration tasks and run-time information. The main topics available on the navigation tree are detailed in the following section. To use the tree, expand a main topic and select an item from the expanded list to display a page on which you can perform the administrative task.

Servers:

Configure application servers, clusters, generic servers, Web servers, and core groups.

Applications:

Install applications onto servers and manage the installed applications.

Resources:

Configure resources and to view information on resources that exist in the administrative cell.

Security:

Access the Security Center, which you use to secure applications and servers.

Environment:

Configure hosts, WebSphere Application Server variables, and other components.

System Administration:

Configure console settings, and manage components and users of a Network Deployment product.

Troubleshooting:

Check for configuration errors and problems, view log files, and enable and disable tracing on a distributed platform.

Monitoring and Tuning:

Monitor and tune your Application Server performance and analyze performance data.

Service Integration:

Iimplement message-oriented and service-oriented applications.

UDDI:

Publish and discover information about Web services.

Administrative console taskbar actions

Use the taskbar of the administrative console to log out of the administrative console and to access the console help.

To view the taskbar, go to the WebSphere Application Server administrative console and look at the horizontal bar near the top of the console. The taskbar provides the following actions.

Logout: Logs you out of the administrative console session and displays the Login page. If you made changes to the administrative configuration since last saving the configuration to the master repository, the Save page is displayed before returning to the Login page.

- Click **Save** to save the changes to the master repository.
- Click **Discard** to exit the session without saving changes.
- Click **Logout** to exit the session without saving changes but with the opportunity to recover your changes when you return to the console.

Help: Opens a new Web browser to online help for the WebSphere Application Server product.

Support: Displays support links that vary based on the products that extend the WebSphere Application Server. Use the support page to access product information such as Frequently Asked Questions (FAQs), technical notes (Technotes), hints and tips, and news. You can additionally install the Support Advisor Search application so that when you click on the support link, a new Web browser that contains the Support Advisor Search application opens. The Support Advisor Search application displays the support links on the support page, but additionally provides federated search capabilities into IBM knowledge databases.

Specifying console preferences

Use this topic to customize how much data displays on an administrative console panel.

Throughout the administrative console are pages that have Preferences fields, Scope fields, and Filter radio buttons. By selecting these fields and radio buttons you can customize how much data is shown.

For example, examine the Preferences field for the Enterprise Applications page:

1. Go to the navigation tree of the administrative console and click **Applications > Enterprise Applications**.
2. Expand **Preferences**.
3. For the **Maximum rows** field, specify the maximum number of rows to display when the collection is large. The default is 20. Rows that exceed the maximum number display on subsequent pages.
4. Select **Retain filter criteria** if you want to retain the last filter criteria that is entered in the filter function. When you return to the Applications page, the page initially uses the retained filter criteria to display the collection of applications in the table following the preferences. Otherwise, clear **Retain filter criteria** and the last filter criteria is not retained.
5. Click **Apply** to apply your selections or click **Reset** to return to the default values. The default is not to enable (not have a check mark beside) **Retain filter criteria**.

Other pages have similar fields and radio buttons that you can use to specify console preferences. While Preferences fields, Scope fields, and Filter buttons control how much data is shown in the console, the **Preferences** option controls general behavior of the console. Click **System administration > Console settings > Preferences** to view the Preferences page.

Preferences settings

Use the Preferences page to specify whether you want the administrative console workspace to refresh automatically after changes, the default scope to be the administrative console node, confirmation dialogs to display, and the workspace banner and descriptions to display.

To view this administrative console page, click **System administration > Console settings > Preferences**.

Turn on workSpace auto-refresh:

Specifies whether you want the administrative console workspace to redraw automatically after the administrative configuration changes.

The default is for the workspace to redraw automatically. If you direct the console to create a new instance of, for example, an application server, the Application Servers page refreshes automatically and shows the new server name in the collection of servers.

Specifying that the workspace not redraw automatically means that you must access a page again by clicking the console navigation tree or links on collection pages to see the changes that are made to the administrative configuration.

Default	true (selected)

No confirmation on workspace discard:

Specifies whether the confirmation dialog is displayed after a request is receive to discard the workspace. The default is to display confirmation dialogs.

Default	false (cleared)

Use default scope (administrative console node):

Specifies whether the default scope is the administrative console node. The default scope not is not the console node.

Default	false (cleared)

Show banner:

Specifies whether the WebSphere Application Server banner along the top of the administrative console is displayed. The default is for the banner to display.

Default	true (selected)

Show Descriptions:

Specifies whether information on the right of the console is shown. The default is to show the information.

Data type	Boolean
Default	true

Administrative console preference settings

Use the preference settings to specify how you want information displayed on an administrative console page.

Maximum rows: Indicates the maximum number of rows to display per page when the collection is large.

Filter history: Indicates whether to use the same filter criteria to display this page the next time you visit it.

Select the **Retain filter criteria** check box to retain the last filter criteria entered. When you return to the page, retained filter criteria control the application collection that is displayed n the table.

Show confirmation for stop command: Select the check box if you want a confirmation that the **stop** command is successful.

Show confirmation for immediate stop command: Select the check box if you want a confirmation that the **immediate stop** command is successful.

Show confirmation for terminate command: Select the check box if you want a confirmation that the **terminate** command is successful.

Administrative console scope settings

Use this page to specify the level at which a resource is visible on the administrative console panel. A resource can be visible in the administrative console collection table at the cell, node, cluster, or server scope. By changing the value for Scope you can see other variables that apply to a resource and might change the contents of the collection table.

Click **Browse** next to a field to see choices for limiting the scope of the field. If a field is read-only, you cannot change the scope. For example, if only one server exists, you cannot switch the scope to a different server.

You always create resources at the current scope that is selected in the administrative console panel, even though the resources might be visible at more than one scope.

Resources such as JDBC providers, namespace bindings, or shared libraries can be defined at multiple scopes. Resources that are defined at more specific scopes override duplicate resources that are defined at more general scopes.

- The application scope has precedence over all the scopes.
- The server scope has precedence over the node, cell, and cluster scopes.
- The cluster scope has precedence over the node and cell scopes.
- The node scope has precedence over the cell scope.

Despite the scope of a defined resource, the resource properties only apply at an individual server level. For example, if you define the scope of a data source at the cell level, all the users in that cell can look up and use that data source, which is unique within that cell. However, resource property settings are local to each server in the cell. For example, if you define the maximum connections as 10, then each server in that cell can have 10 connections.

The cell scope is the most general scope and does not override any other scope. The recommendation is that you generally specify a more specific scope than the cell scope. When you define a resource at a more specific scope, you provide greater isolation for the resource. When you define a resource at a more general scope, you provide less isolation. Greater exposure to cross-application conflicts occur for a resource that you define at a more general scope.

Cell Limits the visibility to all servers on the named cell. The resource factories within the cell scope are:

- Defined for all servers within this cell
- Overridden by any resource factories that are defined within application, server, cluster and node scopes that are in this cell and have the same Java Naming and Directory Interface (JNDI) name

The resource providers that are required by the resource factories must be installed on every node within the cell before applications can bind or use them.

Cluster

Limits the visibility to all the servers on the named cluster. All cluster members must at least be at Version 6 to use cluster scope for the cluster. The resource factories that are defined within the cluster scope:

- Are available for all the members of this cluster to use
- Override any resource factories that have the same JNDI name that is defined within the cell scope

The resource factories that are defined within the cell scope are available for this cluster to use, in addition to the resource factories, that are defined within this cluster scope.

Node Limits the visibility to all the servers on the named node. The node scope is the default scope for most resource types. The resource factories that are defined within the node scope:

- Are available for servers on this node to use
- Override any resource factories that have the same JNDI name defined within the cell scope

The resource factories that are defined within the cell scope are available for servers on this node to use, in addition to the resource factories that are defined within this node scope.

Server

Limits the visibility to the named server. The server scope is the most specific scope for defining resources. The resource factories that are defined within the server scope:

- Are available for applications that are deployed on this server
- Override any resource factories that have the same JNDI name defined within the node and cell scopes

The resource factories that are defined within the node and cell scopes are available for this server to use, in addition to the resource factories that are defined within this server scope.

Application

Limits the visibility to the named application. Application scope resources cannot be configured from the console. Use the WebSphere Application Server Toolkit (AST) or the wsadmin tool to view or modify the application scope resource configuration. The resource factories that are defined within the application scope are available for this application to use only. The application scope overrides all other scopes.

You can configure resources and WebSphere Application Server variables under all five scopes. You can configure namespace bindings and shared libraries only under cell, node, and server scopes.

Accessing help and product information from the administrative console

This topic describes how to use administrative console help and how to link to product documentation from the administrative console.

You must have a connection to the Internet to access information about WebSphere Application Server from the Welcome page of the administrative console.

All of the helps panels that you can access from the administrative console, you can access from the WebSphere Application Server Information Center. This article describes how to access the help panels, the information center, and other product documentation from the administrative console.

- Click **Welcome** on the administrative console navigation tree. In the workspace to the right of the navigation tree, select the appropriate links to access the WebSphere Application Server Information Center, the WebSphere Application Server product information, and the WebSphere Application Server technical information on developerWorks.
- Access help in the following ways:
  - Click **Help** on the administrative console task bar to open a new Web browser for online help.
    - Click on the **Help index** tab and select from the list of help panels to view administrative console help information.
    - Click on the **Search** tab, provide search terms, and then click **Search**. Under Results, select a help panel that contains the search information.
  - Click the **?** icon on the task bar for the particular administrative console panel to open a new Web browser and view the help panel for the corresponding administrative console panel. The help panel is displayed in the Help index for the administrative console.
  - In the help portal that is on the right side of the administrative console panel, do one or all of the following tasks:
    - Click a field label or a list marker in the administrative console panel for the help to display under Field help. Alternatively, place the cursor over the field label or the list marker for the corresponding help to display at the cursor.
    - Click the link under Page help to access the help panel for the administrative console panel. The help panel is the same help panel that displays when you click the **?** icon.
    - Expand the task help to view related tasks.

You can continue to access help information from the administrative console. Alternatively, you can access the help information from the WebSphere Application Server Information Center.

You can continue to access the WebSphere Application Server Information Center, the WebSphere Application Server product information, and the WebSphere Application Server technical information on developerWorks from the administrative console. Alternatively you can access the information from the IBM Web site.

Administrative console: Resources for learning

Use the following links to find relevant supplemental information about the IBM WebSphere Application Server administrative console. The information resides on IBM and non-IBM Internet sites, whose sponsors control the technical accuracy of the information.

These links are provided for convenience. Often, the information is not specific to the IBM WebSphere Application Server product, but is useful all or in part for understanding the product. When possible, links are provided to technical papers and Redbooks that supplement the broad coverage of the release documentation with in-depth examinations of particular product areas.

View links to additional information:

Administration

- IBM WebSphere Application Server Redbooks

  This site contains a listing of all WebSphere Application Server Redbooks.
- IBM developerWorks WebSphere

  This site is the home of technical information for developers working with WebSphere products. You can download WebSphere software, take a fast path to developerWorks zones, such as VisualAge Java or WebSphere Application Server, learn about WebSphere products through a newcomers page, tutorials, technology previews, training, and Redbooks, get answers to questions about WebSphere products, and join the WebSphere community, where you can keep up with the latest developments and technical papers.
- WebSphere Application Server Support page

  Take advantage of the Web-based Support and Service resources from IBM to quickly find answers to your technical questions. You can easily access this extensive Web-based support through the IBM Software Support portal at URL `http://www-3.ibm.com/software/support/` and search by product category, or by product name. For example, if you are experiencing problems specific to WebSphere Application Server, click **WebSphere Application Server** in the product list. The WebSphere Application Server Support page appears.

Using scripting (wsadmin)

The WebSphere administrative (wsadmin) scripting program is a powerful, non-graphical command interpreter environment enabling you to run administrative operations in a scripting language. The wsadmin tool is intended for production environments and unattended operations. You can use the wsadmin tool to perform the same tasks that you can perform using the administrative console.

The following list highlights the topics and tasks available with scripting:

- Getting started with scripting Provides an introduction to WebSphere Application Server scripting and information about using the wsadmin tool. Topics include information about the scripting languages and the scripting objects, and instructions for starting the wsadmin tool.
- Deploying applications Provides instructions for deploying and uninstalling applications. For example, stand-alone Java archive files and Web archive files, the administrative console, remote Enterprise Archive (EAR) files, file transfer applications, and so on.
- Managing deployed applications Includes tasks that you perform after the application is deployed. For example, starting and stopping applications, checking status, modifying listener address ports, querying application state, configuring a shared library, and so on.
- Configuring servers Provides instructions for configuring servers, such as creating a server, modifying and restarting the server, configuring the Java virtual machine, disabling a component, disabling a service, and so on.
- Configuring connections to Web servers Includes topics such as regenerating the plug-in, creating new virtual host templates, modifying virtual hosts, and so on.
- Managing servers Includes tasks that you use to manage servers. For example, stopping nodes, starting and stopping servers, querying a server state, starting a listener port, and so on.
- Configuring security Includes security tasks, for example, enabling and disabling global security, enabling and disabling Java 2 security, and so on.
- Configuring data access Includes topics such as configuring a Java DataBase Connectivity (JDBC) provider, defining a data source, configuring connection pools, and so on.

- Configuring messaging Includes topics about messaging, such as Java Message Service (JMS) connection, JMS provider, WebSphere queue connection factory, MQ topics, and so on.
- Configuring mail, URLs, and resource environment entries Includes topics such as mail providers, mail sessions, protocols, resource environment providers, referenceables, URL providers, URLs, and so on.
- Troubleshooting Provides information about how to troubleshoot using scripting. For example, tracing, thread dumps, profiles, and so on.
- Scripting reference material Includes all of the reference material related to scripting. Topics include the syntax for the wsadmin tool and for the administrative command framework, explanations and examples for all of the scripting object commands, the scripting properties, and so on.

Getting started with scripting

Scripting is a non-graphical alternative that you can use to configure and manage WebSphere Application Server. The WebSphere Application Server wsadmin tool provides the ability to run scripts. The wsadmin tool supports a full range of product administrative activities.

The following figure illustrates the major components involved in a wsadmin scripting solution:

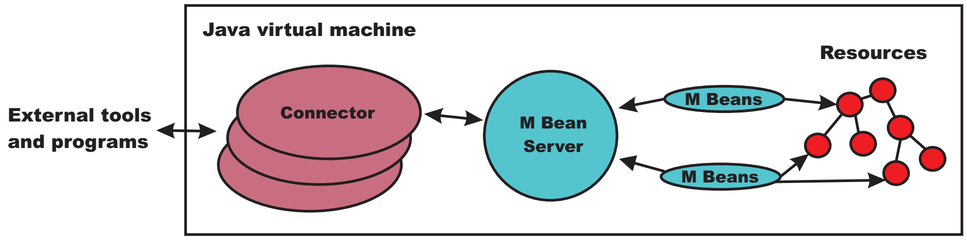

Figure 1: A WebSphere Application Server scripting solution

The wsadmin tool supports two scripting languages: Jacl and Jython. Five objects are available when you use scripts:

- **AdminControl**: Use to run operational commands.
- **AdminConfig**: Use to run configurational commands to create or modify WebSphere Application Server configurational elements.
- **AdminApp**: Use to administer applications.
- **AdminTask**: Use to run administrative commands.
- **Help**: Use to obtain general help.

The scripts use these objects to communicate with MBeans that run in WebSphere Application Server processes. MBeans are Java objects that represent Java Management Extensions (JMX) resources. JMX is an optional package addition to Java 2 Platform Standard Edition (J2SE). JMX is a technology that provides a simple and standard way to manage Java objects.

To perform a task using scripting, you must first perform the following steps:

1. Choose a scripting language. The wsadmin tool only supports Jacl and Jython scripting languages. Jacl is the language specified by default. If you want to use the Jython scripting language, use the -lang option or specify it in the wsadmin.properties file.
2. Start the wsadmin scripting client interactively, as an individual command, in a script, or in a profile.

Before you perform any task using scripting, make sure that you are familiar with the following concepts:

- Java Management Extensions (JMX)
- WebSphere Application Server configuration model
- wsadmin tool

- Jacl syntax or Jython syntax
- Scripting objects

Optionally, you can customize your scripting environment. For more information, see Scripting environment properties.

After you become familiar with the scripting concepts, choose a scripting language, and start the scripting client, you are ready to perform tasks using scripting.

Java Management Extensions (JMX)

Java Management Extensions (JMX) is a framework that provides a standard way of exposing Java resources, for example, application servers, to a system management infrastructure. Using the JMX framework, a provider can implement functions, such as listing the configuration settings, and editing the settings. This framework also includes a notification layer that management applications can use to monitor events such as the startup of an application server.

JMX key features

The key features of the WebSphere Application Server Version 6 implementation of JMX include:

- All processes that run the JMX agent.
- All run-time administration that is performed through JMX operations.
- Connectors that are used to connect a JMX agent to a remote JMX-enabled management application. The following connectors are supported:
  - SOAP JMX Connector
  - Remote Method Invocation over the Internet Inter-ORB Protocol (RMI-IIOP) JMX Connector
- Protocol adapters that provide a management view of the JMX agent through a given protocol. Management applications that connect to a protocol adapter are usually specific to a given protocol.
- The ability to query and update the configuration settings of a run-time object.
- The ability to load, initialize, change, and monitor application components and resources during run-time.

JMX architecture

The JMX architecture is structured into three layers:

- Instrumentation layer - Dictates how resources can be wrapped within special Java beans, called managed beans (MBeans).
- Agent layer - Consists of the MBean server and agents, which provide a management infrastructure. The services that are implemented include:
  - Monitoring
  - Event notification
  - Timers
- Management layer - Defines how external management applications can interact with the underlying layers in terms of protocols, APIs, and so on. This layer uses an implementation of the distributed services specification (JSR-077), which is not yet part of the Java 2 platform, Enterprise Edition (J2EE) specification.

The layered architecture of JMX is summarized in the following figure:

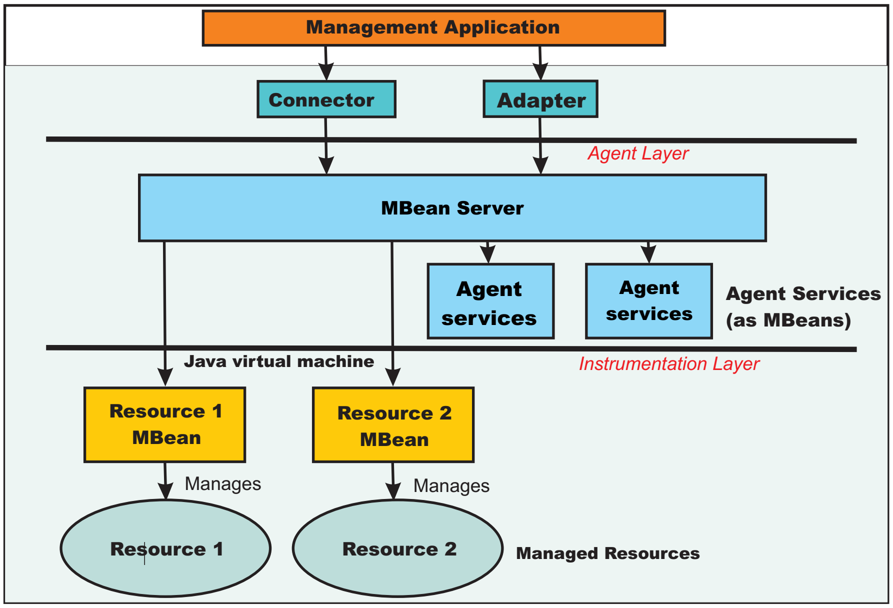

Figure 1: JMX architecture

JMX distributed administration

The following figure shows how the JMX architecture fits into the overall distributed administration topology of a Network Deployment environment:

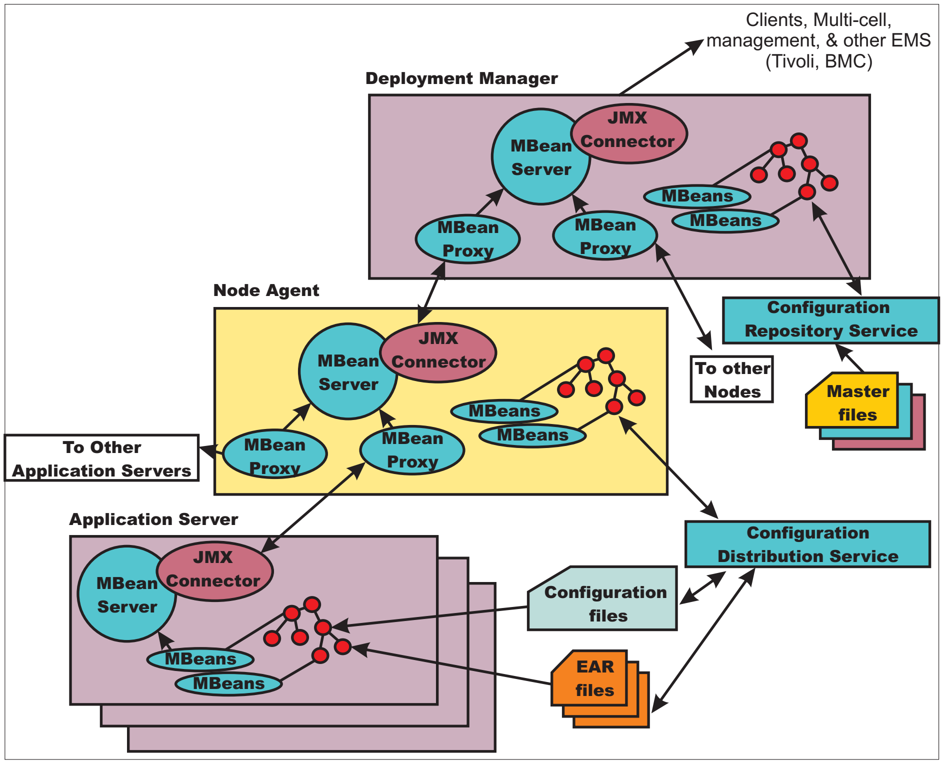

Figure 2: WebSphere Application Server distributed administration of JMX

The key points of this distributed administration architecture include:

- Internal MBeans that are local to the Java virtual machine (JVM) register with the local MBean server.
- External MBeans have a local proxy to their MBean server. The proxy registers with the local MBean server. Using the MBean proxy the local MBean server can pass the message to an external MBean server that is located on:
  - A node agent that has an MBean proxy for all the servers within its node. The MBean proxies for other nodes are not used.
  - The deployment manager has MBean proxies for all the node agents in the cell.

JMX Mbeans

WebSphere Application Server provides a number of MBeans, each of which have different functions and operations available. For example, an application server MBean can expose operations such as start and stop. An application MBean can expose operations such as install and uninstall. Some JMX usage scenarios that you can encounter include:

- External programs that are written to control the Network Deployment run time and its WebSphere resources by programmatically accessing the JMX API.
- Third-party applications that include custom JMX MBeans as part of the deployed code, supporting the JMX API management of application components and resources.

The following example illustrates how to obtain an MBean:

Using Jacl:

```
set am [$AdminControl queryNames type=ApplicationManager,process=server1,*]
```

Using Jacl:

```
am = AdminControl.queryNames('type=ApplicationManager,process=server1,*')
```

Each WebSphere Application Server runtime MBean may have attributes, operations, and notifications. The complete documentation for each MBean supplied with WebSphere Application Server is available in an html table that is installed in each copy of the WebSphere Application Server product. Under the main install directory for the product, there is a directory named web. And under that directory is another directory called mbeanDocs. In the mbeanDocs directory are several html files, one for each supplied with WebSphere Application Server. There is also an index.html file that ties all the individual MBean files together in a top-level navigation tree. Each MBean provides summary of its attributes, operations, and notifications.

JMX benefits

The use of JMX for management functions in WebSphere Application Server provides the following benefits:

- Enables the management of Java applications without significant investment.
- Relies on a core-managed object server that acts as a management agent.
- Java applications can embed a managed object server and make some of its functionality available as one or several MBeans that are registered with the object server.
- Provides a scalable management architecture.
- Every JMX agent service is an independent module that can be plugged into the management agent.
- The API is extensible, allowing new WebSphere Application Server and custom application features to be easily added and exposed through this management interface.
- Integrates existing management solutions.
- JMX smart agents are capable of being managed through HTML browsers or by various management protocols such as Web services, Java Message Service (JMS), and Simple Network Management Protocol (SNMP).

- Each process is self sufficient when it comes to the management of its resources. No central point of control exists. In principle, a JMX-enabled management client can be connected to any managed process and interact with the MBeans that are hosted by that process.
- JMX provides a single, flat, domain-wide approach to system management. Separate processes interact through MBean proxies that support a single management client to seamlessly navigate through a network of managed processes.
- Defines the interfaces that are necessary for management only.
- Provides a standard API for exposing application and administrative resources to management tools.

WebSphere Application Server configuration model

Configuration data is stored in several XML files. The server runtime reads these files when started and responds to the component settings stored there. The configuration data includes settings for the runtime itself, such as JVM options, thread pool sizes, container setting, and port numbers the server will use. Other configuration files define J2EE resources to which the server will connect to obtain data needed by the application logic. Security settings are stored in a separate document from the server and resource configuration. Applcation-specific configuration, such as deployment target lists, session configuration, and cache settings, are stored in files under the root directory of each application.

The configuration model for WebSphere Application Server is large and complex. When viewing the XML data in the various configuration files, you can discern relationship between the configuration objects. Understanding these relationships between configuration objects is essential when writing wsadmin scripts that perform configuration functions.

Full documentation of all of the WebSphere configuration objects is available in an html table that is installed in each copy of the WebSphere product. Under the main install directory for the product, there is a directory named web. And under that directory is another directory called configDocs. In the configDocs directory are several subdirectories, one for each configuration package in the model. There is also an index.html file that ties all the individual configuration packages together in a top-level navigation tree. Each configuration package lists all the supported configuration classes. Each configuration class lists all the supported properties. Properties with names that end with the special @ character imply that property is actually a reference to some other configuration object within the configuration data. Properties with names that end with an * imply that property is actaully a list of other configuration objects.

Jacl

Jacl is an alternate implementation of TCL, and is written entirely in Java code.

The wsadmin tool uses Jacl V1.3.1. The following information is a basic summary of the Jacl syntax:

Basic syntax:

The basic syntax for a Jacl command is the following:

```
Command arg1 arg2 arg3 ...
```

The command is either the name of a built-in command or a Jacl procedure. For example:

```
puts stdout {Hello, world!}
=> Hello, world!
```

In this example, the command is **puts** which takes two arguments, an I/O stream identifier and a string. The **puts** command writes the string to the I/O stream along with a trailing new line character. The arguments are interpreted by the command. In the example, `stdout` is used to identify the standard output stream. The use of `stdout` as a name is a convention employed by the **puts** command and the other I/O commands. `stderr` identifies the standard error output, and `stdin` identifies the standard input.

Variables

The **set** command assigns a value to a variable. This command takes two arguments: the name of the variable and the value. Variable names can be any length and are case sensitive. You do not have to declare Jacl variables before you use them. The interpreter will create the variable when it is first assigned a value. For example:

```
set a 5
=> 5
```

```
set b $a
=> 5
```

The second example assigns the value of variable `a` to variable `b`. The use of dollar sign ($) is indicates variable substitution. You can delete a variable with the **unset** command, for example:

```
unset varName1 varName2 ...
```

You can pass any number of variables to the **unset** command. The **unset** command will give error if a variable is not already defined. You can delete an entire array or just a single array element with the **unset** command. Using the **unset** command on an array is a easy way to clear out a big data structure. The existence of a variable can be tested with the **info exists** command. You may have to test for the existence of the variable because the `incr` parameter requires that a variable exist first, for example:

```
if ![info exists foobar] {set foobar 0} else {incr foobar}
```

Command substitution:

The second form of substitution is command substitution. A nested command is delimited by square brackets, [ ]. The Jacl interpreter evaluates everything between the brackets and evaluates it as a command. For example:

```
set len [string length foobar]
=> 6
```

In this example, the nested command is the following: `string length foobar`. The **string** command performs various operations on strings. In this case, the command asks for the length of the string `foobar`. If there are several cases of command substitution within a single command, the interpreter processes them from left bracket to right bracket. For example:

```
set number "1 2 3 4"
=> 1 2 3 4
```

```
set one [lindex $number 0]
=> 1
```

```
set end [lindex $number end]
=> 4
```

```
set another {123  456  789}
=> 123  456  789
```

```
set stringLen [string length [lindex  $another  1]]
=> 3
```

```
set listLen [llength [lindex $another 1]
=> 1
```

Math expressions:

The Jacl interpreter does not evaluate math expressions. Use the **expr** command to evaluate math expressions. The interpreter treats the **expr** command similar to other commands and leaves the expression parsing up the **expr** command implementation. The implementation of the **expr** command takes all arguments, concatenates them into a single string, and parses the string as a math expression. After the **expr** command computes the answer, it his formatted into a string and returned. For example:

```
expr 7.2 / 3
=> 2.4
```

Backslash substitution:

The final type of substitution done by the Jacl interpreter is backslash substitution. Use this to quote characters that have special meaning to the interpreter. For example, you can specify a literal dollar sign, brace, or bracket by quoting it with a backslash. If you are using lots of backslashes, instead you can group things with curly braces to turn off all interpretation of special characters. There are cases where backslashes are required. For example:

```
set dollar "This is a string \$contain dollar char"
=> This is a string $contain dollar char

set x $dollar
=> This is a string $contain dollar char

set  group {$ {} [] { [ } ]}
=> $ {} [] { [ } ]
```

You can also use backslashes to continue long commands on multiple lines. A new line without the backslash terminates a command. A backslashes that are the last character on a line convert into a space. For example:

```
set  totalLength  [expr  [string  length  "first string"] + \
[string  length  "second string"]]
=> 25
```

Grouping with braces and double quotes:

Use double quotes and curly braces to group words together. Quotes allow substitutions to occur in the group and curly braces prevent substitution. This rule applies to command, variable, and backslash substitutions. For example:

```
set s Hello
=> Hello

puts stdout "The length of $s is [string length $s]."
=> The length of Hello is 5.

puts  stdout  {The length of $s is [string  length  $s].}
=> The length of $s is [string length $s].
```

In the second example, the Jacl interpreter performs variable and command substitution on the second argument from the **puts** command. In the third command, substitutions are prevented so the string is printed as it is.

On distributed systems, special care must also be taken with path descriptions because the Jacl language uses the backslash character (\) as an escape character. To fix this, either replace each backslash with a forward slash, or use double backslashes in distributed path statements. For example: `C:/` or `C:\\`

Procedures and scope:

Jacl uses the **proc** command to define procedures. The basic syntax to define a procedure is the following:

```
proc  name  arglist  body
```

The first argument is the name of the procedure being defined. The name is case sensitive, and in fact it can contain any characters. Procedure names and variable names do not conflict with each other. The second argument is a list of parameters to the procedures. The third argument is a command, or more typically a group of commands that form the procedure body. Once defined, a Jacl procedure is used just like any of the built-in commands. For example:

```
proc divide {x y} {
set result [expr x/y]
puts $result
}
```

Inside the script, this is how to call devide procedure:

```
divide 20 5
```

And it will give the result like below:

```
4
```

It is not really necessary to use the variable c in this example. The procedure body could also written as:

```
return  [expr  sqrt($a  *  $a  +  $b  *  $b)]
```

The return command is optional in this example because the Jacl interpreter returns the value of the last command in the body as the value of the procedure. So, the procedure body could be reduced to:

```
expr  sqrt($a  *  $a  +  $b  *  $b)
```

The result of the procedure is the result returned by the last command in the body. The return command can be used to return a specific value.

There is a single, global scope for procedure names. You can define a procedure inside another procedure, but it is visible everywhere. There is a different name space for variables and procedures therefore you may have a procedure and a variable with the same name without a conflict. Each procedure has a local scope for variables. Variables introduced in the procedures only exist for the duration of the procedure call. After the procedure returns, those variables are undefined. If the same variable name exists in an outer scope, it is unaffected by the use of that variable name inside a procedure. Variables defined outside the procedure are not visible to a procedure, unless the global scope commands are used.

- **global** command - Global scope is the top level scope. This scope is outside of any procedure. You must make variables defined at the global scope accessible to the commands inside procedure by using the **global** command. The syntax for the **global** command is the following:

  ```
  global  varName1  varName2 ...
  ```

Comments

Use the pound character (#) to make comments.

Command line arguments

The Jacl shells pass the command line arguments to the script as the value of the `argv` variable. The number of command line arguments is given by `argc` variable. The name of the program, or script, is not part of `argv` nor is it counted by `argc`. Instead, it is put into the `argv0` variable. The `argv` variable is a list. Use the **lindex** command to extract items from the argument list, for example:

```
set  first  [lindex  $argv  0]
set  second  [lindex  $argv  1]
```

Strings and pattern matching

String are the basic data item in the Jacl language. There are multiple commands that you can use to manipulate strings. The general syntax of the **string** command is the following:

```
string operation stringvalue otherargs
```

The `operation` argument determines the action of the string. The second argument is a string value. There may be additional arguments depending on the operation.

The following table includes a summary of the **string** command:

Command	Description

string compare str1 str2	Compares strings lexicographically. Returns 0 if equal, -1 if str1 sorts before str2, else1.
string first str1 str2	Returns the index in str2 of the first occurrences of str1, or -1 if str1 is not found.
string index string index	Returns the character at the specified index.
string last str1 str2	Returns the index in str2 of the last occurence of str1, or -1 if str1 is not found.
string length string	Returns the number of character in string.
string match pattern str	Returns 1 if str matches the pattern, else 0.
string range str i j	Returns the range of characters in str from i to j
string tolower string	Returns string in lower case.
string toupper string	Returns string in upper case.
string trim string ?chars?	Trims the characters in chars from both ends of string. chars defaults to white space.
string trimleft string ?chars?	Trims the characters in chars from the beginning of string. chars defaults to white space.
string trimright string ?chars?	Trims the characters in chars from the end of string. chars defaults to white space.
string wordend str ix	Returns the index in str of the character after the word containing the character at index ix.
string wordstart str ix	Returns the index in str of the first character in the word containing the character at index ix.

The append command

The first argument of the **append** command is a variable name. It concatenates the remaining arguments onto the current value of the named variable. For example:

```
set  foo  z
=> z

append  foo a b c
=> zabc
```

The regexp command

The **regexp** command provides direct access to the regular expression matcher. The syntax is the following:

```
regexp  ?flags?  pattern  string  ?match  sub1  sub2  ...?
```

The return value is `1` if some part of the string matches the pattern. Otherwise, the return value will be `0`. The pattern does not have to match the whole string. If you need more control than this, you can anchor the pattern to the beginning of the string by starting the pattern with ^, or to the end of the string by ending the pattern with dollar sign, `$`. You can force the pattern to match the whole string by using both characters. For example:

```
set  text1  "This is the first string"
=> This is the first string

regexp  "first string" $text1
=> 1

regexp "second string"  $text1
=> 0
```

Jacl data structures

The basic data structure in the Jacl language is a string. There are two higher level data structures: lists and arrays. Lists are implemented as strings and the structure is defined by the syntax of the string. The syntax rules are the same as for commands. Commands are a particular instance of lists. Arrays are variables that have an index. The index is a string value so you can think of arrays as maps from one string (the index) to another string (the value of the array element).

Jacl lists

The lists of the Jacl language are strings with a special interpretation. In the Jacl language, a list has the same structure as a command. A list is a string with list elements separated by white space. You can use braces or quotes to group together words with white space into a single list element.

The following table includes commands that are related to lists:

Command	Description
list arg1 arg2	Creates a list out of all its arguments.
lindex list i	Returns the i'th element from list.
llength list	Returns the number of elements in list.
lrange list i j	Returns the i'th through j'th elements from list.
lappend listVar arg arg ...	Appends elements to the value of listVar
linsert list index arg arg ...	Inserts elements into list before the element at position index. Returns a new list.
lreplace list i j arg arg ...	Replaces elements i through j of list with the args. Return a new list.
lsearch mode list value	Returns the index of the element in list that matches the value according to the mode, which is -exact, -glob, or -regexp, -glob is the default. Return -1 if not found.
lsort switches list	Sorts elements of the list according to the switches: -ascii, -integer, -real, -increasing, -decreasing, -command command. Return a new list.
concat arg arg arg ...	Joins multiple lists together into one list.
join list joinString	Merges the elements of a list together by separating them with joinString.
split string splitChars	Splits a string up into list elements, using (and discarding) the characters in splitChars as boundaries between list elements.

Arrays

Arrays are the other primary data structure in the Jacl language. An array is a variable with a string-valued index, so you can think of an array as a mapping from strings to strings. Internally an array is implemented with a hash table. The cost of accessing each element is about the same. The index of an array is delimited by parentheses. The index can have any string value, and it can be the result of variable or command substitution. Array elements are defined with the **set** command, for example:

```
set arr(index) value
```

Substitute the dollar sign ($) to obtain the value of an array element, for example:

```
set foo $arr(index)
```

For example:

```
set fruit(best) kiwi
=> kiwi

set fruit(worst) peach
=> peach

set fruit(ok) banana
=> banana

array get fruit
=> ok banana worst peach best kiwi

array exists fruit
=> 1
```

The following table includes array commands:

Command	Description
array exists arr	Returns 1 if arr is an array variable.
array get arr	Returns a list that alternates between an index and the corresponding array value.
array names arr ?pattern?	Return the list of all indices defined for arr, or those that match the string match pattern.
array set arr list	Initializes the array arr from list, which should have the same form as the list returned by get.
array size arr	Returns the number of indices defined for arr.
array startsearch arr	Returns a search token for a search through arr.
array nextelement arr id	Returns the value of the next element in array in the search identified by the token id. Returns an empty string if no more elements remain in the search.
array anymore arr id	Returns 1 if more elements remain in the search.
array donesearch arr id	Ends the search identified by `id`.

Control flow commands

The following looping commands exist:

- `while`
- `foreach`
- `for`

The following are conditional commands:

- `if`
- `switch`

The following is an error handling command:

- `catch`

The following commands fine-tune control flow:

- `break`
- `continue`
- `return`
- `error`

If Then Else

The **if** command is the basic conditional command. If an expression is true, then execute one command body, otherwise execute another command body. The second command body (the else clause) is optional. The syntax of the command is the following:

```
if  boolean  then  body1  else  body2
```

The then and else keywords are optional. For example:

```
if {$x == 0} {
 puts stderr "Divide by zero!"
} else {
 set slope [expr $y/$x]
}
```

Switch

Use the **switch** command to branch to one of many commands depending on the value of an expression. You can choose based on pattern matching as well as simple comparisons. Any number of pattern-body pairs can be specified. If multiple patterns match, only the body of the first matching pattern is evaluated. The general form of the command is the following:

```
switch  flags  value  pat1  body1  pat2  body2  ...
```

You can also group all the pattern-body pairs into one argument:

```
switch  flags  value  {pat1  body1  pat2  body2  ...}
```

There are four possible flags that determines how value is matched.

- `-exact` Matches the value exactly to one of the patterns.
- `-glob` Uses glob-style pattern matching.
- `-regexp` Uses regular expression pattern matching.
- `--` No flag (or end of flags). Useful when value can begin with a dash (-).

For example:

```
switch  -exact  --  $value  {
 foo  {doFoo;  incr  count(foo)}
 bar {doBar;  return  $count(foo)}
 default   {incr  count(other)}
}
```

If the pattern that is associated with the last body is `default`, then the command body is started if no other patterns match. The `default` keyword only works on the last pattern-body pair. If you use the default pattern on an earlier body, it will be treated as a pattern to match the literal string default.

Foreach

The **foreach** command loops over a command body and assigns a loop variable to each of the values in a list. The syntax is the following:

```
foreach loopVar valueList commandBody
```

The first argument is the name of a variable. The command body runs one time for each element in the loop with the loop variable having successive values in the list. For example:

```
set numbers {1 3 5 7 11 13}
foreach num $numbers {
puts $num
}
```

The result from the previous example will be the following output, assuming that only one server exists in the environment. If there is more than one server, the information for all servers returns:

```
1
3
5
7
11
13
```

While

The **while** command takes two arguments; a test and a command body, for example:

```
while  booleanExpr  body
```

The **while** command repeatedly tests the boolean expression and runs the body if the expression is true (non-zero). For example:

```
set i 0
while {$i < 5} {
puts "i is $i"
incr i}
```

The result from the previous example will be like the following output, assuming that there is only one server. If there is more then one servers, it will print all of the servers:

```
i is 0
i is 1
i is 2
i is 3
i is 4
```

For

The **for** command is similar to the C language for statement. It takes four arguments, for example:

```
for initial test final body
```

The first argument is a command to initialize the loop. The second argument is a boolean expression which determines if the loop body will run. The third argument is a command that runs after the loop body: For example:

```
set numbers {1 3 5 7 11 13}
for {set i 0} {$i < [llength $numbers]} {incr i 1} {
puts "i is $i"
}
```

The result from previous example will be like the following output, assuming that there is only one server in the environment. If there is more then one server, it will print all of the servers:

```
i is 1
i is 3
i is 5
i is 7
i is 11
i is 13
```

Break and continue

You can control loop execution with the **break** and **continue** commands. The **break** command causes an immediate exit from a loop. The **continue** command causes the loop to continue with the next iteration.

Catch

An error will occur if you call a command with the wrong number of arguments or if the command detects some error condition particular to its implementation. An uncaught error prevents a script from running. Use the **catch** command trap such errors. The catch command takes two arguments, for example:

```
catch command ?resultVar?
```

The first argument is a command body. The second argument is the name of a variable that will contain the result of the command or an error message if the command raises an error. The **catch** command returns a value of zero if no error was caught or a value of one if the command catches an error. For example:

```
catch {expr 20 / 5} result
==> 0
puts $result
==> 4
catch {expr text / 5} result
==> 1
puts $result
==> syntax error in expression "text / 5"
```

Return

The **return** command is used to return from a procedure. It is needed if you want something to return before the end of the procedure body or if a contrast value needs to be returned.

Namespaces

Jacl keeps track of named entities such as variables, in namespaces. The wsadmin tool also adds entries to the global namespace for the scripting objects, such as, the AdminApp object

When you run a proc command, a local namespace is created and initialized with the names and the values of the parameters in the proc command. Variables are held in the local namespace while you run the proc command. When you stop the proc command, the local namespace is erased. The local namespace of the proc command implements the semantics of the automatic variables in languages such as C and Java.

While variables in the global namespace are visible to the top level code, they are not visible by default from within a proc command. To make them visible, declare the variables globally using the **global** command. For the variable names that you provide, the global command creates entries in the local namespace that point to the global namespace entries that actually define the variables.

If you use a scripting object provided by the wsadmin tool in a proc, you must declare it globally before you can use it, for example:

```
proc { ... } {
  global AdminConfig
  ... [$AdminConfig ...]
}
```

For more information about Jacl, see the Scripting: Resources for Learning article.

Jython

Jython is an alternate implementation of Python, and is written entirely in Java.

The wsadmin tool uses Jython V2.1. The following information is a basic summary of the Jython syntax:

Basic function

The function is either the name of a built-in function or a Jython function. For example:

```
print "Hello, World!"
=> Hello, World!

import sys
sys.stdout.write("Hello World!\n")
=> Hello World!
```

In the example, `print` identifies the standard output stream. You can use the built-in module by running import statements such as the previous example. The statement import runs the code in a module as part of the importing and returns the module object. `sys` is a built-in module of the Python language. In the Python language, modules are name spaces which are places where names are created. Names that reside in modules are called attributes. Modules correspond to files and the Python language creates a module object to contain all the names defined in the file. In other words, modules are name spaces.

Variable

To assign objects to names, the target of an assignment should be on the left side of an equal sign (=) and the object that you are assigning on the right side. The target on the left side can be a name or object component, and the object on the right side can be an arbitrary expression that computes an object. The following rules exist for assigning objects to names:

- Assignments create object references.
- Names are created when you assign them.
- You must assign a name before referencing it.

Variable name rules are similar to the rules for the C language, for example:

- An underscore character (_) or a letter plus any number of letters, digits or underscores

The following reserved words can not be used for variable names:

```
and     assert   break    class   continue
def     del      elif     else    except
exec    inally     for      from    global
if     importin   is       lambda
not    or      pass     print    raise
return  try      while
```

For example:

```
a  = 5
print a
=> 5

b =  a
print b
=> 5

text1, text2, text3, text4  = 'good', 'bad', 'pretty', 'ugly'
print text3
=> pretty
```

The second example assigns the value of variable a to variable b.

Types and operators

The following list contains a few of the built-in object types:

- Numbers. For example:

```
8, 3.133,  999L,  3+4j

num1 = int(10)
print num1
=> 10
```

- Strings. For example:

```
'name',  "name's", ''

print str(12345)
=> '12345'
```

- Lists. For example:

```
x = [1, [2,  'free'], 5]
y = [0, 1, 2, 3]
y.append(5)
print y
=> [0, 1, 2, 3, 5]

y.reverse()
print y
=> [5, 3, 2, 1, 0]

y.sort()
print y
=> [0, 1, 2, 3, 5]

print list("apple")
=> ['a', 'p', 'p', 'l', 'e']

print list((1,2,3,4,5))
=> [1, 2, 3, 4, 5]

test = "This is a test"
test.index("test")
=> 10

test.index('s')
=> 3
```

The following list contains a few of the operators:

- x or y

  y is evaluated only if x is false. For example:

```
print 0 or 1
=> 1
```

- x and y

  y is evaluated only if x is true. For example:

```
print 0 and 1
=>  0
```

- x +y , x - y

  Addition and concatenation, subtraction. For example:

```
print  6 + 7
=> 13

text1 = 'Something'
text2 = ' else'
print text1 + text2
=> Something else

list1 = [0, 1, 2, 3]
list2 = [4, 5, 6, 7]
print list1 + list2
```

```
=> [0, 1, 2, 3, 4, 5, 6, 7]

print  10 - 5
=> 5
```

- x * y, x / y, x % y

  Multiplication and repetition, division, remainder and format. For example:

  ```
  print 5 * 6
  => 30

  print 'test' * 3
  => test test test

  print 30 / 6
  => 5

  print 32 % 6
  => 2
  ```

- x[i], x[i:j], x(...)

  Indexing, slicing, function calls. For example:

  ```
  test = "This is a test"
  print  test[3]
  => s

  print test[3:10]
  => s is a

  print test[5:]
  => is a test

  print x[:-4]
  => This is a print len(test)
  => 14
  ```

- <, <=, >, >=, ==, <>, !=, is is not

  Comparison operators, identity tests. For example:

  ```
  l1 = [1, ('a', 3)]
  l2 = [1, ('a', 2)]
  l1 < l2, l1 == l2, l1 > l2, l1 <> l2, l1 != l2, l1 is l2, l1 is not l2
  => (0, 0, 1, 1, 1, 0, 1)
  ```

Backslash substitution

If a statement needs to span multiple lines, you can also add a black slash (\) at the end of the previous line to indicate you are continuing on the next line. For example:

```
text =  "This is a tests of a long lines" \
" continuing lines here."
print text
=> This is a tests of a long lines continuing lines here.
```

Functions and scope

Jython uses the `def` statement to define functions. Functions related statements include:

- `def`, `return`

  The `def` statement creates a function `boject` and assigns it to a name. The`return` statement sends a result object back to the caller. This is optional, and if it is not present, a function exits so that control flow falls off the end of the function body.

- `global`

The global statement declares module-level variables that are to be assigned. By default, all names assigned in a function are local to that function and exist only while the function runs. To assign a name in the enclosing module, list functions in a global statement.

The basic syntax to define a function is the following:

```
def name (arg1, arg2, ... ArgN):
statements
return value
```

where *name* is the name of the function being defined. It is followed by an open parenthesis, a close parenthesis and a colon. The arguments inside parenthesis include a list of parameters to the procedures. The next line after the colon is the body of the function. A group of commands that form the body of the function. After you define a Jython function, it is used just like any of the built-in functions. For example:

```
def  intersect(seq1, seq2):
  try:
     res = []
     for x in seq1:
     if x in seq2:
       res.append(x)
     return res
  except:
```

To call the function above, use the following command:

```
s1 = "SPAM"
s2 = "SCAM"
intersect(s1, s2)
=> [S, A, M]

intersect([1,2,3], (1.4))
=> [1]
```

Comments

Make comments in the Jython language with the pound character (#).

Command line arguments

The Jython shells pass the command line arguments to the script as the value of the sys.argv. The name of the program, or script, is not part of sys.argv. sys.argv is an array, so you use the index command to extract items from the argument list, for example:

```
import sys
first  =  sys.argv[0]
second  = sys.argv[1]
arglen = len(sys.argv)
```

Basic statements

There are two looping statements: while and for. The conditional statement is if. The error handling statement is try. Finally, there are some statements to fine-tune control flow: break, continue and pass. The following is a list of syntax rules in Python:

- Statements run one after another until you say otherwise. Statements normally end at the end of the line they appear on. When statements are too long to fit on a single line you can also add a back sash (\) at the end of the prior line to indicate you are continuing on the next line.
- Block and statement boundaries are detected automatically. There are no braces, or begin or end delimiter, around blocks of code. Instead, the Python language uses the indentation of statements under a header in order to group the statements in a nested block. Block boundaries are detected by line indentation. All statements indented the same distance to the right belong to the same block of code until that block is ended by a line less indented.

- Compound statements = header; ':', indented statements. All compound statements in the Python language follow the same pattern: a header line terminated with a colon, followed by one or more nested statements indented under the header. The indented statements are called a block.
- Spaces and comments are usually ignored. Spaces inside statements and expressions are almost always ignored (except in string constants and indentation), so are comments.

If

The `if` statement selects actions to perform. The `if` statement may contain other statements, including other `if` statements. The `if` statement can be followed by one or more optional `elif` statements and ends with an optional `else` block.

The general format of an if looks like the following:

```
if test1
 statements1
elif test2
 statements2
else test3
 statements3
```

For example:

```
weather = 'sunny'
if weather == 'sunny':
 print "Nice weather"
elif weather == 'raining':
 print "Bad weather"
else:
 print "Uncertain, don't plan anything"
```

While

The `while` statement consists of a header line with a test expression, a body of one or more indented statements, and an optional `else` statement that runs if control exits the loop without running into a break statement. The `while` statement repeatedly executes a block of indented statements as long as a test at the top keeps evaluating a true value. The general format of an while looks like the following:

```
while test1
 statements1
else
 statements2
```

For example:

```
a = 0; b = 10
while a < b:
 print a
 a = a + 1
```

For

The `for` statement begins with a header line that specifies an assignment target or targets, along with an object you want to step through. The header is followed by a block of indented statements which you want to repeat.

The general format of an while looks like the following:

```
for target in object:
 statements
else:
 statements
```

It assigns items in the sequence object to the target, one by one, and runs the loop body for each. The loop body typically uses the assignment target to refer to the current item in the sequence as if it were a cursor stepping through the sequence. For example:

```
sum = 0
for x in [1, 2, 3, 4]:
  sum = sum + x
```

Break, continue, and pass

You can control running a loop the `break`, `continue` and `pass` statements. The `break` statement jumps out of the closest enclosing loop (past the entire loop statement). The `continue` statements jumps to the top of the closest enclosing loop (to the header line of the loop), and the `pass` statement is an empty statement placeholder.

Try

A statement will raise an error if it is called with the wrong number of arguments, or if it detects some error condition particular to its implementation. An uncaught error aborts execution of a script. The try statement is used to trap such errors. Python try statements come in two flavors, one that handles exceptions and one that executes finalization code whether exceptions occur or not. The `try`, `except`, `else` statement starts with a try header line followed by a block of indented statements, then one or more optional except clauses that name exceptions to be caught, and an optional `else` clause at the end. The `try`, `finally` statements starts with a try header line followed by a block of indented statements, then finally clause that always runs on the way out whether an exception occurred while the try block was running or not.

The general format of the try, except, else function looks like the following:

```
try:
 statements
except name:
 statements
except name, data:
 statements
else
 statements
```

For example:

```
try:
   myfunction()
except:
   import sys
   print 'uncaught exception', sys.exc_type, sys.exc_value

try:
   myfilereader()
except EOFError:
   break
else:
   process next line here
```

The general format of a try and finally looks like the following:

```
try:
 statements
finally:
 statements
```

For example:

```
def divide(x, y):
   return x / y
```

```
def tester(y):
   try:
     print divide(8, y)
   finally:
   print 'on the way out...'
```

For more information about the Jython language, see the Scripting: Resources for Learning article.

Scripting objects

The wsadmin tool operates on configurations and running objects through the following set of management objects: AdminConfig, AdminControl, AdminApp, AdminTask, and Help. Each of these objects has commands that you can use to perform administrative tasks. To use the scripting objects, specify the scripting object, a command, and command parameters. For example:

Using Jacl:

```
$AdminConfig attributes ApplicationServer
```

Using Jython:

```
print AdminConfig.attributes('ApplicationServer')
```

where `AdminConfig` is the scripting object, `attributes` is the command, and `ApplicationServer` is the command parameter.

To find out more specific information about each of the scripting objects, including command and command parameter information, see AdminConfig, AdminApp, AdminControl, AdminTask, or Help.

WebSphere Application Server system management separates administrative functions into two categories: functions that work with the configuration of WebSphere Application Server installations, and functions that work with the currently running objects in WebSphere Application Server installations.

Scripts work with both categories of objects. For example, an application server is divided into two distinct entities. One entity represents the configuration of the server that resides persistently in a repository on permanent storage. You can create, query, change, or remove this configuration without starting an application server process. The **AdminConfig object**, the **AdminTask object**, and the **AdminApp object** handle configuration functionality. You can invoke configuration functions with or without being connected to a server.

The second entity represents the running instance of an application server by a *Java Management Extensions (JMX) MBean*. This instance can have attributes that you can interrogate and change, and operations that you can invoke. These operational actions taken against a running application server do not have an effect on the persistent configuration of the server. The attributes that support manipulation from an MBean differ from the attributes that the corresponding configuration supports. The configuration can include many attributes that you cannot query or set from the running object. The WebSphere Application Server scripting support provides functions to locate configuration objects, and running objects. Objects in the configuration do not always represent objects that are currently running. The **AdminControl object** manages running objects.

You can use the **Help object** to obtain information about the AdminConfig, AdminApp, AdminControl, and AdminTask objects, to obtain interface information about running MBeans, and to obtain help for warnings and error messages.

Help object for scripted administration: The Help object provides general help, online information about running MBeans, and help on messages.

Use the Help object to obtain general help for the other objects supplied by the wsadmin tool for scripting: the AdminApp, AdminConfig, AdminTask, and AdminControl objects. For example, using Jacl, `$Help AdminApp` or using Jython, `Help.Adminapp()`, provides information about the AdminApp object and the available commands.

The Help object also to provides interface information about MBeans running in the system. The commands that you use to get online information about the running MBeans include: **all**, **attributes**, **classname**, **constructors**, **description**, **notification**, **operations**.

You can also use the Help object to obtain information about messages using the **message** command. The **message** command provides aid to understand the cause of a warning or error message and find a solution for the problem. For example, you receive a `WASX7115E` error when running the AdminApp **install** command to install an application, use the following example:

Using Jacl:

```
$Help message WASX7115E
```

Using Jython:

```
print Help.message('WASX7115E')
```

Example output:

```
Explanation: wsadmin failed to read an ear file when
preparing to copy it to a temporary location for AdminApp
processing.  User action: Examine the wsadmin.traceout
log file to determine the problem; there may be file permission problems.
```

The user action specifies the recommended action to correct the problem. It is important to understand that in some cases the user action may not be able to provide corrective actions to cover all the possible causes of an error. It is an aid to provide you with information to troubleshoot a problem.

To see a list of all available commands for the Help object, see the Commands for the Help object article or you can also use the **Help** command, for example:

Using Jacl:

```
$Help help
```

Using Jython:

```
print Help.help()
```

AdminApp object for scripted administration: Use the AdminApp object to manage applications. This object communicates with the WebSphere Application Server run time application management object to make application inquires and changes, for example:

- Installing and uninstalling applications
- Listing applications
- Editing applications or modules

Since applications are part of configuration data, any changes that you make to an application is kept in the configuration session, similar to other configuration data. Be sure to save your application changes so that the data transfers from the configuration session to the master repository.

With the application already installed, the AdminApp object can update application metadata, map virtual hosts to Web modules, and map servers to modules. You must perform any other changes, such as, specifying a library for the application to use or setting session management configuration properties, using the AdminConfig object.

You can run the commands for the AdminApp object in local mode. If a server is running, it is not recommended that you run the scripting client in local mode because any configuration changes that are made in local mode will not be reflected in the running server configuration and vice versa. If you save a conflicting configuration, you could corrupt the configuration. In a deployment manager environment, configuration updates are available only if a scripting client is connected to a deployment manager. When connected to a node agent or a managed application server, you will not be able to update the configuration because the configuration for these server processes are copies of the master configuration which resides in the deployment manager. The copies are created on a node machine when a configuration synchronization occurs between the deployment manager and the node agent. Make configuration changes to the server processes by connecting a scripting client to a deployment manager. For this reason, to change a configuration, do not run a scripting client in local mode on a node machine. It is not a supported configuration.

To see a list of all available commands for the AdminApp object, see the Commands for the AdminApp object article or you can also use the **Help** command, for example:

Using Jacl:

```
$AdminApp help
```

Using Jython:

```
print AdminApp.help()
```

Listing applications with the wsadmin tool:

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

Query the configuration and create a list of installed applications, for example:

- Using Jacl:

  ```
  $AdminApp list
  ```

- Using Jython:

  ```
  AdminApp.list()
  ```

where:

`$`	is a Jacl operator for substituting a variable name with its value
`AdminApp`	is an object allowing application objects management
`list`	is an AdminApp command

Example output:

```
DefaultApplication
SampleApp
app1serv2
```

Editing application configurations with the wsadmin tool:

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

1. Edit the entire application or a single application module. Use one of the following commands:
   - The following command uses the installed application and the command option information to edit the application:
     – Using Jacl:

```
$AdminApp edit appname {options}
```

- Using Jython list:

```
AdminApp.edit('appname', ['options'])
```

- Using Jython string:

```
AdminApp.edit('appname', '[options]')
```

where:

`$`	is a Jacl operator for substituting a variable name with its value
`AdminApp`	is an object allowing application objects management
`edit`	is an AdminApp command
appname	is the name of application or application module to edit. For the application module name, use the module name returned from **listModules** command as the value.
`{options}`	is a list of edit options and tasks similar to the ones for the install command

- The following command changes the application information by prompting you through a series of editing tasks:
  - Using Jacl:

```
$AdminApp editInteractive appname
```

  - Using Jython:

```
AdminApp.editInteractive('appname')
```

where:

`$`	is a Jacl operator for substituting a variable name with its value
`AdminApp`	is an object allowing application objects management
`editInteractive`	is an AdminApp command
appname	is the name of application or application module to edit. For the application module name, use the module name returned from **listModules** command as the value.

2. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 232 article for more information.
3. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 217 article for more information.

AdminControl object for scripted administration: The AdminControl scripting object is used for operational control. It communicates with MBeans that represent live objects running a WebSphere server process. It includes commands to query existing running objects and their attributes and invoke operation on the running objects. In addition to the operational commands, the AdminControl object supports commands to query information on the connected server, convenient commands for client tracing, reconnecting to a server, and start and stop server for network deployment environment.

Many of the operational commands have two sets of signatures so that they can either invoke using string based parameters or using Java Management Extension (JMX) objects as parameters. Depending on the server process to which a scripting client is connected, the number and type of MBeans available varies. If a scripting client is connected to a deployment manager, then all MBeans in all server processes are visible. If a scripting client is connected to a node agent, all MBeans in all server processes on that node are accessible. When connected to an application server, only MBeans running in that application server are visible.

The following steps provide a general method to manage the cycle of an application:

- Install the application.
- Edit the application.
- Update the application.
- Uninstall the application.

To see a list of all available commands for the AdminControl object, see the Commands for the AdminControl object article or you can also use the **Help** command, for example:

Using Jacl:

```
$AdminControl help
```

Using Jython:

```
print AdminControl.help()
```

ObjectName, Attribute, and AttributeList classes:

WebSphere Application Server scripting commands use the underlying Java Management Extensions (JMX) classes, ObjectName, Attribute, and AttributeList, to manipulate object names, attributes and attribute lists respectively.

The WebSphere Application Server ObjectName class uniquely identifies running objects. The ObjectName class consists of the following elements:

- The domain name `WebSphere`.
- Several key properties, for example:
  - **`type`** - Indicates the type of object that is accessible through the MBean, for example, ApplicationServer, and EJBContainer.
  - **`name`** - Represents the display name of the particular object, for example, MyServer.
  - **`node`** - Represents the name of the node on which the object runs.
  - **`process`** - Represents the name of the server process in which the object runs.
  - **`mbeanIdentifier`** - Correlates the MBean instance with corresponding configuration data.

When ObjectName classes are represented by strings, they have the following pattern:

```
[domainName]:property=value[,property=value]*
```

For example, you can specify `WebSphere:name="My Server",type=ApplicationServer,node=n1,*` to specify an application server named `My Server` on node n1. (The asterisk (*) is a wildcard character, used so that you do not have to specify the entire set of key properties.) The AdminControl commands that take strings as parameters expect strings that look like this example when specifying running objects (MBeans). You can obtain the object name for a running object with the **getObjectName** command.

Attributes of these objects consist of a name and a value. You can extract the name and value with the **getName** and the **getValue** methods that are available in the javax.management.Attribute class. You can also extract a list of attributes.

Example: Collecting arguments for the AdminControl object: Verify that the arguments parameter is a single string. Each individual argument in the string can contain spaces. Collect each argument that contains spaces in some way.

- An example of how to obtain an MBean follows:

  Using Jacl:

  ```
  set am [$AdminControl queryNames type=ApplicationManager,process=server1,*]
  ```

  Using Jython:

  ```
  am = AdminControl.queryNames('type=ApplicationManager,process=server1,*')
  ```
- Multiple ways exist to collect arguments that contain spaces. Choose one of the following alternatives:

Using Jacl:

- – `$AdminControl invoke $am startApplication {"JavaMail Sample"}`
- – `$AdminControl invoke $am startApplication {{JavaMail Sample}}`
- – `$AdminControl invoke $am startApplication "\"JavaMail Sample\""`

Using Jython:

- – `AdminControl.invoke(am, 'startApplication', '[JavaMail Sample]')`
- – `AdminControl.invoke(am, 'startApplication', '\"JavaMail Sample\"')`

Example: Identifying running objects: In the WebSphere Application Server, MBeans represent running objects. You can interrogate the MBean server to see the objects it contains. Use the AdminControl object to interact with running MBeans.

- Use the **queryNames** command to see running MBean objects. For example:

  Using Jacl:

  ```
  $AdminControl queryNames *
  ```

  Using Jython:

  ```
  print AdminControl.queryNames('*')
  ```

  This command returns a list of all MBean types. Depending on the server to which your scripting client attaches, this list can contain MBeans that run on different servers:
  - – If the client attaches to a stand-alone WebSphere Application Server, the list contains MBeans that run on that server.
  - – If the client attaches to a node agent, the list contains MBeans that run in the node agent and MBeans that run on all application servers on that node.
  - – If the client attaches to a deployment manager, the list contains MBeans that run in the deployment manager, all of the node agents communicating with that deployment manager, and all application servers on the nodes served by those node agents.
- The list that the `queryNames` command returns is a string representation of JMX `ObjectName` objects. For example:

  ```
  WebSphere:cell=MyCell,name=TraceService,mbeanIdentifier=TraceService,type=TraceService,node=MyNode,process=server1
  ```

  This example represents a `TraceServer` object that runs in *server1* on *MyNode*.
- The single queryNames argument represents the `ObjectName` object for which you are searching. The asterisk ("*") in the example means return all objects, but it is possible to be more specific. As shown in the example, `ObjectName` has two parts: a domain, and a list of key properties. For MBeans created by the WebSphere Application Server, the domain is WebSphere. If you do not specify a domain when you invoke queryNames, the scripting client assumes the domain is WebSphere. This means that the first example query above is equivalent to:

  Using Jacl:

  ```
  $AdminControl queryNames WebSphere:*
  ```

  Using Jython:

  ```
  AdminControl.queryNames('WebSphere:*')
  ```
- WebSphere Application Server includes the following key properties for the `ObjectName` object:
  - – name
  - – type
  - – cell
  - – node
  - – process
  - – mbeanIdentifier

  These key properties are common. There are other key properties that exist. You can use any of these key properties to narrow the scope of the **queryNames** command. For example:

  Using Jacl:

  ```
  $AdminControl queryNames WebSphere:type=Server,node=myNode,*
  ```

  Using Jython:

```
AdminControl.queryNames('WebSphere:type=Server,node=myNode,*')
```

This example returns a list of all MBeans that represent server objects running the node *myNode*. The, * at the end of the ObjectName object is a JMX wildcard designation. For example, if you enter the following:

Using Jacl:

```
$AdminControl queryNames WebSphere:type=Server,node=myNode
```

Using Jython:

```
print AdminControl.queryNames('WebSphere:type=Server,node=myNode')
```

you get an empty list back because the argument to queryNames is not a wildcard. There is no Server MBean running that has exactly these key properties and no others.

- If you want to see all the MBeans representing applications running on a particular node, invoke the following example:

  Using Jacl:

  ```
  $AdminControl queryNames WebSphere:type=Application,node=myNode,*
  ```

  Using Jython:

  ```
  print AdminControl.queryNames('WebSphere:type=Application,node=myNode,*')
  ```

Specifying running objects using the wsadmin tool:

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

Perform the following steps to specify running objects:

1. Obtain the configuration ID with one of the following ways:
   - Obtain the object name with the **completeObjectName** command, for example:
     – Using Jacl:

     ```
     set var [$AdminControl completeObjectName template]
     ```

     – Using Jython:

     ```
     var = AdminControl.completeObjectName(template)
     ```

     where:

set	is a Jacl command
var	is a variable name
$	is a Jacl operator for substituting a variable name with its value
AdminControl	is an object that enables the manipulation of MBeans running in a WebSphere server process
completeObjectName	is an AdminControl command
template	is a string containing a segment of the object name to be matched. The template has the same format as an object name with the following pattern: [domainName]:property=value[,property=value]*. See Object name, Attribute, Attribute list for more information.

     If there are several MBeans that match the template, the **completeObjectName** command only retuns the first match. The matching MBean object name is then assigned to a variable.

     To look for *server1* MBean in *mynode*, use the following example:

     – Using Jacl:

     ```
     set server1 [$AdminControl completeObjectName node=mynode,type=Server,name=server1,*]
     ```

     – Using Jython:

```
server1 = AdminControl.completeObjectName('node=mynode,type=Server,name=server1,*')
```

- Obtain the object name with the **queryNames** command, for example:
  - Using Jacl:

    ```
    set var [$AdminControl queryNames template]
    ```
  - Using Jython:

    ```
    var = AdminControl.queryNames(template)
    ```

  where:

set	is a Jacl command
var	is a variable name
$	is a Jacl operator for substituting a variable name with its value
AdminControl	is an object that enables the manipulation of MBeans running in a WebSphere Application server process.
queryNames	is an AdminControl command
template	is a string containing a segment of the object name to be matched. The template has the same format as an object name with the following pattern: [domainName]:property=value[,property=value]*

2. If there are more than one running objects returned from the **queryNames** command, the objects are returned in a list syntax. One simple way to retrieve a single element from the list is to use the **lindex** command in Jacl and **split** command in Jython. The following example retrieves the first running object from the server list:
   - Using Jacl:

     ```
     set allServers [$AdminControl queryNames type=Server,*]
     set aServer [lindex $allServers 0]
     ```
   - Using Jython:

     ```
     allServers = AdminControl.queryNames('type=Server,*')

     # get line separator
     import  java
     lineSeparator = java.lang.System.getProperty('line.separator')

     aServer = allServers.split(lineSeparator)[0]
     ```

   For other ways to manipulate the list and then perform pattern matching to look for a specified configuration object, refer to the Jacl syntax.

You can now use the running object in with other AdminControl commands that require an object name as a parameter.

Identifying attributes and operations for running objects with the wsadmin tool:

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

Use the Help object **attributes** or **operations** commands to find information on a running MBean in the server.

1. Specify a running object.
2. Use the **attributes** command to display the attributes of the running object:
   - Using Jacl:

     ```
     $Help attributes MBeanObjectName
     ```
   - Using Jython:

```
Help.attributes(MBeanObjectName)
```

where:

`$`	is a Jacl operator for substituting a variable name with its value
`Help`	is the object that provides general help and information for running MBeans in the connected server process
`attributes`	is a Help command
`MBeanObjectName`	is the string representation of the MBean object name obtained in step 2

3. Use the **operations** command to find out the operations supported by the MBean:
   - Using Jacl:

     ```
     $Help operations MBeanObjectname
     ```

     or

     ```
     $Help operations MBeanObjectname operationName
     ```

   - Using Jython:

     ```
     Help.operations(MBeanObjectname)
     ```

     or

     ```
     Help.operations(MBeanObjectname, operationName)
     ```

   where:

`$`	is a Jacl operator for substituting a variable name with its value
`Help`	is the object that provides general help and information for running MBeans in the connected server process
`operations`	is a Help command
`MBeanObjectname`	is the string representation of the MBean object name obtained in step number 2
`operationName`	(optional) is the specified operation for which you want to obtain detailed information

If you do not provide the `operationName`, all operations supported by the MBean return with the signature for each operation. If you specify `operationName`, only the operation that you specify returns and it contains details which include the input parameters and the return value. To display the operations for the server MBean, use the following example:

- Using Jacl:

  ```
  set server [$AdminControl completeObjectName type=Server,name=server1,*]
  $Help operations $server
  ```

- Using Jython:

  ```
  server = AdminControl.completeObjectName('type=Server,name=server1,*')
  print Help.operations(server)
  ```

To display detailed information about the stop operation, use the following example:

- Using Jacl:

  ```
  $Help operations $server stop
  ```

- Using Jython:

  ```
  print Help.operations(server, 'stop')
  ```

Performing operations on running objects using the wsadmin tool:

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

Perform the following steps to perform operations on running objects:

1. Obtain the object name of the running object. For example:
   - Using Jacl:
     ```
     $AdminControl completeObjectName name
     ```
   - Using Jython:
     ```
     AdminControl.completeObjectName(name)
     ```

   where:

$	is a Jacl operator for substituting a variable name with its value
AdminControl	is an object that enables the manipulation of MBeans running in a WebSphere server process
completeObjectName	is an AdminControl command
name	is a fragment of the object name. It is used to find the matching object name. For example: type=Server,name=serv1,*. It can be any valid combination of domain and key properties. For example, type, name, cell, node, process, etc.

2. Set the s1 variable to the running object, for example:
   - Using Jacl:
     ```
     set s1 [$AdminControl completeObjectName type=Server,name=server1,*]
     ```
   - Using Jython:
     ```
     s1 = AdminControl.completeObjectName('type=Server,name=server1,*')
     ```

   where:

set	is a Jacl command
s1	is a variable name
$	is a Jacl operator for substituting a variable name with its value
AdminControl	is an object that enables the manipulation of MBeans running in a WebSphere server process
completeObjectName	is an AdminControl command
type	is the object name property key
Server	is the name of the object
name	is the object name property key
server1	is the name of the server where the operation will be invoked

3. Invoke the operation. For example:
   - Using Jacl:
     ```
     $AdminControl invoke $s1 stop
     ```
   - Using Jython:
     ```
     AdminControl.invoke(s1, 'stop')
     ```

where:

$	is a Jacl operator for substituting a variable name with its value
AdminControl	is an object that enables the manipulation of MBeans running in a WebSphere server process
invoke	is an AdminControl command
s1	is the ID of the server specified in step number 3
stop	is an operation to be invoked on the server

The following example is for operations that require parameters:

- Using Jacl:

```
set traceServ [$AdminControl completeObjectName type=TraceService,process=server1,*]
$AdminControl invoke $traceServ appendTraceString "com.ibm.ws.management.*=all=enabled"
```

- Using Jython:

```
traceServ = AdminControl.completeObjectName('type=TraceService,process=server1,*')
AdminControl.invoke(traceServ, 'appendTraceString',  "com.ibm.ws.management.*=all=enabled")
```

Modifying attributes on running objects with the wsadmin tool:

Before starting this task, the wsadmin tool must be running. See the "Starting the wsadmin scripting client" on page 250 article for more information.

Perform the following steps to modify attributes on running objects:

1. Obtain the name of the running object, for example:
   - Using Jacl:

     ```
     $AdminControl completeObjectName name
     ```

   - Using Jython:

     ```
     AdminControl.completeObjectName(name)
     ```

   where:

$	is a Jacl operator for substituting a variable name with its value
AdminControl	is an object that enables the manipulation of MBeans running in a WebSphere server process
completeObjectName	is an AdminControl command
name	is a fragment of the object name. It is used to find the matching object name. For example: type=TraceService,node=mynode,*. It can be any valid combination of domain and key properties. For example, type, name, cell, node, process, etc.

2. Set the ts1 variable to the running object, for example:
   - Using Jacl:

     ```
     set ts1 [$AdminControl completeObjectName name]
     ```

   - Using Jython:

     ```
     ts1 = AdminControl.completeObjectName(name)
     ```

   where:

set	is a Jacl command

ts1	is a variable name
$	is a Jacl operator for substituting a variable name with its value
AdminControl	is an object that enables the manipulation of MBeans running in a WebSphere server process
completeObjectName	is an AdminControl command
name	is a fragment of the object name. It is used to find the matching object name. For example: `type=TraceService,node=mynode,*`. It can be any valid combination of domain and key properties. For example, type, name, cell, node, process, etc.

3. Modify the running object, for example:
   - Using Jacl:

     ```
     $AdminControl setAttribute $ts1 ringBufferSize 10
     ```

   - Using Jython:

     ```
     AdminControl.setAttribute(ts1, 'ringBufferSize', 10)
     ```

   where:

$	is a Jacl operator for substituting a variable name with its value
AdminControl	is an object that enables the manipulation of MBeans running in a WebSphere server process
setAttribute	is an AdminControl command
ts1	evaluates to the ID of the server specified in step number 3
ringBufferSize	is an attribute of modify objects
10	is the value of the ringBufferSize attribute

   You can also modify multiple attribute name and value pairs, for example:
   - Using Jacl:

     ```
     set ts1 [$AdminControl completeObjectName type=TraceService,process=server1,*]
     $AdminControl setAttributes $ts1 {{ringBufferSize 10} {traceSpecification com.ibm.*=all=disabled}}
     ```

   - Using Jython list:

     ```
     ts1 = AdminControl.completeObjectName('type=TraceService,process=server1,*')
     AdminControl.setAttributes(ts1, [['ringBufferSize', 10], ['traceSpecification',  'com.ibm.*=all=disabled']])
     ```

   - Using Jython string:

     ```
     ts1 =AdminControl.completeObjectName('type=TraceService,process=server1,*')
     AdminControl.setAttributes(ts1, '[[ringBufferSize 10] [traceSpecification  com.ibm.*=all=disabled]]')
     ```

   The new attribute values are returned to the command line.

Synchronizing nodes with the wsadmin tool:

This article only applies to network deployment installations. A node synchronization is necessary in order to propagate configuration changes to the affected node or nodes. By default this occurs periodically, as long as the node can communicate with the deployment manager. It is possible to cause this to happen explicitly by performing the following steps:

1. Set the variable for node synchronize.
   - Using Jacl:

     ```
     set Sync1 [$AdminControl completeObjectName type=NodeSync,node=myNodeName,*]
     ```

- Using Jython:

  ```
  Sync1 = AdminControl.completeObjectName('type=NodeSync,node=myNodeName,*')
  ```

  where:

`set`	is a Jacl command
`Sync1`	is a variable name
`$`	is a Jacl operator for substituting a variable name with its value
`AdminControl`	is an object that enables the manipulation of MBeans running in a WebSphere server process
`completeObjectName`	is an AdminControl command
`type=NodeSync,node=`*`myNodeName`*	is a fragment of the object name whose complete name is returned by this command. It is used to find the matching object name which is, in this case, the SyncNode object for the node *myNodeName*, where *myNodeName* is the name of the node that you use to synchronize configuration changes. For example: `type=Server, name=serv1`. It can be any valid combination of domain and key properties. For example, type, name, cell, node, process, etc.

  Example output:

  ```
  WebSphere:platform=common,cell=myNetwork,version=5.0,name=node
  Sync,mbeanIdentifier=nodeSync,type=NodeSync,node=myBaseNode,
  process=nodeagent
  ```

2. Synchronize by issuing the following command:
   - Using Jacl:

     ```
     $AdminControl invoke $Sync1 sync
     ```

   - Using Jython:

     ```
     AdminControl.invoke(Sync1, 'sync')
     ```

   where:

`$`	is a Jacl operator for substituting a variable name with its value
`AdminControl`	is an object that enables the manipulation of MBeans running in a WebSphere server process
`invoke`	is an AdminControl command
`Sync1`	evaluates to the ID of the server specified in step number 7
`sync`	is an attribute of modify objects

   Example output:

   ```
   true
   ```

   You will receive an output value of `true` if the synchronization completes.

When the synchronization is complete, the files created in the `c:/WebSphere/DeploymentManager/config` directory now exists on the *`mynode`* node in the `c:/WebSphere/AppServer/config` directory.

AdminConfig object for scripted administration: Use the AdminConfig object to manage the configuration information that is stored in the repository. This object communicates with the WebSphere

Application Server configuration service component to make configuration inquires and changes. You can use it to query existing configuration objects, create configuration objects, modify existing objects, remove configuration objects, and obtain help.

Updates to the configuration through a scripting client are kept in a private temporary area called a workspace and are not copied to the master configuration repository until you run a **save** command. The workspace is a temporary repository of configuration information that administrative clients including the administrative console use. The workspace is kept in the `wstemp` subdirectory of your WebSphere Application Server installation. The use of the workspace allows multiple clients to access the master configuration. If the same update is made by more than one client, it is possible that updates made by a scripting client will not save because there is a conflict. If this occurs, the updates will not be saved in the configuration unless you change the default save policy with the **setSaveMode** command.

The AdminConfig commands are available in both connected and local modes. If a server is currently running, it is not recommended that you run the scripting client in local mode because the configuration changes made in the local mode is not reflected in the running server configuration and vice versa. In connnected mode, the availability of the AdminConfig commands depend on the type of server to which a scripting client is connected in a Network Deployment installation.

The AdminConfig commands are available only if a scripting client is connected to a deployment manager. When connected to a node agent or an application server, the AdminConfig commands will not be available because the configuration for these server processes are copies of the master configuration that resides in the deployment manager. The copies are created in a node machine when configuration synchronization occurs between the deployment manager and the node agent. You should make configuration changes to the server processes by connecting a scripting client to a deployment manager. For this reason, to change a configuration, do not run a scripting client in local mode on a node machine. It is not a supported configuration.

The following steps provide a general method to update a configuration object:

- Identify the configuration type and the corresponding attributes.
- Query an existing configuration object to obtain a configuration ID to use.
- Modify the existing configuration object or create a one.
- Save the configuration.

To see a list of all available commands for the AdminConfig object, see the Commands for the AdminConfig object article or you can also use the **Help** command, for example:

Using Jacl:

```
$AdminConfig help
```

Using Jython:

```
print AdminConfig.help()
```

Creating configuration objects using the wsadmin tool:

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

Perform this task if you want to create an object. To create new objects from the default template, use the **create** command. Alternatively, you can create objects using an existing object as a template with the **createUsingTemplate** command.

1. Use the AdminConfig object **listTemplates** command to list available templates:
   - Using Jacl:
     ```
     $AdminConfig listTemplates JDBCProvider
     ```

- Using Jython:

  ```
  AdminConfig.listTemplates('JDBCProvider')
  ```

  where:

`$`	is a Jacl operator for substituting a variable name with its value
`AdminConfig`	is an object representing the WebSphere Application Server configuration
`listTemplates`	is an AdminConfig command
`JDBCProvider`	is an object type

2. Assign the ID string that identifies the existing object to which the new object is added. You can add the new object under any valid object type. The following example uses a node as the valid object type:
   - Using Jacl:

     ```
     set n1 [$AdminConfig getid /Node:mynode/]
     ```

   - Using Jython:

     ```
     n1 =  AdminConfig.getid('/Node:mynode/')
     ```

   where:

`set`	is a Jacl command
`$`	is a Jacl operator for substituting a variable name with its value
`n1`	is a variable name
`AdminConfig`	is an object representing the WebSphere Application Server configuration
`getid`	is an AdminConfig command
`Node`	is an object type
`mynode`	is the host name of the node where the new object is added

3. Specify the template that you want to use:
   - Using Jacl:

     ```
     set t1 [$AdminConfig listTemplates JDBCProvider "DB2 JDBC Provider (XA)"]
     ```

   - Using Jython:

     ```
     t1 = AdminConfig.listTemplates('JDBCProvider', 'DB2 JDBC Provider (XA)')
     ```

   where:

`set`	is a Jacl command
`$`	is a Jacl operator for substituting a variable name with its value
`t1`	is a variable name
`AdminConfig`	is an object representing the WebSphere Application Server configuration
`listTemplates`	is an AdminConfig command
`JDBCProvider`	is an object type
`DB2 JDBC Provider (XA)`	is the name of the template to use for the new object

   If you supply a string after the name of a type, you get back a list of templates with display names that contain the string you supplied. In this example, the AdminConfig **listTemplates** command returns the JDBCProvider template whose name matches *DB2 JDBC Provider (XA)*. This example assumes that the variable that you specify here only holds one template configuration ID. If the environment contains multiple templates with the same string, for example, *DB2 JDBC Provider (XA)*, the variable will hold the configuration IDs of all of the templates. Be sure to identify the specific template that you want to use before you perform the next step, creating an object using a template.

4. Create the object with the following command:
   - Using Jacl:
     ```
     $AdminConfig createUsingTemplate JDBCProvider $n1 {{name newdriver}} $t1
     ```
   - Using Jython:
     ```
     AdminConfig.createUsingTemplate('JDBCProvider', n1, [['name', 'newdriver']], t1)
     ```

   where:

$	is a Jacl operator for substituting a variable name with its value
AdminConfig	is an object representing the WebSphere Application Server configuration
createUsingTemplate	is an AdminConfig command
JDBCProvider	is an object type
n1	evaluates the ID of the host node specified in step number 3
name	is an attribute of JDBCProvider objects
newdriver	is the value of the name attribute
t1	evaluates the ID of the template specified in step number 4

   All **create** commands use a template unless there are no templates to use. If a default template exists, the command creates the object.

5. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 232 article for more information.
6. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 217 article for more information.

Interpreting the output of the AdminConfig attributes command using scripting:

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

The **attributes** command is a wsadmin tool on-line help feature. When you issue the **attributes** command, the information that displays does not represent a particular configuration object. It represents information about configuration object types, or object metadata. This article discusses how to interpret the attribute type display.

- Simple attributes

  Using Jacl:
  ```
  $AdminConfig attributes ExampleType1
  "attr1 String"
  ```
  Types do not display as fully qualified names. For example, `String` is used for `java.lang.String`. There are no ambiguous type names in the model. For example, `x.y.ztype` and `a.b.ztype`. Using only the final portion of the name is possible, and it makes the output easier to read.
- Multiple attributes

  Using Jacl:

```
$AdminConfig attributes ExampleType2
"attr1 String" "attr2 Boolean" "attr3 Integer"
```

All input and output for the scripting client takes place with strings, but `attr2 Boolean` indicates that `true` or `false` are appropriate values. The `attr3 Integer` indicates that string representations of integers (″42″) are needed. Some attributes have string values that can take only one of a small number of predefined values. The wsadmin tool distinguishes these values in the output by the special type name ENUM, for example:

Using Jacl:

```
$AdminConfig attributes ExampleType3
"attr4 ENUM(ALL, SOME, NONE)"
```

where: `attr4` is an ENUM type. When you query or set the attribute, one of the values is `ALL`, `SOME`, or `NONE`. The value `A_FEW` results in an error.

- Nested attributes

  Using Jacl:

  ```
  $AdminConfig attributes ExampleType4
  "attr5 String" "ex5 ExampleType5"
  ```

  The `ExampleType4` object has two attributes: a string, and an `ExampleType5` object. If you do not know what is contained in the ExampleType5 object, you can use another **attributes** command to find out. The **attributes** command displays only the attributes that the type contains directly. It does not recursively display the attributes of nested types.

- Attributes that represent lists

  The values of these attributes are object lists of different types. The `*` character distinguishes these attributes, for example:

  Using Jacl:

  ```
  $AdminConfig attributes ExampleType5
  "ex6 ExampleType6*"
  ```

  In this example, objects of the `ExampleType5` type contain a single attribute, `ex6`. The value of this attribute is a list of `ExampleType6` type objects.

- Reference attributes

  An attribute value that references another object. You cannot change these references using modify commands, but these references display because they are part of the complete representation of the type. Distinguish reference attributes using the `@` sign, for example:

  Using Jacl:

  ```
  $AdminConfig attributes ExampleType6
  "attr7 Boolean" "ex7 ExampleType7@"
  ```

  `ExampleType6` objects contain references to `ExampleType7` type objects.

- Generic attributes

  These attributes have generic types. The values of these attributes are not necessarily this generic type. These attributes can take values of several different specific types. When you use the AdminConfig attributes command to display the attributes of this object, the various possibilities for specific types are shown in parentheses, for example:

  Using Jacl:

  ```
  $AdminConfig attributes ExampleType8
  "name String" "beast AnimalType(HorseType, FishType, ButterflyType)"
  ```

  In this example, the `beast` attribute represents an object of the generic `AnimalType`. This generic type is associated with three specific subtypes. The wsadmin tool gives these subtypes in parentheses after the name of the base type. In any particular instance of `ExampleType8`, the `beast` attribute can have a value of `HorseType`, `FishType`, or `ButterflyType`. When you specify an attribute in this way, using a modify or create command, specify the type of `AnimalType`. If you do not specify the `AnimalType`, a generic `AnimalType` object is assumed (specifying the generic type is possible and legitimate). This is done by specifying `beast:HorseType` instead of `beast`.

Specifying configuration objects using the wsadmin tool:

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

To manage an existing configuration object, identify the configuration object and obtain configuration ID of the object to be used for subsequent manipulation.

1. Obtain the configuration ID with one of the following ways:
   - Obtain the ID of the configuration object with the **getid** command, for example:
     - Using Jacl:

       ```
       set var [$AdminConfig getid /type:name/]
       ```
     - Using Jython:

       ```
       var = AdminConfig.getid('/type:name/')
       ```

     where:

`set`	is a Jacl command
`var`	is a variable name
`$`	is a Jacl operator for substituting a variable name with its value
`AdminConfig`	is an object representing the WebSphere Application Server configuration
`getid`	is an AdminConfig command
`/type:`*`name`*`/`	is the hierarchical containment path of the configuration object
`type`	is the object type **Note:** The name of the object type that you input here is the one based on the XML configuration files and does not have to be the same name that the administrative console displays.
`name`	is the optional name of the object

     You can specify multiple `/type:name/` in the string, for example, `/type:name/type:name/type:name/`. If you just specify the type in the containment path without the name, include the colon, for example, `/type:/`. The containment path must be a path containing the correct hierarchical order. For example, if you specify `/Server:server1/Node:node/` as the containment path, you will not receive a valid configuration ID because `Node` is parent of `Server` and should come before `Server` in the hierarchy.

     This command returns all the configuration IDs that match the representation of the containment and assigns them to a variable.

     To look for all the server configuration IDs resided in mynode, use the following example:
     - Using Jacl:

       ```
       set nodeServers [$AdminConfig getid /Node:mynode/Server:/]
       ```
     - Using Jython:

       ```
       nodeServers = AdminConfig.getid('/Node:mynode/Server:/')
       ```

     To look for server1 configuration ID resided in mynode, use the following example:
     - Using Jacl:

       ```
       set server1 [$AdminConfig getid /Node:mynode/Server:server1/]
       ```
     - Using Jython:

       ```
       server1 = AdminConfig.getid('/Node:mynode/Server:server1/')
       ```

     To look for all the server configuration IDs, use the following example:
     - Using Jacl:

```
set servers [$AdminConfig getid /Server:/]
```

– Using Jython:

```
servers = AdminConfig.getid('/Server:/')
```

- Obtain the ID of the configuration object with the **list** command, for example:
  - Using Jacl:

    ```
    set var [$AdminConfig list type]
    ```

    or

    ```
    set var [$AdminConfig list type scopeId]
    ```

  - Using Jython:

    ```
    var = AdminConfig.list('type')
    ```

    or

    ```
    var = AdminConfig.list('type', 'scopeId')
    ```

  where:

`set`	is a Jacl command
`var`	is a variable name
`$`	is a Jacl operator for substituting a variable name with its value
`AdminConfig`	is an object representing the WebSphere Application Server configuration
`list`	is an AdminConfig command
`type`	is the object type **Note:** The name of the object type that you input here is the one based on the XML configuration files and does not have to be the same name that the administrative console displays.
`scopeId`	is the configuration ID of a cell, node, or server object

  This command returns a list of configuration object IDs of a given type. If you specify the *scopeId*, the list of objects returned is within the scope specified. The list returned is assigned to a variable.

  To look for all the server configuration IDs, use the following example:
  - Using Jacl:

    ```
    set servers [$AdminConfig list Server]
    ```

  - Using Jython:

    ```
    servers = AdminConfig.list('Server')
    ```

  To look for all the server configuration IDs in *mynode*, use the following example:
  - Using Jacl:

    ```
    set scopeid [$AdminConfig getid /Node:mynode/]
    set nodeServers [$AdminConfig list Server $scopeid]
    ```

  - Using Jython:

    ```
    scopeid = AdminConfig.getid('/Node:mynode/')
    nodeServers = AdminConfig.list('Server', scopeid)
    ```

2. If there are more than more configuration IDs returned from the **getid** or **list** command, the IDs are returned in a list syntax. One way to retrieve a single element from the list is to use the **lindex** command. The following example retrieves the first configuration ID from the server object list:
   - Using Jacl:

     ```
     set allServers [$AdminConfig getid /Server:/]
     set aServer [lindex $allServers 0]
     ```

   - Using Jython:

```
allServers = AdminConfig.getid('/Server:/')

 # get line separator
 import  java
 lineSeparator = java.lang.System.getProperty('line.separator')

 arrayAllServers = allServers.split(lineSeparator)
 aServer = arrayAllServers[0]
```

For other ways to manipulate the list and then perform pattern matching to look for a specified configuration object, refer to the Jacl syntax.

You can now use the configuration ID in any subsequent AdminConfig commands that require a configuration ID as a parameter.

Listing attributes of configuration objects using the wsadmin tool:

Before starting this task, the wsadmin tool must be running. See the "Starting the wsadmin scripting client" on page 250 article for more information.

Perform the following steps to create a list of attributes of configuration objects:

1. List the attributes of a given configuration object type, using the **attributes** command, for example:
   - Using Jacl:
     ```
     $AdminConfig attributes type
     ```
   - Using Jython:
     ```
     AdminConfig.attributes('type')
     ```

   where:

`$`	is a Jacl operator for substituting a variable name with its value
`AdminConfig`	is an object representing the WebSphere Application Server configuration
`attributes`	is an AdminConfig command
`type`	is an object type

   This command returns a list of attributes and its data type.

   To get a list of attributes for the JDBCProvider type, use the following example command:
   - Using Jacl:
     ```
     $AdminConfig attributes JDBCProvider
     ```
   - Using Jython:
     ```
     AdminConfig.attributes('JDBCProvider')
     ```
2. List the required attributes of a given configuration object type, using the **required** command, for example:
   - Using Jacl:
     ```
     $AdminConfig required type
     ```
   - Using Jython:
     ```
     AdminConfig.required('type')
     ```

   where:

`$`	is a Jacl operator for substituting a variable name with its value
`AdminConfig`	is an object representing the WebSphere Application Server configuration

required	is an AdminConfig command
type	is an object type

This command returns a list of required attributes.

To get a list of required attributes for the JDBCProvider type, use the following example command:

- Using Jacl:

```
$AdminConfig required JDBCProvider
```

- Using Jython:

```
AdminConfig.required('JDBCProvider')
```

3. List attributes with defaults of a given configuration object type, using the **defaults** command, for example:

- Using Jacl:

```
$AdminConfig defaults type
```

- Using Jython:

```
AdminConfig.defaults('type')
```

where:

$	is a Jacl operator for substituting a variable name with its value
AdminConfig	is an object representing the WebSphere Application Server configuration
defaults	is an AdminConfig command
type	is an object type

This command returns a list of all attributes, types, and defaults.

To get a list of attributes with defaults displayed for the JDBCProvider type, use the following example command:

- Using Jacl:

```
$AdminConfig defaults JDBCProvider
```

- Using Jython:

```
AdminConfig.defaults('JDBCProvider')
```

Modifying configuration objects with the wsadmin tool:

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

Perform the following steps to modify a configuration object:

1. Retrieve the configuration ID of the objects that you want to modify, for example:

- Using Jacl:

```
set jdbcProvider1 [$AdminConfig getid /JDBCProvider:myJdbcProvider/]
```

- Using Jython:

```
jdbcProvider1 = AdminConfig.getid('/JDBCProvider:myJdbcProvider/')
```

where:

set	is a Jacl command
jdbcProvider1	is a variable name
$	is a Jacl operator for substituting a variable name with its value

AdminConfig	is an object representing the WebSphere Application Server configuration
getid	is an AdminConfig command
/JDBCProvider:*myJdbcProvider*/	is the hierarchical containment path of the configuration object
JDBCProvider	is the object type
myJdbcProvider	is the optional name of the object

2. Show the current attribute values of the configuration object with the show command, for example:
   - Using Jacl:
     ```
     $AdminConfig show $jdbcProvider1
     ```
   - Using Jython:
     ```
     AdminConfig.show(jdbcProvider1)
     ```

   where:

$	is a Jacl operator for substituting a variable name with its value
AdminConfig	is an object representing the WebSphere Application Server configuration
show	is an AdminConfig command
jdbcProvider1	evaluates to the ID of host node specified in step number 2

3. Modify the attributes of the configuration object, for example:
   - Using Jacl:
     ```
     $AdminConfig modify $jdbcProvider1 {{description "This is my new description"}}
     ```
   - Using Jython list:
     ```
     AdminConfig.modify(jdbcProvider1, [['description', "This is my new description"]])
     ```
   - Using Jython string:
     ```
     AdminConfig.modify(jdbcProvider1, '[[description "This is my new description"]]')
     ```

   where:

$	is a Jacl operator for substituting a variable name with its value
AdminConfig	is an object representing the WebSphere Application Server configuration
modify	is an AdminConfig command
jdbcProvider1	evaluates to the ID of host node specified in step number 3
description	is an attribute of server objects
This is my new description	is the value of the description attribute

   You can also modify several attributes at the same time. For example:
   - Using Jacl:
     ```
     {{name1 val1} {name2 val2} {name3 val3}}
     ```
   - Using Jython list:
     ```
     [['name1', 'val1'], ['name2', 'val2'], ['name3', 'val3']]
     ```
   - Using Jython string:

```
'[[name1 val1] [name2 val2] [name3 val3]]'
```

4. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 232 article for more information.
5. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 217 article for more information.

Removing configuration objects with the wsadmin tool:

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

Use this task to delete a configuration object from the configuration repository. This action only affects the configuration. If there is a running instance of a configuration object when you remove the configuration, the change has no effect on the running instance.

1. Assign the ID string that identifies the server you want to remove:

   Using Jacl:

   ```
   set s1 [$AdminConfig getid /Node:mynode/Server:myserver/]
   ```

   Using Jython:

   ```
   s1 = AdminConfig.getid('/Node:mynode/Server:myserver/')
   ```

   where:

set	is a Jacl command
s1	is a variable name
$	is a Jacl operator for substituting a variable name with its value
AdminConfig	is an object representing the WebSphere Application Server configuration
getid	is an AdminConfig command
Node	is an object type
mynode	is the host name of the node from which the server is removed
Server	is an object type
myserver	is the name of the server to remove

2. Remove the configuration object. For example:
   - Using Jacl:

     ```
     $AdminConfig remove $s1
     ```

   - Using Jython:

     ```
     AdminConfig.remove(s1)
     ```

   where:

$	is a Jacl operator for substituting a variable name with its value
AdminConfig	is an object representing the WebSphere Application Server configuration
remove	is an AdminConfig command
s1	evaluates the ID of the server specified in step number 2

3. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 232 article for more information.
4. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 217 article for more information.

The WebSphere Application Server configuration no longer contains a specific server object. Running servers are not affected.

Changing the WebSphere Application Server configuration using wsadmin:

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information. For this task, the wsadmin scripting client must be connected to the deployment manager server in a network deployment environment.

You can use the wsadmin AdminConfig and AdminApp objects to make changes to the WebSphere Application Server configuration. The purpose of this article is to illustrate the relationship between the commands used to change the configuration and the files used to hold configuration data. This discussion assumes that you have a network deployment installation, but the concepts are very similar for a WebSphere Application Server installation.

1. Set a variable for creating a server:
   - Using Jacl:
     ```
     set n1 [$AdminConfig getid /Node:mynode/]
     ```
   - Using Jython:
     ```
     n1 = AdminConfig.getid('/Node:mynode/')
     ```

   where:

set	is a Jacl command
n1	is a variable name
$	is a Jacl operator for substituting a variable name with its value
AdminConfig	is an object representing the WebSphere Application Server configuration
getid	is an AdminConfig command
Node	is the object type
mynode	is the name of the object that will be modified

2. Create a server with the following command:
   - Using Jacl:
     ```
     set serv1 [$AdminConfig create Server $n1 {{name myserv}}]
     ```
   - Using Jython list:
     ```
     serv1 = AdminConfig.create('Server', n1, [['name', 'myserv']])
     ```
   - Using Jython string:
     ```
     serv1 = AdminConfig.create('Server', n1, '[[name myserv]]')
     ```

   where:

set	is a Jacl command
serv1	is a variable name
$	is a Jacl operator for substituting a variable name with its value

`AdminConfig`	is an object representing the WebSphere Application Server configuration
`create`	is an AdminConfig command
`Server`	is an AdminConfig object
`n1`	evaluates to the ID of host node specified in step number 2
`name`	is an attribute
`myserv`	is the value of the name attribute

After this command completes, some new files can be seen in a workspace used by the deployment manager server on behalf of this scripting client. A workspace is a temporary repository of configuration information that administrative clients use. Any changes made to the configuration by an administrative client are first made to this temporary workspace. For scripting, only when a **save** command is invoked on the AdminConfig object, these changes are transferred to the real configuration repository. Workspaces are kept in the `wstemp` subdirectory of a WebSphere Application Server installation.

3. Make a configuration change to the server with the following command:
   - Using Jacl:
     ```
     $AdminConfig modify $serv1 {{stateManagement {{initialState STOP}}}}
     ```
   - Using Jython list:
     ```
     AdminConfig.modify(serv1, [['stateManagement', [['initialState', 'STOP']]]])
     ```
   - Using Jython string:
     ```
     AdminConfig.modify(serv1, '[[stateManagement  [[initialState  STOP]]]]')
     ```

   where:

`$`	is a Jacl operator for substituting a variable name with its value
`AdminConfig`	is an object representing the WebSphere Application Server configuration
`modify`	is an AdminConfig command
`serv1`	evaluates to the ID of host node specified in step number 3
`stateManagement`	is an attribute
`initialState`	is a nested attribute within the stateManagement attribute
`STOP`	is the value of the initialState attribute

This command changes the initial state of the new server. After this command completes, one of the files in the workspace is changed.

4. Install an application on the server.
5. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 232 article for more information.
6. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 217 article for more information.

Modifying nested attributes with the wsadmin tool:

The attributes for a WebSphere Application Server configuration object are often deeply nested. For example, a JDBCProvider object has an attribute factory, which is a list of the J2EEResourceFactory type objects. These objects can be DataSource objects that contain a connectionPool attribute with a ConnectionPool type that contains a variety of primitive attributes.

1. Invoke the AdminConfig object commands interactively, in a script, or use the **wsadmin -c** commands from an operating system command prompt.

2. Obtain the configuration ID of the object, for example:

   Using Jacl:

   ```
   set t1 [$AdminConfig getid /DataSource:TechSamp/]
   ```

   Using Jython:

   ```
   t1=AdminConfig.getid('/DataSource:TechSamp/')
   ```

   where:

set	is a Jacl command
t1	is a variable name
$	is a Jacl operator for substituting a variable name with its value
AdminConfig	is an object representing the WebSphere Application Server configuration
getid	is an AdminConfig command
DataSource	is the object type
TechSamp	is the name of the object that will be modified

3. Modify one of the object parents and specify the location of the nested attribute within the parent, for example:

   Using Jacl:

   ```
   $AdminConfig modify $t1 {{connectionPool {{reapTime 2003}}}}
   ```

   Using Jython list:

   ```
   AdminConfig.modify(t1, [["connectionPool", [["reapTime", 2003]]]])
   ```

   Using Jython string:

   ```
   AdminConfig.modify(t1, '[[connectionPool [[reapTime 2003]]]]')
   ```

   where:

$	is a Jacl operator for substituting a variable name with its value
AdminConfig	is an object representing the WebSphere Application Server configuration
modify	is an AdminConfig command
t1	evaluates to the configuration ID of the datasource in step number 2
connectionPool	is an attribute
reapTime	is a nested attribute within the connectionPool attribute
2003	is the value of the reapTime attribute

4. Save the configuration by issuing an AdminConfig **save** command. For example:

   Using Jacl:

   ```
   $AdminConfig save
   ```

   Using Jython:

   ```
   AdminConfig.save()
   ```

   Use the **reset** command of the AdminConfig object to undo changes that you made to your workspace since your last save.

An alternative way to modify nested attributes is to modify the nested attribute directly, for example:

Using Jacl:

```
set techsamp [$AdminConfig getid /DataSource:TechSamp/]
set pool [$AdminConfig showAttribute $techsamp connectionPool]
$AdminConfig modify $pool {{reapTime 2003}}
```

Using Jython list:

```
techsamp=AdminConfig.getid('/DataSource:TechSamp/')
pool=AdminConfig.showAttribute(techsamp,'connectionPool')
AdminConfig.modify(pool,[['reapTime',2003]])
```

Using Jython string:

```
techsamp=AdminConfig.getid('/DataSource:TechSamp/')
pool=AdminConfig.showAttribute(techsamp,'connectionPool')
AdminConfig.modify(pool,'[[reapTime 2003]]')
```

In this example, the first command gets the configuration id of the DataSource, and the second command gets the connectionPool attribute. The third command sets the reapTime attribute on the ConnectionPool object directly.

Saving configuration changes with the wsadmin tool:

The wsadmin tool uses the workspace to hold configuration changes. You must save your changes to transfer the updates to the master configuration repository. If a scripting process ends and you have not saved your changes, the changes are discarded. Use the following commands to save the configuration changes:

- Using Jacl:

  ```
  $AdminConfig save
  ```

- Using Jython:

  ```
  AdminConfig.save()
  ```

where:

$	is a Jacl operator for substituting a variable name with its value
AdminConfig	is an object representing the WebSphere Application Server configuration
save	is an AdminConfig command

If you are using interactive mode with the wsadmin tool, you will be prompted to save your changes before they are discarded. If you are using the -c option with the wsadmin tool, changes are automatically saved.

You can use the **reset** command of the AdminConfig object to undo changes that you made to your configuration since your last save.

AdminTask object for scripted administration: Use the AdminTask object to access a set of administrative commands that provide an alternative way to access the configuration commands and the running object management commands. The administrative commands run simple and complex commands. They provide more user friendly and task-oriented commands. The administrative commands are discovered dynamically when you start a scripting client. The set of available administrative commands depends on the edition of WebSphere Application Server you install. You can use the AdminTask object commands to access these commands.

Administrative commands are grouped based on their function. You can use administrative command groups to find related commands. For example, the administrative commands that are related to server management are grouped into a server management command group. The administrative commands that are related to the security management are grouped into a security management command group. An administrative command can be associated with multiple command groups because it can be useful for multiple areas of system management. Both administrative commands and administrative command groups are uniquely identified by their name.

Two run modes are always available for each administrative command, namely the *batch* and *interactive mode*. When you use an administrative command in interactive mode, you go through a series of steps to collect your input interactively. This process provides users a text-based wizard and a similar user experience to the wizard in the administrative console. You can also use the help command to obtain help for any administrative command and the AdminTask object.

The administrative commands do not replace any existing configuration commands or running object management commands but provide a way to access these commands and organize the inputs. Depending on the administrative command, it can be available in connected or local mode. The set of available administrative commands is determined when you start a scripting client in connected or local mode. If a server is running, it is not recommended that you run the scripting client in local mode because any configuration changes made in local mode are not reflected in the running server configuration and vice versa. If you save a conflicting configuration, you could corrupt the configuration. In a deployment manager environment, configuration updates are available only if a scripting client is connected to a deployment manager. When connected to a node agent or a managed application server, you will not be able to update the configuration because the configuration for these server processes are copies of the master configuration which resides in the deployment manager. The copies are created on a node machine when a configuration synchronization occurs between the deployment manager and the node agent. Make configuration changes to the server processes by connecting a scripting client to a deployment manager. For this reason, to change a configuration, do not run a scripting client in local mode on a node machine. It is not a supported configuration.

Obtaining online help using scripting:

There are three levels of online help available with the administrative commands. The top level help provides general information for the AdminTask object and the commands associated with it. The second level help provides information about all of the available administrative commands and command groups. The third level help provides specific help on a command group, a command, or a step. Command group specific help provides descriptions for the command group that you specify and the commands that belong to the associated group. Command specific help provides description for the specified command, its parameters, and steps, if any. Step specific help provides a description for the specified step and the associated parameters. For command and step specific help, required parameters are marked with a `*` in the help output.

- To obtain general help, use the following examples:

  Using Jacl:

  ```
  $AdminTask help
  ```

  Using Jython:

  ```
  print AdminTask.help()
  ```

  Example output:

  ```
  WASX8001I: The AdminTask object enables the execution of available
             admin commands. AdminTask commands operate in two modes:
             the default mode is one which AdminTask communicates with the
             WebSphere server to accomplish its task. A local mode is also
             available in which no server communication takes place. The local
             mode of operation is invoked by bringing up the scripting client
             using the command line "-conntype NONE" option or setting the
             "com.ibm.ws.scripting.connectiontype=NONE" property in
             wsadmin.properties file.

  The number of admin commands varies and depends on your WebSphere install.
  Use the following help commands to obtain a list of supported commands
  and their parameters:
  ```

```
help -commands
      list all the admin commands
help -commandGroups
      list all the admin command groups
help commandName
      display detailed information for
        the specified command
help commandName stepName
      display detailed information for
      the specified step belonging to
      the specified command
help commandGroupName
      display detailed information for
               the specified command group

There are various flavors to invoke an admin command:

commandName
      invokes an admin command that does not require any argument.

commandName targetObject
      invokes an admin command with the specified target object
      string, for example, the configuration object name of a
      resource adapter. The expected target object varies with
      the admin command invoked. Use help command to get
      information on the target object of an admin command.

commandName options
      invokes an admin command with the specified option
      strings. This invocation syntax is used to invoke an
               admin command that does not require a target object. It
               is also used to enter interactive mode if "-interactive"
               mode is included in the options string.

commandName targetObject options
      invokes an admin command with the specified target
      object and options strings. If "-interactive" is
      included in the options string, then interactive mode
      is entered. The target object and options strings vary
      depending on the admin command invoked. Use help
      command to get information on the target
      object and options.
```

- To list the available command groups, use the following examples:

  Using Jacl:

  ```
  $AdminTask help -commandGroups
  ```

  Using Jython:

  ```
  print AdminTask.help('-commandGroups')
  ```

  Example output:

  ```
  WASX8005I: Available admin command groups:

  ClusterConfigCommands - Commands for configuring application
  server clusters and cluster members.
  JCAManagement - A group of admin commands that helps to configure
  Java2 Connector Architecture(J2C) related resources.
  ```

- To list the available commands, use the following examples:

  Using Jacl:

  ```
  $AdminTask help -commands
  ```

  Using Jython:

  ```
  print AdminTask.help('-commands')
  ```

  Example output:

```
WASX8004I: Available administrative commands:

copyResourceAdapter - copy the specified J2C resource adapter to the specified scope
createCluster - Creates a new application server cluster.
createClusterMember - Creates a new member of an application server cluster.
createJ2CConnectionFactory - Create a J2C connection factory
deleteCluster - Delete the configuration of an application server cluster.
deleteClusterMember - Deletes a member from an application server cluster.
listConnectionFactoryInterfaces - list all of the
defined connection factory interfaces on the
specified J2C resource adapter.
listJ2CConnectionFactories - List J2C connection factories that have a specified
connection factory interface defined in the specified J2C resouce adapter
createJ2CAdminObject - Create a J2C administrative object.
listAdminObjectInterfaces - List all the defined administrative object interfaces
on the specified J2C resource adapter.
interface on the specified J2C resource adapter.
listJ2CAdminObjects - List the J2C administrative objects that have a specified
administrative object interface defined in the specified J2C resource adapter.
createJ2CActivationSpec - Create a J2C activation specification.
listMessageListenerTypes - list all of the defined messageListener
type on the specified J2C resource adapter.
listJ2CActivationSpecs - List the J2C activation specifications that have a
specified message listener type defined in the specified J2C resource adapter.
```

- To obtain help about a command group, use the following examples:

  Using Jacl:

  ```
  $AdminTask help JCAManagement
  ```

  Using Jython:

  ```
  print AdminTask.help('JCAManagement')
  ```

  Example output:

  ```
  WASX8007I: Detailed help for command group: JCAManagement

  Description: A group of administrative commands that help to
  configure Java 2 Connector Architecture (J2C)-related resources.

  Commands:
  createJ2CConnectionFactory - Create a J2C connection factory
  listConnectionFactoryInterfaces - list all of the defined connection
  factory interfaces on the specified J2C resource adapter.
  listJ2CConnectionFactories - List J2C connection factories that have
  a specified connection factory interface defined in the
  specified J2C resouce adapter.
  createJ2CAdminObject - Create a J2C administrative object.
  listAdminObjectInterfaces - List all the defined administrative
  object interfaces on the specified J2C resource adapter.
  listJ2CAdminObjects - List the J2C administrative objects that have a
  specified adminstrative object interface defined in the
  specified J2C resource adapter.
  createJ2CActivationSpec - Create a J2C activation specification.
  listMessageListenerTypes - list all of the defined
  message listener types on the specified J2C resource adapter.
  listJ2CActivationSpecs - List the J2C activation specifications that
  have a specified message listener type defined in the
  specified J2C resource adapter.
  copyResourceAdapter - copy the specified J2C resource
  adapter to the specified scope.
  ```

- Obtaining help about an administrative command:

  Using Jacl:

  ```
  $AdminTask help createJ2CConnectionFactory
  ```

  Using Jython:

  ```
  print AdminTask.help('createJ2CConnectionFactory')
  ```

Example output:

```
WASX8006I: Detailed help for command: createJ2CConnectionFactory

Description: Create a J2C connection factory

*Target object: The parent J2C resource adapter of the created J2C connection factory.

Arguments:
*connectionFactoryInterface - A connection factory interface that is defined in the deployment
 description of the parent J2C resource adapter.
*name - The name of the J2C connection factory.
*jndiName - The JNDI name of the created J2C connection factory.
description - The description for the created J2C connection factory.
authDataAlias - the authentication data alias of the created J2C connection factory.

Steps:
None
```

In the command specific help output previously listed, an administrative command is divided into three input areas: target object, arguments, and steps. Each area can require input depending on the administrative command. If an area requires input, each input is described by its name and a description; except for the target object area which only contains the description of the target object. When you use an administrative command in batch mode, you can use any input name that resides in the argument area as the argument name. If an input is required, a * will be before the name. If an area does not require an input, it is marked None. The following example uses the help output for the **createJ2CConnectionFactory** command:

– Target object area requires the configuration object name of a J2CResourceAdapter to be provided.

– In the arguments area, there are five inputs with three being required inputs. The argument names are connectionFactoryInterface, name, jndiName, description, and authDataAlias. These names are used as the parameter names in the option string to execute an admin command in batch mode, for example:

  ```
  -connectionFactoryInterface javax.resource.cci.ConnectionFactory -name newConnectionFactory
   -jndiName CF/newConnectionFactory
  ```

  See “Administrative command invocation syntax” on page 623 for more information about specifying argument options.

– There is no step associated with this administrative command.

- Obtain help on a command step.

  Step specific help provides the following:

  – A description for the command step.

  – Information indicating if this step supports collection. A collection includes objects of the same type. In a command step, a collection contains objects that have the same set of parameters.

  – Information regarding each step parameter with its name and description. If a step parameter is required, a * exists in front of the name.

  The following example obtain help on a command step:

  Using Jacl:

  ```
  $AdminTask help createCluster clusterConfig
  ```

  Using Jython:

  ```
  print AdminTask.help('createCluster', 'clusterConfig')
  ```

  Example output:

  ```
  WASX8013I: Detailed help for step: clusterConfig

  Description: Specifies the configuration of the new server cluster.

  Collection: No
  ```

```
Arguments:
  *clusterName - Name of server cluster.
  preferLocal - Enables node-scoped routing optimization for the cluster.
```

This example indicates the following:

– It does not support collection. Only one set of parameter values for the clusterName and perferLocal parameters is allowed.

– It contains two input arguments with one argument indicated as required. The required arguments is clusterName and the non-required parameter is perferLocal. The syntax to provide step parameter values is different from the command argument values. You have to provide all argument values of a step and provide them in the exact order as displayed in the step specific help. For any optional argument that you do not want to specify a value, put double quotes ("") in place of a value. If a command step is a collection type, for example, it can contain multiple objects where each object has the same set of arguments, you can specify multiple objects with each object enclosed by its own pair of braces. To execute an administrative command in batch mode and to include this step in the option string, use the following syntax:

  Using Jacl:

  ```
  -clusterConfig {{newCluster false}}
  ```

  Using Jython:

  ```
  -clusterConfig [[newCluster false]]
  ```

  See "Administrative command invocation syntax" on page 623 for more information about specifying parameter options.

Invoking an administrative command in batch mode:

Perform the following steps to invoke an administrative command in batch mode. To invoke an administrative command in interactive mode, see "Invoking an administrative command in interactive mode" on page 242.

1. Invoke the AdminTask object commands interactively, in a script, or use the **wsadmin -c** command from an operating system command prompt.
2. Issue one of the following commands:
   - If an administrative command does not have a target object and an argument, use the following command:

     Using Jacl:

     ```
     $AdminTask commandName
     ```

     Using Jython:

     ```
     AdminTask.commandName()
     ```

     where:

$	is a Jacl operator for substituting a variable name with its value
AdminTask	is an object allowing administrative command management
commandName	is the name of the administrative command being invoked

   - If an administrative command includes a target object but does not include any arguments or steps, use the following command:

     Using Jacl:

     ```
     $AdminTask commandName targetObject
     ```

     Using Jython:

     ```
     AdminTask.commandName(targetObject)
     ```

where:

$	is a Jacl operator for substituting a variable name with its value
AdminTask	is an object allowing administrative command management
commandName	is the name of the administrative command being invoked
targetObject	is the target object string for the invoked administrative command. The expect target object varies with each administrative command. View the online help for the invoked administrative command to learn more about what you should specify as the target object.

- If an administrative command includes an argument or a step but does not include a target object, use the following command:

  Using Jacl:

  ```
  $AdminTask commandName options
  ```

  Using Jython:

  ```
  AdminTask.commandName(options)
  ```

  where:

$	is a Jacl operator for substituting a variable name with its value
AdminTask	is an object allowing administrative command management
commandName	is the name of the administrative command being invoked

options	is the option string for the invoked administrative command. Depending on which administrative command you are invoking, the administrative command can have required or optional option values. The options string is different for each administrative command. View the online help for the invoked administrative command to obtain more information about which options are available. Arguments and steps listed on the online administrative command help are specified as options in the option string. Each option consists of a dash followed immediately by an option name, and then followed by an option value if the option requires a value. If the invoked administrative command includes target objects, arguments, or steps, then the –interactive option is available to enter interactive mode. For example, using the output of the following online help for listDataSource:
	`WASX8006I: Detailed help for command: exportServer`
	
	`Description: export the configuration`
	`of a server to a config archive.`
	
	`Target object: None`
	
	`Arguments:`
	`*serverName - the name of a server`
	`*nodeName - the name of a node. This parameter`
	`becomes optional if the specified server name`
	`is unique across the cell.`
	`*archive - the fully qualified file path of a config`
	`archive.`
	
	`Steps:`
	`None`
	
	Option names are specified with a dash before the names. There are three required options for this administrative command. The required options are -serverName, -nodename, and -archive. In addition, the -interactive option is available. Options are specified in the option string which is enclosed by a pair of {} in Jacl and a pair of [] in Jython.

- If an administrative command includes a target object, and arguments or steps:

  Using Jacl:

  ```
  $AdminTask commandName targetObject options
  ```

  Using Jython:

  ```
  AdminTask.commandName(targetObject, options)
  ```

  where:

`$`	is a Jacl operator for substituting a variable name with its value
`AdminTask`	is an object allowing administrative command management
commandName	is the name of the administrative command being invoked

targetObject

is the target object string for the invoked administrative command. The expected target object varies with each administrative command. View the online help for the invoked administrative command to obtain information about what to specify as a target object. For example, using the output of the following online help for createJ2CConnectionFactory:

```
WASX8006I: Detailed help for command:
createJ2CConnectionFactory

Description: Create a J2C connection factory

*Target object: The parent J2C resource adapter of
the created J2C connection factory.

Arguments:
*connectionFactoryInterface - A connection factory
interface that is defined in the deployment description
of the parent J2C resource adapter.
*name - The name of the J2C connection factory.
*jndiName - The JNDI name of the created J2C
connection factory.
description - The description for the created J2C
connection factory.
authDataAlias - the authentication data alias of the
created J2C connection factory.

Steps:
None
```

The target object is a configuration object name of a J2CResourceAdapter.

options

is the option string for the invoked administrative command. Depending on which administrative command you are invoking, the administrative command can have required or optional option values. The options string is different for each administrative command. View the online help for the invoked administrative command to obtain more information about which options are available. Arguments and steps listed on the online administrative command help are specified as options in the option string. Each option consists of a dash followed immediately by an option name, and then followed by an option value if the option requires a value. If the invoked administrative command includes target objects, arguments, or steps, then the –interactive option is available to enter interactive mode. For example, using the output of the following online help for listDataSource:

```
WASX8006I: Detailed help for command:
createJ2CConnectionFactory

Description: Create a J2C connection factory

*Target object: The parent J2C resource adapter
of the created J2C connection factory.

Arguments:
*connectionFactoryInterface - A connection factory
interface that is defined in the deployment description
of the parent J2C resource adapter.
*name - The name of the J2C connection factory.
*jndiName - The JNDI name of the created J2C
connection factory.
description - The description for the created J2C
connection factory.
authDataAlias - the authentication data alias of the
created J2C connection factory.

Steps:
None
```

Option names are specified with a dash before the names. There are three required options for this administrative command. The required options are -connectionFactoryInterface, -name, and -jndiName. There are two optional options. They are -description and -authDataAlias. In addition, the -interactive option is available. Options are specified in the option string which is enclosed by a pair of {} in Jacl and a pair of [] in Jython.

- The following example invokes an administrative command with no target object, argument, or step:

  Using Jacl:

  ```
  $AdminTask listNodes
  ```

  Using Jython:

  ```
  print AdminTask.listNodes()
  ```

  Example output:

  ```
  myNode
  ```

- The following example invokes an administrative command with a target object string:

  Using Jacl:

```
set s1 [$AdminConfig getid /Server:server1/]
$AdminTask showServerInfo $s1
```

Using Jython:

```
s1 = AdminConfig.getid('/Server:server1/')
print AdminTask.showServerInfo(s1)
```

Example output:

```
{cell myCell}
{serverType APPLICATION_SERVER}
{com.ibm.websphere.baseProductVersion 6.0.0.0}
{node myNode}
{server server1}
```

- The following example invokes an administrative command with an option string:

  Using Jacl:

  ```
  $AdminTask getNodeMajorVersion {-nodeName myNode}
  ```

  Using Jython:

  ```
  print AdminTask.getNodeMajorVersion('[-nodeName myNode]')
  ```

  Example output:

  ```
  6
  ```

- The following example invokes an administrative command with target object and non-step option strings:

  Using Jacl:

  ```
  set ra [$AdminConfig getid /J2CResourceAdapter:myResourceAdapter/]
  $AdminTask createJ2CConnectionFactory
  $ra {-name myJ2CCF -jndiName j2c/cf -connectionFactoryInterface javax.resource.cci.ConnectionFactory}
  ```

  Using Jython:

  ```
  ra = AdminConfig.getid('/J2CResourceAdapter:myResourceAdapter/')
  AdminTask.createJ2CConnectionFactory(ra,
  '[-name myJ2CCF -jndiName j2c/cf -connectionFactoryInterface javax.resource.cci.ConnectionFactory]')
  ```

  Example output:

  ```
  myJ2CCF(cells/myCell/nodes/myNode|resources.xml#J2CConnectionFactory_1069690568269)
  ```

- The following example invokes an administrative command with a target object and a step option:

  Using Jacl:

  ```
  set serverCluster [$AdminConfig getid /ServerCluster:myCluster/]
  $AdminTask createClusterMember $serverCluster {-memberConfig {{myNode myClusterMember "" "" false false}}}
  ```

  Using Jython:

  ```
  serverCluster = AdminConfig.getid('/ServerCluster:myCluster/')
  AdminTask.createClusterMember(serverCluster, '[-memberConfig [[myNode myClusterMember "" "" false false]]]')
  ```

  Example output:

  ```
  myClusterMember(cells/myCell/nodes/myNode|cluster.xml#ClusterMember_3673839301876)
  ```

Invoking an administrative command in interactive mode:

Perform the following steps to invoke an administrative command in interactive mode. To invoke an administrative command in batch mode, see "Invoking an administrative command in batch mode" on page 237.

1. Invoke the AdminTask object commands interactively, in a script, or use the **wsadmin -c** command from an operating system command prompt.
2. Invoke an administrative command in interactive mode by issuing one of the following commands:
   - Use the following command invocation to enter interactive mode without providing another input in the command invocation:

     Using Jacl:

     ```
     $AdminTask commandName {-interactive}
     ```

Using Jython:

```
AdminTask.commandName('[-interactive]')
```

where:

$	is a Jacl operator for substituting a variable name with its value
AdminTask	is an object allowing administrative command management
commandName	is the name of the administrative command being invoked
-interactive	is the interactive option

- Use the following command invocation to enter interactive mode using an administrative command that takes a target object. You do not have to provide a target object to enter interactive mode. Target objects provided in the command invocation will be applied to the command and displayed as the current target object value during interactive prompting.

  Using Jacl:

  ```
  $AdminTask commandName targetObject {-interactive}
  ```

  Using Jython:

  ```
  AdminTask.commandName(targetObject, '[-interactive]')
  ```

  where:

$	is a Jacl operator for substituting a variable name with its value
AdminTask	is an object allowing administrative command management
commandName	is the name of the administrative command being invoked
targetObject	is the target object string for the invoked administrative command. The target object is different for each administrative command. View the online help for the invoked administrative command to learn more about what to specify as a target object.
-interactive	is the interactive option

- Use the following command invocation to enter interactive mode for an administrative command that takes options. You do not have to provide other options to enter interactive mode. Options provided in the command invocation are applied to the command and the option values will be displayed as the current values during interactive prompting.

  Using Jacl:

  ```
  $AdminTask commandName {-interactive commandOptions}
  ```

  Using Jython:

  ```
  AdminTask.commandName('[-interactive commandOptions]')
  ```

  where:

$	is a Jacl operator for substituting a variable name with its value
AdminTask	is an object allowing administrative command management
commandName	is the name of the administrative command being invoked
-interactive	is the interactive option

commandOptions	is the command option available for the associated administrative command. Available command options are different for each administrative command. View the online help for the invoked administrative command to obtain more information about which options are available. Arguments and steps listed on the online administrative command help are specified as command options. Each option consists of a dash followed immediately by an option name, and then followed by an option value if the option requires a value. For example, using the output of the following online help for createJ2CConnectionFactory:
	`WASX8006I: Detailed help for command: createJ2CConnectionFactory`
	
	`Description: Create a J2C connection factory`
	
	`*Target object: The parent J2C resource adapter of the created J2C co`
	
	`Arguments:`
	`*connectionFactoryInterface - A connection factory interface that is`
	`*name - The name of the J2C connection factory.`
	`*jndiName - The JNDI name of the created J2C connection factory.`
	`description - The description for the created J2C connection factory.`
	`authDataAlias - the authentication data alias of the created J2C conn`
	
	`Steps:`
	`None`
	
	In this example, there are five options available:
	• -connectionFactoryInterface
	• -name
	• -jndiName
	• -description
	• -authDataAlias
	Each requires an option value. Only three of the options are required and are denoted with a `*`.

- Use the following command invocation to enter interactive mode for an administrative command that has a target object and options. You do not have to specify a target object to enter interactive mode. The values specified are applied to the command before the command data is displayed. As a result, the values specified will be displayed as the current values during interactive prompting.

  Using Jacl:

  ```
  $AdminTask commandName targetObject {-interactive commandOptions}
  ```

  Using Jython:

  ```
  AdminTask.commandName(targetObject, '[-interactive commandOptions]')
  ```

  where:

`$`	is a Jacl operator for substituting a variable name with its value
`AdminTask`	is an object allowing administrative command management
commandName	is the name of the administrative command being invoked

targetObject	is the target object string for the invoked admin command. The expect target object varies with each admin command. Consult the on-line help on the invoked admin command to learn more about what to specify as target object.
-interactive	is the interactive option

commandOptions	is the command option available for the associated administrative command. Available command options are different for each administrative command. View the online help for the invoked administrative command to obtain more information about which options are available. Arguments and steps listed on the online administrative command help are specified as command options. Each option consists of a dash followed immediately by an option name, and then followed by an option value if the option requires a value. For example, using the output of the following online help for createJ2CConnectionFactory:
	`WASX8006I: Detailed help for command: createJ2CConnectionFactory`
	
	`Description: Create a J2C connection factory`
	
	`*Target object: The parent J2C resource adapter of the created J2C`
	
	`Arguments:`
	`*connectionFactoryInterface - A connection factory interface that`
	`*name - The name of the J2C connection factory.`
	`*jndiName - The JNDI name of the created J2C connection factory.`
	`description - The description for the created J2C connection facto`
	`authDataAlias - the authentication data alias of the created J2C co`
	
	`Steps:`
	`None`
	
	In this example, there are five options available:
	• -connectionFactoryInterface
	• -name
	• -jndiName
	• -description
	• -authDataAlias
	
	Each requires an option value. Only three of the options are required and are denoted with a *.

- The following example invokes an administrative command in interactive mode by specifying the -interactive option:

  Using Jacl:

  ```
  $AdminTask createJ2CConnectionFactory {-interactive}
  ```

  Using Jython:

  ```
  AdminTask.createJ2CConnectionFactory('[-interactive]')
  ```

  Example output:

  ```
  Create a J2C connection factory

  *The J2C resource adapter: "WebSphere Relational ResourceAdapter
  (cells/myCell/nodes/myNode|resources.xml#builtin_rra)"

  A connection factory
  interface (connectionFactoryInterface):javax.resource.cci.ConnectionFactory
  ```

```
*Name (name): myJ2CCF
*The JNDI name (jndiName): j2c/cf
Description (description):
authentication data alias (authDataAlias):

create J2C connection factory

F (Finish)
C (Cancel)

Select [F, C]: [F]

myJ2CCF(cells/myCell/nodes/myNode|resources.xml#J2CConnectionFactory_1069690568269)
```

- The following example invokes an administrative command using the –interactive option with a target object specified in the command invocation:

  Using Jacl:

  ```
  set ra [$AdminConfig getid /J2CResourceAdapter:myResourceAdapter/]
  $AdminTask createJ2CConnectionFactory $ra {-interactive}
  ```

  Using Jython:

  ```
  ra = AdminConfig.getid('/J2CResourceAdapter:myResourceAdapter/')
  AdminTask.createJ2CConnectionFactory(ra, '[-interactive]')
  ```

  Example output:

  ```
  Create a J2C connection factory

  *The J2C resource adapter: ["WebSphere Relational ResourceAdapter
  (cells/myCell/nodes/myNode|resources.xml#builtin_rra)"]

  A connection factory interface (connectionFactoryInterface):
  javax.resource.cci.ConnectionFactory
  *Name (name): myJ2CCF
  *The JNDI name (jndiName): j2c/cf
  Description (description):
  authentication data alias (authDataAlias):

  create J2C Connection Factory

  F (Finish)
  C (Cancel)

  Select [F, C]: [F]

  myJ2CCF(cells/myCell/nodes/myNode|resources.xml#J2CConnectionFactory_1069690568269)
  ```

- The following example invokes an administrative command using the –interactive option where both the target object and the additional command options are specified in the command invocation:

  Using Jacl:

  ```
  set ra [$AdminConfig getid /J2CResourceAdapter:myResourceAdapter/]
  $AdminTask createJ2CConnectionFactory $ra {-name myNewCF -interactive}
  ```

  Using Jython:

  ```
  ra = AdminConfig.getid('/J2CResourceAdapter:myResourceAdapter/')
  AdminTask.createJ2CConnectionFactory(ra, '[-name myNewCF -interactive]')
  ```

  Example output:

  ```
  Create a J2C connection factory

  *The J2C resource adapter: ["WebSphere Relational ResourceAdapter
  (cells/myCell/nodes/myNode|resources.xml#builtin_rra)"]

  A connection factory interface (connectionFactoryInterface):javax.resource.cci.ConnectionFactory
  *Name (name): [myNewCF]
  *The JNDI name (jndiName): j2c/cf
  Description (description):
  ```

```
authentication data alias (authDataAlias):

create J2C Connection Factory

F (Finish)
C (Cancel)

Select [F, C]: [F]

myNewCF(cells/myCell/nodes/myNode|resources.xml#J2CConnectionFactory_3839439380269)
```

Administrative command interactive mode environment: An administrative command can be run in interactive mode by providing the -interactive option in the options string when invoking the command. You can still provide other options, even when using the interactive option. The options values that are specified are applied to the command before the command data is displayed. Whether or not other options are specified, the wsadmin tool steps the user through the command to collect command information.

The general interactive flow sequence is:

1. Collect user inputs for target object and parameters
2. If the command does not include a step, the command execution menu displays to run or cancel the command.
3. If the command includes a step, the menu to select the step displays. When all the required inputs are entered, the menu includes command execution.
4. When a step is selected, if the step supports collection, then the menu to select an object in the collection displays and you can exit the step. If you exit the step, repeat steps 3-5.
5. Collect user inputs for the selected step or for an object in the collection
6. Repeat steps 4 and 5 if from the collection step menu
7. Repeat steps 3-5 if from step selection menu

Depending on what input area is enabled by an administrative command, you can go through part or all of the interactive flow sequence. If an administrative command is run in interactive mode, the syntax to run the command except for the deletion of collection object in batch mode is generated and logged as a WASX7278I message in both the interactive session and in the wsadmin trace file.

Collect user inputs for target object and parameters

The following interactive prompt is used to collect inputs for the Target object and Arguments input areas that are displayed in the command-specific help:

```
Command title

Command Description

*target object title [current or default value]:
*param1 title (param1 name) [choice1, choice2, ...]: [current/default value]
param2 title (param2 name) [choice1, choice2, ...]: [current/default value]
...
```

This screen is usually the first interactive screen that is displayed when an administrative command is invoked interactively unless the invoked command does not contain any target object and non-step command parameters.If a command does not have a target object, then the prompt for the target object is skipped. The number of parameters depends on the number of arguments in the Argument area of the command-specific help. If an input is required, then an asterisk (*) is placed in front of the title. The parameter name is displayed for information and is the name that is used to set this parameter in batch mode. If a parameter value is restricted to a set of values, then the valid choices are displayed. If current or default value is available, it is displayed. You can accept the existing value by clicking Enter. To add or change an existing value, enter a new value and click Enter.

Display command execution menu

If an administrative command does not contain a step, you are presented with the following menu after collecting values for target object and parameters:

```
Command title

F (Finish)
C (Cancel)

Select [F, C]: F
```

The Finish option runs the command and the Cancel option cancels the command. The default selection is F (Finish). This menu is the last menu that is displayed for a non-step command to exit interactive mode by either canceling or running the command.

Display command step selection and execution menu

If an administrative command contains a step, the following menu is displayed after collecting values for target object and parameters:

```
Command title
Command description
 -> *1. step1 title (step1 name)
     2. step2 title (step2 name)
    *3. step3 title (step3 name)
    (4. step4 title (step4 name))
     ...
     n. stepn title (stepn name)

S (Select)
N (Next)
P (Previous)
F (Finish)
C (Cancel)
H (Help)

Select [S, N, P, F, C, H]: S
```

The number of steps that is displayed in the menu depends on the adminstative command. The step name is displayed for information and is the name that is used to set data in this step in batch mode. The following notations are used to describe a step:

- A "->" before the step indicates the current step position.
- A "*" before the step indicates a required step.
- A ( ) enclosing the entire step indicates a disabled step. You cannot navigate to this step by using the Next or Previous options.

Using the menu, you can navigate through steps sequentially by selecting Previous or Next. Select selects the current step, Finish runs the command, Cancel cancels the command, and Help provides on-line help for the command. Not all menu choices are available. Previous is not available if current step is the first step. Next is not be available if current step is the last step. Finish is not available if still steps are still missing required inputs. The default selection is S (Select) if the current step is a valid step and there are still steps missing required inputs. Default selection is F (Finish) if there is no missing required input in any step.

For commands with steps, this is the menu to exit interactive mode by either canceling or executing the command.

Display collection step menu

A step might or might not support collection. A collection refers to objects of the same type. In an administrative command, a collection contains objects with each having the same set of parameters. If a step supporting collection is selected, the wsadmin tool displays the following menu to add and select an object in the collection:

```
Step title (step name)
    | key param1 title (key param1 name), key param2 title (key param2 name), ...
    ---------------------------------------------------------------------------
->  | object1 key param1 value, key param2 value, ...
   *| object2 key param1 value, key param2 value, ...
    ...
key param1 title, key param2 title, ... must be provided to specify a row in batch row.

S (Select Row)
N (Next)
P (Previous)
A (Add Row or Add Row Before)
D (Delete Row)
F (Finish)
H (Help)

Select [S, N, P, A, D, F, H]: F
```

The number of objects that display in the menu depends on the command step. Key parameters are identified by the step to use to uniquely identify an object in a collection. Key parameter values are displayed so as to identify an object to select. As with the command step selection menu, an arrow (->) is used to indicate the current object position, and a asterisk (*) is used to indicate that required input is missing in the object.

Use the menu to navigate through objects sequentially by selecting Previous or Next. Select Row selects the current object, Add Row adds a new object, Add Row Before adds a new object before the current object, Delete Row deletes the current object, Finish returns control back to the step selection and execution menu, and Help provides on-line help for the step. Not all menu choices are available. Previous is not available if there is no object in the collection or the first object is the current object. Next is not available if there is no object in the collection or the last object is the current object. Select Row is available only if there is a current object. Add Row is provided only if there is no object in the collection and the step supports new object to be added. Add Row Before is provided if the step supports new object to be added and there are existing objects in the collection. Delete Row is provided only if there is a current object and the step allows object to be deleted. Finish is not available if there are still objects missing required inputs. Default selection is A (Add Row) when there is no object in the collection and the step supports objects to be added. Default selection is S (Select Row) if there is a current object and there are still objects missing required inputs. Default selection is F (Finish) if there is no required input missing in any object.

Collect user inputs for parameters of a collection object

After a collection object is selected, the parameter value for each parameter is prompted sequentially as shown in the following example:

```
*param1 title (param1 name) [choice1, choice2, ...]: [current/default value]
param2 title (param2 name) [choice1, choice2, ...]: [current/default value]
...
```

The number of parameters depends on the number of arguments in the “Argument” area of the command step specific help. The same “*” notation is used to denote required parameter. If a parameter value is restricted to a set of values, then the valid choices are displayed. If current or default value is available, it is displayed. For each writable parameter, you can accept the existing value by pressing the Enter key. To add or change an existing value, user simply enters a new value and then presses Enter. For a read-only parameter, the parameter and its value are displayed. However, user is not given the prompt to modify its value. Once user steps through all the parameters, wsadmin leads user back to the collection step menu.

Collect user inputs for non-collection step

There are two parts for this step. The first part is to display the current or default parameter values for the selected step as shown below:

```
Step title (step name)

*param1 title (param1 name) [choice1, choice2, ...]: [current/default value]
param2 title (param2 name) [choice1, choice2, ...]: [current/default value]
...

Select [C (Cancel), E (Edit)]: [E]
```

There is no prompting in this part. Instead, this part is more like a help providing parameter information on the selected step. The number of parameters depends on the number of arguments in the `argument` area of the command step specific help. The asterisk (*) notation denotes a required parameter. If a parameter value is restricted to a set of values, then the valid choices will be displayed. If current or default value is available, it is displayed. You can choose to cancel the step or continue to the next part to provide parameter inputs. The default selection is `Edit`. Since it is possible that you are seeing default values assigned to a new piece of data that is not yet set in the step, you should always accept the default selection to continue to the next part. Otherwise, if there is no data in the selected step, selecting Cancel will not result in creating the data.

If you accept the default `Edit` selection, collect user inputs for parameters sequentially just like “Collect user inputs for parameters of a collection object”.

```
*param1 title (param1 name) [choice1, choice2, ...]: [current/default value]
param2 title (param2 name) [choice1, choice2, ...]: [current/default value]
...
```

For each writable parameter, you can accept the existing value by clicking Enter. To add or change an existing value, enter a new value and then press Enter. For a read-only parameter, the parameter and its value are displayed. You will not be given the prompt to modify the value of the parameter. As soon as you step through all the parameters, the wsadmin tool will lead you back to the command step selection and execution menu.

Starting the wsadmin scripting client

The WebSphere Application Server wsadmin tool provides the ability to run scripts. You can use the wsadmin tool to manage a WebSphere Application Server V6.0 installation, as well as configuration, application deployment, and server run-time operations. The WebSphere Application Server only supports the Jacl and Jython scripting languages.

The wsadmin launcher makes several WebSphere Application Server scripting objects available: AdminConfig, AdminControl, AdminApp, AdminTask, and Help. Scripts use these objects for application management, configuration, operational control, and for communication with MBeans that run in WebSphere Application Server processes.

You must start the wsadmin scripting client before you perform any other task using scripting.

1. Locate the command that starts the wsadmin scripting client.

   The command for invoking a scripting process is located in the *install_root*/profiles/*profile_name*/bin directory. Use the `wsadmin.bat` file for a Windows system, and the `wsadmin.sh` file for a Linux or a UNIX system.

2. Start the wsadmin scripting client. You can start the wsadmin scripting client in several different ways. To specify the method for running scripts, perform one of the following wsadmin tool options:

Option for starting the wsadmin scripting client:	Explanation:	Examples:

Run scripting commands interactively	Run wsadmin with an option other than `-f` or `-c` or without an option.
	An interactive shell is displayed with a wsadmin prompt. From the wsadmin prompt, enter any Jacl or Jython command. You can also invoke commands using the AdminControl, AdminApp, AdminConfig, AdminTask, or Help wsadmin objects.
	To leave an interactive scripting session, use the **quit** or **exit** commands. These commands do not take any arguments.
		Using Jacl on Windows systems:
		`wsadmin.bat`
		Using Jacl on Unix systems:
		`wsadmin.sh`
		If security is enabled:
		`wsadmin.sh -user wsadmin -password wsadmin`
		Using Jython on Windows systems:
		`wsadmin.bat -lang jython`
		Using Jython on Unix systems:
		`wsadmin.sh -lang jython`
		By default security is enabled:
		`wsadmin.sh -lang jython -user wsadmin`
		`-password wsadmin`
		Example output:
		`WASX7209I: Connected to process server1 on`
		`node myhost using SOAP connector;`
		`The type of process is: UnManagedProcess`
		`WASX7029I: For help, enter: "$Help help"`
		`wsadmin>$AdminApp list`
		`adminconsole`
		`DefaultApplication`
		`ivtApp`
		`wsadmin>exit`

Run scripting commands as individual commands	Run the wsadmin tool with the -c option.	Using Jacl on Windows systems:
		`wsadmin -c "$AdminApp list"`
		Using Jacl on Unix systems:
		`wsadmin.sh -c "\$AdminApp list"`
		or
		`wsadmin.sh -c '$AdminApp list'`
		Using Jython on Windows systems:
		`wsadmin -lang jython`
		`-c "AdminApp.list()"`
		Using Jython on Linux or Unix systems:
		`wsadmin.sh -lang jython -c 'AdminApp.list()'`
		Example output:
		`WASX7209I: Connected to process "server1"`
		`on node myhost using SOAP connector;`
		`The type of process is: UnManagedProcess`
		`adminconsole`
		`DefaultApplication`
		`ivtApp`

Run scripting commands in a script	Run the wsadmin tool with the `-f` option, and place the commands that you want to run into the file.	Using Jacl on Windows systems:
		`wsadmin -f` *`al.jacl`*
		Using Jacl on Unix systems:
		`wsadmin.sh -f` *`al.jacl`*
		where the `al.jacl` file contains the following commands:
		`set apps [$AdminApp list]`
		`puts $apps`
		Using Jython on Windows systems:
		`wsadmin -lang jython -f` *`al.py`*
		Using Jython on Unix systems:
		`wsadmin.sh -lang jython -f` *`al.py`*
		where the `al.py` file contains the following commands:
		`apps = AdminApp.list()`
		`print apps`
		Example output:
		`WASX7209I: Connected to process "server1"`
		`on node myhost using SOAP connector;`
		`The  type of process is: UnManagedProcess`
		` adminconsole`
		` DefaultApplication`
		` ivtApp`

Run scripting commands in a profile script	A *profile script* is a script that runs before the main script, or before entering interactive mode. You can use profile scripts to set up a scripting environment that is customized for the user or the installation.
	To run scripting commands in a profile script, run the wsadmin tool with the -profile option, and include the commands that you want to run into the profile script.
	To customize the script environment, specify one or more profile scripts to run.
		Using Jacl on Windows systems:
		`wsadmin.bat -profile alprof.jacl`
		Using Jacl on Linux or Unix systems:
		`wsadmin.sh -profile alprof.jacl`
		where the `alprof.jacl` file contains the following commands:
		`set apps [$AdminApp list]`
		`puts "Applications currently`
		`installed:\n$apps"`
		Example output:
		`WASX7209I: Connected to process "server1"`
		`on node myhost using SOAP connector;`
		`The type of process is: UnManagedProcess`
		`Applications currently installed:`
		` adminconsole`
		` DefaultApplication`
		` ivtApp`
		` WASX7029I: For help, enter: "$Help help"`
		` wsadmin>`
		Using Jython on Windows systems:
		`wsadmin.bat -lang jython -profile alprof.py`
		Using Jython on Linux or Unix systems:
		`wsadmin.sh -lang jython -profile alprof.py`
		where the `alprof.py` file contains the following commands:
		`apps = AdminApp.list()`
		`print "Applications currently installed:\n "`
		`+ apps`
		Example output:
		`WASX7209I: Connected to process "server1" on`
		`node myhost using SOAP connector;`
		`The type of process is: UnManagedProcess`
		`Applications currently installed:`
		` adminconsole`
		` DefaultApplication`
		` ivtApp`
		` WASX7029I: For help, enter: "Help.help()"`
		` wsadmin>`

Scripting: Resources for learning

Use the following links to find relevant supplemental information about the Jacl and Jython scripting languages, and about using scripting with WebSphere Application Server. The information resides on IBM and non-IBM Internet sites, whose sponsors control the technical accuracy of the information.

These links are provided for convenience. Often, the information is not specific to the IBM WebSphere Application Server product, but is useful all or in part for understanding the product. When possible, links are provided to technical papers and Redbooks that supplement the broad coverage of the release documentation with in-depth examinations of particular product areas.

Programming instructions and examples

- Java command language
- Jacl: A Tcl implementation in Java

- Charming Jython
- Jython
- Sample scripts for WebSphere Application Server

Deploying applications using scripting

This topic contains the following tasks:

- Installing applications
- Uninstalling applications

Installing applications with the wsadmin tool

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

On a single server installation, the server must be running before you install an application. See the “Starting servers using scripting” on page 302 article for more information. On a network deployment installation, the deployment manager must be running before you install an application. See the “startManager command” on page 671article for more information.

You can install the application in batch mode, using the **install** command, or you can install the application in interactive mode using the **installinteractive** command. Interactive mode prompts you through a series of tasks to provide information. Both the **install** command and the **installinteractive** command support a set of options. See the “Options for the AdminApp object install, installInteractive, edit, editInteractive, update, and updateInteractive commands” on page 437 article for a list of valid options for the **install** and **installinteractive** commands. You can also obtain a list of supported options for an Enterprise Archive (EAR) file using the **options** command, for example:

Using Jacl:

```
$AdminApp options
```

Using Jython:

```
AdminApp.options()
```

For more information for the **options**, **install**, or **installinteractive** commands, see the “Commands for the AdminApp object” on page 415 article.

The application that you install must be an enterprise archive file (EAR), a Web archive (WAR) file, or a Java archive (JAR) file. The archive file must end in `.ear`, `.jar` or `.war` for the wsadmin tool to be able to install it. The wsadmin tool uses these extensions to figure out the archive type. If the file is a WAR or JAR file, it will be automatically wrapped as an EAR file.

If you are installing an application that has the AdminApp useMetaDataFromBinary option specified, then you can only install this application on a WebSphere Application Server V6.x deployment target. This also applies to editing the application, using the AdminApp **edit** command, after you install it. If you use the V5.x wsadmin tool to install or edit an application on a WebSphere Application Server V6.x cell, only the steps available for the V5.x wsadmin tool will be shown.

Perform the following steps to install an application into the run time:

1. Install the application.
   - Using batch mode:
     – For a single server installation only, the following example uses the EAR file and the command option information to install the application:
       - Using Jacl:

```
$AdminApp install c:/MyStuff/application1.ear {-server serv2}
```

- Using Jython list:

```
AdminApp.install('c:/MyStuff/application1.ear', ['-server', 'serv2'])
```

- Using Jython string:

```
AdminApp.install('c:/MyStuff/application1.ear', '[-server serv2]')
```

where:

$	is a Jacl operator for substituting a variable name with its value
AdminApp	is an object supporting application object management
install	is an AdminApp command
MyStuff/application1.ear	is the name of the application to install
server	is an installation option
serv2	is the value of the server option

– For a network deployment installation only, the following command uses the EAR file and the command option information to install the application on a cluster:

- Using Jacl:

```
$AdminApp install c:/MyStuff/application1.ear {-cluster cluster1}
```

- Using Jython list:

```
AdminApp.install('c:/MyStuff/application1.ear', ['-cluster', 'cluster1'])
```

- Using Jython string:

```
AdminApp.install('c:/MyStuff/application1.ear', '[-cluster cluster1]')
```

where:

$	is a Jacl operator for substituting a variable name with its value
AdminApp	is an object allowing application objects to be managed
install	is an AdminApp command
MyStuff/application1.ear	is the name of the application to install
cluster	is an installation option
cluster1	the value of the cluster option which will be cluster name

- Using interactive mode, the following command changes the application information by prompting you through a series of installation tasks:

– Using Jacl:

```
$AdminApp installInteractive c:/MyStuff/application1.ear
```

– Using Jython:

```
AdminApp.installInteractive('c:/MyStuff/application1.ear')
```

where:

$	is a Jacl operator for substituting a variable name with its value
AdminApp	is an object allowing application objects to be managed
installInteractive	is an AdminApp command
MyStuff/application1.ear	is the name of the application to install

2. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 232 article for more information.

3. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 217 article for more information.

Uninstalling applications with the wsadmin tool

Before starting this task, the wsadmin tool must be running. See “Starting the wsadmin scripting client” on page 250 for more information.

Steps to uninstall an application follow:

1. Uninstall the application:

   Specify the name of the application you want to uninstall, not the name of the Enterprise ARchive (EAR) file.

   - Using Jacl:

     ```
     $AdminApp uninstall application1
     ```

   - Using Jython:

     ```
     AdminApp.uninstall('application1')
     ```

   where:

`$`	is a Jacl operator for substituting a variable name with its value
`AdminApp`	is an object supporting application objects management
`uninstall`	is an AdminApp command
`application1`	is the name of the application to uninstall

2. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 232 article for more information.
3. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 217 article for more information.

Uninstalling an application removes it from the WebSphere Application Server configuration and from all the servers that the application was installed on. The application binaries (EAR file contents) are deleted from the installation directory. This occurs when the configuration is saved for single server WebSphere Application Server editions or when the configuration changes are synchronized from deployment manager to the individual nodes for network deployment configurations.

Managing deployed applications using scripting

This topic contains the following tasks:

- “Starting applications with scripting” on page 257
- “Updating installed applications with the wsadmin tool” on page 258
- “Stopping applications with scripting” on page 261
- “Listing the modules in an installed application with scripting” on page 262
- “Querying application state using scripting” on page 266
- “Disabling application loading in deployed targets using scripting” on page 267
- “Configuring applications for session management using scripting” on page 268
- “Configuring applications for session management in Web modules using scripting” on page 271
- “Exporting applications using scripting” on page 275
- “Configuring a shared library using scripting” on page 275
- “Configuring a shared library for an application using scripting” on page 279
- “Setting background applications using scripting” on page 282

Starting applications with scripting

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

Before starting an application, it must be installed. See the “Installing applications with the wsadmin tool” on page 254 article for more information.

Perform the following steps to start an application:

1. Identify the application manager MBean for the server where the application resides and assign it the appManager variable. The following example returns the name of the application manager MBean.
   - Using Jacl:
     ```
     set appManager [$AdminControl queryNames cell=mycell,node=mynode,type=ApplicationManager,
     process=server1,*]
     ```
   - Using Jython:
     ```
     appManager = AdminControl.queryNames('cell=mycell,node=mynode,type=ApplicationManager,
      process=server1,*')
     print appManager
     ```

   where:

set	is a Jacl command
appManager	is a variable name
$	is a Jacl operator for substituting a variable name with its value
AdminControl	is an object that enables the manipulation of MBeans running in a WebSphere server process
queryNames	is an AdminControl command

cell=*mycell*,node=*mynode*,type=*ApplicationManager*,
process=*server1*
	is the hierarchical containment path of the configuration object

print	is a Jython command

   Example output:

   ```
   WebSphere:cell=mycell,name=ApplicationManager,mbeanIdentifier=ApplicationManager,type=ApplicationManager,
    node=mynode,process=server1
   ```

2. Start the application. The following example invokes the startApplication operation on the MBean, providing the application name that you want to start.
   - Using Jacl:
     ```
     $AdminControl invoke $appManager startApplication myApplication
     ```
   - Using Jython:
     ```
     AdminControl.invoke(appManager, 'startApplication', 'myApplication')
     ```

   where:

$	is a Jacl operator for substituting a variable name with its value
AdminControl	is an object that enables the manipulation of MBeans running in a WebSphere server process
invoke	is an AdminControl command
appManager	evaluates to the ID of the server specified in step number 1
startApplication	is an attribute of modify objects

myApplication	is the value of the startApplication attribute

Updating installed applications with the wsadmin tool

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

Before starting an application, it must be installed. See the “Installing applications with the wsadmin tool” on page 254 article for more information.

Both the **update** command and the **updateinteractive** command support a set of options. See the “Options for the AdminApp object install, installInteractive, edit, editInteractive, update, and updateInteractive commands” on page 437 article for a list of valid options for the **update** and **updateinteractive** commands. You can also obtain a list of supported options for an Enterprise Archive (EAR) file using the **options** command, for example:

Using Jacl:

```
$AdminApp options
```

Using Jython:

```
print AdminApp.options()
```

For more information for the **options**, **update**, or **updateinteractive** commands, see the “Commands for the AdminApp object” on page 415 article. Perform the following steps to update an application:

1. Update the installed application using one of the following options:
   - The following command updates a single file in a deployed application:
     – Using Jacl:

       ```
       $AdminApp update app1 file {-operation update -contents c:/apps/app1/my.xml
        -contenturi app1.jar/my.xml}
       ```

     – Using Jython string:

       ```
       AdminApp.update('app1', 'file', '[-operation update -contents c:/apps/app1/my.xml
        -contenturi app1.jar/my.xml]')
       ```

     – Using Jython list:

       ```
       AdminApp.update('app1', 'file', ['-operation', 'update', '-contents', 'c:/apps/app1/my.xml',
        '-contenturi', 'app1.jar/my.xml'])
       ```

     where:

$	is a Jacl operator for substituting a variable name with its value
AdminApp	is an object supporting application objects management
update	is an AdminApp command
app1	is the name of the application to update
file	is the content type value
operation	is an option of the **update** command
update	is the value of the `operation` option
contents	is an option of the **update** command
/apps/app1/my.xml	is the value of the `contents` option
contenturi	is an option of the **update** command
app1.jar/my.xml	is the value of the `contenturi` option

- The following command adds a module to the deployed application, if the module does not exist. Otherwise, the existing module will be updated.
  - Using Jacl:

    ```
    $AdminApp update app1 modulefile {-operation addupdate -contents
    c:/apps/app1/Increment.jar -contenturi Increment.jar -nodeployejb
    -BindJndiForEJBNonMessageBinding {{"Increment Enterprise Java Bean"
     Increment Increment.jar,META-INF/ejb-jar.xml Inc}}}
    ```

  - Using Jython string:

    ```
    AdminApp.update('app1', 'modulefile', '[-operation addupdate -contents
    c:/apps/app1/Increment.jar -contenturi Increment.jar -nodeployejb
    -BindJndiForEJBNonMessageBinding [["Increment Enterprise Java Bean
    " Increment Increment.jar,META-INF/ejb-jar.xml Inc]]]')
    ```

  - Using Jython list:

    ```
    bindJndiForEJBValue = [["Increment Enterprise Java Bean",
    "Increment", " Increment.jar,
     META-INF/ejb-jar.xml", "Inc"]]

    AdminApp.update('app1', 'modulefile', ['-operation', 'addupdate', '-contents',
    'c:/apps/app1/Increment.jar', '-contenturi','Increment.jar' '-nodeployejb',
    `-BindJndiForEJBNonMessageBinding', bindJndiForEJBValue])
    ```

  where:

$	is a Jacl operator for substituting a variable name with its value
AdminApp	is an object supporting application objects management
update	is an AdminApp command
app1	is the name of the application to update
modulefile	is the content type value
operation	is an option of the **update** command
addupdate	is the value of the operation option
contents	is an option of the **update** command
/apps/app1/Increment.jar	is the value of the contents option
contenturi	is an option of the **update** command
Increment.jar	is the value of the contenturi option
nodeployejb	is an option of the **update** command
BindJndiForEJBNonMessageBinding	is an option of the **update** command
″Increment Enterprise Java Bean″ Increment Increment.jar,META-INF/ejb-jar.xml Inc	is the value of the BindJndiForEJBNonMessageBinding option
bindJndiForEJBValue	is a Jython variable containing the value of the BindJndiForEJBNonMessageBinding option

- The following command uses a partial application to update a deployed application:
  - Using Jacl:

    ```
    $AdminApp update app1 partialapp {-contents c:/apps/app1/app1Partial.zip}
    ```

  - Using Jython string:

    ```
    AdminApp.update('app1', 'partialapp', '[-contents c:/apps/app1/app1Partial.zip]')
    ```

  - Using Jython list:

    ```
    AdminApp.update('app1', 'partialapp', ['-contents', 'c:/apps/app1/app1Partial.zip'])
    ```

where:

$	is a Jacl operator for substituting a variable name with its value
AdminApp	is an object supporting application objects management
update	is an AdminApp command
app1	is the name of the application to update
partialapp	is the content type value
contents	is an option of the **update** command
/apps/app1/app1Partial.zip	is the value of the contents option

- The following command updates the entire deployed application:
  - Using Jacl:

    ```
    $AdminApp update app1 app {-operation update -contents c:/apps/app1/newApp1.jar
    -usedefaultbindings -nodeployejb -BindJndiForEJBNonMessageBinding
    {{"Increment Enterprise Java Bean" Increment Increment.jar,META-INF/ejb-jar.xml Inc}}}
    ```
  - Using Jython string:

    ```
    AdminApp.update('app1', 'app', '[-operation update -contents c:/apps/app1/newApp1.ear
    -usedefaultbindings -nodeployejb -BindJndiForEJBNonMessageBinding
    [["Increment Enterprise Java Bean" Increment Increment.jar,META-INF/ejb-jar.xml Inc]]]')
    ```
  - Using Jython list:

    ```
    bindJndiForEJBValue = [["Increment Enterprise Java Bean", "Increment", " Increment.jar,
    META-INF/ejb-jar.xml", "Inc"]]

    AdminApp.update('app1', 'app', ['-operation', 'update', '-contents',
    'c:/apps/app1/NewApp1.ear', '-usedefaultbindings', '-nodeployejb',
    `-BindJndiForEJBNonMessageBinding', bindJndiForEJBValue])
    ```

where:

$	is a Jacl operator for substituting a variable name with its value
AdminApp	is an object supporting application objects management
update	is an AdminApp command
app1	is the name of the application to update
app	is the content type value
operation	is an option of the **update** command
update	is the value of the operation option
contents	is an option of the **update** command
/apps/app1/newApp1.ear	is the value of the contents option
usedefaultbindings	is an option of the **update** command
nodeployejb	is an option of the **update** command
BindJndiForEJBNonMessageBinding	is an option of the **update** command
″Increment Enterprise Java Bean″ Increment Increment.jar,META-INF/ejb-jar.xml Inc	is the value of the BindJndiForEJBNonMessageBinding option
bindJndiForEJBValue	is a Jython variable containing the value of the BindJndiForEJBNonMessageBinding option

2. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 232 article for more information.

3. In a network deployment environment only, synchronize the node. See the "Synchronizing nodes with the wsadmin tool" on page 217 article for more information.

Stopping applications with scripting

Before starting this task, the wsadmin tool must be running. See the "Starting the wsadmin scripting client" on page 250 article for more information.

The following example stops all running applications on a server:

1. Identify the application manager MBean for the server where the application resides, and assign it to the appManager variable.
   - Using Jacl:

     ```
     set appManager [$AdminControl queryNames cell=mycell,node=mynode,type=ApplicationManager,
      process=server1,*]
     ```

   - Using Jython:

     ```
     appManager = AdminControl.queryNames('cell=mycell, node=mynode,type=ApplicationManager,
      process=server1,*')
     print appManager
     ```

   where:

set	is a Jacl command
appManager	is a variable name
$	is a Jacl operator for substituting a variable name with its value
AdminControl	is an object that enables the manipulation of MBeans running in a WebSphere server process
queryNames	is an AdminControl command

cell=*mycell*,node=*mynode*,type=*ApplicationManager*,
process=*server1*
	is the hierarchical containment path of the configuration object

print	is a Jython command

   This command returns the application manager MBean.

   Example output:

   ```
   WebSphere:cell=mycell,name=ApplicationManager,mbeanIdentifier=ApplicationManager,type=ApplicationManager,
    node=mynode,process=server1
   ```

2. Query the running applications belonging to this server and assign the result to the apps variable.
   - Using Jacl:

     ```
     set apps [$AdminControl queryNames cell=mycell,node=mynode,type=Application,process=server1,*]
     ```

   - Using Jython:

     ```
     # get line separator
     import  java.lang.System  as sys
     lineSeparator = sys.getProperty('line.separator')

     apps = AdminControl.queryNames('cell=mycell,node=mynode,type=Application,process=server1,*').split(lineSeparator)
     print apps
     ```

   where:

set	is a Jacl command
apps	is a variable name
$	is a Jacl operator for substituting a variable name with its value

AdminControl	is an object that enables the manipulation of MBeans running in a WebSphere server process
queryNames	is an AdminControl command

cell=*mycell*,node=*mynode*,type=*ApplicationManager*,
process=*server1*
	is the hierarchical containment path of the configuration object

print	is a Jython command

This command returns a list of application MBeans.

Example output:

```
WebSphere:cell=mycell,name=adminconsole,mbeanIdentifier=deployment.xml#ApplicationDeployment_1,
type=Application,node=mynode,Server=server1,process=server1,J2EEName=adminconsole
WebSphere:cell=mycell,name=filetransfer,mbeanIdentifier=deployment.xml#ApplicationDeployment_1,
type=Application,node=mynode,Server=server1,process=server1,J2EEName=filetransfer
```

3. Stop all the running applications.
   - Using Jacl:

     ```
     foreach app $apps {
          set appName [$AdminControl getAttribute $app name]
          $AdminControl invoke $appManager stopApplication $appName}
     ```
   - Using Jython:

     ```
     for app in apps:
         appName = AdminControl.getAttribute(app, 'name')
         AdminControl.invoke(appManager, 'stopApplication', appName)
     ```

   This command stops all the running applications by invoking the stopApplication operation on the MBean, passing in the application name to stop.

Once you complete the steps for this task, all running applications on the server are stopped.

Listing the modules in an installed application with scripting

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

Use the AdminApp object **listModules** command to list the modules in an installed application. For example:

- Using Jacl:

  ```
  $AdminApp listModules DefaultApplication -server
  ```
- Using Jython:

  ```
  print AdminApp.listModules('DefaultApplication', '-server')
  ```

where:

$	is a Jacl operator for substituting a variable name with its value
print	is a Jython command
AdminApp	is an object supporting application object management
listmodules	is an AdminApp command
DefaultApplication	is the name of the application
-server	is an optional option specified

Example output:

```
DefaultApplication#IncCMP11.jar+META-INF/ejb-jar.xml#WebSphere:cell=mycell,node=mynode,server=myserver
DefaultApplication#DefaultWebApplication.war+WEB-INF/web.xml#WebSphere:cell=mycell,node=mynode,server=myserver
```

Example: Listing the modules in an application server: The following example lists all modules on all enterprise applications installed on `server1` in `node1`:

Note: ***** means that the module is installed on server1 node node1 and other node and/or server.

+ means that the module is installed on server1 node node1 only means that the module is not installed on server1 node node1.

```
 1  #----------------------------------------------------------------------------
       2  # setting up variables to keep server name and node name
       3  #------------------------------------------------------------------------
       4  set  serverName  server1

                Web Modules:
                        mtcomps.war
```

Querying application state using scripting

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

The following example queries for the presence of Application MBean to find out whether the application is running.

Using Jacl:

```
$AdminControl completeObjectName type=Application,name=myApplication,*
```

Using Jython:

```
print AdminControl.completeObjectName('type=Application,name=myApplication,*')
```

where:

$	is a Jacl operator for substituting a variable name with its value
AdminControl	is an object that enables the manipulation of MBeans running in a WebSphere server process
completeObjectName	is an AdminControl command
type=Application,name=*myApplication*	is the hierarchical containment path of the configuration object
print	is a Jython command

If *myApplication* is running, then there should be an MBean created for it. Otherwise, the command returns nothing. If *myApplication* is running, the following is the example output:

```
WebSphere:cell=mycell,name=myApplication,mbeanIdentifier=cells/mycell/applications/myApplication.ear/deployments/myApplic
```

Disabling application loading in deployed targets using scripting

Before starting this task, the wsadmin tool must be running. See the "Starting the wsadmin scripting client" on page 250 article for more information.

The following example uses the AdminConfig object to disable application loading in deployed targets:

1. Obtain the deployment object for the application and assign it to the `deployments` variable, for example:
   - Using Jacl:
     ```
     set deployments [$AdminConfig getid /Deployment:myApp/]
     ```
   - Using Jython:
     ```
     deployments = AdminConfig.getid("/Deployment:myApp/")
     ```

   where:

set	is a Jacl command
deployments	is a variable name
$	is a Jacl operator for substituting a variable name with its value
AdminConfig	is an object representing the WebSphere Application Server configuration
getid	is an AdminConfig command
Deployment	is an attribute
myApp	is the value of the attribute

   Example output:
   ```
   myApp(cells/mycell/applications/myApp.ear/deployments/myApp|deployment.xml#Deployment_1)
   ```
2. Obtain the target mappings in the application and assign them to the `targetMappings` variable, for example:
   - Using Jacl:
     ```
     set deploymentObj1 [$AdminConfig showAttribute $deployments deployedObject]
     set targetMap1 [lindex [$AdminConfig showAttribute $deploymentObj1 targetMappings] 0]
     ```
     Example output:
     ```
     (cells/mycell/applications/ivtApp.ear/deployments/ivtApp|deployment.xml#DeploymentTargetMapping_1)
     ```
   - Using Jython:

```
deploymentObj1 = AdminConfig.showAttribute(deployments, 'deployedObject')
targetMap1 = AdminConfig.showAttribute(deploymentObj1, 'targetMappings')
targetMap1 = targetMap1[1:len(targetMap1)-1].split(" ")
print targetMap1
```

Example output:

```
['(cells/mycell/applications/ivtApp.ear/deployments/ivtApp|deployment.xml#DeploymentTargetMapping_1)']
```

where:

set	is a Jacl command
deploymentObj1	is a variable name
$	is a Jacl operator for substituting a variable name with its value
AdminConfig	is an object representing the WebSphere Application Server configuration
showAttribute	is an AdminConfig command
deployments	evaluates to the ID of the deployment object specified in step number 1
deployedObject	is an attribute
targetMap1	a variable name
targetMappings	is an attribute
lindex	a Jacl command
print	a Jython command

3. Disable the loading of the application on each deployed target, for example:
   - Using Jacl:
     ```
     foreach tm $targetMap1 {
           $AdminConfig modify $tm {{enable false}}
     }
     ```
   - Using Jython:
     ```
     for targetMapping in targetMap1:
        AdminConfig.modify(targetMapping, [["enable", "false"]])
     ```
4. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 232 article for more information.
5. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 217 article for more information.

Configuring applications for session management using scripting

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

You can use the AdminApp object to set configurations in an application. Some configuration settings are not available through the AdminApp object. The following example uses the AdminConfig object to configure session manager for the application.

1. Identify the deployment configuration object for the application and assign it to the deployment variable. For example:
   - Using Jacl:
     ```
     set deployments [$AdminConfig getid /Deployment:myApp/]
     ```
   - Using Jython:
     ```
     deployments = AdminConfig.getid('/Deployment:myApp/')
     print deployment
     ```

where:

set	is a Jacl command
deployments	is a variable name
$	is a Jacl operator for substituting a variable name with its value
AdminConfig	is an object representing the WebSphere Application Server configuration
getid	is an AdminConfig command
Deployment	is an attribute
myApp	is the value of the attribute

Example output:

```
myApp(cells/mycell/applications/myApp.ear/deployments/myApp|deployment.xml#Deployment_1)
```

2. Retrieve the applicaton deployment and assign it to the appDeploy variable. For example:
   - Using Jacl:
     ```
     set appDeploy [$AdminConfig showAttribute $deployments deployedObject]
     ```
   - Using Jython:
     ```
     appDeploy = AdminConfig.showAttribute(deployments, 'deployedObject')
     print appDeploy
     ```

   where:

set	is a Jacl command
appDeploy	is a variable name
$	is a Jacl operator for substituting a variable name with its value
AdminConfig	is an object representing the WebSphere Application Server configuration
showAttribute	is an AdminConfig command
deployments	evaluates to the ID of the deployment object specified in step number 1
deployedObject	is an attribute

Example output:

```
(cells/mycell/applications/myApp.ear/deployments/myApp|deployment.xml#ApplicationDeployment_1)
```

3. To obtain a list of attributes you can set for session manager, use the **attributes** command. For example:
   - Using Jacl:
     ```
     $AdminConfig attributes SessionManager
     ```
   - Using Jython:
     ```
     print AdminConfig.attributes('SessionManager')
     ```

   where:

$	is a Jacl operator for substituting a variable name with its value
AdminConfig	is an object representing the WebSphere Application Server configuration
attributes	is an AdminConfig command
SessionManager	is an attribute

Example output:

```
"accessSessionOnTimeout Boolean"
"allowSerializedSessionAccess Boolean"
"context ServiceContext@"
"defaultCookieSettings Cookie"
"enable Boolean"
"enableCookies Boolean"
"enableProtocolSwitchRewriting Boolean"
"enableSSLTracking Boolean"
"enableSecurityIntegration Boolean"
"enableUrlRewriting Boolean"
"maxWaitTime Integer"
"properties Property(TypedProperty)*"
"sessionDRSPersistence DRSSettings"
"sessionDatabasePersistence SessionDatabasePersistence"
"sessionPersistenceMode ENUM(DATABASE, DATA_REPLICATION, NONE)"
"tuningParams TuningParams"
```

4. Set up the attributes for the session manager. The following example sets three top level attributes in the session manager. You can modify the example to set other attributes of session manager including the nested attributes in Cookie, DRSSettings, SessionDataPersistence, and TuningParms object types. To list the attributes for those object types, use the **attributes** command of the AdminConfig object.

   - Using Jacl:

     ```
     set attr1 [list enableSecurityIntegration true]
     set attr2 [list maxWaitTime 30]
     set attr3 [list sessionPersistenceMode NONE]
     set attrs [list $attr1 $attr2 $attr3]
     set sessionMgr [list sessionManagement $attrs]
     ```

     Example output using Jacl:

     ```
     sessionManagement {{enableSecurityIntegration true} {maxWaitTime 30} {sessionPersistenceMode NONE}}
     ```

   - Using Jython:

     ```
     attr1 = ['enableSecurityIntegration', 'true']
     attr2 = ['maxWaitTime', 30]
     attr3 = ['sessionPersistenceMode', 'NONE']
     attrs = [attr1, attr2, attr3]
     sessionMgr = [['sessionManagement', attrs]]
     ```

     Example output using Jython:

     ```
     [[sessionManagement, [[enableSecurityIntegration, true], [maxWaitTime, 30], [sessionPersistenceMode, NONE]]]
     ```

   where:

set	is a Jacl command
attr1, attr2, attr3, attrs, sessionMgr	are variable names
$	is a Jacl operator for substituting a variable name with its value
enableSecurityIntegration	is an attribute
true	is a value of the enableSecurityIntegration attribute
maxWaitTime	is an attribute
30	is a value of the maxWaitTime attribute
sessionPersistenceMode	is an attribute
NONE	is a value of the sessionPersistenceMode attribute

5. Create the session manager for the application. For example:

   - Using Jacl:

     ```
     $AdminConfig create ApplicationConfig $appDeploy [list $sessionMgr]
     ```

- Using Jython:

  ```
  print AdminConfig.create('ApplicationConfig', appDeploy, sessionMgr)
  ```

  where:

`$`	is a Jacl operator for substituting a variable name with its value
`AdminConfig`	is an object representing the WebSphere Application Server configuration
`create`	is an AdminConfig command
`ApplicationConfig`	is an attribute
`appDeploy`	evaluates to the ID of the deployed application specified in step number 2
`list`	is a Jacl command
`sessionMgr`	evaluates to the ID of the session manager specified in step number 4

Example output:

```
(cells/mycell/applications/myApp.ear/deployments/myApp|deployment.xml#ApplicationConfig_1)
```

6. Save the configuration changes. See the "Saving configuration changes with the wsadmin tool" on page 232 article for more information.
7. In a network deployment environment only, synchronize the node. See the "Synchronizing nodes with the wsadmin tool" on page 217 article for more information.

Configuring applications for session management in Web modules using scripting

Before starting this task, the wsadmin tool must be running. See the "Starting the wsadmin scripting client" on page 250 article for more information.

You can use the AdminApp object to set configurations in an application. Some configuration settings are not available through the AdminApp object. This example uses the AdminConfig object to configure session manager for Web module in the application.

1. Identify the deployment configuration object for the application and assign it to the deployment variable. For example:
   - Using Jacl:

     ```
     set deployments [$AdminConfig getid /Deployment:myApp/]
     ```

   - Using Jython:

     ```
     deployments = AdminConfig.getid('/Deployment:myApp/')
     print deployments
     ```

   where:

`set`	is a Jacl command
`deployments`	is a variable name
`$`	is a Jacl operator for substituting a variable name with its value
`AdminConfig`	is an object representing the WebSphere Application Server configuration
`getid`	is an AdminConfig command
`Deployment`	is an attribute
`myApp`	is the value of the attribute

Example output:

```
myApp(cells/mycell/applications/myApp.ear/deployments/myApp|deployment.xml#Deployment_1)
```

2. Get all the modules in the application and assign it to the modules variable. For example:
   - Using Jacl:

     ```
     set appDeploy [$AdminConfig showAttribute $deployments deployedObject]
     set mod1 [$AdminConfig showAttribute $appDeploy modules]
     ```

     Example output:

     ```
     (cells/mycell/applications/myApp.ear/deployments/myApp:deployment.xml#WebModuleDeployment_1)
     (cells/mycell/applications/myApp.ear/deployments/myApp:deployment.xml#EJBModuleDeployment_1)
     (cells/mycell/applications/myApp.ear/deployments/myApp:deployment.xml#WebModuleDeployment_2)
     ```
   - Using Jython:

     ```
     appDeploy = AdminConfig.showAttribute(deployments, 'deployedObject')
     mod1 = AdminConfig.showAttribute(appDeploy, 'modules')
     print mod1
     ```

     Example output:

     ```
     [(cells/mycell/applications/myApp.ear/deployments/myApp|deployment.xml#WebModuleDeployment_1)
     (cells/mycell/applications/myApp.ear/deployments/myApp|deployment.xml#EJBModuleDeployment_1)
     (cells/mycell/applications/myApp.ear/deployments/myApp|deployment.xml#EJBModuleDeployment_2)]
     ```

   where:

set	is a Jacl command
appDeploy	is a variable name
mod1	is a variable name
$	is a Jacl operator for substituting a variable name with its value
AdminConfig	is an object representing the WebSphere Application Server configuration
showAttribute	is an AdminConfig command
deployments	evaluates to the ID of the deployment object specified in step number 1
deployedObject	is an attribute

3. To obtain a list of attributes you can set for session manager, use the attributes command. For example:
   - Using Jacl:

     ```
     $AdminConfig attributes SessionManager
     ```
   - Using Jython:

     ```
     print AdminConfig.attributes('SessionManager')
     ```

   where:

$	is a Jacl operator for substituting a variable name with its value
AdminConfig	is an object representing the WebSphere Application Server configuration
attributes	is an AdminConfig command
SessionManager	is an attribute

   Example output:

```
"accessSessionOnTimeout Boolean"
"allowSerializedSessionAccess Boolean"
"context ServiceContext@"
"defaultCookieSettings Cookie"
"enable Boolean"
```

```
"enableCookies Boolean"
"enableProtocolSwitchRewriting Boolean"
"enableSSLTracking Boolean"
"enableSecurityIntegration Boolean"
"enableUrlRewriting Boolean"
"maxWaitTime Integer"
"properties Property(TypedProperty)*"
"sessionDRSPersistence DRSSettings"
"sessionDatabasePersistence SessionDatabasePersistence"
"sessionPersistenceMode ENUM(DATABASE, DATA_REPLICATION, NONE)"
"tuningParams TuningParams"
```

4. Set up the attributes for session manager. The following example sets four top level attributes in the session manager. You can modify the example to set other attributes in the session manager including the nested attributes in Cookie, DRSSettings, SessionDataPersistence, and TuningParms object types. To list the attributes for those object types, use the **attributes** command of AdminConfig object.

   - Using Jacl:

     ```
     set attr0 [list enable true]
     set attr1 [list enableSecurityIntegration true]
     set attr2 [list maxWaitTime 30]
     set attr3 [list sessionPersistenceMode NONE]
     set attr4 [list enableCookies true]
     set attr5 [list invalidationTimeout 45]
     set tuningParmsDetailList [list $attr5]
     set tuningParamsList [list tuningParams $tuningParmsDetailList]
     set pwdList [list password 95ee608]
     set userList [list userId Administrator]
     set dsNameList [list datasourceJNDIName jdbc/session]
     set dbPersistenceList [list $dsNameList $userList $pwdList]
     set sessionDBPersistenceList [list $dbPersistenceList]
     set sessionDBPersistenceList [list sessionDatabasePersistence $dbPersistenceList]
     set kuki [list maximumAge 1000]
     set cookie [list $kuki]
     set cookieSettings [list defaultCookieSettings $cookie]
     set sessionManagerDetailList [list $attr0 $attr1 $attr2 $attr3 $attr4 $cookieSettings
       $tuningParamsList $sessionDBPersistenceList]
     set sessionMgr [list sessionManagement $sessionManagerDetailList]
     set id [$AdminConfig create ApplicationConfig $appDeploy [list $sessionMgr] configs]
     set targetMappings [lindex [$AdminConfig showAttribute $appDeploy targetMappings] 0]
     set attrs [list config $id]
     $AdminConfig modify $targetMappings [list $attrs]
     ```

     Example output using Jacl:

     ```
     sessionManagement {{enableSecurityIntegration true} {maxWaitTime 30} {sessionPersistenceMode NONE} {enabled true}}
     ```

   - Using Jython:

     ```
     attr0 = ['enable', 'true']
     attr1 = ['enableSecurityIntegration', 'true']
     attr2 = ['maxWaitTime', 30]
     attr3 = ['sessionPersistenceMode', 'NONE']
     attr4 = ['enableCookies', 'true']
     attr5 = ['invalidationTimeout', 45]
     tuningParmsDetailList = [attr5]
     tuningParamsList = ['tuningParams', tuningParmsDetailList]
     pwdList = ['password', '95ee608']
     userList = ['userId', 'Administrator']
     dsNameList = ['datasourceJNDIName', 'jdbc/session']
     dbPersistenceList = [dsNameList, userList, pwdList]
     sessionDBPersistenceList = [dbPersistenceList]
     sessionDBPersistenceList = ['sessionDatabasePersistence', dbPersistenceList]
     kuki = ['maximumAge', 1000]
     cookie = [kuki]
     cookieSettings = ['defaultCookieSettings', cookie]
     sessionManagerDetailList = [attr0, attr1, attr2, attr3, attr4, cookieSettings, tuningParamsList,
       sessionDBPersistenceList]
     sessionMgr = ['sessionManagement', sessionManagerDetailList]
     ```

```
id = AdminConfig.create('ApplicationConfig', appDeploy,[sessionMgr], 'configs')
targetMappings = AdminConfig.showAttribute(appDeploy, 'targetMappings')
targetMappings = targetMappings[1:len(targetMappings)-1]
print targetMappings
attrs = ['config', id]
AdminConfig.modify(targetMappings,[attrs])
```

Example output using Jython:

```
[sessionManagement, [[enableSecurityIntegration, true], [maxWaitTime, 30], [sessionPersistenceMode, NONE]]
```

5. Set up the attributes for Web module. For example:
   - Using Jacl:

     ```
     set nameAttr [list name myWebModuleConfig]
     set descAttr [list description "Web Module config post create"]
     set webAttrs [list $nameAttr $descAttr $sessionMgr]
     ```

     Example output:

     ```
     {name myWebModuleConfig} {description {Web Module config post create}}
     {sessionManagement {{enableSecurityIntegration true} {maxWaitTime 30}
     {sessionPersistenceMode NONE} {enabled true}}}
     ```
   - Using Jython:

     ```
     nameAttr = ['name', 'myWebModuleConfig']
     descAttr = ['description', "Web Module config post create"]
     webAttrs = [nameAttr, descAttr, sessionMgr]
     ```

     Example output:

     ```
     [[name, myWebModuleConfig], [description, "Web Module config post create"],
     [sessionManagement, [[enableSecurityIntegration, true], [maxWaitTime, 30],
     [sessionPersistenceMode, NONE], [enabled, true]]]]
     ```

   where:

set	is a Jacl command
nameAttr, descAttr, webAttrs	are variable names
$	is a Jacl operator for substituting a variable name with its value
name	is an attribute
myWebModuleConfig	is a value of the name attribute
description	is an attribute
Web Module config post create	is a value of the description attribute

6. Create the session manager for each Web module in the application. You can modify the following example to set other attributes of session manager in Web module configuration.
   - Using Jacl:

     ```
     foreach module $mod1 {
          if ([regexp WebModuleDeployment $module] == 1} {
             $AdminConfig create WebModuleConfig $module $webAttrs
        $AdminConfig save
          }
       }
     ```
   - Using Jython:

     ```
     arrayModules = mod1[1:len(mod1)-1].split(" ")
     for module in arrayModules:
      if module.find('WebModuleDeployment') != -1:
       AdminConfig.create('WebModuleConfig', module, webAttrs)
       Adminconfig.save()
     ```

   Example output:

   ```
   myWebModuleConfig(cells/mycell/applications/myApp.ear/deployments/myApp|deployment.xml#WebModuleConfiguration_1)
   ```

7. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 232 article for more information.
8. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 217 article for more information.

Exporting applications using scripting

You can export your applications before you update installed applications or before you migrate to a different version of the WebSphere Application Server product.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

Exporting applications enables you to back them up and preserve their binding information.

- Export an enterprise application to a location of your choice, for example:
  - Using Jacl:

    ```
    $AdminApp export app1 C:/mystuff/exported.ear
    ```
  - Using Jython:

    ```
    AdminApp.export('app1', 'C:/mystuff/exported.ear')
    ```

  where:

`$`	is a Jacl operator for substituting a variable name with its value
`AdminApp`	is an object allowing application objects management
`export`	is an AdminApp command
app1	is the name of the application that will be exported
`/mystuff/exported.ear`	is the name of the file where the exported application will be stored

- Export Data Definition Language (DDL) files in the enterprise bean module of an application to a destination directory, for example:
  - Using Jacl:

    ```
    $AdminApp exportDDL app1 C:/mystuff
    ```
  - Using Jython:

    ```
    AdminApp.exportDDL('app1', 'C:/mystuff')
    ```

  where:

`$`	is a Jacl operator for substituting a variable name with its value
`AdminApp`	is an object allowing application objects management
`exportDDL`	is an AdminApp command
app1	is the name of the application whose DDL files will be exported
/mystuff	is the name of the directory where the DDL files export from the application

Configuring a shared library using scripting

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

Perform the following steps to configure an application server to use a shared library.

1. Identify the server and assign it to the server variable. For example:
   - Using Jacl:

     ```
     set serv [$AdminConfig getid /Cell:mycell/Node:mynode/Server:server1/]
     ```

   - Using Jython:

     ```
     serv = AdminConfig.getid('/Cell:mycell/Node:mynode/Server:server1/')
     print serv
     ```

   where:

`set`	is a Jacl command
`serv`	is a variable name
`$`	is a Jacl operator for substituting a variable name with its value
`AdminConfig`	is an object representing the WebSphere Application Server configuration
`getid`	is an AdminConfig command
`Cell`	is an attribute
`mycell`	is the value of the attribute
`Node`	is an attribute
`mynode`	is the value of the attribute
`Server`	is an attribute
`server1`	is the value of the attribute

   Example output:

   ```
   server1(cells/mycell/nodes/mynode/servers/server1|server.xml#Server_1)
   ```

2. Create the shared library in the server. For example:
   - Using Jacl:

     ```
     $AdminConfig create Library $serv {{name mySharedLibrary}
      {classPath c:/mySharedLibraryClasspath}}
     ```

   - Using Jython:

     ```
     print AdminConfig.create('Library', serv, [['name', 'mySharedLibrary'],
      ['classPath',  'c:/mySharedLibraryClasspath']])
     ```

   where:

`$`	is a Jacl operator for substituting a variable name with its value
`AdminConfig`	is an object representing the WebSphere Application Server configuration
`create`	is an AdminConfig command
`Library`	is an attribute
`serv`	evaluates the ID of the server specified in step number 1
`name`	is an attribute
`mySharedLibrary`	is a value of the name attribute
`classPath`	is an attribute
/`mySharedLibraryClasspath`	is the value of the classpath attribute
`print`	is a Jython command

   Example output:

```
MysharedLibrary(cells/mycell/nodes/mynode/servers/server1|libraries.xml#Library_1)
```

3. Identify the application server from the server and assign it to the appServer variable. For example:
   - Using Jacl:

     ```
     set appServer [$AdminConfig list ApplicationServer $serv]
     ```

   - Using Jython:

     ```
     appServer = AdminConfig.list('ApplicationServer', serv)
     print appServer
     ```

   where:

`set`	is a Jacl command
`appServer`	is a variable name
`$`	is a Jacl operator for substituting a variable name with its value
`AdminConfig`	is an object representing the WebSphere Application Server configuration
`list`	is an AdminConfig command
`ApplicationServer`	is an attribute
`serv`	evaluates the ID of the server specified in step number 1
`print`	is a Jython command

   Example output:

   ```
   server1(cells/mycell/nodes/mynode/servers/server1|server.xml#ApplicationServer_1
   ```

4. Identify the class loader in the application server and assign it to the classLoader variable. For example:
   - To use the existing class loader associated with the server, the following commands use the first class loader:
     – Using Jacl:

       ```
       set classLoad [$AdminConfig showAttribute $appServer classloaders]
       set classLoader1 [lindex $classLoad 0]
       ```

     – Using Jython:

       ```
       classLoad = AdminConfig.showAttribute(appServer, 'classloaders')
       cleanClassLoaders = classLoad[1:len(classLoad)-1]
       classLoader1 = cleanClassLoaders.split(' ')[0]
       ```

     where:

`set`	is a Jacl command
`classLoad`, `classLoader1`	is a variable name
`$`	is a Jacl operator for substituting a variable name with its value
`AdminConfig`	is an object representing the WebSphere Application Server configuration
`showAttribute`	is an AdminConfig command
`appServer`	evaluates the ID of the application server specified in step number 3
`classloaders`	is an attribute
`print`	is a Jython command

   - To create a new class loader, do the following step:
     – Using Jacl:

```
set classLoader1 [$AdminConfig create Classloader $appServer {{mode PARENT_FIRST}}]
```

– Using Jython:

```
classLoader1 = AdminConfig.create('Classloader', appServer, [['mode',  'PARENT_FIRST']])
```

where:

set	is a Jacl command
classLoader1	is a variable name
$	is a Jacl operator for substituting a variable name with its value
AdminConfig	is an object representing the WebSphere Application Server configuration
create	is an AdminConfig command
Classloader	is an attribute
appServer	evaluates the ID of the application server specified in step number 3
mode	is an attribute
PARENT_FIRST	is the value of the attribute
print	is a Jython command

Example output:

```
(cells/mycell/nodes/mynode/servers/server1|server.xml#Classloader_1)
```

5. Associate the created shared library with the application server through the class loader. For example:
   - Using Jacl:

     ```
     $AdminConfig create LibraryRef $classLoader1 {{libraryName MyshareLibrary} {sharedClassloader true}}
     ```

   - Using Jython:

     ```
     print AdminConfig.create('LibraryRef', classLoader1, [['libraryName', 'MyshareLibrary'],
      ['sharedClassloader', 'true']])
     ```

   where:

$	is a Jacl operator for substituting a variable name with its value
AdminConfig	is an object representing the WebSphere Application Server configuration
create	is an AdminConfig command
LibraryRef	is an attribute
classLoader1	evaluates the ID of the class loader specified in step number 4
libraryName	is an attribute
MyshareLibrary	is the value of the attribute
sharedClassloader	is an attribute
true	is the value of the attribute
print	is a Jython command

Example output:

```
(cells/mycell/nodes/mynode/servers/server1|server.xml#LibraryRef_1)
```

6. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 232 article for more information.

7. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 217 article for more information.

Configuring a shared library for an application using scripting

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

You can use the AdminApp object to set certain configurations in the application. This example uses the AdminConfig object to configure a shared library for an application.

1. Identify the shared library and assign it to the library variable. You can either use an existing shared library or create a new one, for example:
   - To create a new shared library, perform the following steps:
     a. Idenitfy the node and assign it to a variable, for example:
        – Using Jacl:

        ```
        set n1 [$AdminConfig getid /Cell:mycell/Node:mynode/]
        ```

        – Using Jython:

        ```
        n1 = AdminConfig.getid('/Cell:mycell/Node:mynode/')
        print n1
        ```

        where:

`set`	is a Jacl command
`n1`	is a variable name
`$`	is a Jacl operator for substituting a variable name with its value
`AdminConfig`	is an object representing the WebSphere Application Server configuration
`getid`	is an AdminConfig command
`Cell`	is the object type
`mycell`	is the name of the object that will be modified
`Node`	is the object type
`mynode`	is the name of the object that will be modified

        Example output:

        ```
        mynode(cells/mycell/nodes/mynode|node.xml#Node_1)
        ```

     b. Create the shared library in the node. The following example creates a new shared library in the node scope. You can modify it to use the cell or server scope.
        – Using Jacl:

        ```
        set library [$AdminConfig create Library $n1 {{name mySharedLibrary} {classPath c:/mySharedLibraryClasspath
        ```

        – Using Jython:

        ```
        library = AdminConfig.create('Library', n1, [['name', 'mySharedLibrary'], ['classPath', 'c:/mySharedLibrary
        print library
        ```

        where:

`set`	is a Jacl command
`library`	is a variable name
`$`	is a Jacl operator for substituting a variable name with its value
`AdminConfig`	is an object representing the WebSphere Application Server configuration
`create`	is an AdminConfig command

`Library`	is an AdminConfig object
`n1`	evaluates to the ID of host node specified in step number 1
`name`	is an attribute
mySharedLibrary	is the value of the name attribute
`classPath`	is an attribute
/mySharedLibraryClasspath	is the value of the classPath attribute

Example output:

```
MySharedLibrary(cells/mycell/nodes/mynode|libraries.xml#Library_1)
```

- To use an existing shared library, issue the following command:
  - Using Jacl:

    ```
    set library [$AdminConfig getid /Library:mySharedLibrary/]
    ```

  - Using Jython:

    ```
    library = AdminConfig.getid('/Library:mySharedLibrary/')
    print library
    ```

  where:

`set`	is a Jacl command
`library`	is a variable name
`$`	is a Jacl operator for substituting a variable name with its value
`AdminConfig`	is an object representing the WebSphere Application Server configuration
`getid`	is an AdminConfig command
`Library`	is an attribute
mySharedLibrary	is the value of the Library attribute

Example output:

```
MySharedLibrary(cells/mycell/nodes/mynode|libraries.xml#Library_1)
```

2. Identify the deployment configuration object for the application and assign it to the deployment variable. For example:
   - Using Jacl:

     ```
     set deployment [$AdminConfig getid /Deployment:myApp/]
     ```

   - Using Jython:

     ```
     deployment = AdminConfig.getid('/Deployment:myApp/')
     print deployment
     ```

   where:

`set`	is a Jacl command
`deployment`	is a variable name
`$`	is a Jacl operator for substituting a variable name with its value
`AdminConfig`	is an object representing the WebSphere Application Server configuration
`getid`	is an AdminConfig command
`Deployment`	is an attribute
myApp	is the value of the Deployment attribute
`print`	is a Jython command

Example output:

```
myApp(cells/mycell/applications/myApp.ear/deployments/myApp|deployment.xml#Deployment_1)
```

3. Retrieve the application deployment and assign it to the appDeploy variable. For example:
   - Using Jacl:

     ```
     set appDeploy [$AdminConfig showAttribute $deployment deployedObject]
     ```

   - Using Jython:

     ```
     appDeploy = AdminConfig.showAttribute(deployment, 'deployedObject')
     print appDeploy
     ```

   where:

set	is a Jacl command
appDeploy	is a variable name
$	is a Jacl operator for substituting a variable name with its value
AdminConfig	is an object representing the WebSphere Application Server configuration
showAttribute	is an AdminConfig command
deployment	evaluates the ID of the deployment configuration object specified in step number 2
deployedObject	is an attribute of modify objects
print	is a Jython command

Example output:

```
(cells/mycell/applications/myApp.ear/deployments/myApp|deployment.xml#ApplicationDeployment_1)
```

4. Identify the class loader in the application deployment and assign it to the classLoader variable. For example:
   - Using Jacl:

     ```
     set classLoad1 [$AdminConfig showAttribute $appDeploy classloader]
     ```

   - Using Jython:

     ```
     classLoad1 = AdminConfig.showAttribute(appDeploy, 'classloader')
     print classLoad1
     ```

   where:

set	is a Jacl command
classLoad1	is a variable name
$	is a Jacl operator for substituting a variable name with its value
AdminConfig	is an object representing the WebSphere Application Server configuration
showAttribute	is an AdminConfig command
appDeploy	evaluates the ID of the application deployment specified in step number 3
classLoader	is an attribute of modify objects
print	is a Jython command

Example output:

```
(cells/mycell/applications/myApp.ear/deployments/myApp|deployment.xml#Classloader_1)
```

5. Associate the shared library in the application through the class loader. For example:

- Using Jacl:

  ```
  $AdminConfig create LibraryRef $classLoad1 {{libraryName MyshareLibrary} {sharedClassloader true}}
  ```

- Using Jython:

  ```
  print AdminConfig.create('LibraryRef', classLoad1, [['libraryName', 'MyshareLibrary'],  ['sharedClassloader', 'true']
  ```

where:

`$`	is a Jacl operator for substituting a variable name with its value
`AdminConfig`	is an object representing the WebSphere Application Server configuration
`create`	is an AdminConfig command
`LibraryRef`	is an AdminConfig object
`classLoad1`	evaluates to the ID of class loader specified in step number 4
`libraryName`	is an attribute
MyshareLibrary	is the value of the libraryName attribute
`sharedClassloader`	is an attribute
true	is the value of the sharedClassloader attribute

Example output:

```
(cells/mycell/applications/myApp.ear/deployments/myApp|deployment.xml#LibraryRef_1)
```

6. Save the configuration changes. See the "Saving configuration changes with the wsadmin tool" on page 232 article for more information.
7. In a network deployment environment only, synchronize the node. See the "Synchronizing nodes with the wsadmin tool" on page 217 article for more information.

Setting background applications using scripting

Before starting this task, the wsadmin tool must be running. See the "Starting the wsadmin scripting client" on page 250 article for more information.

Perform the following steps to enable or disable a background application. Background applications specify whether the application must initialize fully before the server starts. The default setting is `false` and this indicates that server startup will not complete until the application starts. If you set the value to `true`, the application starts on a background thread and server startup continues without waiting for the application to start. The application may not ready for use when the application server starts.

1. Locate the application deployment object for the application. For example:
   - Using Jacl:

     ```
     set applicationDeployment [$AdminConfig getid /Deployment:adminconsole/ApplicationDeployment:/]
     ```

   - Using Jython:

     ```
     applicationDeployment = AdminConfig.getid('/Deployment:adminconsole/ApplicationDeployment:/')
     ```

   where:

`set`	is a Jacl command
`applicationDeployment`	is a variable name
`$`	is a Jacl operator for substituting a variable name with its value
`AdminConfig`	is an object representing the WebSphere Application Server configuration
`getid`	is an AdminConfig command

`Deployment`	is a type
`ApplicationDeployment`	is a type
`adminconsole`	is the name of the application

2. Enable the background application. For example:
   - Using Jacl:
     ```
     $AdminConfig modify $applicationDeployment "{backgroundApplication true}"
     ```
   - Using Jython:
     ```
     AdminConfig.modify(applicationDeployment, ['backgroundApplication', 'true'])
     ```

   where:

`$`	is a Jacl operator for substituting a variable name with its value
`AdminConfig`	is an object representing the WebSphere Application Server configuration
`modify`	is an AdminConfig command
`applicationDeployment`	is a variable name that was set in step 1
`backgroundApplication`	is an attribute
`true`	is the value of the backgroundApplication attribute

3. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 232 article for more information.
4. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 217 article for more information.

Configuring servers with scripting

This topic contains the following tasks:

- “Creating a server using scripting”
- “Configuring the Java virtual machine using scripting” on page 284
- “Configuring enterprise bean containers using scripting” on page 284
- “Configuring a Performance Manager Infrastructure service using scripting” on page 288
- “Limiting the growth of Java virtual machine log files using scripting” on page 290
- “Configuring an ORB service using scripting” on page 292
- “Configuring for processes using scripting” on page 293
- “Configuring transaction properties for a server using scripting” on page 295
- “Setting port numbers kept in the serverindex.xml file using scripting” on page 296
- “Disabling components using scripting” on page 297
- “Disabling services using scripting” on page 298
- “Dynamic caching with scripting” on page 299

Creating a server using scripting

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

Creating an application server involves a configuration command. Perform the following steps to create a server:

1. Obtain the configuration ID of the object and assign it to the `node` variable, for example:

Using Jacl:

```
set node [$AdminConfig getid /Node:mynode/]
```

Using Jython:

```
node = AdminConfig.getid('/Node:mynode/')
```

2. Create the server using the node that you specified in the first step:

   Using Jacl:

```
$AdminConfig create Server $node {{name myserv} {outputStreamRedirect {{fileName myfile.out}}}}
```

   Using Jython:

```
AdminConfig.create('Server', node, [['name', 'myserv'], ['outputStreamRedirect', [['fileName', 'myfile.out']]]])
```

3. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 232 article for more information.
4. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 217 article for more information.

Configuring the Java virtual machine using scripting

An example modifying the Java virtual machine (JVM) of a server to turn on debug follows:

- Identify the server and assign it to the server1 variable.

  Using Jacl:

```
set server1 [$AdminConfig getid /Cell:mycell/Node:mynode/Server:server1/]
```

  Using Jython:

```
server1 = AdminConfig.getid('/Cell:mycell/Node:mynode/Server:server1/')
print server1
```

  Example output:

```
server1(cells/mycell/nodes/mynode/servers/server1|server.xml#Server_1)
```

- Identify the JVM belonging to this server and assign it to the jvm variable.

  Using Jacl:

```
set jvm [$AdminConfig list JavaVirtualMachine $server1]
```

  Using Jython:

```
jvm = AdminConfig.list('JavaVirtualMachine', server1)
print jvm
```

  Example output:

```
(cells/mycell/nodes/mynode/servers/server1:server.xml#JavaVirtualMachine_1)
```

- Modify the JVM to turn on debug.

  Using Jacl:

```
$AdminConfig modify $jvm {{debugMode true} {debugArgs "-Djava.compiler=NONE -Xdebug -Xnoagent
  -Xrunjdwp:transport=dt_socket,server=y,suspend=n,address=7777"}}
```

  Using Jython:

```
AdminConfig.modify(jvm, [['debugMode', 'true'], ['debugArgs',  "-Djava.compiler=NONE -Xdebug -Xnoagent
  -Xrunjdwp:transport=dt_socket,server=y,suspend=n,address=7777"]])
```

- Save the changes with the following command:

  Using Jacl:

```
$AdminConfig save
```

  Using Jython:

```
AdminConfig.save()
```

Configuring enterprise bean containers using scripting

Before starting this task, the wsadmin tool must be running. See “Starting the wsadmin scripting client” on page 250 for more information.

Perform the following steps to configure an enterprise bean container:

1. Identify the application server and assign it to the serv1 variable. For example:
   - Using Jacl:

     ```
     set serv1 [$AdminConfig getid /Cell:mycell/Node:mynode/Server:server1/]
     ```

   - Using Jython:

     ```
     serv1 = AdminConfig.getid('/Cell:mycell/Node:mynode/Server:server1/')
     print serv1
     ```

   where:

set	is a Jacl command
serv1	is a variable name
$	is a Jacl operator for substituting a variable name with its value
AdminConfig	is an object representing the WebSphere Application Server configuration
getid	is an AdminConfig command
/Cell:*mycell*/Node:*mynode*/Server:*server1*/	is the hierarchical containment path of the configuration object
Cell	is the object type
mycell	is the optional name of the object
Node	is the object type
mynode	is the optional name of the object
Server	is the object type
server1	is the optional name of the object

   Example output:

   ```
   server1(cells/mycell/nodes/mynode/servers/server1|server.xml#Server_1)
   ```

2. Identify the EJB container belonging to the server and assign it to the ejbc1 variable. For example:
   - Using Jacl:

     ```
     set ejbc1 [$AdminConfig list EJBContainer $serv1]
     ```

   - Using Jython:

     ```
     ejbc1 = AdminConfig.list('EJBContainer', serv1)
     print ejbc1
     ```

   where:

set	is a Jacl command
ejbc1	is a variable name
$	is a Jacl operator for substituting a variable name with its value
AdminConfig	is an object representing the WebSphere Application Server configuration
list	is an AdminConfig command
EJBContainer	is the object type **Note:** The name of the object type that you input here is the one based on the XML configuration files and does not have to be the same name that the administrative console displays.

serv1	evaluates to the ID of the server specified in step number 1

Example output:

```
(cells/mycell/nodes/mynode/servers/server1|server.xml#EJBContainer_1)
```

3. View all the attributes of the enterprise bean container.
   - The following example command does not show nested attributes:
     - Using Jacl:

       ```
       $AdminConfig show $ejbc1
       ```

       Example output:

       ```
       {cacheSettings (cells/mycell/nodes/mynode/servers/server1|server.xml#EJBCache_1)}
       {components {}}
       {inactivePoolCleanupInterval 30000}
       {parentComponent (cells/mycell/nodes/mynode/servers/server1|server.xml#ApplicationServer_1)
       {passivationDirectory ${USER_INSTALL_ROOT}/temp}
       {properties {}}
       {services {(cells/mycell/nodes/mynode/servers/server1|server.xml#MessageListenerService_1)}
       {stateManagement (cells/mycell/nodes/mynode/servers/server1|server.xml#StateManageable_10)}
       ```

     - Using Jython:

       ```
       print AdminConfig.show(ejbc1)
       ```

       Example output:

       ```
       [cacheSettings (cells/mycell/nodes/myode/servers/server1|server.xml#EJBCache_1)]
       [components []]
       [inactivePoolCleanupInterval 30000]
       [parentComponent (cells/mycell/nodes/myode/servers/server1|server.xml#ApplicationServer_1)
       [passivationDirectory ${USER_INSTALL_ROOT}/temp]
       [properties []]
       [services [(cells/mycell/nodes/myode/servers/server1|server.xml#MessageListenerService_1)]
       [stateManagement (cells/mycell/nodes/mynode/servers/server1|server.xml#StateManageable_10)]
       ```

   where:

$	is a Jacl operator for substituting a variable name with its value
print	is a Jython command
AdminConfig	is an object representing the WebSphere Application Server configuration
showall	is an AdminConfig command
ejbc1	evaluates to the ID of the enterprise bean container specified in step number 2

   - The following command example includes nested attributes:
     - Using Jacl:

       ```
       $AdminConfig showall $ejbc1
       ```

       Example output:

       ```
       {cacheSettings {{cacheSize 2053}
         {cleanupInterval 3000}}}
       {components {}}
       {inactivePoolCleanupInterval 30000}
       {parentComponent (cells/mycell/nodes/mynode/servers/server1|server.xml#ApplicationServer_1)}
       {passivationDirectory ${USER_INSTALL_ROOT}/temp}
       {properties {}}
       {services {{{context (cells/mycell/nodes/mynode/servers/server1|server.xml#EJBContainer_1)}
         {listenerPorts {}}
         {properties {}}
         {threadPool {{inactivityTimeout 3500}
       ```

```
      {isGrowable false}
      {maximumSize 50}
      {minimumSize 10}}}}}}
  {stateManagement {{initialState START}
    {managedObject (cells/mycell/nodes/mynode/servers/server1|server.xml#EJBContainer_1)}}}
```

– Using Jython:

```
print AdminConfig.showall(ejbc1)
```

Example output:

```
[cacheSettings [[cacheSize 2053]
  [cleanupInterval 3000]]]
[components []]
[inactivePoolCleanupInterval 30000]
[parentComponent (cells/mycell/nodes/mynode/servers/server1|server.xml#ApplicationServer_1)]
[passivationDirectory ${USER_INSTALL_ROOT}/temp]
[properties []]
[services [[[context (cells/mycell/nodes/mynode/servers/server1|server.xml#EJBContainer_1)]
  [listenerPorts []]
  [properties []]
  [threadPool [[inactivityTimeout 3500]
    [isGrowable false]
    [maximumSize 50]
    [minimumSize 10]]]]]]
[stateManagement {{initialState START]
  [managedObject (cells/mycell/nodes/mynode/servers/server1|server.xml#EJBContainer_1)]]]
```

where:

$	is a Jacl operator for substituting a variable name with its value
print	is a Jython command
AdminConfig	is an object representing the WebSphere Application Server configuration
showall	is an AdminConfig command
ejbc1	evaluates to the ID of the enterprise bean container specified in step number 2

4. Modify the attributes.
   - The following example modifies the enterprise bean cache settings and it includes nested attributes:
     – Using Jacl:

```
$AdminConfig modify $ejbc1 {{cacheSettings {{cacheSize 2500} {cleanupInterval 3500}}}}
```

– Using Jython:

```
AdminConfig.modify(ejbc1, [['cacheSettings', [['cacheSize', 2500],  ['cleanupInterval', 3500]]]])
```

where:

$	is a Jacl operator for substituting a variable name with its value
AdminConfig	is an object representing the WebSphere Application Server configuration
modify	is an AdminConfig command
ejbc1	evaluates to the ID of the enterprise bean container specified in step number 2
cacheSettings	is an attribute of modify objects
cacheSize	is an attribute of modify objects
2500	is the value of the cacheSize attribute

`cleanupInterval`	is an attribute of modify objects
`3500`	is the value of the cleanupInterval attribute

- The following example modifies the cleanup interval attribute:
  - Using Jacl:

    ```
    $AdminConfig modify $ejbc1 {{inactivePoolCleanupInterval 15000}}
    ```

  - Using Jython:

    ```
    AdminConfig.modify(ejbc1, [['inactivePoolCleanupInterval', 15000]])
    ```

  where:

`$`	is a Jacl operator for substituting a variable name with its value
`AdminConfig`	is an object representing the WebSphere Application Server configuration
`modify`	is an AdminConfig command
`ejbc1`	evaluates to the ID of the enterprise bean container specified in step number 2
`inactivePoolCleanupInterval`	is an attribute of modify objects
`15000`	is the value of the inactivePoolCleanupInterval attribute

5. Save the changes. For example:
   - Using Jacl:

     ```
     $AdminConfig save
     ```

   - Using Jython:

     ```
     AdminConfig.save()
     ```

   where:

`$`	is a Jacl operator for substituting a variable name with its value
`AdminConfig`	is an object representing the WebSphere Application Server configuration
`save`	is an AdminConfig command

Configuring a Performance Manager Infrastructure service using scripting

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

Use the following steps to configure the Performance Manager Infrastructure (PMI) service for an application server:

1. Identify the application server and assign it to the s1 variable, for example:
   - Using Jacl:

     ```
     set s1 [$AdminConfig getid /Cell:mycell/Node:mynode/Server:server1/]
     ```

   - Using Jython:

     ```
     s1 = AdminConfig.getid('Cell:mycell/Node:mynode/Server:server1/')
     ```

   where:

`set`	is a Jacl command

s1	is a variable name
$	is a Jacl operator for substituting a variable name with its value
AdminConfig	is an object representing the WebSphere Application Server configuration
getid	is an AdminConfig command
Cell	is an attribute
mycell	is the value of the Cell attribute
Node	is an attribute
mynode	is the value of the Node attribute
Server	is an attribute
server1	is the value of the Server attribute

Example output:

```
server1(cells/mycell/nodes/mynode/servers/server1|server.xml#Server_1)
```

2. Identify the PMI service that belongs to the server and assign it to the pmi variable, for example:
   - Using Jacl:

     ```
     set pmi [$AdminConfig list PMIService $s1]
     ```

   - Using Jython:

     ```
     pmi = AdminConfig.list('PMIService', s1)
     print pmi
     ```

   where:

set	is a Jacl command
pmi	is a variable name
$	is a Jacl operator for substituting a variable name with its value
AdminConfig	is an object representing the WebSphere Application Server configuration
list	is an AdminConfig command
PMIService	is an AdminConfig object
s1	evaluates to the ID of the application server specified in step number 1

Example output:

```
(cells/mycell/nodes/mynode/servers/server1|server.xml#PMIService_1)
```

3. Modify the attributes, for example:
   - Using Jacl:

     ```
     $AdminConfig modify $pmi {{enable true}
     {initialSpecLevel beanModule=H:cacheModule=H:connectionPoolModule=
     H:j2cModule=H:jvmRuntimeModule=H:orbPerfModule=H:servletSessionsModule
     =H:systemModule=H:threadPoolModule=H:transactionModule=H:
     webAppModule=H:webServicesModule=H:wlmModule=H:wsgwModule=H}}
     ```

   - Using Jython:

     ```
     AdminConfig.modify(pmi, [['enable', 'true'],
     ['initialSpecLevel', 'beanModule=H:cacheModule=H:connectionPoolModule=
     H:j2cModule=H:jvmRuntimeModule=H:orbPerfModule=H:servletSessionsModule=
     H:systemModule=H:threadPoolModule=H:transactionModule=H:webAppModule=H:
     webServicesModule=H:wlmModule=H:wsgwModule=H']])
     ```

This example enables PMI service and sets the specification levels for all of components in the server. The following are the valid specification levels for the components:

N	represents **none**
L	represents **low**
M	represents **medium**
H	represents **high**
X	represents **maximum**

4. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 232 article for more information.
5. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 217 article for more information.

Limiting the growth of Java virtual machine log files using scripting

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

Use the following example to configure the rotation policy settings for Java virtual machine (JVM) logs:

1. Identify the application server and assign it to the server1 variable, for example:
   - Using Jacl:
     ```
     set s1 [$AdminConfig getid /Cell:mycell/Node:mynode/Server:server1/]
     ```
   - Using Jython:
     ```
     s1 = AdminConfig.getid('/Cell:mycell/Node:mynode/Server:server1/')
     print s1
     ```

   where:

`set`	is a Jacl command
`s1`	is a variable name
`$`	is a Jacl operator for substituting a variable name with its value
`AdminConfig`	is an object representing the WebSphere Application Server configuration
`getid`	is an AdminConfig command
`Cell`	is the object type
`mycell`	is the name of the object that will be modified
`Node`	is the object type
`mynode`	is the name of the object that will be modified
`Server`	is the object type
`server1`	is the name of the object that will be modified
`print`	a Jython command

   Example output:
   ```
   server1(cells/mycell/nodes/mynode/servers/server1|server.xml#Server_1)
   ```
2. Identify the stream log and assign it to the log variable, for example:
   - The following example identifies the output stream log:
     – Using Jacl:
       ```
       set log [$AdminConfig showAttribute $s1 outputStreamRedirect]
       ```

- Using Jython:

  ```
  log = AdminConfig.showAttribute(s1, 'outputStreamRedirect')
  ```

- The following example identifies the error stream log:
  - Using Jacl:

    ```
    set log [$AdminConfig showAttribute $s1 errorStreamRedirect]
    ```

  - Using Jython:

    ```
    log = AdminConfig.showAttribute(s1, 'errorStreamRedirect')
    ```

Example output:

```
(cells/mycell/nodes/mynode/servers/server1|server.xml#StreamRedirect_2)
```

3. List the current values of the stream log, for example:
   - Using Jacl:

     ```
     $AdminConfig show $log
     ```

   - Using Jython:

     ```
     AdminConfig.show(log)
     ```

   Example output:

   ```
   {baseHour 24}
   {fileName ${SERVER_LOG_ROOT}/SystemOut.log}
   {formatWrites true}
   {maxNumberOfBackupFiles 1}
   {messageFormatKind BASIC}
   {rolloverPeriod 24}
   {rolloverSize 1}
   {rolloverType SIZE}
   {suppressStackTrace false}
   {suppressWrites false}
   ```

4. Modify the rotation policy for the stream log.
   - The following example sets the rotation log file size to two megabytes:
     - Using Jacl:

       ```
       $AdminConfig modify $log {{rolloverSize 2}}
       ```

     - Using Jython:

       ```
       AdminConfig.modify(log, ['rolloverSize', 2])
       ```

   - The following example sets the rotation policy to manage itself. It is based on the age of the file with the rollover algorithm loaded at midnight, and the log file rolling over every 12 hours:
     - Using Jacl:

       ```
       $AdminConfig modify $log {{rolloverType TIME} {rolloverPeriod 12} {baseHour 24}}
       ```

     - Using Jython:

       ```
       AdminConfig.modify(log, [['rolloverType', 'TIME'] ['rolloverPeriod', 12] ['baseHour', 24]])
       ```

   - The following example sets the log file to roll over based on both time and size:
     - Using Jacl:

       ```
       $AdminConfig modify $log {{rolloverType BOTH} {rolloverSize 2} {rolloverPeriod 12} {baseHour 24}}
       ```

     - Using Jython:

       ```
       AdminConfig.modify(log, [['rolloverType', 'BOTH'] ['rolloverSize', 2] ['rolloverPeriod', 12] ['baseHour', 24]])
       ```

5. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 232 article for more information.
6. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 217 article for more information.

Configuring an ORB service using scripting

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

Perform the following steps to modify the Object Request Broker (ORB) service for an application server:

1. Identify the application server and assign it to the server variable:
   - Using Jacl:
     ```
     set s1 [$AdminConfig getid /Cell:mycell/Node:mynode/Server:server1/]
     ```
   - Using Jython:
     ```
     s1 = AdminConfig.getid('/Cell:mycell/Node:mynode/Server:server1/')
     print s1
     ```

   where:

`set`	is a Jacl command
`s1`	is a variable name
`$`	is a Jacl operator for substituting a variable name with its value
`AdminConfig`	is an object representing the WebSphere Application Server configuration
`getid`	is an AdminConfig command
`Cell`	is the object type
`mycell`	is the name of the object that will be modified
`Node`	is the object type
`mynode`	is the name of the object that will be modified
`Server`	is the object type
`server1`	is the name of the object that will be modified
`print`	a Jython command

   Example output:
   ```
   server1(cells/mycell/nodes/mynode/servers/server1|server.xml#Server_1)
   ```

2. Identify the ORB belonging to the server and assign it to the orb variable:
   - Using Jacl:
     ```
     set orb [$AdminConfig list ObjectRequestBroker $s1]
     ```
   - Using Jython:
     ```
     orb = AdminConfig.list('ObjectRequestBroker', s1)
     print orb
     ```

   where:

`set`	is a Jacl command
`orb`	is a variable name
`$`	is a Jacl operator for substituting a variable name with its value
`AdminConfig`	is an object representing the WebSphere Application Server configuration
`list`	is an AdminConfig command
`ObjectRequestBroker`	is an AdminConfig object
`s1`	evaluates to the ID of server specified in step number 1

print	a Jython command

Example output:

```
(cells/mycell/nodes/mynode/servers/server1|server.xml#ObjectRequestBroker_1)
```

3. Modify the attributes. The following example modifies the connection cache maximum and pass by value attributes. You can modify the example to change the value of other attributes.
   - Using Jacl:
     ```
     $AdminConfig modify $orb {{connectionCacheMaximum 252} {noLocalCopies true}}
     ```
   - Using Jython:
     ```
     AdminConfig.modify(orb, [['connectionCacheMaximum', 252], ['noLocalCopies',  'true']])
     ```

   where:

$	is a Jacl operator for substituting a variable name with its value
AdminConfig	is an object representing the WebSphere Application Server configuration
modify	is an AdminConfig command
orb	evaluates to the ID of ORB specified in step number 2
connectionCacheMaximum	is an attribute
252	is the value of the connectionCacheMaximum attribute
noLocalCopies	is an attribute
true	is the value of the noLocalCopies attribute

4. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 232 article for more information.
5. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 217 article for more information.

Configuring for processes using scripting

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

Perform the following steps to configure a process:

1. Identify the server and assign it to the s1 variable. For example:
   - Using Jacl:
     ```
     set s1 [$AdminConfig getid /Cell:mycell/Node:mynode/Server:server1/]
     ```
   - Using Jython:
     ```
     s1 = AdminConfig.getid('/Cell:mycell/Node:mynode/Server:server1/')
     print s1
     ```

   where:

set	is a Jacl command
s1	is a variable name
$	is a Jacl operator for substituting a variable name with its value
AdminConfig	is an object representing the WebSphere Application Server configuration
getid	is an AdminConfig command

`Cell`	is the object type
`mycell`	is the name of the object that will be modified
`Node`	is the object type
`mynode`	is the name of the object that will be modified
`Server`	is the object type
`server1`	is the name of the object that will be modified
`print`	a Jython command

Example output:

```
server1(cells/mycell/nodes/mynode/servers/server1|server.xml#Server_1)
```

2. Identify the process definition belonging to this server and assign it to the processDef variable. For example:
   - Using Jacl:

     ```
     set processDef [$AdminConfig list JavaProcessDef $s1]
     set processDef [$AdminConfig showAttribute $s1 processDefinition]
     ```
   - Using Jython:

     ```
     processDef = AdminConfig.list('JavaProcessDef', s1)
     print processDef
     processDef = AdminConfig.showAttribute(s1, 'processDefinition')
     ```

   Example output:

   ```
   (cells/mycell/nodes/mynode/servers/server1|server.xml#JavaProcessDef_1)
   ```
3. Change the attributes.
   - On distributed systems, the following example changes the working directory.
     - Using Jacl:

       ```
       $AdminConfig modify $processDef {{workingDirectory c:/temp/user1}}
       ```
     - Using Jython:

       ```
       AdminConfig.modify(processDef, [['workingDirectory', 'c:/temp/user1']])
       ```
   - The following example modifies the stderr file name:
     - Using Jacl:

       ```
       set errFile [list stderrFilename \${LOG_ROOT}/server1/new_stderr.log]
       set attr [list $errFile]
       $AdminConfig modify $processDef [subst {{ioRedirect {$attr}}}]
       ```
     - Using Jython:

       ```
       errFile = ['stderrFilename', '\${LOG_ROOT}/server1/new_stderr.log']
       attr = [errFile]
       AdminConfig.modify(processDef, [['ioRedirect', [attr]]])
       ```
   - The following example modifies the process priority:
     - Using Jacl:

       ```
       $AdminConfig modify $processDef {{execution {{processPriority 15}}}}
       ```
     - Using Jython:

       ```
       AdminConfig.modify(processDef, [['execution', [['processPriority', 15]]]])
       ```
   - The following example changes the maximum startup attempts. You can modify this example to change other attributes in the process definition object.
     - Using Jacl:

       ```
       $AdminConfig modify $processDef {{monitoringPolicy {{maximumStartupAttempts 1}}}}
       ```
     - Using Jython:

       ```
       AdminConfig.modify(processDef, [['monitoringPolicy', [['maximumStartupAttempts',  1]]]])
       ```
4. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 232 article for more information.
5. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 217 article for more information.

Configuring transaction properties for a server using scripting

Before starting this task, the wsadmin tool must be running. See the "Starting the wsadmin scripting client" on page 250 article for more information.

Perform the following steps to configure the runtime transaction properties for an application server.

1. Identify the transaction service MBean for the application server. The following command returns the transaction service MBean for *server1*.

   - Using Jacl:

     ```
     set ts [$AdminControl completeObjectName cell=mycell,node=mynode,process=server1,type=TransactionService,*]
     ```

   - Using Jython:

     ```
     ts = AdminControl.completeObjectName('cell=mycell,node=mynode,process=server1,type=TransactionService,*')
     print ts
     ```

   where:

set	is a Jacl command
ts	is a variable name
$	is a Jacl operator for substituting a variable name with its value
AdminControl	is an object that enables the manipulation of MBeans running in a WebSphere server process
completeObjectName	is an AdminControl command

cell=*mycell*,node=*mynode*,process=*server1*,
type=TransactionService
	is a fragment of the object name whose complete name is returned by this command. It is used to find the matching object name which is, in this case, the transaction object MBean for the node *mynode*, where *mynode* is the name of the node that you use to synchronize configuration changes. For example: type=TransactionService, process=server1. It can be any valid combination of domain and key properties. For example, type, name, cell, node, process, etc.

   Example output:

   ```
   WebSphere:cell=mycell,name=TransactionService,mbeanIdentifier=TransactionService,type=TransactionService,
    node=mynode,process=server1
   ```

2. Modify the attributes.

   - Using Jacl:

     ```
     $AdminControl invoke $ts {{transactionLogDirectory c:/WebSphere/AppServer/tranlog/server1}
      {clientInactivityTimeout 30} {totalTranLifetimeTimeout 180}}
     ```

   - Using Jython:

     ```
     AdminControl.invoke(ts, [['transactionLogDirectory',  'c:/WebSphere/AppServer/tranlog/server1'],
      ['clientInactivityTimeout', 30],  ['totalTranLifetimeTimeout', 180]])
     ```

   where:

$	is a Jacl operator for substituting a variable name with its value
AdminControl	is an object that enables the manipulation of MBeans running in a WebSphere server process
invoke	is an AdminControl command
ts	evaluates to the ID of the transaction service specified in step number 1
transactionLogDirectory	is an attribute

c:/WebSphere/AppServer/tranlog/server1	is the value of the transactionLogDirectory attribute
clientInactivityTimeout	is an attribute
30	is the value of the clientInactivityTimeout attribute specified in seconds. A value of 0 means that there is no timeout limit.
totalTranLifetimeTimeout	is an attribute
180	is the value of the totalTranLifetimeTimeout attribute specified in milliseconds. A value of 0 means that there is no timeout limit.

Setting port numbers kept in the serverindex.xml file using scripting

Before starting this task, the wsadmin tool must be running. See the "Starting the wsadmin scripting client" on page 250 article for more information.

This topic provides reference information about modifying port numbers in the `serverindex.xml` file. The end points of the `serverindex.xml` file are part of different objects in the configuration.

Use the following attributes to modify the end point information of the end point attributes for a process:

- **`BOOTSTRAP_ADDRESS`** `of server1 process`

  An attribute of the NameServer object that exists inside the server. It is used by the naming client to specify the naming server to look up the initial context. To modify its end point, obtain the ID of the NameServer object and issue a **modify** command, for example:

  – Using Jacl:

  ```
  set s [$AdminConfig getid /Cell:mycell/Node:mynode/Server:server1/]
  set ns [$AdminConfig list NameServer $s]
  $AdminConfig modify $ns {{BOOTSTRAP_ADDRESS {{port 2810} {host myhost}}}}
  ```

  – Using Jython:

  ```
  s = AdminConfig.getid('/Cell:mycell/Node:mynode/Server:server1/')
  ns = AdminConfig.list('NameServer', s)
  AdminConfig.modify(ns, [['BOOTSTRAP_ADDRESS', [['host', 'myhost'],  ['port', 2810]]]])
  ```

- **`SOAP_CONNECTOR-ADDRESS`** `of server1 process`

  An attribute of the SOAPConnector object that exists inside the server. It is the port that is used by HTTP transport for incoming SOAP requests. To modify its end point, obtain the ID of the SOAPConnector object and issue a modify command, for example:

  – Using Jacl:

  ```
  set s [$AdminConfig getid /Cell:mycell/Node:mynode/Server:server1/]
  set soap [$AdminConfig list SOAPConnector $s]
  $AdminConfig modify $soap {{SOAP_CONNECTOR_ADDRESS {{host myhost} {port 8881}}}}
  ```

  – Using Jython:

  ```
  s = AdminConfig.getid('/Cell:mycell/Node:mynode/Server:server1/')
  soap = AdminConfig.list('SOAPConnector', s)
  AdminConfig.modify(soap, [['SOAP_CONNECTOR_ADDRESS', [['host', 'myhost'],  ['port', 8881]]]])
  ```

- **`DRS_CLIENT_ADDRESS`** `of server1 process`

  An attribute of the SystemMessageServer object that exists inside the server. It is the port used to configure the Data Replication Service (DRS) which is a JMS-based message broker system for dynamic caching. The DRS_CLIENT_ADDRESS attribute is not available if a replication domain and a replicator entry have not been added to the server.

  To modify the end point of the DRS_CLIENT_ADDRESS attribute, obtain the ID of the SystemMessageServer object and issue a **modify** command, for example:

  – Using Jacl:

  ```
  set s [$AdminConfig getid /Cell:mycell/Node:mynode/Server:server1/]
  set sms [$AdminConfig list SystemMessageServer $s]
  $AdminConfig modify $sms {{DRS_CLIENT_ADDRESS {{host myhost} {port 7874}}}}
  ```

  - Using Jython:

    ```
    s = AdminConfig.getid('/Cell:mycell/Node:mynode/Server:server1/')
    sms = AdminConfig.list('SystemMessageServer', s)
    AdminConfig.modify(sms, [['DRS_CLIENT_ADDRESS', [['host', 'myhost'], ['port', 7874]]]])
    ```

- `JMSSERVER_QUEUED_ADDRESS and JMSSERVER_DIRECT_ADDRESS of server1 process`

  An attribute of the JMSServer object that exists inside the server. These are ports used to configure the WebSphere Application Server JMS provider topic connection factory settings. To modify its end point, obtain the ID of the JMSServer object and issue a **modify** command, for example:

  - Using Jacl:

    ```
    set s [$AdminConfig getid /Cell:mycell/Node:mynode/Server:server1/]
    set jmss [$AdminConfig list JMSServer $s]
    $AdminConfig modify $jmss {{JMSSERVER_QUEUED_ADDRESS {{host myhost} {port 5560}}}}
    $AdminConfig modify $jmss {{JMSSERVER_DIRECT_ADDRESS {{host myhost} {port 5561}}}}
    ```

  - Using Jython:

    ```
    s = AdminConfig.getid('/Cell:mycell/Node:mynode/Server:server1/')
    jmss = AdminConfig.list('JMSServer', s)
    AdminConfig.modify(jmss, [['JMSSERVER_QUEUED_ADDRESS', [['host', 'myhost'], ['port', 5560]]]])
    AdminConfig.modify(jmss, [['JMSSERVER_DIRECT_ADDRESS', [['host', 'myhost'], ['port', 5561]]]])
    ```

- `NODE_DISCOVERY_ADDRESS of nodeagent process`

  An attribute of the NodeAgent object that exists inside the server. It is the port used to receive the incoming process discovery messages inside a node agent process. To modify its end point, obtain the ID of the NodeAgent object and issue a **modify** command, for example:

  - Using Jacl:

    ```
    set nodeAgentServer [$AdminConfig getid /Cell:mycell/Node:mynode/Server:nodeagent/]
    set nodeAgent [$AdminConfig list NodeAgent $nodeAgentServer]
    $AdminConfig modify $nodeAgent {{NODE_DISCOVERY_ADDRESS {{host myhost} {port 7272}}}}
    ```

  - Using Jython:

    ```
    nodeAgentServer = AdminConfig.getid('/Cell:mycell/Node:mynode/Server:nodeagent/')
    nodeAgent = AdminConfig.list('NodeAgent', nodeAgentServer)
    AdminConfig.modify(nodeAgent, [['NODE_DISCOVERY_ADDRESS', [['host', 'myhost'], ['port', 7272]]]])
    ```

- `CELL_DISCOVERY_ADDRESS of dmgr process`

  An attribute of the deploymentManager object that exists inside the server. It is the port used to receive the incoming process discovery messages inside a deployment manager process. To modify its end point, obtain the ID of the deploymentManager object and issue a **modify** command, for example:

  - Using Jacl:

    ```
    set netmgr [$AdminConfig getid /Cell:mycell/Node:managernode/Server:dmgr/]
    set deploymentManager [$AdminConfig list CellManager $netmgr]
    $AdminConfig modify $deploymentManager {{CELL_MULTICAST_DISCOVERY_ADDRESS {{host myhost} {port 7272}}}}
    $AdminConfig modify $deploymentManager {{CELL_DISCOVERY_ADDRESS {{host myhost} {port 7278}}}}
    ```

  - Using Jython:

    ```
    netmgr = AdminConfig.getid('/Cell:mycell/Node:managernode/Server:dmgr/')
    deploymentManager = AdminConfig.list('CellManager', netmgr)
    AdminConfig.modify(deploymentManager, [['CELL_MULTICAST_DISCOVERY_ADDRESS', [['host', 'myhost'],  ['port', 7272]]]]
    AdminConfig.modify(deploymentManager, [['CELL_DISCOVERY_ADDRESS', [['host', 'myhost'], ['port', 7278]]]])
    ```

Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 232 article for more information.

In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 217 article for more information.

Disabling components using scripting

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

Perform the following steps to disable the name server component of a configured server. You can modify this example to disable a different component.

1. Identify the server component and assign it to the nameServer variable.
   - Using Jacl:
     ```
     set nameServer [$AdminConfig list NameServer $server]
     ```
   - Using Jython:
     ```
     nameServer = AdminConfig.list('NameServer', server)
     print nameServer
     ```

   Example output:
   ```
   (cells/mycell/nodes/mynode/servers/server1|server.xml#NameServer_1)
   ```
2. List the components belonging to the server and assign them to the components variable.
   - Using Jacl:
     ```
     set components [$AdminConfig list Component $server]
     ```
   - Using Jython:
     ```
     components = AdminConfig.list('Component', server)
     print components
     ```

   The components variable contains a list of components.

   Example output:
   ```
   (cells/mycell/nodes/mynode/servers/server1|server.xml#ApplicationServer_1)
   (cells/mycell/nodes/mynode/servers/server1|server.xml#EJBContainer_1)
   (cells/mycell/nodes/mynode/servers/server1|server.xml#NameServer_1)
   (cells/mycell/nodes/mynode/servers/server1|server.xml#WebContainer_1)
   ```
3. Identify the name server component and assign it to the nameServer variable.

   Since the name server component is the third element in the list, retrieve this element by using index 2.
   - Using Jacl:
     ```
     set nameServer [lindex $components 2]
     ```
   - Using Jython:
     ```
     # get line separator
     import  java
     lineSeparator = java.lang.System.getProperty('line.separator')
     arrayComponents = components.split(lineSeparator)
     nameServer = arrayComponents[2]
     print nameServer
     ```

   Example output:
   ```
   (cells/mycell/nodes/mynode/servers/server1|server.xml#NameServer_1)
   ```
4. Disable the name server component by changing the nested initialState attribute belonging to the stateManagement attribute. For example:
   - Using Jacl:
     ```
     $AdminConfig modify $nameServer {{stateManagement {{initialState STOP}}}}
     ```
   - Using Jython:
     ```
     AdminConfig.modify(nameServer, [['stateManagement', [['initialState', 'STOP']]]])
     ```
5. Save the configuration changes. See the "Saving configuration changes with the wsadmin tool" on page 232 article for more information.
6. In a network deployment environment only, synchronize the node. See the "Synchronizing nodes with the wsadmin tool" on page 217 article for more information.

Disabling services using scripting

Before starting this task, the wsadmin tool must be running. See the "Starting the wsadmin scripting client" on page 250 article for more information.

Perform the following steps to disable the trace service of a configured server. You can modify this example to disable a different service.

1. Identify the server and assign it to the server variable. For example:
   - Using Jacl:
     ```
     set server [$AdminConfig getid /Cell:mycell/Node:mynode/Server:server1/]
     ```
   - Using Jython:
     ```
     server = AdminConfig.getid('/Cell:mycell/Node:mynode/Server:server1/')
     print server
     ```

   Example output:
   ```
   server1(cells/mycell/nodes/mynode/servers/server1|server.xml#Server_1)
   ```
2. List all the services belonging to the server and assign them to the services variable. The following example returns a list of services:
   - Using Jacl:
     ```
     set services [$AdminConfig list Service $server]
     ```
   - Using Jython:
     ```
     services = AdminConfig.list('Service', server)
     print services
     ```

   Example output:
   ```
   (cells/mycell/nodes/mynode/servers/server1|server.xml#AdminService_1)
   (cells/mycell/nodes/mynode/servers/server1|server.xml#DynamicCache_1)
   (cells/mycell/nodes/mynode/servers/server1|server.xml#MessageListenerService_1)
   (cells/mycell/nodes/mynode/servers/server1|server.xml#ObjectRequestBroker_1)
   (cells/mycell/nodes/mynode/servers/server1|server.xml#PMIService_1)
   (cells/mycell/nodes/mynode/servers/server1|server.xml#RASLoggingService_1)
   (cells/mycell/nodes/mynode/servers/server1|server.xml#SessionManager_1)
   (cells/mycell/nodes/mynode/servers/server1|server.xml#TraceService_1)
   (cells/mycell/nodes/mynode/servers/server1|server.xml#TransactionService_1)
   ```
3. Identify the trace service and assign it to the traceService variable.

   Since trace service is the 7th element in the list, retrieve this element by using index 6.
   - Using Jacl:
     ```
     set traceService [$AdminConfig list TraceService $server]
     ```
   - Using Jython:
     ```
     traceService = AdminConfig.list('TraceService', server)
     print traceService
     ```

   Example output:
   ```
   (cells/mycell/nodes/mynode/servers/server1|server.xml#TraceService_1)
   ```
4. Disable the trace service by modifying the enable attribute. For example:
   - Using Jacl:
     ```
     $AdminConfig modify $traceService {{enable false}}
     ```
   - Using Jython:
     ```
     AdminConfig.modify(traceService, [['enable', 'false']])
     ```
5. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 232 article for more information.
6. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 217 article for more information.

Dynamic caching with scripting

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

To see a list of parameters associated with dynamic caching, use the **attributes** command. For example:

```
$AdminConfig attributes DynamicCache
```

Perform the following steps to enable servlet caching:

1. Locate the server object. The following example selects the first server found:

   Using Jacl:

   ```
   set s1 [$AdminConfig getid /Server:server1/]
   ```

   Using Jython:

   ```
   s1 = AdminConfig.getid('/Server:server1/')
   ```

2. List the web containers and assign them to the `wc` variable, for example:

   Using Jacl:

   ```
   set wc [$AdminConfig list WebContainer $s1]
   ```

   Using Jython:

   ```
   wc = AdminConfig.list('WebContainer', s1)
   ```

3. Set the enableServletCaching attribute to `true` and assign it to the `serEnable` variable, for example:

   Using Jacl:

   ```
   set serEnable "{enableServletCaching true}"
   ```

   Using Jython:

   ```
   serEnable = [['enableServletCaching', 'true']]
   ```

4. Enable caching, for example:

   Using Jacl:

   ```
   $AdminConfig modify $wc $serEnable
   ```

   Using Jython:

   ```
   AdminConfig.modify(wc, serEnable)
   ```

Configuring connections to Webservers with scripting

This topic contains the following tasks:

- “Regenerating the node plug-in configuration using scripting”
- “Creating new virtual hosts using templates with scripting” on page 301

Regenerating the node plug-in configuration using scripting

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

Perform the following steps to regenerate the node plug-in configuration:

1. Identify the plug-in and assign it to the `generator` variable, for example:

   Using Jacl:

   ```
   set generator [$AdminControl completeObjectName type=PluginCfgGenerator,node=mynode,*]
   ```

   Using Jython:

   ```
   generator = AdminControl.completeObjectName('type=PluginCfgGenerator,node=mynode,*')
   ```

2. Regenerate the node plug-in:

   Using Jacl:

   ```
   $AdminControl invoke $generator generate "c:/WebSphere/DeloymentManager/config mycell mynode null plugin-cfg.xml"
   ```

   Using Jython:

   ```
   AdminControl.invoke(generator, 'generate', "c:/WebSphere/DeloymentManager/config mycell mynode null plugin-cfg.xml")
   ```

Creating new virtual hosts using templates with scripting

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

Some configuration object types have templates that you can use when you create a virtual host. You can create a new virtual host using a preexisting template or by creating a new custom template. Perform the following steps to create a new virtual host using a template:

1. If you want to create a new custom template, perform the following steps:
   a. Copy and paste the following file into a new file, *myvirtualhostname.xml*:
      ```
      <WAS-ROOT>\config\templates\default\virtualhosts.xml
      ```
   b. Edit and customize the new *myvirtualhostname.xml* file.
   c. Place the new file in the following directory:
      ```
      <WAS-ROOT>\config\templates\custom\
      ```

   If you want the new custom template to appear with the list of templates, restart the deployment manager on a network deployment edition, or use the AdminConfig object **reset** command. For example:
   - Using Jacl:
     ```
     $AdminConfig reset
     ```
   - Using Jython:
     ```
     AdminConfig.reset()
     ```

   The administrative console does not support the use of custom templates. The new template that you create will not be visible in the administrative console panels.
2. Use the AdminConfig object **listTemplates** command to list available templates, for example:
   - Using Jacl:
     ```
     $AdminConfig listTemplates VirtualHost
     ```
   - Using Jython:
     ```
     print AdminConfig.listTemplates('VirtualHost')
     ```

   Example output:
   ```
   default_host(templates/default:virtualhosts.xml#VirtualHost_1)
   my_host(templates/custom:virtualhostname.xml#VirtualHost_1)
   ```
3. Create a new virtual host. For example:
   - Using Jacl:
     ```
     set cell [$AdminConfig getid /Cell:NetworkDeploymentCell/]
     set vtempl [$AdminConfig listTemplates VirtualHost my_host]
     $AdminConfig createUsingTemplate VirtualHost $cell {{name newVirHost}} $vtempl
     ```
   - Using Jython:
     ```
     cell = AdminConfig.getid('/Cell:NetworkDeploymentCell/')
     vtempl = AdminConfig.listTemplates('VirtualHost', 'my_host')
     AdminConfig.createUsingTemplate('VirtualHost', cell, [['name', 'newVirHost']], vtempl)
     ```
4. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 232 article for more information.
5. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 217 article for more information.

Managing servers with scripting

This topic contains the following tasks:

- “Stopping a node using scripting” on page 302
- “Starting servers using scripting” on page 302

- "Stopping servers using scripting" on page 303
- "Querying server state using scripting" on page 304
- "Listing running applications on running servers using scripting" on page 304
- "Starting listener ports using scripting" on page 306
- "Managing generic servers using scripting" on page 307
- "Setting development mode for server objects using scripting" on page 308
- "Disabling parallel startup using scripting" on page 308
- "Removing multicast endpoints using scripting" on page 309
- "Obtaining server version information with scripting" on page 309

Stopping a node using scripting

Before starting this task, the wsadmin tool must be running. See the "Starting the wsadmin scripting client" on page 250 article for more information.

Stopping the node agent on a remote machine process is an asynchronous action where the stop is initiated, and then control returns to the command line. Perform the following task to stop a node:

1. Identify the node that you want to stop and assign it to a variable:

   Using Jacl:

   ```
   set na [$AdminControl queryNames type=NodeAgent,node=mynode,*]
   ```

   Using Jython:

   ```
   na = AdminControl.queryNames('type=NodeAgent,node=mynode,*')
   ```

2. Stop the node:

   Using Jacl:

   ```
   $AdminControl invoke $na stopNode
   ```

   Using Jython:

   ```
   AdminControl.invoke(na, 'stopNode')
   ```

Starting servers using scripting

Before starting this task, the wsadmin tool must be running. See the "Starting the wsadmin scripting client" on page 250 article for more information.

Use the **startServer** command to start the server. This command has several syntax options. For example:

- To start a server on a WebSphere Application Server single server edition, choose one of the following options:
  - The following examples specify the server name only:

    Using Jacl:

    ```
    $AdminControl startServer serverName
    ```

    Using Jython:

    ```
    AdminControl.startServer('serverName')
    ```

  - The following example starts an application server with the node specified:
    - Using Jacl:

      ```
      $AdminControl startServer server1 mynode
      ```

    - Using Jython:

      ```
      print AdminControl.startServer('server1', 'mynode')
      ```

    Example output:

```
WASX7319I: The serverStartupSyncEnabled attribute is set to false.  A start
will be attempted for server "server1" but the configuration information for
node "mynode" may not be current.
WASX7262I: Start completed for server "server1" on node "mynode"
```

- The following example specify the server name and wait time:
  - Using Jacl:

    ```
    $AdminControl startServer serverName 10
    ```

  - Using Jython:

    ```
    AdminControl.startServer('serverName', 10)
    ```

  where *10* is the number of milliseconds that the process should wait before starting the server.

- To start a server on a WebSphere Application Server network deployment edition, choose one of the following options:
  - The following example specifies the server name and the node name:
    - Using Jacl:

      ```
      $AdminControl startServer serverName nodeName
      ```

    - Using Jython:

      ```
      AdminControl.startServer('serverName', 'nodeName')
      ```

  - The following example specifies the server name, the node name, and the wait time:
    - Using Jacl:

      ```
      $AdminControl startServer serverName nodeName 10
      ```

    - Using Jython:

      ```
      AdminControl.startServer('serverName', 'nodeName', 10)
      ```

    where *10* is the number of milliseconds that the process should wait before starting the server.

Stopping servers using scripting

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

Use the **stopServer** command to stop the server. This command has several syntax options. For example:

- To stop a server on a WebSphere Application Server single server edition, choose one of the following options:
  - The following examples specify the server name only:

    Using Jacl:

    ```
    $AdminControl stopServer serverName
    ```

    Using Jython:

    ```
    AdminControl.stopServer('serverName')
    ```

  - The following examples stop an application server with the node specified:
    - Using Jacl:

      ```
      $AdminControl stopServer serverName mynode
      ```

    - Using Jython:

      ```
      print AdminControl.stopServer('serverName', 'mynode')
      ```

    Example output:

    ```
    WASX7337I: Invoked stop for server "serverName" Waiting for stop completion.
    WASX7264I: Stop completed for server "serverName" on node "mynode"
    ```

  - The following examples specify the server name and immediate:
    - Using Jacl:

      ```
      $AdminControl stopServer serverName immediate
      ```

    - Using Jython:

```
AdminControl.stopServer('serverName', immediate)
```

- To stop a server on a WebSphere Application Server network deployment edition, choose one of the following options:
  - The following example specifies the server name and the node name:
    - Using Jacl:
      ```
      $AdminControl stopServer serverName nodeName
      ```
    - Using Jython:
      ```
      AdminControl.stopServer('serverName', 'nodeName')
      ```
  - The following example specifies the server name, the node name, and immediate:
    - Using Jacl:
      ```
      $AdminControl stopServer serverName nodeName immediate
      ```
    - Using Jython:
      ```
      AdminControl.stopServer('serverName', 'nodeName', immediate)
      ```

Querying server state using scripting

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

Perform the following steps to query the server state:

1. Identify the server and assign it to the server variable. The following example returns the server MBean that matches the partial object name string:
   - Using Jacl:
     ```
     set server [$AdminControl completeObjectName cell=mycell,node=mynode,name=server1,type=Server,*]
     ```
   - Using Jython:
     ```
     server = AdminControl.completObjectName('cell=mycell,node=mynode,name=server1,type=Server,*')
     print server
     ```

   Example output:
   ```
   WebSphere:cell=mycell,name=server1,mbeanIdentifier=server.xml#Server_1,type=Server,node=mynode,
    process=server1,processType=ManagedProcess
   ```
2. Query for the state attribute. For example:
   - Using Jacl:
     ```
     $AdminControl getAttribute $server state
     ```
   - Using Jython:
     ```
     print AdminControl.getAttribute(server, 'state')
     ```

   The **getAttribute** command returns the value of a single attribute.

   Example output:
   ```
   STARTED
   ```

Listing running applications on running servers using scripting

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

Use the following example to list all the running applications on all the running servers on each node of each cell:

- Using Jacl:
  ```
  *Provide this example as a Jacl script file and run it with  the "-f" option:
  1  #----------------------------------------------------------------
  2  # lines 4 and 5 find all the cell and process them one at a time
  3  #----------------------------------------------------------------
  ```

```
4  set cells [$AdminConfig list Cell]
5  foreach cell $cells {
6     #-----------------------------------------------------------------------
7     # lines 10 and 11 find all the nodes belonging to the cell and
8     # process them at a time
9     #-----------------------------------------------------------------------
10    set nodes [$AdminConfig list Node $cell]
11    foreach node $nodes {
12       #--------------------------------------------------------------
13       # lines 16-20 find all the running servers belonging to the cell
14       # and node, and process them one at a time
15       #--------------------------------------------------------------
16       set cname [$AdminConfig showAttribute $cell name]
17       set nname [$AdminConfig showAttribute $node name]
18       set servs [$AdminControl queryNames type=Server,cell=$cname,node=$nname,*]
19       puts "Number of running servers on node $nname: [llength $servs]"
20       foreach server $servs {
21           #---------------------------------------------------------
22           # lines 25-31 get some attributes from the server to display;
23           # invoke an operation on the server JVM to display a property.
24           #---------------------------------------------------------
25           set sname [$AdminControl getAttribute $server name]
26           set ptype [$AdminControl getAttribute $server processType]
27           set pid   [$AdminControl getAttribute $server pid]
28           set state [$AdminControl getAttribute $server state]
29           set jvm [$AdminControl queryNames type=JVM,cell=$cname,node=$nname,process=$sname,*]
30           set osname [$AdminControl invoke $jvm getProperty os.name]
31           puts "  $sname ($ptype) has pid $pid; state: $state; on $osname"
32
j3           #---------------------------------------------------------
34           # line 37-42 find the applications running on this server and
35           # display the application name.
35           #---------------------------------------------------------
37           set apps [$AdminControl queryNames type=Application,cell=$cname,node=$nname,process=$sname,*]
38           puts "  Number of applications running on $sname: [llength $apps]"
39           foreach app $apps {
40              set aname [$AdminControl getAttribute $app name]
41              puts "    $aname"
42           }
43           puts "-----------------------------------------------------"
44           puts ""
45
46        }
47     }
48  }
```

- Using Jython:

```
* Provide this example as a Jython script file and run it with the "-f" option:

1   #----------------------------------------------------------------
2   # lines 7 and 8 find all the cell and process them one at a time
3   #----------------------------------------------------------------
4   # get line separator
5   import  java.lang.System  as  sys
6   lineSeparator = sys.getProperty('line.separator')
7   cells = AdminConfig.list('Cell').split(lineSeparator)
8   for cell in cells:
9        #-----------------------------------------------------------------------
10      # lines 13 and 14 find all the nodes belonging to the cell and
11      # process them at a time
12      #-----------------------------------------------------------------------
13      nodes = AdminConfig.list('Node', cell).split(lineSeparator)
14      for node in nodes:
15         #--------------------------------------------------------------
16         # lines 19-23 find all the running servers belonging to the cell
17         # and node, and process them one at a time
18         #--------------------------------------------------------------
19         cname = AdminConfig.showAttribute(cell, 'name')
```

```
20         nname = AdminConfig.showAttribute(node, 'name')
21         servs = AdminControl.queryNames('type=Server,cell=' + cname + ',node=' + nname + ',*').
       split(lineSeparator)
22         print "Number of running servers on node " + nname + ": %s \n" % (len(servs))
23         for server in servs:
24           #---------------------------------------------------------
25           # lines 28-34 get some attributes from the server to display;
26           # invoke an operation on the server JVM to display a property.
27           #---------------------------------------------------------
28           sname = AdminControl.getAttribute(server, 'name')
29           ptype = AdminControl.getAttribute(server, 'processType')
30           pid   = AdminControl.getAttribute(server, 'pid')
31           state = AdminControl.getAttribute(server, 'state')
32            jvm = AdminControl.queryNames('type=JVM,cell=' +
 cname + ',node=' + nname + ',process=' + sname + ',*')
33           osname = AdminControl.invoke(jvm, 'getProperty', 'os.name')
34            print " " + sname + " " +  ptype + " has pid " + pid + "; state: " + state + "; on " +
 osname + "\n"
35
36            #---------------------------------------------------------
37            # line 40-45 find the applications running on this server and
38           # display the application name.
39           #---------------------------------------------------------
40           apps = AdminControl.queryNames('type=Application,cell=' +
 Cname + ',node=' + nname + ',process=' + sname + ',*').split(lineSeparator)
41           print "Number of applications running on " + sname + ": %s \n" % (len(apps))
42           for app in apps:
43              aname = AdminControl.getAttribute(app, 'name')
44              print aname + "\n"
45          print "----------------------------------------------------"
46          print "\n"
```

- Example output:

```
Number of running servers on node mynode: 2
mynode (NodeAgent) has pid 3592; state: STARTED; on Windows 2000
Number of applications running on mynode: 0
----------------------------------------------------

server1 (ManagedProcess) has pid 3972; state: STARTED; on Windows 2000
Number of applications running on server1: 0
----------------------------------------------------

Number of running servers on node mynodeManager: 1
dmgr (DeploymentManager) has pid 3308; state: STARTED; on Windows 2000
Number of applications running on dmgr: 2
adminconsole
filetransfer
----------------------------------------------------
```

Starting listener ports using scripting

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

Perform the following steps to start a listener port on an application server. The following example returns a list of listener port MBeans:

1. Identify the listener port MBeans for the application server and assign it to the lPorts variable.
   - Using Jacl:

     ```
     set lPorts [$AdminControl queryNames type=ListenerPort,cell=mycell,node=mynode,process=server1,*]
     ```

   - Using Jython:

     ```
     lPorts = AdminControl.queryNames('type=ListenerPort,cell=mycell,node=mynode,process=server1,*')
     print lPorts
     ```

   Example output:

```
WebSphere:cell=mycell,name=ListenerPort,mbeanIdentifier=server.xml#ListenerPort_1,type=ListenerPort,
  node=mynode,process=server1
WebSphere:cell=mycell,name=listenerPort,mbeanIdentifier=ListenerPort,type=server.xml#ListenerPort_2,
  node=mynode,process=server1
```

2. Start the listener port if it is not started. For example:
   - Using Jacl:

```
foreach lPort $lPorts {
     set state [$AdminControl getAttribute $lport started]
     if {$state == "false"} {
        $AdminControl invoke $lPort start
     }
  }
```

   - Using Jython:

```
# get line separator
import  java
lineSeparator = java.lang.System.getProperty('line.separator')

lPortsArray = lPorts.split(lineSeparator)
for lPort in lPortsArray:
 state = AdminControl.getAttribute(lPort, 'started')
 if state == 'false':
  AdminControl.invoke(lPort, 'start')
```

   These pieces of Jacl and Jython code loop through the listener port MBeans. For each listener port MBean, get the attribute value for the started attribute. If the attribute value is set to `false`, then start the listener port by invoking the start operation on the MBean.

Managing generic servers using scripting

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

A generic server is a server that the WebSphere Application Server manages but did not supply. You can use WebSphere Application Server to define, start, stop, and monitor generic servers.

- To define a generic server, use the following example:
  – Using Jacl:

```
$AdminTask createGenericServer mynode {-name generic1 -ConfigProcDef
{{"/usr/bin/myStartCommand" "arg1 arg2" "" "" "/tmp/workingDirectory" "/tmp/stopCommand" "argy argz"}}}
$AdminConfig save
```

  – Using Jython:

```
AdminTask.createGenericServer('mynode', '[-name generic1 -ConfigProcDef
[[c:\tmp\myStartCommand.exe "a b c" "" "" C:\tmp\myStopCommand "x y z"]]]')
AdminConfig.save()
```

- To start a generic server, use the `launchProcess` parameter, for example:
  – Using Jacl:

```
set nodeagent [$AdminControl queryNames *:*,type=NodeAgent]
$AdminControl invoke $nodeagent launchProcess generic1
```

  – Using Jython:

```
nodeagent = AdminControl.queryNames ('*:*,type=NodeAgent')
AdminControl.invoke(nodeagent, 'launchProcess', 'generic1')
```

  Example output:

```
true
```

  or

```
false
```

- To stop a generic server, use the `terminate` parameter, for example:
  – Using Jacl:

```
set nodeagent [$AdminControl queryNames *:*,type=NodeAgent]
$AdminControl invoke $nodeagent terminate generic1
```

  - Using Jython:

```
nodeagent = AdminControl.queryNames ('*:*,type=NodeAgent')
AdminControl.invoke(nodeagent, 'terminate', 'generic1')
```

  Example output:

```
true
```

  or

```
false
```

- To monitor the server state, use the `getProcessStatus` parameter, for example:
  - Using Jacl:

```
$AdminControl invoke $nodeagent getProcessStatus generic1
```

  Using Jython:

```
AdminControl.invoke(nodeagent, 'getProcessStatus', 'generic1')
```

  Example output:

```
RUNNING
```

  or

```
STOPPED
```

Setting development mode for server objects using scripting

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

Perform the following steps to set the development mode for a server object:

1. Locate the server object. The following example selects the first server found:
   - Using Jacl:

```
set server [$AdminConfig getid /Server:server1/]
```

   - Using Jython:

```
server = AdminConfig.getid('/Server:server1/')
```

2. Enable development mode:
   - Using Jacl:

```
$AdminConfig modify $server "{developmentMode true}"
```

   - Using Jython:

```
AdminConfig.modify(server, [['developmentMode', 'true']])
```

3. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 232 article for more information.
4. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 217 article for more information.

Disabling parallel startup using scripting

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

Perform the following steps to disable parallel startup:

1. Locate the server object. The following example selects the first server found:
   - Using Jacl:

```
set server[$AdminConfig getid /Server:server1/]
```

   - Using Jython:

```
server = AdminConfig.getid('/Server:server1/']
```

2. Enable development mode. For example:
   - Using Jacl:

     ```
     $AdminConfig modify $server "{parallelStartEnabled false}"
     ```
   - Using Jython:

     ```
     AdminConfig.modify(server, [['parallelStartEnabled', 'false']])
     ```
3. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 232 article for more information.
4. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 217 article for more information.

Removing multicast endpoints using scripting

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

WebSphere Application Server uses multicast broadcasting at the node level to allow a node agent to discover the managed processes in the node. The IPv4 and IPv6 multicast addresses are not compatible. Both the IPv4 and IPv6 multicast addresses are defined in the node agent configuration and when a node agent starts both addresses will be tried in sequence. It is recommended that you disable one of the multicast addresses after installation. By limiting multicast discovery to one protocol, the node agent will run more efficiently. Perform the following steps to remove a multicast endpoint:

1. Remove the multicast end point:
   - Using Jacl:

     ```
     set se [$AdminConfig getid /Node:y2001/ServerIndex:/]
     set eprs [lindex [$AdminConfig showAttribute $se endPointRefs] 0]
     foreach ep $eprs {
        set epName [$AdminConfig showAttribute $ep endPointName]
        if {$epName == "NODE_MULTICAST_DISCOVERY_ADDRESS"} {
           puts "Removing NODE_MULTICAST_DISCOVERY_ADDRESS..."
           $AdminConfig remove $ep
        }
     }
     ```
   - Using Jython:

     ```
     se = AdminConfig.getid('/Node:y2001/ServerIndex:/')
     import java
     lineseparator = java.lang.System.getProperty('line.separator')
     eprs = AdminConfig.showAttribute(se, ['endPointRefs']).split(lineseparator)[0]
     print eprs
     for ep in eprs:
        epName = AdminConfig.showAttribute(ep, ['endPointName'])
        if (epName) == "[NODE_MULTICAST_DISCOVERY_ADDRESS]":
           print "Removing NODE_MULTICAST_DISCOVERY_ADDRESS..."
           AdminConfig.remove(ep)
     ```
2. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 232 article for more information.
3. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 217 article for more information.

Obtaining server version information with scripting

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

Perform the following steps to query the server version information:

1. Identify the server and assign it to the server variable.

- Using Jacl:

  ```
  set server [$AdminControl completeObjectName type=Server,name=server1,node=mynode,*]
  ```
- Using Jython:

  ```
  server = AdminControl.completeObjectName('type=Server,name=server1,node=mynode,*')
  print server
  ```

  Example output:

```
WebSphere:cell=mycell,name=server1,mbeanIdentifier=server.xml#Server_1,type=Server,node=mynode,
  process=server1,processType=ManagedProcess
```

2. Query the server version. The server version information is stored in the serverVersion attribute. The **getAttribute** command returns the attribute value of a single attribute, passing in the attribute name.
   - Using Jacl:

     ```
     $AdminControl getAttribute $server1 serverVersion
     ```
   - Using Jython:

     ```
     print AdminControl.getAttribute(server1, 'serverVersion')
     ```

   Example output for a Network Deployment installation follows:

```
IBM WebSphere Application Server Version Report
   ---------------------------------------------------------------------------

        Platform Information
        ------------------------------------------------------------------------

                Name: IBM WebSphere Application Server
                Version: 5.0

        Product Information
        ------------------------------------------------------------------------

                ID: BASE
                Name: IBM WebSphere Application Server
                Build Date: 9/11/02
                Build Level: r0236.11
                Version: 5.0.0

        Product Information
        ------------------------------------------------------------------------

                ID: ND
                Name: IBM WebSphere Application Server for Network Deployment
                Build Date: 9/11/02
                Build Level: r0236.11
                Version: 5.0.0

   ---------------------------------------------------------------------------
   End Report
   ---------------------------------------------------------------------------
```

Configuring security with scripting

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

If you enable security for a WebSphere Application Server cell, supply authentication information to communicate with servers.

The `sas.client.props` and the `soap.client.props` files are located in the properties directory for each WebSphere Application Server profile, *`profilePath`*`/properties`.

- The nature of the properties file updates required for running in secure mode depend on whether you connect with a Remote Method Invocation (RMI) connector, or a Simple Object Access Protocol (SOAP) connector:
  – If you use a Remote Method Invocation (RMI) connector, set the following properties in the `sas.client.props` file with the appropriate values:

    ```
    com.ibm.CORBA.loginUserid=
    com.ibm.CORBA.loginPassword=
    ```

    Also, set the following property:

    ```
    com.ibm.CORBA.loginSource=properties
    ```

    The default value for this property is `prompt` in the `sas.client.props` file. If you leave the default value, a dialog box appears with a password prompt. If the script is running unattended, it appears to hang.
  – If you use a Simple Object Access Protocol (SOAP) connector, set the following properties in the `soap.client.props` file with the appropriate values:

    ```
    com.ibm.SOAP.securityEnabled=true
    com.ibm.SOAP.loginUserid=
    com.ibm.SOAP.loginPassword=
    ```
- To specify user and password information, choose one of the following methods:
  – Specify user name and password on a command line, using the **-user** and **-password** commands. For example:

    ```
    wsadmin.sh -conntype RMI -port 2809 -user u1 -password secret1
    ```
  – Specify user name and password in the `sas.client.props` file for a RMI connector or the `soap.client.props` file for a SOAP connector.

  If you specify user and password information on a command line and in the `sas.client.props` file or the `soap.client.props` file, the command line information overrides the information in the `props` file.

  Warning: On UNIX system, the use of -password option may result in security exposure as the password information becomes visible to the system status program such as ps command which can be invoked by other user to display all the running processes. Do not use this option if security exposure is a concern. Instead, specify user and password information in the soap.client.props file for SOAP connector or sas.client.props file for RMI connector. The soap.client.props and sas.client.props files are located in the properties directory of your WebSphere profile.

Enabling and disabling global security using scripting

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

The default profile sets up procedures so that you can enable and disable global security based on LocalOS registry.

- You can use the **help** command to find out the arguments that you need to provide with this call, for example:
  – Using Jacl:

    ```
    securityon help
    ```

    Example output:

    ```
    Syntax: securityon user password
    ```
  – Using Jython:

    ```
    securityon()
    ```

    Example output:

    ```
    Syntax: securityon(user, password)
    ```
- To enable global security based on the LocalOS registry, use the following procedure call and arguments:

- Using Jacl:

  ```
  securityon user1 password1
  ```

- Using Jython:

  ```
  securityon('user1', 'password1')
  ```

- To disable global security based on the LocalOS registry, use the following procedure call:
  - Using Jacl:

    ```
    securityoff
    ```

  - Using Jython:

    ```
    securityoff()
    ```

Enabling and disabling Java 2 security using scripting

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

Perform the following steps to enable or disable Java 2 security:

1. Identify the security configuration object and assign it to the security variable:
   - Using Jacl:

     ```
     set security [$AdminConfig list Security]
     ```

   - Using Jython:

     ```
     security = AdminConfig.list('Security')
     print security
     ```

   Example output:

   ```
   (cells/mycell|security.xml#Security_1)
   ```

2. Modify the enforceJava2Security attribute to enable or disable Java 2 security. For example:
   - To enable Java 2 security:
     - Using Jacl:

       ```
       $AdminConfig modify $security {{enforceJava2Security true}}
       ```

     - Using Jython:

       ```
       AdminConfig.modify(security, [['enforceJava2Security', 'true']])
       ```

   - To disable Java 2 security:
     - Using Jacl:

       ```
       $AdminConfig modify $security {{enforceJava2Security false}}
       ```

     - Using Jython:

       ```
       AdminConfig.modify(security, [['enforceJava2Security', 'false']])
       ```

3. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 232 article for more information.
4. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 217 article for more information.

Configuring data access with scripting

This topic contains the following tasks:

- “Configuring a JDBC provider using scripting” on page 313
- “Configuring new data sources using scripting” on page 314
- “Configuring new connection pools using scripting” on page 315
- “Configuring new data source custom properties using scripting” on page 315
- “Configuring new J2CAuthentication data entries using scripting” on page 316

- “Configuring new WAS40 data sources using scripting” on page 317
- “Configuring new WAS40 connection pools using scripting” on page 318
- “Configuring new WAS40 custom properties using scripting” on page 319
- “Configuring new J2C resource adapters using scripting” on page 320
- “Configuring custom properties for J2C resource adapters using scripting” on page 321
- “Configuring new J2C connection factories using scripting” on page 322
- “Configuring new J2C authentication data entries using scripting” on page 324
- “Configuring new J2C administrative objects using scripting” on page 326
- “Configuring new J2C activation specs using scripting” on page 325
- “Testing data source connections using scripting” on page 328

Configuring a JDBC provider using scripting

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

Perform the following steps to configure a new JDBC provider:

1. Identify the parent ID and assign it to the node variable. The following example uses the node configuration object as the parent. You can modify this example to use the cell, cluster, server, or application configuration object as the parent.
   - Using Jacl:
     ```
     set node [$AdminConfig  getid  /Cell:mycell/Node:mynode/]
     ```
   - Using Jython:
     ```
     node = AdminConfig.getid('/Cell:mycell/Node:mynode/')
     print node
     ```

   Example output:
   ```
   mynode(cells/mycell/nodes/mynode|node.xml#Node_1)
   ```
2. Identify the required attributes:
   - Using Jacl:
     ```
     $AdminConfig required JDBCProvider
     ```
   - Using Jython:
     ```
     print AdminConfig.required('JDBCProvider')
     ```

   Example output:
   ```
   Attribute     Type
   name     String
   implementationClassName   String
   ```
3. Set up the required attributes and assign it to the jdbcAttrs variable. You can modify the following example to setup non-required attributes for JDBC provider.
   - Using Jacl:
     ```
     set n1 [list name JDBC1]
     set implCN [list implementationClassName myclass]
     set  jdbcAttrs [list  $n1  $implCN]
     ```
     Example output:
     ```
     {name {JDBC1}} {implementationClassName {myclass}}
     ```
   - Using Jython:
     ```
     n1 = ['name', 'JDBC1']
     implCN = ['implementationClassName', 'myclass']
     jdbcAttrs = [n1,  implCN]
     print jdbcAttrs
     ```
     Example output:

```
[['name', 'JDBC1'], ['implementationClassName', 'myclass']]
```

4. Create a new JDBC provider using node as the parent:
   - Using Jacl:
     ```
     $AdminConfig create JDBCProvider $node $jdbcAttrs
     ```
   - Using Jython:
     ```
     AdminConfig.create('JDBCProvider', node, jdbcAttrs)
     ```

   Example output:
   ```
   JDBC1(cells/mycell/nodes/mynode|resources.xml#JDBCProvider_1)
   ```
5. Save the configuration changes. See the "Saving configuration changes with the wsadmin tool" on page 232 article for more information.
6. In a network deployment environment only, synchronize the node. See the "Synchronizing nodes with the wsadmin tool" on page 217 article for more information.

Configuring new data sources using scripting

Before starting this task, the wsadmin tool must be running. See the "Starting the wsadmin scripting client" on page 250 article for more information.

Perform the following steps to configure a new data source:

1. Identify the parent ID:
   - Using Jacl:
     ```
     set newjdbc [$AdminConfig getid /Cell:mycell/Node:mynode/JDBCProvider:JDBC1/]
     ```
   - Using Jython:
     ```
     newjdbc = AdminConfig.getid('/Cell:mycell/Node:mynode/JDBCProvider:JDBC1/')
     print newjdbc
     ```

   Example output:
   ```
   JDBC1(cells/mycell/nodes/mynode|resources.xml#JDBCProvider_1)
   ```
2. Obtain the required attributes:
   - Using Jacl:
     ```
     $AdminConfig required DataSource
     ```
   - Using Jython:
     ```
     print AdminConfig.required('DataSource')
     ```

   Example output:
   ```
   Attribute   Type
   name    String
   ```
3. Setting up required attributes:
   - Using Jacl:
     ```
     set name [list name DS1]
     set dsAttrs [list $name]
     ```
   - Using Jython:
     ```
     name = ['name', 'DS1']
     dsAttrs = [name]
     ```
4. Create a data source:
   - Using Jacl:
     ```
     set newds [$AdminConfig create DataSource $newjdbc $dsAttrs]
     ```
   - Using Jython:
     ```
     newds = AdminConfig.create('DataSource', newjdbc, dsAttrs)
     print newds
     ```

   Example output:
   ```
   DS1(cells/mycell/nodes/mynode|resources.xml#DataSource_1)
   ```

5. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 232 article for more information.
6. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 217 article for more information.

Configuring new connection pools using scripting

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

Perform the following steps to configure a new connection pool:

1. Identify the parent ID:
   - Using Jacl:
     ```
     set newds [$AdminConfig getid /Cell:mycell/Node:mynode/JDBCProvider:JDBC1/DataSource:DS1/]
     ```
   - Using Jython:
     ```
     newds = AdminConfig.getid('/Cell:mycell/Node:mynode/JDBCProvider:JDBC1/DataSource:DS1/')
     ```

   Example output:
   ```
   DS1(cells/mycell/nodes/mynode|resources.xml$DataSource_1)
   ```
2. Creating connection pool:
   - Using Jacl:
     ```
     $AdminConfig create ConnectionPool $newds {}
     ```
   - Using Jython:
     ```
     print AdminConfig.create('ConnectionPool', newds, [])
     ```

   Example output:
   ```
   (cells/mycell/nodes/mynode|resources.xml#ConnectionPool_1)
   ```
3. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 232 article for more information.
4. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 217 article for more information.

Configuring new data source custom properties using scripting

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

Perform the following steps to configure a new data source custom property:g

1. Identify the parent ID:
   - Using Jacl:
     ```
     set newds [$AdminConfig getid /Cell:mycell/Node:mynode/JDBCProvider:JDBC1/DataSource:DS1/]
     ```
   - Using Jython:
     ```
     newds = AdminConfig.getid('/Cell:mycell/Node:mynode/JDBCProvider:JDBC1/DataSource:DS1/')
     print newds
     ```

   Example output:
   ```
   DS1(cells/mycell/nodes/mynode|resources.xml$DataSource_1)
   ```
2. Get the J2EE resource property set:
   - Using Jacl:
     ```
     set propSet [$AdminConfig showAttribute $newds propertySet]
     ```
   - Using Jython:
     ```
     propSet = AdminConfig.showAttribute(newds, 'propertySet')
     print propSet
     ```

Example output:

```
(cells/mycell/nodes/mynode|resources.xml#J2EEResourcePropertySet_8)
```

3. Get required attribute:
   - Using Jacl:
     ```
     $AdminConfig required J2EEResourceProperty
     ```
   - Using Jython:
     ```
     print AdminConfig.required('J2EEResourceProperty')
     ```

   Example output:

   ```
   Attribute     Type
   name         String
   ```
4. Set up attributes:
   - Using Jacl:
     ```
     set name [list name RP4]
     set rpAttrs [list $name]
     ```
   - Using Jython:
     ```
     name = ['name', 'RP4']
     rpAttrs = [name]
     ```
5. Create a J2EE resource property:
   - Using Jacl:
     ```
     $AdminConfig create J2EEResourceProperty $propSet $rpAttrs
     ```
   - Using Jython:
     ```
     print AdminConfig.create('J2EEResourceProperty', propSet, rpAttrs)
     ```

   Example output:

   ```
   RP4(cells/mycell/nodes/mynode|resources.xml#J2EEResourceProperty_8)
   ```
6. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 232 article for more information.
7. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 217 article for more information.

Configuring new J2CAuthentication data entries using scripting

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

Perform the following steps to configure a new J2CAuthentication data entry:

1. Identify the parent ID:
   - Using Jacl:
     ```
     set security [$AdminConfig getid /Cell:mycell/Security:/]
     ```
   - Using Jython:
     ```
     security = AdminConfig.getid('/Cell:mycell/Security:/')
     print security
     ```

   Example output:

   ```
   (cells/mycell|security.xml#Security_1)
   ```
2. Get required attributes:
   - Using Jacl:
     ```
     $AdminConfig required JAASAuthData
     ```
   - Using Jython:
     ```
     print AdminConfig.required('JAASAuthData')
     ```

   Example output:

```
Attribute       Type
alias           String
userId          String
password        String
```

3. Set up required attributes:
   - Using Jacl:

     ```
     set alias [list alias myAlias]
     set userid [list userId myid]
     set password [list password secret]
     set jaasAttrs [list $alias $userid $password]
     ```

     Example output:

     ```
     {alias myAlias} {userId myid} {password secret}
     ```

   - Using Jython:

     ```
     alias = ['alias', 'myAlias']
     userid = ['userId', 'myid']
     password = ['password', 'secret']
     jaasAttrs = [alias, userid, password]
     print jaasAttrs
     ```

     Example output:

     ```
     [['alias', 'myAlias'], ['userId', 'myid'], ['password', 'secret']]
     ```

4. Create JAAS auth data:
   - Using Jacl:

     ```
     $AdminConfig create JAASAuthData $security $jaasAttrs
     ```

   - Using Jython:

     ```
     print AdminConfig.create('JAASAuthData', security, jaasAttrs)
     ```

   Example output:

   ```
   (cells/mycell|security.xml#JAASAuthData_2)
   ```

5. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 232 article for more information.
6. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 217 article for more information.

Configuring new WAS40 data sources using scripting

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

Perform the following steps to configure a new WAS40 data source:

1. Identify the parent ID:
   - Using Jacl:

     ```
     set newjdbc [$AdminConfig getid "/JDBCProvider:Cloudscape JDBC Provider/"]
     ```

   - Using Jython:

     ```
     newjdbc = AdminConfig.getid('/JDBCProvider:Cloudscape JDBC Provider/')
     print newjdbc
     ```

   Example output:

   ```
   JDBC1(cells/mycell/nodes/mynode|resources.xml$JDBCProvider_1)
   ```

2. Get required attributes:
   - Using Jacl:

     ```
     $AdminConfig required WAS40DataSource
     ```

   - Using Jython:

     ```
     print AdminConfig.required('WAS40DataSource')
     ```

Example output:

```
Attribute    Type
name    String
```

3. Set up required attributes:
   - Using Jacl:
     ```
     set name [list name was4DS1]
     set ds4Attrs [list $name]
     ```
   - Using Jython:
     ```
     name = ['name', 'was4DS1']
     ds4Attrs = [name]
     ```
4. Create WAS40DataSource:
   - Using Jacl:
     ```
     set new40ds [$AdminConfig create WAS40DataSource $newjdbc $ds4Attrs]
     ```
   - Using Jython:
     ```
     new40ds = AdminConfig.create('WAS40DataSource', newjdbc, ds4Attrs)
     print new40ds
     ```

   Example output:

   ```
   was4DS1(cells/mycell/nodes/mynode|resources.xml#WAS40DataSource_1)
   ```
5. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 232 article for more information.
6. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 217 article for more information.

Configuring new WAS40 connection pools using scripting

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

Perform the following steps to configure a new WAS40 connection pool:

1. Identify the parent ID:
   - Using Jacl:
     ```
     set new40ds [$AdminConfig getid /Cell:mycell/Node:mynode/Server:server1/JDBCProvider:JDBC1/WAS40DataSource:was4DS1/]
     ```
   - Using Jython:
     ```
     new40ds = AdminConfig.getid('/Cell:mycell/Node:mynode/Server:server1/JDBCProvider:JDBC1/WAS40DataSource:was4DS1/')
     print new40ds
     ```

   Example output:

   ```
   was4DS1(cells/mycell/nodes/mynodes:resources.xml$WAS40DataSource_1)
   ```
2. Get required attributes:
   - Using Jacl:
     ```
     $AdminConfig required WAS40ConnectionPool
     ```
   - Using Jython:
     ```
     print AdminConfig.required('WAS40ConnectionPool')
     ```

   Example output:

   ```
   Attribute       Type
   minimumPoolSize     Integer
   maximumPoolSize     Integer
   connectionTimeout   Integer
   idleTimeout        Integer
   orphanTimeout       Integer
   statementCacheSize  Integer
   ```
3. Set up required attributes:

- Using Jacl:

  ```
  set mps [list minimumPoolSize 5]
  set minps [list minimumPoolSize 5]
  set maxps [list maximumPoolSize 30]
  set conn [list connectionTimeout 10]
  set idle [list idleTimeout 5]
  set orphan [list orphanTimeout 5]
  set scs [list statementCacheSize 5]
  set 40cpAttrs [list $minps $maxps $conn $idle $orphan $scs]
  ```

  Example output:

  ```
  {minimumPoolSize 5} {maximumPoolSize 30}
  {connectionTimeout 10} {idleTimeout 5}
  {orphanTimeout 5} {statementCacheSize 5}
  ```

- Using Jython:

  ```
  minps = ['minimumPoolSize', 5]
  maxps = ['maximumPoolSize', 30]
  conn = ['connectionTimeout', 10]
  idle = ['idleTimeout', 5]
  orphan = ['orphanTimeout', 5]
  scs = ['statementCacheSize', 5]
  cpAttrs = [minps, maxps, conn, idle, orphan, scs]
  print cpAttrs
  ```

  Example output:

  ```
  [[minimumPoolSize, 5], [maximumPoolSize, 30],
  [connectionTimeout, 10], [idleTimeout, 5],
  [orphanTimeout, 5], [statementCacheSize, 5]]
  ```

4. Create was40 connection pool:
   - Using Jacl:

     ```
     $AdminConfig create WAS40ConnectionPool $new40ds $40cpAttrs
     ```

   - Using Jython:

     ```
     print AdminConfig.create('WAS40ConnectionPool', new40ds, 40cpAttrs)
     ```

   Example output:

   ```
   (cells/mycell/nodes/mynode:resources.xml#WAS40ConnectionPool_1)
   ```

5. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 232 article for more information.
6. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 217 article for more information.

Configuring new WAS40 custom properties using scripting

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

Perform the following steps to configure a new WAS40 custom properties:

1. Identify the parent ID:
   - Using Jacl:

     ```
     set new40ds [$AdminConfig getid /Cell:mycell/Node:mynode/JDBCProvider:JDBC1/WAS40DataSource:was4DS1/]
     ```

   - Using Jython:

     ```
     new40ds = AdminConfig.getid('/Cell:mycell/Node:mynode/JDBCProvider:JDBC1/WAS40DataSource:was4DS1/')
     print new40ds
     ```

   Example output:

   ```
   was4DS1(cells/mycell/nodes/mynodes|resources.xml$WAS40DataSource_1)
   ```

2. Get required attributes:
   - Using Jacl:

```
set propSet [$AdminConfig showAttribute $newds propertySet]
```

- Using Jython:

  ```
  propSet = AdminConfig.showAttribute(newds, 'propertySet')
  print propSet
  ```

Example output:

```
(cells/mycell/nodes/mynode|resources.xml#J2EEResourcePropertySet_9)
```

3. Get required attribute:
   - Using Jacl:

     ```
     $AdminConfig required J2EEResourceProperty
     ```

   - Using Jython:

     ```
     print AdminConfig.required('J2EEResourceProperty')
     ```

   Example output:

   ```
   Attribute    Type
   name         String
   ```

4. Set up required attributes:
   - Using Jacl:

     ```
     set name [list name RP5]
     set rpAttrs [list $name]
     ```

   - Using Jython:

     ```
     name = ['name', 'RP5']
     rpAttrs = [name]
     ```

5. Create J2EE Resource Property:
   - Using Jacl:

     ```
     $AdminConfig create J2EEResourceProperty $propSet $rpAttrs
     ```

   - Using Jython:

     ```
     print AdminConfig.create('J2EEResourceProperty', propSet, rpAttrs)
     ```

   Example output:

   ```
   RP5(cells/mycell/nodes/mynode|resources.xml#J2EEResourceProperty_9)
   ```

6. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 232 article for more information.
7. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 217 article for more information.

Configuring new J2C resource adapters using scripting

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

Perform the following steps to configure a new J2C resource adapter:

1. Identify the parent ID and assign it to the node variable. The following example uses the node configuration object as the parent. You can modify this example to use the cell, cluster, server, or application configuration object as the parent.
   - Using Jacl:

     ```
     set node [$AdminConfig getid /Cell:mycell/Node:mynode/]
     ```

   - Using Jython:

     ```
     node = AdminConfig.getid('/Cell:mycell/Node:mynode/')
     print node
     ```

   Example output:

   ```
   mynode(cells/mycell/nodes/mynode|node.xml#Node_1)
   ```

2. Identify the required attributes:

- Using Jacl:

  ```
  $AdminConfig required J2CResourceAdapter
  ```

- Using Jython:

  ```
  print AdminConfig.required('J2CResourceAdapter')
  ```

Example output:

```
Attribute     Type
name         String
```

3. Set up the required attributes:
   - Using Jacl:

     ```
     set rarFile c:/currentScript/cicseci.rar
     set option  [list  -rar.name  RAR1]
     ```

   - Using Jython:

     ```
     rarFile = 'c:/currentScript/cicseci.rar'
     option  = '[-rar.name  RAR1]'
     ```

4. Create a resource adapter:
   - Using Jacl:

     ```
     set newra [$AdminConfig installResourceAdapter $rarFile mynode $option]
     ```

   - Using Jython:

     ```
     newra = AdminConfig.installResourceAdapter(rarFile, 'mynode', option)
     print newra
     ```

   Example output:

   ```
   RAR1(cells/mycell/nodes/mynode|resources.xml#J2CResourceAdapter_1)
   ```

5. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 232 article for more information.
6. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 217 article for more information.

Configuring custom properties for J2C resource adapters using scripting

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

Perform the following steps to configure a new custom property for a J2C resource adapters:

1. Identify the parent ID and assign it to the newra variable.
   - Using Jacl:

     ```
     set newra [$AdminConfig getid /Cell:mycell/Node:mynode/J2CResourceAdapter:RAR1/]
     ```

   - Using Jython:

     ```
     newra = AdminConfig.getid('/Cell:mycell/Node:mynode/J2CResourceAdapter:RAR1/')
     print newra
     ```

   Example output:

   ```
   RAR1(cells/mycell/nodes/mynode|resources.xml#J2CResourceAdapter_1)
   ```

2. Get the J2EE resource property set:
   - Using Jacl:

     ```
     set propSet [$AdminConfig showAttribute $newra propertySet]
     ```

   - Using Jython:

     ```
     propSet = AdminConfig.showAttribute(newra, 'propertySet')
     print propSet
     ```

   Example output:

   ```
   (cells/mycell/nodes/mynode|resources.xml#PropertySet_8)
   ```

3. Identify the required attributes:

- Using Jacl:

  ```
  $AdminConfig required J2EEResourceProperty
  ```

- Using Jython:

  ```
  print AdminConfig.required('J2EEResourceProperty')
  ```

  Example output:

  ```
  Attribute     Type
  name         String
  ```

4. Set up the required attributes:
   - Using Jacl:

     ```
     set name [list name RP4]
     set rpAttrs [list $name]
     ```

   - Using Jython:

     ```
     name = ['name', 'RP4']
     rpAttrs = [name]
     ```

5. Create a J2EE resource property:
   - Using Jacl:

     ```
     $AdminConfig create J2EEResourceProperty $propSet $rpAttrs
     ```

   - Using Jython:

     ```
     print AdminConfig.create('J2EEResourceProperty', propSet, rpAttrs)
     ```

   Example output:

   ```
   RP4(cells/mycell/nodes/mynode|resources.xml#J2EEResourceProperty_8)
   ```

6. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 232 article for more information.
7. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 217 article for more information.

Configuring new J2C connection factories using scripting

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

Perform the following steps to configure a new J2C connection factory:

1. Identify the parent ID and assign it to the newra variable.
   - Using Jacl:

     ```
     set newra [$AdminConfig getid /Cell:mycell/Node:mynode/J2CResourceAdapter:RAR1/]
     ```

   - Using Jython:

     ```
     newra = AdminConfig.getid('/Cell:mycell/Node:mynode/J2CResourceAdapter:RAR1/')
     print newra
     ```

   Example output:

   ```
   RAR1(cells/mycell/nodes/mynode|resources.xml#J2CResourceAdapter_1)
   ```

2. There are two ways to configure a new J2C connection factory. Perform one of the following:
   - Using the AdminTask object:
     a. List the connection factory interfaces:
        – Using Jacl:

        ```
        $AdminTask listConnectionFactoryInterfaces $newra
        ```

        – Using Jacl:

        ```
        AdminTask.listConnectionFactoryInterfaces(newra)
        ```

        Example output:

        ```
        javax.sql.DataSource
        ```

b. Create a J2CConnectionFactory:
   - Using Jacl:

     ```
     $AdminTask createJ2CConnectionFactory $newra { -name cf1 -jndiName eis/cf1
       -connectionFactoryInterface avax.sql.DataSource
     ```

   - Using Jacl:

     ```
     AdminTask.createJ2CConnectionFactory(newra, '['-name', 'cf1', '-jndiName', 'eis/cf1',
       '-connectionFactoryInterface', 'avax.sql.DataSource']')
     ```

- Using the AdminConfig object:

a. Identify the required attributes:
   - Using Jacl:

     ```
     $AdminConfig required J2CConnectionFactory
     ```

   - Using Jython:

     ```
     print AdminConfig.required('J2CConnectionFactory')
     ```

   Example output:

   ```
   Attribute Type
   connectionDefinition ConnectionDefinition@
   ```

b. If your resource adapter is JCA1.5 and you have multiple connection definitions defined, it is required that you specify the ConnectionDefinition attribute. If your resource adapter is JCA1.5 and you have only one connection definition defined, it will be picked up automatically. If your resource adapter is JCA1.0, you do not need to specify the ConnectionDefinition attribute. Perform the following command to list the connection definitions defined by the resource adapter:
   - Using Jacl:

     ```
     $AdminConfig list ConnectionDefinition $newra
     ```

   - Using Jython:

     ```
     print AdminConfig.list('ConnectionDefinition', $newra)
     ```

c. Set up the required attributes:
   - Using Jacl:

     ```
     set name [list name J2CCF1]
     set j2ccfAttrs [list $name]
     set jname [list jndiName eis/j2ccf1]
     ```

   - Using Jython:

     ```
     name = ['name', 'J2CCF1']
     j2ccfAttrs = [name]
     jname = ['jndiName', eis/j2ccf1]
     ```

d. If you are specifying the ConnectionDefinition attribute, also set up the following:
   - Using Jacl:

     ```
     set cdattr [list connectionDefinition $cd]
     ```

   - Using Jython:

     ```
     cdattr = ['connectionDefinition', $cd]
     ```

e. Create a J2C connection factory:
   - Using Jacl:

     ```
     $AdminConfig create J2CConnectionFactory $newra $j2ccfAttrs
     ```

   - Using Jython:

     ```
     print AdminConfig.create('J2CConnectionFactory', newra, j2ccfAttrs)
     ```

   Example output:

   ```
   J2CCF1(cells/mycell/nodes/mynode|resources.xml#J2CConnectionFactory_1)
   ```

3. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 232 article for more information.

4. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 217 article for more information.

Configuring new J2C authentication data entries using scripting

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

Perform the following steps to configure a new J2C authentication data entry:

1. Identify the parent ID and assign it to the security variable.
   - Using Jacl:
     ```
     set security [$AdminConfig getid /Security:mysecurity/]
     ```
   - Using Jython:
     ```
     security = AdminConfig.getid('/Security:mysecurity/')
     ```
2. Identify the required attributes:
   - Using Jacl:
     ```
     $AdminConfig required JAASAuthData
     ```
   - Using Jython:
     ```
     print AdminConfig.required('JAASAuthData')
     ```

   Example output:
   ```
   Attribute     Type
   alias         String
   userId          String
   password          String
   ```
3. Set up the required attributes:
   - Using Jacl:
     ```
     set alias [list alias myAlias]
     set userid [list userId myid]
     set password [list password secret]
     set jaasAttrs [list $alias $userid $password]
     ```
     Example output:
     ```
     {alias myAlias} {userId myid} {password secret}
     ```
   - Using Jython:
     ```
     alias = ['alias', 'myAlias']
     userid = ['userId', 'myid']
     password = ['password', 'secret']
     jaasAttrs = [alias, userid, password]
     ```
     Example output:
     ```
     [[alias, myAlias], [userId, myid], [password, secret]]
     ```
4. Create JAAS authentication data:
   - Using Jacl:
     ```
     $AdminConfig create JAASAuthData $security $jaasAttrs
     ```
   - Using Jython:
     ```
     print AdminConfig.create('JAASAuthData', security, jaasAttrs)
     ```

   Example output:
   ```
   (cells/mycell/nodes/mynode|resources.xml#JAASAuthData_2)
   ```
5. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 232 article for more information.
6. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 217 article for more information.

Configuring new J2C activation specs using scripting

Before starting this task, the wsadmin tool must be running. See the "Starting the wsadmin scripting client" on page 250 article for more information.

Perform the following steps to configure a J2C activation specs:

1. Identify the parent ID and assign it to the newra variable.
   - Using Jacl:
     ```
     set newra [$AdminConfig getid /Cell:mycell/Node:mynode/J2CResourceAdapter:RAR1/]
     ```
   - Using Jython:
     ```
     newra = AdminConfig.getid('/Cell:mycell/Node:mynode/J2CResourceAdapter:RAR1/')
     print newra
     ```

   Example output:
   ```
   RAR1(cells/mycell/nodes/mynode|resources.xml#J2CResourceAdapter_1)
   ```
2. There are two ways to configure a new J2C administrative object. Perform one of the following:
   - Using the AdminTask object:
     a. List the administrative object interfaces:

        Using Jacl:
        ```
        $AdminTask listMessageListenerTypes $newra
        ```
        Using Jython:
        ```
        AdminTask.listMessageListenerTypes(newra)
        ```
        Example output:
        ```
        javax.jms.MessageListener
        ```
     b. Create a J2C administrative object:

        Using Jacl:
        ```
        $AdminTask createJ2CActivationSpec $newra { -name ac1 -jndiName eis/ac1
          -message ListenerType javax.jms.MessageListener}
        ```
        Using Jython:
        ```
        AdminTask.createJ2CActivationSpec(newra, ['-name', 'ao1', '-jndiName', 'eis/ao1', '-message',
          'ListenerType', 'javax.jms.MessageListener'])
        ```
   - Using the AdminConfig object:
     a. Using Jacl:
        ```
        $AdminConfig required J2CActivationSpec
        ```
        Using Jython:
        ```
        print AdminConfig.required('J2CActivationSpec')
        ```
        Example output:
        ```
        Attribute Type
        activationSpec ActivationSpec@
        ```
     b. If your resource adapter is JCA V1.5 and you have multiple activation specs defined, it is required that you specify the activation spec attribute. If your resource adapter is JCA V1.5 and you have only one activation spec defined, it will be picked up automatically. If your resource adapter is JCA V1.0, you do not need to specify the activationSpec attribute. Perform the following command to list the activation specs defined by the resource adapter:

        Using Jacl:
        ```
        $AdminConfig list ActivationSpec $newra
        ```
        Using Jython:
        ```
        print AdminConfig.list('ActivationSpec', $newra)
        ```
     c. Set the administrative object that you need to a variable:

        Using Jacl:

```
set ac ActivationSpecID
set name [list name J2CAC1]
set jname [jndiName eis/j2cac1]
set j2cacAttrs [list $name $jname]
```

Using Jython:

```
ac = ActivationSpecID
name = ['name', 'J2CAC1']
jname = ['jndiName', 'eis/j2cac1']
j2cacAttrs = [name, jname]
```

d. If you are specifying the ActivationSpec attribute, also set up the following:

Using Jacl:

```
set cdcttr [list activationSpec $ac]
```

Using Jython:

```
cdattr = ['activationSpec', ac]
```

e. Create a J2C activation spec object:

Using Jacl:

```
$AdminConfig create J2CActivationSpec $newra $j2cacAttrs
```

Using Jython:

```
print AdminConfig.create('J2CActivationSpec', newra,j2cacAttrs)
```

Example output:

```
J2CAC1(cells/mycell/nodes/mynode|resources.xml#J2CActivationSpec_1)
```

3. Save the configuration changes. See the "Saving configuration changes with the wsadmin tool" on page 232 article for more information.
4. In a network deployment environment only, synchronize the node. See the "Synchronizing nodes with the wsadmin tool" on page 217 article for more information.

Configuring new J2C administrative objects using scripting

Before starting this task, the wsadmin tool must be running. See the "Starting the wsadmin scripting client" on page 250 article for more information.

Perform the following steps to configure a J2C administrative object:

1. Identify the parent ID and assign it to the `newra` variable.
   - Using Jacl:

     ```
     set newra [$AdminConfig getid /Cell:mycell/Node:mynode/J2CResourceAdapter:RAR1/]
     ```
   - Using Jython:

     ```
     newra = AdminConfig.getid('/Cell:mycell/Node:mynode/J2CResourceAdapter:RAR1/')
     print newra
     ```

   Example output:

   ```
   RAR1(cells/mycell/nodes/mynode|resources.xml#J2CResourceAdapter_1)
   ```
2. There are two ways to configure a new J2C administrative object. Perform one of the following:
   - Using the AdminTask object:
     a. List the administrative object interfaces:

        Using Jacl:

        ```
        $AdminTask listAdminObjectInterfaces $newra
        ```

        Using Jython:

        ```
        AdminTask.listAdminObjectInterfaces(newra)
        ```

        Example output:

        ```
        com.ibm.test.message.FVTMessageProvider
        ```
     b. Create a J2C administrative object:

Using Jacl:

```
$AdminTask createJ2CAdminObject $newra { -name ao1 -jndiName eis/ao1
  -adminObjectInterface com.ibm.test.message.FVTMessageProvider }
```

Using Jython:

```
AdminTask.createJ2CAdminObject(newra, ['-name', 'ao1', '-jndiName', 'eis/ao1', '-adminObjectInterface',
  'com.ibm.test.message.FVTMessageProvider'])
```

- Using the AdminConfig object:
  a. Using Jacl:

  ```
  $AdminConfig required J2CAdminObject
  ```

  Using Jython:

  ```
  print AdminConfig.required('J2CAdminObject')
  ```

  Example output:

  ```
  Attribute Type
  adminObject AdminObject@
  ```

  b. If your resource adapter is JCA V1.5 and you have multiple administrative objects defined, it is required that you specify the administrative object attribute. If your resource adapter is JCA V1.5 and you have only one administrative object defined, it will be picked up automatically. If your resource adapter is JCA V1.0, you do not need to specify the administrative object attribute. Perform the following command to list the administrative objects defined by the resource adapter:

  Using Jacl:

  ```
  $AdminConfig list AdminObject $newra
  ```

  Using Jython:

  ```
  print AdminConfig.list('AdminObject', $newra)
  ```

  c. Set the administrative objects that you need to a variable:

  Using Jacl:

  ```
  set ao AdminObjectId
  set name [list name J2CAO1]
  set jname [jndiName eis/j2cao1]
  set j2caoAttrs [list $name $jname]
  ```

  Using Jython:

  ```
  ao = AdminObjectId
  name = ['name', 'J2CAO1']
  set jname = ['jndiName', eis/j2cao1]
  j2caoAttrs = [name, jname]
  ```

  d. If you are specifying the AdminObject attribute, also set up the following:

  Using Jacl:

  ```
  set cdattr [list adminObject $ao]
  ```

  Using Jython:

  ```
  cdattr = ['adminObject', ao]
  ```

  e. Create a J2C administrative object:

  Using Jacl:

  ```
  $AdminConfig create J2CAdminObject $newra $j2caoAttrs
  ```

  Using Jython:

  ```
  print AdminConfig.create('J2CAdminObject', newra, j2caoAttrs)
  ```

  Example output:

  ```
  J2CAO1(cells/mycell/nodes/mynode|resources.xml#J2CAdminObject_1)
  ```

3. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 232 article for more information.

4. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 217 article for more information.

Testing data source connections using scripting

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

Perform the following steps to test a data source to ensure a connection to the database.

1. Identify the DataSourceCfgHelper MBean and assign it to the dshelper variable.
   - Using Jacl:

     ```
     set ds [$AdminConfig getid /DataSource:DS1/]
     $AdminControl testConnection $ds
     ```
   - Using Jython:

     ```
     ds = AdminConfig.getid('/DataSource:DS1/')
     AdminControl.testConnection(ds)
     ```

   Example output:

   ```
   WASX7217I: Connection to provided datasource was successful.
   ```
2. Test the connection. The following example invokes the testConnectionToDataSource operation on the MBean, passing in the classname, userid, password, database name, JDBC driver class path, language, and country.
   - Using Jacl:

     ```
     $AdminControl invoke $dshelper testConnectionToDataSource "COM.ibm.db2.jdbc.DB2XADataSource db2admin db2admin
     {{databaseName sample}} c:/sqllib/java/db2java.zip en US"
     ```
   - Using Jython:

     ```
     print AdminControl.invoke(dshelper, 'testConnectionToDataSource',
     'COM.ibm.db2.jdbc.DB2XADataSource dbuser1 dbpwd1
       "{{databaseName jtest1}}" c:/sqllib/java12/db \"\" \"\"')
     ```

   Example output:

   ```
   WASX7217I: Connection to provided data source was successful.
   ```

Configuring messaging with scripting

This topic contains the following tasks:

- “Configuring the message listener service using scripting”
- “Configuring new JMS providers using scripting” on page 330
- “Configuring new JMS destinations using scripting” on page 331
- “Configuring new JMS connections using scripting” on page 332
- “Configuring new WebSphere queue connection factories using scripting” on page 333
- “Configuring new WebSphere topic connection factories using scripting” on page 334
- “Configuring new WebSphere queues using scripting” on page 335
- “Configuring new WebSphere topics using scripting” on page 336
- “Configuring new MQ queue connection factories using scripting” on page 337
- “Configuring new MQ topic connection factories using scripting” on page 338
- “Configuring new MQ queues using scripting” on page 339
- “Configuring new MQ topics using scripting” on page 340

Configuring the message listener service using scripting

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

Perform the following steps to configure the message listener service for an application server:

1. Identify the application server and assign it to the server variable:
   - Using Jacl:
     ```
     set server [$AdminConfig getid /Cell:mycell/Node:mynode/Server:server1/]
     ```
   - Using Jython:
     ```
     server = AdminConfig.getid('/Cell:mycell/Node:mynode/Server:server1/')
     print server
     ```

   Example output:
   ```
   server1(cells/mycell/nodes/mynode/servers/server1|server.xml#Server_1)
   ```
2. Identify the message listener service belonging to the server and assign it to the mls variable:
   - Using Jacl:
     ```
     set mls [$AdminConfig list MessageListenerService $server]
     ```
   - Using Jython:
     ```
     mls = AdminConfig.list('MessageListenerService', server)
     print mls
     ```

   Example output:
   ```
   (cells/mycell/nodes/mynode/servers/server1|server.xml#MessageListenerService_1)
   ```
3. Modify various attributes with one of the following examples:
   - This example command changes the thread pool attributes:
     – Using Jacl:
     ```
     $AdminConfig modify $mls {{threadPool {{inactivityTimeout 4000} {isGrowable true} {maximumSize 100}
       {minimumSize 25}}}}
     ```
     – Using Jython:
     ```
     AdminConfig.modify(mls, [['threadPool', [['inactivityTimeout', 4000], ['isGrowable',  'true'],
       ['maximumSize', 100], ['minimumSize', 25]]]])
     ```
   - This example modifies the property of the first listener port:
     – Using Jacl:
     ```
     set lports [$AdminConfig showAttribute $mls listenerPorts]
     set lport [lindex $lports 0]
     $AdminConfig modify $lport {{maxRetries 2}}
     ```
     – Using Jython:
     ```
     lports = AdminConfig.showAttribute(mls, 'listenerPorts')
     cleanLports = lports[1:len(lports)-1]
     lport = cleanLports.split(" ")[0]
     AdminConfig.modify(lport, [['maxRetries', 2]])
     ```
   - This example adds a listener port:
     – Using Jacl:
     ```
     set new [$AdminConfig create ListenerPort $mls {{name my} {destinationJNDIName di}
      {connectionFactoryJNDIName jndi/fs}}]
     $AdminConfig create StateManageable $new {{initialState START}}
     ```
     – Using Jython:
     ```
     new = AdminConfig.create('ListenerPort', mls, [['name', 'my'], ['destinationJNDIName', 'di'],
      ['connectionFactoryJNDIName', 'jndi/fsi']])
     print new
     print AdminConfig.create('StateManageable', new, [['initialState', 'START']])
     ```

     Example output:
     ```
     my(cells/mycell/nodes/mynode/servers/server1:server.xml#ListenerPort_1079471940692)
     (cells/mycell/nodes/mynode/servers/server1:server.xml#StateManageable_107947182623)
     ```
4. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 232 article for more information.

5. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 217 article for more information.

Configuring new JMS providers using scripting

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

Perform the following steps to configure a new JMS provider:

1. Identify the parent ID:
   - Using Jacl:
     ```
     set node [$AdminConfig getid /Cell:mycell/Node:mynode/]
     ```
   - Using Jython:
     ```
     node = AdminConfig.getid('/Cell:mycell/Node:mynode/')
     print node
     ```

   Example output:
   ```
   mynode(cells/mycell/nodes/mynode|node.xml#Node_1)
   ```
2. Get required attributes:
   - Using Jacl:
     ```
     $AdminConfig required JMSProvider
     ```
   - Using Jython:
     ```
     print AdminConfig.required('JMSProvider')
     ```

   Example output:
   ```
   Attribute        Type
   name     String
   externalInitialContextFactory    String
   externalProviderURL               String
   ```
3. Set up required attributes:
   - Using Jacl:
     ```
     set name [list name JMSP1]
     set extICF [list externalInitialContextFactory  "Put the external initial context factory here"]
     set extPURL [list externalProviderURL "Put the external provider URL here"]
     set jmspAttrs [list $name $extICF $extPURL]
     ```
   - Using Jython:
     ```
     name = ['name', 'JMSP1']
     extICF = ['externalInitialContextFactory',  "Put the external initial context factory here"]
     extPURL = ['externalProviderURL', "Put the external provider URL here"]
     jmspAttrs = [name, extICF, extPURL]
     print jmspAttrs
     ```

   Example output:
   ```
   {name JMSP1} {externalInitialContextFactory {Put the external initial context factory here }}
     {externalProviderURL {Put the external provider URL here}}
   ```
4. Create the JMS provider:
   - Using Jacl:
     ```
     set newjmsp [$AdminConfig create JMSProvider $node $jmspAttrs]
     ```
   - Using Jython:
     ```
     newjmsp = AdminConfig.create('JMSProvider', node, jmspAttrs)
     print newjmsp
     ```

   Example output:
   ```
   JMSP1(cells/mycell/nodes/mynode|resources.xml#JMSProvider_1)
   ```
5. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 232 article for more information.

6. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 217 article for more information.

Configuring new JMS destinations using scripting

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

Perform the following steps to configure a new JMS destination:

1. Identify the parent ID:
   - Using Jacl:
     ```
     set newjmsp [$AdminConfig getid /Cell:mycell/Node:myNode/JMSProvider:JMSP1]
     ```
   - Using Jython:
     ```
     newjmsp = AdminConfig.getid('/Cell:mycell/Node:myNode/JMSProvider:JMSP1')
     print newjmsp
     ```

   Example output:
   ```
   JMSP1(cells/mycell/nodes/mynode|resources.xml#JMSProvider_1)
   ```
2. Get required attributes:
   - Using Jacl:
     ```
     $AdminConfig required GenericJMSDestination
     ```
   - Using Jython:
     ```
     print AdminConfig.required('GenericJMSDestination')
     ```

   Example output:
   ```
   Attribute       Type
   name       String
   jndiName    String
   externalJNDIName  String
   ```
3. Set up required attributes:
   - Using Jacl:
     ```
     set name [list name JMSD1]
     set jndi [list jndiName jms/JMSDestination1]
     set extJndi [list externalJNDIName jms/extJMSD1]
     set jmsdAttrs [list $name $jndi $extJndi]
     ```
   - Using Jython:
     ```
     name = ['name', 'JMSD1']
     jndi = ['jndiName', 'jms/JMSDestination1']
     extJndi = ['externalJNDIName', 'jms/extJMSD1']
     jmsdAttrs = [name, jndi, extJndi]
     print jmsdAttrs
     ```

   Example output:
   ```
   {name JMSD1} {jndiName jms/JMSDestination1} {externalJNDIName jms/extJMSD1}
   ```
4. Create generic JMS destination:
   - Using Jacl:
     ```
     $AdminConfig create GenericJMSDestination $newjmsp  $jmsdAttrs
     ```
   - Using Jython:
     ```
     print AdminConfig.create('GenericJMSDestination', newjmsp,  jmsdAttrs)
     ```

   Example output:
   ```
   JMSD1(cells/mycell/nodes/mynode|resources.xml#GenericJMSDestination_1)
   ```
5. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 232 article for more information.
6. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 217 article for more information.

Configuring new JMS connections using scripting

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

Perform the following steps to configure a new JMS connection:

1. Identify the parent ID:
   - Using Jacl:
     ```
     set newjmsp [$AdminConfig getid /Cell:mycell/Node:myNode/JMSProvider:JMSP1]
     ```
   - Using Jython:
     ```
     newjmsp = AdminConfig.getid('/Cell:mycell/Node:myNode/JMSProvider:JMSP1')
     print newjmsp
     ```

   Example output:
   ```
   JMSP1(cells/mycell/nodes/mynode|resources.xml#JMSProvider_1)
   ```
2. Get required attributes:
   - Using Jacl:
     ```
     $AdminConfig required GenericJMSConnectionFactory
     ```
   - Using Jython:
     ```
     print AdminConfig.required('GenericJMSConnectionFactory')
     ```

   Example output:
   ```
   Attribute       Type
   name       String
   jndiName    String
   externalJNDIName  String
   ```
3. Set up required attributes:
   - Using Jacl:
     ```
     set name [list name JMSCF1]
     set jndi [list jndiName jms/JMSConnFact1]
     set extJndi [list externalJNDIName jms/extJMSCF1]
     set jmscfAttrs [list $name $jndi $extJndi]
     ```
     Example output:
     ```
     {name JMSCF1} {jndiName jms/JMSConnFact1} {externalJNDIName jms/extJMSCF1}
     ```
   - Using Jython:
     ```
     name = ['name', 'JMSCF1']
     jndi = ['jndiName', 'jms/JMSConnFact1']
     extJndi = ['externalJNDIName', 'jms/extJMSCF1']
     jmscfAttrs = [name, jndi, extJndi]
     print jmscfAttrs
     ```
     Example output:
     ```
     [[name, JMSCF1], [jndiName, jms/JMSConnFact1], [externalJNDIName, jms/extJMSCF1]]
     ```
4. Create generic JMS connection factory:
   - Using Jacl:
     ```
     $AdminConfig create GenericJMSConnectionFactory $newjmsp $jmscfAttrs
     ```
   - Using Jython:
     ```
     print AdminConfig.create('GenericJMSConnectionFactory', newjmsp, jmscfAttrs)
     ```

   Example output:
   ```
   JMSCF1(cells/mycell/nodes/mynode|resources.xml#GenericJMSConnectionFactory_1)
   ```
5. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 232 article for more information.
6. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 217 article for more information.

Configuring new WebSphere queue connection factories using scripting

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

Perform the following steps to configure a new WebSphere queue connection factory:

1. Identify the parent ID:
   - Using Jacl:

     ```
     set newjmsp [$AdminConfig getid /Cell:mycell/Node:mynode/JMSProvider:JMSP1/]
     ```
   - Using Jython:

     ```
     newjmsp = AdminConfig.getid('/Cell:mycell/Node:myNode/JMSProvider:JMSP1/')
     print newjmsp
     ```

   Example output:

   ```
   JMSP1(cells/mycell/nodes/mynode|resources.xml#JMSProvider_1)
   ```
2. Get required attributes:
   - Using Jacl:

     ```
     $AdminConfig required WASQueueConnectionFactory
     ```
   - Using Jython:

     ```
     print AdminConfig.required('WASQueueConnectionFactory')
     ```

   Example output:

   ```
   Attribute       Type
   name       String
   jndiName    String
   ```
3. Set up required attributes:
   - Using Jacl:

     ```
     set name [list name WASQCF]
     set jndi [list jndiName jms/WASQCF]
     set mqcfAttrs [list $name $jndi]
     ```

     Example output:

     ```
     {name WASQCF} {jndiName jms/WASQCF}
     ```
   - Using Jython:

     ```
     name = ['name', 'WASQCF']
     jndi = ['jndiName', 'jms/WASQCF']
     mqcfAttrs = [name, jndi]
     print mqcfAttrs
     ```

     Example output:

     ```
     [[name, WASQCF], [jndiName, jms/WASQCF]]
     ```
4. Create was queue connection factories:
   - Using Jacl:

     ```
     $AdminConfig create WASQueueConnectionFactory $newjmsp $mqcfAttrs
     ```
   - Using Jython:

     ```
     print AdminConfig.create('WASQueueConnectionFactory', newjmsp, mqcfAttrs)
     ```

   Example output:

   ```
   WASQCF(cells/mycell/nodes/mynode|resources.xml#WASQueueConnectionFactory_1)
   ```
5. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 232 article for more information.
6. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 217 article for more information.

Configuring new WebSphere topic connection factories using scripting

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

Perform the following steps to configure a new WebSphere topic connection factory:

1. Identify the parent ID:
   - Using Jacl:
     ```
     set newjmsp [$AdminConfig getid /Cell:mycell/Node:mynode/JMSProvider:JMSP1/]
     ```
   - Using Jython:
     ```
     newjmsp = AdminConfig.getid('/Cell:mycell/Node:myNode/JMSProvider:JMSP1/')
     print newjmsp
     ```

   Example output:
   ```
   JMSP1(cells/mycell/nodes/mynode|resources.xml#JMSProvider_1)
   ```
2. Get required attributes:
   - Using Jacl:
     ```
     $AdminConfig required WASTopicConnectionFactory
     ```
   - Using Jython:
     ```
     print AdminConfig.required('WASTopicConnectionFactory')
     ```

   Example output:
   ```
   Attribute           Type
   name                String
   jndiName            String
   port                ENUM(DIRECT, QUEUED)
   ```
3. Set up required attributes:
   - Using Jacl:
     ```
     set name [list name WASTCF]
     set jndi [list jndiName jms/WASTCF]
     set port [list port QUEUED]
     set mtcfAttrs [list $name $jndi $port]
     ```
     Example output:
     ```
     {name WASTCF} {jndiName jms/WASTCF} {port QUEUED}
     ```
   - Using Jython:
     ```
     name = ['name', 'WASTCF']
     jndi = ['jndiName', 'jms/WASTCF']
     port = ['port', 'QUEUED']
     mtcfAttrs = [name, jndi, port]
     print mtcfAttrs
     ```
     Example output:
     ```
     [[name, WASTCF], [jndiName, jms/WASTCF], [port, QUEUED]]
     ```
4. Create was topic connection factories:
   - Using Jacl:
     ```
     $AdminConfig create WASTopicConnectionFactory $newjmsp $mtcfAttrs
     ```
   - Using Jython:
     ```
     print AdminConfig.create('WASTopicConnectionFactory', newjmsp, mtcfAttrs)
     ```

   Example output:
   ```
   WASTCF(cells/mycell/nodes/mynode|resources.xml#WASTopicConnectionFactory_1)
   ```
5. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 232 article for more information.
6. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 217 article for more information.

Configuring new WebSphere queues using scripting

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

Perform the following steps to configure a new WebSphere queue:

1. Identify the parent ID:
   - Using Jacl:

     ```
     set newjmsp [$AdminConfig getid /Cell:mycell/Node:mynode/JMSProvider:JMSP1/]
     ```

   - Using Jython:

     ```
     newjmsp = AdminConfig.getid('/Cell:mycell/Node:myNode/JMSProvider:JMSP1/')
     print newjmsp
     ```

   Example output:

   ```
   JMSP1(cells/mycell/nodes/mynode|resources.xml#JMSProvider_1)
   ```

2. Get required attributes:
   - Using Jacl:

     ```
     $AdminConfig required WASQueue
     ```

   - Using Jython:

     ```
     print AdminConfig.required('WASQueue')
     ```

   Example output:

   ```
   Attribute       Type
   name       String
   jndiName    String
   ```

3. Set up required attributes:
   - Using Jacl:

     ```
     set name [list name WASQ1]
     set jndi [list jndiName jms/WASQ1]
     set wqAttrs [list $name $jndi]
     ```

     Example output:

     ```
     {name WASQ1} {jndiName jms/WASQ1}
     ```

   - Using Jython:

     ```
     name = ['name', 'WASQ1']
     jndi = ['jndiName', 'jms/WASQ1']
     wqAttrs = [name, jndi]
     print wqAttrs
     ```

     Example output:

     ```
     [[name, WASQ1], [jndiName, jms/WASQ1]]
     ```

4. Create was queue:
   - Using Jacl:

     ```
     $AdminConfig create WASQueue $newjmsp $wqAttrs
     ```

   - Using Jython:

     ```
     print AdminConfig.create('WASQueue', newjmsp, wqAttrs)
     ```

   Example output:

   ```
   WASQ1(cells/mycell/nodes/mynode|resources.xml#WASQueue_1)
   ```

5. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 232 article for more information.
6. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 217 article for more information.

Configuring new WebSphere topics using scripting

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

Perform the following steps to configure a new WebSphere topic:

1. Identify the parent ID:
   - Using Jacl:
     ```
     set newjmsp [$AdminConfig getid /Cell:mycell/Node:mynode/JMSProvider:JMSP1/]
     ```
   - Using Jython:
     ```
     newjmsp = AdminConfig.getid('/Cell:mycell/Node:myNode/JMSProvider:JMSP1/')
     print newjmsp
     ```

   Example output:
   ```
   JMSP1(cells/mycell/nodes/mynode|resources.xml#JMSProvider_1)
   ```
2. Get required attributes:
   - Using Jacl:
     ```
     $AdminConfig required WASTopic
     ```
   - Using Jython:
     ```
     print AdminConfig.required('WASTopic')
     ```

   Example output:
   ```
   Attribute       Type
   name       String
   jndiName    String
   topic        String
   ```
3. Set up required attributes:
   - Using Jacl:
     ```
     set name [list name WAST1]
     set jndi [list jndiName jms/WAST1]
     set topic [list topic "Put your topic here"]
     set wtAttrs [list $name $jndi $topic]
     ```
     Example output:
     ```
     {name WAST1} {jndiName jms/WAST1} {topic {Put your topic here}}
     ```
   - Using Jython:
     ```
     name = ['name', 'WAST1']
     jndi = ['jndiName', 'jms/WAST1']
     topic = ['topic', "Put your topic here"]
     wtAttrs = [name, jndi, topic]
     print wtAttrs
     ```
     Example output:
     ```
     [[name, WAST1], [jndiName, jms/WAST1], [topic, "Put your topic here"]]
     ```
4. Create was topic:
   - Using Jacl:
     ```
     $AdminConfig create WASTopic $newjmsp $wtAttrs
     ```
   - Using Jython:
     ```
     print AdminConfig.create('WASTopic', newjmsp, wtAttrs)
     ```

   Example output:
   ```
   WAST1(cells/mycell/nodes/mynode|resources.xml#WASTopic_1)
   ```
5. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 232 article for more information.
6. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 217 article for more information.

Configuring new MQ queue connection factories using scripting

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

Perform the following steps to configure a new MQ queue connection factory:

1. Identify the parent ID:
   - Using Jacl:
     ```
     set newjmsp [$AdminConfig getid /Cell:mycell/Node:mynode/JMSProvider:JMSP1/]
     ```
   - Using Jython:
     ```
     newjmsp = AdminConfig.getid('/Cell:mycell/Node:myNode/JMSProvider:JMSP1')
     print newjmsp
     ```

   Example output:
   ```
   JMSP1(cells/mycell/nodes/mynode|resources.xml#JMSProvider_1)
   ```
2. Get required attributes:
   - Using Jacl:
     ```
     $AdminConfig required MQQueueConnectionFactory
     ```
   - Using Jython:
     ```
     print AdminConfig.required('MQQueueConnectionFactory')
     ```

   Example output:
   ```
   Attribute       Type
   name       String
   jndiName    String
   ```
3. Set up required attributes:
   - Using Jacl:
     ```
     set name [list name MQQCF]
     set jndi [list jndiName jms/MQQCF]
     set mqqcfAttrs [list $name $jndi]
     ```
     Example output:
     ```
     {name MQQCF} {jndiName jms/MQQCF}
     ```
   - Using Jython:
     ```
     name = ['name', 'MQQCF']
     jndi = ['jndiName', 'jms/MQQCF']
     mqqcfAttrs = [name, jndi]
     print mqqcfAttrs
     ```
     Example output:
     ```
     [[name, MQQCF], [jndiName, jms/MQQCF]]
     ```
4. Set up a template:
   - Using Jacl:
     ```
     set template [lindex [$AdminConfig listTemplates MQQueueConnectionFactory] 0]
     ```
   - Using Jython:
     ```
     import java
     lineseparator = java.lang.System.getProperty('line.separator')
     template = AdminConfig.listTemplates('MQQueueConnectionFactory').split(lineseparator)[0]
     print template
     ```

   Example output:
   ```
   Example non-XA WMQ QueueConnectionFactory(templates/
   system:JMS-resource-provider-templates.xml
   #MQQueueConnectionFactory_3)
   ```
5. Create MQ queue connection factory:
   - Using Jacl:

```
$AdminConfig createUsingTemplate MQQueueConnectionFactory $newjmsp $mqqcfAttrs $template
```

- Using Jython:

  ```
  print AdminConfig.createUsingTemplate('MQQueueConnectionFactory', newjmsp, mqqcfAttrs, template)
  ```

Example output:

```
MQQCF(cells/mycell/nodes/mynode:resources.xml#MQQueueConnectionFactory_1)
```

6. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 232 article for more information.
7. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 217 article for more information.

Configuring new MQ topic connection factories using scripting

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

Perform the following steps to configure a new MQ topic connection factory:

1. Identify the parent ID:
   - Using Jacl:

     ```
     set newjmsp [$AdminConfig getid /Cell:mycell/Node:mynode/JMSProvider:JMSP1/]
     ```

   - Using Jython:

     ```
     newjmsp = AdminConfig.getid('/Cell:mycell/Node:myNode/JMSProvider:JMSP1')
     print newjmsp
     ```

   Example output:

   ```
   JMSP1(cells/mycell/nodes/mynode:resources.xml#JMSProvider_1)
   ```

2. Get required attributes:
   - Using Jacl:

     ```
     $AdminConfig required MQTopicConnectionFactory
     ```

   - Using Jython:

     ```
     print AdminConfig.required('MQTopicConnectionFactory')
     ```

   Example output:

   ```
   Attribute       Type
   name       String
   jndiName    String
   ```

3. Set up required attributes:
   - Using Jacl:

     ```
     set name [list name MQTCF]
     set jndi [list jndiName jms/MQTCF]
     set mqtcfAttrs [list $name $jndi]
     ```

     Example output:

     ```
     {name MQTCF} {jndiName jms/MQTCF}
     ```

   - Using Jython:

     ```
     name = ['name', 'MQTCF']
     jndi = ['jndiName', 'jms/MQTCF']
     mqtcfAttrs = [name, jndi]
     print mqtcfAttrs
     ```

     Example output:

     ```
     [[name, MQTCF], [jndiName, jms/MQTCF]]
     ```

4. Set up a template:
   - Using Jacl:

     ```
     set template [lindex [$AdminConfig listTemplates MQTopicConnectionFactory] 0]
     ```

- Using Jython:

  ```
  import java
  lineseparator = java.lang.System.getProperty('line.separator')
  template = AdminConfig.listTemplates('MQTopicConnectionFactory').split(lineseparator)[0]
  print template
  ```

  Example output:

  ```
  Example non-XA WMQ TopicConnectionFactory(templates/system:
  JMS-resource-provider-templates.xml
  #MQTopicConnectionFactory_5)
  ```

5. Create mq topic connection factory:
   - Using Jacl:

     ```
     $AdminConfig create MQTopicConnectionFactory $newjmsp $mqtcfAttrs $template
     ```

   - Using Jython:

     ```
     print AdminConfig.create('MQTopicConnectionFactory', newjmsp, mqtcfAttrs, template)
     ```

   Example output:

   ```
   MQTCF(cells/mycell/nodes/mynode:resources.xml#MQTopicConnectionFactory_1)
   ```

6. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 232 article for more information.
7. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 217 article for more information.

Configuring new MQ queues using scripting

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

Perform the following steps to configure a new MQ queue:

1. Identify the parent ID:
   - Using Jacl:

     ```
     set newjmsp [$AdminConfig getid /Cell:mycell/Node:mynode/JMSProvider:JMSP1/]
     ```

   - Using Jython:

     ```
     newjmsp = AdminConfig.getid('/Cell:mycell/Node:myNode/JMSProvider:JMSP1')
     print newjmsp
     ```

   Example output:

   ```
   JMSP1(cells/mycell/nodes/mynode|resources.xml#JMSProvider_1)
   ```

2. Get required attributes:
   - Using Jacl:

     ```
     $AdminConfig required MQQueue
     ```

   - Using Jython:

     ```
     print AdminConfig.required('MQQueue')
     ```

   Example output:

   ```
   Attribute       Type
   name       String
   jndiName    String
   baseQueueName  String
   ```

3. Set up required attributes:
   - Using Jacl:

     ```
     set name [list name MQQ]
     set jndi [list jndiName jms/MQQ]
     set baseQN [list baseQueueName "Put the base queue name here"]
     set mqqAttrs [list $name $jndi $baseQN]
     ```

     Example output:

```
{name MQQ} {jndiName jms/MQQ} {baseQueueName {Put the base queue name here}}
```

- Using Jython:

  ```
  name = ['name', 'MQQ']
  jndi = ['jndiName', 'jms/MQQ']
  baseQN = ['baseQueueName', "Put the base queue name here"]
  mqqAttrs = [name, jndi, baseQN]
  print mqqAttrs
  ```

  Example output:

  ```
  [[name, MQQ], [jndiName, jms/MQQ], [baseQueueName, "Put the base queue name here"]]
  ```

4. Set up a template:
   - Using Jacl:

     ```
     set template [lindex [$AdminConfig listTemplates MQQueue] 0]
     ```

   - Using Jython:

     ```
     import java
     lineseparator = java.lang.System.getProperty('line.separator')
     template = AdminConfig.listTemplates('MQQueue').split(lineseparator)[0]
     print template
     ```

   Example output:

   ```
   Example.JMS.WMQ.Q1(templates/system:JMS-resource-provider-
   templates.xml#MQQueue_1)
   ```

5. Create MQ queue factory:
   - Using Jacl:

     ```
     $AdminConfig create MQQueue $newjmsp $mqqAttrs $template
     ```

   - Using Jython:

     ```
     print AdminConfig.create('MQQueue', newjmsp, mqqAttrs, template)
     ```

   Example output:

   ```
   MQQ(cells/mycell/nodes/mynode|resources.xml#MQQueue_1)
   ```

6. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 232 article for more information.
7. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 217 article for more information.

Configuring new MQ topics using scripting

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

Perform the following steps to configure a new MQ topic:

1. Identify the parent ID:
   - Using Jacl:

     ```
     set newjmsp [$AdminConfig getid /Cell:mycell/Node:mynode/JMSProvider:JMSP1/]
     ```

   - Using Jython:

     ```
     newjmsp = AdminConfig.getid('/Cell:mycell/Node:myNode/JMSProvider:JMSP1')
     print newjmsp
     ```

   Example output:

   ```
   JMSP1(cells/mycell/nodes/mynode|resources.xml#JMSProvider_1)
   ```

2. Get required attributes:
   - Using Jacl:

     ```
     $AdminConfig required MQTopic
     ```

   - Using Jython:

     ```
     print AdminConfig.required('MQTopic')
     ```

Example output:

```
Attribute           Type
name                String
jndiName            String
baseTopicName       String
```

3. Set up required attributes:
   - Using Jacl:

     ```
     set name [list name MQT]
     set jndi [list jndiName jms/MQT]
     set baseTN [list baseTopicName "Put the base topic name here"]
     set mqtAttrs [list $name $jndi $baseTN]
     ```

     Example output:

     ```
     {name MQT} {jndiName jms/MQT} {baseTopicName {Put the base topic name here}}
     ```

   - Using Jython:

     ```
     name = ['name', 'MQT']
     jndi = ['jndiName', 'jms/MQT']
     baseTN = ['baseTopicName', "Put the base topic name here"]
     mqtAttrs = [name, jndi, baseTN]
     print mqtAttrs
     ```

     Example output:

     ```
     [[name, MQT], [jndiName, jms/MQT], [baseTopicName, "Put the base topic name here"]]
     ```

4. Create MQ topic factory:
   - Using Jacl:

     ```
     $AdminConfig create MQTopic $newjmsp $mqtAttrs
     ```

   - Using Jython:

     ```
     print AdminConfig.create('MQTopic', newjmsp, mqtAttrs)
     ```

   Example output:

   ```
   MQT(cells/mycell/nodes/mynode|resources.xml#MQTopic_1)
   ```

5. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 232 article for more information.
6. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 217 article for more information.

Configuring mail, URLs, and resource environment entries with scripting

This topic contains the following tasks:

- “Configuring new mail providers using scripting” on page 342
- “Configuring new mail sessions using scripting” on page 342
- “Configuring new protocols using scripting” on page 343
- “Configuring new custom properties using scripting” on page 344
- “Configuring new resource environment providers using scripting” on page 345
- “Configuring custom properties for resource environment providers using scripting” on page 346
- “Configuring new referenceables using scripting” on page 347
- “Configuring new resource environment entries using scripting” on page 348
- “Configuring custom properties for resource environment entries using scripting” on page 349

- “Configuring custom properties for URLs using scripting” on page 353

Configuring new mail providers using scripting

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

Perform the following steps to configure a new mail provider:

1. Identify the parent ID:
   - Using Jacl:
     ```
     set node [$AdminConfig getid /Cell:mycell/Node:mynode/]
     ```
   - Using Jython:
     ```
     node = AdminConfig.getid('/Cell:mycell/Node:mynode/')
     print node
     ```

   Example output:
   ```
   mynode(cells/mycell/nodes/mynode|node.xml#Node_1)
   ```
2. Get required attributes:
   - Using Jacl:
     ```
     $AdminConfig required MailProvider
     ```
   - Using Jython:
     ```
     print AdminConfig.required('MailProvider')
     ```

   Example output:
   ```
   Attribute       Type
   name       String
   ```
3. Set up required attributes:
   - Using Jacl:
     ```
     set name [list name MP1]
     set mpAttrs [list $name]
     ```
   - Using Jython:
     ```
     name = ['name', 'MP1']
     mpAttrs = [name]
     ```
4. Create the mail provider:
   - Using Jacl:
     ```
     set newmp [$AdminConfig create MailProvider $node $mpAttrs]
     ```
   - Using Jython:
     ```
     newmp = AdminConfig.create('MailProvider', node, mpAttrs)
     print newmp
     ```

   Example output:
   ```
   MP1(cells/mycell/nodes/mynode|resources.xml#MailProvider_1)
   ```
5. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 232 article for more information.
6. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 217 article for more information.

Configuring new mail sessions using scripting

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

Perform the following steps to configure a new mail session:

1. Identify the parent ID:
   - Using Jacl:

```
set newmp [$AdminConfig getid /Cell:mycell/Node:mynode/MailProvider:MP1/]
```

- Using Jython:

  ```
  newmp = AdminConfig.create('MailProvider', node, mpAttrs)
  print newmp
  ```

  Example output:

  ```
  MP1(cells/mycell/nodes/mynode|resources.xml#MailProvider_1)
  ```

2. Get required attributes:
   - Using Jacl:

     ```
     $AdminConfig required MailSession
     ```

   - Using Jython:

     ```
     print AdminConfig.required('MailSession')
     ```

   Example output:

   ```
   Attribute       Type
   name       String
   jndiName       String
   ```

3. Set up required attributes:
   - Using Jacl:

     ```
     set name [list name MS1]
     set jndi [list jndiName mail/MS1]
     set msAttrs [list $name $jndi]
     ```

     Example output:

     ```
     {name MS1} {jndiName mail/MS1}
     ```

   - Using Jython:

     ```
     name = ['name', 'MS1']
     jndi = ['jndiName', 'mail/MS1']
     msAttrs = [name, jndi]
     print msAttrs
     ```

     Example output:

     ```
     [[name, MS1], [jndiName, mail/MS1]]
     ```

4. Create the mail session:
   - Using Jacl:

     ```
     $AdminConfig create MailSession $newmp $msAttrs
     ```

   - Using Jython:

     ```
     print AdminConfig.create('MailSession', newmp, msAttrs)
     ```

   Example output:

   ```
   MS1(cells/mycell/nodes/mynode|resources.xml#MailSession_1)
   ```

5. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 232 article for more information.
6. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 217 article for more information.

Configuring new protocols using scripting

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

Perform the following steps to configure a new protocol:

1. Identify the parent ID:
   - Using Jacl:

     ```
     set newmp [$AdminConfig getid /Cell:mycell/Node:mynode/MailProvider:MP1/]
     ```

- Using Jython:

  ```
  newmp = AdminConfig.create('MailProvider', node, mpAttrs)
  print newmp
  ```

  Example output:

  ```
  MP1(cells/mycell/nodes/mynode|resources.xml#MailProvider_1)
  ```

2. Get required attributes:
   - Using Jacl:

     ```
     $AdminConfig required ProtocolProvider
     ```

   - Using Jython:

     ```
     print AdminConfig.required('ProtocolProvider')
     ```

   Example output:

   ```
   Attribute       Type
   protocol      String
   classname       String
   ```

3. Set up required attributes:
   - Using Jacl:

     ```
     set protocol [list protocol "Put the protocol here"]
     set classname [list classname "Put the class name here"]
     set ppAttrs [list $protocol $classname]
     ```

     Example output:

     ```
     {protocol protocol1} {classname classname1}
     ```

   - Using Jython:

     ```
     protocol = ['protocol', "Put the protocol here"]
     classname = ['classname', "Put the class name here"]
     ppAttrs = [protocol, classname]
     print ppAttrs
     ```

     Example output:

     ```
     [[protocol, protocol1], [classname, classname1]]
     ```

4. Create the protocol provider:
   - Using Jacl:

     ```
     $AdminConfig create ProtocolProvider $newmp $ppAttrs
     ```

   - Using Jython:

     ```
     print AdminConfig.create('ProtocolProvider', newmp, ppAttrs)
     ```

   Example output:

   ```
   (cells/mycell/nodes/mynode|resources.xml#ProtocolProvider_4)
   ```

5. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 232 article for more information.
6. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 217 article for more information.

Configuring new custom properties using scripting

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

Perform the following steps to configure a new custom property:

1. Identify the parent ID:
   - Using Jacl:

     ```
     set newmp [$AdminConfig getid /Cell:mycell/Node:mynode/MailProvider:MP1/]
     ```

   - Using Jython:

```
newmp = AdminConfig.create('MailProvider', node, mpAttrs)
print newmp
```

Example output:

```
MP1(cells/mycell/nodes/mynode|resources.xml#MailProvider_1)
```

2. Get the J2EE resource property set:
   - Using Jacl:

     ```
     set propSet [$AdminConfig showAttribute $newmp propertySet]
     ```

   - Using Jython:

     ```
     propSet = AdminConfig.showAttribute(newmp, 'propertySet')
     print propSet
     ```

   Example output:

   ```
   (cells/mycell/nodes/mynode|resources.xml#PropertySet_2)
   ```

3. Get required attributes:
   - Using Jacl:

     ```
     $AdminConfig required J2EEResourceProperty
     ```

   - Using Jython:

     ```
     print AdminConfig.required('J2EEResourceProperty')
     ```

   Example output:

   ```
   Attribute       Type
   name      String
   ```

4. Set up the required attributes:
   - Using Jacl:

     ```
     set name [list name CP1]
     set cpAttrs [list $name]
     ```

     Example output:

     ```
     {name CP1}
     ```

   - Using Jython:

     ```
     name = ['name', 'CP1']
     cpAttrs = [name]
     print cpAttrs
     ```

     Example output:

     ```
     [[name, CP1]]
     ```

5. Create a J2EE resource property:
   - Using Jacl:

     ```
     $AdminConfig create J2EEResourceProperty $propSet $cpAttrs
     ```

   - Using Jython:

     ```
     print AdminConfig.create('J2EEResourceProperty', propSet, cpAttrs)
     ```

   Example output:

   ```
   CP1(cells/mycell/nodes/mynode|resources.xml#J2EEResourceProperty_2)
   ```

6. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 232 article for more information.
7. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 217 article for more information.

Configuring new resource environment providers using scripting

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

Perform the following steps to configure a new resource environment provider:

1. Identify the parent ID and assign it to the node variable.
   - Using Jacl:
     ```
     set node [$AdminConfig  getid  /Cell:mycell/Node:mynode/]
     ```
   - Using Jython:
     ```
     node = AdminConfig.getid('/Cell:mycell/Node:mynode/')
     print node
     ```

   Example output:
   ```
   mynode(cells/mycell/nodes/mynode|node.xml#Node_1)
   ```
2. Identify the required attributes:
   - Using Jacl:
     ```
     $AdminConfig required ResourceEnvironmentProvider
     ```
   - Using Jython:
     ```
     print AdminConfig.required('ResourceEnvironmentProvider')
     ```

   Example output:
   ```
   Attribute     Type
   name     String
   ```
3. Set up the required attributes and assign it to the repAttrs variable:
   - Using Jacl:
     ```
     set n1 [list name REP1]
     set repAttrs [list $name]
     ```
   - Using Jython:
     ```
     n1 = ['name', 'REP1']
     repAttrs = [n1]
     ```
4. Create a new resource environment provider:
   - Using Jacl:
     ```
     set newrep [$AdminConfig create ResourceEnvironmentProvider $node $repAttrs]
     ```
   - Using Jython:
     ```
     newrep = AdminConfig.create('ResourceEnvironmentProvider', node, repAttrs)
     print newrep
     ```

   Example output:
   ```
   REP1(cells/mycell/nodes/mynode|resources.xml#ResourceEnvironmentProvider_1)
   ```
5. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 232 article for more information.
6. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 217 article for more information.

Configuring custom properties for resource environment providers using scripting

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

Perform the following steps to configure a new custom property for a resource environment provider:

1. Identify the parent ID and assign it to the newrep variable.
   - Using Jacl:
     ```
     set newrep [$AdminConfig getid /Cell:mycell/Node:mynode/ResourceEnvironmentProvider:REP1/]
     ```
   - Using Jython:
     ```
     newrep = AdminConfig.getid('/Cell:mycell/Node:mynode/ResourceEnvironmentProvider:REP1/')
     print newrep
     ```

   Example output:
   ```
   REP1(cells/mycell/nodes/mynode|resources.xml#ResourceEnvironmentProvider_1)
   ```

2. Identify the required attributes:
   - Using Jacl:
     ```
     $AdminConfig required J2EEResourceProperty
     ```
   - Using Jython:
     ```
     print AdminConfig.required('J2EEResourceProperty')
     ```

   Example output:
   ```
   Attribute     Type
   name     String
   ```
3. Set up the required attributes and assign it to the repAttrs variable:
   - Using Jacl:
     ```
     set name [list name RP]
     set rpAttrs [list $name]
     ```
   - Using Jython:
     ```
     name = ['name', 'RP']
     rpAttrs = [name]
     ```
4. Get the J2EE resource property set:
   - Using Jacl:
     ```
     set propSet [$AdminConfig showAttribute $newrep propertySet]
     ```
   - Using Jython:
     ```
     propSet = AdminConfig.showAttribute(newrep, 'propertySet')
     print propSet
     ```

   Example output:
   ```
   (cells/mycell/nodes/mynode|resources.xml#PropertySet_1)
   ```
5. Create a J2EE resource property:
   - Using Jacl:
     ```
     $AdminConfig create J2EEResourceProperty $propSet $rpAttrs
     ```
   - Using Jython:
     ```
     print AdminConfig.create('J2EEResourceProperty', propSet, rpAttrs)
     ```

   Example output:
   ```
   RP(cells/mycell/nodes/mynode|resources.xml#J2EEResourceProperty_1)
   ```
6. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 232 article for more information.
7. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 217 article for more information.

Configuring new referenceables using scripting

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

Perform the following steps to configure a new referenceable:

1. Identify the parent ID and assign it to the newrep variable.
   - Using Jacl:
     ```
     set newrep [$AdminConfig  getid  /Cell:mycell/Node:mynode/ResourceEnvironmentProvider:REP1/]
     ```
   - Using Jython:
     ```
     newrep = AdminConfig.getid('/Cell:mycell/Node:mynode/ResourceEnvironmentProvider:REP1/')
     print newrep
     ```

   Example output:
   ```
   REP1(cells/mycell/nodes/mynode|resources.xml#ResourceEnvironmentProvider_1)
   ```

2. Identify the required attributes:
   - Using Jacl:
     ```
     $AdminConfig required Referenceable
     ```
   - Using Jython:
     ```
     print AdminConfig.required('Referenceable')
     ```

   Example output:
   ```
   Attribute     Type
   factoryClassname   String
   classname   String
   ```
3. Set up the required attributes:
   - Using Jacl:
     ```
     set fcn [list factoryClassname REP1]
     set cn [list classname NM1]
     set refAttrs [list $fcn $cn]
     ```
   - Using Jython:
     ```
     fcn = ['factoryClassname', 'REP1']
     cn = ['classname', 'NM1']
     refAttrs = [fcn, cn]
     print refAttrs
     ```

   Example output:
   ```
   {factoryClassname {REP1}} {classname {NM1}}
   ```
4. Create a new referenceable:
   - Using Jacl:
     ```
     set newref [$AdminConfig create Referenceable  $newrep  $refAttrs]
     ```
   - Using Jython:
     ```
     newref = AdminConfig.create('Referenceable',  newrep,  refAttrs)
     print newref
     ```

   Example output:
   ```
   (cells/mycell/nodes/mynode|resources.xml#Referenceable_1)
   ```
5. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 232 article for more information.
6. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 217 article for more information.

Configuring new resource environment entries using scripting

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

Perform the following steps to configure a new resource environment entry:

1. Identify the parent ID and assign it to the newrep variable.
   - Using Jacl:
     ```
     set newrep [$AdminConfig  getid  /Cell:mycell/Node:mynode/ResourceEnvironmentProvider:REP1/]
     ```
   - Using Jython:
     ```
     newrep = AdminConfig.getid('/Cell:mycell/Node:mynode/ResourceEnvironmentProvider:REP1/')
     print newrep
     ```

   Example output:
   ```
   REP1(cells/mycell/nodes/mynode|resources.xml#ResourceEnvironmentProvider_1)
   ```
2. Identify the required attributes:
   - Using Jacl:
     ```
     $AdminConfig required ResourceEnvEntry
     ```

- Using Jython:

  ```
  print AdminConfig.required('ResourceEnvEntry')
  ```

  Example output:

  ```
  Attribute     Type
  name      String
  jndiName   String
  referenceable   Referenceable@
  ```

3. Set up the required attributes:
   - Using Jacl:

     ```
     set name [list name REE1]
     set jndiName [list jndiName myjndi]
     set newref [$AdminConfig getid /Cell:mycell/Node:mynode/Referenceable:/]
     set ref [list referenceable $newref]
     set reeAttrs [list $name $jndiName $ref]
     ```

   - Using Jython:

     ```
     name = ['name', 'REE1']
     jndiName = ['jndiName', 'myjndi']
     newref = AdminConfig.getid('/Cell:mycell/Node:mynode/Referenceable:/')
     ref = ['referenceable', newref]
     reeAttrs = [name, jndiName, ref]
     ```

4. Create the resource environment entry:
   - Using Jacl:

     ```
     $AdminConfig create ResourceEnvEntry $newrep $reeAttrs
     ```

   - Using Jython:

     ```
     print AdminConfig.create('ResourceEnvEntry', newrep, reeAttrs)
     ```

   Example output:

   ```
   REE1(cells/mycell/nodes/mynode|resources.xml#ResourceEnvEntry_1)
   ```

5. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 232 article for more information.
6. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 217 article for more information.

Configuring custom properties for resource environment entries using scripting

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

Perform the following steps to configure a new custom property for a resource environment entry:

1. Identify the parent ID and assign it to the newree variable.
   - Using Jacl:

     ```
     set newree [$AdminConfig  getid  /Cell:mycell/Node:mynode/ResourceEnvEntry:REE1/]
     ```

   - Using Jython:

     ```
     newree = AdminConfig.getid('/Cell:mycell/Node:mynode/ResourceEnvEntry:REE1/')
     print newree
     ```

   Example output:

   ```
   REE1(cells/mycell/nodes/mynode|resources.xml#ResourceEnvEntry_1)
   ```

2. Create the J2EE custom property set:
   - Using Jacl:

     ```
     set propSet [$AdminConfig showAttribute $newree propertySet]
     ```

   - Using Jython:

     ```
     propSet = AdminConfig.showAttribute(newree, 'propertySet')
     print propSet
     ```

Example output:

```
(cells/mycell/nodes/mynode|resources.xml#J2EEResourcePropertySet_5)
```

3. Identify the required attributes:
   - Using Jacl:
     ```
     $AdminConfig required J2EEResourceProperty
     ```
   - Using Jython:
     ```
     print AdminConfig.required('J2EEResourceProperty')
     ```

   Example output:

   ```
   Attribute     Type
   name      String
   ```
4. Set up the required attributes:
   - Using Jacl:
     ```
     set name [list name RP1]
     set rpAttrs [list $name]
     ```
   - Using Jython:
     ```
     name = ['name', 'RP1']
     rpAttrs = [name]
     ```
5. Create the J2EE custom property:
   - Using Jacl:
     ```
     $AdminConfig create J2EEResourceProperty $propSet $rpAttrs
     ```
   - Using Jython:
     ```
     print AdminConfig.create('J2EEResourceProperty', propSet, rpAttrs)
     ```

   Example output:

   ```
   RPI(cells/mycell/nodes/mynode|resources.xml#J2EEResourceProperty_1)
   ```
6. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 232 article for more information.
7. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 217 article for more information.

Configuring new URL providers using scripting

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

Perform the following steps to configure a new URL provider:

1. Identify the parent ID and assign it to the node variable.
   - Using Jacl:
     ```
     set node [$AdminConfig  getid  /Cell:mycell/Node:mynode/]
     ```
   - Using Jython:
     ```
     node = AdminConfig.getid('/Cell:mycell/Node:mynode/')
     print node
     ```

   Example output:

   ```
   mynode(cells/mycell/nodes/mynode|node.xml#Node_1)
   ```
2. Identify the required attributes:
   - Using Jacl:
     ```
     $AdminConfig required URLProvider
     ```
   - Using Jython:
     ```
     print AdminConfig.required('URLProvider')
     ```

   Example output:

```
Attribute     Type
streamHandlerClassName   String
protocol       String
name         String
```

3. Set up the required attributes:
   - Using Jacl:
     ```
     set name [list name URLP1]
     set shcn [list streamHandlerClassName "Put the stream handler classname here"]
     set protocol [list protocol "Put the protocol here"]
     set urlpAttrs [list $name $shcn $protocol]
     ```
     Example output:
     ```
     {name URLP1} {streamHandlerClassName {Put the stream handler classname here}} {protocol {Put the protocol here}}
     ```
   - Using Jython:
     ```
     name = ['name', 'URLP1']
     shcn = ['streamHandlerClassName', "Put the stream handler classname here"]
     protocol = ['protocol', "Put the protocol here"]
     urlpAttrs = [name, shcn, protocol]
     print urlpAttrs
     ```
     Example output:
     ```
     [[name, URLP1], [streamHandlerClassName, "Put the stream handler classname here"],
     [protocol, "Put the protocol here"]]
     ```
4. Create a URL provider:
   - Using Jacl:
     ```
     $AdminConfig create URLProvider $node $urlpAttrs
     ```
   - Using Jython:
     ```
     print AdminConfig.create('URLProvider', node, urlpAttrs)
     ```

   Example output:
   ```
   URLP1(cells/mycell/nodes/mynode|resources.xml#URLProvider_1)
   ```
5. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 232 article for more information.
6. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 217 article for more information.

Configuring custom properties for URL providers using scripting

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

Perform the following steps to configure custom properties for URL providers:

1. Identify the parent ID and assign it to the newurlp variable.
   - Using Jacl:
     ```
     set newurlp [$AdminConfig  getid  /Cell:mycell/Node:mynode/URLProvider:URLP1/]
     ```
   - Using Jython:
     ```
     newurlp = AdminConfig.getid('/Cell:mycell/Node:mynode/URLProvider:URLP1/')
     print newurlp
     ```

   Example output:
   ```
   URLP1(cells/mycell/nodes/mynode|resources.xml#URLProvider_1)
   ```
2. Get the J2EE resource property set:
   - Using Jacl:
     ```
     set propSet [$AdminConfig showAttribute $newurlp propertySet]
     ```
   - Using Jython:

```
propSet = AdminConfig.showAttribute(newurlp, 'propertySet')
print propSet
```

Example output:

```
(cells/mycell/nodes/mynode|resources.xml#PropertySet_7)
```

3. Identify the required attributes:
   - Using Jacl:

     ```
     $AdminConfig required J2EEResourceProperty
     ```

   - Using Jython:

     ```
     print AdminConfig.required('J2EEResourceProperty')
     ```

   Example output:

   ```
   Attribute     Type
   name         String
   ```
4. Set up the required attributes:
   - Using Jacl:

     ```
     set name [list name RP2]
     set rpAttrs [list $name]
     ```

   - Using Jython:

     ```
     name = ['name', 'RP2']
     rpAttrs = [name]
     ```
5. Create a J2EE resource property:
   - Using Jacl:

     ```
     $AdminConfig create J2EEResourceProperty $propSet $rpAttrs
     ```

   - Using Jython:

     ```
     print AdminConfig.create('J2EEResourceProperty', propSet, rpAttrs)
     ```

   Example output:

   ```
   RP2(cells/mycell/nodes/mynode|resources.xml#J2EEResourceProperty_1)
   ```
6. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 232 article for more information.
7. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 217 article for more information.

Configuring new URLs using scripting

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

Perform the following example to configure a new URL:

1. Identify the parent ID and assign it to the newurlp variable.
   - Using Jacl:

     ```
     set newurlp [$AdminConfig  getid  /Cell:mycell/Node:mynode/URLProvider:URLP1/]
     ```

   - Using Jython:

     ```
     newurlp = AdminConfig.getid('/Cell:mycell/Node:mynode/URLProvider:URLP1/')
     print newurlp
     ```

   Example output:

   ```
   URLP1(cells/mycell/nodes/mynode|resources.xml#URLProvider_1)
   ```
2. Identify the required attributes:
   - Using Jacl:

     ```
     $AdminConfig required URL
     ```

   - Using Jython:

     ```
     print AdminConfig.required('URL')
     ```

Example output:

```
Attribute     Type
name         String
spec         String
```

3. Set up the required attributes:
   - Using Jacl:

     ```
     set name [list name URL1]
     set spec [list spec "Put the spec here"]
     set urlAttrs [list $name $spec]
     ```

     Example output:

     ```
     {name URL1} {spec {Put the spec here}}
     ```

   - Using Jython:

     ```
     name = ['name', 'URL1']
     spec = ['spec', "Put the spec here"]
     urlAttrs = [name, spec]
     ```

     Example output:

     ```
     [[name, URL1], [spec, "Put the spec here"]]
     ```

4. Create a URL:
   - Using Jacl:

     ```
     $AdminConfig create URL $newurlp $urlAttrs
     ```

   - Using Jython:

     ```
     print AdminConfig.create('URL', newurlp, urlAttrs)
     ```

   Example output:

   ```
   URL1(cells/mycell/nodes/mynode|resources.xml#URL_1)
   ```

5. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 232 article for more information.
6. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 217 article for more information.

Configuring custom properties for URLs using scripting

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

Perform the following steps to configure a new custom property for a URL:

1. Identify the parent ID and assign it to the newurl variable.
   - Using Jacl:

     ```
     set newurl [$AdminConfig getid /Cell:mycell/Node:mynode/URLProvider:URLP1/URL:URL1/]
     ```

   - Using Jython:

     ```
     newurl = AdminConfig.getid('/Cell:mycell/Node:mynode/URLProvider:URLP1/URL:URL1/')
     print newurl
     ```

   Example output:

   ```
   URL1(cells/mycell/nodes/mynode|resources.xml#URL_1)
   ```

2. Create a J2EE resource property set:
   - Using Jacl:

     ```
     set propSet [$AdminConfig showAttribute $newurl propertySet]
     ```

   - Using Jython:

     ```
     propSet = AdminConfig.showAttribute(newurl, 'propertySet')
     print propSet
     ```

   Example output:

```
(cells/mycell/nodes/mynode|resources.xml#J2EEResourcePropertySet_7)
```

3. Identify the required attributes:
   - Using Jacl:
     ```
     $AdminConfig required J2EEResourceProperty
     ```
   - Using Jython:
     ```
     print AdminConfig.required('J2EEResourceProperty')
     ```

   Example output:
   ```
   Attribute     Type
   name         String
   ```
4. Set up the required attributes:
   - Using Jacl:
     ```
     set name [list name RP3]
     set rpAttrs [list $name]
     ```
   - Using Jython:
     ```
     name = ['name', 'RP3']
     rpAttrs = [name]
     ```
5. Create a J2EE resource property:
   - Using Jacl:
     ```
     $AdminConfig create J2EEResourceProperty $propSet $rpAttrs
     ```
   - Using Jython:
     ```
     print AdminConfig.create('J2EEResourceProperty', propSet, rpAttrs)
     ```

   Example output:
   ```
   RP3(cells/mycell/nodes/mynode|resources.xml#J2EEResourceProperty_7)
   ```
6. Save the configuration changes. See the "Saving configuration changes with the wsadmin tool" on page 232 article for more information.
7. In a network deployment environment only, synchronize the node. See the "Synchronizing nodes with the wsadmin tool" on page 217 article for more information.

Troubleshooting with scripting

This topic contains the following tasks:

- "Tracing operations with the wsadmin tool"
- "Configuring traces using scripting" on page 355
- "Turning traces on and off in servers processes using scripting" on page 356
- "Dumping threads in server processes using scripting" on page 357
- "Setting up profile scripts to make tracing easier using scripting" on page 357

Tracing operations with the wsadmin tool

Before starting this task, the wsadmin tool must be running. See the "Starting the wsadmin scripting client" on page 250 article for more information.

Perform the following steps to trace operations:

Enable wsadmin client tracing with the following command:

- Using Jacl:
  ```
  $AdminControl trace com.ibm.*=all=enabled
  ```
- Using Jython:
  ```
  AdminControl.trace('com.ibm.*=all=enabled')
  ```

where:

$	is a Jacl operator for substituting a variable name with its value
AdminControl	is an object that enables the manipulation of MBeans running in a WebSphere server process
trace	is an AdminControl command
com.ibm.*=all=enabled	indicates to turn on tracing

The following command disables tracing:

- Using Jacl:

```
$AdminControl trace com.ibm.*=all=disabled
```

- Using Jython:

```
AdminControl.trace('com.ibm.*=all=disabled')
```

where:

$	is a Jacl operator for substituting a variable name with its value
AdminControl	is an object that enables the manipulation of MBeans running in a WebSphere server process
trace	is an AdminControl command
com.ibm.*=all=disabled	indicates to turn off tracing

The trace command changes the trace settings for the current session. You can change this setting persistently by editting the wsadmin.properties file. The property com.ibm.ws.scripting.traceString is read by the launcher during initialization. If it has a value, the value is used to set the trace.

A related property, com.ibm.ws.scripting.traceFile, designates a file to receive all trace and logging information. The wsadmin.properties file contains a value for this property. Run the wsadmin tool with a value set for this property. It is possible to run without this property set, where all logging and tracing goes to the administrative console.

Configuring traces using scripting

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

Perform the following steps to set the trace for a configured server:

1. Identify the server and assign it to the server variable:
   - Using Jacl:

     ```
     set server [$AdminConfig getid /Cell:mycell/Node:mynode/Server:server1/]
     ```

   - Using Jython:

     ```
     server = AdminConfig.getid('/Cell:mycell/Node:mynode/Server:server1/')
     print server
     ```

   Example output:

   ```
   server1(cells/mycell/nodes/mynode/servers/server1|server.xml#Server_1)
   ```

2. Identify the trace service belonging to the server and assign it to the tc variable:
   - Using Jacl:

     ```
     set tc [$AdminConfig list TraceService $server]
     ```

   - Using Jython:

     ```
     tc = AdminConfig.list('TraceService', server)
     print tc
     ```

Example output:

```
(cells/mycell/nodes/mynode/servers/server1|server.xml#TraceService_1)
```

3. Set the trace string. The following example sets the trace string for a single component:
   - Using Jacl:
     ```
     $AdminConfig modify $tc {{startupTraceSpecification com.ibm.websphere.management.*=all=enabled}}
     ```
   - Using Jython:
     ```
     AdminConfig.modify(tc, [['startupTraceSpecification',  'com.ibm.websphere.management.*=all=enabled']])
     ```
4. The following command sets the trace string for multiple components:
   - Using Jacl:
     ```
     $AdminConfig modify $tc {{startupTraceSpecification com.ibm.websphere.management.*=all=
       enabled:com.ibm.ws.management.*=all=enabled:com.ibm.ws.runtime.*=all=enabled}}
     ```
   - Using Jython:
     ```
     AdminConfig.modify(tc, [['startupTraceSpecification',  'com.ibm.websphere.management.
       *=all=enabled:com.ibm.ws.management.*=all=
       enabled:com.ibm.ws.runtime.*=all=enabled']])
     ```
5. Save the configuration changes. See the "Saving configuration changes with the wsadmin tool" on page 232 article for more information.
6. In a network deployment environment only, synchronize the node. See the "Synchronizing nodes with the wsadmin tool" on page 217 article for more information.

Turning traces on and off in servers processes using scripting

Before starting this task, the wsadmin tool must be running. See the "Starting the wsadmin scripting client" on page 250 article for more information.

Perform the following steps to turning traces on and off in server processes:

1. Identify the object name for the TraceService MBean running in the process:
   - Using Jacl:
     ```
     $AdminControl completeObjectName type=TraceService,node=mynode,process=server1,*
     ```
   - Using Jython:
     ```
     AdminControl.completeObjectName('type=TraceService,node=mynode,process=server1,*')
     ```
2. Obtain the name of the object and set it to a variable:
   - Using Jacl:
     ```
     set ts [$AdminControl completeObjectName type=TraceService,process=server1,*]
     ```
   - Using Jython:
     ```
     ts = AdminControl.completeObjectName('type=TraceService,process=server1,*')
     ```
3. Turn tracing on or off for the server. For example:
   - To turn tracing on, perform the following step:
     - Using Jacl:
       ```
       $AdminControl setAttribute $ts traceSpecification com.ibm.*=all=enabled
       ```
     - Using Jython:
       ```
       AdminControl.setAttribute(ts, 'traceSpecification', 'com.ibm.*=all=enabled')
       ```
   - To turn tracing off, perform the following step:
     - Using Jacl:
       ```
       $AdminControl setAttribute $ts traceSpecification com.ibm.*=all=disabled
       ```
     - Using Jython:
       ```
       AdminControl.setAttribute(ts, 'traceSpecification', 'com.ibm.*=all=disabled')
       ```

Dumping threads in server processes using scripting

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

Use the AdminControl object to dump the Java threads of a running server. The following example produces a Java core file. You can use this file for problem determination.

- Using Jacl:

```
set jvm [$AdminControl completeObjectName type=JVM,process=server1,*]
$AdminControl invoke $jvm dumpThreads
```

- Using Jython:

```
jvm = AdminControl.completeObjectName('type=JVM,process=server1,*')
AdminControl.invoke(jvm, 'dumpThreads')
```

Setting up profile scripts to make tracing easier using scripting

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 250 article for more information.

Set up a profile script to make tracing easier. The following profile script example turns tracing on and off for `server1`:

- Using Jacl:

```
proc ton {} {
  global AdminControl
  set ts [$AdminControl queryNames type=TraceService,node=mynode,process=server1,*]
  $AdminControl setAttribute $ts traceSpecification com.ibm.=all=enabled
}

proc toff {} {
  global AdminControl
  set ts [$AdminControl queryNames type=TraceService,node=mynode,process=server1,*]
  $AdminControl setAttribute $ts traceSpecification com.ibm.*=all=disabled
}

proc dt {} {
  global AdminControl
  set jvm [$AdminControl queryNames type=JVM,node=mynode,process=server1,*]
  $AdminControl invoke $jvm dumpThreads
}
```

- Using Jython:

```
def ton():
       global lineSeparator
       ts = AdminControl.queryNames('type=TraceService,node=mynode,process=server1,*')

       AdminControl.setAttribute(ts, 'traceSpecification', 'com.ibm.=all=enabled')

def toff():
       global lineSeparator
       ts = AdminControl.queryNames('type=TraceService,node=mynode,process=server1,*')

       AdminControl.setAttribute(ts, 'traceSpecification', 'com.ibm.*=all=disabled')

def dt():
       global lineSeparator
       jvm = AdminControl.queryNames('type=JVM,node=mynode,process=server1,*')
       AdminControl.invoke(jvm, 'dumpThreads')
```

If you start the wsadmin tool with this profile script, you can use the **ton** command to turn on tracing in the server, the **toff** command to turn off tracing, and the **dt** command to dump the Java threads. For more information about running scripting commands in a profile script, see the “Starting the wsadmin scripting client” on page 250 article.

Scripting reference material

This topic contains the following tasks:

- “Wsadmin tool”
- “Commands for the AdminConfig object” on page 375
- “Commands for the AdminControl object” on page 396
- “Commands for the AdminApp object” on page 415
- “Commands for the AdminTask object” on page 489
- “Administrative command invocation syntax” on page 623
- “Commands for the Help object” on page 362
- “Properties used by scripted administration” on page 624

Wsadmin tool

The WebSphere Application Server wsadmin tool runs scripts. You can use the wsadmin tool to manage WebSphere Application Server as well as the configuration, application deployment, and server run-time operations.

The command-line invocation syntax for the wsadmin scripting client is as follows:

```
wsadmin [-h(help)]

[-?]

[-c <commands>]

[-p <properties_file_name>]

[-profile <profile_script_name>]

[-profileName <profile_name>]

[-f <script_file_name>]

[-javaoption java_option]

[-lang language]

[-wsadmin_classpath classpath]

[-conntype SOAP [-host host_name] [-port port_number] [-user userid] [-password password] |

     RMI [-host host_name] [-port port_number] [-user userid] [-password password] |

     NONE
]

[script parameters]
```

Where *script parameters* represent any arguments other than the ones listed previously. The argc variable contains the argument number, and the argv variable contains the contents.

Options

-c Designates to run a single command.

Multiple -c options can exist on the command line. They run in the order that you designate. You must save after using this command.

-f Designates a script to run.

Only one -f option can exist on the command line.

-javaoption
Specifies a valid Java standard or a non-standard option.

Multiple -javaoption options can exist on the command line.

-lang
Specifies the language of the script file, the command, or an interactive shell. The possible languages include: Jacl and Jython. The options for the -lang argument include: jacl and jython.

This option overrides language determinations that are based on a script file name, or the com.ibm.ws.scripting.defaultLang property. The `-lang` argument has no default value. If the command line or the property does not supply the script language, and the wsadmin tool cannot determine it, an error message generates. This argument is required if not determined from the script file name.

-p
Specifies a properties file.

The file listed after -p, represents a Java properties file that the scripting process reads. Three levels of default properties files load before the properties file that you specify on the command line. The first level is the installation default, `wsadmin.properties`, which is located in the WebSphere Application Server `properties` directory. The second level is the user default, `wsadmin.properties`, which is located in your `home` directory. The third level is the properties file that the environment variable `WSADMIN_PROPERTIES` points to.

Multiple -p options can exist on the command line. They invoke in the order that you supply them.

-profile
Specifies a profile script.

The profile script runs before other commands, or scripts. If you specify `-c`, the profile script runs before it invokes this command. If you specify `-f`, the profile script runs before it runs the script. In interactive mode, you can use the profile script to perform any standard initialization that you want. You can specify multiple -profile options on the command line, and they invoke in the order that you supply them.

-profileName
Specifies the profile from which the wsadmin tool will run. Specify this option if one the following reasons apply:

- You run the wsadmin tool from the `WAS_HOME/bin` directory and you do not have a default profile or you want to run in a profile other than the default profile.
- You are currently in a profile `bin` directory but want to run the wsadmin tool from a different profile.

-?
Provides syntax help.

-help
Provides syntax help.

-conntype
Specifies the type of connection to use.

This argument consists of a string that determines the type, for example, SOAP, and the options that are specific to that connection type. Possible types include: `SOAP`, `RMI`, and `NONE`.

Use the -conntype NONE option to run in local mode. The result is that the scripting client is not connected to a running server. You can manage server configuration, the installation and the uninstallation of applications without the application server running.

-wsadmin_classpath

Use this option to make additional classes available to your scripting process.

Follow this option with a class path string. For example:

```
c:/MyDir/Myjar.jar;d:/yourdir/yourdir.jar
```

The class path is then added to the class loader for the scripting process.

You can also specify this option in a properties file that is used by the wsadmin tool. The property is com.ibm.ws.scripting.classpath. If you specify -wsadmin_classpath on the command line, the value of this property overrides any value that is specified in a properties file. The class path property and the command-line options are not concatenated.

-host

Specify a hostname to which wsadmin should attempt to connect. The default wsadmin.properties file located in the properties directory of each WebSphere profile provides localhost as the value of the host property if this option is not specified.

-password

Specify a password to be used by the connector to connect to the server if security is enabled in the server.

Warning: On UNIX system, the use of -password option may result in security exposure as the password information becomes visible to the system status program such as ps command which can be invoked by other user to display all the running processes. Do not use this option if security exposure is a concern. Instead, specify user and password information in the soap.client.props file for SOAP connector or sas.client.props file for RMI connector. The soap.client.props and sas.client.props files are located in the properties directory of your WebSphere profile.

-username

Specify a user name to be used by the connector to connect to the server if security is enabled in the server.

-port

Specify a port to be used by the connector. The default wsadmin.properties file located in the properties directory of each WebSphere Application Server profile provides a value in the port property to connect to the local server.

In the following syntax examples, *mymachine* is the name of the host in the `wsadmin.properties` file that is specified by the com.ibm.ws.scripting.port property:

SOAP connection to the local host

Use the options that are defined in the `wsadmin.properties` file.

SOAP connection to the *mymachine* host

Using Jacl:

```
wsadmin -f test1.jacl -profile setup.jacl -conntype SOAP -port mymachinesoapportnumber -host mymachine
```

Using Jython:

```
wsadmin -lang jython -f  test1.py -profile setup.py -conntype SOAP -port mymachinesoapportnumber -host mymachine
```

Initial and maximum Java heap size

Using Jacl:

```
wsadmin -javaoption -Xms128m -javaoption -Xmx256m -f test.jacl
```

Using Jython:

```
wsadmin -lang jython -javaoption -Xms128m -javaoption -Xmx256m -f test.py
```

RMI connection with security

Using Jacl:

```
wsadmin -conntype RMI -port  rmiportnumber -userid userid -password password
```

Using Jython:

```
wsadmin -lang jython -conntype RMI -port  rmiportnumber -userid userid -password password
```

Warning: On UNIX system, the use of -password option may result in security exposure as the password information becomes visible to the system status program such as ps command which can be invoked by other user to display all the running processes. Do not use this option if security exposure is a concern. Instead, specify user and password information in the soap.client.props file for SOAP connector or sas.client.props file for RMI connector. The soap.client.props and sas.client.props files are located in the properties directory of your WebSphere profile.

Local mode of operation to perform a single command

Using Jacl:

```
wsadmin -conntype NONE -c "$AdminApp uninstall app"
```

or

Using Jython:

```
wsadmin -lang jython -conntype NONE -c "AdminApp.uninstall('app')"
```

or

wsadmin tool performance tips: The following performance tips are for the wsadmin tool:

- If the deployment manager is running at a higher service maintenance level than that of the node agent, you must run the `wsadmin.sh` or the `wsadmin.bat` from the `bin` directory of the deployment manager.
- When you launch a script using the `wsadmin.bat` or the `wsadmin.sh` files, a new process is created with a new Java virtual machine (JVM) API. If you use scripting with multiple wsadmin **-c** commands from a batch file or a shell script, these commands run slower than if you use a single wsadmin **-f** command. The -f option runs faster because only one process and JVM API are created for installation and the Java classes for the installation load only once.

  The following example, illustrates running multiple application installation commands from a batch file:

  Using Jacl:

  ```
  wsadmin -c "$AdminApp install c:\\myApps\\App1.ear {-appname appl1}"
  wsadmin -c "$AdminApp install c:\\myApps\\App2.ear {-appname appl2}"
  wsadmin -c "$AdminApp install c:\\myApps\\App3.ear {-appname appl3}"
  ```

  or

  Using Jython:

  ```
  wsadmin -lang jython -c "AdminApp.install('c:\myApps\App1.ear', '[-appname appl1]')"
  wsadmin -lang jython -c "AdminApp.install('c:\myApps\App2.ear', '[-appname appl2]')"
  wsadmin -lang jython -c "AdminApp.install('c:\myApps\App3.ear', '[-appname appl3]')"
  ```

  or

  Or, for example, using Jacl, you can create the *appinst.jacl* file that contains the commands:

  ```
  $AdminApp install c:\\myApps\\App1.ear {-appname appl1}
  $AdminApp install c:\\myApps\\App2.ear {-appname appl2}
  $AdminApp install c:\\myApps\\App3.ear {-appname appl3}
  ```

  Invoke this file using the following command: `wsadmin -f` *`appinst.jacl`*

  Or using Jython, you can create the *appinst.py* file, that contains the commands:

  ```
  AdminApp.install('c:\myApps\App1.ear', '[-appname appl1]')
  AdminApp.install('c:\myApps\App2.ear', '[-appname appl2]')
  AdminApp.install('c:\myApps\App3.ear', '[-appname appl3]')
  ```

  Then invoke this file using the following command: `wsadmin -lang jython -f` *`appinst.py`*.
- Use the AdminControl **queryNames** and **completeObjectName** commands carefully with a large installation. For example, if only a few beans exist on a single machine, the `$AdminControl queryNames *` command performs well. If a scripting client connects to the deployment manager in a multiple machine environment, use a command only if it is necessary for the script to obtain a list of all the

MBeans in the system. If you need the MBeans on a node, it is easier to invoke "$AdminControl queryNames node=mynode,*". The JMX system management infrastructure forwards requests to the system to fulfill the first query, *. The second query, node=mynode,* is targeted to a specific machine.

- The WebSphere Application Server is a distributed system, and scripts perform better if you minimize remote requests. If some action or interrogation is required on several items, for example, servers, it is more efficient to obtain the list of items once and iterate locally. This procedure applies to the actions that the AdminControl object performs on running MBeans, and actions that the AdminConfig object performs on configuration objects.

Commands for the Help object

The Help object provides general help and dynamic online information about the currently running MBeans. You can use the Help object as an aid in writing and running scripts with the AdminControl object.

The following commands are available for the Help object:

Command name:	Description:	Parameters and return values:	Examples:

AdminApp	Provides a summary of all of the available methods for the AdminApp object.	• Parameters: none
		• Returns: string
			Example usage:
			Using Jacl:
			`$Help AdminApp`
			Using Jython:
			`print Help.AdminApp()`
			Example output:
			`WASX7095I: The AdminApp object`
			`allows application objects to`
			`be manipulated -- this includes`
			`installing, uninstalling, editing,`
			`and listing.  Most of the commands`
			`supported by AdminApp operate in two`
			`modes: the default mode is one`
			`in which AdminApp communicates with the`
			`WebSphere Application Server to accomplish`
			`its tasks.  A local mode is also`
			`possible, in which no server`
			`communication takes place.  The local`
			`mode of operation is invoked`
			`by bringing up the scripting client with`
			`no server connected using the command line`
			`"-conntype NONE" option or setting the`
			`"com.ibm.ws.scripting.connectionType=NONE"`
			`property in the wsadmin.properties.`
			
			`The following commands are supported`
			`by AdminApp; more detailed information`
			`about each of these commands`
			`is available by using the`
			`"help" command of AdminApp and`
			`supplying the name of the command`
			`as an argument.`
			
			`deleteUserAndGroupEntries`
			`Deletes all the user/group`
			`information for all the roles and all`
			`the username/password information for RunAs`
			`roles for a given application.`
			
			`edit Edit the properties of an application`
			
			`editInteractive Edit the properties`
			`of an application interactively`
			
			`export Export application to a file`
			
			`exportDDL Export DDL from`
			`application to a directory`
			
			`help Show help information`
			
			`install Installs an application,`
			`given a file name and an option string.`
			
			`installInteractive Installs an application`
			`in interactive mode, given a file name`
			`and an option string.`
			
			`list List all installed applications`

AdminApp continued			`listModules List the modules in a specified application`
			`options Shows the options available, either for a given file, or in general.`
			`publishWSDL Publish WSDL files for a given application`
			`taskInfo Shows detailed information pertaining to a given installation task for a given file`
			`uninstall Uninstalls an application, given an application name and an option string`
			`updateAccessIDs Updates the user/group binding information with accessID from user registry for a given application`
			`view View an application or module, given an application or module name`

AdminConfig	Provides a summary of all the available methods for the AdminConfig object.	• Parameters: None
		• Returns: string
			Example usage:
			Using Jacl:
			`$Help AdminConfig`
			Using Jython:
			`print Help.AdminConfig()`
			Example output:
			`WASX7053I: The following functions are supported by AdminConfig:`
			`create Creates a configuration object, given a type, a parent, and a list of attributes`
			`create Creates a configuration object, given a type, a parent, a list of attributes, and an attribute name for the new object`
			`remove Removes the specified configuration object`
			`list Lists all configuration objects of a given type`
			`list Lists all configuration objects of a given type, contained within the scope supplied`
			`show Show all the attributes of a given configuration object`
			`show Show specified attributes of a given configuration object`
			`modify Change specified attributes of a given configuration object`
			`getId Show the configId of an object, given a string version of its containment`
			`contents Show the objects which a given type contains`
			`parents Show the objects which contain a given type`
			`attributes Show the attributes for a given type`
			`types Show the possible types for configuration`
			`help Show help information`

AdminControl	Provides a summary of the help commands and ways to invoke an administrative command.	• Parameters: None
		• Returns: string
			Example usage:
			Using Jacl:
			`$Help AdminControl`
			Using Jython:
			`print Help.AdminControl()`
			Example output:
			`WASX7027I: The following functions are supported by AdminControl:`
			`getHost returns String representation of connected host`
			`getPort returns String representation of port in use`
			`getType returns String representation of connection type in use`
			`reconnect reconnects with server`
			`queryNames Given ObjectName and QueryExp, retrieves set of ObjectNames that match.`
			`queryNames Given String version of ObjectName, retrieves String of ObjectNames that match.`
			`getMBeanCount returns number of registered beans`
			`getDomainName returns "WebSphere"`
			`getDefaultDomain returns "WebSphere"`
			`getMBeanInfo Given ObjectName, returns MBeanInfo structure for MBean`
			`isInstanceOf Given ObjectName and class name, true if MBean is of that class`
			`isRegistered true if supplied ObjectName is registered`
			`isRegistered true if supplied String version of ObjectName is registered`
			`getAttribute Given ObjectName and name of attribute, returns value of attribute`
			`getAttribute Given String version of ObjectName and name of attribute, returns value of attribute`
			`getAttributes Given ObjectName and array of attribute names, returns AttributeList`
			`getAttributes Given String version of ObjectName and attribute names, returns String of name value pairs`

			setAttribute Given ObjectName and Attribute object, set attribute for MBean specified setAttribute Given String version of ObjectName, attribute name and attribute value, set attribute for MBean specified setAttributes Given ObjectName and AttributeList object, set attributes for the MBean specified invoke Given ObjectName, name of method, array of parameters and signature, invoke method on MBean specified invoke Given String version of ObjectName, name of method, String version of parameter list, invoke method on MBean specified. invoke Given String version of ObjectName, name of method, String version of parameter list, and String version of array of signatures, invoke method on MBean specified. makeObjectName Return an ObjectName built with the given string completeObjectName Return a String version of an object name given a template name trace Set the wsadmin trace specification help Show help information

<table>
<tr>
<td>AdminTask</td>
<td>Provides a summary of help commands and ways to invoke an administrative command.</td>
<td>

- Parameters: None
- Returns: string

</td>
<td>
Example usage:

Using Jacl:

```
$AdminTask help
```

Using Jython:

```
print AdminTask.help()
```

Example output:

```
WASX8001I: The AdminTask object enables the
 available administrative commands.
AdminTask commands operate in two modes:
the default mode is one which AdminTask
communicates with the WebSphere Application
 Server to accomplish its task. A local mode
is also available in which no server
communication takes place. The local mode of
operation is invoked by bringing up the
scripting client busing the command line
"-conntype NONE" option or setting the
"com.ibm.ws.scripting.connectiontype=NONE"
 property in wsadmin.properties file.

The number of administrative commands varies
and depends on your WebSphere Application
Server installation. Use the following help
commands to obtain a list of supported
commands and their parameters:

help -commands      list all the
 administrative commands
help -commandGroups    list all the
 administrative command groups
help commandName      display detailed
 information for the specified command
help commandName stepName display detailed
 information for the specified step
 belonging to the specified command
help commandGroupName   display detailed
 information for the specified command group

There are various flavors to invoke an
administrative  command. They are

commandName invokes an administrative
 command that does not require any argument.

commandName targetObject invokes an admin
 command with the target object string,
 for example the configuration object name
 of a resource adapter. The expected target
 object varies with the administrative
 command invoked. Use help command to get
 information on the target object of an
 administrative command.

commandName  options invokes an administrative
 command with the specified option strings.
 This invocation syntax is used to invoke
 an administrative command that does not
 require a target object. It is also used
 to enter interactive mode if "-interactive"
 mode is included in the options string.
```
</td>
</tr>
</table>

AdminTask continued			`commandName targetObject options invokes an administrative command with the specified target object and options strings. If "-interactive" is included in the options string, then interactive mode is entered. The target object and options strings vary depending on the admin command invoked. Use help command to get information on the target object and options.`

all	Provides a summary of the information that the MBean defines by name.	• Parameters: name - string
		• Returns: string
			Example usage:
			Using Jacl:
			`$Help all [$AdminControl queryNames type`
			`=TraceService,process=server1,node=pongo,*]`
			Using Jython:
			`print Help.all(AdminControl.queryNames`
			`('type=TraceService,process=server1,`
			`node=pongo,*'))`
			Example output:
			`Name: WebSphere:cell=pongo,name=`
			`TraceService,mbeanIdentifier=cells/`
			`pongo/nodes/pongo/servers/server1/`
			`server.xml#TraceService_1,`
			`type=TraceService,node=pongo,process=server1`
			`Description: null`
			`Class name:`
			`javax.management.modelmbean.RequiredModelMBean`
			
			`Attribute         Type      Access`
			`ringBufferSize       int       RW`
			`traceSpecification   java.lang.String   RW`
			
			`Operation`
			`int getRingBufferSize()`
			`void setRingBufferSize(int)`
			`java.lang.String getTraceSpecification()`
			`void setTraceState(java.lang.String)`
			`void appendTraceString(java.lang.String)`
			`void dumpRingBuffer(java.lang.String)`
			`void clearRingBuffer()`
			`[Ljava.lang.String;`
			`listAllRegisteredComponents()`
			`[Ljava.lang.String;`
			`listAllRegisteredGroups()`
			`[Ljava.lang.String;`
			`listComponentsInGroup(java.lang.String)`
			`[Lcom.ibm.websphere.ras.TraceElementState;`
			`getTracedComponents()`
			`[Lcom.ibm.websphere.ras.TraceElementState;`
			`getTracedGroups()`
			`java.lang.String getTraceSpecification`
			`   (java.lang.String)`
			`void processDumpString(java.lang.String)`
			`void checkTraceString(java.lang.String)`
			`void setTraceOutputToFile(java.lang.String,`
			`int, int, java.lang.String)`
			`void setTraceOutputToRingBuffer(int,`
			`java.lang.String)`
			`java.lang.String rolloverLogFileImmediate`
			`(java.lang.String, java.lang.String)`
			
			`Notifications`
			`jmx.attribute.changed`
			
			`Constructors`

attributes	Provides a summary of all the attributes that the MBean defines by name.	- Parameters: name - string
		- Returns: string
			Example usage:
			Using Jacl:
			`$Help attributes [$AdminControl queryNames type=TraceService,process=server1,node=pongo,*]`
			Using Jython:
			`print Help.attributes (AdminControl.queryNames('type=TraceService, process=server1,node=pongo,*'))`
			Example output:
			`Attribute Type Access`
			`ringBufferSize java.lang.Integer RW`
			`traceSpecification string RW`

classname	Provides a class name that the MBean defines by name.	- Parameters: name - string
		- Returns: string
			Example usage:
			Using Jacl:
			`$Help classname [$AdminControl queryNames type=TraceService,process=server1,node=pongo,*]`
			Using Jython:
			`print Help.classname(AdminControl.queryNames ('type=TraceService,process=server1,node=pongo,*'))`
			Example output:
			`javax.management.modelmbean.RequiredModelMBean`

constructors	Provides a summary of all of the constructors that the MBean defines by name.	- Parameters: name - string
		- Returns: string
			Example usage:
			Using Jacl:
			`$Help constructors [$AdminControl queryNames type=TraceService,process=server1,node=pongo,*]`
			Using Jython:
			`print Help.constructors (AdminControl.queryNames('type=TraceService, process=server1,node=pongo,*'))`
			Example output:
			`Constructors`

description	Provides a description that the MBean defines by name.	- Parameters: name - string
		- Returns: string
			Example usage:
			Using Jacl:
			`$Help description [$AdminControl queryNames type=TraceService,process=server1,node=pongo,*]`
			Using Jython:
			`print Help.description(AdminControl.queryNames ('type=TraceService,process=server1,node=pongo,*'))`
			Example output:
			`Managed object for overall server process.`

help	Provides a summary of all the available methods for the Help object.	• Parameters: None • Returns: string	Example output: WASX7028I: The Help object has two purposes: First, provide general help information for the bjects supplied by the wsadmin tool for scripting: Help, AdminApp, AdminConfig, and AdminControl. Second, provide a means to obtain interface information about the MBeans that run in the system. For this purpose, a variety of commands are available to get information about the operations,attributes, and other interface information about particular MBeans. The following commands are supported by Help; more detailed information about each of these commands is available by using the "help" command of Help and by supplying the name of the command as an argument. attributes given an MBean, returns help for attributes operations given an MBean, returns help for operations constructors given an MBean, returns help for constructors description given an MBean, returns help for description notifications given an MBean, returns help for notifications classname given an MBean, returns help for class name all given an MBean, returns help for all the previous help returns this help text AdminControl returns general help text for the AdminControl object AdminConfig returns general help text for the AdminConfig object AdminApp returns general help text for the AdminApp object AdminTask returns general help text for the AdminTask object wsadmin returns general help text for the wsadmin script launcher message given a message ID, returns an explanation and a user action

message	Displays information for a message ID.	• Parameters: message ID
		• Returns: string
			Example usage:
			Using Jacl:
			`$Help message CNTR0005W`
			Using Jython:
			`print Help.message('CNTR0005W')`
			Example output:
			`Explanation: The container was unable to passivate an enterprise bean due to exception {2}User action: Take action based upon message in exception {2}`

notifications	Provides a summary of all the notifications that the MBean defines by name.	• Parameters: name - string
		• Returns: string
			Example usage:
			Using Jacl:
			`$Help notifications [$AdminControl queryNames type=TraceService,process=server1, node=pongo,*]`
			Using Jython:
			`print Help.notifications (AdminControl.queryNames('type=TraceService, process=server1,node=pongo,*'))`
			Example output:
			`Notification`
			`websphere.messageEvent.audit`
			`websphere.messageEvent.fatal`
			`websphere.messageEvent.error`
			`websphere.seriousEvent.info`
			`websphere.messageEvent.warning`
			`jmx.attribute.changed`

operations	Provides a summary of all the operations that the MBean defines by name.	• Parameters: name - string
		• Returns: string
			Example usage:
			Using Jacl:
			`$Help operations [$AdminControl queryNames`
			`type=TraceService,process=server1,node=pongo,*]`
			Using Jython:
			`print Help.operations(AdminControl.queryNames`
			`('type=TraceService,process=server1,node=pongo,*'))`
			Example output:
			`Operation`
			`int getRingBufferSize()`
			`void setRingBufferSize(int)`
			`java.lang.String getTraceSpecification()`
			`void setTraceState(java.lang.String)`
			`void appendTraceString(java.lang.String)`
			`void dumpRingBuffer(java.lang.String)`
			`void clearRingBuffer()`
			`[Ljava.lang.String;`
			`listAllRegisteredComponents()`
			`[Ljava.lang.String;`
			`listAllRegisteredGroups()`
			`[Ljava.lang.String;`
			`listComponentsInGroup(java.lang.String)`
			`[Lcom.ibm.websphere.ras.TraceElementState;`
			`getTracedComponents()`
			`[Lcom.ibm.websphere.ras.TraceElementState;`
			`getTracedGroups()`
			`java.lang.String`
			`   getTraceSpecification(java.lang.String)`
			`void processDumpString(java.lang.String)`
			`void checkTraceString(java.lang.String)`
			`void setTraceOutputToFile(java.lang.String,`
			`int, int, java.lang.String)`
			`void setTraceOutputToRingBuffer`
			`(int, java.lang.String)`
			`java.lang.String rolloverLogFileImmediate`
			`(java.lang.String, java.lang.String)`

operations	Provides the signature of the opname operation for the MBean that is defined by name.	• Parameters: name - string, opname - string
		• Returns: string
			Example usage:
			Using Jacl:
			`$Help operations [$AdminControl queryNames`
			`type=TraceService,process=server1,node=pongo,*]`
			` processDumpString`
			Using Jython:
			`print Help.operations(AdminControl.queryNames`
			`('type=TraceService,process=server1,node=pongo,*'),`
			`'processDumpString')`
			Example output:
			`void processDumpString(string)`
			
			`Description: Write the contents of the Ras`
			`services ring buffer to the specified file.`
			
			`Parameters:`
			
			`Type         string`
			`Name         dumpString`
			`Description  A String in the specified format`
			`to process or null.`

Commands for the AdminConfig object

Use the AdminConfig object to invoke configuration commands and to create or change elements of the WebSphere Application Server configuration, for example, creating a data source.

You can start the scripting client without a running server, if you only want to use local operations. To run in local mode, use the -conntype NONE option to start the scripting client. You receive a message that you are running in the local mode. If a server is currently running, running the AdminConfig tool in local mode is not recommended. This is because any configuration changes made in local mode will not be reflected in the running server configuration and vice versa. If you save a conflicting configuration, you could corrupt the configuration. In a deployment manager environment, configuration updates are available only if a scripting client is connected to a deployment manager. When connected to a node agent or a managed application server, you will not be able to update the configuration because the configuration for these server processes are copies of the master configuration which resides in the deployment manager. The copies are created on a node machine when a configuration synchronization occurs between the deployment manager and the node agent. Make configuration changes to the server processes by connecting a scripting client to a deployment manager. For this reason, to change a configuration, do not run a scripting client in local mode on a node machine. It is not a supported configuration.

The following commands are available for the AdminConfig object:

Command name:	**Description:**	**Parameters and return values:**	**Examples:**

attributes	Returns a list of the top level attributes for a given type.	• Parameters: object type
		The name of the object type that you input here is the one based on the XML configuration files and does not have to be the same name that the administrative console displays.
		• Returns: A list of attributes.
			Example usage:
			Using Jacl:
			`$AdminConfig attributes ApplicationServer`
			Using Jython:
			`print AdminConfig.attributes`
			` ('ApplicationServer')`
			Example output:
			`"properties Property*" "serverSecurity`
			` ServerSecurity"`
			`"server Server@" "id Long" "stateManagement`
			` StateManageable"`
			`"name String" "moduleVisibility EEnumLiteral`
			` (MODULE,`
			`COMPATIBILITY, SERVER, APPLICATION)"`
			` "services Service*"`
			`"statisticsProvider StatisticsProvider"`

checkin	Checks a file that the document URI describes into the configuration repository.
	This method only applies to deployment manager configurations.
		• Parameters: document URI, filename, opaque object
		• Returns: None
			Example usage:
			Using Jacl:
			`$AdminConfig checkin`
			`cells/MyCell/Node/MyNode/serverindex.xml`
			`c:\\mydir\myfile $obj`
			Using Jython:
			`AdminConfig.checkin`
			`('cells/MyCell/Node/`
			`  MyNode/serverindex.xml',`
			`'c:\mydir\myfile',  obj)`
			The document URI is relative to the root of the configuration repository, for example, `c:\WebSphere\AppServer\config`.
			The file that is specified by `filename` is used as the source of the file to check. The *opaque* object is an object that the **extract** command of the AdminConfig object returns by a prior call.

convertToCluster	Converts a server so that it is the first member of a new server cluster.	• Parameters: server ID, cluster name
		• Returns: The configuration ID of the new cluster.
			Example usage:
			Using Jacl:
			`set serverid [$AdminConfig getid`
			`  /Server:myServer/]`
			`$AdminConfig convertToCluster`
			`  $serverid myCluster`
			Using Jython:
			`serverid = AdminConfig.getid`
			`  ('/Server:myServer/')`
			`AdminConfig.convertToCluster`
			`  (serverid, 'myCluster')`
			Example output:
			`myCluster`
			`(cells/mycell/clusters/myCluster|`
			`  cluster.xml#ClusterMember_2`

create	Creates configuration objects.	- Parameters using Jacl: type- string; parent ID- string; attributes- string
		- Parameters using Jython: type- string; parent ID- string; attributes- string or type- string; parent ID- string; attributes- Jython list
		- Returns: A string with configuration object names.
			The name of the object type that you input here is the one that is based on the XML configuration files. This name does not have to be the same name that the administrative console displays.
			Example usage:
			Using Jacl:
			`set jdbc1 [$AdminConfig getid`
			`  /JDBCProvider:jdbc1/]`
			`$AdminConfig create DataSource $jdbc1`
			`  {{name ds1}}`
			Using Jython with string attributes:
			`jdbc1 = AdminConfig.getid`
			`  ('/JDBCProvider:jdbc1/')`
			`AdminConfig.create('DataSource', jdbc1,`
			`  '[[name ds1]]')`
			Using Jython with object attributes:
			`jdbc1 = AdminConfig.getid`
			`  ('/JDBCProvider:jdbc1/')`
			`AdminConfig.create('DataSource', jdbc1,`
			`  [['name', 'ds1']])`
			Example output:
			`ds1(cells/mycell/nodes/DefaultNode/servers/server1|`
			`resources.xml#DataSource_6)`

createClusterMember	Creates a new server as a member of an existing cluster.
	This method creates a new server object on the node that the node id parameter specifies. This server is created as a new member of the existing cluster that is specified by the cluster id parameter, and contains attributes that are specified in the member attributes parameter. The server is created using the server template that is specified by the template id attribute, and that contains the name specified by the memberName attribute. The memberName attribute is required.
		• Parameters using Jacl: cluster ID- string; node ID- string; member attributes- string
		• Parameters using Jython: cluster ID- string; node ID- string; member attributes- string or cluster ID- string; node ID- string; member attributes- Jython list
		• Returns: The configuration ID of the new cluster member.
			The name of the object type that you input here is the one that is based on the XML configuration files. This name does not have to be the same name that the administrative console displays.
			Example usage:
			Using Jacl:
			`set clid [$AdminConfig getid`
			`/ServerCluster:myCluster/]`
			`set nodeid [$AdminConfig getid /Node:mynode/]`
			`$AdminConfig createClusterMember $clid`
			`$nodeid`
			`{{memberName newMem1} {weight 5}}`
			Using Jython with string attributes:
			`clid = AdminConfig.getid`
			`('/ServerCluster:myCluster/')`
			`nodeid = AdminConfig.getid('/Node:mynode/')`
			`AdminConfig.createClusterMember`
			`(clid, nodeid,`
			`'[[memberName newMem1] [weight 5]]')`
			Using Jython with object attributes:
			`clid = AdminConfig.getid('/ServerCluster:myCluster/')`
			`nodeid = AdminConfig.getid('/Node:mynode/')`
			`AdminConfig.createClusterMember(clid, nodeid,`
			`[['memberName', 'newMem1'], ['weight', 5]])`
			Example output:
			`myCluster`
			`(cells/mycell/clusters/myCluster|cluster.xml#`
			`ClusterMember_2)`

createDocument	Creates a new document in the configuration repository.
	The documentURI parameter names the document to create in the repository. The filename parameter must be a valid local file name where the contents of the document exist.
		• Parameters: documentURI, filename
		• Returns: None
			Example usage:
			Using Jacl:
			`$AdminConfig createDocument cells/mycell/myfile.xml`
			`c:\\mydir\\myfile`
			Using Jython:
			`AdminConfig.createDocument('cells/mycell/myfile.xml',`
			`'c:\mydir\myfile')`

createUsing Template	Creates a type of object with the given parent, using a template.	• Parameters using Jacl: type-string; parent id-string; attributes-string; template ID-string
		• Parameters using Jython: type-string; parent id- string; attributes-string; template ID-string or type-string; parent id-string; attributes-Jython list; template ID-string
		• Returns: The configuration ID of a new object.
			Example usage:
			Using Jacl:
			`set node [$AdminConfig getid /Node:`*mynode*`/]`
			`set templ [$AdminConfig listTemplates JDBCProvider`
			`"DB2 JDBC Provider (XA)"]`
			`$AdminConfig createUsingTemplate JDBCProvider $node`
			`{{name `*newdriver*`}} $templ`
			Using Jython using string attributes:
			`node = AdminConfig.getid('/Node:mynode/')`
			`templ = AdminConfig.listTemplates('JDBCProvider',`
			`"DB2 JDBC Provider (XA)")`
			`AdminConfig.createUsingTemplate('JDBCProvider',`
			` node, '[[name newdriver]]', templ)`
			Using Jython using object attributes:
			`node = AdminConfig.getid('/Node:mynode/')`
			`templ = AdminConfig.listTemplates('JDBCProvider',`
			`"DB2 JDBC Provider (XA)")`
			`AdminConfig.createUsingTemplate('JDBCProvider',`
			`node, [['name', 'newdriver']], templ)`

defaults	Displays the default values for attributes of a given type.
	This method displays all of the possible attributes contained by an object of a specific type. If the attribute has a default value, this method also displays the type and default value for each attribute.
		• Parameters: type
		The name of the object type that you input here is the one based on the XML configuration files. This name does not have to be the same name that the administrative console displays.
		• Returns: A string that contains a list of attributes with its type and value.
			Example usage:
			Using Jacl:
			`$AdminConfig defaults TuningParams`
			Using Jython:
			`print AdminConfig.defaults('TuningParams')`
			Example output:
			`Attribute                Type     Default`
			
			`usingMultiRowSchema      Boolean  false`
			`maxInMemorySessionCount  Integer  1000`
			`allowOverflow            Boolean  true`
			`scheduleInvalidation     Boolean  false`
			`writeFrequency           ENUM`
			`writeInterval            Integer  120`
			`writeContents            ENUM`
			`invalidationTimeout      Integer  30`
			`invalidationSchedule     InvalidationSchedule`

deleteDocument	Deletes a document from the configuration repository.
	The documentURI parameter names the document to delete from the repository.
		• Parameters: documentURI
		• Returns: None
			Example usage:
			Using Jacl:
			`$AdminConfig deleteDocument cells/mycell/myfile.xml`
			Using Jython:
			`AdminConfig.deleteDocument('cells/mycell/myfile.xml')`

existsDocument	Tests for the existence of a document in the configuration repository.
	The documentURI parameter names the document to test in the repository.
		• Parameters: documentURI
		• Returns: A true value, if the document exists.
			Example usage:
			Using Jacl:
			`$AdminConfig existsDocument cells/mycell/myfile.xml`
			Using Jython:
			`AdminConfig.existsDocument('cells/mycell/myfile.xml')`
			Example output:
			`1`

extract	Extracts a configuration repository file that is described by the document URI and places it in the file named by `filename`. This method only applies to deployment manager configurations.	• Parameters: document URI, filename
		• Returns: An opaue java.lang.Object to use when checking in the file.
			Example usage:
			Using Jacl:
			`set obj [$AdminConfig extract cells/MyCell/nodes/`
			`MyNode/serverindex.xml`
			`c:\\mydir\myfile]`
			Using Jython:
			`obj = AdminConfig.extract('cells/MyCell/nodes/`
			`MyNode/serverindex.xml',`
			`'c:\mydir\myfile')`
			The document URI is relative to the root of the configuration repository, for example, `c:\WebSphere\AppServer\config`.
			If the file that is specified by the filename parameter exists, the extracted file replaces it.

getCrossDocumentValidationEnabled	Returns a message with the current cross-document enablement setting.
	This method returns true if cross-document validation is enabled.
		• Parameters: None
		• Returns: A string that contains the message with the cross-document validation setting.
			Example usage:
			Using Jacl:
			`$AdminConfig getCrossDocumentValidationEnabled`
			Using Jython:
			`print AdminConfig.getCrossDocumentValidationEnabled()`
			Example output:
			`WASX7188I: Cross-document validation enablement set to`
			`true`

getid	Returns the configuration ID of an object.	• Parameters: containment path
		• Returns: The configuration ID for an object that is described by the containment path.
			Example usage:
			Using Jacl:
			`$AdminConfig getid /Cell:testcell/Node:testNode/`
			`JDBCProvider:Db2JdbcDriver/`
			Using Jython:
			`AdminConfig.getid('/Cell:testcell/Node:testNode/`
			`JDBCProvider:Db2JdbcDriver/')`
			Example output:
			`Db2JdbcDriver(cells/testcell/nodes/testnode|`
			`resources.xml#JDBCProvider_1)`

getObjectName	Returns a string version of the object name for the corresponding running MBean.
	This method returns an empty string if no corresponding running MBean exists.
		- Parameters: configuration ID
		- Returns: A string that contains the object name.
			Example usage:
			Using Jacl:
			`set server [$AdminConfig getid /Node:mynode/Server:server1/]`
			`$AdminConfig getObjectName $server`
			Using Jython:
			`server = AdminConfig.getid('/Node:mynode/Server:server1/')`
			`AdminConfig.getObjectName(server)`
			Example output:
			`WebSphere:cell=mycell,name=server1,mbeanIdentifier=cells/`
			`mycell/nodes/mynode/servers/server1/server.xml#Server_1,`
			`type=Server,node=mynode,process=server1,processType=`
			`UnManagedProcess`

getSaveMode	Returns the mode that is used when you invoke a **save** command.
	Possible values include the following:
	- overwriteOnConflict - Saves changes even if they conflict with other configuration changes
	- rollbackOnConflict - Causes a save operation to fail if changes conflict with other configuration changes. This value is the default.
		- Parameters: None
		- Returns: A string that contains the current save mode setting.
			Example usage:
			Using Jacl:
			`$AdminConfig getSaveMode`
			Using Jython:
			`print AdminConfig.getSaveMode()`
			Example output:
			`rollbackOnConflict`

getValidationLevel	Returns the validation used when files are extracted from the repository.	• Parameters: None
		• Returns: A string that contains the validation level.
			Example usage:
			Using Jacl:
			`$AdminConfig getValidationLevel`
			Using Jython:
			`AdminConfig.getValidationLevel()`
			Example output:
			`WASX7189I: Validation level set to HIGH`

getValidation SeverityResult	Returns the number of validation messages with the given severity from the most recent validation.	• Parameters: severity
		• Returns: A string that indicates the number of validation messages of the given severity.
			Example usage:
			Using Jacl:
			`$AdminConfig getValidationSeverityResult 1`
			Using Jython:
			`AdminConfig.getValidationSeverityResult(1)`
			Example output:
			`16`

hasChanges	Returns `true` if unsaved configuration changes exist.	• Parameters: None
		• Returns: A string that indicates whether unsaved configuration changes exist.
			Example usage:
			Using Jacl:
			`$AdminConfig hasChanges`
			Using Jython:
			`AdminConfig.hasChanges()`
			Example output:
			`1`

help	Displays static help information for the AdminConfig object.	• Parameters: None
		• Returns: A list of options.
			Example usage:
			Using Jacl:
			`$AdminConfig help`
			Using Jython:
			`print AdminConfig.help()`
			Example output:
			`WASX7053I: The AdminConfig object communicates with the`
			`configuration service in a WebSphere Application Server`
			`to manipulate configuration data`
			`for an Application Server installation.  The AdminConfig`
			`object has commands to list, create,`
			`remove, display, and modify configuration data, as well`
			`as commands to display information about configuration`
			`data types.`
			
			`Most of the commands supported by the AdminConfig object`
			`operate in two modes:`
			`the default mode is one in which the AdminConfig object`
			`communicates with the Application Server to accomplish`
			` its tasks.  A local mode is also possible, in which no`
			`server communication takes place.  The local mode of`
			`operation is invoked by bringing up the scripting client`
			`without a server connected using the command line`
			`"-conntype NONE" option or setting the`
			`"com.ibm.ws.scripting.connectionType=NONE" property in`
			`the wsadmin.properties file.`
			
			`The following commands are supported by the AdminConfig`
			`object; more detailed information about each of these`
			`commands is available by using the help command of the`
			`AdminConfig object and by supplying the name of the`
			`command as an argument.`
			
			`attributes      Shows the attributes for a given type`
			`checkin         Checks a file into the configuration`
			`          repository.`
			`convertToCluster`
			`                Converts a server to be the first member`
			`         of a new server cluster`
			`create          Creates a configuration object, given`
			`         a type, a parent, and a list of attributes,`
			`         and optionally an attribute name for the`
			`                new object`
			`createClusterMember`
			`                Creates a new server that is a member of an`
			`                existing cluster.`
			`createDocument  Creates a new document in the configuration`
			`         repository.`
			`installResourceAdapter`
			`                Installs a J2C resource adapter with the`
			`         given RAR file name and an option string`
			`         in the node.`
			`createUsingTemplate`
			`            Creates an object using a particular`
			`         template type.`
			`defaults      Displays the default values for the`
			`         attributes of a given type.`
			`deleteDocument  Deletes a document from the configuration`
			`         repository.`
			`existsDocument  Tests for the existence of a document in`
			`         the configuration repository.`

help continued			extract Extracts a file from the configuration repository. getCrossDocumentValidationEnabled Returns true if cross-document validation is enabled. getid Show the configuration ID of an object, given a string version of its containment getObjectName Given a configuration ID, returns a string version of the ObjectName for the corresponding running MBean, if any. getSaveMode Returns the mode used when "save" is invoked getValidationLevel Returns the validation that is used when files are extracted from the repository. getValidationSeverityResult Returns the number of messages of a given severity from the most recent validation. hasChanges Returns true if unsaved configuration changes exist help Shows help information list Lists all the configuration objects of a given type listTemplates Lists all the available configuration templates of a given type. modify Changes the specified attributes of a given configuration object parents Shows the objects which contain a given type queryChanges Returns a list of unsaved files remove Removes the specified configuration object required Displays the required attributes of a given type. reset Discards the unsaved configuration changes save Commits the unsaved changes to the configuration repository setCrossDocumentValidationEnabled Sets the cross-document validation enabled mode. setSaveMode Changes the mode used when "save" is invoked setValidationLevel Sets the validation used when files are extracted from the repository. show Shows the attributes of a given configuration object showall Recursively shows the attributes of a given configuration object, and all the objects that are contained within each attribute. showAttribute Displays only the value for the single attribute that is specified. types Shows the possible types for configuration validate Invokes validation

installResource Adapter	Installs a Java 2 Connector (J2C) resource adapter with the given Resource Adapter Archive (RAR) file name and an option string in the node.
	The RAR file name is the fully qualified file name that resides in the node that you specify. The valid options include the following options:
	• `rar.name`
	• `rar.desc`
	• `rar.archivePath`
	• `rar.classpath`
	• `rar.nativePath`
	• `rar.threadPoolAlias`
	• `rar.propertiesSet`
		• Parameters: RAR file name, node, options
		• Returns: The configuration ID of the new J2CResourceAdapter object.
			Example usage:
			Using Jacl:
			`$AdminConfig installResourceAdapter c:/rar/mine.rar mynode {-rar.name myResourceAdapter -rar.desc "My rar file"}`
			Using Jython:
			`print AdminConfig.installResourceAdapter('c:/rar/mine.rar', 'mynode', '[-rar.name myResourceAdapter -rar.desc "My rar file"]')`
			Example output:
			`myResourceAdapter(cells/mycell/nodes/mynode|resources.xml#J2CResourceAdapter_1)`

installResource Adapter continued	The rar.name option is the name for the J2C resource adapter. If you do not specify this option, the display name in the RAR deployment descriptor is used. If that name is not specified, the RAR file name is used. The rar.desc option is a description of the J2CResourceAdapter. The rar.archivePath is the name of the path where you extract the file. If you do not specify this option, the archive is extracted to the $\{CONNECTOR_INSTALL_ROOT\} directory. The rar.classpath option is the additional class path. rar.propertiesSet is constructed with the following: name String value String type String *desc String *required true/false * means the item is optional Each attribute of the property are specified in a set of {}. A property is specified in a set of {}. You can specify multiple properties in {}.		

installResource Adapter continued	When you edit the installed application with the embedded RAR, only existing J2C connection factory, J2C activation specs, and J2C administrative objects will be edited. No new J2C objects will be created.		

list	Returns a list of objects of a given type, possibly scoped by a parent.	- Parameters: Object type
		The name of the object type that you input here is the one that is based on the XML configuration files and does not have to be the same name that the administrative console displays.
		- Returns: A list of objects.
			Example usage:
			Using Jacl:
			`$AdminConfig list JDBCProvider`
			Using Jython:
			`print AdminConfig.list('JDBCProvider')`
			Example output:
			`Db2JdbcDriver(cells/mycell/nodes/DefaultNode|`
			`  resources.xml#JDBCProvider_1)`
			`Db2JdbcDriver(cells/mycell/nodes/DefaultNode/servers/`
			`  deploymentmgr|`
			`resources.xml#JDBCProvider_1)`
			`Db2JdbcDriver(cells/mycell/nodes/DefaultNode/servers/`
			`nodeAgent|resources.xml#JDBCProvider_1)`

listTemplates	Displays a list of template object IDs.	- Parameters: object type
		The name of the object type that you input here is the one that is based on the XML configuration files and does not have to be the same name that the administrative console displays.
		- Returns: A list of template IDs.
			Example usage:
			Using Jacl:
			`$AdminConfig listTemplates JDBCProvider`
			Using Jython:
			`print AdminConfig.listTemplates('JDBCProvider')`
			This example displays a list of all the JDBCProvider templates that are available on the system.

<table>
<tr><td>modify</td><td>Supports the modification of object attributes.</td><td>• Parameters using Jacl: object-string; attributes-string
• Parameters using Jython: object-string; attributes-string or object-string; attributes-Jython list
• Returns: None</td><td>Example usage:
Using Jacl:
$AdminConfig modify ConnFactory1(cells/mycell/nodes/ DefaultNode/servers/ deploymentmgr|resources.xml#GenericJMSConnectionFactory_1) {{userID newID} {password newPW}}
Using Jython with string attributes:
AdminConfig.modify('ConnFactory1(cells/mycell/nodes/ DefaultNode/servers/ deploymentmgr|resources.xml#GenericJMSConnectionFactory_1)', '[[userID newID] [password newPW]]')
Using Jython with object attributes:
AdminConfig.modify('ConnFactory1(cells/mycell/nodes/ DefaultNode/servers/ deploymentmgr|resources.xml#GenericJMSConnectionFactory_1)', [['userID', 'newID'], ['password', 'newPW']])</td></tr>
<tr><td>parents</td><td>Obtains information about object types.</td><td>• Parameters: object type
The name of the object type that you input here is the one that is based on the XML configuration files and does not have to be the same name that the administrative console displays.
• Returns: A list of object types.</td><td>Example usage:
Using Jacl:
$AdminConfig parents JDBCProvider
Using Jython:
AdminConfig.parents('JDBCProvider')
Example output:
Cell
Node
Server</td></tr>
<tr><td>queryChanges</td><td>Returns a list of unsaved configuration files.</td><td>• Parameters: None
• Returns: A string that contains a list of files with unsaved changes.</td><td>Example usage:
Using Jacl:
$AdminConfig queryChanges
Using Jython:
AdminConfig.queryChanges()
Example output:
WASX7146I: The following configuration files contain unsaved changes:
cells/mycell/nodes/mynode/servers/server1|resources.xml</td></tr>
<tr><td>remove</td><td>Removes a configuration object.</td><td>• Parameters: Object
• Returns: None</td><td>Example usage:
Using Jacl:
$AdminConfig remove ds1(cells/mycell/nodes/DefaultNode/ servers/server1:resources.xml#DataSource_6)
Using Jython:
AdminConfig.remove('ds1(cells/mycell/nodes/DefaultNode/ servers/server1:resources.xml#DataSource_6)')</td></tr>
</table>

required	Displays the required attributes that are contained by an object of a certain type.	• Parameters: Type
		The name of the object type that you input here is the one that is based on the XML configuration files. It does not have to be the same name that the administrative console displays.
		• Returns: A string that contains a list of the required attributes with its type.
			Example usage:
			Using Jacl:
			`$AdminConfig required URLProvider`
			Using Jython:
			`print AdminConfig.required('URLProvider')`
			Example output:
			`Attribute                        Type`
			`streamHandlerClassName           String`
			`protocol                         String`

reset	Resets the temporary workspace that holds updates to the configuration.	• Parameters: None
		• Returns: None
			Example usage:
			Using Jacl:
			`$AdminConfig reset`
			Using Jython:
			`AdminConfig.reset()`

save	Saves changes in the configuration repository.	• Parameters: None
		• Returns: None
			Example usage:
			Using Jacl:
			`$AdminConfig save`
			Using Jython:
			`AdminConfig.save()`

setCrossDocumentValidationEnabled	Sets the cross-document validation enabled mode. Values include `true` or `false`.	• Parameters: Flag
		• Returns: None
			Example usage:
			Using Jacl:
			`$AdminConfig setCrossDocumentValidationEnabled true`
			Using Jython:
			`AdminConfig.setCrossDocumentValidationEnabled('true')`

setSaveMode	Toggles the behavior of the **save** command. The default value is `rollbackOnConflict`. When a conflict is discovered while saving, the unsaved changes are not committed. The alternative value is `overwriteOnConflict`, which saves the changes to the configuration repository even if conflicts exist.	• Parameters: Mode
		• Returns: None
			Example usage:
			Using Jacl:
			`$AdminConfig setSaveMode overwriteOnConflict`
			Using Jython:
			`AdminConfig.setSaveMode('overwriteOnConflict')`

setValidationLevel	Sets the validation that is used when files are extracted from the repository.
	Five validation levels are available: `none`, `low`, `medium`, `high`, or `highest`.
		• Parameters: Level
		• Returns: A string that contains the validation level setting.
			Example usage:
			Using Jacl:
			`$AdminConfig setValidationLevel high`
			Using Jython:
			`AdminConfig.setValidationLevel('high')`
			Example output:
			`WASX7189I: Validation level set to HIGH`

show	Returns the top-level attributes of the given object.	• Parameters: Object, attributes
		• Returns: A string that contains the attribute value.
			Example usage:
			Using Jacl:
			`$AdminConfig show Db2JdbcDriver(cells/mycell/ nodes/DefaultNode|resources.xm#JDBCProvider_1)`
			Example output with Jacl:
			`{name "Sample Datasource"} {description "Data source for the Sample entity beans"}`
			Using Jython:
			`print AdminConfig.show('Db2JdbcDriver(cells/mycell/nodes/ DefaultNode|resources.xm#JDBCProvider_1)')`
			Example output with Jython:
			`[name "Sample Datasource"] [description "Data source for the Sample entity beans"]`

showall	Recursively shows the attributes of a given configuration object.	- Parameters: Object, attributes
		- Returns: A string that contains the attribute value.
			Example usage:
			
			Using Jacl:
			
			$AdminConfig showall "Default Datasource(cells/mycell/
			nodes/DefaultNode/servers/server1:resources.xml#
			DataSource_1)
			
			Example output with Jacl:
			
			{authMechanismPreference BASIC_PASSWORD}
			{category default}
			{connectionPool {{agedTimeout 0}
			{connectionTimeout 1000}
			{maxConnections 30}
			{minConnections 1}
			{purgePolicy FailingConnectionOnly}
			{reapTime 180}
			{unusedTimeout 1800}}}
			{datasourceHelperClassname
			  com.ibm.websphere.rsadapter.CloudscapeDataStoreHelper}
			{description "Datasource for the WebSphere Default
			  Application"}
			{jndiName DefaultDatasource}
			{name "Default Datasource"}
			{propertySet {{resourceProperties {{{description
			"Location of Cloudscape default database."}
			{name databaseName}
			{type string}
			{value ${WAS_INSTALL_ROOT}/bin/DefaultDB}}
			  {{name remoteDataSourceProtocol}
			{type string}
			{value {}}} {{name shutdownDatabase}
			{type string}
			{value {}}} {{name dataSourceName}
			{type string}
			{value {}}} {{name description}
			{type string}
			{value {}}} {{name connectionAttributes}
			{type string}
			{value {}}} {{name createDatabase}
			{type string}
			{value {}}}}}}}
			{provider "Cloudscape JDBC Driver(cells/pongo/nodes/pongo/
			servers/server1|resources.xml#JDBCProvider_1)"}
			{relationalResourceAdapter "WebSphere Relational
			  Resource Adapter(cells/pongo/
			nodes/pongo/servers/server1|resources.xml#builtin_rra)"}
			{statementCacheSize 0}
			
			Using Jython:
			
			AdminConfig.showall("Default Datasource(cells/mycell/nodes/
			DefaultNode/servers/server1:resources.xml#DataSource_1)")
			
			Example output with Jython:
			
			 [authMechanismPreference BASIC_PASSWORD]
			[category default]
			[connectionPool [[agedTimeout []]
			[connectionTimeout 1000]
			[maxConnections 30]
			[minConnections 1]
			[purgePolicy FailingConnectionOnly]
			[reapTime 180]
			[unusedTimeout 1800]]]
			[datasourceHelperClassname
			 com.ibm.websphere.rsadapter.CloudscapeDataStoreHelper]
			[description "Datasource for the WebSphere Default
			 Application"]
			[jndiName DefaultDatasource]
			[name "Default Datasource"]

showall continued			[propertySet [[resourceProperties [[[description "Location of Cloudscape default database."] [name databaseName] [type string] [value ${WAS_INSTALL_ROOT}/bin/DefaultDB]] [[name remoteDataSourceProtocol] [type string] [value []]] [[name shutdownDatabase] [type string] [value []]] [[name dataSourceName] [type string] [value []]] [[name description] [type string] [value []]] [[name connectionAttributes] [type string] [value []]] [[name createDatabase] [type string] [value []]]]]]] [provider "Cloudscape JDBC Driver(cells/pongo/nodes/pongo/ servers/server1|resources.xml#JDBCProvider_1)"] [relationalResourceAdapter "WebSphere Relational Resource Adapter(cells/pongo/nodes/pongo/servers/server1| resources.xml#builtin_rra)"] [statementCacheSize 0]

showAttribute	Displays only the value for the single attribute that you specify.
	The output of this command is different from the output of the **show** command when a single attribute is specified. The **showAttribute** command does not display a list that contains the attribute name and value. It only displays the attribute value.
		• Parameters: Configuration ID, attribute
		• Returns: A string that contains the attribute value.
			Example usage:
			Using Jacl:
			`set ns [$AdminConfig getid /Node:mynode/]`
			`$AdminConfig showAttribute $ns hostName`
			Using Jython:
			`ns = AdminConfig.getid('/Node:mynode/')`
			`print AdminConfig.showAttribute(ns, 'hostName')`
			Example output:
			`mynode`

types	Returns a list of the configuration object types that you can manipulate.	• Parameters: None
		• Returns: A list of object types.
			Example usage:
			Using Jacl:
			`$AdminConfig types`
			Using Jython:
			`print AdminConfig.types()`
			Example output:
			`AdminService`
			`Agent`
			`ApplicationConfig`
			`ApplicationDeployment`
			`ApplicationServer`
			`AuthMechanism`
			`AuthenticationTarget`
			`AuthorizationConfig`
			`AuthorizationProvider`
			`AuthorizationTableImpl`
			`BackupCluster`
			`CMPConnectionFactory`
			`CORBAObjectNameSpaceBinding`
			`Cell`
			`CellManager`
			`Classloader`
			`ClusterMember`
			`ClusteredTarget`
			`CommonSecureInteropComponent`

uninstallResourceAdapter	Uninstalls a Java 2 Connector (J2C) resource adapter with the given J2C resource adapter configuration ID and an option list.
	One option is valid for this command: * `force`
	This option forces the uninstallation of the resource adapter without checking whether the resource adapter is being used by an application. The application that is using it will not be uninstalled. If you do not specify the force option and the specified resource adapter is still in use, the resource adapter is not uninstalled.
		• Parameters: J2C resource adapter configuration ID, list of options
		• Returns: The configuration ID of J2CResourceAdapter object that is removed.
			Example usage:
			Using Jacl:
			`set j2cra [$AdminConfig getid /J2CResourceAdapter:MyJ2CRA/]`
			`$AdminConfig uninstallResourceAdapter $j2cra {-force}`
			`$AdminConfig save`
			Using Jython:
			`j2cra = AdminConfig.getid('/J2CResourceAdapter:MyJ2CRA/')`
			`print AdminConfig.uninstallResourceAdapter(j2cra, '[-force]')`
			`AdminConfig.save()`
			Example output:
			`WASX7397I: The following J2CResourceAdapter objects are removed:`
			`MyJ2CRA(cells/juniarti/nodes/juniarti|`
			`resources.xml#J2CResourceAdapter_1069433028609)`

uninstallResource Adapter continued	When you remove a J2CResourceAdapter object from the configuration repository, the installed directory will be removed at the time of synchronization. A stop request will be sent to the J2CResourceAdapter MBean that was removed.		

validate	Invokes validation.
	This command requests configuration validation results based on the files in your workspace, the value of the cross-document validation enabled flag, and the validation level setting. Optionally, you can specify a configuration ID to set the scope. If you specify a configuration ID, the scope of this request is the object named by the config id parameter.
		• Parameters: config id (optional)
		• Returns: A string that contains results of the validation.
			Example usage:
			Using Jacl:
			`$AdminConfig validate`
			Using Jython:
			`print AdminConfig.validate()`
			Example output:
			`WASX7193I: Validation results are logged in c:\WebSphere5\ AppServer\logs\wsadmin.valout: Total number of messages: 16 WASX7194I: Number of messages of severity 1: 16`

Commands for the AdminControl object

Use the AdminControl object to invoke operational commands that deal with running objects in the WebSphere Application Server. Many of the AdminControl commands have multiple signatures so that they can either invoke in a raw mode using parameters that are specified by Java Management Extensions (JMX), or by using strings for parameters. In addition to operational commands, the AdminControl object supports some utility commands for tracing, reconnecting with a server, and converting data types.

The following commands are available for the AdminControl object:

Command name:	Description:	Parameters and return values:	Examples:

completeObjectName	Creates a string representation of a complete ObjectName value that is based on a fragment. This command does not communicate with the server to find a matching ObjectName value. If it finds several MBeans that match the fragment, the command returns the first one.	• Parameters: name-java.lang.String
		• Returns: java.lang.String
			Example usage:
			Using Jacl:
			`set serverON [$AdminControl completeObjectName node=mynode,type=Server,*]`
			Using Jython:
			`serverON = AdminControl.completeObjectName ('node=mynode,type=Server,*')`

getAttribute	Returns the value of the attribute for the name that you provide.	• Parameters: name-java.lang.String; attribute-java.lang.String
		• Returns: java.lang.String
			Example usage:
			Using Jacl:
			`set objNameString [$AdminControl completeObjectName WebSphere:type=Server,*]`
			`$AdminControl getAttribute $objNameString processType`
			Using Jython:
			`objNameString = AdminControl.completeObjectName ('WebSphere:type=Server,*')`
			`AdminControl.getAttribute(objNameString, 'processType')`

getAttribute_jmx	Returns the value of the attribute for the name that you provide.	• Parameters: name-ObjectName; attribute-java.lang.String
		• Returns: java.lang.String
			Example usage:
			Using Jacl:
			`set objNameString [$AdminControl`
			` completeObjectName WebSphere:type=Server,*]`
			`set objName [java::new`
			`  javax.management.ObjectName`
			` $objNameString]`
			`$AdminControl getAttribute_jmx`
			` $objName processType`
			Using Jython:
			`objNameString =`
			`  AdminControl.completeObjectName`
			`('WebSphere:type=Server,*')`
			`import  javax.management  as  mgmt`
			`objName =  mgmt.ObjectName(objNameString)`
			`AdminControl.getAttribute_jmx(objName,`
			`'processType')`

getAttributes	Returns the attribute values for the names that you provide.	• Parameters using Jacl: name-String; attributes-java.lang.String
		• Parameters using Jython: name-String; attributes-java.lang.String or name-String; attributes-java.lang.Object[]
		• Returns: java.lang.String
			Example usage:
			Using Jacl:
			`set objNameString [$AdminControl`
			` completeObjectName WebSphere:type=Server,*]`
			`$AdminControl getAttributes $objNameString`
			` "cellName nodeName"`
			Using Jython with string attributes:
			`objNameString =`
			`  AdminControl.completeObjectname`
			` ('WebSphere:type=Server,*)`
			`AdminControl.getAttributes(objNameString,`
			` '[cellName nodeName]')`
			Using Jython with object attributes:
			`objNameString =`
			` AdminControl.completeObjectname`
			` ('WebSphere:type=Server,*)`
			`AdminControl.getAttributes(objNameString,`
			` ['cellName', 'nodeName'])`

getAttributes_jmx	Returns the attribute values for the names that you provide.	• Parameters: name-ObjectName; attributes-java.lang.String[]
		• Returns: javax.management.AttributeList
			Example usage:
			Using Jacl:
			`set objectNameString [$AdminControl`
			` completeObjectName WebSphere:type=Server,*]`
			`set objName [$AdminControl makeObjectName`
			` $objectNameString]`
			`set attrs [java::new {String[]} 2`
			` {cellName nodeName}]`
			`$AdminControl getAttributes_jmx $objName`
			` $attrs`
			Using Jython:
			`objectNameString = AdminControl.completeObjectName`
			` ('type=Server,*')`
			`objName = AdminControl.makeObjectName`
			` (objectNameString)`
			`attrs = ['cellName', 'nodeName']`
			`AdminControl.getAttributes_jmx(objName,`
			` attrs)`

getCell	Returns the name of the connected cell.	- Parameters: None
		- Returns: java.lang.String
			Example usage:
			Using Jacl:
			`$AdminControl getCell`
			Using Jython:
			`AdminControl.getCell()`
			Example output:
			`Mycell`

getConfigId	Creates a configuration ID from an ObjectName or an ObjectName fragment. Use this ID with the `$AdminConfig` command. Not all MBeans that run have configuration objects that correspond. If several MBeans correspond to an ObjectName fragment, a warning is created and a configuration ID builds for the first MBean it finds.	- Parameters: name-java.lang.String
		- Returns: java.lang.String
			Example usage:
			Using Jacl:
			`set threadpoolCID [$AdminControl getConfigId node=mynode,type=ThreadPool,*]`
			Using Jython:
			`threadpoolCID = AdminControl.getConfigId ('node=mynode,type=ThreadPool,*')`

getDefaultDomain	Returns the default domain name from the server.	- Parameters: None
		- Returns: java.lang.String
			Example usage:
			Using Jacl:
			`$AdminControl getDefaultDomain`
			Using Jython:
			`AdminControl.getDefaultDomain()`
			Example output:
			`WebSphere`

getDomainName	Returns the domain name from the server.	• Parameters: None
		• Returns: java.lang.String
			Example usage:
			Using Jacl:
			`$AdminControl getDomainName`
			Using Jython:
			`AdminControl.getDomainName()`
			Example output:
			`WebSphere`

getHost	Returns the name of your host.	• Parameters: None
		• Returns: java.lang.String
			Example usage:
			Using Jacl:
			`$AdminControl getHost`
			Using Jython:
			`AdminControl.getHost()`
			Example output:
			`myhost`

getMBeanCount	Returns the number of MBeans that are registered in the server.	• Parameters: None
		• Returns: java.lang.Integer
			Example usage:
			Using Jacl:
			`$AdminControl getMBeanCount`
			Using Jython:
			`AdminControl.getMBeanCount()`
			Example output:
			`114`

getMBeanInfo_jmx	Returns the Java Management Extension MBeanInfo structure that corresponds to an ObjectName value. No string signature exists for this command, because the Help object displays most of the information available from the **getMBeanInfo** command.	• Parameters: name-ObjectName
		• Returns: javax.management.MBeanInfo
			Example usage:
			Using Jacl:
			`set objectNameString [$AdminControl`
			` completeObjectName type=Server,*]`
			`set objName [$AdminControl makeObjectName`
			` $objectNameString]`
			`$AdminControl getMBeanInfo_jmx $objName`
			Using Jython:
			`objectNameString =`
			` AdminControl.completeObjectName('type=Server,*')`
			`objName = AdminControl.makeObjectName`
			` (objectNameString)`
			`AdminControl.getMBeanInfo_jmx(objName)`
			Example output:
			`javax.management.modelmbean.`
			` ModelMBeanInfoSupport@10dd5f35`

getNode	Returns the name of the connected node.	• Parameters: None
		• Returns: java.lang.String
			Example usage:
			Using Jacl:
			`$AdminControl getNode`
			Using Jython:
			`AdminControl.getNode()`
			Example output:
			`Myhost`

getPort	Returns the name of your port.	• Parameters: None
		• Returns: java.lang.String
			Example usage:
			Using Jacl:
			`$AdminControl getPort`
			Using Jython:
			`AdminControl.getPort()`
			Example output:
			`8877`

getPropertiesForDataSource	Deprecated, no replacement.
	This command incorrectly assumes the availability of a configuration service when running in connected mode.
		• Parameters: configId-java.lang.String
		• Returns: java.lang.String
			Example usage:
			Using Jacl:
			`set ds [lindex [$AdminConfig list DataSource] 0]`
			`$AdminControl getPropertiesForDataSource $ds`
			Using Jython:
			`ds = AdminConfig.list('DataSource')`
			
			`# get line separator`
			`import  java.lang.System  as  sys`
			`lineSeparator = sys.getProperty('line.separator')`
			
			`dsArray = ds.split(lineSeparator)`
			`AdminControl.getPropertiesForDataSource(dsArray[0])`
			Example output:
			`WASX7389E: Operation not supported -`
			` getPropertiesForDataSource command`
			`is not supported.`

getType	Returns the connection type.	• Parameters: None
		• Returns: java.lang.String
			Example usage:
			Using Jacl:
			`$AdminControl getType`
			Using Jython:
			`AdminControl.getType()`
			Example output:
			`SOAP`

help	Returns general help text for the AdminControl object.	• Parameters: None
		• Returns: java.lang.String
			Example usage:
			Using Jacl:
			`$AdminControl help`
			Using Jython:
			`AdminControl.help()`
			Example output:
			`WASX7027I: The AdminControl object enables`
			`the manipulation of MBeans that run in a`
			`WebSphere Application Server process.`
			`The number and type of MBeans that are`
			`available to the scripting client depend`
			`on the server to which the client is`
			`connected.  If the client is connected to a`
			`deployment manager, then all the MBeans`
			`running in the Deployment`
			`Manager are visible, as are all the MBeans`
			`running in the node agents that are`
			`connected to this deployment manager, and`
			`all the MBeans that run in the application`
			`servers on those nodes.`
			
			`The following commands are supported by`
			`the AdminControl object; more detailed`
			`information about each of these commands`
			`is available by using the "help" command`
			`of the AdminControl object and supplying`
			`the name of the command as an argument.`
			
			`Many of these commands support two`
			`different sets of signatures: one that`
			`accepts and returns strings, and one`
			`low-level set that works with JMX objects`
			`like ObjectName and AttributeList. In most`
			`situations, the string signatures are`
			`likely to be more useful,but JMX-object`
			`signature versions are supplied as well.`
			`Each of these JMX-object signature`
			`commands has "_jmx" appended to the`
			`command name,so an "invoke" command, as`
			`well as a "invoke_jmx" command are`
			`supported.`
			
			`completeObjectName`
			`  Return a String version`
			`  of an object name given a`
			`     template name`
			`getAttribute_jmx`
			`     Given ObjectName and name of`
			`   attribute, returns value of`
			`      attribute`
			`getAttribute`
			`  Given String version of ObjectName`
			`  and name of attribute,returns value`
			`  of attribute`
			`getAttributes_jmx`
			`     Given ObjectName and array of`
			`   attribute names, returns`
			`     AttributeList`
			`getAttributes`
			`  Given String version of ObjectName`
			`  and attribute names,returns String`
			`  of name value pairs`

help continued			getCell returns the cell name of the connected server getConfigId Given String version of ObjectName, return a config id for the corresponding configuration object, if any. getDefaultDomain returns "WebSphere" getDomainName returns "WebSphere" getHost returns String representation of connected host getMBeanCount returns number of registered beans getMBeanInfo_jmx Given ObjectName, returns MBeanInfo structure for MBean getNode returns the node name of the connected server getPort returns String representation of port in use getType returns String representation of connection type in use help Show help information invoke_jmx Given ObjectName, name of command, array of parameters and signature, invoke command on MBean specified invoke Invoke a command on the specified MBean isRegistered_jmx true if supplied ObjectName is registered isRegistered true if supplied String version of ObjectName is registered makeObjectName Return an ObjectName built with the given string queryNames_jmx Given ObjectName and QueryExp, retrieves set of ObjectNames that match. queryNames Given String version of ObjectName, retrieves String of ObjectNames that match. reconnect reconnects with server setAttribute_jmx Given ObjectName and Attribute object, set attribute for MBean specified setAttribute Given String version of ObjectName, attribute name and attribute value, set attribute for MBean specified setAttributes_jmx Given ObjectName and AttributeList object, set attributes for the MBean specified startServer Given the name of a server, start that server. stopServer Given the name of a server, stop that server. testConnection Test the connection to a DataSource object trace Set the wsadmin trace specification

help	Returns help text for the specific command of the AdminControl object. The command name is not case sensitive.	- Parameters: command-java.lang.String
		- Returns: java.lang.String
			Example usage:
			Using Jacl:
			`$AdminControl help getAttribute`
			Using Jython:
			`AdminControl.help('getAttribute')`
			Example output:
			`WASX7043I: command: getAttribute`
			`Arguments: object name, attribute`
			`Description: Returns value of "attribute"`
			`for the MBean described by "object name."`

invoke	Invokes the object operation without any parameter. Returns the result of the invocation.	- Parameters: name-java.lang.String; operationName-java.lang.String
		- Returns: java.lang.String
			Example usage:
			Using Jacl:
			`set objNameString [$AdminControl`
			` completeObjectName WebSphere:type=Server,*]`
			`$AdminControl invoke $objNameString stop`
			Using Jython:
			`objNameString =`
			` AdminControl.completeObjectName`
			` ('WebSphere:type=Server,*')`
			`AdminControl.invoke(objNameString, 'stop')`

invoke	Invokes the object operation using the parameter list that you supply. The signature generates automatically. The types of parameters are supplied by examining the MBeanInfo that the MBean supplies. Returns the string result of the invocation. The string that is returned is controlled by the Mbean method that you invoked. If the Mbean method is synchronous, then control is returned back to the wsadmin tool only when the operation is complete. If the Mbean method is asynchronous, control is returned back to the wsadmin tool immediately even though the invoked task might not be complete.	- Parameters: name-java.lang.String; operationName-java.lang.String; params-java.lang.String
		- Returns: java.lang.String
			Example usage:
			Using Jacl:
			`set objNameString [$AdminControl completeObjectName WebSphere:type=Server,*]`
			`$AdminControl invoke $objNameString appendTraceString com.ibm.*=all=enabled`
			Using Jython:
			`objNameString = AdminControl.completeObjectName ('WebSphere:type=Server,*')`
			`AdminControl.invoke(objNameString, 'appendTraceString', 'com.ibm.*=all=enabled')`

invoke	Invokes the object operation by conforming the parameter list to the signature. Returns the result of the invocation.	• Parameters: name-java.lang.String; operationName-java.lang.String; params-java.lang.String; sigs-java.lang.String
		• Returns: java.lang.String
			Example usage:
			Using Jacl:
			`set objNameString [$AdminControl`
			` completeObjectName WebSphere:type=Server,*]`
			`$AdminControl invoke $objNameString`
			` appendTraceString com.ibm.*=all=enabled`
			` java.lang.String`
			Using Jython:
			`objNameString = AdminControl.completeObjectName`
			` ('WebSphere:type=Server,*')`
			`AdminControl.invoke(objNameString,`
			` 'appendTraceString', 'com.ibm.*=all=enabled',`
			` 'java.lang.String')`

invoke_jmx	Invokes the object operation by conforming the parameter list to the signature. Returns the result of the invocation.	• Parameters: name-ObjectName; operationName-java.lang.String; params-java.lang.Object[]; signature-java.lang.String[]
		• Returns: java.lang.Object
			Example usage:
			`set objNameString [$AdminControl`
			` completeObjectName WebSphere:type=TraceService,*]`
			`set objName [java::new javax.management.ObjectName`
			` $objNameString]`
			`set parms [java::new {java.lang.Object[]}`
			` 1 com.ibm.ejs.sm.*=all=disabled]`
			`set signature [java::new`
			` {java.lang.String[]} 1 java.lang.String]`
			`$AdminControl invoke_jmx $objName`
			` appendTraceString $parms $signature`
			Using Jython:
			`objNameString = AdminControl.completeObjectName`
			`  ('WebSphere:type=TraceService,*')`
			`import  javax.management  as  mgmt`
			`objName =  mgmt.ObjectName(objNameString)`
			`parms = ['com.ibm.ejs.sm.*=all=disabled']`
			`signature = ['java.lang.String']`
			`AdminControl.invoke_jmx(objName,`
			` 'appendTraceString', parms, signature)`

isRegistered	If the ObjectName value is registered in the server, then the value is `true`.	• Parameters: name-java.lang.String
		• Returns: Boolean
			Example usage:
			Using Jacl:
			`set objNameString [$AdminControl`
			`completeObjectName WebSphere:type=Server,*]`
			`$AdminControl isRegistered $objNameString`
			Using Jython:
			`objNameString =`
			`AdminControl.completeObjectName`
			` ('WebSphere:type=Server,*')`
			`AdminControl.isRegistered(objNameString)`

isRegistered_jmx	If the ObjectName value is registered in the server, then the value is `true`.	• Parameters: name-ObjectName
		• Returns: Boolean
			Example usage:
			Using Jacl:
			`set objectNameString [$AdminControl completeObjectName type=Server,*]`
			`set objName [$AdminControl makeObjectName $objNameString]`
			`$AdminControl isRegistered_jmx $objName`
			Using Jython:
			`objectNameString = AdminControl.completeObjectName ('type=Server,*')`
			`objName = AdminControl.makeObjectName (objectNameString)`
			`AdminControl.isRegistered_jmx(objName)`

makeObjectName	A convenience command that creates an ObjectName value that is based on the strings input. This command does not communicate with the server, so the ObjectName value that results might not exist. If the string you supply contains an extra set of double quotes, they are removed. If the string does not begin with a Java Management Extensions (JMX) domain, or a string followed by a colon, then the WebSphere Application Server string appends to the name.	• Parameters: name-java.lang.String
		• Returns: javax.management.ObjectName
			Example usage:
			Using Jacl:
			`set objectNameString [$AdminControl completeObjectName type=Server,node=mynode,*]`
			`set objName [$AdminControl makeObjectName $ objNameString]`
			Using Jython:
			`objectNameString = AdminControl.completeObjectName ('type=Server,node=mynode,*')`
			`objName = AdminControl.makeObjectName (objectNameString)`

queryNames	Returns a string that lists all the ObjectName objects based on the name template.	• Parameters: name-java.lang.String
		• Returns: java.lang.String
			Example usage:
			Using Jacl:
			`$AdminControl queryNames WebSphere:type=Server,*`
			Using Jython:
			`AdminControl.queryNames('WebSphere:type=Server,*')`
			Example output:
			`WebSphere:cell=BaseApplicationServerCell,`
			` name=server1,mbeanIdentifier=server1,type=Server,`
			` node=mynode,process=server1`

queryNames_jmx	Returns a set of ObjectName objects that are based on the ObjectName object and the QueryExp query that you provide.	• Parameters: name-javax.management.ObjectName;query-javax.management.QueryExp
		• Returns: java.util.Set
			Example usage:
			Using Jacl:
			`set objectNameString [$AdminControl`
			` completeObjectName type=Server,*]`
			`set objName [$AdminControl`
			` makeObjectName $objNameString]`
			`set null [java::null]`
			`$AdminControl queryNames_jmx $objName $null`
			Using Jython:
			`objectNameString =`
			` AdminControl.completeObjectName`
			` ('type=Server,*')`
			`objName = AdminControl.makeObjectName`
			` (objectNameString)`
			`AdminControl.queryNames_jmx(objName,`
			` None)`
			Example output:
			`[WebSphere:cell=BaseApplicationServerCell,`
			`name=server1,mbeanIdentifier=server1,type=`
			`Server,node=mynode,process=server1]`

reconnect	Reconnects to the server, and clears information out of the local cache.	• Parameters: None
		• Returns: None
			Example usage:
			Using Jacl:
			`$AdminControl reconnect`
			Using Jython:
			`AdminControl.reconnect()`
			Example output:
			`WASX7074I: Reconnect of SOAP connector to`
			`host myhost completed.`

setAttribute	Sets the attribute value for the name that you provide.	• Parameters: name-java.lang.String; attributeName-java.lang.String; attributeValue-java.lang.String • Returns: None	Example usage: Using Jacl: set objNameString [$AdminControl completeObjectName WebSphere:type= TraceService,*] $AdminControl setAttribute $objNameString traceSpecification com.ibm.*=all=disabled Using Jython: objNameString = AdminControl.completeObjectName ('WebSphere:type=TraceService,*') AdminControl.setAttribute(objNameString, 'traceSpecification', 'com.ibm.*=all=disabled')
setAttribute_jmx	Sets the attribute value for the name that you provide.	• Parameters: name-ObjectName; attribute-javax.management.Attribute • Returns: None	Example usage: Using Jacl: set objectNameString [$AdminControl completeObjectName WebSphere:type= TraceService,*] set objName [$AdminControl makeObjectName $objectNameString] set attr [java::new javax.management.Attribute traceSpecification com.ibm.*=all=disabled] $AdminControl setAttribute_jmx $objName $attr Using Jython: objectNameString = AdminControl.completeObjectName ('WebSphere:type=TraceService,*') import javax.management as mgmt objName = AdminControl.makeObjectName (objectNameString) attr = mgmt.Attribute('traceSpecification', 'com.ibm.*=all=disabled') AdminControl.setAttribute_jmx(objName, attr)
setAttributes	Sets the attribute values for the names that you provide and returns a list of successfully set names.	• Parameters using Jacl: name-String; attributes-java.lang.String • Parameters using Jython: name-String; attributes-java.lang.String or name-String; attributes-java.lang.Object[] • Returns: java.lang.String	Example usage: Using Jacl: set objNameString [$AdminControl completeObjectName WebSphere:type= TracesService,*] $AdminControl setAttributes $objNameString {{traceSpecification com.ibm.ws.*=all=enabled}} Using Jython with string attributes: objNameString = AdminControl.completeObjectName ('WebSphere:type=TracesService,*') AdminControl.setAttributes(objNameString, '[[traceSpecification "com.ibm.ws.*=all=enabled"]]') Using Jython with object attributes: objNameString = AdminControl.completeObjectName ('WebSphere:type=TracesService,*') 473 AdminControl.setAttributes(objNameString, [['traceSpecification', 'com.ibm.ws.*=all=enabled']])

setAttributes_jmx	Sets the attribute values for the names that you provide and returns a list of successfully set names.	• Parameters: name-ObjectName; attributes-javax.management.AttributeList
		• Returns: javax.management.AttributeList
			Example usage:
			Using Jacl:
			`set objectNameString [$AdminControl`
			` completeObjectName WebSphere:type=TraceService,*]`
			`set objName [$AdminControl makeObjectName`
			` $objectNameString]`
			`set attr [java::new javax.management.Attribute`
			` traceSpecification com.ibm.ws.*=all=enabled]`
			`set alist`
			` [java::new javax.management.AttributeList]`
			`$alist add $attr`
			`$AdminControl setAttributes_jmx $objName $alist`
			Using Jython:
			`objectNameString =`
			` AdminControl.completeObjectName`
			` ('WebSphere:type=TraceService,*')`
			`import  javax.management  as  mgmt`
			`objName = AdminControl.makeObjectName`
			` (objectNameString)`
			`attr = mgmt.Attribute('traceSpecification',`
			` 'com.ibm.ws.*=all=enabled')`
			`alist = mgmt.AttributeList()`
			`alist.add(attr)`
			`AdminControl.setAttributes_jmx(objName,`
			` alist)`

startServer	Starts the specified application server by locating it in the configuration. This command uses the default wait time. You can only use this command if the scripting client is connected to a node agent. This command returns a message to indicate if the server starts successfully.	• Parameters: server name-java.lang.String
		• Returns: java.lang.String
			Example usage:
			Using Jacl:
			`$AdminControl startServer server1`
			Using Jython:
			`AdminControl.startServer('server1')`

startServer	Starts the specified application server by locating it in the configuration. The start process waits the number of seconds specified by the wait time for the server to start. You can only use this command if the scripting client is connected to a node agent. This command returns a message to indicate if the server starts successfully.	• Parameters: server name-java.lang.String, wait time-java.lang.String
		• Returns: java.lang.String
			Example usage:
			Using Jacl:
			`$AdminControl startServer server1 100`
			Using Jython:
			`AdminControl.startServer('server1', 100)`

startServer	Starts the specified application server by locating it in the configuration. This command uses the default wait time. You can use this command when the scripting client is either connected to a node agent or to a deployment manager process. It returns a message to indicate if the server starts successfully.	• Parameters: server name-java.lang.String, node name-java.lang.String
		• Returns: java.lang.String
			Example usage:
			Using Jacl:
			`$AdminControl startServer server1 myNode`
			Using Jython:
			`AdminControl.startServer('server1', 'myNode')`

startServer	Starts the specified application server by locating it in the configuration. The start process waits the number of seconds specified by the wait time for the server to start. You can use this command when the scripting client is either connected to a node agent or to a deployment manager process. This command returns a message to indicate if the server starts successfully.	• Parameters: server name-java.lang.String, node name-java.lang.String, wait time-java.lang.String
		• Returns: java.lang.String
			Example usage:
			Using Jacl:
			`$AdminControl startServer server1 myNode 100`
			Using Jython:
			`AdminControl.startServer('server1', 'myNode', 100)`

stopServer	Stops the specified application server. The command returns a message to indicate if the server stops successfully.	• Parameters: server name-java.lang.String
		• Returns: java.lang.String
			Example usage:
			Using Jacl:
			`$AdminControl stopServer server1`
			Using Jython:
			`AdminControl.stopServer('server1')`

stopServer	Stops the specified application server. If you set the flag to `immediate`, the server stops immediately. Otherwise, a normal stop occurs. This command returns a message to indicate if the server stops successfully.	• Parameters: server name-java.lang.String, immediate flag-java.lang.String
		• Returns: java.lang.String
			Example usage:
			Using Jacl:
			`$AdminControl stopServer server1 immediate`
			Using Jython:
			`AdminControl.stopServer('server1', 'immediate')`

stopServer	Stops the specified application server. This command returns a message to indicate if the server stops successfully.	• Parameters: server name-java.lang.String, node name-java.lang.String
		• Returns: java.lang.String
			Example usage:
			Using Jacl:
			`$AdminControl stopServer server1 myNode`
			Using Jython:
			`AdminControl.stopServer('server1', 'my Node')`

stopServer	Stops the specified application server. If you set the flag to `immediate`, the server stops immediately. Otherwise, a normal stop occurs. This command returns a message to indicate if the server stops successfully.	• Parameters: server name-java.lang.String, node name-java.lang.String, immediate flag-java.lang.String
		• Returns: java.lang.String
			Example usage:
			Using Jacl:
			`$AdminControl stopServer server1 myNode immediate`
			Using Jython:
			`AdminControl.stopServer('server1', 'my Node', 'immediate')`

testConnection	A convenience command communicates with the DataSourceCfgHelper MBean to test a DataSource connection. This command works with the DataSource that resides in the configuration repository. If the DataSource to be tested is in the temporary workspace that holds the update to the repository, you have to save the update to the configuration repository before running this command. Use this command with the configuration ID that corresponds to the DataSource and the WAS40DataSource object types. The return value is a message that contains the message indicating a successful connection or a connection with warning. If the connection fails, an exception is created from the server indicating the error.	• Parameters: configId-java.lang.String
		• Returns: java.lang.String
			Example usage:
			Using Jacl:
			`set ds [lindex [$AdminConfig list DataSource] 0]`
			`$AdminControl testConnection $ds`
			Using Jython:
			`# get line separator`
			`import java.lang.System as sys`
			`lineSeparator = sys.getProperty('line.separator')`
			`ds = AdminConfig.list('DataSource').split`
			` (lineSeparator)[0]`
			`AdminControl.testConnection(ds)`
			Example output:
			`WASX7217I: Connection to provided`
			`datasource was successful.`

testConnection	Deprecated.
	This command can give false results and does not work when connected to a node agent. As of V5.0.2, the preferred way to test a data source connection is with the **testConnection** command that passes in the DataSource configId parameter as the only parameter.
		- Parameters: configId-java.lang.String; props-java.lang.String
		- Returns: java.lang.String
			Example usage:
			Using Jacl:
			`set ds [lindex [$AdminConfig list DataSource] 0]`
			`$AdminControl testConnection $ds {{prop1 val1}}`
			Using Jython:
			`# get line separator`
			`import java.lang.System as sys`
			`lineSeparator = sys.getProperty('line.separator')`
			`ds = AdminConfig.list('DataSource').split`
			` (lineSeparator)[0]`
			`AdminControl.testConnection(ds, '[[prop1 val1]]')`
			Example output:
			`WASX7390E: Operation not supported -`
			`testConnection command with config id`
			`and properties arguments is not supported.`
			`Use testConnection command with`
			`config id argument only.`

trace	Sets the trace specification for the scripting process to the value that you specify.	- Parameters: traceSpec-java.lang.String
		- Returns: None
			Example usage:
			Using Jacl:
			`$AdminControl trace com.ibm.ws.scripting.*=`
			` all=enabled`
			Using Jython:
			`AdminControl.trace('com.ibm.ws.scripting.*=`
			` all=enabled')`

Commands for the AdminApp object

Use the AdminApp object to install, modify, and administer applications. The AdminApp object interacts with the WebSphere Application Server management and configuration services to make application inquiries and changes. This interaction includes installing and uninstalling applications, listing modules, exporting, and so on.

You can start the scripting client when no server is running, if you want to use only local operations. To run in local mode, use the `-conntype NONE` option to start the scripting client. You receive a message that you are running in the local mode. Running the AdminApp object in local mode when a server is currently running is not recommended. This is because any configuration changes made in local mode will not be reflected in the running server configuration and vice versa. If you save a conflicting configuration, you could corrupt the configuration. In a deployment manager environment, configuration updates are available only if a scripting client is connected to a deployment manager. When connected to a node agent or a managed application server, you will not be able to update the configuration because the configuration for these server processes are copies of the master configuration which resides in the deployment manager. The copies are created on a node machine when a configuration synchronization occurs between the deployment manager and the node agent. Make configuration changes to the server processes by connecting a scripting client to a deployment manager. For this reason, to change a configuration, do not run a scripting client in local mode on a node machine. It is not a supported configuration.

The following commands are available for the AdminApp object:

Command name:	Description:	Parameters and return values:	Examples:

deleteUserAndGroupEntries	Deletes users or groups for all roles, and deletes user IDs and passwords for all of the RunAs roles that are defined in the application.	• Parameters: appname
		• Returns: None
			Example usage:
			Using Jacl:
			`$AdminApp deleteUserAndGroupEntries myapp`
			Using Jython:
			`AdminApp.deleteUserAndGroupEntries('myapp')`

edit	Edits an application or module in non-interactive mode.
	The **edit** command changes the application deployment. Specify these changes in the options parameter. No options are required for the **edit** command.
		• Parameters using Jacl: appname - string; options - string
		• Parameters using Jython: appname - string; options - string or appname - string; options - Jython list
		• Returns: string
			Example usage:
			Using Jacl:
			`$AdminApp edit "JavaMail Sample"`
			` {-MapWebModToVH {{"JavaMail`
			`Sample WebApp" mtcomps.war,WEB-INF/web.xml`
			` newVH}}}`
			Using Jython with string options:
			`AdminApp.edit("JavaMail Sample",`
			` '[-MapWebModToVH [["JavaMail`
			`32 Sample WebApp" mtcomps.war,WEB-INF/web.xml`
			` newVH]]]')`
			Using Jython with list options:
			`option = [["JavaMail 32 Sample WebApp",`
			` "mtcomps.war,WEB-INF/web.xml",`
			`"newVH"]]`
			`mapVHOption = ["-MapWebModToVH", option]`
			`AdminApp.edit("JavaMail Sample", mapVHOption)`

editInteractive	Edits an application or module in interactive mode.
	The **editInteractive** command changes the application deployment. Specify these changes in the options parameter. No options are required for the **editInteractive** command.
		• Parameters using Jacl: appname - string; options - string
		• Parameters using Jython: appname - string; options - string or appname - string; options - Jython list
		• Returns: string
			Example usage:
			Using Jacl:
			`$AdminApp editInteractive ivtApp`
			Using Jython:
			`AdminApp.editInteractive('ivtApp')`

export	Exports the application appname parameter to a file that you specify by file name.	• Parameters: appname, filename
		• Returns: None
			Example usage:
			Using Jacl:
			`$AdminApp export "My App" /usr/me/myapp.ear`
			Using Jython:
			`AdminApp.export("My App", '/usr/me/myapp.ear')`

exportDDL	Extracts the data definition language (DDL) from the application appname parameter to the directoryname parameter that a directory specifies. The options parameter is optional.	• Parameters: appname, directoryname, options
		• Returns: None
			Example usage:
			Using Jacl:
			`$AdminApp exportDDL "My App" /usr/me/DDL {-ddlprefix myApp}`
			Using Jython:
			`AdminApp.exportDDL("My App", '/usr/me/DDL', '[-ddlprefix myApp]')`

help	Displays general help for the AdminApp object.	- Parameters: None
		- Returns: None
			Example usage:
			Using Jacl:
			`$AdminApp help`
			Using Jython:
			`print AdminApp.help()`
			Example output:
			`WASX7095I: The AdminApp object allows`
			`application objects to be manipulated`
			`including installing, uninstalling,`
			`editing,and listing.  Most of the commands`
			`supported by AdminApp operate in two modes:`
			`the default mode is one in which AdminApp`
			`communicates with the WebSphere Application`
			`Server to accomplish its tasks.  A local`
			`mode is also possible, in which no server`
			`communication takes place.  The local mode`
			`of operation is invoked by including the`
			`"-conntype NONE" flag in the option string`
			`supplied to the command.`
			
			`The following commands are supported by`
			`AdminApp; more detailed information about`
			`each of these commands is available by`
			`using the "help" command of AdminApp`
			`and supplying the name of the command`
			`as an argument.`
			
			`edit            Edit the properties of an`
			`       application`
			`editInteractive Edit the properties of an`
			`       application interactively`
			`export          Export application to a file`
			`exportDDL      Extract DDL from application`
			`        to a directory`
			`help            Show help information`
			`install         Installs an application,`
			`       given a file name and an`
			`       option string.`
			`installInteractive`
			`                Installs an application`
			`       in interactive mode, given`
			`       a file name and an option`
			`       string.`
			`list            List all installed`
			`       applications`
			`listModules     List the modules in a`
			`       specified application`
			`options         Shows the options available,`
			`       either for a given file,`
			`       or in general.`
			`taskInfo        Shows detailed information`
			`       pertaining to a given`
			`       installation task for a`
			`       given file`
			`uninstall       Uninstalls an application,`
			`       given an application name`
			`                and an option string`

help	Displays help for an AdminApp command or installation option.	• Parameters: operation name
		• Returns: none
			Example usage:
			Using Jacl:
			`$AdminApp help uninstall`
			Using Jython:
			`print AdminApp.help('uninstall')`
			Example output:
			`WASX7102I: Method: uninstall`
			`Arguments: application name, options`
			`Description: Uninstalls application named`
			`by "application name" using the options`
			`supplied by String 2.`
			`Method: uninstall`
			`Arguments: application name`
			`Description: Uninstalls the application`
			`specified by`
			`"application name" using default options.`

install	Installs an application in non-interactive mode, given a fully qualified file name and a string of installation options. The options parameter is optional.	• Parameters using Jacl: earfile- string; options- string
		• Parameters using Jython: earfile- string; options- string or earfile- string; options- Jython list
		• Returns: None
			Example usage:
			Using Jacl:
			`$AdminApp install c:/apps/myapp.ear`
			Using Jython:
			`AdminApp.install('c:/apps/myapp.ear')`
			Many options are available for this command. You can obtain a list of valid options for an Enterprise Archive (EAR) file with the following command:
			Using Jacl:
			`$AdminApp options myApp.ear`
			Using Jython:
			`AdminApp.options('myApp.ear')`
			You can also obtain help for each object with the following command:
			Using Jacl:
			`$AdminApp help MapModulesToServers`
			Using Jython:
			`AdminApp.help('MapModulesToServers')`

installInteractive	Installs an application in interactive mode, given a fully qualified file name and a string of installation options. The options parameter is optional.	• Parameters using Jacl: earfile- string; options- string
		• Parameters using Jython: earfile- string; options- string or earfile- string; options- Jython list
		• Returns: None
			Example usage:
			Using Jacl:
			`$AdminApp installInteractive c:/websphere/`
			`appserver/installableApps/jmsample.ear`
			Using Jython:
			`AdminApp.installInteractive('c:/websphere/`
			`appserver/installableApps/jmsample.ear')`

list	Lists the applications that are installed in the configuration.	- Parameters: None
		- Returns: application names
			Example usage:
			Using Jacl:
			`$AdminApp list`
			Using Jython:
			`print AdminApp.list()`
			Example output:
			`adminconsole`
			`DefaultApplication`
			`ivtApp`

listModules	Lists the modules in an application.
	The options parameter is optional. The valid option is -server. This option lists the application servers on which the modules are installed.
		- Parameters: appname, options
		- Returns: modules in the application
			Example usage:
			Using Jacl:
			`$AdminApp listModules ivtApp`
			Using Jython:
			`print AdminApp.listModules('ivtApp')`
			Example output:
			`ivtApp#ivtEJB.jar+META-INF/ejb-jar.xml`
			`ivtApp#ivt_app.war+WEB-INF/web.xml`
			This example is formed by the concatenation of appname, #, module URI, +, and DD URI. You can pass this string to the **edit** and **editInteractive** AdminApp commands.

options	Displays a list of options for installing an Enterprise Archive (EAR) file.	• Parameters: earfile • Returns: Information about the valid installation options for an Enterprise Archive (EAR) file.	Example usage: Using Jacl: $AdminApp options c:/websphere/appserver/installableApps/ ivtApp.ear Using Jython: AdminApp.options ('c:/websphere/appserver/installableApps/ ivtApp.ear') Example usage: WASX7112I: The following options are valid for "c:/websphere/appserver/installableapps/ ivtApp.ear" MapRolesToUsers BindJndiForEJBNonMessageBinding MapEJBRefToEJB MapWebModToVH MapModulesToServers EnsureMethodProtectionFor10EJB GetServerName preCompileJSPs nopreCompileJSPs distributeApp nodistributeApp useMetaDataFromBinary nouseMetaDataFromBinary deployejb nodeployejb createMBeansForResources nocreateMBeansForResources reloadEnabled noreloadEnabled deployws nodeployws usedefaultbindings defaultbinding.force allowPermInFilterPolicy noallowPermInFilterPolicy verbose update update.ignore.old update.ignore.new installed.ear.destination appname reloadInterval validateinstall deployejb.rmic deployejb.dbtype deployejb.dbschema deployejb.classpath deployws.classpath deployws.jardirs defaultbinding.datasource.jndi defaultbinding.datasource.username defaultbinding.datasource.password defaultbinding.cf.jndi defaultbinding.cf.resauth defaultbinding.ejbjndi.prefix defaultbinding.virtual.host defaultbinding.strategy.file server node cell cluster contextroot custom

options	Displays a list of options for editing an existing application.	• Parameters: Application name
		• Returns: Information about the valid edit options for an application.
			Example usage:
			Using Jacl:
			`$AdminApp options ivtApp`
			Using Jython:
			`AdminApp.options('ivtApp')`
			Example output:
			`WASX7112I: The following options are valid for "ivtApp"`
			`MapRolesToUsers`
			`BindJndiForEJBNonMessageBinding`
			`MapEJBRefToEJB`
			`MapWebModToVH`
			`MapModulesToServers`
			`distributeApp`
			`nodistributeApp`
			`useMetaDataFromBinary`
			`nouseMetaDataFromBinary`
			`createMBeansForResources`
			`nocreateMBeansForResources`
			`reloadEnabled`
			`noreloadEnabled`
			`verbose`
			`installed.ear.destination`
			`reloadInterval`

options	Displays a list of options for editing a module in an existing application.	• Parameters: application module name. This parameter requires the same module name format as the output that is returned by the **listModules** command.
		• Returns: Information about the valid edit options for a module.
			Example usage:
			Using Jacl:
			`$AdminApp options ivtApp#ivtEJB.jar+META-INF/ejb-jar.xml`
			Using Jython:
			`AdminApp.options('ivtApp#ivtEJB.jar+META-INF/ejb-jar.xml')`
			Example output:
			`WASX7112I: The following options are valid for "ivtApp#ivtEJB.jar+META-INF/ejb-jar.xml"`
			`MapRolesToUsers`
			`BindJndiForEJBNonMessageBinding`
			`MapModulesToServers`
			`verbose`

options	Displays a list of options for installing or updating an application or application module file.	• Parameters:
		file, operation - The following list includes the valid values:
		– installapp - Installing the file that is specified
		– updateapp - Updating an existing application with the file that is specified
		– addmodule - Adding the module file that is specified to an existing application
		– updatemodule - Updating an existing module in an application with the module file that is specified
		• Returns: Information about the valid options that are available for the operation that is requested with the input file.
			Example using the updateapp operation:
			Using Jacl:
			`$AdminApp options`
			` c:/websphere/appserver/installableApps/`
			`ivtApp.ear updateapp`
			Using Jython:
			`AdminApp.options`
			` ('c:/websphere/appserver/installableApps/`
			`ivtApp.ear', 'updateapp')`
			Example using the addmodule operation:
			Using Jacl:
			`$AdminApp options myModule.jar addmodule`
			Using Jython:
			`AdminApp.options`
			` ('DefaultWebApplication.war', 'addmodule')`
			Example output using the updateapp operation:
			`WASX7112I: The following options are valid`
			`for "c:/websphere/appserver/installableApps/`
			`ivtApp.ear"`
			`MapRolesToUsers`
			`BindJndiForEJBNonMessageBinding`
			`MapEJBRefToEJB`
			`MapWebModToVH`
			`MapModulesToServers`
			`EnsureMethodProtectionFor10EJB`
			`GetServerName`
			`preCompileJSPs`
			`nopreCompileJSPs`
			`distributeApp`
			`nodistributeApp`
			`useMetaDataFromBinary`
			`nouseMetaDataFromBinary`
			`deployejb`
			`nodeployejb`
			`createMBeansForResources`
			`nocreateMBeansForResources`
			`reloadEnabled`
			`noreloadEnabled`
			`deployws`
			`nodeployws`
			`usedefaultbindings`
			`defaultbinding.force`
			`allowPermInFilterPolicy`
			`noallowPermInFilterPolicy`
			`verbose`
			`update`
			`update.ignore.old`
			`update.ignore.new`
			`installed.ear.destination`
			`reloadInterval`
			`deployejb.rmic`
			`deployejb.dbtype`
			`deployejb.dbschema`
			`deployejb.classpath`
			`deployws.classpath`
			`deployws.jardirs`

options continued			defaultbinding.datasource.jndi defaultbinding.datasource.username defaultbinding.datasource.password defaultbinding.cf.jndi defaultbinding.cf.resauth defaultbinding.ejbjndi.prefix defaultbinding.virtual.host defaultbinding.strategy.file appname contextroot custom contenturi contents operation Example output using the addmodule operation: WASX7112I: The following options are valid for "DefaultWebApplication.war" MapRolesToUsers MapEJBRefToEJB MapWebModToVH MapModulesToServers GetServerName preCompileJSPs nopreCompileJSPs deployejb nodeployejb deployws nodeployws usedefaultbindings defaultbinding.force verbose defaultbinding.datasource.jndi defaultbinding.datasource.username defaultbinding.datasource.password defaultbinding.cf.jndi defaultbinding.cf.resauth defaultbinding.ejbjndi.prefix defaultbinding.virtual.host defaultbinding.strategy.file server node cell cluster contextroot custom contenturi contents operation
publishWSDL	Publishes Web Services Description Language (WSDL) files for the application that is specified in the appname parameter to the file that is specified in the filename parameter.	• Parameters: appname, filename • Returns: None	Example usage: Using Jacl: $AdminApp publishWSDL JAXRPCHandlerServer c:/temp/a.zip Using Jython: AdminApp.publishWSDL ('JAXRPCHandlerServer', 'c:/temp/a.zip')

publishWSDL	Publishes Web Services Description Language (WSDL) files for the application that is specified in the appname parameter to the file that is specified in the filename parameter using the SOAP address prefixes that are specified in the soapAddressPrefixes parameter.	• Parameters: appname, filename, soapAddressPrefixes
		• Returns: None
			Example usage:
			Using Jacl:
			`$AdminApp publishWSDL JAXRPCHandlersServer`
			` c:/temp/a.zip`
			`{{JAXRPCHandlersServerApp.war`
			`  {{http http://localhost:9080}}}}`
			Using Jython:
			`AdminApp.publishWSDL('JAXRPCHandlersServer',`
			` 'c:/temp/a.zip',`
			`'[[JAXRPCHandlersServerApp.war`
			` [[http http://localhost:9080]]]]')`

searchJNDI References	Lists applications that refer to the Java Naming and Directory Interface (JNDI) name on a specific node.	• Parameters: Node configuration ID, options
		• Returns: string
			Example usage:
			The following example assumes that an installed application named `MyApp` has a JNDI name of `eis/J2CCF1`.
			Using Jacl:
			`$AdminApp searchJNDIReferences $node`
			` {-JNDIName eis/J2CCF1 -verbose}`
			Using Jython:
			`print AdminApp.searchJNDIReferences(node,`
			` '[-JNDIName eis/J2CCF1 -verbose]')`
			Example output:
			`WASX7410W: This operation may take a while`
			`depending on the number of applications`
			`installed in your system.`
			`MyApp`
			`MapResRefToEJB :ejb-jar-ic.jar : [eis/J2CCF1]`

taskInfo	Provides information about a particular task option for an application file.	• Parameters: earfile, task name
		• Returns: None
			Example usage:
			Using Jacl:
			`$AdminApp taskInfo`
			` c:/websphere/appserver/installableApps/`
			`jmsample.ear MapWebModToVH`
			Using Jython:
			`print AdminApp.taskInfo`
			` ('c:/websphere/appserver/installableApps/`
			`jmsample.ear', 'MapWebModToVH')`
			Example output:
			`MapWebModToVH: Selecting virtual hosts for`
			`Web modules Specify the virtual host where`
			`you want to install the Web modules that are`
			`contained in your application. Web modules`
			` can be installed on the same virtual host`
			`or dispersed among several hosts. Each`
			`element of the MapWebModToVH task consists`
			`of the following three fields: "webModule,"`
			` "uri," "virtualHost." Of these fields,`
			`the following fields might be assigned`
			`new values: "virtualHost"and the following`
			`are required: "virtualHost"`
			
			`The current contents of the task after`
			`running default bindings are:`
			`webModule: JavaMail Sample WebApp`
			`uri: mtcomps.war,WEB-INF/web.xml`
			`virtualHost: default_host`

uninstall	Uninstalls an existing application.	• Parameters: appname- string
		• Returns: None
			Example usage:
			Using Jacl:
			`$AdminApp uninstall myApp`
			Using Jython:
			`AdminApp.uninstall('myApp')`
			Example output:
			`ADMA5017I: Uninstallation of myapp started.`
			`ADMA5104I: Server index entry for`
			`myCellManager was updated successfully.`
			`ADMA5102I: Deletion of config data for myapp`
			`from config repository completed successfully.`
			`ADMA5011I: Cleanup of temp dir for app myapp`
			`done.`
			`ADMA5106I: Application myapp uninstalled`
			`successfully.`

updateAccessIDs	Updates the access ID information for users and groups that are assigned to various roles that are defined in the application. The access IDs are read from the user registry and saved in the application bindings. This operation improves run-time performance of the application. Call this command after installing an application or after editing security role-specific information for an installed application. This method cannot be invoked when the -conntype option is set to `NONE`. You must be connected to a server to invoke this command.
	The bALL Boolean parameter retrieves and saves all access IDs for users and groups in the application bindings. Specify `false` if you want to retrieve access IDs for users or groups that do not have an access ID in the application bindings.
		• Parameters: appname, bALL
		• Returns: None
			Example usage:
			Using Jacl:
			`$AdminApp updateAccessIDs myapp true`
			Using Jython:
			`AdminApp.updateAccessIDs('myapp', 'true')`

view	View the task that is specified by the taskname option parameter for the application or by the module that is specified by the name parameter. Use -tasknames as the option to get a list of valid task names for the application. Otherwise, specify one or more task names as the option.	• Parameters: name, taskname option
		• Returns: string
			Example usage:
			Using Jacl:
			`$AdminApp view adminconsole {-tasknames}`
			Using Jython:
			`AdminApp.view('adminconsole', ['-tasknames'])`
			Example output:
			`MapModulesToServers`
			`MapWebModToVH`
			`MapRolesToUsers`
			Using Jacl:
			`$AdminApp view adminconsole`
			` {-MapModulesToServers}`
			Using Jython:
			`AdminApp.view('adminconsole',`
			` ['-MapModulesToServers'])`
			Example output:
			`MapModulesToServers: Selecting Application`
			` Servers`
			
			`Specify the application server where you`
			`want to install the modules that are`
			`contained in your application. Modules can`
			`be installed on the same server or dispersed`
			`among several servers:`
			
			`Module:  adminconsole`
			`URI:  adminconsole.war,WEB-INF/web.xml`
			`Server:  WebSphere:cell=juniartiNetwork,`
			`node=juniartiManager,server=dmgr`
			Example usage:
			Using Jacl:
			`$AdminApp view adminconsole#adminconsole.war+`
			`WEB-INF/web.xml {-MapRolesToUsers}`
			Using Jython:
			`AdminApp.view`
			` ('adminconsole#adminconsole.war+WEB-INF/`
			`web.xml',  ['-MapRolesToUsers'])`
			Example output:
			`MapRolesToUsers: Mapping Users to Roles`
			
			`Each role that is defined in the application`
			`or the module must be mapped to a user or a`
			`group from the user registry of the domain:`
			
			`Role:  administrator`
			`Everyone?:  No`
			`All Authenticated?:  No`
			`Mapped Users:`
			`Mapped Groups:`

view continued			Role: operator Everyone?: No All Authenticated?: No Mapped Users: Mapped Groups: Role: configurator Everyone?: No All Authenticated?: No Mapped Users: Mapped Groups: Role: monitor Everyone?: No All Authenticated?: No Mapped Users: Mapped Groups:

update	Updates an application in non-interactive mode. Provide the application name, content type, and update options.	• Parameters using Jacl: appname, content type, options – string format
		• Parameters using Jython: appname, content type, option- string or list format
		• Returns: String
		This command supports the addition, removal, and update of application subcomponents or the entire application.
		Use the content type parameter to indicate if you want to update part of the application or the entire application. The following list includes the valid content type values for the **update** command:
		– `app` - Indicates that you want to update the entire application. This option is the same as indicating the update option with the **install** command. With the `app` value as the content type, you must specify the operation option with update as the value. Provide the new enterprise archive file (EAR) file using the contents option. You can also specify binding information and application options. By default, binding information for installed modules is merged with the binding information for updated modules. To change this default behavior, specify the update.ignore.old or the update.ignore.new options.
			Example usage:
			Using Jacl:
			`$AdminApp update myApp file {-operation`
			`add -contents`
			`c:/apps/myApp/web.xml`
			` -contenturi META-INF/web.xml}`
			Using Jython with string options:
			`AdminApp.update('myApp', 'file',`
			`'[-operation add -contents`
			`c:/apps/myApp/web.xml`
			`-contenturi META-INF/web.xml]')`
			Using Jython with list options:
			`AdminApp.update('myApp', 'file',`
			`['-operation', 'add',`
			`'-contents',  'c:/apps/myApp/web.xml',`
			`'-contenturi',`
			`'META-INF/web.xml'])`
			Example output:
			`Update of singleFile has started.`
			`ADMA5009I: Application archive extracted at`
			`C:\DOCUME~1\lavena\LOCALS~1\Temp\`
			` app_fb5a1960f0\ext`
			`Added files from partial ear: []`
			`performFileOperation:`
			`source=C:\DOCUME~1\lavena\LOCALS~1\Temp\`
			`app_fb5a1960f0\ext, dest=C:\DOCUME~1\lavena\`
			`LOCALS~1\Temp\`
			`app_fb5a1960f0\mrg, uri= META-INF/web.xml,`
			`op= add`
			`Copying file from C:\DOCUME~1\lavena\`
			`LOCALS~1\Temp\app_fb5a1960f0\ext/`
			`META-INF/web.xml to`
			`C:\DOCUME~1\lavena\LOCALS~1\Temp`
			`\app_fb5a1960f0\mrg\META-INF\web.xml`
			`Collapse list is: []`
			`FileMergeTask completed successfully`
			`ADMA5005I: Application singleFile`
			`configured in WebSphere repository`
			`delFiles: []`
			`delM: null`
			`addM: null`

update continued		• `file` - Indicates that you want to update a single file. You can add, remove, or update individual files at any scope within the deployed application. With the `file` value as the content type, you must perform operations on the file using the `operation` option. Depending on the type of operation, additional options are required. For file additions and updates, you must provide file content and the file URI relative to the root of the EAR file using the contents and contenturi options. For file deletion, you must provide the file URI relative to the root of the EAR file using the contenturi option which is the only required input. Any other options that you provide are ignored.	`Pattern for remove loose and mod:`
			`Loose add pattern: META-INF/[^/]*|`
			`WEB-INF/[^/]*|.*wsdl`
			`root file to be copied: META-INF/web.xml to`
			`C:\asv\b0403.04\WebSphere\AppServer\`
			`wstemp\Scriptfb5a191b4e\workspace\cells\`
			`BAMBIE\applications\`
			`singleFile.ear\deployments\singleFile/`
			`META-INF/web.xml`
			`ADMA5005I: Application singleFile`
			`configured in WebSphere repository`
			`xmlDoc: [#document: null]`
			`root element: [app-delta: null]`
			`****** delta file name: C:\asv\b0403.04\`
			`WebSphere\AppServer\wstemp\Scriptfb5a191`
			`b4e\workspace\cells\BAMBIE\applications\`
			`singleFile.ear/deltas/delta-1079548405564`
			`ADMA5005I: Application singleFile`
			`configured in WebSphere repository`
			`ADMA6011I: Deleting directory tree`
			`C:\DOCUME~1\lavena\LOCALS~1\Temp\app_fb5a1960f0`
			`ADMA5011I: Cleanup of temp dir for app`
			`singleFile done.`
			`Update of singleFile has ended.`

update continued		• modulefile - Indicates that you want to update a module. You can add, remove, or update an individual application module. If you specify the modulefile value as the content type, you must indicate the operation that you want to perform on the module using the operation option. Depending on the type of operation, further options are required. For installing new modules or updating existing modules in an application, you must indicate the file content and the file URI relative to the root of the EAR file using the contents and contenturi options. You can also specify binding information and application options that pertain to the new or updated modules. For module updates, the binding information for the installed module is merged with the binding information for the input module by default. To change the default behavior, specify the update.ignore.old or the update.ignore.new options. To delete a module, indicate the file URI relative to the root of the EAR file.	

update continued		- `partialapp` - Indicates that you want to update a partial application. Using a subset of application components provided in a zip file format you can update, add, and delete files and modules. The zip file is not a valid Java 2 platform, Enterprise Edition (J2EE) archive. Instead, it contains application artifacts in the same hierarchical structure as they display in an EAR file. For more information on how to construct the partial application zip file, see the Java API section. If you indicate the `partialapp` value as the content type, use the contents option to specify the location of the zip file. When a partial application is provided as an update input, binding information and application options cannot be specified and are ignored, if provided. For a list of the valid options for the **update** command, see "Options for the AdminApp object install, installInteractive, edit, editInteractive, update, and updateInteractive commands" on page 437.	

updateInteractive	Updates an application in interactive mode. Provide the application name, content type, and update options.	- Parameters using Jacl: appname, content type, options - string format
		- Parameters using Jython: appname, content type, option - string or list format
		- Returns: String
		Use the **updateInteractive** command to add, remove, and update application subcomponents or an entire application. When you update an application module or an entire application using interactive mode, the steps that you use to configure binding information are similar to those that apply to the **installInteractive** command. If you update a file or a partial application, the steps that you use to configure the binding information are not available. In this case, the steps are the same as the ones you use with the **update** command.
		Use the content type parameter to indicate if you want to update part of the application or the entire application. The following list contains the valid content type values for the **updateInteractive** command:
		– `app` - Indicates that you want to update the entire application. This option is the same as indicating the update option with **install** command. With the `app` value as the content type, you must specify the operation option with update as the value. Provide the new enterprise archive file (EAR) file using the contents option. You can also specify binding information and application options. By default, binding information for installed modules is merged with the binding information for updated modules. To change this default behavior, specify the update.ignore.old or the update.ignore.new options.
			Example usage:
			Using Jacl:
			`$AdminApp updateInteractive myApp modulefile`
			`{-operation`
			`add -contents c:/apps/myApp/Increment.jar`
			`-contenturi`
			`Increment.jar -nodeployejb`
			` -BindJndiForEJBNonMessageBinding`
			`{{"Increment Enterprise JavaBeans"`
			` Increment Increment.`
			`jar,META-INF/ejb-jar.xml Inc}}}`
			Using Jython string:
			`AdminApp.updateInteractive('myApp',`
			`'modulefile', '[-operation add -contents`
			`c:/apps/myApp/Increment.jar -contenturi`
			`Increment.jar -nodeployejb`
			`-BindJndiForEJBNonMessageBinding`
			`[["Increment Enterprise JavaBeans"`
			`Increment Increment.jar,META-INF/`
			`ejb-jar.xml Inc]]]')`
			Using Jython list:
			`bindJndiForEJBValue = [["Increment Enterprise`
			`JavaBeans", "Increment", "Increment.jar,`
			`META-INF/ejb-jar.xml", "Inc"]]`
			
			`AdminApp.updateInteractive('myApp',`
			`'modulefile', ['-operation', 'add',`
			`'-contents',  'c:/apps/myApp/Increment.jar',`
			` '-contenturi', 'Increment.jar',`
			`'-nodeployejb',`
			`'-BindJndiForEJBNonMessageBinding',`
			`bindJndiForEJBValue])`
			Example output:
			`Getting tasks for: myApp`
			`WASX7266I: A was.policy file exists for this`
			`application; would you like to display it? [No]`
			
			`Task[4]: Binding enterprise beans to JNDI`
			`names Each non message driven enterprise`
			`bean in your application or module must be`
			`bound to a JNDI name.`
			
			`EJB Module:  Increment Enterprise Java Bean`
			`EJB:  Increment`
			`URI:  Increment.jar,META-INF/ejb-jar.xml`
			`JNDI Name:  [Inc]:`
			
			`Task[10]: Specifying the default data source`
			`for EJB 2.x modules`
			`Specify the default data source for`
			`the EJB 2.x Module containing 2.x CMP beans.`

updateInteractive continued		• file - Indicates that you want to update a single file. You can add, remove, or update individual files at any scope within the deployed application. With the file value as the content type, you must perform operations on the file using the operation option. Depending on the type of operation, additional options are required. For file additions and updates, you must provide file content and the file URI relative to the root of the EAR file using the contents and contenturi options. For file deletion, you must provide the file URI relative to the root of the EAR file using the contenturi option which is the only required input. Any other options that you provide are ignored.
		• modulefile - Indicates that you want to update a module. You can add, remove, or update an individual application module. If you specify the modulefile value as the content type, you must indicate the operation that you want to perform on the module using the operation option. Depending on the type of operation, additional options are required. For installing new modules or updating existing modules in an application, you must indicate the file content and the file URI relative to the root of the EAR file using the contents and the contenturi options. You can also specify binding information and application options that pertain to the new or updated modules. For module updates, the binding information for the installed module is merged with the binding information for the input module by default. To change the default behavior, specify the update.ignore.old or the update.ignore.new options. To delete a module, indicate the file URI relative to the root of the EAR file.

updateInteractive continued		• partialapp - Indicates that you want to update a partial application. Using subset of application components provided in a zip file format you can update, add, and delete files and modules. The zip file is not a valid Java 2 platform, Enterprise Edition (J2EE) archive. Instead, this file contains application artifacts in the same hierarchical structure as they are displayed in an EAR file. For more information on how to construct the partial application zip file, see the Java API section. If you indicate the partialapp value as the content type, use the contents option to specify the location of the zip file. When a partial application is provided as an update input, the binding information and application options cannot be specified and are ignored, if provided. For a list of the valid options for the **updateInteractive** command, see "Options for the AdminApp object install, installInteractive, edit, editInteractive, update, and updateInteractive commands" on page 437.	Task[22]: Specifying EJB deploy options Specify the options to deploy EJB. ....EJB Deploy option is not enabled. Options for the AdminApp object install, installInteractive, edit, editInteractive, update, and updateInteractive commands: This article lists the available options for the **install**, **installInteractive**, **edit**, **editInteractive**, **update**, and **updateInteractive** commands of the AdminApp object. The options listed in this article apply to all of these commands except where noted.

See Commands for the AdminApp object for more detailed information on how to use the commands. See Usage table for the options of the AdminApp object install, installInteractive, update, updateInteractive, edit, and editInteractive commands for a list of applicable commands for each option.

The following options are available for the **install**, **installInteractive**, **edit**, **editInteractive**, **update**, and **updateInteractive** commands:

Option name:	Description:	Examples:

ActSpecJNDI	Binds J2C activation specs to destination JNDI names. You can bind J2C activation specs in your application or module to a destination JNDI name. This option is optional. Each element of the ActSpecJNDI option consists of the following fields: RARModule, uri, j2cid, j2c.jndiName. j2c.jndiName field, can be assigned a value. The current contents of the option after running default bindings include:
	• RARModule: <rar module name>
	• uri: <rar name>,META-INF/ra.xml
	• j2cid: <messageListenerType>
	• j2c.jndiName: null
	• Object identifier: javax.jms.MessageListener
	You can only use this option if the activation spec has the `Destination` property defined in the ra.xml file and the introspected type of the `Destination` property is the following: `javax.jms.Destination`
		Using Jacl:
		`$AdminApp install $embeddedEar {-ActSpecJNDI {{"FVT Resource Adapter" jca15cmd.rar,META-INF/ra.xml javax.jms.MessageListener jndi5} {"FVT Resource Adapter" jca15cmd.rar,META-INF/ra.xml javax.jms.MessageListener2 jndi6}}}`
		Using Jython:
		`AdminApp.install(embeddedEar, ['-ActSpecJNDI', [["FVT Resource Adapter", 'jca15cmd.rar,META-INF/ra.xml', 'javax.jms.MessageListener', 'jndi5'], ["FVT Resource Adapter", 'jca15cmd.rar,META-INF/ra.xml', 'javax.jms.MessageListener2', 'jndi6']]])`

ActSpecJNDI continued	Use the **taskInfo** command of the AdminApp object to obtain information about the data that is needed for your application. You need to provide data for rows or entries that are either missing information, or require an update.	
allowPermInFilter Policy	Specifies to continue with the application deployment process even when the application contains policy permissions that are in the filter policy. This option does not require a value.	
appname	Specifies the name of the application. The default is the display name of the application.	

BackendIdSelection	Specifies the backend ID for the enterprise bean Java archive (JAR) modules that have container-managed persistence (CMP) beans. An enterprise bean JAR module can support multiple backend configurations as specified using an application assembly tool.
	Use this option to change the backend ID during installation.
		Using Jacl:
		`$AdminApp install c:/myapp.ear {-BackendIdSelection`
		`{{Annuity20EJB Annuity20EJB.jar,META-INF/ejb-jar.xml  DB2UDBNT_V72_1}}}`
		Using Jython:
		`AdminApp.install('c:/myapp.ear', '[-BackendIdSelection`
		`[[Annuity20EJB Annuity20EJB.jar,META-INF/ejb-jar.xml  DB2UDBNT_V72_1]]]')`

BindJndiForEJB MessageBinding	Binds enterprise beans to listener port names or Java Naming and Directory Interface (JNDI) names. Use this option to provide missing data or update a task. Ensure each message-driven enterprise bean in your application or module is bound to a listener port name.
	Each element of the BindJndiForEJBMessageBinding option consists of the following fields: EJBModule, EJB, uri, listenerPort, JNDI, jndi.dest, and actspec.auth. Some of these fields, can be assigned values: listenerPort, JNDI, jndi.dest, and actspec.auth.
	The current contents of the option after running default bindings include:
	• EJBModule: Ejb1
	• EJB: MessageBean
	• uri: ejb-jar-ic.jar,META-INF/ejb-jar.xml
	• listenerPort: MessageBeanPort
	• JNDI: null
	• jndi.dest: null
	• actspec.auth: null
		Using Jacl:
		`$AdminApp install $ear {-BindJndiForEJBMessageBinding`
		`{{Ejb1 MessageBean`
		`ejb-jar-ic.jar,META-INF/ejb-jar.xml myListenerPort`
		`jndi1 jndiDest1 actSpecAuth1}}}`
		Using Jython:
		`AdminApp.install(ear, ['-BindJndiForEJBMessageBinding',`
		`[['Ejb1', 'MessageBean',`
		`'ejb-jar-ic.jar,META-INF/ejb-jar.xml', 'myListenerPort',`
		`'jndi1', 'jndiDest1', 'actSpecAuth1']]])`

BindJndiForEJB MessageBinding continued	Use the **taskInfo** command of the AdminApp object to obtain information about the data that is needed for your application. You need to provide data for rows or entries that are either missing information, or require an update.	

BindJndiForEJB NonMessageBinding	Binds enterprise beans to Java Naming and Directory Interface (JNDI) names.
	Ensure each non message-driven enterprise bean in your application or module is bound to a JNDI name. Use this option to provide missing data or update a task.
	Use the **taskInfo** command of the AdminApp object to obtain information about the data that is needed for your application. You need to provide data for rows or entries that are either missing information, or require an update.
		Using Jacl:
		`$AdminApp install c:/myapp.ear {-BindJndiForEJBNonMessageBinding {{"Increment Bean Jar" Inc Increment.jar,META-INF/ejb-jar.xml IncBean}}}`
		Using Jython:
		`AdminApp.install('c:/myapp.ear', '[-BindJndiForEJBNonMessageBinding [["Increment Bean Jar" Inc Increment.jar,META-INF/ejb-jar.xml IncBean]]]')`

cell	Specifies the cell name to install or update an entire application or to update an application in order to add a new module. If you want to update an entire application, this option only applies if the application contains a new module that does not exist in the installed application.	
cluster	Specifies the cluster name to install or update an entire application or to update an application in order to add a new module. This option only applies in a Network Deployment environment. If you want to update an entire application, this option only applies if the application contains a new module that does not exist in the installed application.	

contents	Specifies the file that contains the content that you want to update. For example, depending on the content type, the file could be an EAR file, a module, a partial zip, or a single file. The path to the file must be local to the scripting client. The `contents` option is required unless you have specified the `delete` option.	
contenturi	Specifies the URI of the file that you are adding, updating, or removing from an application. This option only applies to the **update** command. The `contenturi` option is required if the content type is `file` or `modulefile`. This option is ignored for other content types.	
contextroot	Specifies the context root that you use when installing a stand-alone Web archive (WAR) file.	

CorrectOracleIsolation Level	Specifies the isolation level for the Oracle type provider. Use this option to provide missing data or to update a task.
	The last field of each entry specifies the isolation level. Valid isolation level values are `2` or `4`.
	Use the **taskInfo** command of the AdminApp object to obtain information about the data that is needed for your application. You only need to provide data for rows or entries that are either missing information, or require an update.
		Using Jacl:
		`$AdminApp install c:/myapp.ear {-CorrectOracleIsolationLevel {{AsyncSender jms/MyQueueConnectionFactory jms/Resource1 2}}`
		Using Jython:
		`AdminApp.install('c:/myapp.ear', '[-CorrectOracleIsolationLevel [[AsyncSender jms/MyQueueConnectionFactory jms/Resource1 2]]]')`

CorrectUseSystem Identity	Replaces RunAs System to RunAs Roles.
	The enterprise beans that you install contain a RunAs system identity. You can optionally change this identity to a RunAs role. Use this option to provide missing data or update a task.
	Use the **taskInfo** command of the AdminApp object to obtain information about the data that is needed for your application. You need to provide data for rows or entries that are either missing information, or require an update.
		Using Jacl:
		`$AdminApp install c:/myapp.ear {-CorrectUseSystemIdentity`
		` {{Inc "Increment Bean Jar"`
		`Increment.jar,META-INF/ejb-jar.xml getValue() RunAsUser2`
		` user2 password2} {Inc "Increment`
		`Bean Jar" Increment.jar,META-INF/ejb-jar.xml Increment()`
		` RunAsUser2 user2 password2}}}`
		Using Jython:
		`AdminApp.install('c:/myapp.ear', '[-CorrectUseSystemIdentity`
		` [[Inc "Increment Bean Jar"`
		`Increment.jar,META-INF/ejb-jar.xml getValue() RunAsUser2`
		` user2 password2] [Inc "Increment`
		`Bean Jar" Increment.jar,META-INF/ejb-jar.xml Increment()`
		`RunAsUser2 user2 password2]]]')`

createMBeansFor Resources	Specifies that MBeans are created for all resources such as, servlets, JavaServer Pages (JSP) files, and enterprise beans, that are defined in an application when the application starts on a deployment target. This option does not require a value. The default setting is the nocreateMBeansForResources option.	

custom	Specifies a name-value pair using the format `name=value`. Use the `custom` option to pass options to application deployment extensions. See the application deployment extension documentation for available custom options.	

DataSourceFor10 CMPBeans	Specifies optional data sources for individual 1.x container-managed persistence (CMP) beans. Use this option to provide missing data or to update a task.
	Mapping a specific data source to a CMP bean overrides the default data source for the module that contains the enterprise bean. Each element of the DataSourceFor10CMPBeans option consists of the following fields: EJBModule, EJB, uri, JNDI, userName, password, login.config.name, and auth.props. Of these fields, the following can be assigned values: JNDI, userName, password, login.config.name, and auth.props.
		Using Jacl:
		`$AdminApp install c:/app1.ear {-DataSourceFor10CMPBeans`
		`  {{"Increment CMP 1.1 EJB"`
		`IncCMP11 IncCMP11.jar,META-INF/ejb-jar.xml myJNDI user1 password1`
		`loginName1 authProps1}}}`
		Using Jython:
		`AdminApp.install('c:/app1.ear', ['-DataSourceFor10CMPBeans',`
		` [["Increment CMP 1.1 EJB", 'IncCMP11',`
		` 'IncCMP11.jar,META-INF/ejb-jar.xml', 'myJNDI', 'user1',`
		` 'password1', 'loginName1', 'authProps1']]])`

DataSourceFor10 CMPBeans continued	The current contents of the option after running default bindings include: - EJBModule: Increment CMP 1.1 EJB - EJB: IncCMP11 - uri: IncCMP11.jar,META-INF/ejb-jar.xml - JNDI: DefaultDatasource - userName: null - password: null - login.config.name: DefaultPrincipalMapping - auth.props: - LoginConfiguration: Name - Properties If the login.config.name is set to DefaultPrincipalMapping, a property is created with the name com.ibm.mapping.authDataAlias . The value of the property is set by the auth.props. If the login.config name is not set to DefaultPrincipalMapping, the auth.props can specify multiple properties. The string format is websphere:name= <name1>,value=<value1>,description=<desc1>. Specify multiple properties using the plus sign (+) .	

DataSourceFor10 CMPBeans continued	Use the **taskInfo** command of the AdminApp object to obtain information about the data that is needed for your application. You need to provide data for rows or entries that are missing information, or require an update.	

DataSourceFor20 CMPBeans	Specifies optional data sources for individual 2.x container-managed persistence (CMP) beans. Use this option to provide missing data or to update a task.
	Mapping a specific data source to a CMP bean overrides the default data source for the module that contains the enterprise bean. Each element of the DataSourceFor20CMPBeans option consists of the following fields: EJBModule, EJB, uri, JNDI, resAuth, login.config.name, and auth.props. Of these fields, the following can be assigned values: JNDI, resAuth, login.config.name, and auth.props.
		Using Jacl:
		`$AdminApp install c:/app1.ear {-DataSourceFor20CMPBeans {{"Increment Enterprise Java Bean" Increment Increment.jar, META-INF/ejb-jar.xml jndi1 container}}}`
		Using Jython:
		`AdminApp.install('c:/app1.ear', ['-DataSourceFor20CMPBeans', [["Increment Enterprise Java Bean", 'Increment', 'Increment.jar, META-INF/ejb-jar.xml', 'jndi1', 'container']]])`

DataSourceFor20 CMPBeans continued	The current contents of the option after running default bindings includes the following: • EJBModule: Increment enterprise bean • EJB: Increment • uri: Increment.jar,META-INF/ejb-jar.xml • JNDI: DefaultDatasource • resAuth: cmpBinding.perConnectionFactory • login.config.name: DefaultPrincipalMapping • auth.props: • LoginConfiguration: Name • Properties	

DataSourceFor20 CMPBeans continued	The last field in each entry of this task specifies the value for resource authorization. Valid values for resource authorization are `per connection factory` or `container`. If the login.config.name is set to DefaultPrincipalMapping, a property is created with the name com.ibm.mapping.authDataAlias . The value of the property is set by the auth.props. If the login.config name is not set to DefaultPrincipalMapping, the auth.props can specify multiple properties. The string format is websphere:name= <name1>,value=<value1>,description=<desc1>. Specify multiple properties using the plus sign (+) . Use the **taskInfo** command of the AdminApp object to obtain information about the data needed for your application. You only need to provide data for rows or entries that are missing information, or require an update.	

DataSourceFor10 EJBModules	Specifies the default data source for the enterprise bean module that contains 1.x container-managed persistence (CMP) beans. Use this option to provide missing data or update a task.
	Each element of the DataSourceFor10EJBModules option consists of the following fields: EJBModule, uri, JNDI, userName, password, login.config.name, and auth.props. Of these fields, the following can be assigned values: JNDI, userName, password, login.config.name, and auth.props.
		Using Jacl:
		`$AdminApp install c:/app1.ear {-DataSourceFor10EJBModules {{"Increment CMP 1.1 EJB" IncCMP11.jar,META-INF/ejb-jar.xml yourJNDI user2 password2 loginName authProps}}}`
		Using Jython:
		`AdminApp.install('c:/app1.ear', ['-DataSourceFor10EJBModules', [["Increment CMP 1.1 EJB", 'IncCMP11.jar,META-INF/ejb-jar.xml', 'yourJNDI', 'user2', 'password2', 'loginName', 'authProps']]])`

DataSourceFor10 EJBModules continued	The current contents of the option after running default bindings include: • EJBModule: Increment CMP 1.1 enterprise bean • uri: IncCMP11.jar,META-INF/ejb-jar.xml • JNDI: DefaultDatasource • userName: null • password: null • login.config.name: DefaultPrincipalMapping • auth.props: • LoginConfiguration: Name • Properties If the login.config.name is set to DefaultPrincipalMapping, a property is created with the name com.ibm.mapping.authDataAlias . The value of the property is set by the auth.props. If the login.config name is not set to DefaultPrincipalMapping, the auth.props can specify multiple properties. The string format is websphere:name= <name1>,value=<value1>,description=<desc1>. Specify multiple properties using the plus sign (+) .	

DataSourceFor10 EJBModules continued	Use the **taskInfo** command of the AdminApp object to obtain information about the data that is needed for your application. You need to provide data for rows or entries that are either missing information, or require an update.	

DataSourceFor20 EJBModules	Specifies the default data source for the enterprise bean 2.x module that contains 2.x container managed persistence (CMP) beans. Use this option to provide missing data or update a task.
	Each element of the DataSourceFor20EJBModules option consists of the following fields: EJBModule, uri, JNDI, resAuth, login.config.name, and auth.props. Of these fields, the following can be assigned values: JNDI, resAuth, login.config.name, and auth.props.
	The current contents of the option after running default bindings include:
	• EJBModule: Increment enterprise bean
	• uri: Increment.jar,META-INF/ejb-jar.xml
	• JNDI: DefaultDatasource
	• resAuth: cmpBinding.perConnectionFactory
	• login.config.name: DefaultPrincipalMapping
	• auth.props:
	• LoginConfiguration: Name
	• Properties
		Using Jacl:
		`$AdminApp install c:/app1.ear {-DataSourceFor20EJBModules`
		`{{"Increment Enterprise Java Bean" Increment.jar,META-INF/ejb-jar.xml`
		` jndi2 container}}}`
		Using Jython:
		`AdminApp.install('c:/app1.ear', ['-DataSourceFor20EJBModules',`
		`[["Increment Enterprise Java Bean", 'Increment.jar,META-INF/ejb-jar.xml',`
		` 'jndi2', 'container']]])`

DataSourceFor20 EJBModules	The last field in each entry of this task specifies the value for resource authorization. Valid values for resource authorization are `per connection factory` or `container`. If the login.config.name is set to DefaultPrincipalMapping, a property is created with the name com.ibm.mapping.authDataAlias . The value of the property is set by the auth.props. If the login.config name is not set to DefaultPrincipalMapping, the auth.props can specify multiple properties. The string format is websphere:name= <name1>,value=<value1>,description=<desc1>. Specify multiple properties using the plus sign (+) . Use the **taskInfo** command of the AdminApp object to obtain information about the data that is needed for your application. You need to provide data for rows or entries that are either missing information, or require update.	

defaultbinding.cf.jndi	Specifies the Java Naming and Directory Interface (JNDI) name for the default connection factory.	
defaultbinding.cf.resauth	Specifies the RESAUTH for the connection factory.	
defaultbinding.datasource.jndi	Specifies the Java Naming and Directory Interface (JNDI) name for the default data source.	
defaultbinding.datasource.password	Specifies the password for the default data source.	
defaultbinding.datasource.username	Specifies the user name for the default data source.	
defaultbinding.ejbjndi.prefix	Specifies the prefix for the enterprise bean Java Naming and Directory Interface (JNDI) name.	
defaultbinding.force	Specifies that the default bindings override the current bindings.	
defaultbinding.strategy.file	Specifies a custom default bindings strategy file.	
defaultbinding.virtual.host	Specifies the default name for a virtual host.	
depl.extension.reg	Deprecated. No replication option is available.	

deployejb	Specifies to run the EJBDeploy tool during installation. This option does not require a value. If you pre-deploy the application Enterprise Archive (EAR) file using the EJBDeploy tool then the default value is `nodeployejb`. If not, the default value is `deployejb`.	
deployejb.classpath	Specifies an extra class path for the EJBDeploy tool.	
deployejb.dbschema	Specifies the database schema for the EJBDeploy tool.	

deployejb.dbtype	Specifies the database type for the EJBDeploy tool.
	Possible values include:
	`CLOUDSCAPE_V5`
	`DB2UDB_V72`
	`DB2UDBOS390_V6`
	`DB2UDBISERIES`
	`INFORMIX_V73`
	`INFORMIX_V93`
	`MSSQLSERVER_V7`
	`MSSQLSERVER_2000`
	`ORACLE_V8`
	`ORACLE_V9I`
	`SYBASE_V1200`
	For a list of current supported database vendor types, run `ejbdeploy -?`.	

deployejb.rmic	Specifies extra RMIC options to use for the EJBDeploy tool.	

deployws	Specifies to deploy Web services during installation. This option does not require a value. The default value is: `nodeployws`.	
deployws.classpath	Specifies the extra class path to use when you deploy Web services.	
deployws.jardirs	Specifies the extra extension directories to use when you deploy Web services.	
distributeApp	Specifies that the application management component distributes application binaries. This option does not require a value. This setting is the default.	

EmbeddedRar	Binds Java 2 Connector objects to JNDI names. You must bind each Java 2 Connector object in your application or module, such as, J2C connection factories, J2C activation specs and J2C administrative objects, to a JNDI name. Each element of the EmbeddedRar option contains the following fields: RARModule, uri, j2cid, j2c.name, j2c.jndiName. You can assign the following values to the fields: j2c.name, j2c.jndiName. The current contents of the option after running default bindings include: RARModule: <rar module name> uri: <rar name>,META-INF/ra.xml j2cid: <identifier of the J2C object> j2c.name: j2cid j2c.jndiName: eis/j2cid Where j2cid is: J2C connection factory :connectionFactoryInterface J2C admin object :adminObjectInterface J2C activation spec : message listener type If the ID is not unique in the ra.xml file, -<number> will be added. For example, javax.sql.DataSource-2.	Using Jacl: $AdminApp install $embeddedEar {-EmbeddedRar {{"FVT Resource Adapter" jca15cmd.rar,META-INF/ra.xml javax.sql.DataSource javax.sql.DataSource1 eis/javax.sql.javax.sql.DataSSource1} {"FVT Resource Adapter" jca15cmd.rar,META-INF/ra.xml javax.sql.DataSource2 javax.sql.DataSource2 eis/javax.sql.DataSource2} {"FVT Resource Adapter" jca15cmd.rar,META-INF/ra.xml javax.jms.MessageListener javax.jms.MessageListener1 eis/javax.jms.MessageListener1} {"FVT Resource Adapter" jca15cmd.rar,META-INF/ra.xml javax.jms.MessageLListener2 javax.jms.MessageListener2 eis/javax.jms.MessageListener2} {"FVT Resource Adapter" jca15cmd.rar,META-INF/ra.xml fvt.adapter.message.FVTMessageProvider fvt.adapter.message. FVTMessageProvider1 eis/fvt.adapter.message.FVTMessageProvider1} {"FVT Resource Adapter" jca15cmd.rar,META-INF/ra.xml fvt.adapter.message.FVTMessageProvider2 fvt. adapter.message.FVTMessageProvider2 eis/fvt.adapter. message.FVTMessageProvider2}}} Using Jython: AdminApp.install(embeddedEar, ['-EmbeddedRar', [["FVT Resource Adapter", 'jca15cmd.rar,META-INF/ra.xml', 'javax.sql.DataSource', 'javax.sql.DataSource1', 'eis/javax.sql.javax.sql.DataSSource1'], ["FVT Resource Adapter", 'jca15cmd.rar,META-INF/ra.xml javax.sql.DataSource2', 'javax.sql.DataSource2', 'eis/javax.sql.DataSource2'], ["FVT Resource Adapter", 'jca15cmd.rar,META-INF/ra.xml', 'javax.jms.MessageListener', 'javax.jms.MessageListener1', 'eis/javax.jms.MessageListener1'], ["FVT Resource Adapter", 'jca15cmd.rar,META-INF/ra.xml', 'javax.jms.MessageLListener2', 'javax.jms.MessageListener2', 'eis/javax.jms.MessageListener2'], ["FVT Resource Adapter", 'jca15cmd.rar,META-INF/ra.xml fvt.adapter.message.FVTMessageProvider', 'fvt.adapter.message.FVTMessageProvider1', 'eis/fvt.adapter.message. FVTMessageProvider1'], ["FVT Resource Adapter", 'jca15cmd.rar,META-INF/ ra.xml', 'fvt.adapter.message.FVTMessageProvider2', 'fvt.adapter.message. FVTMessageProvider2', 'eis/fvt.adapter.message.FVTMessageProvider2']]])

EmbeddedRar continued	Use the **taskInfo** command of the AdminApp object to obtain information about the data that is needed for your application. You need to provide data for rows or entries that are either missing information, or require an update.	

EnsureMethod ProtectionFor10EJB	Selects method protections for unprotected methods of 1.x enterprise beans. Specify to leave the method as unprotected, or assign protection which denies all access. Use this option to provide missing data or to update a task.
	Use the **taskInfo** command of the AdminApp object to obtain information about the data that is needed for your application. You need to provide data for rows or entries that are either missing information, or require an update.
		Using Jacl:
		`$AdminApp install c:/myapp.ear {-EnsureMethodProtectionFor10EJB`
		` {{"Increment EJB Module"`
		` IncrementEJBBean.jar,META-INF/ejb-jar.xml ""} {"Timeout EJB Module"`
		` TimeoutEJBBean.jar,META-INF/ejb-jar.xml`
		` methodProtection.denyAllPermission}}}`
		Using Jython:
		`AdminApp.install('c:/myapp.ear', '[-EnsureMethodProtectionFor10EJB`
		` [["Increment EJB Module"`
		`IncrementEJBBean.jar,META-INF/ejb-jar.xml ""] ["Timeout EJB Module"`
		` TimeoutEJBBean.jar,META-INF/ejb-jar.xml`
		` methodProtection.denyAllPermission]]]')`
		The last field in each entry of this task specifies the value of the protection. Valid protection values include: `methodProtection.denyAllPermission`. You can also leave the value blank if you want the method to remain unprotected.

EnsureMethodProtectionFor20EJB	Selects method protections for unprotected methods of 2.x enterprise beans. Specify to assign a security role to the unprotected method, add the method to the exclude list, or mark the method as cleared. You can assign multiple roles for a method by separating roles names with commas. Use this option to provide missing data or to update a task.
	Use the **taskInfo** command of the AdminApp object to obtain information about the data that is needed for your application. You need to provide data for rows or entries that are either missing information, or require an update the existing data.
		Using Jacl:
		`$AdminApp install c:/myapp.ear {-EnsureMethodProtectionFor20EJB`
		` {{CustomerEjbJar`
		`customerEjb.jar,META-INF/ejb-jar.xml methodProtection.uncheck}`
		` {SupplierEjbJar`
		`supplierEjb.jar,META-INF/ejb-jar.xml methodProtection.exclude}}}`
		Using Jython:
		`AdminApp.install('c:/myapp.ear', '[-EnsureMethodProtectionFor20EJB`
		` [[CustmerEjbJar`
		`customerEjb.jar,META-INF/ejb-jar.xml methodProtection.uncheck]`
		` [SupplierEjbJar`
		`supplierEjb.jar,META-INF/ejb-jar.xml methodProtection.exclude]]]')`
		The last field in each entry of this task specifies the value of the protection. Valid protection values include: `methodProtection.uncheck`, `methodProtection.exclude`, or a list of security roles that are separated by commas.

installdir	Deprecated. This option is replaced by the `installed.ear.destination` option.	
installed.ear.destination	Specifies the directory to place application binaries.	

MapModulesToServers	Specifies the application server where you want to install modules that are contained in your application. You can install modules on the same server, or disperse them among several servers. Use this option to provide missing data or to update to a task.
	
	Use the **taskInfo** command of the AdminApp object to obtain information about the data that is needed for your application. You need to provide data for rows or entries that are either missing information, or require an update.
		Using Jacl:
		`$AdminApp install c:/myapp.ear {-MapModulesToServers`
		` {{"Increment Bean Jar"`
		`Increment.jar,META-INF/ejb-jar.xml WebSphere:cell=mycell,`
		` node=mynode,server=server1}`
		`{"Default Application" default_app.war,WEB-INF/web.xml WebSphere:`
		`cell=mycell,node=mynode,server=server1}`
		`{"Examples Application" examples.war,WEB-INF/web.xml WebSphere:`
		`cell=mycell,node=mynode,server=server1}}}`
		
		Using Jython:
		`AdminApp.install('c:/myapp.ear', '[-MapModulesToServers`
		` [["Increment Bean Jar"`
		`Increment.jar,META-INF/ejb-jar.xml WebSphere:cell=mycell,`
		`node=mynode,server=server1]`
		`["Default Application" default_app.war,WEB-INF/web.xml`
		`WebSphere:cell=mycell,node=mynode,server=server1]`
		`["Examples Application" examples.war,WEB-INF/web.xml WebSphere:`
		`cell=mycell,node=mynode,server=server1]]]')`

MapEJBRefToEJB	Maps enterprise Java references to enterprise beans. You must map each enterprise bean reference defined in your application to an enterprise bean. Use this option to provide missing data or update to a task.
	Use the **taskInfo** command of the AdminApp object to obtain information about the data needed for your application. You only need to provide data for rows or entries that are missing information, or those where you want to update the existing data.
		Using Jacl:
		`$AdminApp install c:/myapp.ear {-MapEJBRefToEJB`
		` {{"Examples Application" ""`
		`examples.war,WEB-INF/web.xml BeenThereBean com.ibm.websphere.`
		`beenthere.BeenThere IncBean}}}`
		Using Jython:
		`AdminApp.install('c:/myapp.ear', '[-MapEJBRefToEJB`
		` [["Examples Application" ""`
		`examples.war,WEB-INF/web.xml BeenThereBean com.ibm.websphere.`
		`beenthere.BeenThere IncBean]]]')`

MapMessage DestinationRefToEJB	Maps message destination references to Java Naming and Directory Interface (JNDI) names of administrative objects from the installed resource adapters. You must map each message destination reference that is defined in your application to an administrative object. Use this option to provide missing data or to update a task.
	The current contents of the option after running default bindings include:
	• EJB Module: ejb-jar-ic.jar
	• EJB: MessageBean
	• URI: ejb-jar-ic.jar,META-INF/ejb-jar.xml
	• JNDI Name: [eis/J2CACT1]:
	• Destination JNDI Name: [jms/TopicName]:
	• The default JNDI name will be picked up from the corresponding message destination reference.
		Using Jacl:
		`$AdminApp install $earfile {-MapMessageDestinationRefToEJB`
		`{{ejb-jar-ic.jar Publisher ejb-jar-ic.jar,META-INF/ejb-jar.xml`
		` MyConnection jndi2}`
		`{ejb-jar-ic.jar Publisher ejb-jar-ic.jar,META-INF/ejb-jar.xml`
		` PhysicalTopic jndi3}`
		`{ejb-jar-ic.jar Publisher ejb-jar-ic.jar,META-INF/ejb-jar.xml`
		` jms/ABC jndi4}}}`
		Using Jython:
		`AdminApp.install(ear1, ['-MapMessageDestinationRefToEJB',`
		`[['ejb-jar-ic.jar', 'Publisher', 'ejb-jar-ic.jar,META-INF/`
		`ejb-jar.xml', 'MyConnection', 'jndi2'],`
		`['ejb-jar-ic.jar', 'Publisher', 'ejb-jar-ic.jar,META-INF/`
		`ejb-jar.xml', 'PhysicalTopic', 'jndi3'],`
		`['ejb-jar-ic.jar', 'Publisher', 'ejb-jar-ic.jar,META-INF/`
		`ejb-jar.xml', 'jms/ABC', 'jndi4']]])`

MapMessage DestinationRefToEJB continued	Use the **taskInfo** command of the AdminApp object to obtain information about the data that is needed for your application. You need to provide data for rows or entries that are either missing information, or require an update.	

MapResEnvRefToRes	Maps resource environment references to resources. You must map each resource environment reference that is defined in your application to a resource. Use this option to provide missing data or to update a task.
	Use the **taskInfo** command of the AdminApp object to obtain information about the data that is needed for your application. You need to provide data for rows or entries that are either missing information, or require an update.
		Using Jacl:
		`$AdminApp install c:/myapp.ear {-MapResEnvRefToRes`
		`{{AsyncSender AsyncSender`
		`asyncSenderEjb.jar,META-INF/ejb-jar.xml jms/ASYNC_SENDER_QUEUE`
		`javax.jms.Queue jms/Resource2}}}`
		Using Jython:
		`AdminApp.install('c:/myapp.ear', '[-MapResEnvRefToRes`
		`[[AsyncSender AsyncSender`
		`asyncSenderEjb.jar,META-INF/ejb-jar.xml jms/ASYNC_SENDER_QUEUE`
		`javax.jms.Queue jms/Resource2]]]')`

MapResRefToEJB	Maps resource references to resources. You must map each resource reference that is defined in your application to a resource. Use this option to provide missing data or to update a task.
	Each element of the MapResRefToEJB option consists of the following fields: module, EJB, uri, referenceBinding, resRef.type, JNDI, login.config.name, and auth.props. Of these fields, the following can be assigned values: JNDI, login.config.name, auth.props. The JNDI field is required.
	The current contents of the option after running default bindings include:
	• Module: deplmtest.jar
	• EJB: MailEJBObject
	• uri: deplmtest.jar,META-INF/ejb-jar.xml
	• referenceBinding: mail/MailSession9
	• resRef.type: javax.mail.Session
	• JNDI: mail/DefaultMailSession
	• login.config.name: DefaultPrincipalMapping
	• auth.props:
		Using Jacl:
		`$AdminApp install c:/app1.ear {-MapResRefToEJB {{deplmtest.jar`
		`MailEJBObject deplmtest.jar,META-INF/ejb-jar.xml mail/MailSession9`
		`javax.mail.Session jndi1 login1 authProps1} {"JavaMail Sample WebApp" ""`
		`mtcomps.war,WEB-INF/web.xml mail/MailSession9 javax.mail.`
		`Session jndi2 login2 authProps2}}}`
		Using Jython:
		`AdminApp.install('c:/app1.ear', ['-MapResRefToEJB', [['deplmtest.jar',`
		`'MailEJBObject', 'deplmtest.jar,META-INF/ejb-jar.xml mail/MailSession9',`
		`'javax.mail.Session', 'jndi1', 'login1', 'authProps1'],`
		`["JavaMail Sample WebApp", "",`
		`'mtcomps.war,WEB-INF/web.xml', 'mail/MailSession9', 'javax.mail.`
		`Session', 'jndi2', 'login2', 'authProps2']]])`

MapResRefToEJB continued	If the login.config.name is set to DefaultPrincipalMapping, a property is created with the name com.ibm.mapping.authDataAlias . The value of the property is set by the auth.props. If the login.config name is not set to DefaultPrincipalMapping, the auth.props can specify multiple properties. The string format is websphere:name= <name1>,value=<value1>,description=<desc1>. Specify multiple properties using the plus sign (+) . Use the **taskInfo** command of the AdminApp object to obtain information about the data that is needed for your application. You need to provide data for rows or entries that are either missing information, or require an update.	

MapRolesToUsers	Maps users to roles. You must map each role that is defined in the application or module to a user or group from the domain user registry. You can specify multiple users or groups for a single role by separating them with a pipe (|). Use this option to provide missing data or to update a task.
	Use the **taskInfo** command of the AdminApp object to obtain information about the data that is needed for your application. You need to provide data for rows or entries that are either missing information, or require an update.
		Using Jacl:
		`$AdminApp install c:/myapp.ear {-MapRolesToUsers {{"All Role" No Yes "" ""} {"Every Role" Yes No "" ""} {DenyAllRole No No user1 group1}}}`
		Using Jython:
		`AdminApp.install('c:/myapp.ear', '[-MapRolesToUsers [["All Role" No Yes "" ""] ["Every Role" Yes No "" ""] [DenyAllRole No No user1 group1]]]')`
		where `{{″All Role″ No Yes ″″ ″″}` corresponds to the following:
		″**All Role**″
		Represents the role name
		No Indicates to allow access to everyone (yes/no)
		Yes Indicates to allow access to all authenticated users (yes/no)
		″″ Indicates the mapped users
		″″ Indicates the mapped groups

MapRunAsRolesToUsers	Maps RunAs Roles to users. The enterprise beans you that install contain predefined RunAs roles. Enterprise beans that need to run as a particular role for recognition while interacting with another enterprise bean use RunAs roles. Use this option to provide missing data or to update a task.
	Use the **taskInfo** command of the AdminApp object to obtain information about the data that is needed for your application. You need to provide data for rows or entries that are either missing information, or require an update.
		Using Jacl:
		`$AdminApp install c:/myapp.ear {-MapRunAsRolesToUsers`
		`{{UserRole user1 password1}`
		`{AdminRole administrator administrator}}}`
		Using Jython:
		`AdminApp.install('c:/myapp.ear', '[-MapRunAsRolesToUsers`
		`[[UserRole user1 password1]`
		`[AdminRole administrator administrator]]]')`

MapWebModToVH	Selects virtual hosts for Web modules. Specify the virtual host where you want to install the Web modules that are contained in your application. You can install Web modules on the same virtual host, or disperse them among several hosts. Use this option to provide missing data or to update a task.
	Use the **taskInfo** command of the AdminApp object to obtain information about the data that is needed for your application. You need to provide data for rows or entries that are either missing information, or require an update.
		Using Jacl:
		`$AdminApp install c:/myapp.ear {-MapWebModToVH {{"Default Application"`
		`default_app.war,WEB-INF/web.xml default_host} {"Examples Application"`
		`examples.war,WEB-INF/web.xml default_host}}}`
		Using Jython:
		`AdminApp.install('c:/myapp.ear', '[-MapWebModToVH [["Default Application"`
		`default_app.war,WEB-INF/web.xml default_host] ["Examples Application"`
		`examples.war,WEB-INF/web.xml default_host]]]')`

noallowPermInFilterPolicy	Specifies not to continue with the application deployment process when the application contains policy permissions that are in the filter policy. This option is the default setting and it does not require a value.	

node	Specifies the node name to install or update an entire application or to update an application in order to add a new module. If you want to update an entire application, this option only applies if the application contains a new module that does not exist in the installed application.	
nocreateMBeansForResources	Specifies that MBeans are not created for all resources such as, servlets, JSPs, and enterprise beans, that are defined in an application when the application starts on a deployment target. This option is the default setting and it does not require a value.	
nodeployejb	Specifies not to run the EJBDeploy tool during installation. This option is the default setting and it does not require a value.	
nodeployws	Specifies not to deploy Web services during installation. This option is the default setting and it does not require a value.	

nodistributeApp	Specifies that the application management component does not distribute application binaries. This option does not require a value. The default setting is the distributeApp option.	
noreloadEnabled	Disables class reloading. This option does not require a value. The default setting is the `reloadEnabled` option.	
nopreCompileJSPs	Specifies not to precompile JavaServer Pages files. This option is the default setting and it does not require a value.	
noprocessEmbeddedConfig	Use this option to ignore the embedded configuration data that is include in the application. This option does not required a value. If the application Enterprise Archive (EAR) file does not contain embedded configuration data, the noprocessEmbeddedConfig option is the default setting. Otherwise, the default setting is the processEmbeddedConfig option.	

nouseMetaDataFromBinary	Specifies that the metadata that is used at run time, for example, deployment descriptors, bindings, extensions, and so on, come from the configuration repository. This option is the default setting and it does not require a value. Use this option to indicate that the metadata that is used at run time comes from the enterprise archive file (EAR) file.	
nousedefaultbindings	Specifies not to use default bindings for installation. This option is the default setting and it does not require a value.	

operation	Specifies the operation that you want to perform. This option only applies to the **update** command. The valid values include:
	- `add` - Adds new content.
	- `addupdate` - Adds or updates content based on the existence of content in the application.
	- `delete` - Deletes content.
	- `update` - Updates existing content.
	The operation option is required if the content type is file or modulefile. If the value of the content type is `app`, the value of the operation option must be `update`.
		The following examples show how to use the options for the **update** command to update a single file in a deployed application:
		Using Jacl:
		`$AdminApp update app1 file {-operation update -contents c:/apps/app1/my.xml -contenturi app1.jar/my.xml}`
		Using Jython string:
		`AdminApp.update('app1', 'file', '[-operation update -contents c:/apps/app1/my.xml -contenturi app1.jar/my.xml]')`
		Using Jython list:
		`AdminApp.update('app1', 'file', ['-operation', 'update', '-contents', 'c:/apps/app1/my.xml', '-contenturi', app1.jar/my.xml'])`
		where `AdminApp` is the scripting object, `update` is the command, `app1` is the name of the application you want to update, `file` is the content type, `operation` is an option of the **update** command, `update` is the value of the `operation`option, `contents` is an option of the **update** command, */apps/app1/my.xml* is the value of the `contents` option, `contenturi` is an option of the **update** command, *app1.jar/my.xml* is the value of the `contenturi` option.

processEmbeddedConfig	Use this option to process the embedded configuration data that is included in the application. This option does not required a value. If the application Enterprise Archive (EAR) file contains embedded configuration data, this option is the default setting. If not, the default setting is the nonprocessEmbeddedConfig option.	
preCompileJSPs	Specifies to precompile the JavaServer Pages files. This option does not require a value. The default is nopreCompileJSPs.	
reloadEnabled	Specifies that the file system of the application will be scanned for updated files so that changes reload dynamically. This option is the default setting and it does not require a value.	
reloadInterval	Specifies the time period in seconds that the file system of the application will be scanned for updated files. Valid range is greater than zero. The default is three seconds.	

server	Specifies the server name to install or update an entire application or to update an application in order to add a new module. If you want to update an application, this option only applies if the application contains a new module that does not exist in the installed application.	

update	Updates the installed application with a new version of the enterprise archive file (EAR) file. This option does not require a value. The application that is being updated, which is specified by the appname option, must already be installed in the WebSphere Application Server configuration. The update action merges bindings from the new version with the bindings from the old version, uninstalls the old version, and installs the new version. The binding information from new version of the EAR file is preferred over the corresponding one from the old version. If any element of binding is missing in the new version, the corresponding element from the old version is used.	

update.ignore.new	Specifies that during the update action, bindings from the new version of the application are ignored. This option does not require a value. This option applies only if you specify one of the following items: • The update option for the **install** command. • The modulefile or app as the content type for the **update** command.	
update.ignore.old	Specifies that during the update action, the bindings from the installed version of the application are ignored. This option does not require a value. This option applies only if you specify one of the following items: • The update option for the **install** command. • The modulefile or app as the content type for the **update** command.	

useMetaDataFromBinary	Specifies that the metadata that is used at run time, for example, deployment descriptors, bindings, extensions, and so on, come from the EAR file. This option does not require a value. The default value is `nouseMetaDataFromBinary`, which means that the metadata that is used at run time comes from the configuration repository.	
usedefaultbindings	Specifies to use default bindings for installation. This option does not require a value. The default setting is nousedefaultbindings.	

validateinstall	Specifies the level of application installation validation. Valid option values include: • off - Specifies no application deployment validation. This value is the default. • warn - Performs application deployment validation and continues with the application deployment process even when reported warnings or error messages exist. • fail - Performs application deployment validation and does not to continue with the application deployment process when reported warnings or error messages exist.	
verbose	Causes additional messages to display during installation. This option does not require a value.	

WebServicesClientBindDeployedWSDL	The immutable values for this option identify the client Web service that you are modifying. The scoping fields include: Module, EJB, and Web service. The single mutable value for this task is the deployed WSDL file name. It indicates the Web Services Description Language (WSDL) the client uses.
	The Module field identifies the enterprise or Web application within the application. If the module is an enterprise bean , the EJB field identifies a particular enterprise bean within the module. The Web service field identifies the Web service within the enterprise bean or the Web application module. This identifier corresponds to the wsdl:service attribute in the WSDL file, prepended with `service/`, for example, `service/WSLoggerService2`.
		Using Jacl:
		`$AdminApp install WebServicesSamples.ear`
		` {-WebServicesClientBindDeployedWSDL`
		`{{AddressBookW2JE.jar AddressBookW2JE service/WSLoggerService2`
		`META-INF/wsdl/DeployedWsdl1.wsdl}}}`
		Using Jython:
		`AdminApp.install('WebServicesSamples.ear',`
		` '[-WebServicesClientBindDeployedWSDL`
		`[[AddressBookW2JE.jar AddressBookW2JE service/WSLoggerService2`
		`META-INF/wsdl/DeployedWsdl1.wsdl]]]')`

WebServicesClientBind DeployedWSDL continued	The deployed WSDL attribute names a WSDL file relative to the client module. An example of a deployed WSDL for a Web application is the following: `WEB-INF/wsdl/WSLoggerService`.	

WebServicesClientBind PortInfo	The immutable values identify the port of a client Web service that you are modifying. The scoping fields include: Module, EJB, Web service and Port. The mutable values for this task include: `Sync Timeout`, `BasicAuth ID`, `BasicAuth Password`, `SSL Config`, and `Overridden Endpoint URI`. The basic authentication and Secure Sockets Layer (SSL) fields affect transport level security, not Web services security.	Using Jacl:
		`$AdminApp install WebServicesSamples.ear`
		` {-WebServicesClientBindPortInfo`
		`{{AddressBookW2JE.jar AddressBookW2JE`
		`service/WSLoggerService2 WSLoggerJMS 3000 newHTTP_ID newHTTP_pwd`
		`sslAliasConfig http://yunus:9090/WSLoggerEJB/services/WSLoggerJMS}}}`
		Using Jython:
		`AdminApp.install('WebServicesSamples.ear',`
		` '[-WebServicesClientBindPortInfo`
		`[[AddressBookW2JE.jar AddressBookW2JE`
		`service/WSLoggerService2 WSLoggerJMS 3000 newHTTP_ID newHTTP_pwd`
		`sslAliasConfig http://yunus:9090/WSLoggerEJB/services/WSLoggerJMS]]]')`

WebServicesClientBindPreferredPort	Associates a preferred port (implementation) with a port type (interface) for a client Web service. The immutable values identify a port type of the client Web service that you are modifying. The scoping fields include: Module, EJB, Web service and Port Type. The mutable value for this task is `Port`.
	• Port Type - QName ("{namespace} localname") of a port type that is defined by a wsdl:portType attribute in the WSDL file that identifies an interface.
	• Port - QName of a port defined by a wsdl:port attribute within a wsdl:service attribute in a WSDL file that identifies an implementation that has preference.
		Using Jacl:
		`$AdminApp install WebServicesSamples.ear {-WebServicesClientBindPreferredPort {{AddressBookW2JE.jar AddressBookW2JE service/WSLoggerService2 WSLoggerJMS WSLoggerJMSPort}}}`
		Using Jython:
		`AdminApp.install('WebServicesSamples.ear', '[-WebServicesClientBindPreferredPort [[AddressBookW2JE.jar AddressBookW2JE service/WSLoggerService2 WSLoggerJMS WSLoggerJMSPort]]]')`

WebServicesServerBindPort	Sets two attributes of a Web service port. The immutable values identify the port of a Web service that you are modifying. The scope fields include: Module, Web service and Port. The mutable values include: `WSDL Service Name`, and `Scope`.
	The scope determines the life cycle of implementing the Java bean. The valid values include: `Request` (new instance for each request), `Application` (one instance for each web-app), and `Session` (new instance for each HTTP session).
	The scope attribute does not apply to Web services that a Java Message Service (JMS) transport. The scope attribute does not apply to enterprise beans.
	The WSDL service name identifies a service when more than one service has the same port name. The WSDL service name is represented as a QName string, for example, `{namespace}localname` .
		Using Jacl:
		`$AdminApp install WebServicesSamples.ear {-WebServicesServerBindPort {{AddressBookW2JE.jar service/WSLoggerService2 WSLoggerJMS {} Session}}}`
		Using Jython:
		`AdminApp.install('WebServicesSamples.ear', '[-WebServicesServerBindPort [[AddressBookW2JE.jar service/WSLoggerService2 WSLoggerJMS "" Session]]]')`

WebServicesClient CustomProperty	Supports the configuration of the name value parameter for the description of the client bind file of a Web service. The immutable values identify the port of the Web service that you are modifying. The scope fields include: Module, Web service, and Port. The mutable values include: `name` and `value`.
	The format of the `name` and `value` values include a string that represents multiple name and value pairs by using the + character as a separator. For example, name string = ″n1+n2+n3″ value string = ″v1+v2+v3″ yields name/value pairs: {{″n1″ ″v1″}, {″n2″ ″v2″}, {″n3″ ″ v3″}}
		Using Jacl:
		`$AdminApp edit WebServicesSamples {-WebServicesServerCustomProperty`
		`{{AddressBookW2JE.jar AddressBookService AddressBook http.proxyHost`
		`+http.proxyPort myhost+80}}}`
		Using Jython:
		`AdminApp.edit ( 'WebServicesSamples', '[ -WebServicesServerCustomProperty`
		`[[AddressBookW2JE.jar AddressBookService AddressBook`
		`http.proxyHost+http.proxyPort myhost+80]]]')`

WebServicesServer CustomProperty	Supports the configuration of the name value parameter for the description of the server bind file of a Web service. The scoping fields include the following: Module, EJB, and Web service. The mutable values for this task include: `name` and `value`.
	The format of the these values include a string that represents multiple name and value pairs by using the plus (+) character as a separator. For example, name string = ″n1+n2+n3″ value string = ″v1+v2+v3″ yields name/value pairs: {{″n1″ ″v1″}, {″n2″ ″v2″}, {″n3″ ″ v3″}}
		Using Jacl:
		`$AdminApp edit WebServicesSamples {-WebServicesServerCustomProperty {{AddressBookW2JE.jar AddressBookService AddressBook com.ibm.websphere.webservices.http.responseContentEncoding deflate}}}`
		Using Jython:
		`AdminApp.edit ( 'WebServicesSamples', '[ -WebServicesServerCustomProperty [[AddressBookW2JE.jar AddressBookService AddressBook com.ibm.websphere.webservices.http.responseContentEncoding deflate]]]')`

Usage table for the options of the AdminApp object install, installInteractive, update, updateInteractive, edit, and editInteractive commands:

The following table lists all of the options available for the **install**, **installInteractive**, **update**, **updateInteractive**, **edit**, and **editInteractive** commands of the AdminApp object. The table indicates the applicable commands for each option.

Option name	install and install Interactive commands - install an application	update and update Interactive commands - Update an application	update and update Interactive commands - Add a module	update and update Interactive commands - Update a module	edit and edit Interactive commands - Edit an application	edit and edit Interactive commands - Edit a module

Example: Obtaining option information for AdminApp object commands: Use the **taskInfo** command of the AdminApp object to obtain information about the data that is needed for your application. You need to provide data for rows or entries that are either missing information, or require an update.

- You can use the **options** command to see the requirements for an enterprise archive file (EAR) file if you construct installation command lines. The **taskInfo** command provides detailed information for each task option with a default binding applied to the result.
- The options for the AdminApp **install** command can be complex if you specify various types of binding information, for example, Java Naming and Directory Interface (JNDI) name, data sources for enterprise

bean modules, or virtual hosts for Web modules. An easy way to specify command-line installation options is to use a feature of the **installInteractive** command that generates the options for you. After you install the application interactively once and specify all the updates that you need, look for message WASX7278I in the wsadmin output log. The default output log for wsadmin is `wsadmin.traceout`. You can cut and paste the data in this message into a script, and modify it. For example:

```
WASX7278I: Generated command line: install c:/websphere/appserver/installableapps/jmsample.ear
{-BindJndiForEJBNonMessageBinding {{deplmtest.jar MailEJBObject deplmtest.jar,META-INF/ejb-jar.xml ejb/JMSampEJB1 }}
-MapResRefToEJB {{deplmtest.jar MailEJBObject deplmtest.jar,META-INF/ejb-jar.xml mail/MailSession9
javax.mail.Session mail/DefaultMailSessionX } {"JavaMail Sample WebApp"  mtcomps.war,WEB-INF/web.xml
mail/MailSession9 javax.mail.Session mail/DefaultMailSessionY }} -MapWebModToVH {{"JavaMail Sample WebApp"
mtcomps.war,WEB-INF/web.xml newhost }} -nopreCompileJSPs -novalidateApp -installed.ear.destination
c:/mylocation -distributeApp -nouseMetaDataFromBinary}
```

Commands for the AdminTask object

Use AdminTask object to run an administrative command. Administrative commands are discovered dynamically when you start the wsadmin tool. The administrative commands that are available for your use, and what you can do with them, depends on the edition of the WebSphere Application Server that you have.

You can start the scripting client without a server running by using the `-conntype NONE` option with the wsadmin tool. The AdminTask administrative commands are available in both connected and local modes. If a server is currently running, it is not recommended to run the AdminTask commands in local mode. This is because any configuration changes made in local mode will not be reflected in the running server configuration and vice versa. If you save a conflicting configuration, you could corrupt the configuration. In a deployment manager environment, configuration updates are available only if a scripting client is connected to a deployment manager. When connected to a node agent or a managed application server, you will not be able to update the configuration because the configuration for these server processes are copies of the master configuration which resides in the deployment manager. The copies are created on a node machine when a configuration synchronization occurs between the deployment manager and the node agent. Make configuration changes to the server processes by connecting a scripting client to a deployment manager. For this reason, to change a configuration, do not run a scripting client in local mode on a node machine. It is not a supported configuration.

The following commands are available for the AdminTask object:

Command name:	Group name:	Description:	Target object:	Parameters and return values:	Examples:

addNode Group Member	Node Group Commands group	The **addNode Group Member** command adds a member to a node group. Nodes may be members of more than one node group. The command will do validity checking to ensure the following:
		• Distributed and z/OS nodes are not combined in the same node group.
			The target object is the node group where the member will be created. This target object is required.	• Parameters:
				- nodeName The name of the node to be added to a node group. This parameter is required.
				• Returns: Node group member object ID
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask addNodeGroupMember WBINodeGroup { -nodeName WBINode}`
					• Using Jython:
					`AdminTask.addNodeGroupMember( 'WBINodeGroup', '[-nodeName WBINode]')`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask addNodeGroupMember { -interactive}`
					• Using Jython:
					`AdminTask.addNodeGroupMember ( '[-interactive]')`

add SIBWS Inbound Port	SIB WebServices group	The **add SIBWS Inbound Port** command adds the configuration for an inbound port to an inbound service. This command will fail if:
		• the port name is already in use by another inbound port for the inbound service or the end point listener that you specified.
		• the template port that you specified does not exist in the template WSDL of the inbound service.
			The object name of the inbound service to which the port will be added.	• Parameters:
				name
				The name of the port. (required)
				endpointListener
				The name of the associated end point listener. (required)
				node
				The node where the endpoint listener is located. You must specify the node parameter, the server parameter, or the cluster parameter. (conditional)
				server
				The server where the endpoint listener is located. You must specify the node parameter, the server parameter, or the cluster parameter. (conditional)
				cluster
				The cluster where the endpoint listener is located. You must specify the node parameter, the server parameter, or the cluster parameter. (conditional)
				templatePort
				The name of the port in the template WSDL to use as a basis for the binding of the port. (optional)
				• Returns: The object name of the inbound port object that was created.
					Batch mode example usage:
					• Using Jacl:
					`set inPort [`
					`$AdminTask addSIBWSInboundPort`
					`$inService {`
					`-name "`*`MyServiceSoap`*`"`
					`-endpointListener "`*`SOAPHTTP1`*`"`
					`-node "`*`MyNode`*`"`
					`-server "`*`server1`*`"}]`
					• Using Jython:
					`inPort =`
					`AdminTask.addSIBWSInboundPort(`
					`inService, '[`
					`-name `*`MyServiceSoap`*
					`-endpointListener `*`SOAPHTTP1`*
					`-node `*`MyNode`*
					`-server `*`server1`*`]')`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask addSIBWSInboundPort {`
					`-interactive}`
					• Using Jython:
					`AdminTask.addSIBWSInboundPort (`
					`'[-interactive]')`

add SIBWS Outbound Port	SIB WebServices group	The **add SIBWS Outbound Port** command adds the configuration for an outbound port to an outbound service.	The object name of the outbound service for which the port will be associated.	• Parameters:
				name
				The name of the port in the WSDL of the service provider. (required)
				node
				Node where the port destination will be localized. You must specify the node parameter, the server parameter, or the cluster parameter. (conditional)
				server
				The server where the port destination will be localized. You must specify the node parameter, the server parameter, or the cluster parameter. (conditional)
				cluster
				The cluster where the port destination will be localized. You must specify the node parameter, the server parameter, or the cluster parameter. (conditional)
				destination
				The name of the port destination. (optional)
				userId
				The user ID to use to retrieve the WSDL. (optional)
				password
				The password to use to retrieve the WSDL. (optional)
				• Returns: The object name of the outbound port object that you created.
					Batch mode example usage:
					• Using Jacl:
					`set outPort [`
					` $AdminTask`
					` addSIBWSOutboundPort`
					` $outService {`
					`  -name "MyServiceSoap"`
					`  -node "MyNode"`
					`  -server "server"}]`
					• Using Jython:
					`outPort =`
					` AdminTask`
					`.addSIBWSOutboundPort(`
					`  outService, '[`
					`  -name MyServiceSoap`
					`  -node MyNode`
					`  -server server]')`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask`
					` addSIBWSOutboundPort {`
					` -interactive}`
					• Using Jython:
					`AdminTask`
					`.addSIBWSOutboundPort (`
					` '[-interactive]')`

add SIBus Member	SIB Admin Commands group	Use this command to add a server or a cluster to a SIB bus.	None	- Parameters: **bus** name of bus to add member to (String, required) **node** to specify a server bus member, supply node and server name, but not cluster name (String, optional) **server** to specify a server bus member, supply node and server name, but not cluster name (String, optional) **cluster** to specify a cluster bus member, supply cluster name but not node and server name (String, optional) **createDefault Datasource** set this to true if a default data source should be created when the messaging engine is created. (Boolean, optional) **datasource JndiName** the JNDI name of the data source to be referenced from the datastore created when the member is added to the bus (String, optional) - Returns:	**Batch mode example usage:** - Using Jacl: $AdminTask addSIBusMember { -bus *busname* -node *nodename* -server *servername* -description *text*} - Using Jython: AdminTask.addSIBusMember('[-bus *busname* -node *nodename* -server *servername* -description "*text*"]') **Interactive mode example usage:** - Using Jacl: $AdminTask addSIBusMember { -interactive} - Using Jython: AdminTask.addSIBusMember ('[-interactive]')

addWSGWTargetService	WSGateway group	The **add WSGW Target Service** command adds a target to a gateway service. You must specify the target Service parameter or the target Destination parameter.	Object name of the Gateway Service object	• Parameters:
				name
				The administrative name of the target service. (Required)
				target Destination
				The name of the target destination. This can be within the same bus as the gateway destination or in a different bus. If the target destination is not within the same bus as the gateway destination, you must also specify the targetBus parameter. You must either specify the target Destination parameter or the target Service parameter. (Conditional)
				target Service
				The name of the target outbound service. You must either specify the target Destination parameter or the target Service parameter. (Conditional)
				targetBus
				The name of the WPM bus that contains the target. (Optional)
				• Returns: The object name of the target service object that you created.
					Batch mode example usage:
					• Using Jacl:
					`set gwTarget [`
					` $AdminTask`
					` addWSGWTargetService`
					` $gwService {`
					`  -name "`*AnotherTarget*`"`
					`  -targetService`
					` "`*AnotherService*`"}]`
					• Using Jython:
					`gwTarget=`
					` AdminTask.`
					`addWSGWTargetService(`
					`  gwService, '[`
					`  -name `*AnotherTarget*
					`  -targetService`
					` `*AnotherService*`]')`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask`
					`addWSGWTargetService {`
					` -interactive}`
					• Using Jython:
					`AdminTask`
					`.addWSGWTargetService`
					` ('[ -interactive]')`

compareNodeVersion	ManagedObjectMetadata group	The **compareNodeVersion** command compares the WebSphere Application Server version given a node that you specify and an input version.	None	• Parameters:
				- nodeName
				The name of the node associated with the metadata you want this command to return.
				- version
				A version number that you want to compare to the WebSphere Application Server version number.
				• Returns:
				– 0 if node version matches the input version
				– -1 if node version is smaller than the input version
				– 1 is node version is higher than the input version
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask compareNodeVersion {-nodeName` *`node1`* `-version` *`5`*`}`
					• Using Jython:
					`AdminTask.compareNodeVersion('[-nodeName` *`node1`* `-version` *`5`*`]')`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask compareNodeVersion {-interactive}`
					• Using Jython:
					`AdminTask.compareNodeVersion ('[-interactive]')`

configureTAM					**Interactive mode example usage:**
					• Using Jacl:
					`$AdminTask configureTAM {-interactive}`
					• Using Jython:
					`AdminTask.configureTAM ('[-interactive]')`

connect SIBWS Endpoint Listener	SIB Web Services group	The **connect SIBWS Endpoint Listener** command connects an end point listener to a bus.	Object name of the end point listener that you want to create.	• Parameters:
				bus
				The name of the bus to which the end point listener will be connected. (required)
				replyDestination
				The name of the reply destination for the connection. (optional)
				• Returns: The SIBWS bus connection property object.
					Batch mode example usage:
					• Using Jacl:
					`set busConn [ $AdminTask connectSIBWSEndpointListener $epl {-bus "MyBus"}]`
					• Using Jython:
					`busConn = AdminTask .connectSIBWSEndpointListener (epl, '[-bus MyBus]')`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask connectSIBWSEndpointListener { -interactive}`
					• Using Jython:
					`AdminTask .connectSIBWSEndpointListener ('[-interactive]')`

copy Resource Adapter	JCA management group	Use the **copy Resource Adapter** command to create a Java 2 Connector (J2C) resource adapter under the scope that you specify.	J2CResource Adapter _object _ID	• Parameters:
				- name Indicates the name of the new J2C resource adapter. This parameter is required.
				- scope Indicates the scope object ID. This parameter is required.
				- use Deep Copy If you set this parameter to `true`, all of the J2C connection factory, J2C activation specification, and J2C administrative objects will be copied to the new J2C resource adapter (deep copy). If you set this parameter to `false`, the objects are not created (shallow copy). The default is `false`.
				• Returns: J2C resource adapter object ID
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask copyResourceAdapter $ra [subst { -name newRA -scope $scope}]`
					• Using Jython:
					`AdminTask .copyResourceAdapter( ra, '[-name newRA -scope scope]')`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask copyResourceAdapter { -interactive}`
					• Using Jython:
					`AdminTask .copyResourceAdapter ('[-interactive]')`

create Application Server					**Interactive mode example usage:**
					• Using Jacl:
					`$AdminTask createApplicationServer {-interactive}`
					• Using Jython:
					`AdminTask .createApplicationServer ('[-interactive]')`

create Application Server Template					**Interactive mode example usage:**
					- Using Jacl:
					`$AdminTask createApplicationServerTemplate {-interactive}`
					- Using Jython:
					`AdminTask .createApplicationServerTemplate ('[-interactive]')`

createChain	Channel Framework Management group	The **createChain** command creates a new chain of transport channels based on a chain template.	The instance of the transport channel service under which the new chain is created. (ObjectName, required)	- Parameters:
				- template
				The chain template on which to base the new chain. (ObjectName, required)
				- name
				The name of the new chain. (String, required)
				- endPoint
				The name of the end point to be used by the instance of the TCP inbound channel in the new chain if the chain is an inbound chain. (ObjectName, optional)
				- Returns: The object name of the channel chain that was created.
					Batch mode example usage:
					- Using Jacl:
					`$AdminTask`
					` createChain (`
					` cells/rohitbuildCell01`
					`/nodes`
					`/rohitbuildCellManager01`
					`/servers`
					` /dmgr|server.xml#`
					`TransportChannelService_1) {`
					` -template` *WebContainer*
					`(templates`
					`/chains|webcontainer`
					`-chains.xml#Chain_1)`
					`-name` *trialChain1* `}`
					`$AdminTask createChain (`
					` cells/rohitbuildCell01`
					`/nodes/`
					` rohitbuildCellManager01`
					`/servers`
					` /dmgr|server.xml#`
					`TransportChannelService_1)`
					` {-template`
					 WebContainer
					`(templates/chains`
					`|webcontainer`
					` -chains.xml#Chain_1)`
					`-name` *trialChain1*
					` -endPoint (`
					` cells/rohitbuildCell01/`
					`nodes`
					`/rohitbuildCellManager01`
					` |serverindex.xml`
					`#EndPoint_3) }`
					- Using Jython:
					`AdminTask.createChain`
					`('cells/rohitbuildCell01`
					`/nodes/`
					`rohitbuildCellManager01`
					`/servers`
					` /dmgr|server.xml#`
					`TransportChannelService_1',`
					` '[-template "WebContainer`
					`(templates`
					`/chains|webcontainer`
					` -chains.xml#Chain_1)"`
					`-name trialChain]')`
					`AdminTask.createChain`
					`('cells`
					` /rohitbuildCell01/nodes`
					` /rohitbuildCellManager01/`
					`servers/dmgr|server.xml`
					` #TransportChannelService_1',`
					` '[-template`
					`"WebContainer(templates`
					` /chains|webcontainer-chains.`
					`xml#Chain_1)" -name`
					` trialChain`
					` -endPoint "(cells/`
					`rohitbuildCell01/nodes`
					` /rohitbuildCellManager01`
					`|serverindex`
					`.xml#EndPoint_3)"]')`

createChain continued					**Interactive mode example usage:**
					• Using Jacl:
					`$AdminTask createChain {-interactive}`
					• Using Jython:
					`AdminTask.createChain ( '[-interactive]')`

create Cluster	Cluster Config Commands	The **create Cluster** command creates a new server cluster. A server cluster consists of a group of application servers which are referred to as cluster members. Optionally, a replication domain can be created for the new cluster, and an existing server can be included as the first cluster member.	None	• **Parameters for step one:**
				-clusterConfig
				Specifies the configuration of the new server cluster. This command step is required. The following parameters can be specified for this step.
				clusterName
				The name of the new server cluster. This parameter is required.
				preferLocal
				Enables or disables node scoped routing optimization within this cluster. This parameter is optional. The value is true or false. It not specified, the default value is true.
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask createCluster { -clusterConfig {{cluster1 true}}}`
					`$AdminTask createCluster { -clusterConfig {{cluster1 true}} -replicationDomain {{true}}}`
					`$AdminTask createCluster { -clusterConfig {{ cluster1 true}} -convertServer {{ server1 node1 "" "" ""}}}`
					• Using Jython:
					`AdminTask.createCluster('[ -clusterConfig [[cluster1 true]]]')`
					`AdminTask.createCluster('[ -clusterConfig [[cluster1 true]] -replicationDomain [[true]]]')`
					`AdminTask.createCluster('[ -clusterConfig [[cluster1 true]] -convertServer [[ server1 node1 "" "" ""]]]')`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask createCluster {-interactive}`
					• Using Jython:
					`AdminTask.createCluster ('[ -interactive]')`

create Cluster continued				**Parameters for step two:** **-replication Domain** Specifies the configuration of a replication domain for this cluster. A replication domain is used to support HTTP session data replication. This command step is optional. The following parameters can be specified for this step: **createDomain** Creates a replication domain with a name set to the name of the new cluster. This parameter is optional. The value is true or false. It not specified, the default value is false.	

create Cluster continued				**Parameters for step three:** **-convertServer** Specifies information about an existing application server to convert to be the first member of the cluster. This command step is optional. The following parameters can be specified for this step: **serverNode** The name of the node with the server to be converted to the first cluster member. This parameter is required for the command step. You must also specify the serverName parameter. **serverName** The name of the application server to be converted to the first cluster member. This parameter is required for the command step. You must also specify the serverNode parameter. **memberWeight** The weight of the cluster member. The weight controls the amount of work directed to the application server. If the weight is greater than the weight assigned to other cluster members, the server will receive a larger share of the workload. The value is a number between 0 and 100. If none is specified, the default is 2.	

create Cluster continued				**nodeGroup** The name of the node group which this cluster member‘s node, and all future cluster members‘ nodes, must belong to. All cluster members must reside on nodes in the same node group. This parameter is optional. If specified, it must be one of the node groups which this member‘s node belongs to. If not specified, the default value will be the first node group listed for this member‘s node. **replicatorEntry** Specifies a replicator entry for the converted member will be created in the cluster‘s replication domain. A replicator entry is used to provide HTTP session data replication. This command parameter is optional. The value is true or false which indicates whether the replicator entry will be created. The default value is false. You can specify this parameter only if the createDomain parameter was set to true in the replication Domain command step. **Returns:** ObjectName of cluster created.	

createClusterMember	Cluster Config Commands	The createClusterMember command creates a member of a server cluster. A cluster member is an application server that belongs to a cluster. If this is the first member of the cluster, you must specify a template to use as the model for the cluster member. The template can be either a default server template, or an existing application server	cluster Object ID - The configuration object ID of the cluster which the new member will belong to. If this is not specified, then the cluster Name parameter must be specified. The object name can be obtained programmatically via Java using the WebSphere Config Service API, or via wsadmin scripting using the Admin Config command.	• **Parameters:**
				-clusterName
				The name of the cluster which the new member will belong to. If this parameter is not specified, then the cluster object ID must be specified in the command target.
				• **Parameters for step one:**
				-memberConfig
				Specifies the attributes of the new cluster member to be created in the cluster. This command step is required. The following parameters can be specified for this step:
				memberName
				The name of the server to be created for the new cluster member. This parameter is required.
				memberNode
				The name of the node where the new cluster member will be created. This parameter is required.
					Batch mode example usage:
					• Using Jacl:
					First member creation using template name:
					`$AdminTask createClusterMember {`
					`-clusterName cluster1`
					`-memberConfig`
					`{{node1 member1 "" ""`
					`true false}}`
					`-firstmember {{`
					`serverTemplateName`
					`"" "" "" ""}}}`
					First member creation using server and node for template:
					`$AdminTask createClusterMember {`
					`-clusterName cluster1`
					`-memberConfig`
					`{{node1 member1 "" ""`
					`true false}}`
					`-firstmember {{`
					`"" node1 server1 "" ""}}}`
					Second member creation:
					`$AdminTask`
					`createClusterMember {`
					`-clusterName cluster1`
					`-memberConfig`
					`{{node1 member2 "" ""`
					`true false}}}`
					• Using Jython:
					First member creation using template name:
					`AdminTask.createClusterMember`
					`('[`
					`-clusterName cluster1`
					`-memberConfig`
					`[[node1 member1 "" ""`
					`true false]]`
					`-firstMember [[`
					`serverTemplateName`
					`"" "" "" ""]]]')`
					First member creation using server and node for template:
					`AdminTask.createClusterMember`
					`('[`
					`-clusterName cluster1`
					`-memberConfig`
					`[[node1 member1 "" ""`
					`true false]]`
					`-firstMember [[`
					`"" node1 server1`
					`"" ""]]]')`
					Second member creation:
					`AdminTask.createClusterMember`
					`('[`
					`-clusterName cluster1`
					`-memberConfig`
					`[[node1 member2 "" ""`
					`true false]]]')`

create Cluster Member continued				• **Parameters for step one continued:**
				memberWeight
				The weight of the new cluster member. This controls the amount of work directed to the application server. If the weight is greater than the weight assigned to other cluster members, the server will receive a larger share of the workload.
				genUniquePorts
				Generates unique port numbers for each HTTP transport defined in the server. The new server will not have HTTP transports which conflict with any other servers defined on the same node. The value is true or false. The default value is true .
				replicatorEntry
				Specifies a replicator entry for the new cluster member will be created in the cluster‘s replication domain. A replicator entry is used to provide HTTP session data replication. This command parameter is optional. The value is true or false which indicates whether the entry is created. Default value is false. Specify this parameter only if a replication domain has been created for the
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask createClusterMember {-interactive}`
					• Using Jython:
					`AdminTask.createClusterMember ('[-interactive]')`

create Cluster Member continued				• **Parameters for step two:** **-firstMember** Specifies additional information necessary to create the first cluster member. This command step is required when creating the first member of the cluster, and is executable only when creating the first member of the cluster. The target of this command step is a Boolean value indicating whether or not to perform this step. The default value is true if any of the step parameters are specified; otherwise the default value is false. The following parameters can be specified for this step: **templateName** The name of an application server template to use when creating the new cluster member. If you specify a template, you cannot specify the template ServerNode and template ServerName parameters to use an existing application server as a template. You are required to specify either the templateName,or the template ServerNode and template ServerName parameters in this step.	

create Cluster Member continued				• **Parameters for step two continued:** **template erverNode** The name of the node with an existing application server to use as the template when creating the new cluster member. If you specify the template ServerNode parameter, you must also specify the template ServerName parameter, and you cannot specify the templateName parameter. You are required to specify either the templateName parameter, or the template ServerNode and template ServerName parameters, in this step. **template ServerName** The name of the existing application server used as the model when creating a new cluster member. If you specify the template ServerName parameter, you must also specify the template ServerNode parameter, and cannot specify the templateName parameter. You must specify either the templateName parameter, or the template ServerNode and template ServerName parameters, in this command	

create Cluster Member continued				• **Parameters for step two continued:** **nodeGroup** The name of the node group which this cluster member‘s node, and all future cluster members‘ nodes, must belong to. All cluster members must reside on nodes in the same node group. This parameter is optional. If specified, it must be one of the node groups which this member‘s node belongs to. If not specified, the default value will be the first node group listed for this member‘s node. **coreGroup** The name of the core group this cluster member, and all future cluster members, must belong to. All cluster members must belong to the same core group. This parameter is optional. If not specified, the default value is the default core group defined in the cell. • **Returns:** ObjectName of cluster member created.	

create Core Group	Core Group Management group	The **create Core Group** command creates a new core group. The core group that you create will contain no members.	None	- Parameters:
				- coreGroupName The name of the core group that you are creating. (String required)
				- Returns: None
					Batch mode example usage:
					- Using Jacl:
					`$AdminTask createCoreGroup { -coreGroupName MyCoreGroup}`
					- Using Jython:
					`AdminTask.createCoreGroup('[ -coreGroupName MyCoreGroup]')`
					Interactive mode example usage:
					- Using Jacl:
					`$AdminTask createCoreGroup { -interactive}`
					- Using Jython:
					`AdminTask.createCoreGroup ('[ -interactive]')`

create Core Group Access Point	Core Group Bridge Management group	The **create Core Group Access Point** command creates a default core group access point for the core group that you specify and adds it to the default access point group. If the default access point group does not exist, the command creates a default access point group.	Core group bridge settings object for the cell. (ObjectName, required).	- Parameters:
				- coreGroupName The name of the core group for which the core group access point will be created. (String required)
				- Returns: None
					Batch mode example usage:
					- Using Jacl:
					`$AdminTask createCoreGroupAccessPoint (cells/rohitbuildCell01|coregroupbridge.xml#CoreGroupBridgeSettings_1) "-coreGroupName DefaultCoreGroup"`
					- Using Jython:
					`AdminTask.createCoreGroupAccessPoint('cells/rohitbuildCell01|coregroupbridge.xml#CoreGroupBridgeSettings_1', '[-coreGroupName DefaultCoreGroup]')`
					Interactive mode example usage:
					- Using Jacl:
					`$AdminTask createCoreGroupAccessPoint {interactive}`
					- Using Jython:
					`AdminTask.createCoreGroupAccessPoint ('[-interactive]')`

create Default CGAP					**Interactive mode example usage:**
					- Using Jacl:
					`$AdminTask createDefaultCGAP {-interactive}`
					- Using Jython:
					`AdminTask.createDefaultCGAP ('[-interactive]')`

create Generic Server	Serve r Management group
	Step: Config ProcDef
		Use the **create Generic Server** command to create a new generic server in the configuration. A generic server is a server that the WebSphere Application Server manages but did not supply. The **create Generic Server** command provides an additional step, Config ProcDef, that you can use to configure the parameters that are specific to generic servers.	None	• Parameters:
				- name
				The name of the server that you want to create.
				- templateName
				Picks up a server template. This step provides a list of application server templates for the node and server type. The default value is the default templates for the server type. (String, optional)
				- genUniquePorts
				The port for the server.
				- templateLocation
				The location of the server template.
				- startCommand
				Indicates the path to the command that will run when this generic server is started. (String, optional)
				- startCommand Args
				Indicates the arguments to pass to the startCommand when the generic server is started. (String, optional)
				- executable TargetKind
				Specifies whether a Java class name (use `JAVA_CLASS`) or the name of an executable JAR file (use `EXECUTABLE_JAR`) will be used as the executable target for this process. This field should be left blank for binary executables. This parameter is only applicable for
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask createGenericServer jim667BaseNode {-name jgeneric -ConfigProcDef {{ "/usr/bin/myStartCommand" "arg1 arg2" "" "" "/tmp/workingDirectory" "/tmp/stopCommand" "argy argz"}}}`
					• Using Jython:
					`AdminTask .createGenericServer( jim667BaseNode, '[-name jgeneric -ConfigProcDef [[ /usr/bin/myStartCommand "arg1 arg2" "" "" /tmp/workingDirectory /tmp/StopCommand "argy argz"]]]')`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask createGenericServer { -interactive}`
					• Using Jython:
					`AdminTask.createGenericServer ('[-interactive]')`

create Generic Server continued				• Parameters: **- executable Target** Specifies the name of the executable target (a Java class containing a main() method or the name of an executable JAR), depending on the executable target type. This field should be left blank for binary executables. This parameter is only applicable for Java processes. (String, optional) **- working Directory** Specifies the working directory for the generic server. **- stopCommand** Indicates the path to the command that will run when this generic server is stopped. (String, optional) **- stopCommand Args** Indicates the arguments to pass to the stopCommand parameter when the generic server is stopped. (String, optional) • Returns: null	

create Generic Server Template					**Interactive mode example usage:**
					• Using Jacl:
					`$AdminTask createGenericServerTemplate {-interactive}`
					• Using Jython:
					`AdminTask .createGenericServerTemplate ('[-interactive]')`

create J2C Activation Spec	JCA management group	Use the **create J2C Activation Spec** command to create a Java 2 Connector (J2C) activation specification under a J2C resource adapter and attributes that you specify. Use the message ListenerType parameter to indicate the activation specification that is defined for the J2C resource adapter.	J2C Resource Adapter _object _ID	• Parameters:
				- message ListenerType Identifies the activation specification for the J2C activation specification to be created. Use this parameter to identify the activation specification template for the J2C resource adapter that you specify.
				- name Indicates the name of the J2C activation specification that you are creating.
				- jndiName Indicates the name of the Java Naming and Directory Interface (JNDI).
				- destination JndiName Indicates the name of the Java Naming and Directory Interface (JNDI) of corresponding destination.
				- authentication Alias Indicates the authentication alias of the J2C activation specification that you are creating.
				- description Description of the created J2C activation spec.
				• Returns: J2CActivationSpec object ID
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask createJ2CActivationSpec $ra {-name J2CActSpec -jndiName eis/ActSpec1 -messageListenerType javax.jms.MessageListener }`
					• Using Jython:
					`AdminTask .createJ2CActivationSpec( ra, '[-name J2CActSpec -jndiName eis/ActSpec1 -messageListenerType javax.jms.MessageListener]')`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask createJ2CActivationSpec {-interactive}`
					• Using Jython:
					`AdminTask .createJ2CActivationSpec ('[-interactive]')`

create J2C Admin Object	JCA management group	Use the **create J2C Admin Object** command to create a administrative object under a resource adapter with attributes that you specify. Use the administrative object interface to indicate the administrative object defined in the resource adapter.	J2CResourceAdapter_object_ID	• Parameters:
				-adminObjectInterface
				Specifies the administrative object interface to identify the administrative object for the resource adapter that you specify. This parameter is required.
				-name
				Indicates the name of the administrative object.
				-jndiName
				Specifies the name of the Java Naming and Directory Interface (JNDI).
				-description
				Description of the created J2C admin object.
				• Returns: J2CAdminObject object ID
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask`
					` createJ2CAdminObject`
					` $ra {-adminObjectInterface`
					` fvt.adapter`
					`.message.FVTMessage`
					`Provider -name J2CA01`
					` -jndiName eis/J2CA01}`
					• Using Jython:
					`AdminTask`
					`.createJ2CAdminObject(`
					`ra, '[-adminObjectInterface`
					` fvt.adapter.message`
					`.FVTMessageProvider`
					` -name J2CA01 -jndiName`
					` eis/J2CA01]')`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask`
					` createJ2CAdminObject`
					` {-interactive}`
					• Using Jython:
					`AdminTask`
					`.createJ2CAdminObject`
					` ('[-interactive]')`

create J2C Connection Factory	JCA management group	Use the **create J2C Connection Factory** command to create a Java 2 connection factory under a Java 2 resource adapter and attributes that you specify. Use the connection factory interfaces to indicate the connection definitions defined for the Java 2 resource adapter.	J2C Connection Factory _object _ID	• Parameters:
				-connection Factory Interface
				Identifies the connection definition for the Java 2 resource adapter that you specify. This parameter is required.
				-name
				Indicates the name of the connection factory.
				-jndiName
				Indicates the name of the Java Naming and Directory Interface (JNDI).
				-description
				Description of the created J2C connection factory.
				• Returns: J2C connectionfactory object ID.
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask createJ2CConnectionFactory $ra {-connectionFactoryInterfaces javax.sql.DataSource -name J2CCF1 -jndiName eis/J2CCF1}`
					• Using Jython:
					`AdminTask. createJ2CConnectionFactory (ra, '[-connectionFactoryInterfaces javax.sql.DataSource -name J2CCF1 -jndiName eis/J2CCF1]')`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask createJ2CConnectionFactory {-interactive}`
					• Using Jython:
					`AdminTask .createJ2CConnectionFactory ('[-interactive]')`

create Node Group	Node Group Commands group	The **create Node Group** command creates a new node group. A node group consists of a group of nodes which are referred to as node group members. Optionally, you can create a short name and description for the new node group.	The node group name to be created. This target object is required.	• Parameters:
				- shortName
				The short name of the node group. This parameter is optional.
				- description
				The description of the node group. This parameter is optional.
				• Returns: Node group object ID
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask createNodeGroup WBINodeGroup`
					• Using Jython:
					`AdminTask .createNodeGroup( 'WBINodeGroup')`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask createNodeGroup {-interactive}`
					• Using Jython:
					`AdminTask.createNodeGroup ('[-interactive]')`

create Node Group Property	Node Group Commands group	The **create Node Group Property** command creates custom properties for a node group.	The name of the node group. This target object is required.	• Parameters:
				- name
				The name of the custom property to create. This parameter is required.
				- value
				The value of the custom property. This parameter is optional.
				- description
				The description of the custom property. This parameter is optional.
				• Returns: Properties object ID
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask createNodeGroupProperty WBINodeGroup { -name Channel -value "channel1"}`
					• Using Jython:
					`AdminTask .createNodeGroupProperty( 'WBINodeGroup', '[-name Channel -value channel1]')`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask createNodeGroupProperty {-interactive}`
					• Using Jython:
					`AdminTask .createNodeGroupProperty ('[-interactive]')`

create SIB Destination	SIB Admin Commands	Use this command to create a SIB destination.	None	• Parameters: **bus** name of the bus where this destination is to be configured (String, required) **name** destination name (String, required) **type** The destination type. Valid value include: Queue, TopicSpace, WebService or Port. If the type is not TopicSpace, you must use the node/server or cluster option to specify a bus member. (String, required) **cluster** to assign the destination to a cluster, supply cluster name, but not node and server name. (optional) **node** to assign the destination to a server, supply node name server name, but not cluster name. (optional) **server** to assign the destination to a server, supply node name server name, but not cluster name. (optional) **aliasBus** if this is an alias destination, the source bus name of alias mapping. (optional)	**Batch mode example usage:** • Using Jacl: $AdminTask createSIBDestination {-bus *busname* -name *destname* -type TopicSpace} • Using Jython: AdminTask .createSIBDestination ('[-bus *busname* -name *destname* -type TopicSpace]') **Interactive mode example usage:** • Using Jacl: $AdminTask createSIBDestination {-interactive} • Using Jython: AdminTask .createSIBDestination ('[-interactive]')

create SIB Destination continued				• Parameters continued: **targetBus** if this is an alias destination, the name of the bus that the destination it maps to is configured on. (optional) **targetName** if this is an alias destination, the name of the destination it maps to. (optional) **foreignBus** if this is a foreign destination, the name of the foreign bus. (optional) **description** description. (optional) **reliability** the reliability quality of service for message flows through this destination, from BEST_EFFORT _NON-PERSISTENT to ASSURED _PERSISTENT, in order of increasing reliability. Higher levels of reliability have higher impacts on the performance. (optional) **maxReliability** the maximum reliability quality of service that is accepted for values specified by producers. (optional)	

create SIB Destination continued				**Parameters continued:** **override OfQOS ByProducer Allowed** controls the quality of service for message flows between producers and the destination. Select this option to use the quality of service specified by producers instead of the quality defined for the destination. (optional) **defaultPriority** the default priority for message flows through this destination, in the range 0 (lowest) through 9 (highest). This default priority is used for messages that do not contain a priority value (Integer, optional). (optional) **maxFailed Deliveries** the maximum number of times that service tries to deliver a message to the destination before forwarding it to the exception destination (Integer, optional). (optional) **exception Destination** the name of another destination to which the system sends a message that cannot be delivered to this destination within the specified maximum number of failed deliveries. (optional) **sendAllowed** clear this option (setting it to false) to stop producers from being able to send messages to this destination. (optional)	

create SIB Destination continued				**Parameters for step one continued:** **receiveAllowed** clear this option (setting it to false) to prevent consumers from being able to receive messages from this destination. (optional) **quiesceMode** select this option (setting it to true) to indicate that the destination is quiescing. In quiesce mode, new messages for the destination cannot be added to the bus, but any messages already in the bus can still be sent to, and processed by, the destination (Boolean, optional, default=False). (optional) **receiveExclusive** select this option (setting it to true) to allow only one consumer to attach to a destination (Boolean, optional, default=False). (optional) **topicAccess Check Required** topic access check required (Boolean, optional) **replyDestination** clear this option (setting it to false) to stop producers from being able to send messages to this destination. (optional) **replyDestination Bus** clear this option (setting to false) to prevent consumers from being able to receive messages from destination. (optional).	

create SIB Destination continued				**Parameters for step one:** **delegate Authorization CheckToTarget** indicates whether the authorization check should be delegated to the alias or target destination (Boolean, optional) **defaultForward RoutingPath** the default forward routing path. **bus** bus name **destination** destination name **Returns:** A new SIB destination.	

create SIB Engine	SIB Admin Commands	Use the **create SIB Engine** command to create a new messaging engine for a bus member.	None	• Parameters: **bus** name of the bus to which the messaging engine is to belong (String, optional) **node** to create a messaging engine on a server, supply node and server name, but not cluster name (String, optional) **server** to create a messaging engine on a server, supply node and server name, but not cluster name (String, optional) **cluster** to create a messaging engine on a cluster, supply cluster name, but not node and server name (String, optional) **description** description of the messaging engine (String, optional) **initialState** Indicates if the messaging engine is started or stopped when the associated application server starts. Until started, the messaging engine is unavailable. Valid values are `Stopped` and `Started`. (String, optional)	**Batch mode example usage:** • Using Jacl: $AdminTask createSIBEngine {-bus *busname* -node *nodeName* -server *severname*} • Using Jython: AdminTask.createSIBEngine ('[-bus *busname* -node *nodeName* -server *severname*]') **Interactive mode example usage:** • Using Jacl: $AdminTask createSIBEngine {-interactive} • Using Jython: AdminTask.createSIBEngine ('[-interactive]')

create SIB Engine continued				• Parameters continued: **destinationHighMsgs** the maximum total number of messages that the messaging engine can place on its message points (Long, optional) **createDefaultDatasource** Set to `true` if a default data source should be created when the messaging engine is created (Boolean, optional) **datasourceJndiName** JNDI name of the data source to be referenced from the datastore created when the messaging engine is created (String, optional) • Returns: A new SIB messaging engine.	

create SIB JMS Activation Spec	SIB JMS Admin Commands	Use the **create SIB JMS Activation Spec** command to create a SIB JMS activation specification.	Scope of the SIB JMS resource adapter to which the activation specification will be added.	• Parameters:
				name
				name of new activation specification (String, required)
				jndiName
				JNDI name of the activation specification (String, required)
				destinationJndi Name
				JNDI name of a destination (String, required)
				description
				a JMS activation specification is used by the default messaging provider to validate the activation-configuration properties for a JMS message-driven bean (MDB) (String, optional)
				acknowledge Mode
				how the session acknowledges any messages it receives (String, optional)
				authentication Alias
				authentication alias (String, optional)
				busName
				name of the SIB bus to connect to (String, required)
				clientId
				client identifier. Required for durable topic subscriptions (String, optional)
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask createSIBJMSActivationSpec $ra {-name` *`specname`* `-jndiName` *`specname`*`}`
					• Using Jython:
					`AdminTask .createSIBJMSActivationSpec (ra, '[-name` *`specname`* `-jndiName` *`specname`*`]')`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask createSIBJMSActivationSpec {-interactive}`
					• Using Jython:
					`AdminTask .createSIBJMSActivationSpec ('[-interactive]')`

create SIB JMS Activation Spec continued				• Parameters: **destinationType** Indicates if the message-driven bean uses a queue or topic destination. (String, optional) **durable Subscription Home** The name of the durable subscription home. This identifies the messaging engine where all durable subscriptions accessed through this activation specification are managed (String, optional) **maxBatchSize** the maximum number of messages received from the messaging engine in a single batch (Integer, optional) **maxConcurrency** the maximum number of endpoints to which messages are delivered concurrently (Integer, optional) **messageSelector** the JMS message selector used to determine which messages the message-driven bean (MDB) receives (String, optional) **password** password (String, optional)	

create SIB JMS Activation Spec continued				• Parameters: **subscription Durability** whether a JMS topic subscription is durable or nondurable (String, optional) **subscriptionName** the subscription name needed for durable topic subscriptions (String, optional) **shareDurable Subscriptions** used to control how durable subscriptions are shared (String, optional, default = AsCluster) **userName** user name (String, optional) • Returns: A new SIB JMS activation specification.	

create SIB JMS Connection Factory	SIB JMS Admin Commands	Use the **create SIB JMS Connection Factory** command to create a generic, queue or topic SIB JMS connection factory.	Scope of the SIB JMS resource adapter to which the SIB JMS connection factory will be added.	• Parameters:
				name
				The name of the SIB JMS connection factory (String, required)
				jndiName
				the JNDI name of the SIB JMS connection factory (String, required)
				type
				The type of connection factory to create. To create a queue connection factory, set the value to `Queue`. To create a topic connection factory, set to `Topic`. To create a generic connection factory, do not set a value. (String, optional)
				authDataAlias
				Specifies a user ID and password to be used to authenticate connections to the JMS provider for application-managed authentication (String, optional)
				category
				classifies or groups the connection factory (String, optional)
				description
				description of the connection factory (String, optional)
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask`
					`createSIBJMSConnectionFactory`
					` $ra {`
					`-name`
					`connectionfactory_name`
					` -jndiName` *`jndi_name`*`}`
					• Using Jython:
					`AdminTask`
					`.createSIBJMSConnectionFactory`
					`(ra, '[`
					`-name`
					`connectionfactory_name`
					` -jndiName`
					`jndi_name``]')`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask`
					`createSIBJMSConnectionFactory`
					` {-interactive}`
					• Using Jython:
					`AdminTask`
					`.createSIBJMSConnectionFactory`
					` ('[-interactive]')`

create SIB JMS Connection Factory continued				• Parameters: **logMissingTransactionContext** whether or not the container logs that there is a missing transaction context when a connection is obtained (Boolean, optional, default = False) **manageCachedHandles** Indicates if cached handles (handles held in instance variables in a bean) should be tracked by the container (Boolean, optional, default = False) **xaRecoveryAuthAlias** the authentication alias used during XA recovery processing (String, optional) **busName** the SIB bus name (String, optional) **clientID** user-defined string, only required for durable subscriptions (String, optional) **userName** The user name that is used to create connections from the connection factory (String, optional)	

create SIB JMS Connection Factory continued				- Parameters: **password** the password that is used to create connections from the connection factory (String, optional) **nonPersistent Mapping** non-persistent mapping value. Valid values include: `Best EffortNon Persistent`, `ExpressNon Persistent`, `ReliableNon Persistent`, `Reliable Persistent`, `Assured Persistent`, `AsSIB Destination` and `None` (String, optional) **persistent Mapping** persistent mapping value. Valid values include: `BestEffortNon Persistent`, `ExpressNon Persistent`, `ReliableNon Persistent`, `Reliable Persistent`, `Assured Persistent`, `AsSIBDestination` and `None` (String, optional) **durable Subscription Home** durable subscription home value (String, optional) **readAhead** read-ahead value. Valid values include: `Default`, `AlwaysOn` and `AlwaysOff` (String, optional)	

create SIB JMS Connection Factory continud				• Parameters: **target** the name of a target that resolves to a group of messaging engines (String, optional) **targetType** specifies the type of the name in the target parameter. Valid values are `BusMember`, `Custom` and `ME` (String, optional) **targetSignificance** this property specifies the significance of the target group (String, optional) **remoteProtocol** the name of the protocol that should be used to connect to a remote messaging engine (String, optional) **providerEnd Points** A list of endpoint triplets seperated by commas, for example: `host:port:chain` (String, optional) **connection Proximity** the proximity of acceptable messaging engines. Valid values include: `Bus`, `Host`, `Cluster` and `Server` (String, optional)	

create SIB JMS Connection Factory continud				• Parameters: **tempQueueName Prefix** temporary queue name prefix (String, optional) **tempTopicName Prefix** temporary topic name prefix (String, optional) **share DataSource WithCMP** used to control how data sources are shared (Boolean, optional) **shareDurable Subscriptions** used to control how durable subscriptions are shared. Legal values are ″AsCluster″, ″AlwaysShared″ and ″NeverShared″ (String, optional, default = AsCluster) • Returns: A new SIB JMS connection factory.	

create SIB JMS Queue	SIB JMS Admin Commands	Use the **create SIB JMS Queue** command to create a SIB JMS queue.	Scope of the SIB JMS resource adapter to which the SIB JMS queue will be added.	- Parameters:
				name
				The name of the SIB JMS queue. (String, required)
				jndiName
				The JNDI name of the SIB JMS queue. (String, required)
				description
				A description of the SIB JMS queue (String, optional)
				queueName
				The name of the underlying SIB queue to which the queue points (String, required)
				deliveryMode
				The delivery mode for messages. Legal values are ″Application″, ″NonPersistent″ and ″Persistent″ (String, optional)
				timeToLive
				the time in milliseconds to be used for message expiration (Long, optional)
				priority
				the priority for messages. Whole number in the range 0 to 9 (Integer, optional)
				readAhead
				read-ahead value. Legal values are ″AsConnection″, ″AlwaysOn″ and ″AlwaysOff″ (String, optional)
				busName
				the name of the bus on which the queue resides (String, optional)
				- Returns: A new SIB JMS queue.
					Batch mode example usage:
					- Using Jacl:
					`$AdminTask createSIBJMSQueue $ra {-name` *`queue_name`* `-jndiName` *`jndi_name`* `-queueName` *`queue_name`*`}`
					- Using Jython:
					`AdminTask .createSIBJMSQueue(ra, '[-name` *`queue_name`* `-jndiName` *`jndi_name`* `-queueName` *`queue_name`*`]')`
					Interactive mode example usage:
					- Using Jacl:
					`$AdminTask createSIBJMSQueue {-interactive}`
					- Using Jython:
					`AdminTask .createSIBJMSQueue ('[-interactive]')`

create SIB JMS Topic	SIB JMS Admin Commands	Use this command to create a SIB JMS topic.	Scope of the SIB JMS resource adapter to which the SIB JMS topic will be added.	• Parameters:
				name
				The name of the SIB JMS topic (String, required)
				jndiName
				the SIB JMS topic's JNDI name (String, required)
				description
				a description of the SIB JMS queue (String, optional)
				topicSpace
				the name of the underlying SIB topic space to which the topic points (String, required)
				***topicName**
				the topic to be used inside the topic space (for example, stock/IBM) (String, required)
				deliveryMode
				the delivery mode for messages. Legal values are ″Application″, ″NonPersistent″ and ″Persistent″ (String, optional)
				timeToLive
				the time in milliseconds to be used for message expiration (Long, optional)
				priority
				the priority for messages. Whole number in the range 0 to 9 (Integer, optional)
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask createSIBJMSTopic $ra {-name topic_name -jndiName jndi_name -topicName topic_name -topicSpace topicspace_name}`
					• Using Jython:
					`AdminTask .createSIBJMSTopic(ra, '[-name topic_name -jndiName jndi_name -topicName topic_name -topicSpace topicspace_name]')`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask createSIBJMSTopic {-interactive}`
					• Using Jython:
					`AdminTask .createSIBJMSTopic ('[-interactive]')`

create SIB JMS Topic continued				• Parameters continued: **readAhead** read-ahead value. Legal values are ″AsConnection″, ″AlwaysOn″ and ″AlwaysOff″ (String, optional) **busName** the name of the bus on which the topic resides (String, optional) • Returns: A new SIB JMS topic.	

create SIB Mediation	SIB Admin Commands	Use this command to create a SIB mediation.	None	• Parameters: **bus** name of the bus where the mediation is to be created (String, required) **mediationName** name to be given to the mediation (String, required) **description** description of the mediation (String, optional) **handler ListName** name of the handler list that was defined when the mediation was deployed (String, required) **globalTransaction** whether or not a global transaction is started for each message processed (Boolean, optional, default = False) **allow Concurrent Mediation** whether or not to apply the mediation to multiple messages concurrently, and preserve message ordering (Boolean, optional, default = False)	**Batch mode example usage:** • Using Jacl: $AdminTask createSIBMediation {-bus *bus_name* -mediationName *mediation_name* -handlerListName *handlerList_name*} • Using Jython: AdminTask .createSIBMediation('[-bus *bus_name* -mediationName *mediation_name* -handlerListName *handlerList_name*]') **Interactive mode example usage:** • Using Jacl: $AdminTask createSIBMediation {-interactive} • Using Jython: AdminTask .createSIBMediation ('[-interactive]')

create SIB Mediation continued				- Parameters: **discriminator** the text string that must not be present in a message for the mediation to process the message (String, optional) - Returns: A new SIB mediation.	

create SIBWS Endpoint Listener	SIB Web Services group	The **create SIBWS Endpoint Listener** command creates an end point listener object with no SIBWS bus connection property objects.	Object name of the server where the end point listener will be created.	- Parameters:
				name The name of the end point listener within the server. (required)
				urlRoot The root of the end point address URL for Web services that you access through the end point listener. (required)
				wsdlUrlRoot The root of the HTTP URL where you can retrieve the WSDL associated with this end point listener. (required)
				- Returns: The SIBWS end point object.
					Batch mode example usage:
					- Using Jacl:
					`set epl [$AdminTask createSIBWSEndpointListener $server {-name "soaphttp1" -urlRoot "http://myserver.com /wsgwsoaphttp1" -wsdlUrlRoot "http://myserver.com /wsgwsoaphttp1"}]`
					- Using Jython:
					`epl = AdminTask .createSIBWSEndpointListener (server, '[-name soaphttp1 -urlRoot http://myserver.com /wsgwsoaphttp1 -wsdlUrlRoot http://myserver.com /wsgwsoaphttp1]')`
					Interactive mode example usage:
					- Using Jacl:
					`$AdminTask createSIBWSEndpointListener {-interactive}`
					- Using Jython:
					`AdminTask .createSIBWSEndpointListener ('[-interactive]')`

create SIBWS Inbound Service	SIB Web Services group	The **create SIBWS Inbound Service** command creates a new inbound service object that represents a protocol attachment that service requesters will use. If you specify the UDDI Reference option, the wsdlLocation option is assumed to be a UDDI service key in the following format where each `n` is a hex digit: `nnnnnnnn nnnn-nnnn -nnnn-nnnn -nnnnnnnn`.	The object name of the messaging bus within which the service will be created.	• Parameters:
				name
				The administrative name of the inbound service. (required)
				destination
				The name of the underlying WPM destination. (required)
				wsdlLocation
				The location of the template WSDL. The value of this parameter can be a URL or a UDDI service key (UUID). (required)
				wsdl ServiceName
				The name of the service in the WSDL. You must specify this parameter or the wsdlServiceNamespace parameter. (conditional)
				wsdlService Namespace
				The namespace of the service in the WSDL. You must specify this parameter or the wsdlServiceName parameter. (conditional)
				uddiReference
				The reference of the UDDI registry for the WSDL. (optional)
				userId
				The user ID to use to retrieve the WSDL. (optional)
				password
				The password to use to retrieve the WSDL. (optional)
				• Returns: The object name of the created inbound service object.
					Batch mode example usage:
					• Using Jacl:
					`set inService [$AdminTask createSIBWSInboundService $bus {-name "`*`MyService`*`" -destination $destName -wsdlLocation "`*`http://myserver.com/MyService.wsdl`*`"}]`
					• Using Jython:
					`inService = AdminTask.createSIBWSInboundService(bus, '[-name `*`MyService`*` -destination `*`destName`*` -wsdlLocation `*`http://myserver.com/MyService.wsdl`*`]')`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask createSIBWSInboundService {-interactive}`
					• Using Jython:
					`AdminTask.createSIBWSInboundService('[-interactive]')`

create SIBWS Outbound Service	SIB Web Services group	The **create SIBWS Outbound Service** command creates a new outbound service object that represents a protocol attachment to a service provider. This command requires the identification of a single service element within a WSDL document.	The object name of the messaging bus within which the service is created.	- Parameters:
				name The administrative name of the outbound service. (required)
				wsdlLocation The location of the WSDL of the service provider. It can be a URL or a UDDI service key (UUID). (required)
				wsdlServiceName The name of the service in the WSDL. You must specify the wsdl ServiceName parameter or the wsdlService Namespsace parameter. (conditional)
				wsdlServiceNamespace Namespace of the service in the WSDL. You must specify the wsdlServiceName parameter or the wsdlService Namespsace parameter. (conditional)
				uddiReference The reference of the UDDI registry for the WSDL. (optional)
				destination The name of the service destination. (optional)
				userId The user ID to use to retrieve the WSDL. (optional)
				password The password to use to retrieve the WSDL. (optional)
				- Returns: The object name of the
					Batch mode example usage:
					- Using Jacl:
					`set outService [$AdminTask`
					` createSIBWSOutboundService`
					` $bus {-name`
					` "`*`MyService`*`"`
					` -wsdlLocation`
					` "`*`http://myserver.com`*
					`/MyService.wsdl``"}]`
					- Using Jython:
					`outService =`
					`  AdminTask`
					`.createSIBWSOutboundService`
					`(bus, '[-name `*`MyService`*
					` -wsdlLocation`
					` http://myserver.com`
					`/MyService.wsdl``]')`
					Interactive mode example usage:
					- Using Jacl:
					`$AdminTask`
					`createSIBWSOutboundService`
					` {-interactive}`
					- Using Jython:
					`AdminTask`
					`.createSIBWSOutboundService`
					` ('[-interactive]')`

create SI Bus	SIB Admin Commands	Use this command to create a new bus on the current node.	None	• Parameters:
				bus
				name of bus to create, which must be unique in the cell (String, required)
				description
				descriptive information about the bus (String, required)
				secure
				enable or disable bus security (Boolean, optional, default = False)
				interEngine AuthAlias
				name of the authentication alias used to authorize communication between messaging engines on the bus (String, optional)
				mediationsAuth Alias
				name of the authentication alias used to authorize mediations to access the bus (String, optional)
				protocol
				the protocol used to send and receive messages between messaging engines, and between API clients and messaging engines (String, optional)
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask createSIBus {-bus busname -description text -secure True -mediationsAuthAlias name -protocol protocol -discardOnDelete False}`
					• Using Jython:
					`AdminTask.createSIBus ('[-bus busname -description "text" -secure True -mediationsAuthAlias name -protocol protocol -discardOnDelete False]')`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask createSIBus {-interactive}`
					• Using Jython:
					`AdminTask.createSIBus ('[-interactive]')`

create SI Bus continued				- Parameters: **discardOnDelete** indicate whether or not any messages left in the data store of a queue should be discarded when the queue is deleted (Boolean, optional, default = False) **destinationHighMsgs** the maximum number of messages that any queue on the bus can hold (Long, optional) **configuration Reload Enabled** indicate whether configuration files should be dynamically reloaded for this bus (Boolean, optional, default = True) - Returns: A new SIB bus.	

createServerType	None	Use the **create Server Type** command to define a server type.	None	• Parameters:
				-version
				(String, required)
				-serverType
				(String, required)
				-createTemplateCommand
				(String, required)
				-createCommand
				(String, required)
				-defaultTemplateName
				The default value is: default. (String, optional)
				-configValidator
				(String, optional)
				• Returns: The identification of the server type that you created, `javax.management.ObjectName`.
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask createServerType {-version version -serverType serverType -createTemplateCommand name -createCommand name}`
					• Using Jython:
					`AdminTask.createServerType ('[-version version -serverType serverType -createTemplateCommand name -createCommand name]')`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask createServerType {-interactive}`
					• Using Jython:
					`AdminTask.createServerType ('[-interactive]')`

create TCP End Point	None	The **create TCP End Point** command creates a new named end point you can associate with a TCP inbound channel.	Parent instance of the Transport Channel Service that contains the TCP Inbound Channel. (Object Name, required)	- Parameters:
				-name
				Name for the new Named EndPoint. (String, required)
				- host
				Host for the new Named EndPoint. (String, required)
				- port
				Port for the new NamedEndPoint. (String, required)
				- Returns: Object name of the created NamedEndPoint.
					Batch mode example usage:
					- Using Jacl:
					`$AdminTask createTCPEndPoint (cells/rohitbuildCell01 /nodes/ rohitbuildCellManager01 /servers/dmgr |server.xml #TransportChannelService_1)`
					`{-name Sample_End_Pt_Name -host rohitbuild.raleigh.ibm.com -port 8978}`
					- Using Jython:
					`AdminTask.createTCPEndPoint ('cells/rohitbuildCell01 /nodes /rohitbuildCellManager01 /servers /dmgr|server.xml #TransportChannelService_1', '[-name Sample_End_Pt_Name -host rohitbuild.raleigh.ibm.com -port 8978]')`
					Interactive mode example usage:
					- Using Jacl:
					`$AdminTask createTCPEndPoint {-interactive}`
					- Using Jython:
					`AdminTask.createTCPEndPoint ('[-interactive]')`

create Unmanaged Node	Unmanaged Node Commands group	Use the **create Unmanaged Node** command to create a new unmanaged node in the configuration. An unmanaged node is a node that does not have a node agent nor a deployment manager. Unmanaged nodes may contain Web servers, such as IBM IHS server.	None	• Parameters:
				- nodeName
				The name that will represent the node in the configuration repository. (String, required)
				- hostName
				The host name of the system associated with this node. (String, required)
				- nodeOperating System
				The operating system in use on the system associated with this node. Valid entries include the following: `os400`, `aix`, `hpux`, `linux`, `solaris`, `windows`, and `os390`.(String required)
				• Returns: null
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask createUnmanagedNode {-nodeName myNode -hostName myHost -nodeOperatingSystem linux}`
					• Using Jython:
					`AdminTask .createUnmanagedNode ('[-nodeName jjNode -hostName jjHost -nodeOperatingSystem linux]')`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask createUnmanagedNode {-interactive}`
					• Using Jython:
					`AdminTask .createUnmanagedNode ('[-interactive]')`

create WSGW Gateway Service	WS Gateway group	The **create WSGW Gateway Service** command creates a new Gateway Service with associated Inbound Service and Target Service object. Configuration of the Inbound Port and Outbound Service/Port associated with these is done using separate commands.	Object Name of the gateway instance which the gateway service is created	- Parameters:
				-name Administrative name of the Gateway Service. (required)
				-wsdlLocation Location of the template WSDL. May be a URL or a UDDI business key (UUID). (conditional)
				-wsdl ServiceName The name of the service in the WSDL. (conditional)
				-wsdlService Namespace The namespace of the service in the WSDL. (conditional)
				-targetDestination The name of the target destination. (conditional)
				-targetService The name of the target outbound service. (conditional)
				-request Destination The name of the gateway destination. (optional)
				-replyDestination The name of the gateway reply destination. (optional)
				-targetBus The name of the WPM bus containing the target. (optional)
					Batch mode example usage:
					- Using Jacl:
					`set gwService [$AdminTask createWSGWGatewayService $wsgw {-name` *`MyGatewayService`* `-targetService` *`MyService`*`}]`
					- Using Jython:
					`gwService = AdminTask .createWSGWGatewayService (wsgw, '[-name` *`MyGatewayService`* `-targetService` *`MyService`*`]')`
					Interactive mode example usage:
					- Using Jacl:
					`$AdminTask createWSGWGatewayService {-interactive}`
					- Using Jython:
					`$AdminTask createWSGWGatewayService ('[-interactive]')`

create WSGW Gateway Service continued				• Parameters: **-uddiReference** The reference of the UDDI registry for the WSDL. (optional) **-userId** The user id to use to retrieve the WSDL. (optional) **-password** The password to use to retrieve the WSDL. (optional) • Returns: ObjectName of the created GatewayService object	

create WSGW Proxy Service	WS Gateway group	The **create WSGW Proxy Service** command creates a new proxy service with an associated inbound service, and a target service object with an associated outbound service. Configuration of the inbound port objects associated with the inbound service is done using separate commands.	The object name of the gateway instance within which the proxy service is created.	• Parameters:
				name The administrative name of the proxy service. (required)
				node The node where the destinations will be localized. (conditional)
				server The server where the destinations will be localized. (conditional)
				cluster Cluster where the destinations will be localized. (conditional)
				-requestDestination The name of the proxy request destination. (optional)
				-replyDestination The name of the proxy reply destination. (optional)
				-wsdlLocation The location of the proxy WSDL (URL). (optional)
				• Returns: The object name of the proxy service object that you created.
					Batch mode example usage:
					• Using Jacl:
					`set proxyService [$AdminTask createWSGWProxyService $wsgw {-name` *`MyProxyService`* `-node` *`MyNode`* `-server` *`server1`*`}]`
					• Using Jython:
					`proxyService = AdminTask .createWSGWProxyService (wsgw, '[-name` *`MyProxyService`* `-node` *`MyNode`* `-server` *`server1`*`]')`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask createWSGWProxyService {-interactive}`
					• Using Jython:
					`AdminTask .createWSGWProxyService ('[-interactive]')`

create Web Server	Server Management group	Use the **create Web Server** command to create a Web server definition. This command is a two step process. The first step creates a Web server definition using a template. The parameters of the second step configure the Web server definition properties. Web server definitions generate and propagate the `plugin-config.xml` file for each Web server. For IHS only, the Web server definitions allow you to administer and configure IHS Web servers using the administrative console. These functions include the following: Start, Stop, View logs, View and Edit configuration file.	None	- **Parameters for step one:**
				nodeName
				The name of the node. (String, required)
				name
				The name of the server. (String, required)
				templateName
				The name of the template that you want to use. Templates include the following: `IHS`, `iPlanet`, `IIS`, `DOMINO`, `APACHE`. The default template is `IHS`. (String, required)
				genUniquePorts
				Indicates that you want to generate unique ports. (optional)
				- **Parameters for step two:**
				serverConfig
				Create the Web server. (String, required)
				webPort
				The port for the Web server. (String, required)
				configurationFile
				The configuration file. The default is the path relative to the installation root, for example, `conf/httpd.conf`. (String, optional)
				webInstallRoot
				The installation path for the Web server. (String, required)
					Batch mode example usage:
					- Using Jacl:
					`$AdminTask createWebServer {-name web1 -serverConfig {{webPort WebserverInstallRoot PluginInstallRoot Configuration _file_name Windows_Server_Name errorLogPath accessLogPath WebProtocol}} -remoteServerConfig {{AdminPort UserID Password AdminProtocol}}`
					- Using Jython:
					`AdminTask.createWebServer ('[-name web1 -serverConfig [[webPort WebserverInstallRoot PluginInstallRoot Configuration _file_name Windows_Server _Name errorLogPath accessLogPath WebProtocol]] -remoteServerConfig [[AdminPort UserID Password AdminProtocol]]]')`
					where `-serverConfig` is second step of the command.
					– WebPort - is the port for the Webserver (required for all webservers)
					– Webserver InstallRoot - is the install path (directory) for webserver. necessary for IHS Admin Function.
					– Plugin Install Root - is install root where the plugin for the webserver is installed. Necessary for all webservers.
					– Configuration file name - is the file path for the IBM HTTP Server. This is necessary for View and edit of the IHS Configuration file only.

create Web Server continued				• **Parameters for step two continued:**
				pluginInstallRoot
				The plug-in installation path. (String, required)
				serviceName
				The service name. (String, optional)
				errorLogfile
				The error log for viewing. The default is the path relative to the installation root, for example, `logs/error_log`. (String, optional)
				accessLogfile
				The access log for viewing. The default is the path relative to the installation root, for example, `logs /access_log`. (String, optional)
				webProtocol
				Parameters for the IHS administration server running with an unmanaged or remote Web server. Options include `HTTP` or `HTTPS`. The default is `HTTP`. (String, required)
				adminPort
				The port of the IHS administrative server. (String, required)
				adminUserID
				The user ID. This value should match the one for authentication in the `admin.conf`. (String, required)
					• Windows Service Name - The windows service name on which IHS is to be started. This is necessary for Start and stop of the IHS webserver only.
					• ErrorLogPath - This is the path for the IHS error log (error.log)
					• AccessLogPath - This is the path for the IHS access log (access.log)
					• WebServerProtocol - HTTP or HTTPS
					where -remoteServerConfig is 3rd step of the command
					These parameters are only necessary if the IHS webserver is installed on a machine remote from WebSphere.
					• Admin Server Port - This is the port for the ADministration server. The administration server is installed on the same machine as the IBM HTTP Server. The admin server handles admin request to the IHS webserver.
					• UserID - This is the userID for authentication, if authentication is activated on the Administration server in the admin configuration file (admin.conf).
					• Passwd - This is the password for the specified authentication UserID. The password is generated by htpasswd utility in the admin.passwd file.
					• Admin ServerProtocol - HTTP or HTTPS
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask createWebServer -interactive`
					• Using Jython:
					`AdminTask.createWebServer ('[-interactive]')`

create Web Server continued				• **Parameters for step two continued:** **adminPasswrd** The administrative password. (String, required) **adminProtocol** The administrative protocol title. Options include `HTTP` or `HTTPS`. The default is `HTTP`. (String, required) • **Parameters for step three:** Parameters for IHS administration server running with an unmanaged or remote Web server (installed on machine different from WebSphere Application Server) **adminPortTitle (adminPort)** Port of IHS administration **admin UserIDTitle (adminUserID)** The user ID. This value should match the authentication in the admin.conf file. **adminPasswd Title (adminPasswd)** password **Admin Protocol Title (adminProtocol)** This parameter is required. The value is either HTTP or HTTPS. The default value is HTTP. • **Returns:** None	

delete Chain	Channel Framework Management group	The **delete Chain** command deletes an existing chain and, optionally, the transport channels in the chain.	The chain to be deleted. (Object Name ,required)	- Parameters:
				- delete Channels
				If the value of this attribute is true, non-shared transport channels used by the specified chain will be deleted. (Boolean, optional)
				- Returns: None
					Batch mode example usage:
					- Using Jacl:
					`$AdminTask deleteChain trialChain1 (cells/rohitbuildCell01 /nodes /rohitbuildCellManager01 /servers /dmgr|server.xml#Chain _1093554462922)`
					`$AdminTask deleteChain trialChain (cells/rohitbuildCell01 /nodes /rohitbuildCellManager01 /servers /dmgr|server.xml #Chain_1093554378078) {-deleteChannels true}`
					- Using Jython:
					`AdminTask.deleteChain ('trialChain1 (cells/rohitbuildCell01 /nodes /rohitbuildCellManager01 /servers/dmgr |server.xml #TransportChannelService_1)')`
					`AdminTask.deleteChain ('trialChain1 (cells/rohitbuildCell01 /nodes /rohitbuildCellManager01 /servers /dmgr |server.xml #TransportChannelService_1) ', '[-deleteChannels true]')`
					Interactive mode example usage:
					- Using Jacl:
					`$AdminTask deleteChain {-interactive}`
					- Using Jython:
					`AdminTask.deleteChain ('[-interactive]')`

delete Cluster	Cluster Config Commands	The delete Cluster command deletes the configuration of a server cluster. A server cluster consists of a group of application servers which are referred to as cluster members. When a server cluster is deleted, all of its members are deleted.
		Use the delete Cluster Member command to delete the configuration of an individual cluster member.
			cluster Object ID - The configuration object ID of the cluster to be deleted. If the cluster‘s object ID is not specified, then the cluster Name parameter must be specified. The object name can be obtained programmatically via Java using the WebSphere Config Service API, or via wsadmin scripting using the AdminConfig command.	• **Parameters:**
				-clusterName
				The name of the cluster to be deleted. If this parameter is not specified, then the cluster object ID must be specified in the command target.
				• **Parameters for step one:**
				-replication Domain
				Specifies the removal of the replication domain for this cluster. This command step is optional. The following parameters can be specified for this step:
				deleteDomain
				Deletes the replication domain for this cluster. This parameter is optional. The value is true or false which indicates whether the domain will be deleted. The default value is false. . Deleting the replication domain deletes all replicator entries defined in the domain.
				• **Returns:** None
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask deleteCluster { -clusterName cluster1 }`
					`$AdminTask deleteCluster { -clusterName cluster1 -replicationDomain {{true}}}`
					• Using Jython:
					`AdminTask.deleteCluster ('[-clusterName cluster1]')`
					`AdminTask.deleteCluster ('[-clusterName cluster1 -replicationDomain [[true]]]')`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask deleteCluster -interactive`
					• Using Jython:
					`AdminTask.deleteCluster ('[-interactive]')`

delete Cluster Member	Cluster Config Commands	The **delete Cluster Member** command deletes the configuration of a cluster member. A cluster member is an application server that belongs to a server cluster.
		Use the **delete Cluster** command to delete the configuration of a cluster.
			member Object ID - The configuration object ID of the cluster member to be deleted. If this is not specified, then the cluster Name, member Node and member Name parameters must be specified. The object name can be obtained programmatically via Java using the WebSphere Config Service API, or via wsadmin scripting using the Admin Config command.	• **Parameters:**
				-clusterName
				The name of the cluster which the member to be deleted belongs to. If this parameter is specified, then the member Name and member Node parameters must also be specified. If this is not specified, then the member object ID must be specified in the command target.
				-memberName
				The server name of the member to be deleted from the cluster. If this parameter is specified, then the clusterName and memberNode parameters must also be specified. If this is not specified, then the member object ID must be specified in the command target.
				-memberNode
				The name of the node having the cluster member to be deleted. If this parameter is specified, then the memberName and clusterName parameters must also be specified. If this is not specified, then the cluster member object ID must be specified in the command target.
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask deleteClusterMember {-clusterName cluster1 -memberNode node1 -memberName member1}`
					`$AdminTask deleteClusterMember {-clusterName cluster1 -memberNode node1 -memberName member2 -replicationEntry {{true}}}`
					• Using Jython:
					`AdminTask .deleteClusterMember ('[-clusterName cluster1 -memberNode node1 -memberName member1]')`
					`AdminTask .deleteClusterMember ('[-clusterName cluster1 -memberNode node1 -memberName member2 -replicationEntry [[true]]]')`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask deleteClusterMember -interactive`
					• Using Jython:
					`AdminTask .deleteClusterMember ('[-interactive]')`

delete Cluster Member continued				• **Parameters for step one:** **-replicatorEntry** Specifies the removal of a replicator entry for this cluster member. This command step is optional. The following parameters can be specified for this step: **deleteEntry** Delete the replicator entry having this cluster member‘s name from the cluster‘s replication domain. This parameter is optional. The value is true or false which indicates whether to delete the replicator entry. The default value is false. • **Returns:** None	

delete Core Group	Core Group Management group	The **delete Core Group** command deletes an existing core group. The core group that you specify must not contain any members. You cannot delete the default core group.	None	• Parameters:
				- core GroupName The name of the existing core group that will be deleted. (String required)
				• Returns: None
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask deleteCoreGroup {-coreGroupName *MyCoreGroup*}`
					• Using Jython:
					`AdminTask .deleteCoreGroup ('[-coreGroupName *MyCoreGroup*]')`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask deleteCoreGroup {-interactive}`
					• Using Jython:
					`AdminTask .deleteCoreGroup ('[-interactive]')`

delete Core Group Access Points	Core Group Bridge Management group	The **delete Core Group Access Points** command deletes all the core group access points associated with a group that you specify.	Core group bridge settings object for the cell. (Object Name, required)	• Parameters: **- core GroupName** The name of the core group whose core group access points will be deleted. (String required) • Returns: None	**Batch mode example usage:** • Using Jacl: $AdminTask deleteCoreGroupAccessPoints (cells/ rohitbuildCell01 |coregroupbridge.xml# CoreGroupBridgeSettings_1) "-coreGroupName *DefaultCoreGroup*" • Using Jython: AdminTask .deleteCoreGroupAccessPoints ('(cells/rohitbuildCell01 |coregroupbridge.xml #CoreGroupBridgeSettings_1)', '[-coreGroupName *DefaultCoreGroup*]') **Interactive mode example usage:** • Using Jacl: $AdminTask deleteCoreGroupAccessPoints {-interactive} • Using Jython: AdminTask .deleteCoreGroupAccessPoints ('[-interactive]')
delete SIB Destination	SIB Admin Commands	Use the **delete SIB Destination** command to delete a bus destination. This command deletes the named destination of the named bus and deletes all related message points.	None	• Parameters: **bus** name of the bus on which the destination to be deleted exists (String, required) **name** name of the destination to be deleted (String, required) • Returns: None	**Batch mode example usage:** • Using Jacl: $AdminTask deleteSIBDestination {-bus *busname* -name *destname*} • Using Jython: AdminTask .deleteSIBDestination ('[-bus *busname* -name *destname*]') **Interactive mode example usage:** • Using Jacl: $AdminTask deleteSIBDestination {-interactive} • Using Jython: AdminTask .deleteSIBDestination ('[-interactive]')

delete SIB Engine	SIB Admin Commands	Use the **delete SIB Engine** command to delete the default or named bus messaging engine from the named SIB bus. A server can only have one messaging engine, so when using this command to delete a messaging engine from a server there is no need to supply the engine name. A cluster can have more than one messaging engine so the name of the engine must be supplied.	None	- Parameters:
				***bus** name of the bus to which the messaging engine to be deleted belongs (String, required)
				node to delete a messaging engine on a server, supply node and server name, but not cluster name (String, optional)
				server to delete a messaging engine on a server, supply node and server name, but not cluster name (String, optional)
				cluster to delete a messaging engine on a cluster, supply cluster name, but not node and server name (String, optional)
				engine name of the messaging engine to delete. This is optional, and is only required when deleting a messaging engine from a cluster (String, optional)
				- Returns: None
					Batch mode example usage:
					- Using Jacl:
					`$AdminTask deleteSIBEngine {-bus *busname* -node *nodeName* -server *severname*}`
					- Using Jython:
					`AdminTask.deleteSIBEngine ('[-bus *busname* -node *nodeName* -server *severname*]')`
					Interactive mode example usage:
					- Using Jacl:
					`$AdminTask deleteSIBEngine {-interactive}`
					- Using Jython:
					`AdminTask .deleteSIBEngine ('[-interactive]')`

delete SIB JMS Activation Spec	SIB JMS Admin Commands	Use the **delete SIB JMS Activation Spec** command to delete an activation specification.	None	- Parameters:
				name The name of the activation specification that you want to delete. (String, (required)
				- Returns: None
					Batch mode example usage:
					- Using Jacl:
					`$AdminTask deleteSIBJMSActivationSpec {-name *specname*}`
					- Using Jython:
					`AdminTask .deleteSIBJMSActivationSpec ('[-name *specname*]')`
					Interactive mode example usage:
					- Using Jacl:
					`$AdminTask deleteSIBJMSActivationSpec {-interactive}`
					- Using Jython:
					`AdminTask .deleteSIBJMSActivationSpec ('[-interactive]')`

delete SIB JMS Connection Factory	SIB JMS Admin Commands	Use the **delete SIB JMS Connection Factory** command to	None	- Parameters:
				name The name of the SIB JMS connection factory (String, required)
				- Returns: None
					Batch mode example usage:
					- Using Jacl:
					`$AdminTask deleteSIBJMSConnectionFactory {-name *factory_name*}`
					- Using Jython:
					`AdminTask .deleteSIBJMSConnectionFactory ('[-name *factory_name*]')`
					Interactive mode example usage:
					- Using Jacl:
					`$AdminTask deleteSIBJMSConnectionFactory {-interactive}`
					- Using Jython:
					`AdminTask .deleteSIBJMSConnectionFactory ('[-interactive]')`

delete SIB JMS Queue	SIB JMS Admin Commands	Use the **delete SIB JMS Queue** command to delete a JMS queue.	None	• Parameters:
				name
				The name of the SIB JMS queue. (String, required)
				• Returns: None
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask deleteSIBJMSQueue {-name queue_name}`
					• Using Jython:
					`AdminTask .deleteSIBJMSQueue ('[-name queue_name]')`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask deleteSIBJMSQueue {-interactive}`
					• Using Jython:
					`AdminTask .deleteSIBJMSQueue ('[-interactive]')`

delete SIB JMS Topic	SIB JMS Admin Commands	Use the **delete SIB JMS Topic** command to delete a JMS topic.	None	• Parameters:
				name
				The name of the SIB JMS topic (String, required)
				• Returns: None
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask deleteSIBJMSTopic {-name topic_name}`
					• Using Jython:
					`AdminTask .deleteSIBJMSTopic ('[-name topic_name]')`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask deleteSIBJMSTopic {-interactive}`
					• Using Jython:
					`AdminTask .deleteSIBJMSTopic ('[-interactive]')`

delete SIB Mediation	SIB Admin Commands	Use this command to delete the named mediation from the named bus.	None	• Parameters:
				bus
				name of the bus that owns the mediation (String, required)
				mediation Name
				name of the mediation to be deleted (String, required)
				• Returns: None
					Batch mode example usage:
					• Using Jacl:
					• Using Jython:
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask deleteSIBMediation {-interactive}`
					• Using Jython:
					`AdminTask .deleteSIBMediation ('[-interactive]')`

delete SIBWS EndpointListener	SIB Web Services group	The **delete SIBWS Endpoint Listener** command deletes the configuration oa an end point listener. This command fails if there are inbound port objects associated with the end point listener.	Object name of the end point listener that you want to delete.	• Parameters: None
				• Returns: None
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask deleteSIBWSEndpointListener $epl`
					• Using Jython:
					`AdminTask .deleteSIBWSEndpointListener (epl)`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask deleteSIBWSEndpointListener {-interactive}`
					• Using Jython:
					`AdminTask .deleteSIBWSEndpointListener ('[-interactive]')`

delete SIBWS Inbound Service	SIB Web Services group	The **delete SIBWS Inbound Service** command deletes an inbound service object and any inbound port objects that are associated.	The object name of the inbound service object that you want to delete.	• Parameters:
				userId The user ID to use to interact with UDDI registries. (optional)
				password The password to use to interact with UDDI registries. (optional)
				• Returns: None
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask deleteSIBWSInboundService $inService`
					• Using Jython:
					`AdminTask .deleteSIBWSInboundService (inService)`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask deleteSIBWSInboundService {-interactive}`
					• Using Jython:
					`AdminTask .deleteSIBWSInboundService ('[-interactive]')`

delete SIBWS Outbound Service	SIB Web Services group	The **delete SIBWS Outbound Service** command deletes an outbound service object and any outbound port objects that are associated. Resources that are associated with the outbound service or outbound ports, for example, WS-Security configuration, are disassociated from the outbound service and the outbound ports but are not deleted.	Object name of the outbound service object that you want to delete.	• Parameters: None
				• Returns: None
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask deleteSIBWSOutboundService $outService`
					• Using Jython:
					`AdminTask .deleteSIBWSOutboundService (outService)`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask deleteSIBWSOutboundService {-interactive}`
					• Using Jython:
					`AdminTask .deleteSIBWSOutboundService ('[-interactive]')`

deleteSIBus	SIB Admin Commands	Use this command to delete the named SIB bus. Also deletes all SIB mediations and SIB destinations owned by the bus.	None	- Parameters:
				bus
				name of bus to be deleted from the current cell (String, required)
				- Returns: None
					Batch mode example usage:
					- Using Jacl:
					`$AdminTask deleteSIBus {-bus bus_name}`
					- Using Jython:
					`AdminTask.deleteSIBus ('[-bus bus_name]')`
					Interactive mode example usage:
					- Using Jacl:
					`$AdminTask deleteSIBus {-interactive}`
					- Using Jython:
					`AdminTask.deleteSIBus ('[-interactive]')`

deleteServer	None	Use the **deleteServer** command to delete the server scope configuration and the server entry that corresponds to it in the `server index.xml` file. You can also use this command to delete a Web server.	None	- Parameters:
				-nodeName
				(String, required)
				-serverName
				(String, required)
				- Returns: None
					Batch mode example usage:
					- Using Jacl:
					`$AdminTask deleteServer {-nodeName node_name -serverName server_name}`
					- Using Jython:
					`AdminTask.deleteServer ('[-nodeName node_name -serverName server_name]')`
					Interactive mode example usage:
					- Using Jacl:
					`$AdminTask deleteServer {-interactive}`
					- Using Jython:
					`AdminTask.deleteServer ('[-interactive]')`

delete Server Template	None	Use the **delete Server Template** command to delete server templates. You cannot delete templates defined by the system. You can only delete server templates that you created. This command deletes the directory that hosts the server template.	A server template identification, `javax.management.ObjectName`. This target object is required.	• Returns: Void	**Interactive mode example usage:**
					• Using Jacl:
					`$AdminTask deleteServerTemplate {-interactive}`
					• Using Jython:
					`AdminTask.deleteServerTemplate('[-interactive]')`

delete WSGW Gateway Service	WS Gateway group	The **delete WSGW Gateway Service** command deletes a gateway service. It deletes the gateway destination the corresponding reply destination, inbound service, and inbound port enablement objects, and all of the target service objects that are associated. This command does not delete the destinations that are associated with the target services.	Object name of the gateway service object	- Parameters: None
				- Returns: None
					Batch mode example usage:
					- Using Jacl:
					`$AdminTask deleteWSGWGatewayService $gwService`
					- Using Jython:
					`AdminTask .deleteWSGWGatewayService (gwService)`
					Interactive mode example usage:
					- Using Jacl:
					`$AdminTask deleteWSGWGatewayService {-interactive}`
					- Using Jython:
					`AdminTask .deleteWSGWGatewayService ('[-interactive]')`

delete WSGW Proxy Service	WS Gateway group	The **delete WSGW Proxy Service** command deletes a proxy service including the proxy destinations, outbound service, outbound ports, inbound service, and inbound port enablement objects.	Object name of the Proxy Service object	- Parameters: None
				- Returns: None
					Batch mode example usage:
					- Using Jacl:
					`$AdminTask deleteWSGWProxyService $proxyService`
					- Using Jython:
					`AdminTask .deleteWSGWProxyService (proxyService)`
					Interactive mode example usage:
					- Using Jacl:
					`$AdminTask deleteWSGWProxyService {-interactive}`
					- Using Jython:
					`AdminTask .deleteWSGWProxyService ('[-interactive]')`

disconnect SIBWS Endpoint Listener	SIB Web Services group	The **disconnect SIBWS Endpoint Listener** command disconnects an end point listener from a bus.	Object name of the end point listener to be disconnected.	• Parameters: **bus** The name of the bus from which to be disconnected. (required) • Returns: None	**Batch mode example usage:** • Using Jacl: $AdminTask disconnectSIBWS EndpointListener $epl {-bus "*MyBus*"} • Using Jython: AdminTask .disconnectSIBWS EndpointListener (epl,'[-bus *MyBus*]') **Interactive mode example usage:** • Using Jacl: $AdminTask disconnectSIBWS EndpointListener {-interactive} • Using Jython: AdminTask .disconnectSIBWS EndpointListener ('[-interactive]')
does Core Group Exist	Core Group Managemen group	The **does Core Group Exist** command returns a boolean value that indicates if the core group that you specify exists.	None	• Parameters: **coreGroupName** The name of the core group. (String, required) • Returns: A boolean value.	**Batch mode example usage:** • Using Jacl: $AdminTask doesCoreGroupExist {-coreGroupName *MyCoreGroup*} • Using Jython: AdminTask .doesCoreGroupExist ('[-coreGroupName *MyCoreGroup*]') **Interactive mode example usage:** • Using Jacl: $AdminTask doesCoreGroupExist {-interactive} • Using Jython: AdminTask .doesCoreGroupExist ('[-interactive]')

export Server	Configuration archive Operations group	Use the **export Server** command to export the server configuration to a node defined in the configuration archive.
		The **export Server** command virtualizes the server configuration and exports a server to a configuration archive. This process breaks any existing associations between the server configurations in the configuration archive and the configurations in the system. This process also removes applications from the server that you specify, breaks the relationship between the server that you specify and the core group of the server, cluster, or SIBus membership. The **exportServer** command exports the metadata file of the node where the server resides. You can use this information
			None	• Parameters:
				-archive
				The fully qualified path of the exported configuration archive. (String, required)
				-nodeName
				The node name of the server. This parameter is only required when the server name is not unique across the cell. (String, optional)
				-serverName
				The server name. (String, required)
				• Returns: None
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask exportServer {-archive c:\myServer.ear -nodeName node1 -serverName server1}`
					• Using Jython:
					`AdminTask.exportServer ('[-archive c:\myServer.ear -nodeName node1 -serverName server1]')`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask exportServer {-interactive}`
					• Using Jython:
					`AdminTask.exportServer ('[-interactive]')`

export Was profile	configuration archive Operations group	Use the **export Was profile** command to export the entire cell configuration to a configuration archive.	None	- Parameters:
				archive
				The fully qualified file path of the exported configuration archive. (String, required)
				- Returns: None
					Batch mode example usage:
					- Using Jacl:
					`$AdminTask exportWasprofile {-archive c:\myCell.ear}`
					- Using Jython:
					`AdminTask .exportWasprofile ('[-archive c:\myCell.ear]')`
					Interactive mode example usage:
					- Using Jacl:
					`$AdminTask exportWasprofile {-interactive}`
					- Using Jython:
					`AdminTask .exportWasprofile ('[-interactive]')`

get All Core Group ames	Core Group Management group	The **get All Core Group Names** command returns a string that contains the names of all of the existing core groups	None	- Parameters: None
				- Returns: String array (String[ ])
					Batch mode example usage:
					- Using Jacl:
					`$AdminTask getAllCoreGroupNames`
					- Using Jython:
					`AdminTask .getAllCoreGroupNames()`
					Interactive mode example usage:
					- Using Jacl:
					`$AdminTask getAllCoreGroupNames {-interactive}`
					- Using Jython:
					`AdminTask .getAllCoreGroupNames ('[-interactive]')`

get Core Group Name For Server	Core Group Management group	The **get Core Group Name For Server** command returns the name of the core group for which the server you specify is currently a member.	None	• Parameters:
				- nodeName The name of the node that contains the server. (String, required)
				- serverName The name of the server. (String, required)
				• Returns: The name of the core group that currently contains the server that you specified. (String)
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask getCoreGroupNameForServer {-nodeName` *`myNode`* `-serverName` *`myServer`*`}`
					• Using Jython:
					`AdminTask .getCoreGroupNameForServer ('[-nodeName` *`myNode`* `-serverName` *`myServer`*`]')`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask getCoreGroupNameForServer {-interactive}`
					• Using Jython:
					`AdminTask .getCoreGroupNameForServer ('[-interactive]')`

get Default Core Group Name	Core Group Management group	The **get Default Core Group Name** command returns the name of the default core group.	None	• Parameters: None
				• Returns: String
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask getDefaultCoreGroupName`
					• Using Jython:
					`AdminTask .getDefaultCoreGroupName()`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask getDefaultCoreGroupName {-interactive}`
					• Using Jython:
					`AdminTask .getDefaultCoreGroupName ('[-interactive]')`

get Metadata Properties	Managed Object Metadata group	The **get Metadata Properties** command obtains all metadata for the node that you specify.	None	• Parameters:
				- nodeName
				The name of the node associated with the metadata you want this command to return.
				• Returns: The list of metadata properties.
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask getMetadataProperties {-nodeName node1}`
					• Using Jython:
					`AdminTask .getMetadataProperties ('[-nodeName node1]')`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask getMetadataProperties {-interactive}`
					• Using Jython:
					`AdminTask .getMetadataProperties ('[-interactive]')`

get Metadata Property	Managed Object Metadata group	The **get Metadata Property** command obtains metadata with the specified key for the node that you specify.	None	• Parameters:
				- nodeName
				The name of the node associated with the metadata you want this command to return.
				- propertyName
				Metadata property key.
				• Returns: The requested property for the node that you specified.
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask getMetadataProperty {-nodeName node1 -propertyName com.ibm.websphere .baseProductVersion}`
					• Using Jython:
					`AdminTask .getMetadataProperty ('[-nodeName node1 -propertyName com.ibm.websphere .baseProductVersion]')`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask getMetadataProperty {-interactive}`
					• Using Jython:
					`AdminTask .getMetadataProperty ('[-interactive]')`

get Named TCP End Point	Core Group Bridge Management group	The **get Named TCP End Point** command returns the port associated with the bridge interface that you specify. The port that is returned is the one that is specified on the TCP inbound channel of the transport channel chain for bridge interface that you specify.	The bridge interface object for which the port will be listed. (Object Name, required)	• Parameters: None
				• Returns: The port (named end point) object name of the TCP inbound channel instance which resides on the DCS transport channel chain of the bridge interface.
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask getNamedTCPEndPoint (cells/rohitbuildCell01|coregroupbridge.xml #BridgeInterface_2)`
					• Using Jython:
					`AdminTask .getNamedTCPEndPoint ('(cells/rohitbuildCell01 |coregroupbridge.xml #BridgeInterface_2)')`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask getNamedTCPEndPoint {-interactive}`
					• Using Jython:
					`AdminTask .getNamedTCPEndPoint ('[-interactive]')`

get Node Base Product Version	Managed Object Metadata group	The **get Node Base Product Version** command returns the version of the WebSphere Application Server for a node that you specify. This command only returns the version for a distributed installation of the product.	None	• Parameters:
				- nodeName
				The name of the node associated with the metadata you want this command to return.
				• Returns: WebSphere Application Server version for the node that you specify.
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask getNodeBaseProductVersion {-nodeName` *node1*`}`
					• Using Jython:
					`AdminTask .getNodeBaseProductVersion ('[-nodeName` *node1*`]')`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask getNodeBaseProductVersion {-interactive}`
					• Using Jython:
					`AdminTask .getNodeBaseProductVersion ('[-interactive]')`

get Node Major Version	Managed Object Metadata group	The **get Node Major Version** command returns the major version of the WebSphere Application Server for a node that you specify. It only returns the version for a distributed installation of the product.	None	• Parameters:
				nodeName The name of the node associated with the metadata you want this command to return.
				• Returns: WebSphere Application Server major version for the node that you specified.
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask getNodeMajorVersion {-nodeName *node1*}`
					• Using Jython:
					`AdminTask .getNodeMajorVersion ('[-nodeName *node1*]')`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask getNodeMajorVersion {-interactive}`
					• Using Jython:
					`AdminTask .getNodeMajorVersion ('[-interactive]')`

get Node Minor Version	Managed Object Metadata group		None	• Parameters:
				- nodeName The name of the node associated with the metadata you want this command to return.
				• Returns: WebSphere Application Server minor version for the node that you specified.
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask getNodeMinorVersion {-nodeName *node1*}`
					• Using Jython:
					`AdminTask .getNodeMinorVersion ('[-nodeName *node1*]')`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask getNodeMinorVersion {-interactive}`
					• Using Jython:
					`AdminTask .getNodeMinorVersion ('[-interactive]')`

get Node Platform OS	Managed Object Metadata group	The **get Node Platform OS** command returns the operating system name for a node that you specify.	None	• Parameters:
				- nodeName The name of the node associated with the metadata you want this command to return.
				• Returns: The operating system name of the node that you specified.
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask getNodePlatformOS {-nodeName node1}`
					• Using Jython:
					`AdminTask .getNodePlatformOS ('[-nodeName node1]')`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask getNodePlatformOS {-interactive}`
					• Using Jython:
					`AdminTask .getNodePlatformOS ('[-interactive]')`

get Node Sysplex Name	Managed Object Metadata group	The **get Node Sysplex Name** command returns the sysplex name for a node that you specify.	None	• Parameters:
				- nodeName The name of the node associated with the metadata you want this command to return.
				• Returns: The sysplex name of the given node.
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask getNodeSysplexName {-nodeName node1}`
					• Using Jython:
					`AdminTask .getNodeSysplexName ('[-nodeName node1]')`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask getNodeSysplexName {-interactive}`
					• Using Jython:
					`AdminTask .getNodeSysplexName ('[-interactive]')`

get Server Type					**Interactive mode example usage:**
					• Using Jacl:
					`$AdminTask getServerType {-interactive}`
					• Using Jython:
					`AdminTask.getServerType ('[-interactive]')`

get TCP End Point	None	The **get TCP End Point** command obtains the named end point associated with either a TCP inbound channel or a chain that contains a TCP inbound channel.	TCP Inbound Channel, or containing chain, instance that is associated with a Named EndPoint. (Object Name, required)	• Parameters: None
				• Returns: Object name of an existing named end point that is associated with the TCP inbound channel instance or a channel chain.
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask getTCPEndPoint`
					`TCP_1(cells`
					`/rohitbuildCell01/`
					`nodes/rohitbuildCellManager01`
					`/servers/dmgr|server.xml`
					`#TCPInboundChannel_1)`
					`$AdminTask getTCPEndPoint`
					`DCS`
					`(cells/rohitbuildCell01`
					`/nodes/`
					`rohitbuildCellManager01`
					`/servers`
					`/dmgr|server.xml#Chain_3)`
					• Using Jython:
					`AdminTask.getTCPEndPoint`
					`('TCP_1(cells/rohitbuildCell01/`
					`nodes/rohitbuildCellManager01`
					`/servers/dmgr`
					`|server.xml`
					`#TCPInboundChannel_1)')`
					`AdminTask.getTCPEndPoint`
					`('DCS(cells/rohitbuildCell01`
					`/nodes/`
					`rohitbuildCellManager01`
					`/servers`
					`/dmgr|server.xml#Chain_3)')`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask getTCPEndPoint`
					`{-interactive}`
					• Using Jython:
					`AdminTask.getTCPEndPoint`
					`('[-interactive]')`

import Server	Configuration archive Operations group	Use the **import Server** command to import a server that resides in a configuration archive to the system. This command imports all the server scope configurations defined in the configuration archive to system configuration.	None	• Parameters:
				-archive
				The fully qualified path of the configuration archive. (String, required)
				-node InArchive
				The node name of the server defined in the configuration archive. (String, optional if there is only one node defined in the configuration archive, required if there are multiple nodes defined in the configuration archive)
				-server InArchive
				The name of the server defined in the configuration archive. (String, optional if there is only one server defined on the specified *nodeIn Configuration* archive, required if there are multiple servers defined under the specified *nodeIn Configuration* archive)
				-nodeName
				The node name where the server is imported. (String, optional if there is only one node)
				-serverName
				The server name where the server is imported. If the server name that you specify matches an existing server name under the node, an exception is thrown. (String, optional, default:serve
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask importServer {-archive c:\myServer.ear -nodeInArchive node1 -serverInArchive server1}`
					• Using Jython:
					`AdminTask.importServer ('[-archive c:\myServer.ear -nodeInArchive node1 -serverInArchive server1]')`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask importServer {-interactive}`
					• Using Jython:
					`AdminTask.importServer ('[-interactive]')`

import Server continued				• Parameters continued: **-serverName** The server name where the server is imported. If the server name that you specify matches an existing server name under the node, an exception is thrown. (String, optional, default:serverInArchive) **-coreGroup** The core group name to which the server should belong. (String, optional) • Returns: None	

help	None	The **help** command provides a summary of the help commands and ways to invoke an administrative command.	None	• Parameters: None
				• Returns: A general help description
					• Using Jacl:
					`$AdminTask help`
					• Using Jython:
					`print AdminTask.help()`

help	None	The **help** command provides a list of available administrative commands if the option string is `-commands` or administrative command groups if the option string is `-commandGroups`. Valid options include `-commands` and `-commandGroups`.	None	• Parameters:
				- options
				• Returns: A summary of all available administrative commands.
					• Using Jacl:
					`$AdminTask help -commands`
					• Using Jython:
					`AdminTask.help('-commands')`

help	None	If you provide the step name, this command provides help information for a given step of an administrative command. Otherwise, it provides help information for a given admin command or administrative command group. The stepName parameter is optional.	None	• Parameters:
				– - commandName
				– - stepName
				• Returns: A summary of the specified command group, administrative command, or step.
					• Using Jacl:
					`$AdminTask help createJ2CConnectionFactory`
					• Using Jython:
					`AdminTask.help ('createJ2CConnectionFactory')`

import Was profile	configuration archive Operations group	Use the **import Was profile** command to import a cell configuration in the configuration archive to the system. Only a base single server configuration is supported for this command.	None	• Parameters:
				archive
				The fully qualified file path of the configuration archive. (String, required)
				• Returns: Void
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask importWasprofile {-archive c:\myCell.ear}`
					• Using Jython:
					`AdminTask.importWasprofile ('[-archive c:\myCell.ear]')`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask importWasprofile {-interactive}`
					• Using Jython:
					`AdminTask.importWasprofile ('[-interactive]')`

is Node ZOS	Managed Object Metadata group	The **is Node ZOS** command tests if a node that you specify is running on the z/OS platform. This command does not apply to distributed platforms or WebSphere Application Server-Express.	None	- Parameters:
				- nodeName
				The name of the node associated with the metadata you want this command to return.
				- Returns: A `true` value if the node operating system is z/OS. A `false` value if the node operating system is not z/OS.
					Batch mode example usage:
					- Using Jacl:
					`$AdminTask isNodeZOS {-nodeName` *`node1`*`}`
					- Using Jython:
					`AdminTask.isNodeZOS ('[-nodeName` *`node1`*`]')`
					Interactive mode example usage:
					- Using Jacl:
					`$AdminTask isNodeZOS {-interactive}`
					- Using Jython:
					`AdminTask.isNodeZOS ('[-interactive]')`

list Admin Object Interfaces	JCA management group	Use the **list Admin Object Interfaces** command to list the administrative object interfaces defined under the resource adapter that you specify.	J2C Resouce adapter object ID	- Parameters: None
				- Returns: A list of administrative object interfaces.
					Batch mode example usage:
					- Using Jacl:
					`$AdminTask listAdminObjectInterfaces $ra`
					- Using Jython:
					`AdminTask .listAdminObjectInterfaces (ra)`

list Chain Templates	Channel Framework Management group	The **list Chain Templates** command displays a list of templates that you can use to create chains in this configuration. All templates have a certain type of transport channel as the last transport channel in the chain.	None	• Parameters:
				- acceptorFilter The templates returned by this method all have a transport channel instance of the specified type as the last transport channel in the chain. (String, optional)
				• Returns: A list of all the chain template object names. If you specify the acceptorFilter parameter, the list that returns is filtered to match the filter that you specified.
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask listChainTemplates {}`
					`$AdminTask listChainTemplates "-acceptorFilter` *`WebContainerInboundChannel`*`"`
					• Using Jython:
					`AdminTask .listChainTemplates()`
					`AdminTask .listChainTemplates ('[-acceptorFilter` *`WebContainerInboundChannel`*`]')`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask listChainTemplates {-interactive}`
					• Using Jython:
					`AdminTask .listChainTemplates ('[-interactive]')`

list Chains	Channel Framework Management group	The **list Chains** command lists all the chains configured under a particular instance of the transport channel service.	The instance of the transport channel service under which the chains are configured. (Object Name, required)	• Parameters:
				- acceptorFilter
				The chains that are returned by this parameter will have a transport channel instance of the type that you specify as the last transport channel in the chain. (String, optional)
				- endPoint Filter:
				The chains returned by this parameter will have a TCP inbound channel using an end point with the name that you specify.(String, optional)
				• Returns: A list of all the channel chain object names that match the specified filters. If no you do not specify any parameters, all of the channel chains that are configured under the particular instance of transport channel service are returned.
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask listChains (cells/rohitbuildCell01/nodes/rohitbuildNode01/servers/server2|server.xml#TransportChannelService_1093445762328)`
					`$AdminTask listChains (cells/rohitbuildCell01/nodes/rohitbuildNode01/servers/server2|server.xml#TransportChannelService_1093445762328) {-acceptorFilter` *`WebContainerInboundChannel`*`}`
					`$AdminTask listChains (cells/rohitbuildCell01/nodes/rohitbuildNode01/servers/server2|server.xml#TransportChannelService_1093445762328) {-endPointFilter` *`WC_adminhost`*`}`
					• Using Jython:
					`AdminTask.listChains('(cells/rohitbuildCell01/nodes/rohitbuildNode01/servers/server2|server.xml#TransportChannelService_1093445762328)')`
					`AdminTask.listChains('(cells/rohitbuildCell01/nodes/rohitbuildNode01/servers/server2|server.xml#TransportChannelService_1093445762328)', '[-acceptorFilter WebContainerInboundChannel]')`
					`AdminTask.listChains('(cells/rohitbuildCell01/nodes/rohitbuildNode01/servers/server2|server.xml#TransportChannelService_1093445762328)', '[-endPointFilter WC_adminhost]')`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask listChains {-interactive}`
					• Using Jython:
					`AdminTask.listChains ('[-interactive]')`

list Connection Factory Interfaces	JCA management group	Use the **list Connection Factory Interfaces** command to list all of the connection factory interfaces defined under the Java 2 resource adapter that you specify.	J2C Resource Adapter object ID	• Parameters: None
				• Returns: A list of connection factory interfaces.
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask listConnectionFactory Interfaces $ra`
					• Using Jython:
					`AdminTask .listConnectionFactory Interfaces (ra)`

list Core Groups	Core Group Bridge Management group	The **list Core Groups** command returns a collection of core groups that are related to the core group that you specify.	The name of the core group for which the related core groups will be listed. (String, required)	• Parameters:
				- cgBridge Settings The group bridge settings object for the cell. (Object Name, required)
				• Returns: A set of core group names.
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask listCoreGroups DefaultCoreGroup "-cgBridgeSettings (cells/rohitbuildCell01 |coregroupbridge.xml# CoreGroupBridgeSettings_1)"`
					• Using Jython:
					`AdminTask.listCoreGroups ('DefaultCoreGroup', '[-cgBridgeSetting (cells/rohitbuildCell01 |coregroupbridge.xml #CoreGroupBridgeSettings_1)]')`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask listCoreGroups {-interactive}`
					• Using Jython:
					`AdminTask.listCoreGroups ('[-interactive]')`

list Eligible Bridge Interfaces	Core Group Bridge Management group	The **list Eligible Bridge Interfaces** command returns a collection of node, server and transport channel chain combinations that are eligible to become bridge interfaces for the specified core group access point.	The core group access point object for which bridge interfaces will be listed. (Object Name, required)	• Parameters: None
				• Returns: A set of bridge interfaces. (Set of String) Each bridge interface is represented by a combination of a node, a server and a DCS channel chain: <node *name*>, <server *name*>, <DCS Channel Chain *objectName*. For example, an element of the set returned by this command may look like the following: `rohitbuild dmgr DCS-Secure (cells/rohitbuildCell/nodes/rohitbuild/servers/dmgr|server.xml#Chain_4)`
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask listEligibleBridgeInterfaces CGAP_DCG_2 (cells/rohitbuildCell01|coregroupbridge.xml#CoreGroupAccessPoint_1089636614062)`
					• Using Jython:
					`AdminTask.listEligibleBridgeInterfaces('CGAP_DCG_2 (cells/rohitbuildCell01|coregroupbridge.xml#CoreGroupAccessPoint_1089636614062)')`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask listEligibleBridgeInterfaces {-interactive}`
					• Using Jython:
					`AdminTask.listEligibleBridgeInterfaces('[-interactive]')`

list J2C Activation Specs	JCA management group	Use the **list J2c Activation Specs** command to list the activation specs contained under the resource adapter and message listener type that you specify.	J2C Resource Adapter object ID	• Parameters:
				-message ListenerType Specifies the message listener type for the resource adapter for which you are making a list. This parameter is required.
				• Returns: A list of activation specs that has specified message Listener type.
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask listJ2CActivationSpecs $ra {-messageListenerType javax.jms.MessageListener}`
					• Using Jython:
					`AdminTask.listJ2CActivationSpecs(ra, '[-messageListenerType javax.jms.MessageListener]')`

list J2C Admin Objects	JCA Management group	Use the **list J2C Admin Objects** command to list administrative objects that contains the administrative object interface that you specify.	J2C Resource Adapter object ID	• Parameters:
				-adminObject Interface
				Specifies the administrative object interface for which you want to list. This parameter is required.
				• Returns: A list of administrative objects that has specified adminObject Interface.
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask listJ2CAdminObjects $ra {-adminObjectInterface fvt.adaptor.message .FVTMessageProvider}`
					• Using Jython:
					`AdminTask .listJ2CAdminObjects (ra, '[-adminObjectInterface fvt.adaptor.message .FVTMessageProvider]')`

list J2C Connection Factories	JCA management group	Use the **list J2C Connection Factories** command to list the Java 2 connection factories under the resource adapter and connection factory interface that you specify	J2C Resource Adapter object ID	• Parameters:
				-connection Factory Interface
				Indicates the name of the connection factory that you want to list. This parameter is required.
				• Returns: A list of J2C connection Factory that has the specified connection Factory Interface.
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask listJ2CConnectionFactories $ra {-connectionFactoryInterface javax.sql.DataSource}`
					• Using Jython:
					`AdminTask .listJ2CConnectionFactories (ra, '[-connectionFactoryInterface javax.sql.DataSource]')`

list Managed Nodes	Unmanaged Node Commands group	Use the **list Managed Nodes** command to list the managed nodes (nodes that have a node agent defined) in a configuration.	None	• Parameters: None
				• Returns: List
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask listManagedNodes`
					• Using Jython:
					`AdminTask.listManagedNodes()`

list Message Listener Types	JCA Management group	Use the **list Message Listener Types** command to list the message listener types defined under the resource adapter that you specify.	J2C Resource Adapter object ID	• Parameters: None
				• Returns: A list of message listener types.
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask listMessageListenerTypes $ra`
					• Using Jython:
					`AdminTask .listMessageListenerTypes (ra)`

list Node Group Properties	Node Group Commands group	The **list Node Group Properties** command displays all of the custom properties of a node group.	The target object is name of the node group. This target object is required.	- Parameters: None
				- Returns: A list of all of the custom properties of a node group.
					Batch mode example usage:
					- Using Jacl:
					`$AdminTask listNodeGroupProperties WBINodeGroup`
					- Using Jython:
					`AdminTask .listNodeGroupProperties ('WBINodeGroup')`
					Interactive mode example usage:
					- Using Jacl:
					`$AdminTask listNodeGroupProperties {-interactive}`
					- Using Jython:
					`AdminTask .listNodeGroupProperties ('[-interactive]')`

list Node Groups	Node Group Commands group	The **list Node Groups** command returns the list of node groups from the configuration repository. You can pass an optional node name to the command that returns the list of node groups where the node resides.	The target object is name of the node. This target object is optional.	- Parameters: None
				- Returns: A list of the node groups in the cell.
					Batch mode example usage:
					- Using Jacl:
					`$AdminTask listNodeGroups`
					`$AdminTask listNodeGroups` *`nodeName`*
					- Using Jython:
					`AdminTask.listNodeGroups`
					`AdminTask.listNodeGroups ('`*`nodeName`*`')`
					Interactive mode example usage:
					- Using Jacl:
					`$AdminTask listNodeGroups {-interactive}`
					- Using Jython:
					`AdminTask.listNodeGroups ('[-interactive]')`

list Nodes	Node Group Commands group	The **list Nodes** command displays all of the nodes in the cell.	The target object is name of the node group. This target object is optional.	• Parameters: None
				• Returns: A list of all the nodes in the cell
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask listNodes`
					• Using Jython:
					`AdminTask.listNodes()`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask listNodes {-interactive}`
					• Using Jython:
					`AdminTask.listNodes ('[-interactive]')`

list SIB Destinations	SIB Admin Commands	Use this command to get a list of SIB destinations of the named type owned by a named SIB bus. If no type is named, all destinations owned by the named bus are listed.	None	• Parameters:
				bus
				Bus name (String, required)
				name
				Destination name (String, required)
				type
				type of destination to list - Queue, TopicSpace, WebService or Port (String, optional)
				• Returns: List of SIB destinations.
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask listSIBDestinations {-bus` *`busname`* `-name` *`destname`* `-type Queue}`
					• Using Jython:
					`AdminTask .listSIBDestinations ('[-bus` *`busname`* `-name` *`destname`* `-type Queue]')`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask listSIBDestinations {-interactive}`
					• Using Jython:
					`AdminTask .listSIBDestinations ('[-interactive]')`

list SIB Engines	SIB Admin Commands	Use the **list SIB Engines** command to get a list of bus messaging engines. Supplying only the bus parameter will result in a list of all engines associated with the named bus. Supplying only the node and server parameters will result in a list of all engines owned by the named node/server. Supplying only the cluster parameter will result in a list of all engines owned by the named cluster. All other parameter combinations are illegal.	None	• Parameters:
				bus
				name of the bus whose engines are to be listed (String, optional)
				node
				node name. To list messaging engines on a server, supply node and server name, but not cluster name (String, optional)
				server
				server name. To list messaging engines on a server, supply node and server name, but not cluster name (String, optional)
				cluster
				cluster name. To list messaging engines on a cluster, supply cluster name, but not node and server name (String, optional)
				• Returns: A list of SIB messaging engines.
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask`
					`listSIBEngines {-bus`
					` `*`busname`*` -node`
					`nodeName`
					` -server `*`severname`*`}`
					• Using Jython:
					`AdminTask.listSIBEngines`
					`('[-bus`
					` `*`busname`*` -node`
					`nodeName`
					` -server `*`severname`*`]')`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask listSIBEngines`
					`{-interactive}`
					• Using Jython:
					`AdminTask.listSIBEngines`
					`('[-interactive]')`

list SIB JMS Activation Specs	SIB JMS Admin Commands				**Interactive mode example usage:**
					• Using Jacl:
					`$AdminTask`
					` listSIBJMSActivationSpecs`
					` {-interactive}`
					• Using Jython:
					`AdminTask`
					`.listSIBJMSActivationSpecs`
					` ('[-interactive]')`

list SIB JMS Connection Factories	SIB JMS Admin Commands	Use the **list SIB JMS Connection Factories** command to list all of the JMS connection factories for the default messaging provider at the scope that you specify.	None	• Parameters:
				type
				Filters the list of connection factories. Valid values include:
				– all - Lists all the JMS connection factories (unified, queue, and topic) at the scope that you specify.
				– queue - Lists all of the JMS queue connection factories at the scope that you specify.
				– topic - Lists all of the JMS topic connection factories at the scope that you specify.
				If you do no specify the type option, this command will return only the unified JMS connection factories at the scope that you specified.
				• Returns: A list of connection factories at the scope that you specified.
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask listSIBJMSConnectionFactories {-type queue}`
					• Using Jython:
					`AdminTask.listSIBJMSConnectionFactories('[-type queue]')`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask listSIBJMSConnectionFactories {-interactive}`
					• Using Jython:
					`AdminTask.listSIBJMSConnectionFactories('[-interactive]')`

list SIB JMS Queues	SIB JMS Admin Commands	Use the **list SIB JMS Queues** command to list all the JMS queues for the default messaging provider at the specified scope.	None	• Parameters: None
				• Returns: None
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask listSIBJMSQueues`
					• Using Jython:
					`AdminTask.listSIBJMSQueues()`

list SIB JMS Topics	SIB JMS Admin Commands	Lists all JMS topics for the default messaging provider at the specified scope.	None	• Parameters: None
				• Returns: A list of JMS topics.
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask listSIBJMSTopics`
					• Using Jython:
					`AdminTask.listSIBJMSTopics()`

list SIB Mediations	SIB Admin Commands	Use this command to list the mediations on a named SIB bus.	None	• Parameters:
				bus
				name of the SIB bus where the mediations to be listed are to be found (String, required)
				• Returns: A list of SIB mediations.
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask listSIBMediations {-bus bus_name}`
					• Using Jython:
					`AdminTask.listSIBMediations ('[-bus bus_name]')`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask listSIBMediations {-interactive}`
					• Using Jython:
					`AdminTask .listSIBMediations ('[-interactive]')`

list SI Bus Members	SIB Admin Commands	Use this command to list all servers and clusters which are members of the named SIB bus.	None	• Parameters:
				bus
				name of the SIB bus whose members are to be listed (String, required)
				• Returns: List containing the IDs of bus members – servers and clusters.
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask listSIBusMembers {-bus bus_name}`
					• Using Jython:
					`AdminTask .listSIBusMembers ('[-bus bus_name]')`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask listSIBusMembers {-interactive}`
					• Using Jython:
					`AdminTask .listSIBusMembers ('[-interactive]')`

list SI Buses	SIB Admin Commands	Use this command to list all SIB buses in the cell.	None	• Parameters: None
				• Returns: None
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask listSIBuses`
					• Using Jython:
					`AdminTask.listSIBuses()`

list SSL Repertoires	None	The **list SSL Repertoires** command lists all of the Secure Sockets Layer (SSL) configuration instances you can associate with an SSL inbound channel.	SSL Inbound Channel instance for which the SSL Config candidates are listed.	• Parameters: None • Returns: A list of eligible SSL configuration object names.	**Batch mode example usage:** • Using Jacl: $AdminTask listSSLRepertoires SSL_3 (*cells/rohitbuildCell01/nodes/rohitbuildNode01/servers/server2|server.xml#SSLInboundChannel_1093445762330*) • Using Jython: AdminTask.listSSLRepertoires('SSL_3(*cells/rohitbuildCell01/nodes/rohitbuildNode01/servers/server2|server.xml#SSLInboundChannel_1093445762330*)') **Interactive mode example usage:** • Using Jacl: $AdminTask listSSLRepertoires {-interactive} • Using Jython: AdminTask.listSSLRepertoires('[-interactive]')
list Server Templates	None	Use the **list Server Templates** command to query available server templates based on server type, platform, or release level.	None	• Parameters: **-serverType** (String, optional) **-platform** (String, optional) **-release Version** (String, optional) • Returns: A list of server template identifications that match with the criteria that you specify with the command parameters. If you do no specify any parameters, all server templates are returned.	**Batch mode example usage:** • Using Jacl: $AdminTask listServerTemplates {-serverType *server_Type*} • Using Jython: AdminTask.listServerTemplates('[-serverType *server_Type*]') **Interactive mode example usage:** • Using Jacl: $AdminTask listServerTemplates {-interactive} • Using Jython: AdminTask.listServerTemplates('[-interactive]')

list Server Types	None	Use the **list Server Types** command to query defined server types on a node.	The identification of a node in the cell, `javax .management.ObjectName`. This target object is optional.	• Returns: A list of server types that you can define on a node. If you do not specify the target object, this command returns all of the server types defined in the entire cell.	**Interactive mode example usage:**
					• Using Jacl:
					`$AdminTask listServerTypes {-interactive}`
					• Using Jython:
					`AdminTask.listServerTypes ('[-interactive]')`

list Servers					**Interactive mode example usage:**
					• Using Jacl:
					`$AdminTask listServers {-interactive}`
					• Using Jython:
					`AdminTask.listServers ('[-interactive]')`

list TAM Settings					**Interactive mode example usage:**
					• Using Jacl:
					`$AdminTask listTAMSettings {-interactive}`
					• Using Jython:
					`AdminTask.listTAMSettings ('[-interactive]')`

list TCP End Points	None	The **list TCP End Points** command lists all named end points that can be associated with a TCP inbound channel.	TCP Inbound Channel instance for which named end points candidates are listed. (ObjectName, required)	• Parameters: **- exclude Distinguished** Shows only non-distinguished named end points. This parameter does not require a value. (Boolean, optional) **- unusedOnly** Shows the named end points not in use by other TCP inbound channel instances. This parameter does not require a value. (Boolean, optional) • Returns: A list of object names for the eligible named end points.	**Batch mode example usage:** • Using Jacl: $AdminTask listTCPEndPoints TCP_1(cells /rohitbuildCell01/ nodes /rohitbuildCellManager01 /servers /dmgr|server.xml# TCPInboundChannel_1) $AdminTask listTCPEndPoints TCP_1(cells /rohitbuildCell01/ nodes /rohitbuildCellManager01 /servers /dmgr|server.xml# TCPInboundChannel_1) {-excludeDistinguished} $AdminTask listTCPEndPoints TCP_1(cells /rohitbuildCell01/ nodes /rohitbuildCellManager01 /servers /dmgr|server.xml #TCPInboundChannel_1) {-excludeDistinguished -unusedOnly} • Using Jython: AdminTask .listTCPEndPoints ('TCP_1 (cells/rohitbuildCell01 /nodes /rohitbuildCellManager01 /servers /dmgr|server.xml #TCPInboundChannel_1)', '[-excludeDistinguished]') AdminTask .listTCPEndPoints ('TCP_1(cells /rohitbuildCell01/ nodes /rohitbuildCellManager01 /servers /dmgr|server.xml# TCPInboundChannel_1)', '[-excludeDistinguished]') AdminTask.listTCPEndPoints ('TCP_1 (cells/rohitbuildCell01 /nodes /rohitbuildCellManager01 /servers/dmgr|server.xml #TCPInboundChannel_1)', '[-excludeDistinguished -unusedOnly]')

list TCP End Points continued					**Interactive mode example usage:**
					• Using Jacl:
					`$AdminTask`
					`listTCPEndPoints`
					`{-interactive}`
					• Using Jython:
					`AdminTask`
					`.listTCPEndPoints`
					`('[-interactive]')`

list TCP Thread Pools	None	The **list TCP Thread Pools** command lists all of the thread pools that can be associated with a TCP inbound channel or TCP outbound channel.	TCP Inbound Channel or TCP Outbound Channel instance for which Thread Pool candidates are listed. (Object Name, required)	• Parameters: None
				• Returns: A list of eligible thread pool object names.
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask`
					`listTCPThreadPools`
					`TCP_1(cells`
					`/rohitbuildCell01/`
					`nodes`
					`/rohitbuildCellManager01`
					`/servers/dmgr|server.xml#`
					`TCPInboundChannel_1)`
					• Using Jython:
					`AdminTask`
					`.listTCPThreadPools`
					`('TCP_1(cells`
					`/rohitbuildCell01/`
					`nodes`
					`/rohitbuildCellManager01`
					`/servers`
					`/dmgr|server.xml#`
					`TCPInboundChannel_1)')`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask`
					`listTCPThreadPools`
					`{-interactive}`
					• Using Jython:
					`AdminTask`
					`.listTCPThreadPools`
					`('[-interactive]')`

list Unmanaged Nodes	Unmanaged Node Commands group	Use the **list Unmanaged Nodes** command to list the unmanaged nodes in a configuration.	None	• Parameters: None
				• Returns: List
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask listUnmanagedNodes`
					• Using Jython:
					`AdminTask .listUnmanagedNodes()`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask listUnmanagedNodes {-interactive}`
					• Using Jython:
					`AdminTask .listUnmanagedNodes ('[-interactive]')`

mediate SIB Destination	SIB Admin Commands	Use the **mediate SIB Destination** command to mediate a bus destination. The bus, destination, and mediation definitions must exist prior to using this command. The destination must not be mediated already.	None	• Parameters:
				bus
				the name of the bus where the destination is to be mediated (String, required)
				destinationName
				the name of the destination to be mediated (String, required)
				mediationName
				the name to be given to the mediation (String, required)
				node
				if mediating a destination to a server, specify the node and server name, but not the cluster name (String, optional)
				server
				if mediating a destination to a server, specify the node and server name, but not the cluster name (String, optional)
				cluster
				if mediating a destination to a cluster, specify the cluster name, but not the node or server name (String, optional)
				• Returns: None
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask mediateSIBDestination {-bus busname -name destname -mediationName mediationName}`
					• Using Jython:
					`AdminTask.mediateSIBDestination ('[-bus busname -name destname -mediationName mediationName]')`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask mediateSIBDestination {-interactive}`
					• Using Jython:
					`AdminTask.mediateSIBDestination ('[-interactive]')`

modify Node Group	Node Group Commands group	The **modify Node Group** command modifies the configuration of a node group. The node group name can not be changed. However, its short name and description are allowed. Also, its node membership can be modified.	The target object is the node group name. This target object is required.	• Parameters:
				- shortName The short name of the node group. This parameter is optional.
				- description The description of the node group. This parameter is optional.
				• Returns: Node group object ID.
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask modifyNodeGroup WBINodeGroup {-shortName WBIGroup -description "Default node group"}`
					• Using Jython:
					`AdminTask.modifyNodeGroup WBINodeGroup('[-shortName WBIGroup -description "WBI" node group]')`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask modifyNodeGroup {-interactive}`
					• Using Jython:
					`AdminTask.modifyNodeGroup ('[-interactive]')`

modify Node Group Property	Node Group Commands group	The **modify Node Group Property** command modifies custom properties for a node group	The name of the node group. This target object is required.	• Parameters:
				- name The name of the custom property to modify. This parameter is required.
				- value The value of the custom property. This parameter is optional.
				- description The description of the custom property. This parameter is optional.
				• Returns: Properties object ID
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask modifyNodeGroupProperty WBINodeGroup {-name Channel -value "channel1"}`
					• Using Jython:
					`AdminTask.modifyNodeGroupProperty ('WBINodeGroup', '[-name Channel -value channel1]')`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask modifyNodeGroupProperty {-interactive}`
					• Using Jython:
					`AdminTask.modifyNodeGroupProperty ('[-interactive]')`

modify SIB Destination	SIB Admin Commands	Use the **modify SIB Destination** command to modify the attributes of a SIB destination. The bus and name parameters are used to identify the SIB destination and cannot be modified.	None	• Parameters:
				bus
				bus name (String, required)
				name
				destination name (String, required)
				description
				description (String, optional)
				reliability
				the reliability quality of service for message flows through this destination, from BEST_EFFORT_NONPERSISTENT to ASSURED_PERSISTENT, in order of increasing reliability. Higher levels of reliability have higher impacts on the performance (String, optional)
				maxReliability
				the maximum reliability quality of service that is accepted for values specified by producers (String, optional)
				overrideOf QOSByProducerAllowed
				controls the quality of service for message flows between producers and the destination. Select this option to use the quality of service specified by producers instead of the quality defined for the destination (String, optional)
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask modifySIBDestination {-bus` *`busname`* `-name` *`destname`*`}`
					• Using Jython:
					`AdminTask.modifySIBDestination ('[-bus` *`busname`* `-name` *`destname`*`]')`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask modifySIBDestination {-interactive}`
					• Using Jython:
					`AdminTask.modifySIBDestination ('[-interactive]')`

modify SIB Destination continued				• Parameters: **defaultPriority** the default priority for message flows through this destination, in the range 0 (lowest) through 9 (highest). This default priority is used for messages that do not contain a priority value (Integer, optional) **maxFailed Deliveries** the maximum number of times that service tries to deliver a message to the destination before forwarding it to the exception destination (Integer, optional) **exception Destination** the name of another destination to which the system sends a message that cannot be delivered to this destination within the specified maximum number of failed deliveries (String, optional) **sendAllowed** clear this option (setting it to false) to stop producers from being able to send messages to this destination (String, optional) **receiveAllowed** clear this option (setting it to false) to prevent consumers from being able to receive messages from	

modify SIB Engine	SIB Admin Commands	Use the **modify SIB Engine** command to modify the attributes of a bus messaging engine. The bus, node, server, cluster and engine parameters are used to identify the engine and cannot be modified. A server can only have one messaging engine, so when using this command to modify a messaging engine from a server there‘s no need to supply the engine name. However, since a cluster can have more than one messaging engine, the engine‘s name must be supplied.	None	- Parameters:
				bus
				the name of the bus to which the messaging engine is to belong (String, required)
				node
				to modify a messaging engine on a server, supply node and server name, but not cluster name (String, optional)
				server
				to modify a messaging engine on a server, supply node and server name, but not cluster name (String, optional)
				cluster
				to modify a messaging engine on a cluster, supply cluster name, but not node and server name (String, optional)
				engine
				the name of the engine to be modified. This is only required if the engine belongs to a cluster (String, optional)
				description
				description of the messaging engine (String, optional)
					Batch mode example usage:
					- Using Jacl:
					`$AdminTask modifySIBEngine {-bus` *`busname`* `-node` *`nodeName`* `-server` *`severname`*`}`
					- Using Jython:
					`AdminTask.modifySIBEngine ('[-bus` *`busname`* `-node` *`nodeName`* `-server` *`severname`*`]')`
					Interactive mode example usage:
					- Using Jacl:
					`$AdminTask modifySIBEngine {-interactive}`
					- Using Jython:
					`AdminTask.modifySIBEngine ('[-interactive]')`

modify SIB Engine continued				• Parameters: **initialState** whether the messaging engine is started or stopped when the associated application server is first started. Until started, the messaging engine is unavailable. (Stopped | Started) (String, optional) **destinationHighMsgs** the maximum total number of messages that the messaging engine can place on its message points (Long, optional) • Returns: None	

modify SIB JMS Activation Spec	SIB JMS Admin Commands	Use the **modify SIB JMS Activation Spec** command to modify the properties of an activation specification.	None	• Parameters:
				name The name of the activation specification that you want to modify. (String, (required)
				propertyList A list of name-value pairs. (required)
				• Returns: None
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask modifySIBJMSActivationSpec {-name specname -propertyList propertyList}`
					• Using Jython:
					`AdminTask.modifySIBJMSActivationSpec ('[-name specname -propertyList propertyList]')`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask modifySIBJMSActivationSpec {-interactive}`
					• Using Jython:
					`AdminTask.modifySIBJMSActivationSpec ('[-interactive]')`

modify SIB JMS Connection Factory	SIB JMS Admin Commands	Use the **modify SIB JMS Connection Factory** command to modify a unified JMS connection factory at the current scope.	None	- Parameters:
				name
				The name of the SIB JMS connection factory. (String, required)
				jndiName
				The JNDI name of the SIB JMS connection factory. (String, required)
				type
				The type of connection factory to modify. To modify a queue connection factory, set the value to Queue. To modify a topic connection factory, set the value to Topic. If you want to create a generic connection factory, do not specify this option. (String, optional)
				busName
				the SIB bus name (String, optional)
				category
				Classifies or groups the connection factory. (String, optional)
				clientID
				A user-defined string. Only required for durable subscriptions. (String, optional)
				connection Proximity
				The proximity of acceptable messaging engines. Valid values include: Bus, Host, Cluster and Server. (String, optional)
				description
					Batch mode example usage:
					- Using Jacl:
					`$AdminTask modifySIBJMSConnectionFactory {-name *factory_name* -jndiName *jndi_name*}`
					- Using Jython:
					`AdminTask .modifySIBJMSConnectionFactory ('[-name *factory_name* -jndiName *jndi_name*]')`
					Interactive mode example usage:
					- Using Jacl:
					`$AdminTask modifySIBJMSConnectionFactory {-interactive}`
					- Using Jython:
					`AdminTask .modifySIBJMSConnectionFactory ('[-interactive]')`

modify SIB JMS Connection Factory continued				• Parameters: **durable Subscription Home** The durable subscription home value. (String, optional) **nonPersistent Mapping** The non-persistent mapping value. Valid values are BestEffort NonPersistent, Express NonPersistent, Reliable NonPersistent, ReliablePersistent, AssuredPersistent, AsSIBDestination and None. (String, optional) **password** The password that is used to modify connections from the connection factory. (String, optional) **provider EndPoints** A list of endpoint triplets separated by commas. For example: `host:port:chain` (String, optional) **readAhead** The read ahead value. Valid values include: Default, AlwaysOn, and AlwaysOff. (String, optional) **remoteProtocol** The name of the protocol used to connect to a remote messaging engine. (String, optional) **remoteTarget Group** (String, optional) **remoteTargetType** (String, optional)	

modify SIB JMS Queue	SIB JMS Admin Commands	Use the **modify SIB JMS Queue** command to modify a unified JMS queue at the current scope.	None	• Parameters:
				name
				The name of the SIB JMS queue. (String, required)
				jndiName
				The JNDI name of the SIB JMS queue. (String, required)
				description
				A description of the SIB JMS queue (String, optional)
				queueName
				The name of the underlying SIB queue to which the queue points (String, required)
				deliveryMode
				The delivery mode for messages. Legal values are ″Application″, ″NonPersistent″ and ″Persistent″ (String, optional)
				timeToLive
				the time in milliseconds to be used for message expiration (Long, optional)
				priority
				the priority for messages. Whole number in the range 0 to 9 (Integer, optional)
				readAhead
				read-ahead value. Legal values are ″AsConnection″, ″AlwaysOn″ and ″AlwaysOff″ (String, optional)
				timeToLive
				(optional)
				• Returns: None
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask modifySIBJMSQueue {-name` *queue_name* `-jndiName` *jndi_name* `-queueName` *queue_name*`}`
					• Using Jython:
					`AdminTask.modifySIBJMSQueue ('[-name` *queue_name* `-jndiName` *jndi_name* `-queueName` *queue_name*`]')`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask modifySIBJMSQueue {-interactive}`
					• Using Jython:
					`AdminTask.modifySIBJMSQueue ('[-interactive]')`

modify SIB JMS Topic	SIB JMS Admin Commands	Use the **modify SIB JMS Topic** command to modify the JMS topic at the current scope.	None	• Parameters:
				name
				The name of the SIB JMS topic (String, required)
				jndiName
				the SIB JMS topic's JNDI name (String, required)
				description
				a description of the SIB JMS queue (String, optional)
				topicSpace
				the name of the underlying SIB topic space to which the topic points (String, required)
				***topicName**
				the topic to be used inside the topic space (for example, stock/IBM) (String, required)
				deliveryMode
				the delivery mode for messages. Legal values are ″Application″, ″NonPersistent″ and ″Persistent″ (String, optional)
				timeToLive
				the time in milliseconds to be used for message expiration (Long, optional)
				priority
				the priority for messages. Whole number in the range 0 to 9 (Integer, optional)
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask modifySIBJMSTopic {-name topic_name -jndiName jndi_name -topicName topic_name -topicSpace topicspace_name}`
					• Using Jython:
					`AdminTask.modifySIBJMSTopic ('[-name topic_name -jndiName jndi_name -topicName topic_name -topicSpace topicspace_name]')`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask modifySIBJMSTopic {-interactive}`
					• Using Jython:
					`AdminTask.modifySIBJMSTopic ('[-interactive]')`

modify SIB JMS Topic continued				- Parameters: **readAhead** read-ahead value. Legal values are ″AsConnection″, ″AlwaysOn″ and ″AlwaysOff″ (String, optional) **busName** the name of the bus on which the topic resides (String, optional) - Returns: None	

modify SIB Mediation	SIB Admin Commands	Use this command to modify the attributes of a SIB mediation. The bus and mediation Name parameters identify the mediation and cannot be modified.	None	- Parameters:
				bus the name of the bus that owns the mediation (String, required)
				mediationName name of the mediation to be modified (String, required)
				description description of the mediation (String, optional)
				handlerList Name the name of the handler list that was defined when the mediation was deployed (String, optional)
				globalTransaction whether or not a global transaction is started for each message processed (Boolean, optional)
				allowConcurrent Mediation whether or not to apply the mediation to multiple messages concurrently, and preserve message ordering (Boolean, optional)
				selector the text string that must be present in a message for the mediation to process the message (String, optional)
				discriminator the text string that must not be present in a message for the mediation to process the message (String
					Batch mode example usage:
					- Using Jacl:
					`$AdminTask modifySIBMediation {-bus` *`bus_name`* `-jndiName` *`jndi_name`*`}`
					- Using Jython:
					`AdminTask.modifySIBMediation ('[-bus` *`bus_name`* `-mediationName` *`mediation_name`*`]')`
					Interactive mode example usage:
					- Using Jacl:
					`$AdminTask modifySIBMediation {-interactive}`
					- Using Jython:
					`AdminTask.modifySIBMediation ('[-interactive]')`

modify SIBus	SIB Admin Commands	Use this command to modify the attributes of the named bus. He “bus” parameter identifies the bus to be modified, and is not used to change the name of the bus.	None	- Parameters:
				bus
				name of bus to modify (String, required)
				description
				description of bus modify (String, optional)
				secure
				enable or disable bus security (Boolean, optional)
				interEngineAuthAlias
				name of the authentication alias used to authorize communication between messaging engines on the bus.
				mediations AuthAlias
				name of the authentication alias used to authorize mediations to access the bus (String, optional)
				protocol
				the protocol used to send and receive messages between messaging engines, and between API clients and messaging engines (String, optional)
					Batch mode example usage:
					- Using Jacl:
					`$AdminTask modifySIBus {-bus busname -description text -secure True -mediationsAuthAlias name -protocol protocol -discardOnDelete False}`
					- Using Jython:
					`AdminTask.modifySIBus ('[-busbusname -description "text" -secure True -mediationsAuthAlias name -protocol protocol -discardOnDelete False]')`
					Interactive mode example usage:
					- Using Jacl:
					`$AdminTask modifySIBus {-interactive}`
					- Using Jython:
					`AdminTask.modifySIBus ('[-interactive]')`

modify SIBus continued				• Parameters: **discardOnDelete** indicate whether or not any messages left in a queue’s data store should be discarded when the queue is deleted (Boolean, optional) **destinationHighMsgs** the maximum number of messages that any queue on the bus can hold (Long, optional) **configurationReloadEnabled** indicate whether configuration files should be dynamically reloaded for this bus (Boolean, optional) • Returns: None	

modify SIBus Member	SIB Admin Commands	Use this command to modify the attributes of the bus member identified by the bus, node, server and cluster parameters.	None	- Parameters:
				bus
				name of bus to which the member belongs(String, required)
				node
				to specify a server bus member, supply node and server name, but not cluster name (String, optional)
				server
				to specify a server bus member, supply node and server name, but not cluster name (String, optional)
				cluster
				to specify a cluster bus member, supply cluster name but not node and server name (String, optional)
				- Returns: None
					Batch mode example usage:
					- Using Jacl:
					`$AdminTask modifySIBusMember {-bus `*`busname`*` -node `*`nodename`*` -server `*`servername`*` -description `*`text`*`}`
					- Using Jython:
					`AdminTask.modifySIBusMember ('[-bus `*`busname`*` -node `*`nodename`*` -server `*`servername`*` -description "`*`text`*`"]')`
					Interactive mode example usage:
					- Using Jacl:
					`$AdminTask modifySIBusMember {-interactive}`
					- Using Jython:
					`AdminTask.modifySIBusMember ('[-interactive]')`

move Cluster To Core Group	Core Group Management group	The **move Cluster To Core Group** command moves all of servers in a cluster that you specify from a core group to another core group. All of the servers in cluster must be members of the same core group.	None	• Parameters:
				- source The name of the core group that contains the cluster that you want to move. The core group must exist prior to running this command. The cluster that you specify must be a member of this core group. (String, required)
				- target The name of the core group where you want to move the cluster. (String, required)
				- clusterName The name of the cluster that you want to move. (String, required)
				• Returns: None
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask moveClusterToCoreGroup {-source OldCoreGroup -target NewCoreGroup -clusterName ClusterOne}`
					• Using Jython:
					`AdminTask.moveClusterToCoreGroup ('[-source OldCoreGroup -target NewCoreGroup -clusterName ClusterOne]')`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask moveClusterToCoreGroup {-interactive}`
					• Using Jython:
					`AdminTask.moveClusterToCoreGroup ('[-interactive]')`

move Server To Core Group	Core Group Management group	The **move Server To Core Group** command moves a server to a core group that you specify. When the server is added to the core group that you specify, it will be removed from the core group where it originally resided.	None	• Parameters: **- source** The name of the core group that contains the server that you want to move. The core group must already exist with the server that you specify being a member of the core group. (String, required) **- target** The name of the core group where you want to move the server. The core group that you specify must exist prior to running the command. (String, required) **- nodeName** The name of the node that contains the server that you want to move. (String, required) **- serverName** The name of the server that you want to move. (String, required) • Returns: None	**Batch mode example usage:** • Using Jacl: $AdminTask moveServerToCoreGroup {-source *OldCoreGroup* -target *NewCoreGroup* -nodeName *myNode* -serverName *myServer*} • Using Jython: AdminTask.moveServerToCoreGroup ('[-source *OldCoreGroup* -target *NewCoreGroup* -nodeName *myNode* -serverName *myServer*]') **Interactive mode example usage:** • Using Jacl: $AdminTask moveServerToCoreGroup {-interactive} • Using Jython: AdminTask.moveServerToCoreGroup ('[-interactive]')

publish SIB WS Inbound Service	SIB Web Services group	The publish SIB WS Inbound Service command publishes the WSDL document for the inbound service and the associated ports to the registry and business defined by the UDDI Publication object.	The object name of the inbound service object.	• Parameters:
				uddiPublication
				The name of the UDDI publication for the service. (required)
				userId
				The user ID to use to retrieve the WSDL. (optional)
				password
				The password to use to retrieve the WSDL. (optional)
				• Returns: None
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask publishSIBWSInboundService $inService {-uddiPublication "MyUddi"}`
					• Using Jython:
					`AdminTask.publishSIBWSInboundService (inService, '[-uddiPublication MyUddi]')`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask publishSIBWSInboundService {-interactive}`
					• Using Jython:
					`AdminTask.publishSIBWSInboundService ('[-interactive]')`

reconfigure TAM					**Interactive mode example usage:**
					• Using Jacl:
					`$AdminTask reconfigureTAM {-interactive}`
					• Using Jython:
					`AdminTask.reconfigureTAM ('[-interactive]')`

refresh SIB WS Inbound Service WSDL	SIB Web Services group	The **refresh SIB WS Inbound Service WSDL** command loads the WSDL document from the WSDL Location parameters of the inbound service and locates the WSDL Location-specified service element. If the service element is not present, this command fails. If the outbound ports are not a subset of the ports in the loaded WSDL document, this command fails.
		If the WSDL will be retrieved through a proxy, the server on which the command is running must have the system properties that identify the proxy server set correctly.
			The object name of the inbound service object.	• Parameters:
				userId
				The user ID to use to retrieve the WSDL. (optional)
				password
				The password to use to retrieve the WSDL. (optional)
				• Returns: None
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask refreshSIBWSInboundServiceWSDL $inService`
					• Using Jython:
					`AdminTask .refreshSIBWSInboundServiceWSDL (inService)`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask refreshSIBWSInboundServiceWSDL {-interactive}`
					• Using Jython:
					`AdminTask .refreshSIBWSInboundServiceWSDL ('[-interactive]')`

refresh SIB WS Outbound Service WSDL	SIB Web Services group	The **refresh SIB WS Outbound Service WSDL** command loads the WSDL document from the WSDL Location parameters of the outbound service and locates the WSDL Location specified service element. If the service element is not present, this command fails. If the outbound ports are not a subset of the ports in the loaded WSDL document, this command fails.
		If the WSDL will be retrieved through a proxy, the server on which the command is running must have the system properties that identify the proxy server set correctly.
			The object name of the outbound service object.	• Parameters:
				userId The user ID to use to retrieve the WSDL. (optional)
				password The password to use to retrieve the WSDL. (optional)
				• Returns: None
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask refreshSIBWSOutboundServiceWSDL $outService`
					• Using Jython:
					`AdminTask .refreshSIBWSOutboundServiceWSDL (outService)`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask refreshSIBWSOutboundServiceWSDL {-interactive}`
					• Using Jython:
					`AdminTask .refreshSIBWSOutboundServiceWSDL ('[-interactive]')`

remove Node Group	Node Group Commands group	The **remove Node Group** command removes the configuration of a node group. You can remove a node group if it does not contain any members. Also, the default node group can not be removed.	The name of the node group to be removed. This target object is required.	• Parameters: None
				• Returns: Node group object ID.
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask removeNodeGroup WBINodeGroup`
					• Using Jython:
					`AdminTask.removeNodeGroup ('WBINodeGroup')`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask removeNodeGroup {-interactive}`
					• Using Jython:
					`AdminTask.removeNodeGroup ('[-interactive]')`

remove Node Group Member	Node Group Commands group	The **remove Node Group Member** command removes the configuration of a node group member.
		• A node must always be a member of at least one node group.
		• You cannot remove a node from a node group that is part of a cluster in that node group.
			The target object is the node group containing the member to be removed. This target object is required.	• Parameters:
				- nodeName The name of the node to be removed from a node group. This parameter is required.
				• Returns: Node group member object ID.
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask removeNodeGroupMember WBINodeGroup {-nodeName WBINode}`
					• Using Jython:
					`AdminTask.removeNodeGroupMember ('WBINodeGroup', '[-nodeName WBINode]')`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask removeNodeGroupMember {-interactive}`
					• Using Jython:
					`AdminTask.removeNodeGroupMember ('[-interactive]')`

remove Node Group Property	Node Group Commands group	The **remove Node Group Property** command removes custom properties of a node group.	The name of the node group. This target object is required.	• Parameters:
				- name The name of the custom property to remove. This parameter is required.
				• Returns: Properties object ID
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask removeNodeGroupProperty WBINodeGroup {-name Channel}`
					• Using Jython:
					`AdminTask.removeNodeGroupProperty ('WBINodeGroup', '[-name Channel]')`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask removeNodeGroupProperty {-interactive}`
					• Using Jython:
					`AdminTask.removeNodeGroupProperty ('[-interactive]')`

remove SIB WS Inbound Port	SIB Web Services group	The **remove SIB WS Inbound Port** command removes the configuration of an inbound port.	The object name of the inbound port object that you want to remove.	• Parameters: None
				• Returns: None
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask removeSIBWSInboundPort $inPort`
					• Using Jython:
					`AdminTask .removeSIBWSInboundPort(inPort)`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask removeSIBWSInboundPort {-interactive}`
					• Using Jython:
					`AdminTask.removeSIBWSInboundPort ('[-interactive]')`

remove SIB WS Outbound Port	SIB Web Services group	The remove SIB WS Outbound Port command removes the configuration of an outbound port. If the port that you delete is the default port for the outbound service, one of the remaining ports, if any, will be chosen as the new default. Resources that are associated with the outbound port, for example, WS-Security configuration, are disassociated from the outbound port but not deleted.	Object name of the outbound port object that you want to remove.	• Parameters: None
				• Returns: None
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask removeSIBWSOutboundPort`
					`$outPort`
					• Using Jython:
					`AdminTask.removeSIBWSOutboundPort`
					`(outPort)`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask removeSIBWSOutboundPort`
					`{-interactive}`
					• Using Jython:
					`AdminTask.removeSIBWSOutboundPort`
					`('[-interactive]')`

remove SI Bus Member	SIB Admin Commands	Use this command to remove a server or a cluster from a SIB bus. As well as removing the server or cluster from the SIB bus, this command also deletes all SIB messaging engines associated with the bus, all queue points and publication points owned by those engines, and all queue point references and publication point references which refer to the deleted queue points and publication points.	None	- Parameters: **bus** name of SIB bus to remove member from (String, required) **node** to specify a server bus member, supply node and server name, but not cluster name (String, optional) **server** to specify a server bus member, supply node and server name, but not cluster name (String, optional) **cluster** to specify a cluster bus member, supply cluster name but not node and server name (String, optional) - Returns:	**Batch mode example usage:** - Using Jacl: $AdminTask removeSIBusMember {-bus *busname* -node *nodename* -server *servername*} - Using Jython: AdminTask.removeSIBusMember ('[-bus *busname* -node *nodename* -server *servername*]') **Interactive mode example usage:** - Using Jacl: $AdminTask removeSIBusMember {-interactive} - Using Jython: AdminTask.removeSIBusMember ('[-interactive]')
remove Unmanaged Node	Unmanaged Node Commands group	Use the **remove Unmanaged Node** command to remove an unmanaged node from the configuation.	None	- Parameters: **- nodeName** The name of the unmanaged node. (String, required) - Returns: null	**Batch mode example usage:** - Using Jacl: $AdminTask removeUnmanagedNode {-nodeName myNode } - Using Jython: AdminTask.removeUnmanagedNode ('[-nodeName myNode]') **Interactive mode example usage:** - Using Jacl: $AdminTask removeUnmanagedNode {-interactive} - Using Jython: AdminTask.createUnmanagedNode ('[-interactive]')

remove WS GW Target Service	WS Gateway group	The **remove WS GW Target Service** command removes a target service from the gateway service. The destinations that are associated with the target service are not deleted. If the target service that you remove is the default target service, the default is set to the first target service in the set or cleared if there are none left.	object name of the Target Service object	• Parameters: None
				• Returns: None
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask removeWSGWTargetService $gwTarget`
					• Using Jython:
					`AdminTask.removeWSGWTargetService (gwTarget)`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask removeWSGWTargetService {-interactive}`
					• Using Jython:
					`AdminTask.removeWSGWTargetService ('[-interactive]')`

set Default SIB WS Outbound Port	SIB Web Services group	The **set Default SIB WS Outbound Port** command updates the default outbound port for an outbound service.	The object name of the outbound service whose default port you want to update.	• Parameters:
				name
				The name of the port that you want to set as the default. (required)
				• Returns: None
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask setDefaultSIBWSOutboundPort $outService {-name "MyServiceSoap"}`
					• Using Jython:
					`AdminTask .setDefaultSIBWSOutboundPort (outService, '[-name MyServiceSoap]')`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask setDefaultSIBWSOutboundPort {-interactive}`
					• Using Jython:
					`AdminTask .setDefaultSIBWSOutboundPort ('[-interactive]')`

show SIB Destination	SIB Admin Commands	Use the **show SIB Destination** command to get the attribute names/values of a SIB destination. The bus and name parameter identify the SIB destination whose attributes are required.	None	• Parameters:
				bus
				bus name (String, required)
				name
				destination name (String, required)
				• Returns: The attribute names and values of the named SIB destination on the named bus.
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask showSIBDestination {-bus busname -name destname}`
					• Using Jython:
					`AdminTask.showSIBDestination ('[-bus busname -name destname]')`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask showSIBDestination {-interactive}`
					• Using Jython:
					`AdminTask.showSIBDestination ('[-interactive]')`

show SIB Engine	SIB Admin Commands	Use the **show SIB Engine** command to get the attribute names/values of a SIB messaging engine belonging to a given bus member. If the bus member is a server, only the bus, node and server parameters need be supplied. A server only has 1 engine, so the engine parameter is not necessary. If the bus member is a cluster, the bus, cluster and engine parameters must be supplied, since a cluster can have more than one engine.	None	• Parameters:
				bus
				the name of the bus to which the messaging engine to be shown belongs (String, required)
				node
				to show a messaging engine that belongs to a server, supply node and server name, but not cluster name (String, optional)
				server
				to show a messaging engine that belongs to a server, supply node and server name, but not cluster name (String, optional)
				cluster
				to show a messaging engine that belongs to a cluster, supply cluster name, but not node and server name (String, optional)
				engine
				The name of the engine to show. If the bus member has only one messaging engine, you do not need to specify the engine option. If the bus member has several messaging engines, you must specify the name of the engine for which you want to display details. (String, optional)
				• Returns: The attribute names and values of the identified SIB messaging engine.
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask showSIBEngine {-bus busname -node nodeName -server severname}`
					• Using Jython:
					`AdminTask.showSIBEngine('[-bus busname -node nodeName -server severname]')`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask showSIBEngine {-interactive}`
					• Using Jython:
					`AdminTask.showSIBEngine ('[-interactive]')`

show SIB JMS Activation Spec	SIB Admin Commands	The show SIB JMS Activation Spec command shows details about a JMS activation specification.	None	• Parameters:
				bus
				The name of the bus that owns the mediation (String, required)
				mediationName
				The name of the mediation to be shown (String, required)
				• Returns: A list
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask showSIBJMSActivationSpec {-bus bus_name -mediationName mediation_name}`
					• Using Jython:
					`AdminTask.showSIBJMSActivationSpec ('[-bus bus_name -mediationName mediation_name]')`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask showSIBJMSActivationSpec {-interactive}`
					• Using Jython:
					`AdminTask.showSIBJMSActivationSpec ('[-interactive]')`

show SIB JMS Connection Factory	SIB JMS Admin Commands	The **show SIB JMS Connection Factory** command shows details about a JMS connection factory.	None	• Parameters:
				name
				The name of the SIB JMS connection factory (String, required)
				• Returns: A set of property value pairs for the JMS connection factory that you specified.
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask showSIBJMSConnectionFactory {-name factory_name}`
					• Using Jython:
					`AdminTask .showSIBJMSConnectionFactory ('[-name factory_name]')`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask showSIBJMSConnectionFactory {-interactive}`
					• Using Jython:
					`AdminTask .showSIBJMSConnectionFactory ('[-interactive]')`

show SIB JMS Queue	SIB JMS Admin Commands	Use the **show SIB JMS Queue** command to show the details about a JMS queue.	None	- Parameters: **name** The name of the SIB JMS queue. (String, required) - Returns: A set of property value pairs for the JMS queue that you specified.	**Batch mode example usage:** - Using Jacl: $AdminTask showSIBJMSQueue {-name *queue_name*} - Using Jython: AdminTask.showSIBJMSQueue ('[-name *queue_name*]') **Interactive mode example usage:** - Using Jacl: $AdminTask showSIBJMSQueue {-interactive} - Using Jython: AdminTask.showSIBJMSQueue ('[-interactive]')
show SIB JMS Topic	SIB JMS Admin Commands	Use this command to show the details for a JMS topic.	None	- Parameters: **- name** The name of the SIB JMS topic (String, required) - Returns: A set of property value pairs for the JMS topic that you specified.	**Batch mode example usage:** - Using Jacl: $AdminTask showSIBJMSTopic {-name *topic_name*} - Using Jython: AdminTask.showSIBJMSTopic ('[-name *topic_name*]') **Interactive mode example usage:** - Using Jacl: $AdminTask showSIBJMSTopic {-interactive} - Using Jython: AdminTask.showSIBJMSTopic ('[-interactive]')
show SIB Mediation	SIB Admin Commands	Use this command to get the attribute names/values of a SIB mediation.	None	- Parameters: **bus** the name of the bus that owns the mediation (String, required) **mediationName** the name of the mediation to be shown (String, required) - Returns: The attribute names and values of the identified SIB mediation.	**Batch mode example usage:** - Using Jacl: $AdminTask showSIBMediation {-bus *bus_name* -mediationName *mediation_name*} - Using Jython: AdminTask.showSIBMediation ('[-bus *bus_name* -mediationName *mediation_name*]') **Interactive mode example usage:** - Using Jacl: $AdminTask showSIBMediation {-interactive} - Using Jython: AdminTask.showSIBMediation ('[-interactive]')

show SIBus	SIB Admin Commands	Use this command to get the attribute names/values of a SIB bus.	None	• Parameters:
				bus
				bus name (String, required)
				• Returns: The attribute names and values of the identified SIB bus.
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask showSIBus {-bus bus_name}`
					• Using Jython:
					`AdminTask.showSIBus('[-bus bus_name]')`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask showSIBus {-interactive}`
					• Using Jython:
					`AdminTask.showSIBus ('[-interactive]')`

show SIBus Member	SIB Admin Commands	Use this command to get the attribute names/values of a SIB bus member.	None	• Parameters:
				bus
				name of bus to show member from (String, required)
				node
				to specify a server bus member, supply node and server name, but not cluster name (String, optional)
				server
				to specify a server bus member, supply node and server name, but not cluster name (String, optional)
				cluster
				to specify a cluster bus member, supply cluster name but not node and server name (String, optional)
				• Returns: The attribute names and values of the identified SIB bus member.
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask showSIBusMember {-bus busname -node nodename -server servername}`
					• Using Jython:
					`AdminTask.showSIBusMember ('[-bus busname -node nodename -server servername]')`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask showSIBusMember {-interactive}`
					• Using Jython:
					`AdminTask.showSIBusMember ('[-interactive]')`

show Server Info					**Interactive mode example usage:**
					• Using Jacl:
					`$AdminTask showServerInfo {-interactive}`
					• Using Jython:
					`AdminTask.showServerInfo ('[-interactive]')`

show Server Type Info					**Interactive mode example usage:**
					• Using Jacl:
					`$AdminTask showServerTypeInfo {-interactive}`
					• Using Jython:
					`AdminTask.showServerTypeInfo ('[-interactive]')`

show Template Info	None	Use the **show Template Info** command to query metadata information for a specific template. This command will only work for server templates.	The identification of a server template, `javax.management.ObjectName`. This target object is required.	• Returns: A property object that holds the metadata information regarding a specific template.	**Interactive mode example usage:**
					• Using Jacl:
					`$AdminTask showTemplateInfo {-interactive}`
					• Using Jython:
					`AdminTask.showTemplateInfo ('[-interactive]')`

unconfigure TAM					**Interactive mode example usage:**
					• Using Jacl:
					`$AdminTask unconfigureTAM {-interactive}`
					• Using Jython:
					`AdminTask.unconfigureTAM ('[-interactive]')`

unmediate SIB Destination	SIB Admin Commands	Use this command to unmediate the named destination on the named bus. Unmediating a destination simply removes the association between a SIB destination and a SIB mediation.	None	• Parameters:
				bus
				the name of the bus where the destination is currently mediated (String, required)
				destinationName
				the name of the destination to be unmediated (String, required)
				• Returns: None
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask unmediateSIBDestination {-bus bus_name -destinationName destination_name}`
					• Using Jython:
					`AdminTask.unmediateSIBDestination ('[-bus bus_name -destinationName destination_name]')`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask unmediateSIBDestination {-interactive}`
					• Using Jython:
					`AdminTask.unmediateSIBDestination ('[-interactive]')`

unpublish SIB WS Inbound Service	SIB Web Services group	The **unpublish SIB WS Inbound Service** command removes the WSDL document for the inbound service, including the ports, from the registry and business defined by the UDDI publication object.	The object name of the inbound service object.	• Parameters:
				uddi Publication
				The name of the UDDI publication for the service. (required)
				userId
				The user ID to use to retrieve the WSDL. (optional)
				password
				The password to use to retrieve the WSDL. (optional)
				• Returns: None
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask unpublishSIBWSInboundService $inService {-uddiPublication "MyUddi"}`
					• Using Jython:
					`AdminTask .unpublishSIBWSInboundService (inService, '[-uddiPublication MyUddi]')`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask unpublishSIBWSInboundService {-interactive}`
					• Using Jython:
					`AdminTask .unpublishSIBWSInboundService ('[-interactive]')`

update App On Cluster	None	The **update App On Cluster** command can be used to synchronize nodes and restart cluster members for an application update deployed to a cluster. After application update, this command can be used to synchronize the nodes without stopping all the cluster members on all the nodes at one time.
		This command synchronizes one node at a time. Each node is synchronized by first stopping the cluster members on which the application is targetted and then performing nodesync operation and then restarting the cluster members.
			None	• Parameters:
				-Application Names The names of the applications that are updated.
				-timeout The timeout value in seconds for each node synchronization. The default is 300 seconds.
				• Returns: None
					Batch mode example usage:
					• Using Jacl:
					`$AdminTask updateAppOnCluster {-ApplicationNames app1}`
					`$AdminTask updateAppOnCluster { -ApplicationNames app1 -timeout 600}`
					• Using Jython:
					`AdminTask.updateAppOnCluster ('[-ApplicationNames app1]')`
					`AdminTask.updateAppOnCluster ('[-ApplicationNames app1 -timeout 600]')`
					Interactive mode example usage:
					• Using Jacl:
					`$AdminTask updateAppOnCluster -interactive`
					• Using Jython:
					`AdminTask.updateAppOnCluster ('[-interactive]')`

update App On Cluster		This command may take more than the default connector timeout period depending on the number of nodes that the target cluster spans. Be sure to set proper timeout values in the soap.client .props file, when a SOAP connector is used, and in the sas.client .props file, when a RMI connector is used. This command is not supported in local mode.			

Administrative command invocation syntax

You can use an administrative command in batch mode or interactive mode. The following is the syntax for using an administrative command:

Using Jacl:

```
$AdminTask cmdName [targetObject] [options]
```

where `options` include:

```
{
  [-paramName paramValue] [-paramName] ...
  [-stepName {{stepParamValue ...} ...} ...]
  [-delete {-stepName {{stepKeyParamValue ...} ...} ...} ...]
  [-interactive]
}
```

Using Jython:

```
AdminTask.cmdName(['targetObject'], [options])
```

where `options` include:

```
'[
[-paramName paramValue] [-paramName ...]
[-stepName [[stepParamValue ...] ...] ...]
[-delete [-collectionStepName [[stepKeyParamValue ...] ...] ...] ...]
[-interactive]
]'
```

where:

cmdName	represents the name of an administrative command to be run.
targetObject	represents the target object on which the command operates. Depending on the administrative command, this input can be required, optional, or nonexistent. This input corresponds to the Target object that is displayed in the command-specific help.
paramName	represents the parameter name of the executed command. Depending on the administrative command, this input can be required, optional, or nonexistent. Each parameter name corresponds to an argument name that is displayed in the Arguments area of the command specific help.
paramValue	represents the parameter value to set for the preceding parameter name. Parameters are specified as name-value pairs. The parameter value is not required if a parameter has Boolean as its value type. If you specify the parameter name only, without specifying a value for a Boolean type parameter, the value is set to true.
stepName	represents the step name of the command. This input corresponds to a step name that is displayed in the Steps area of the command-specific help.
stepParamValue ...	represents the values of the parameters for a step. Provide all the parameter values of a step in the correct order as displayed in the step-specific help. For any optional parameters that you do not want to specify a value, put ″″ instead of the value. If a command step is a collection type, for example, it contains multiple objects where each object has the same set of parameters, then you can specify multiple objects with each object enclosed by a pair of braces. For collection type steps, each step parameter is a key or non-key. Key parameters in a step are used to uniquely identify an object in the collection. If data exists in the step, key parameter values that are provided in the input are compared with key parameter values in the existing data. If a match is found, the existing data is updated. Otherwise, if the specified step allows the addition of new objects, the input values are added.
delete	represents the option to delete existing data from specified step that supports collection.
collectionStepName	represents the collection step name .
stepKeyParamValue ...	represents the values of key parameters to uniquely identify an object to be deleted from a collection step. You must provide the key parameter values of an object in the order that they are displayed in the step specific help.
interactive	represents the option to enter interactive mode.
[ ]	represents a Jython list bracket.
[ ]	indicates that the parameters or options inside the brackets are optional. Do not type these brackets as part of the syntax.

Properties used by scripted administration

This article explains the Java properties that are used by scripted administration. Three levels of default property files load before any property file that is specified on the command line. The first level represents an installation default, located in the properties directory for each WebSphere Application Server profile called wsadmin.properties. The second level represents a user default, and is located in the Java user.home property. This properties file is also called wsadmin.properties. The third level is a properties file that is pointed to by the WSADMIN_PROPERTIES environment variable. This environment variable is defined in the environment where the wsadmin tool starts. If one or more of these property files is present, they are interpreted before any properties file that is present on the command line. These three levels of property files load in the order that they are specified. The properties file that is loaded last overrides the ones loaded earlier.

The following Java properties are used by scripting:

com.ibm.ws.scripting.classpath:

Searches for classes and resources, and is appended to the list of paths.

com.ibm.ws.scripting.connectionType:

Determines the connector to use. This value can either be `SOAP`, `RMI`, or `NONE`. The `wsadmin.properties` file specifies `SOAP` as the connector.

com.ibm.ws.scripting.host:

Determines the host to use when attempting a connection. If not specified, the default is the local machine.

com.ibm.ws.scripting.port:

Specifies the port to use when attempting a connection. The `wsadmin.properties` file specifies `8879` as the SOAP port for a single server installation.

com.ibm.ws.scripting.defaultLang:

Indicates the language to use when running scripts. The `wsadmin.properties` file specifies Jacl as the scripting language.

The supported scripting languages are Jacl and Jython.

com.ibm.ws.scripting.traceString:

Turns on tracing for the scripting process. The default has tracing turned off.

com.ibm.ws.scripting.traceFile:

Determines where trace and log output is directed. The `wsadmin.properties` file specifies the `wsadmin.traceout` file that is located in the `logs` directory of each WebSphere Application Server profile as the value of this property.

If multiple users work with the wsadmin tool simultaneously, set different traceFile properties in the user properties files. If the file name contains double-byte character set (DBCS) characters, use a unicode format, such as `\uxxxx`, where `xxxx` is a number.

com.ibm.ws.scripting.validationOutput:

Determines where the validation reports are directed. The default file is `wsadmin.valout` which is located in the `logs` directory of each WebSphere Application Server profile.

If multiple users work with the wsadmin tool simultaneously, set different validationOutput properties in the user properties files. If the file name contains double-byte character set (DBCS) characters, use unicode format, such as `\uxxxx`, where `xxxx` is a number.

com.ibm.ws.scripting.emitWarningForCustomSecurityPolicy:

Controls whether the WASX7207W message is emitted when custom permissions are found.

The possible values are `true` and `false`. The default value is `true`.

com.ibm.ws.scripting.tempdir:

Determines the directory to use for temporary files when installing applications.

The Java virtual machine API uses `java.io.temp` as the default value.

com.ibm.ws.scripting.validationLevel:

Determines the level of validation to use when configuration changes are made from the scripting interface.

Possible values are: `NONE`, `LOW`, `MEDIUM`, `HIGH`, `HIGHEST`. The default is `HIGHEST`.

com.ibm.ws.scripting.crossDocumentValidationEnabled:

Determines whether the validation mechanism examines other documents when changes are made to one document.

Possible values are `true` and `false`. The default value is `true`.

com.ibm.ws.scripting.profiles:

Specifies a list of profile scripts to run automatically before running user commands, scripts, or an interactive shell.

The `wsadmin.properties` file specifies `securityProcs.jacl` and `LTPA_LDAPSecurityProcs.jacl` as the values of this property. If Jython is specified with the wsadmin -lang option, the wsadmin tool performs a conversion to change the profile script names that are specified in this property to use the file extension that matches the language specified. Use the provided script procedures with the default settings to make security configuration easier.

Using Ant to automate tasks

To support using Apache Ant with Java 2 Platform, Enterprise Edition (J2EE) applications running on the application server, the product provides a copy of the Ant tool and a set of Ant tasks that extend the capabilities of Ant to include product-specific functions. Ant has become a very popular tool among Java programmers.

Apache Ant is a Java-based build tool. In theory, it is similar to Make, but Ant is different. Instead of a model in which it is extended with shell-based commands, Ant is extended using Java classes. Instead of writing shell commands, XML-based configuration files are used. These files reference a target tree in which various tasks are run. Each task is run by an object that implements a particular Task interface.

By combining the following tasks with those provided by Ant, you can create build scripts that compile, package, install, and test your application on the application server:

- Install and uninstall applications
- Start and stop servers in a base configuration
- Run administrative scripts or commands
- Run the Enterprise JavaBeans (EJB) deployment tool
- Run the JavaServer Pages (JSP) file precompilation tool

For more detailed information about Ant, refer to the Apache organization Web site.

- To run Ant and have it automatically see the WebSphere classes, use the “ws_ant command.”
- Use “Ant tasks for deployment and server operation.”

  This topic describes where to find the API documentation for the Apache Ant tasks for deploying applications and operating application servers.
- Use “Ant tasks for building application code.”

  This topic describes where to find the API documentation for the Apache Ant tasks for building applications.

ws_ant command

This topic describes where to find information about the ws_ant command, which is provided for using with Apache Ant, a Java-based build tool that is popular among Java programmers.

In theory, Ant is similar to Make, but Ant is different. Instead of a model in which it is extended with shell-based commands, Ant is extended using Java classes. Instead of writing shell commands, XML-based configuration files are used. These files reference a target tree in which various tasks are run. Each task is run by an object that implements a particular Task interface.

For the Apache Ant tool that is provided by this product, see the following file:

```
install_root/bin/ws_ant.bat|sh
```

Ant tasks for deployment and server operation

This topic describes where to find the API documentation for the Apache Ant tasks for deploying applications and operating application servers.

The Apache Ant tasks for the product reside in the Java package: `com.ibm.websphere.ant.tasks`. The API documentation for this package contains detailed information about all of the Ant tasks that are provided and how to use them. The API documentation is available in the **Reference** section of the information center.

Ant tasks for building application code

This topic describes where to find the documentation for the Ant tasks provided for building application code using the Application Server Toolkit (which is a CD included with WebSphere Application Server as a separately installable toolkit).

Within the Application Server Toolkit product documentation, open the section **Working with Ant**. You can locate the topic by searching for **Working with Ant**, or from the navigation view, select **Help > Help Contents > Developing Java Applications > Developing enterprise applications > J2EE applications > Working with Ant**.

Using administrative programs (JMX)

This topic describes how to use Java application programming interfaces (APIs) to administer WebSphere Application Server and to manage your applications.

You can administer WebSphere Application Server and your applications through tools that come with the product or through programming with the Java APIs.

The wsadmin scripting tool, the administrative console, and the administrative command-line tools come with the product. These administrative tools provide most of the functions that you need to manage the product and the applications that run in WebSphere Application Server. You can use the command-line tools from automation scripts to control the servers. Scripts that are written for the wsadmin scripting tool offer a wide range of possible custom solutions that you can develop quickly.

Investigate these tools with the Java APIs to determine the best ways to administer WebSphere Application Server and your applications. For information on the Java APIs, view Java Management Extensions (JMX) API documentation

WebSphere Application Server supports access to the administrative functions through a set of Java classes and methods. You can write a Java program that performs any of the administrative features of the WebSphere Application Server administrative tools. You can also extend the basic WebSphere Application Server administrative system to include your own managed resources.

You can prepare, install, uninstall, edit, and update applications through programming. Preparing an application for installation involves collecting various types of WebSphere Application Server-specific binding information to resolve references that are defined in the application deployment descriptors. This information can also be modified after installation by editing a deployed application. Updating consists of adding, removing or replacing a single file or a single module in an installed application, or supplying a partial application that manipulates an arbitrary set of files and modules in the deployed application. Updating the entire application uninstalls the old application and installs the new one. Uninstalling an application removes it entirely from the WebSphere Application Server configuration.

Perform any or all of the following tasks to manage WebSphere Application Server and your Java 2 Platform, Enterprise Edition (J2EE) applications through programming.

- Create a custom Java administrative client program using the Java administrative APIs.

  This topic describes how to develop a Java program that uses the WebSphere Application Server administrative APIs to access the administrative system of WebSphere Application Server.
- Extend the WebSphere Application Server administrative system with custom MBeans.

  This topic describes how to extend the WebSphere Application Server administration system by supplying and registering new JMX MBeans in one of the Application Server processes. In this case, you can use the administrative classes and methods to add newly managed objects to the administrative system.
- Deploy and manage a custom Java administrative client program for use with multiple Java 2 Platform, Enterprise Edition application servers.

  This topic describes how to connect to a J2EE server, and how to manage multiple vendor servers.
- Manage applications through programming

  This topic describes how, through Java MBean programming, to install, update, and delete a J2EE application on WebSphere Application Server.

Depending on which tasks you complete, you have created your own administrative program, extended the WebSphere Application Server administrative console, connected and managed vendor servers, or managed your applications through programming.

You can continue to administer WebSphere Application Server and your applications through programming or in combination with the tools that come with the WebSphere Application Server.

Creating a custom Java administrative client program using WebSphere Application Server administrative Java APIs

This section describes how to develop a Java program for accessing the WebSphere Application Server administrative system by using the WebSphere Application Server administrative application programming interfaces (APIs).

This task assumes a basic familiarity with Java Management Extensions (JMX) API programming. See the JMX API documentation for information.

When you develop and run administrative clients that use various JMX connectors and that have security enabled, use the following guidelines. When you follow these guidelines, you guarantee the behavior among different implementations of JMX connectors. Any programming model that strays from these guidelines is unsupported.

1. Create and use a single administrative client before you create and use another administrative client.
2. Create and use an administrative client on the same thread.
3. Use one of the following ways to specify a user ID and password to create a new administrative client:
   - Specify a default user ID and password in the property file.
   - Specify a user ID and password other than the default. Once you create an administrative client with a non-default user ID and password, specify the non-default user ID and password when you create subsequent administrative clients.

Develop an administrative client program.

Developing an administrative client program

This page contains examples of key features of an administrative client program that utilizes WebSphere Application Server administrative APIs and Java Management Extensions (JMX). WebSphere Application Server administrative APIs provide control of the operational aspects of your distributed system as well as the ability to update your configuration. This page also demonstrates examples of operational control. For information, view the Administrative API documentation, the JMX API documentation, or the MBean API documentation.

1. Create an AdminClient instance. An administrative client program needs to invoke methods on the AdminService object that is running in the deployment manager (or the application server in the base installation). The AdminClient class provides a proxy to the remote AdminService object through one of the supported Java Management Extensions (JMX) connectors. The following example shows how to create an AdminClient instance:

```
Properties connectProps = new Properties();
connectProps.setProperty(
AdminClient.CONNECTOR_TYPE, AdminClient.CONNECTOR_TYPE_SOAP);

connectProps.setProperty(AdminClient.CONNECTOR_HOST, "localhost");
connectProps.setProperty(AdminClient.CONNECTOR_PORT, "8879");
AdminClient adminClient = null;
try
{
       adminClient = AdminClientFactory.createAdminClient(connectProps);
}
catch (ConnectorException e)
{
       System.out.println("Exception creating admin client: " + e);
}
```

2. Find an MBean Once you obtain an AdminClient instance, you can use it to access managed resources in the administration servers and application servers. Each managed resource registers an MBean with the AdminService through which you can access the resource. The MBean is represented by an ObjectName instance that identifies the MBean. An ObjectName consists of a domain name followed by an unordered set of one or more key properties. For the WebSphere Application Server, the domain name is `WebSphere` and the key properties defined for administration are as follows:

type	The type of MBean. For example: Server, TraceService, Java Virtual Machine (JVM).
name	The name identifier for the individual instance of the MBean.
cell	The name of the cell that the MBean is running.
node	The name of the node that the MBean is running.

process	The name of the process that the MBean is running.

You can locate an MBean by querying for them with ObjectNames that match desired key properties. The following example shows how to find the MBean for the NodeAgent of node MyNode:

```
String nodeName = "MyNode";
String query = "WebSphere:type=NodeAgent,node=" + nodeName + ",*";
ObjectName queryName = new ObjectName(query);
ObjectName nodeAgent = null;
Set s = adminClient.queryNames(queryName, null);
if (!s.isEmpty())
    nodeAgent = (ObjectName)s.iterator().next();
else
    System.out.println("Node agent MBean was not found");
```

3. Use the MBean. What a particular MBean allows you to do depends on that MBean's management interface. It may declare attributes that you can obtain or set. It may declare operations that you can invoke. It may declare notifications for which you can register listeners. For the MBeans provided by the WebSphere Application Server, you can find information about the interfaces they support in the MBean API documentation. The following example invokes one of the operations available on the NodeAgent MBean that we located above. The following example will start the *MyServer* application server:

```
String opName = "launchProcess";
String signature[] = { "java.lang.String" };
String params[] = { "MyServer" };
try
{
     adminClient.invoke(nodeAgent, opName, params, signature);
}
catch (Exception e)
{
     System.out.println("Exception invoking launchProcess: " + e);
}
```

4. Register for events. In addition to managing resources, the Java Management Extensions (JMX) API also supports application monitoring for specific administrative events. Certain events produce notifications, for example, when a server starts. Administrative applications can register as listeners for these notifications. The WebSphere Application Server provides a full implementation of the JMX notification model, and provides additional function so you can receive notifications in a distributed environment. For a complete list of the notifications emitted from WebSphere Application Server MBeans, refer to the `com.ibm.websphere.management.NotificationConstants` class in the API documentation. The following is an example of how an object can register itself for event notifications emitted from an MBean using the node agent ObjectName:

```
adminClient.addNotificationListener(nodeAgent, this, null, null);
```

In this example, the `null` value will result in receiving all of the node agent MBean event notifications. You can also use the `null` value with the `handback` object.

5. Handle the events. Objects receive JMX event notifications via the handleNotification method which is defined by the NotificationListener interface and which any event receiver must implement. The following example is an implementation of handleNotification that reports the notifications that it receives:

```
public void handleNotification(Notification n, Object handback)
{
     System.out.println("***************************************************");
     System.out.println("* Notification received at " + new Date().toString());
     System.out.println("* type      = " + ntfyObj.getType());
     System.out.println("* message   = " + ntfyObj.getMessage());
     System.out.println("* source    = " + ntfyObj.getSource());
     System.out.println(
     "* seqNum    = " + Long.toString(ntfyObj.getSequenceNumber()));
```

```
        System.out.println("* timeStamp = " + new Date(ntfyObj.getTimeStamp()));
        System.out.println("* userData  = " + ntfyObj.getUserData());
        System.out.println("***************************************************");
    }
```

Administrative client program example: The following example is a complete administrative client program. Copy the contents to a file named `MyAdminClient.java`. After changing the node name and server name to the appropriate values for your configuration, you can compile and run it using the instructions from ″Creating a custom Java administrative client program using WebSphere Application Server administrative Java APIs″ in the information center.

```
import java.util.Date;
import java.util.Properties;
import java.util.Set;

    public void handleNotification(Notification ntfyObj, Object handback)
    {
        // Each notification that the NodeAgent MBean generates will result in
        // this method being called
        ntfyCount++;
        System.out.println("***************************************************");
        System.out.println("* Notification received at " + new Date().toString());
        System.out.println("* type      = " + ntfyObj.getType());
        System.out.println("* message   = " + ntfyObj.getMessage());
        System.out.println("* source    = " + ntfyObj.getSource());
        System.out.println(
        "* seqNum    = " + Long.toString(ntfyObj.getSequenceNumber()));
        System.out.println("* timeStamp = " + new Date(ntfyObj.getTimeStamp()));
        System.out.println("* userData  = " + ntfyObj.getUserData());
        System.out.println("***************************************************");

    }

    private void countNotifications()
    {
        // Run until killed
        try
        {
            while (true)
            {
                Thread.currentThread().sleep(60000);
                System.out.println(ntfyCount + " notification have been received");
            }
        }
        catch (InterruptedException e)
        {
        }
    }

}
```

Extending the WebSphere Application Server administrative system with custom MBeans

You can extend the WebSphere Application Server administration system by supplying and registering new Java Management Extensions (JMX) MBeans (see JMX 1.0 Specification for details) in one of the WebSphere processes. JMX MBeans represent the management interface for a particular piece of logic. All of the managed resources within the standard WebSphere infrastructure are represented as JMX MBeans. There are a variety of ways in which you can create your own MBeans and register them with the JMX MBeanServer running in any WebSphere process. For more information, view the MBean API documentation.

1. Create custom JMX MBeans.

   You have some alternatives to select from, when creating MBeans to extend the WebSphere administrative system. You can use any existing JMX MBean from another application. You can register any MBean that you tested in a JMX MBean server outside of the WebSphere Application Server environment in a WebSphere Application Server process, including standard MBeans, dynamic MBeans, open MBeans, and model MBeans.

   In addition to any existing JMX MBeans, and ones that were written and tested outside of the WebSphere Application Server environment, you can use the special distributed extensions provided by WebSphere and create a WebSphere ExtensionMBean provider. This alternative provides better integration with all of the distributed functions of the WebSphere administrative system. An ExtensionMBean provider implies that you supply an XML file that contains an MBean Descriptor based on the DTD shipped with the WebSphere Application Server. This descriptor tells the WebSphere system all of the attributes, operations, and notifications that your MBean supports. With this information, the WebSphere system can route remote requests to your MBean and register remote Listeners to receive your MBean event notifications.

   All of the internal WebSphere MBeans follow the Model MBean pattern (see WebSphere Application Server administrative MBean documentation for details). Pure Java classes supply the real logic for management functions, and the WebSphere MBeanFactory class reads the description of these functions from the XML MBean Descriptor and creates an instance of a ModelMBean that matches the descriptor. This ModelMBean instance is bound to your Java classes and registered with the MBeanServer running in the same process as your classes. Your Java code now becomes callable from any WebSphere Application Server administrative client through the ModelMBean created and registered to represent it.

2. Register the new MBeans. There are various ways to register your MBean.

   You can register your MBean with the WebSphere Application Server administrative service.

   You can register your MBean with the MBeanServer in a WebSphere Application Server process. The following list describes the available options in order of preference:

   - Go through the MBeanFactory class. If you want the greatest possible integration with the WebSphere Application Server system, then use the MBeanFactory class to manage the life cycle of your MBean through the activateMBean and deactivateMBean methods of the MBeanFactory class. Use these methods, by supplying a subclass of the RuntimeCollaborator abstract superclass and an XML MBean descriptor file. Using this approach, you supply a pure Java class that implements the management interface defined in the MBean descriptor. The MBeanFactory class creates the actual ModelMBean and registers it with the WebSphere Application Server administrative system on your behalf.

     This option is recommended for registering model MBeans.
   - Use the JMXManageable and CustomService interface. You can make the process of integrating with WebSphere administration even easier, by implementing a CustomService interface, that also implements the JMXManageable interface. Using this approach, you can avoid supplying the RuntimeCollaborator. When your CustomService interface is initialized, the WebSphere MBeanFactory class reads your XML MBean descriptor file and creates, binds, and registers an MBean to your CustomService interface automatically. After the shutdown method of your CustomService is called, the WebSphere Application Server system automatically deactivates your MBean.
   - Go through the AdminService interface. You can call the registerMBean() method on the AdminService interface and the invocation is delegated to the underlying MBeanServer for the process, after appropriate security checks. You can obtain a reference to the AdminService using the getAdminService() method of the AdminServiceFactory class.

     This option is recommended for registering standard, dynamic, and open MBeans. Implement the UserCollaborator class to use the MBeans and to provide a consistent level of support for them across distributed and z/OS platforms.
   - Get MBeanServer instances directly. You can get a direct reference to the JMX MBeanServer instance running in any WebSphere Application Server process, by calling the getMBeanServer() method of the MBeanFactory class. You get a reference to the MBeanFactory class by calling the

getMBeanFactory() method of the AdminService interface. Registering the MBean directly with the MBeanServer instance can result in that MBean not participating fully in the distributed features of the WebSphere Application Server administrative system.

Regardless of the approach used to create and register your MBean, you must set up proper Java 2 security permissions for your new MBean code. The WebSphere AdminService and MBeanServer are tightly protected using Java 2 security permissions and if you do not explicitly grant your code base permissions, security exceptions are thrown when you attempt to invoke methods of these classes. If you are supplying your MBean as part of your application, you can set the permissions in the `was.policy` file that you supply as part of your application metadata. If you are using a CustomService interface or other code that is not delivered as an application, you can edit the `library.policy` file in the node configuration, or even the `server.policy` file in the `properties` directory for a specific installation.

Best practices for standard, dynamic, and open MBeans

This article discusses recommended guidelines for standard, dynamic, and open MBeans.

The underlying interface for the WebSphere Application Server administrative service is AdminService. Remote access occurs through the AdminControl scripting object.

For WebSphere Application Server Version 5, the MBean registration and capabilities are as follows:

MBean type	Registered with:	Capabilities
Model	WebSphere Application Server administrative service	Local access is through the WebSphere Application Server administrative service or the MBean server. Remote access is through the WebSphere Application Server administrative service, and WebSphere Application Server security.
Standard, dynamic, or open	MBean server	Local access is through the WebSphere Application Server administrative service or the MBean server on the distributed platform.

For V6, you can optionally register standard, dynamic, and open custom MBeans with the WebSphere Application Server administrative service to take advantage of the capabilities that in V5 are available only to model MBeans.

V6 introduces a special run-time collaborator that you use with standard, dynamic or open custom MBeans to register the custom MBeans with the WebSphere Application Server administrative service. The standard, dynamic, and open MBeans display in the administrative service as model MBeans. The administrative service uses the capabilities available to MBeans that are registered with the administrative service.

For WebSphere Application Server Version 6, the MBean registration and capabilities are as follows:

MBean type	Registered with:	Capabilities
Model, and optionally standard, dynamic, or open	WebSphere Application Server administrative service	Local access is through the WebSphere Application Server administrative service or the MBean server. Remote access is through the WebSphere Application Server administrative service, and WebSphere Application Server security.

Standard, dynamic, or open	MBean server	Local access is through the WebSphere Application Server administrative service or the MBean server on the distributed platform.

Creating and registering standard, dynamic, and open custom MBeans

You can create standard, dynamic, and open custom MBeans and register them with the WebSphere Application Server administrative service.

This task assumes a basic familiarity with MBean programming. For information on MBean programming see MBean Java application programming interface (API) documentation.

Perform the following tasks to create and register a standard, dynamic, or open custom MBean.

1. Create your particular MBean class or classes.
2. Write an MBean descriptor in the XML language for your MBean.
3. Register your MBean by inserting code that uses the WebSphere Application Server run-time com.ibm.websphere.management.UserMBeanCollaborator collaborator class into your application code.
4. Package the class files for your MBean interface and implementation, the descriptor XML file, and your application Java archive (JAR) file.

After you successfully complete the steps, you have a standard, dynamic, or open custom MBean that is registered and activated with the WebSphere Application Server administrative service.

The following example shows how to create and register a standard MBean with the WebSphere Application Server administrative service:

```
SnoopMBean.java:

/**
 * Use the SnoopMBean MBean, which has a standard mbean interface.
 */
public interface SnoopMBean {
    public String getIdentification();
    public void snoopy(String parm1);
}

SnoopMBeanImpl.java:

/**
 * SnoopMBeanImpl - SnoopMBean implementation
 */
public class SnoopMBeanImpl implements SnoopMBean {
    public String getIdentification() {
        System.out.println(">>> getIdentification() called...");
        return "snoopy!";
    }

    public void snoopy(String parm1) {
        System.out.println(">>> snoopy(" + parm1 + ") called...");
    }
}
```

Define the following MBean descriptor for your MBean in an .xml file. The getIdentification method is set to run with the unicall option and the snoopy method is set to use the multicall option. These options are used only for z/OS platform applications. The WebSphere Application Server for z/OS options are not applicable to the distributed platforms, but they do not need to be removed. The options are ignored on the distributed platforms.

SnoopMBean.xml:

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE MBean SYSTEM "MbeanDescriptor.dtd">
<MBean type="SnoopMBean"
 version="5.0"
 platform="dynamicproxy"
 description="Sample SnoopMBean to be initialized inside an EJB.">

 <attribute name="identification" getMethod="getIdentification"

       type="java.lang.String" proxyInvokeType="unicall"/>

 <operation name="snoopy" role="operation"  type="void" targetObjectType="objectReference"
impact="ACTION" proxyInvokeType="multicall">
  <signature>
   <parameter name="parm1" description="test parameter" type="java.lang.String"/>
  </signature>
 </operation>
</MBean>
```

Assume that your MBean is used in an enterprise bean. Register your MBean in the enterprise bean ejbCreate method and unregister it in the ejbRemove method.

```
//The method MBeanFactory.activateMBean() requires four parameters:
//String type: The type value that you put in this MBean's descriptor. For this example
//the string type is SnoopMBean.
//RuntimeCollaborator co: The UserMBeanCollaborator user MBean collaborator instance
//that you create
//String id: Unique name that you pick
//String desciptor: The MBean descriptor file name

import com.ibm.websphere.management.UserMBeanCollaborator;
//Import other classes here.
.
.
.
static private ObjectName snoopyON = null;
static private Object lockObj = "this is a lock";
.
.
.
/**
 * ejbCreate method: Register your Mbean.
 */
public void ejbCreate() throws javax.ejb.CreateException {
    synchronized (lockObj) {
        System.out.println(">>> SnoopMBean activating for --|" + this + "|--");
        if (snoopyON != null) {
            return;
        }
        try {
            System.out.println(">>> SnoopMBean activating...");
            MBeanFactory mbfactory = AdminServiceFactory.getMBeanFactory();
            RuntimeCollaborator snoop = new UserMBeanCollaborator(new SnoopMBeanImpl());
            snoopyON = mbfactory.activateMBean("SnoopMBean", snoop, "snoopMBeanId", "SnoopMBean.xml");
            System.out.println(">>> SnoopMBean activation COMPLETED! --|" + snoopyON + "|--");
        } catch (Exception e) {
            System.out.println(">>> SnoopMBean activation FAILED:");
            e.printStackTrace();
        }
    }
}
.
```

```
.
.
/**
 * ejbRemove method: Unregister your MBean.
 */
public void ejbRemove() {
    synchronized (lockObj) {
        System.out.println(">>> SnoopMBean Deactivating for --|" + this + "|--");
        if (snoopyON == null) {
            return;
        }
        try {
            System.out.println(">>> SnoopMBean Deactivating ==|" + snoopyON +
                "|== for --|" + this + "|--");
            MBeanFactory mbfactory = AdminServiceFactory.getMBeanFactory();
            mbfactory.deactivateMBean(snoopyON);
            System.out.println(">>> SnoopMBean Deactivation COMPLETED!");
        } catch (Exception e) {
            System.out.println(">>> SnoopMBean Deactivation FAILED:");
            e.printStackTrace();
        }
    }
}
```

Compile the MBean Java files and package the resulting class files with the descriptor .xml file, into the enterprise bean JAR file.

Java 2 security permissions

When you enable Java 2 security, you must grant Java 2 security permissions to application-specific code for Java Management Extensions (JMX) and WebSphere Application Server administrative privileges. With these permissions, your application code can call WebSphere Application Server administrative methods and JMX methods.

Use the following permission to invoke all the JMX class methods and interface methods:

```
permission javax.management.MBeanPermission "*", "*";
```

Consult the Java Management Extensions (JMX) API documentation for specific actions under the MBeanPermission class.

Use the following permission for WebSphere Application Server administrative application programming interfaces (APIs):

```
permission com.ibm.websphere.security.WebSphereRuntimePermission "AdminPermission";
```

Developing administrative programs for multiple Java 2 Platform, Enterprise Edition application servers

You can develop an administrative client to manage multiple vendor application servers through existing MBean support in the WebSphere Application Server.

Existence of MBeans for stopped components

The WebSphere Application Server completely implements the Java 2 Platform, Enterprise Edition (J2EE) Management specification. However, some differences in details between the J2EE specification and the WebSphere Application Server implementation are important for you to understand when you access WebSphere Application Server components. These differences are important to you when you access application MBeans because you can use either the WebSphere Application Server programming model or the J2EE programming model.

In the WebSphere Application Server programming model, if an MBean exists, you can assume that it is running. If an MBean does not exist, you can assume that it is stopped. Transient states between the started state and the stopped state are the same as the stopped state, which means that no MBean exists.

In the J2EE programming model, the MBean always exists regardless of the state of the component.

You can determine the state of a component by querying the state attribute. However, the state attribute only exists for MBeans that are state manageable, meaning that they implement the StateManageable interface. State manageable MBeans have start(), startRecursive(), and stop() operations whether these MBeans are J2EE MBeans or WebSphere Application Server MBeans. Additionally, the WebSphere Application Server defines the stateful interface. The stateful interface means that the component has a state and emits the j2ee.state.notifications method, but that the component cannot directly manage the state. For example, a Web module cannot stop itself. However, the application that contains the Web module can stop it.

Not all MBeans that have a state are state-manageable. Servlets, J2EE modules and enterprise beans, for example, are all stateful, but are not state manageable. The J2EE server is not state-manageable because no start() operation is available on a server.

The J2EEApplication MBean is an example of a state manageable MBean. When the WebSphere Application Server starts, each application activates a J2EEApplication MBean for itself. A J2EEApplication MBean has a J2EE type of J2EEApplication (for example, `ObjectName *:*,j2eeType=J2EEApplication`). If the application starts, it also activates an Application MBean with a type of Application (for example, `*:*,type=Application`). When the application changes state, the Application MBean is activated or deactivated. However, the J2EEApplication MBean is always activated. You can retrieve the application state changes by getting the state attribute.

The modules attribute on the J2EEApplication component returns an array of object names, one for every module in the application. The Application Server activates an MBean for each of these modules only after the Application Server starts the application. The managed enterprise bean isRegistered(ObjectName) method returns `false` if the application, and therefore the module, is not running.

All of the attributes that are defined in the J2EE management specification return valid values when the managed object stops. Other attributes and operations, for example those that are specifically defined for the Application Server, use the com.ibm.websphere.management.exception.ObjectNotRunningException exception if they are accessed when the object is stopped.

If you install the application while the server runs, the application installs the J2EEApplication MBean when the installation completes. Conversely, when the application uninstalls the J2EEApplication MBean, the application deactivates the MBean.

Mapping key properties

The following table lists the mapping from the J2EE management-defined j2eeType key property to the WebSphere Application Server type key property. You can use either key property to access MBeans. However, only use the j2eeType key property if you want to connect to application servers other than WebSphere Application Server.

j2eeType key property	type key property
J2EEDomain	J2EEDomain [new]
J2EEServer	Server
JVM	JVM
J2EEApplication	Application [separate MBean from j2eeType

WebModule	WebModule
ResourceAdapterModule	ResourceAdapterModule
EJBModule	EJBModule
EJB and subtypes / Servlet / ResourceAdapter	EJB and subtypes / Servlet / ResourceAdapter
JavaMailResource	MailProvider
JNDIResource	NameServer
JMSResource	JMSProvider
JTAResource	TransactionService
RMI_IIOPResource	ORB
URLResource	URLProvider
JDBCResource	JDBCProvider
JDBCDataSource	DataSource
JDBCDriver	JDBCDriver [new]
JCAResource	J2CResourceAdapter
JCAConnectionFactory	J2CConnectionFactory
JCAManagedConnectionFactory	J2CManagedConnectionFactory [new]

Optional WebSphere Application Server interfaces

The following table shows the optional J2EE management interfaces that WebSphere Application Server provides.

j2eeType key property	EventProvider interface	StateManageable interface	StatisticsProvider interface
J2EEDomain	No	No	No
J2EEServer	Yes	Stateful	No
JVM	No	No	Yes
J2EEApplication	Yes	Yes	No
WebModule	Yes	Stateful	No
ResourceAdapterModule	Yes	Stateful	No
EJBModule	Yes	Stateful	No
AppClientModule	Yes	Stateful	No
EJB and subtypes / Servlet / ResourceAdapter	No	No	Yes
JavaMailResource	No	No	No
JNDIResource	No	No	No
JMSResource	No	No	No
JTAResource	Yes	No	Yes
RMI_IIOPResource	No	No	Yes
URLResource	No	No	No
JDBCResource	No	No	Yes
JDBCDataSource	No	No	No
JDBCDriver	No	No	No

JCAResource	Yes	No	Yes
JCAConnectionFactory	No	No	No
JCAManagedConnectionFactory	No	No	No

Deploying and managing a custom Java administrative client program with multiple Java 2 Platform, Enterprise Edition application servers

This section describes how to connect to a Java 2 Platform, Enterprise Edition (J2EE) server, and how to manage multiple vendor servers.

The WebSphere Application Server completely implements the J2EE Management specification, also known as JSR-77 (Java Specification Requests 77). However, some differences in details between the J2EE specification and the WebSphere Application Server implementation are important for you to understand when you develop a Java administrative client program to manage multiple vendor servers. For information, see the Java Platform, Enterprise Edition (J2EE) Management Specification and the MBean application programming interface (API) documentation.

When your administrative client program accesses WebSphere Application Servers exclusively, you can use the Java APIs and WebSphere Application Server-defined MBeans to manage them. If your program needs to access both WebSphere Application Servers and other J2EE servers, use the API defined in the J2EE Management specification.

1. Connect to a J2EE server.

   Connect to a server by looking up the Management enterprise bean from the Java Naming and Directory Interface (JNDI). The Management enterprise bean supplies a remote interface to the MBean server that runs in the application server. The Management enterprise bean works almost exactly like the WebSphere Application Server administrative client, except that it does not provide WebSphere Application Server specific functionality. The following example shows how to look up the Management enterprise bean.

   ```
   import javax.management.j2ee.ManagementHome;
   import javax.management.j2ee.Management;

   Properties props = new Properties();

   props.setProperty(Context.PROVIDER_URL, "iiop://myhost:2809");
   Context ic = new InitialContext(props);
   Object obj = ic.lookup("ejb/mgmt/MEJB");
   ManagementHome mejbHome = (ManagementHome)
           PortableRemoteObject.narrow(obj, ManagementHome.class);
   Management mejb = mejbHome.create();
   ```

   The example gets an initial context to an application server by passing the host and port of the Remote Method Invocation (RMI) connector. You must explicitly code the RMI port, in this case 2809. The lookup method looks up the `ejb/mgmt/MEJB` path, which is the location of the Management enterprise bean home. The example then creates the mejb stateless session bean, which you use in the next step.

2. Manage multiple vendor application servers.

   After you create the mejb stateless session bean, you can use it to manage your application servers. Components from the application servers appear as MBeans, which the specification defines. These MBeans all have the j2eeType key property. This key property is one of a set of types that the specification defines. All of these types have a set of exposed attributes.

   Use the following example to guide you in managing multiple vendor application servers. The example uses the Java virtual machine (JVM) MBean to determine what the current heap size is for the application server.

```
ObjectName jvmQuery = new ObjectName("*:j2eeType=JVM,*");
Set s = mejb.queryNames(jvmQuery, null);
ObjectName jvmMBean = (ObjectName) s.iterator().next();
boolean hasStats = ((Boolean) mejb.getAttribute(jvmMBean,
        "statisticsProvider")).booleanValue();
if (hasStats) {
    JVMStats stats = (JVMStats) mejb.getAttribute(jvmMBean,
                                                  "stats");
    String[] statisticNames = stats.getStatisticNames();
    if (Arrays.asList(statisticNames).contains("heapSize")) {
        System.out.println("Heap size: " + stats.getHeapSize());
    }
}
```

The queryNames() method first queries the JVM MBean. The getAttribute method gets the statisticsProvider attribute and determine if this MBean provides statistics. If the MBean does, the example accesses the stats attribute, and then invokes the getHeapSize() method to get the heap size.

The strength of this example is that the example can run on any vendor application server. It demonstrates that an MBean can optionally implement defined interfaces, in this case the StatisticsProvider interface. If an MBean implements the StatisticsProvider interface, you can see if an application server supports a particular statistic, in this case the heap size. The specification defines the heap size, although this value is optional. If the application server supports the heap size, you can display the heap size for the JVM.

Migrating Java Management Extensions V1.0 to Java Management Extensions V1.2

Each Java Virtual Machine (JVM) in WebSphere Application Server includes an embedded implementation of Java Management Extensions (JMX). In Application Server, Version 5, the JVMs contain an implementation of the JMX 1.0 specification. In Application Server, Version 6, the JVMs contain an implementation of the JMX 1.2 specification. The JMX 1.0 implementation used in Version 5 is the TMX4J package that IBM Tivoli products supply. The JMX 1.2 specification used in Version 6 is the open source mx4j package. The JMX implementation change across the releases does not affect the behavior of the JMX MBeans in the Application Server. No Application Server administrative application programming interfaces (APIs) are altered due to the change from the JMX V1.0 specification to the JMX V1.2 specification.

The JMX V1.2 specification is backward compatible with the JMX 1.0 specification. However, you might need to migrate custom MBeans that are supplied by products other than the Application Server from Version 5 to Version 6. The primary concern for these custom MBeans is related to the values that are used in key properties of the JMX ObjectName class for the MBean. The open source mx4j implementation more stringently enforces property validation according to the JMX 1.2 specification. Test the custom MBeans that you deployed in Version 5 in Version 6, to ensure compatibility. Full details of the JMX V1.2 specification changes from the JMX V1.0 specification are available in the JMX 1.2 specification.

Java Management Extensions interoperability

WebSphere Application Server Version 6 implements Java Management Extensions (JMX) Version 1.2, while WebSphere Application Server Version 5 implements JMX Version 1.0.

Due to the evolution of the JMX specification, the serialization format for JMX objects, such as the javax.management.ObjectName object, differs between the V5 implementation and the V6 implementation. The V6 JMX run time is enhanced to be aware of the version of the client with which it is communicating. The V6 run time makes appropriate transformations on these incompatible serialized formats to support communication between the different version run times. A V5 wsadmin script or a V5 administrative client can call a V6 deployment manager, node, or server. A V6 wsadmin script or a V6 administrative client can call a V5 node or server.

When a V5 wsadmin script or a V5 administrative client calls a V6 MBean, the instances of classes that are new in V6 cannot be passed back to V5 because these classes are not present in the V5 environment. The problem occurs infrequently. However, it usually occurs when an exception embeds a nested exception that is new in V6. The symptom is usually a serialization exception or a NoClassDefFoundException exception.

Due to changes in the JMX implementation from V5 to V6, different exceptions are created when a method on an MBean is invoked for V5 than when a method on an MBean is invoked for V6. For example, when a method gets or sets an unknown attribute for V5, the MBeanRuntimeException exception is created. When a method gets or sets an unknown attribute for V6, the MBeanException exception that wraps a ServiceNotFoundException exception is created.

An instance of a user-defined class that implements the Serializable interface that is passed as a parameter or return value during MBean invocation, or sent as part of a notification, cannot contain a non-transient instance variable that is in the javax.management.package package. If the instance does, it cannot be properly deserialized when passed between V5 and V6 run times.

Due to changes in the supported format for the ObjectName class from V5 to V6, the configuration ID in V6 contains a vertical bar (|), whereas in V5, the ID contains a colon (:). This change is reflected in the output for wsadmin clients. For example, for a V5 client, the output is:

```
wsadmin>  $AdminConfig list Cell
     DefaultCellNetwork(cells/DefaultCellNetwork:cell.xml#Cell_1)
```

whereas for a V6 client, the output is:

```
wsadmin>  $AdminConfig list Cell
     DefaultCellNetwork(cells/DefaultCellNetwork|cell.xml#Cell_1)
```

The change to the configuration ID generally is not a problem because configuration IDs are generated dynamically. When a V5 client passes a configuration ID that contains a colon, the JMX run time, for upward compatibility, automatically transforms the configuration ID that contains a colon into a configuration ID that contains a vertical bar. Similarly, a reverse transformation is performed for backward compatibility.

Do not save the configuration ID and then try to use it later. Only query the ID and use it.

Managing applications through programming

This topic describes how, through Java MBean programming, to install, update, and delete a Java 2 Platform, Enterprise Edition (J2EE) application on WebSphere Application Server.

This task assumes a basic familiarity with MBean programming. For information on MBean programming see MBean Java application programming interface (API) documentation.

Before you can install or change an application on WebSphere Application Server, you must first create or update your application and assemble it using an assembly tool.

Besides installing, uninstalling, and updating applications through programming, you can additionally install, uninstall, and update J2EE applications through the administrative console or the wsadmin tool. All three ways provide identical updating capabilities.

1. Perform any or all of the following tasks to manage your J2EE applications through programming.
   a. Install an application.

      This article provides an example for initially installing an application on WebSphere Application Server.

   b. Uninstall an application.

This article provides an example for uninstalling an application that resides on WebSphere Application Server.

   c. Update an application.

      This article provides an example for updating the installed application on WebSphere Application Server with a new application. When you completely update an application, the deployed application is uninstalled and the new enterprise archive (EAR) file is installed.

   d. Add to, update, or delete part of an application.

      This article provides an example that you can use to add to, update, or delete part of an application on WebSphere Application Server.

   e. Add a module.

      This article provides an example for adding a module to an application that resides on WebSphere Application Server.

   f. Update a module.

      This article provides an example for updating a module that resides on WebSphere Application Server. When you update a module, the deployed module is uninstalled and the updated module is installed.

   g. Delete a module.

      This article provides an example for deleting a module that resides on WebSphere Application Server. When you delete a module, the deployed module is uninstalled.

   h. Add a file.

      This article provides an example for adding a file to an application that resides on WebSphere Application Server.

   i. Update a file.

      This article provides an example for updating a file on WebSphere Application Server. When you update a file, the deployed file is uninstalled and the updated file is installed.

   j. Delete a file.

      This article provides an example for deleting a file on WebSphere Application Server. When you delete a file, the deployed file is uninstalled.

2. Save your changes to the master configuration repository.

If you have further application updates, you can do the updates through programming, the administrative console, or the wsadmin tool.

Installing an application through programming

You can install an application through the administrative console, the wsadmin tool, or programming. Use this example to install an application through programming.

This task assumes a basic familiarity with MBean programming. For information on MBean programming see MBean Java application programming interface (API) documentation.

Before you can install an application on WebSphere Application Server, you must first create or update your application and assemble it using an assembly tool.

Perform the following tasks to install an application through programming.

1. Populate the enterprise archive (EAR) file with WebSphere Application Server-specific binding information.
   a. Create the controller and populate the EAR file with appropriate options.
   b. Optionally run the default binding generator.
   c. Save and close the EAR file.
   d. Retrieve the saved options table that will be passed to the installApplication MBean (API).

2. Connect to WebSphere Application Server.
3. Create the application management proxy.
4. If the preparation phase (population of the EAR file) is not performed, the do the following actions:
   a. Create an options table to be passed to the installApplication MBean API.
   b. Create a table for module to server relations and add the table to the options table.

      Refer to the com.ibm.websphere.management.application.AppManagement class in the Application Server API documentation to understand various options that can be passed to the installApplication MBean API.
5. Create the notification filter for listening to installation events.
6. Add the listener.
7. Install the application.
8. Wait for some timeout so that the program does not end.
9. Listen to Java Management Extensions (JMX) notifications to understand completion of the operation.
10. When the installation is done, remove the listener and quit.

After you successfully run the code, the application is installed.

The following example shows how to install an application based on the previous steps:

```
import java.lang.*;
import java.io.*;
import java.util.*;
import java.lang.reflect.*;
import com.ibm.websphere.management.application.*;
import com.ibm.websphere.management.application.client.*;
import com.ibm.websphere.management.*;

import javax.management.*;

public class Install {

    public static void main (String [] args) {

        try {
  String earFile = "C:/test/test.ear";
  String appName = "MyApp";

// Preparation phase: Begin
// Through the preparation phase you populate the enterprise archive (EAR) file with
// WebSphere Application Server-specific binding information. For example, you can specify
// Java Naming and Directory Interface (JNDI) names for enterprise beans, or virtual hosts
// for Web modules, and so on.

// First, create the controller and populate the EAR file with the appropriate options.
  Hashtable prefs = new Hashtable();
  prefs.put(AppConstants.APPDEPL_LOCALE, Locale.getDefault());

// You can optionally run the default binding generator by using the following options.
// Refer to Java documentation for the AppDeploymentController class to see all the
// options that you can set.
  Properties defaultBnd = new Properties();
  prefs.put (AppConstants.APPDEPL_DFLTBNDG, defaultBnd);
  defaultBnd.put (AppConstants.APPDEPL_DFLTBNDG_VHOST, "default_host");

// Create the controller.
  AppDeploymentController controller = AppDeploymentController
    .readArchive(earFile, prefs);
  AppDeploymentTask task = controller.getFirstTask();
  while (task != null)
  {
// Populate the task data.
```

```
   String[][] data = task.getTaskData();
// Manipulate task data which is a table of stringtask.
   setTaskData (data);
   task = controller.getNextTask();
  }
  controller.saveAndClose();

  Hashtable options = controller.getAppDeploymentSavedResults();
// The previous options table contains the module-to-server relationship if it was set by
// using tasks.
//Preparation phase: End

// Get a connection to WebSphere Application Server.
  String host = "localhost";
  String port = "8880";
  String target = "WebSphere:cell=cellName,node=nodeName,server=server1";

  Properties config = new Properties();
  config.put (AdminClient.CONNECTOR_HOST,  host);
  config.put (AdminClient.CONNECTOR_PORT,  port);
  config.put (AdminClient.CONNECTOR_TYPE, AdminClient.CONNECTOR_TYPE_SOAP);
  System.out.println ("Config: " + config);
     AdminClient _soapClient = AdminClientFactory.createAdminClient(config);

// Create the application management proxy, AppManagement.
  AppManagement proxy = AppManagementProxy. getJMXProxyForClient (_soapClient);

// If code for the preparation phase has been run, then you already have the options table.
// If not, create a new table and add the module-to-server relationship to it by uncommenting
// the next statement.
//Hashtable options = new Hashtable();
  options.put (AppConstants.APPDEPL_LOCALE, Locale.getDefault());

// Uncomment the following statements to add the module to the server relationship table if
//  the preparation phase does not collect it.
//Hashtable module2server = new Hashtable();
//module2server.put ("*", target);
//options.put (AppConstants.APPDEPL_MODULE_TO_SERVER, module2server);

//Create the notification filter for listening to installation events.
  NotificationFilterSupport myFilter = new NotificationFilterSupport();
  myFilter.enableType (AppConstants.NotificationType);

//Add the listener.
  NotificationListener listener = new AListener(_soapClient, myFilter,
      "Install: " + appName, AppNotification.INSTALL);

// Install the application.
  proxy.installApplication (earFile, appName, options, null);
  System.out.println ("After install App is called..");

// Wait for some timeout. The installation application programming interface (API) is
//  asynchronous and so returns immediately.
// If the program does not wait here, the program ends.
  Thread.sleep(300000); // Wait so that the program does not end.

        }
        catch (Exception e) {
            e.printStackTrace();
        }

    }

}

// Specify the Java Management Extensions (JMX) notification listener for JMX events.
```

```
class AListener implements NotificationListener
{
    AdminClient _soapClient;
    NotificationFilterSupport  myFilter;
    Object handback;
    ObjectName on;
    String eventTypeToCheck;

    public AListener(AdminClient cl, NotificationFilterSupport fl, Object h,
        String eType) throws Exception
    {
        _soapClient = cl;
        myFilter = fl;
        handback = h;
        eventTypeToCheck = eType;

        Iterator iter = _soapClient.queryNames (new ObjectName("WebSphere:type=
            AppManagement,*"), null).iterator();
        on = (ObjectName)iter.next();
        System.out.println ("ObjectName: " + on);
        _soapClient.addNotificationListener (on, this, myFilter, handback);
    }

    public void handleNotification (Notification notf, Object handback)
    {
            AppNotification ev = (AppNotification) notf.getUserData();
            System.out.println ("!! JMX event Recd: (handback obj= " + handback+ "): " + ev);

            //When the installation is done, remove the listener and quit.

            if (ev.taskName.equals (eventTypeToCheck) &&
                (ev.taskStatus.equals (AppNotification.STATUS_COMPLETED) ||
                 ev.taskStatus.equals (AppNotification.STATUS_FAILED)))
            {
                    try
                    {
                            _soapClient.removeNotificationListener (on, this);
                    }
            catch (Throwable th)
                    {
                        System.out.println ("Error removing listener: " + th);
                    }
                    System.exit (0);
        }
    }
}
```

Once you install the application, you must explicitly start the application or restart the server.

Starting an application through programming:

You can start an application through the administrative console, the wsadmin tool, or programming. Use this example to start an application through programming.

This task assumes a basic familiarity with MBean programming. For information on MBean programming see MBean Java application programming interface (API) documentation.

Before you can start an application on WebSphere Application Server, you must first install your application.

Perform the following tasks to start an application through programming.

1. Connect the administrative client to WebSphere Application Server.

2. Create the application management proxy.
3. Call the startApplication method on the proxy by passing the application name and optionally the list of targets on which to start the application.

After you successfully run the code, the application is started.

The following example shows how to start an application following the previously listed steps:

```
//Do a get of the administrative client to connect to
//WebSphere Application Server.

AdminClient client = ...;
String appName = "myApp";
Hashtable prefs = new Hashtable();
// Use the AppManagement MBean to start and stop applications on all or some targets.
// The AppManagement MBean is on the deployment manager in the Network Deployment product
// or on server1 in WebSphere Application Server.
// Query and get the AppManagement MBean.
ObjectName on = new ObjectName ("WebSphere:type=AppManagement,process=dmgr,*");
Iterator iter = client.queryNames (on, null).iterator();
ObjectName appmgmtON = (ObjectName)iter.next();

//Start the application on all targets.
AppManagement proxy = AppManagementProxy.getJMXProxyForClient(client);
String started = proxy.startApplication(appName, prefs, null);
System.out.println("Application started on folloing servers: " + started);

//Start the application on some targets.
//String targets = "WebSphere:cell=cellname,node=nodename,server=
       servername+WebSphere:cell=cellname,cluster=clusterName";
//String started1 = proxy.startApplication(appName, targets, prefs, null);
//System.out.println("Application started on following servers: " + started1)
```

Uninstalling an application through programming

You can uninstall an application through the administrative console, the wsadmin tool, or programming. Use this example to uninstall an application through programming.

This task assumes a basic familiarity with MBean programming. For information on MBean programming see MBean Java application programming interface (API) documentation.

Before you can uninstall an application on WebSphere Application Server, you must first install it.

Perform the following tasks to uninstall an application through programming.

1. Get a connection to WebSphere Application Server.
2. Get the application management proxy.
3. Create the notification filter for listening to uninstallation events.
4. Add the listener.
5. Uninstall the application.
6. Wait for some timeout so that the program does not end.
7. Listen to Java Management Extensions (JMX) notifications to understand completion of the operation.
8. When the uninstallation is done, remove the listener and quit.

After you successfully run the code, the application is uninstalled.

The following example shows how to uninstall an application based on the previous steps:

```
import java.lang.*;
import java.io.*;
import java.util.*;
import java.lang.reflect.*;
import com.ibm.websphere.management.application.*;
import com.ibm.websphere.management.application.client.*;
import com.ibm.websphere.management.*;

import javax.management.*;

public class Uninstall {

    public static void main (String [] args) {

        try {

// Get a connection to the server.
  String host = "localhost";
  String port = "8880";
  String target = "WebSphere:cell=cellName,node=nodeName,server=server1";

  Properties config = new Properties();
  config.put (AdminClient.CONNECTOR_HOST,  host);
  config.put (AdminClient.CONNECTOR_PORT,  port);
  config.put (AdminClient.CONNECTOR_TYPE, AdminClient.CONNECTOR_TYPE_SOAP);
  System.out.println ("Config: " + config);
     AdminClient _soapClient = AdminClientFactory.createAdminClient(config);

  // Get the application management proxy.
  AppManagement proxy = AppManagementProxy. getJMXProxyForClient (_soapClient);

  String appName = "MyApp";
  Hashtable options = new Hashtable();
  options.put (AppConstants.APPDEPL_LOCALE, Locale.getDefault());

  //Create the notification filter.
  NotificationFilterSupport myFilter = new NotificationFilterSupport();
  myFilter.enableType (AppConstants.NotificationType);

  //Add the listener.
  NotificationListener listener = new AListener(_soapClient, myFilter,
     "Install: " + appName, AppNotification.UNINSTALL);

  // Uninstall the application.
  proxy.uninstallApplication (appName, options, null);
  System.out.println ("After uninstall App is called..");

// Wait for some timeout. The installation application programming interface (API) is
//  asynchronous and so returns immediately.
// If the program does not wait here, the program ends.
  Thread.sleep(300000); // Wait so that the program does not end.

        }
        catch (Exception e) {
            e.printStackTrace();
        }

    }

}

// Specify the Java Management Extensions (JMX) notification listener for JMX events.
class AListener implements NotificationListener
{
    AdminClient _soapClient;
    NotificationFilterSupport  myFilter;
    Object handback;

        handback = h;
        eventTypeToCheck = eType;

        Iterator iter = _soapClient.queryNames (new ObjectName("WebSphere:
            type=AppManagement,*"), null).iterator();
        on = (ObjectName)iter.next();
        System.out.println ("ObjectName: " + on);
        _soapClient.addNotificationListener (on, this, myFilter, handback);
    }

    public void handleNotification (Notification notf, Object handback)
    {
            AppNotification ev = (AppNotification) notf.getUserData();
            System.out.println ("!! JMX event Recd: (handback obj= " + handback+
               "): " + ev);

            //When the unistallation is done, remove the listener and quit

            if (ev.taskName.equals (eventTypeToCheck) &&
                (ev.taskStatus.equals (AppNotification.STATUS_COMPLETED) ||
                 ev.taskStatus.equals (AppNotification.STATUS_FAILED)))
            {
                    try
                    {
                            _soapClient.removeNotificationListener (on, this);
                    }
            catch (Throwable th)
                    {
                        System.out.println ("Error removing listener: " + th);
                    }
                    System.exit (0);
        }
    }
}
```

Updating an application through programming

You can update an existing application through the administrative console, the wsadmin tool, or programming. Use this example to completely update an application through programming.

This task assumes a basic familiarity with MBean programming. For information on MBean programming see MBean Java application programming interface (API) documentation.

Before you can update an application on WebSphere Application Server, you must first install your application.

Perform the following tasks to completely updaste an application through programming.

1. Connect to WebSphere Application Server.
2. Create the application management proxy.
3. Create the notification filter for listening to events.
4. Add the listener.
5. Prepare the enterprise archive (EAR) file by populating it with binding information.
6. Update the application.
7. Wait for some timeout so that the program does not end.
8. Listen to Java Management Extensions (JMX) notifications to understand completion of the operation.

9. When the update is done, remove the listener and quit.

After you successfully run the code, the application is updated.

The following example shows how to update an application based on the previous steps:

```
import java.lang.*;
import java.io.*;
import java.util.*;
import java.lang.reflect.*;
import com.ibm.websphere.management.application.*;
import com.ibm.websphere.management.application.client.*;
import com.ibm.websphere.management.*;

import javax.management.*;

public class aa {

    public static void main (String [] args) {

        try {

  // Connect to WebSphere Application Server.
  String host = "localhost";
  String port = "8880";
  String target = "WebSphere:cell=cellName,node=nodeName,server=server1";

  Properties config = new Properties();
  config.put (AdminClient.CONNECTOR_HOST,  host);
  config.put (AdminClient.CONNECTOR_PORT,  port);
  config.put (AdminClient.CONNECTOR_TYPE, AdminClient.CONNECTOR_TYPE_SOAP);
  System.out.println ("Config: " + config);
     AdminClient _soapClient = AdminClientFactory.createAdminClient(config);

  // Create the application management proxy, AppManagement.
  AppManagement proxy = AppManagementProxy. getJMXProxyForClient (_soapClient);

  String appName = "MyApp";
  String fileContents = "C:/test/test.ear";

  // Create the notification filter.
  NotificationFilterSupport myFilter = new NotificationFilterSupport();
  myFilter.enableType (NotificationConstants.TYPE_APPMANAGEMENT);
  //Add the listener.
  NotificationListener listener = new AListener(_soapClient, myFilter,
      "Install: " + appName, AppNotification.INSTALL);

// Refer to the installation example to see how you can prepare the enterprise
      archive (EAR)
// file by populating it with binding information.
// If code for the preparation phase has started, then you already have the options table.
// If not, create a new table and add the module-to-server relationship to it by uncommenting
// the next statement.
//Hashtable options = new Hashtable();
  options.put (AppConstants.APPDEPL_LOCALE, Locale.getDefault());
  options.put ((AppConstants.APPUPDATE_CONTENTTYPE, AppConstants.APPUPDATE_CONTENT_APP);

// Uncomment the following statements to add the module to the server relationship table if
//  the preparation phase does not collect it
//Hashtable module2server = new Hashtable();
//module2server.put ("*", target);
//options.put (AppConstants.APPDEPL_MODULE_TO_SERVER, module2server);
// Update the application.
  proxy.updateApplication (   appName,
                 null,
                 fileContents,
                 AppConstants.APPUPDATE_UPDATE,
                options,
                null);

// Wait for some timeout. The installation application programming interface (API) is
//  asynchronous and so returns immediately.
// If the program does not wait here, the program ends.
  Thread.sleep(300000); // Wait so that the program does not end.

        }
        catch (Exception e) {
            e.printStackTrace();
        }

    }

}

// Specify the Java Management Extensions (JMX) notification listener for JMX events.
class AListener implements NotificationListener
{
    AdminClient _soapClient;
    NotificationFilterSupport  myFilter;
    Object handback;
    ObjectName on;
    String eventTypeToCheck;

    public AListener(AdminClient cl, NotificationFilterSupport fl, Object h,
       String eType) throws Exception
    {
        _soapClient = cl;
        myFilter = fl;
        handback = h;
        eventTypeToCheck = eType;

        Iterator iter = _soapClient.queryNames (new ObjectName
             ("WebSphere:type=AppManagement,*"), null).iterator();
        on = (ObjectName)iter.next();
        System.out.println ("ObjectName: " + on);
        _soapClient.addNotificationListener (on, this, myFilter, handback);
    }

    public void handleNotification (Notification notf, Object handback)
    {
            AppNotification ev = (AppNotification) notf.getUserData();
            System.out.println ("!! JMX event Recd: (handback obj= " +
                 handback+ "): " + ev);

            //When the installation is done, remove the listener and quit

            if (ev.taskName.equals (eventTypeToCheck) &&
                (ev.taskStatus.equals (AppNotification.STATUS_COMPLETED) ||
                 ev.taskStatus.equals (AppNotification.STATUS_FAILED)))
            {
                    try
                    {
                            _soapClient.removeNotificationListener (on, this);
                    }
            catch (Throwable th)
                    {
                        System.out.println ("Error removing listener: " + th);
                    }
                    System.exit (0);
        }
    }
}
```

Adding to, updating, or deleting part of an application through programming

You can add to, update, or delete part of an existing application through the administrative console, the wsadmin tool, or programming. This example changes part of an application through programming. You can use this example whether you add to, update, or delete part of an existing application. Multiple changes to an application can be packaged in a single .zip file.

To learn about the structure of the .zip file, see updating applications through the administrative console.

This task assumes a basic familiarity with MBean programming. For information on MBean programming see MBean Java application programming interface (API) documentation.

Before you can add to, update, or delete part of an application on WebSphere Application Server, you must first install your application.

Perform the following tasks to add to, update, or delete part of an application through programming.

1. Connect to WebSphere Application Server.
2. Create the application management proxy.
3. Create the notification filter.
4. Add the listener.
5. Partially change the existing application.
6. Wait for some timeout so that the program does not end.
7. Listen to Java Management Extensions (JMX) notifications to understand completion of the operation.
8. When the update is done, remove the listener and quit.

After you successfully run the code, you have changed the application.

The following example shows how to add to, update, or delete part of an application based on the previous steps:

```
//Inputs:
//partialApp specifies the location of the partial application.
//appName specifies the name of the application.

String partialApp = "C:/apps/partial.zip";
String appName = "MyApp";

//Do a get of the administrative client to connect to
//WebSphere Application Server.

AdminClient client = ...;

//Create the application management proxy.
AppManagement proxy = AppManagementProxy. getJMXProxyForClient (client);

// Create the notification filter.
NotificationFilterSupport myFilter = new NotificationFilterSupport();
myFilter.enableType (NotificationConstants.TYPE_APPMANAGEMENT);
//Add the listener.
NotificationListener listener = new AListener(_soapClient, myFilter,
    "Install: " + appName, AppNotification.UPDATE);
//Partially change the existing application, MyApp.

Hashtable options = new Hashtable();
options.put (AppConstants.APPDEPL_LOCALE, Locale.getDefault());
options.put (AppConstants.APPUPDATE_CONTENTTYPE, AppConstants.
     APPUPDATE_CONTENT_PARTIALAPP);

proxy.updateApplication ( appName,
    null,
    partialApp,
    null,
    options,
    null);

// Wait for some timeout. The installation application programming interface (API) is
//  asynchronous and so returns immediately.
// If the program does not wait here, the program ends.
  Thread.sleep(300000); // Wait so that the program does not end.
        }
        catch (Exception e) {
            e.printStackTrace();
        }

    }

}
// Specify the Java Management Extensions (JMX) notification listener for JMX events.
class AListener implements NotificationListener
{
    AdminClient _soapClient;
    NotificationFilterSupport  myFilter;
    Object handback;
    ObjectName on;
    String eventTypeToCheck;

    public AListener(AdminClient cl, NotificationFilterSupport fl, Object h,
        String eType) throws Exception
    {
        _soapClient = cl;
        myFilter = fl;
        handback = h;
        eventTypeToCheck = eType;

        Iterator iter = _soapClient.queryNames (new ObjectName("WebSphere:
            type=AppManagement,*"), null).iterator();
        on = (ObjectName)iter.next();
        System.out.println ("ObjectName: " + on);
        _soapClient.addNotificationListener (on, this, myFilter, handback);
    }

    public void handleNotification (Notification notf, Object handback)
    {
            AppNotification ev = (AppNotification) notf.getUserData();
            System.out.println ("!! JMX event Recd: (handback obj= " +
                handback+ "): " + ev);

            //When the installation is done, remove the listener and quit

            if (ev.taskName.equals (eventTypeToCheck) &&
                (ev.taskStatus.equals (AppNotification.STATUS_COMPLETED) ||
                 ev.taskStatus.equals (AppNotification.STATUS_FAILED)))
            {
                    try
                    {
                            _soapClient.removeNotificationListener (on, this);
                    }
            catch (Throwable th)
                    {
                        System.out.println ("Error removing listener: " + th);
                    }
                    System.exit (0);
        }
    }
}
```

Preparing a module and adding it to an existing application through programming

You can add a module to an existing application through the administrative console, the wsadmin tool, or programming. Use this example to add a module through programming.

This task assumes a basic familiarity with MBean programming. For information on MBean programming see MBean Java application programming interface (API) documentation.

Before you can add a module to an application on WebSphere Application Server, you must install the application.

Perform the following tasks to add a module to an application through programming.

1. Create an application deployment controller instance to populate the module file with binding information.
2. Save the binding information in the module.
3. Get the installation options.
4. If the preparation phase (population of the EAR file) is not performed, the do the following actions:
   a. Create an options table to be passed to the updateApplication MBean API.
   b. Create a table for module to server relations and add the table to the options table.
5. Connect to WebSphere Application Server.
6. Create the application management proxy.
7. Create the notification filter.
8. Add the listener.
9. Add the module to the application.
10. Specify the target for the new module.
11. Wait for some timeout so that the program does not end.
12. Listen to Java Management Extensions (JMX) notifications to understand completion of the operation.
13. When the module addition is done, remove the listener and quit.

After you successfully run the code, the module is added to the application.

The following example shows how to add a module to an application based on the previous steps:

```
//Inputs:
//moduleName specifies the name of the module that you add to the application.
//moduleURI specifies a URI that gives the target location of the module
// archive contents on a file system. The URI provides the location of the new
// module after installation. The URI is relative to the application URL.
//uniquemoduleURI specfies the URI that gives the target location of the
// deployment descriptor file. The URI is relative to the application URL.
//target specifies the cell, node, and server on which the module is installed.

String moduleName = "C:/apps/foo,jar";
String moduleURI = "Increment.jar";
String uniquemoduleURI = "Increment.jar+META-INF/ejb-jar.xml";
String target = "WebSphere:cell=cellname,node=nodename,server=servername";

//Create an application deployment controller instance, AppDeploymentController,
//to populate the Java aArchive (JAR) file with binding information.
//The binding information is WebSphere Application Server-specific deployment information.

Hashtable preferences = new Hashtable();
preferences.put (AppConstants.APPDEPL_LOCALE, Locale.getDefault());
preferences.put (AppConstants.APPUPDATE_CONTENTTYPE, AppConstants.APPUPDATE_
    CONTENT_MODULEFILE);
AppDeploymentController controller = AppManagementFactory.readArchiveForUpdate(
    moduleName,
    moduleURI,
    AppConstants.APPUPDATE_ADD,
    preferences,
    null);
```

If the module that you add to the application lacks any bindings, add the bindings so that the module addition works. Collect and add the bindings by using the public APIs provided with WebSphere Application Server. Refer to Java documentation for the com.ibm.websphere.management.application.client.AppDeploymentController instance to learn more about how to collect and populate tasks with WebSphere Application Server specific-binding information.

```
//After you collect all the binding information, save it in the module.
controller.saveAndClose();

//Get the installation options.
Hashtable options = controller. getAppDeploymentSavedResults();

//Connect the administrative client, AdminClient, to WebSphere Application Server.
    AdminClient client = ...;

//Create the application management proxy.
AppManagement proxy = AppManagementProxy. getJMXProxyForClient (client);

//Update the existing application, MyApp, by adding the module.
String appName = "MyApp";

options.put (AppConstants.APPUPDATE_CONTENTTYPE,
   AppConstants. APPUPDATE_CONTENT_MODULEFILE);

//Create the notification filter.
  NotificationFilterSupport myFilter = new NotificationFilterSupport();
  myFilter.enableType (NotificationConstants.TYPE_APPMANAGEMENT);
  //Add the listener.
  NotificationListener listener = new AListener(_soapClient, myFilter,
      "Install: " + appName, AppNotification.UPDATE);

//Specify the target for the new module.
Hashtable mod2svr = new Hashtable();
options.put (AppConstants.APPDEPL_MODULE_TO_SERVER, mod2svr);
mod2svr.put (uniquemoduleURI, target);
proxy.updateApplication ( appName,
    moduleURI,
    moduleName,
    AppConstants.APPUPDATE_ADD,
    options,
    null);

// Wait for some timeout. The installation application programming interface (API) is
//  asynchronous and so returns immediately.
// If the program does not wait here, the program ends.
  Thread.sleep(300000); // Wait so that the program does not end.
        }
        catch (Exception e) {
            e.printStackTrace();
        }

    }

}
// Specify the Java Management Extensions (JMX) notification listener for JMX events.
class AListener implements NotificationListener
{
    AdminClient _soapClient;
    NotificationFilterSupport  myFilter;
    Object handback;
    ObjectName on;
    String eventTypeToCheck;

    public AListener(AdminClient cl, NotificationFilterSupport fl, Object h,
        String eType) throws Exception
    {
        _soapClient = cl;
        myFilter = fl;
        handback = h;
        eventTypeToCheck = eType;

        Iterator iter = _soapClient.queryNames (new ObjectName("WebSphere:
            type=AppManagement,*"), null).iterator();
        on = (ObjectName)iter.next();
        System.out.println ("ObjectName: " + on);
        _soapClient.addNotificationListener (on, this, myFilter, handback);
    }

    public void handleNotification (Notification notf, Object handback)
    {
            AppNotification ev = (AppNotification) notf.getUserData();
            System.out.println ("!! JMX event Recd: (handback obj= " +
                handback+ "): " + ev);

            //When the installation is done, remove the listener and quit

            if (ev.taskName.equals (eventTypeToCheck) &&
                (ev.taskStatus.equals (AppNotification.STATUS_COMPLETED) ||
                 ev.taskStatus.equals (AppNotification.STATUS_FAILED)))
            {
                    try
                    {
                            _soapClient.removeNotificationListener (on, this);
                    }
            catch (Throwable th)
                    {
                        System.out.println ("Error removing listener: " + th);
                    }
                    System.exit (0);
        }
    }
}
```

Preparing and updating a module through programming

You can update a module for an existing application through the administrative console, the wsadmin tool, or programming. When you update a module, you replace the existing module with a new version. Use this example to update a module through programming.

This task assumes a basic familiarity with MBean programming. For information on MBean programming see MBean Java application programming interface (API) documentation.

Before you can update a module on WebSphere Application Server, you must first install the application.

Perform the following tasks to update a module through programming.

1. Create an application deployment controller instance to populate the Java archive file with binding information.
2. Save the binding information in the module.
3. Get the installation options.
4. If the preparation phase (population of the EAR file) is not performed, the do the following actions:
   a. Create an options table to be passed to the updateApplication MBean API.
   b. Create a table for module to server relations and add the table to the options table.

5. Connect to WebSphere Application Server.
6. Create the application management proxy.
7. Create the notification filter.
8. Add the listener.
9. Replace the module in the application.
10. Specify the target for the new module.
11. Wait for some timeout so that the program does not end.
12. Listen to Java Management Extensions (JMX) notifications to understand completion of the operation.
13. When the module addition is done, remove the listener and quit.

After you successfully run the code, the existing module is replaced with the new one.

The following example shows how to add a module to an application based on the previous steps:

```
//Inputs:
//moduleName specifies the name of the module that you add to the application.
//moduleURI specifies a URI that gives the target location of the module
// archive contents on a file system. The URI provides the location of the new
// module after installation. The URI is relative to the application URL.
//uniquemoduleURI specfies the URI that gives the target location of the
// deployment descriptor file. The URI is relative to the application URL.
//target specifies the cell, node, and server on which the module is installed.
//appName specifies the name of the application to update.
String moduleName = "C:/apps/foo,jar";
String moduleURI = "Increment.jar";
String uniquemoduleURI = "Increment.jar+META-INF/ejb-jar.xml";
String target = "WebSphere:cell=cellname,node=nodename,server=servername";
String appName = "MyApp";

//Get the administrative client to connect to
//WebSphere Application Server.
AdminClient client = ...;
AppManagement proxy = AppManagementProxy. getJMXProxyForClient (client);

Vector tasks = proxy.getApplicationInfo (appName, new Hashtable(), null);

//Create an application deployment controller instance, AppDeploymentController,
//to populate the Java archive (JAR) file with binding information.
//The binding information is WebSphere Application Server-specific deployment information.

Hashtable preferences = new Hashtable();
preferences.put (AppConstants.APPDEPL_LOCALE, Locale.getDefault());
preferences.put (AppConstants.APPUPDATE_CONTENTTYPE, AppConstants.APPUPDATE_
    CONTENT_MODULEFILE);
AppDeploymentController controller = AppManagementFactory.readArchiveForUpdate(
    moduleName,
    moduleURI,
    AppConstants.APPUPDATE_UPDATE,
    preferences,
    tasks);
```

If the module that you update for the application lacks any bindings, add the bindings so that the module update works. Collect and add the bindings by using the public APIs that are provided with WebSphere Application Server. Refer to Java documentation for the AppDeploymentController instance to learn more about how to collect and populate tasks with WebSphere Application Server-specific binding information.

```
//After you collect all the binding information, save it in the module.
controller.saveAndClose();

//Create the notification filter.
  NotificationFilterSupport myFilter = new NotificationFilterSupport();
  myFilter.enableType (NotificationConstants.TYPE_APPMANAGEMENT);
  //Add the listener.
  NotificationListener listener = new AListener(_soapClient, myFilter, "Install:
      " + appName, AppNotification.UPDATE);

//Get the installation options.
Hashtable options = controller. getAppDeploymentSavedResults();

//Update the existing application by adding the module.

options.put (AppConstants.APPUPDATE_CONTENTTYPE,
   AppConstants. APPUPDATE_CONTENT_MODULEFILE);

//Specify the target for the new module
Hashtable mod2svr = new Hashtable();
options.put (AppConstants.APPDEPL_MODULE_TO_SERVER, mod2svr);
mod2svr.put (uniquemoduleURI, target);

proxy.updateApplication ( appName,
    moduleURI,
    moduleName,
    AppConstants.APPUPDATE_UPDATE,
    options,
    null);
// Wait; the installation application programming interface (API) is
//  asynchronous and so returns immediately.
// If the program does not wait here, the program ends.
  Thread.sleep(300000); // Wait so that the program does not end.
        }
        catch (Exception e) {
            e.printStackTrace();
        }

    }

}
// Specify the Java Management Extensions (JMX) notification listener for JMX events.
class AListener implements NotificationListener
{
    AdminClient _soapClient;
    NotificationFilterSupport  myFilter;
    Object handback;
    ObjectName on;
    String eventTypeToCheck;

    public AListener(AdminClient cl, NotificationFilterSupport fl, Object h,
         String eType) throws Exception
    {
        _soapClient = cl;
        myFilter = fl;
        handback = h;
        eventTypeToCheck = eType;

        Iterator iter = _soapClient.queryNames (new ObjectName("WebSphere:type=
             AppManagement,*"), null).iterator();
        on = (ObjectName)iter.next();
        System.out.println ("ObjectName: " + on);
        _soapClient.addNotificationListener (on, this, myFilter, handback);
    }

    public void handleNotification (Notification notf, Object handback)
    {
            AppNotification ev = (AppNotification) notf.getUserData();
            System.out.println ("!! JMX event Recd: (handback obj= " +
                 handback+ "): " + ev);
            //When the installation is done, remove the listener and quit

            if (ev.taskName.equals (eventTypeToCheck) &&
                (ev.taskStatus.equals (AppNotification.STATUS_COMPLETED) ||
                 ev.taskStatus.equals (AppNotification.STATUS_FAILED)))
            {
                    try
                    {
                            _soapClient.removeNotificationListener (on, this);
                    }
            catch (Throwable th)
                    {
                        System.out.println ("Error removing listener: " + th);
                    }
                    System.exit (0);
        }
    }
}
```

Deleting a module through programming

You can delete a module from an existing application through the administrative console, the wsadmin tool, or programming. Use this example to delete a module through programming.

This task assumes a basic familiarity with MBean programming. For information on MBean programming see MBean Java application programming interface (API) documentation.

Before you can delete a module from an application on WebSphere Application Server, you must first install the application.

Perform the following tasks to delete a module through programming.

1. Connect to WebSphere Application Server.
2. Create the application management proxy.
3. Create the notification filter for listening to events.
4. Add the listener.
5. Delete the module.
6. Wait for some timeout so that the program does not end.
7. Listen to Java Management Extensions (JMX) notifications to understand completion of the operation.
8. When the module is deleted, remove the listener and quit.

After you successfully run the code, the existing module is deleted from the application.

The following example shows how to delete a module from an application based on the previous steps:

```
//moduleURI specifies a URI that gives the target location of the module.
//appName specifies the name of the application to update.
String moduleURI = "Increment.jar";
String appName = "MyApp";

//Get the administrative client to connect to
//WebSphere Application Server.
AdminClient client = ...;

//Create the application management proxy.

AppManagement proxy = AppManagementProxy. getJMXProxyForClient (client);

//Create the notification filter.
  NotificationFilterSupport myFilter = new NotificationFilterSupport();
  myFilter.enableType (NotificationConstants.TYPE_APPMANAGEMENT);
  //Add the listener.
  NotificationListener listener = new AListener(_soapClient, myFilter, "Install: " + appName, AppNotification.UPDATE);
```

```
//Update the existing application, MyApp, by deleting the module.
Hashtable options = new Hashtable();
options.put (AppConstants.APPDEPL_LOCALE, Locale.getDefault());
options.put (AppConstants.APPUPDATE_CONTENTTYPE, AppConstants.APPUPDATE_CONTENT_MODULEFILE);

proxy.updateApplication ( appName,
    moduleURI,
    null,
    AppConstants.APPUPDATE_DELETE,
    options,
    null);

// Wait; the installation application programming interface (API) is
//  asynchronous and so returns immediately.
// If the program does not wait here, the program ends.
  Thread.sleep(300000); // Wait so that the program does not end.
        }
        catch (Exception e) {
            e.printStackTrace();
        }

    }

}
// Specify the Java Management Extensions (JMX) notification listener for JMX events.
class AListener implements NotificationListener
{
    AdminClient _soapClient;
    NotificationFilterSupport  myFilter;
    Object handback;
    ObjectName on;
    String eventTypeToCheck;

    public AListener(AdminClient cl, NotificationFilterSupport fl, Object h,
         String eType) throws Exception
    {
        _soapClient = cl;
        myFilter = fl;
        handback = h;
        eventTypeToCheck = eType;

        Iterator iter = _soapClient.queryNames (new ObjectName("WebSphere:
            type=AppManagement,*"), null).iterator();
        on = (ObjectName)iter.next();
        System.out.println ("ObjectName: " + on);
        _soapClient.addNotificationListener (on, this, myFilter, handback);
    }

    public void handleNotification (Notification notf, Object handback)
    {
            AppNotification ev = (AppNotification) notf.getUserData();
            System.out.println ("!! JMX event Recd: (handback obj= " +
                handback+ "): " + ev);

            //When the installation is done, remove the listener and quit

            if (ev.taskName.equals (eventTypeToCheck) &&
                (ev.taskStatus.equals (AppNotification.STATUS_COMPLETED) ||
                 ev.taskStatus.equals (AppNotification.STATUS_FAILED)))
            {
                    try
                    {
                            _soapClient.removeNotificationListener (on, this);
                    }
            catch (Throwable th)
```

```
                    {
                        System.out.println ("Error removing listener: " + th);
                    }
                    System.exit (0);
            }
        }
}
```

Adding a file through programming

You can add a file to an existing application through the administrative console, the wsadmin tool, or programming. This example describes how to add a file through programming.

This task assumes a basic familiarity with MBean programming. For information on MBean programming see MBean Java application programming interface (API) documentation.

Before you can add a file to an application on WebSphere Application Server, you must first install the application.

Perform the following tasks to add a file to an application through programming.

1. Connect to WebSphere Application Server.
2. Create the application management proxy.
3. Create the notification filter for listening to events.
4. Add the listener.
5. Add the file to the application.
6. Wait for some timeout so that the program does not end.
7. Listen to Java Management Extensions (JMX) notifications to understand completion of the operation.
8. When the file is added to the application, remove the listener and quit.

After you successfully run the code, the file is added to the application.

The following example shows how to add a file to an application based on the previous steps:

```
import java.lang.*;
import java.io.*;
import java.util.*;
import java.lang.reflect.*;
import com.ibm.websphere.management.application.*;
import com.ibm.websphere.management.application.client.*;
import com.ibm.websphere.management.*;

import javax.management.*;

public class FileAdd {

    public static void main (String [] args) {

        try {

// Get a connection to WebSphere Application Server.
  String host = "localhost";
  String port = "8880";
  String target = "WebSphere:cell=cellName,node=nodeName,server=server1";

  Properties config = new Properties();
  config.put (AdminClient.CONNECTOR_HOST,  host);
  config.put (AdminClient.CONNECTOR_PORT,  port);
  config.put (AdminClient.CONNECTOR_TYPE, AdminClient.CONNECTOR_TYPE_SOAP);
  System.out.println ("Config: " + config);
     AdminClient _soapClient = AdminClientFactory.createAdminClient(config);

 // Create the application management proxy, AppManagement.
```

```
  AppManagement proxy = AppManagementProxy. getJMXProxyForClient (_soapClient);

  String appName = "MyApp";
  String fileURI = "test.war/com/acme/abc.jsp";
  String fileContents = "C:/temp/abc.jsp";

  //Create the notification filter.
  NotificationFilterSupport myFilter = new NotificationFilterSupport();
  myFilter.enableType (NotificationConstants.TYPE_APPMANAGEMENT);

  //Add the listener.
  NotificationListener listener = new AListener(_soapClient, myFilter,
     "Install: " + appName, AppNotification.UPDATE);

  Hashtable options = new Hashtable();
  options.put (AppConstants.APPDEPL_LOCALE, Locale.getDefault());
  options.put (AppConstants.APPUPDATE_CONTENTTYPE, AppConstants.APPUPDATE_CONTENT_FILE);

  // Update the application
  proxy.updateApplication (   appName,
                 fileURI,
                 fileContents,
                 AppConstants.APPUPDATE_ADD,
                 options,
                 null);

// Wait; the installation Application Programming Interface (API) is
//  asynchronous and so returns immediately.
// If the program does not wait here, the program ends.
  Thread.sleep(90000); // Wait so that the program does not end.

        }
        catch (Exception e) {
            e.printStackTrace();
        }

    }

}

// Specify the Java Management Extensions (JMX) notification listener for JMX events.
class AListener implements NotificationListener
{
    AdminClient _soapClient;
    NotificationFilterSupport  myFilter;
    Object handback;
    ObjectName on;
    String eventTypeToCheck;

    public AListener(AdminClient cl, NotificationFilterSupport fl, Object h,
        String eType) throws Exception
    {
        _soapClient = cl;
        myFilter = fl;
        handback = h;
        eventTypeToCheck = eType;

        Iterator iter = _soapClient.queryNames (new ObjectName("WebSphere:
           type=AppManagement,*"), null).iterator();
        on = (ObjectName)iter.next();
        System.out.println ("ObjectName: " + on);
        _soapClient.addNotificationListener (on, this, myFilter, handback);
    }

    public void handleNotification (Notification notf, Object handback)
    {
            AppNotification ev = (AppNotification) notf.getUserData();
            System.out.println ("!! JMX event Recd: (handback obj= " +
                handback+ "): " + ev);

            //When the installation is done, remove the listener and quit

            if (ev.taskName.equals (eventTypeToCheck) &&
                (ev.taskStatus.equals (AppNotification.STATUS_COMPLETED) ||
                 ev.taskStatus.equals (AppNotification.STATUS_FAILED)))
            {
                    try
                    {
                            _soapClient.removeNotificationListener (on, this);
                    }
            catch (Throwable th)
                    {
                        System.out.println ("Error removing listener: " + th);
                    }
                    System.exit (0);
        }
    }
}
```

Updating a file through programming

You can update a file for an existing application through the administrative console, the wsadmin tool, or programming. This example describes how to update a file through programming.

This task assumes a basic familiarity with MBean programming. For information on MBean programming see MBean Java application programming interface (API) documentation.

Before you can update a file for an application on WebSphere Application Server, you must first install the application.

Perform the following tasks to update a file through programming.

1. Connect to WebSphere Application Server.
2. Create the application management proxy.
3. Create the notification filter for listening to events.
4. Add the listener.
5. Update the file in the application.
6. Wait for some timeout so that the program does not end.
7. Listen to Java Management Extensions (JMX) notifications to understand completion of the operation.
8. When the installation is done, remove the listener and quit.

After you successfully run the code, the file is updated for the application.

The following example shows how to add a file to an application based on the previous steps:

```
//Inputs:
//fileContents specifies the name of the file that you add to the application.
//appName specifies the name of the application.
//fileURI specifies a URI that gives the target location of the file. The URI
// provides the location of the new module after installation. The URI is
// relative to the application URL.

                            _soapClient.removeNotificationListener (on, this);
                    }
            catch (Throwable th)
                    {
                        System.out.println ("Error removing listener: " + th);
                    }
                    System.exit (0);
        }
    }
}
```

Deleting a file through programming

You can delete a file from an existing application through the administrative console, the wsadmin tool, or programming. Use this example to delete a file through programming.

This task assumes a basic familiarity with MBean programming. For information on MBean programming see MBean Java application programming interface (API) documentation.

Before you can delete a file from an application on WebSphere Application Server, you must first install the application.

Perform the following tasks to delete a file through programming.

1. Connect to WebSphere Application Server.
2. Create the application management proxy.
3. Create the notification filter for listening to events.
4. Add the listener.
5. Delete the file from the application.
6. Wait for some timeout so that the program does not end.
7. Listen to Java Management Extensions (JMX) notifications to understand completion of the operation.
8. When the file is deleted from the application, remove the listener and quit.

After you successfully run the code, the file is deleted from the application.

The following example shows how to delete a file based on the previous steps:

```
//Inputs:
//fileURI specifies a URI that gives the target location of the file. The URI
// provides the location of the new module after installation. The URI is
// relative to the application URL.
//appName specifies the name of the application.

String fileURI = "Increment.jar/com/acme/Foo.class";
String appName = "MyApp";

//Get the administrative client to connect to
//WebSphere Application Server.
AdminClient client = ...;

//Create the application management proxy.
AppManagement proxy = AppManagementProxy. getJMXProxyForClient (client);

//Create the notification filter.
  NotificationFilterSupport myFilter = new NotificationFilterSupport();
  myFilter.enableType (NotificationConstants.TYPE_APPMANAGEMENT);
  //Add the listener.
  NotificationListener listener = new AListener(_soapClient, myFilter,
      "Install: " + appName, AppNotification.UPDATE);

//Update the existing application, MyApp, by deleting the file.
Hashtable options = new Hashtable();
options.put (AppConstants.APPDEPL_LOCALE, Locale.getDefault());
options.put (AppConstants.APPUPDATE_CONTENTTYPE, AppConstants.APPUPDATE_CONTENT_FILE);

proxy.updateApplication ( appName,
    fileURI,
    null,
    AppConstants.APPUPDATE_DELETE,
    options,
    null);

// Wait for some timeout. The installation Application Programming Interface (API) is
//  asynchronous and so returns immediately.
// If the program does not wait here, the program ends.
  Thread.sleep(300000); // Wait so that the program does not end.
        }
        catch (Exception e) {
            e.printStackTrace();
        }

    }

}
// Specify the Java Management Extensions (JMX) notification listener for JMX events.
class AListener implements NotificationListener
{
    AdminClient _soapClient;
    NotificationFilterSupport  myFilter;
    Object handback;
    ObjectName on;
    String eventTypeToCheck;

    public AListener(AdminClient cl, NotificationFilterSupport fl, Object h,
         String eType) throws Exception
    {
        _soapClient = cl;
        myFilter = fl;
        handback = h;
        eventTypeToCheck = eType;

        Iterator iter = _soapClient.queryNames (new ObjectName("WebSphere:
            type=AppManagement,*"), null).iterator();
        on = (ObjectName)iter.next();
        System.out.println ("ObjectName: " + on);
        _soapClient.addNotificationListener (on, this, myFilter, handback);
    }

    public void handleNotification (Notification notf, Object handback)
    {
            AppNotification ev = (AppNotification) notf.getUserData();
            System.out.println ("!! JMX event Recd: (handback obj= " +
                 handback+ "): " + ev);

            //Once the installation is done, remove the listener and quit

            if (ev.taskName.equals (eventTypeToCheck) &&
                (ev.taskStatus.equals (AppNotification.STATUS_COMPLETED) ||
                 ev.taskStatus.equals (AppNotification.STATUS_FAILED)))
            {
                    try
                    {
```

```
                    _soapClient.removeNotificationListener (on, this);
                }
            catch (Throwable th)
                {
                    System.out.println ("Error removing listener: " + th);
                }
                System.exit (0);
        }
    }
}
```

Using command line tools

There are several command line tools that you can use to start, stop, and monitor WebSphere server processes and nodes. These tools only work on local servers and nodes. They cannot operate on a remote server or node. To administer a remote server, you can use the wsadmin scripting program connected to the deployment manager for the cell in which the target server or node is configured. See Deploying and managing using scripting for more information about using the wsadmin scripting program. You can also use the V5 administrative console which runs in the deployment manager for the cell. For more information about using the administrative console, see Deploying and managing with the GUI.

All command line tools function relative to a particular profile. If you run a command from a *install_root*/WebSphere/AppServer/bin directory, the command will run within the default profile. If you want to specify a different profile, perform one of the following:

- Specify the -profileName option. The profile that you specify with this option will be used instead of the default profile. For example:
  1. Change to the *install_root*/WebSphere/AppServer/bin directory.
  2. Type the following command: startServer *server1* -profileName *AppServerProfile*

  In this example, the command will function inside the *AppServerProfile* profile.
- Run the command from the bin directory of a specific profile. For example:
  1. Change to the *install_root*/WebSphere/AppServer/profiles/*MyProfile*/bin directory.
  2. Type the following command: startServer *server1*

  In this example, the command will function inside the *MyProfile* profile.

For more information about using profiles, including how to obtain a list of profiles, see the wasprofile command article.

To use the command line tools, perform the following steps:

1. Open a system command prompt.
2. Change to the bin directory.
3. Run the command.

The command runs the requested function and displays the results on the screen. Refer to the command log file for additional information. When you use the -trace option for the command, the additional trace data is captured in the command log file. The directory location for the log files is under the default system log root directory, except for commands related to a specific server instance, in which case the log directory for that server is used. You can override the default location for the command log file using the -logfile option for the command.

Example: Security and the command line tools

If you want to enable WebSphere Application Server security, you need to provide the command line tools with authentication information. Without authentication information, the command line tools receive an `AccessDenied` exception when you attempt to use them with security enabled. There are multiple ways to provide authentication data:

- Most command line tools support a -username and -password option for providing basic authentication data. Specify the user ID and password for an administrative user. For example, you can use a member of the administrative console users with operator or administrator privileges, or the administrative user ID configured in the user registry. The following example demonstrates the **stopNode** command, which specifies command line parameters:

  ```
  stopNode -username adminuser -password adminpw
  ```
- You can place the authentication data in a properties file that the command line tools read. The default file for this data is the `sas.client.props` file in the `properties` directory for the WebSphere Application Server.

startServer command

The **startServer** command reads the configuration file for the specified application server and starts the server. Depending on the options you specify, you can launch a new Java virtual machine (JVM) API to run the server process, or write the launch command data to a file. For more information about where to run this command, see the Using command tools article.

If you are using the Windows platform and the you have the application server running as a Windows service, the **startServer** command will start the associated Windows service and it will be responsible for starting the application server.

Syntax

The command syntax is as follows:

```
startServer <server> [options]
```

where `server` is the name of the application server you want to start. This argument is required.

Parameters

The following options are available for the **startServer** command:

-nowait
Tells the **startServer** command not to wait for successful initialization of the launched server process.

-quiet
Suppresses the progress information that the **startServer** command prints in normal mode.

-logfile <fileName>
Specifies the location of the log file to which information is written.

-profileName
Defines the profile of the Application Server process in a multi-profile installation. The -profileName option is not required for running in a single profile environment. The default for this option is the default profile.

-replacelog
Replaces the log file instead of appending to the current log.

-trace
Generates trace information to the log file for debugging purposes.

-timeout <seconds>
Specifies the waiting time before server initialization times out and returns an error.

-statusport <portNumber>
Specifies that an administrator can set the port number for server status callback.

-script [<script fileName>] -background
Generates a launch script with the **startServer** command instead of launching the server process directly. The launch script name is an optional argument. If you do not supply the launch script name, the default script file name is `start_<server>` based on the *<server>* name passed as the first argument to the **startServer** command. The `-background` parameter is an optional parameter that specifies that the generated script will run in the background when you execute it.

-J <java_option>
Specifies options to pass through to the Java interpreter.

-help
Prints a usage statement.

-? Prints a usage statement.

Usage scenario

The following examples demonstrate correct syntax:

```
startServer server1

startServer server1 -script (produces the start_server1.sh or .bat files)

startServer server1 -trace (produces the startserver.log file)
```

stopServer command

The **stopServer** command reads the configuration file for the specified server process. This command sends a Java Management Extensions (JMX) command to the server telling it to shut down. By default, the **stopServer** command does not return control to the command line until the server completes the shut down process. There is a -nowait option to return immediately, as well as other options to control the behavior of the **stopServer** command. For more information about where to run this command, see the Using command tools article.

If you are using the Windows platform and the you have the application server running as a Windows service, the **stopServer** command will start the associated Windows service and it will be responsible for starting the application server.

Syntax

The command syntax is as follows:

```
stopServer <server> [options]
```

where *server* is the name of the configuration directory of the server you want to stop. This argument is required.

Parameters

The following options are available for the **stopServer** command:

-nowait
Tells the **stopServer** command not to wait for successful shutdown of the server process.

-quiet
Suppresses the progress information that the **stopServer** command prints in normal mode.

-logfile <fileName>
Specifies the location of the log file to which information is written.

-profileName
Defines the profile of the Application Server process in a multi-profile installation. The -profileName option is not required for running in a single profile environment. The default for this option is the default profile.

-replacelog
Replaces the log file instead of appending to the current log.

-trace
Generates trace information into a file for debugging purposes.

-timeout <seconds>
Specifies the time to wait for server shutdown before timing out and returning an error.

-statusport <portNumber>
Supports an administrator in setting the port number for server status callback.

-conntype <type>
Specifies the Java Management Extensions (JMX) connector type to use for connecting to the deployment manager. Valid types are Simple Object Access Protocol (SOAP), or Remote Method Invocation (RMI).

-port <portNumber>
Specifies the server Java Management Extensions (JMX) port to use explicitly, so that you can avoid reading the configuration files to obtain the information.

-username <name>
Specifies the user name for authentication if security is enabled in the server. Acts the same as the -user option.

-user <name>
Specifies the user name for authentication if security is enabled in the server. Acts the same as the -username option.

-password <password>
Specifies the password for authentication if security is enabled in the server.

Note: If you are running in a secure environment but have not provided a user ID and password, you will receive the following error message:

```
ADMN0022E: Access denied for the stop operation on Server MBean due
to insufficient or empty credentials.
```

To solve this problem, provide the user ID and password information.

-help
Prints a usage statement.

-? Prints a usage statement.

Usage scenario

The following examples demonstrate correct syntax:

```
stopServer server1

stopServer server1 -nowait

stopServer server1 -trace (produces the stopserver.log file)
```

startManager command

The **startManager** command reads the configuration file for the Network Deployment manager process and constructs a **launch** command. Depending on the options you specify, the **startManager** command launches a new Java virtual machine (JVM) API to run the manager process, or writes the **launch** command data to a file. You must run this command from the *install_root*/WebSphere/AppServer/profiles/standalone/bin directory of a Network Deployment installation.

If you are using the Windows platform and the you have the deployment manager running as a Windows service, the **startManager** command will start the associated Windows service and it will be responsible for starting the deployment manager.

Syntax

The command syntax is as follows:

```
startManager [options]
```

Parameters

The following options are available for the **startManager** command:

-nowait
Tells the **startManager** command not to wait for successful initialization of the deployment manager process.

-quiet
Suppresses the progress information that the **startManager** command prints in normal mode.

-logfile <fileName>
Specifies the location of the log file to which information gets written.

-profileName
Defines the profile of the Application Server process in a multi-profile installation. The -profileName option is not required for running in a single profile environment. The default for this option is the default profile.

-replacelog
Replaces the log file instead of appending to the current log.

-trace
Generates trace information into a file using the **startManager** command for debugging purposes.

-timeout <seconds>
Specifies the waiting time before deployment manager initialization times out and returns an error.

-statusport <portNumber>
Specifies that an administrator can set the port number for deployment manager status callback.

-script [<script fileName>] -background
Generates a launch script with the **startManager** command instead of launching the deployment manager process directly. The launch script name is an optional argument. If you do not provide the launch script name, the default script file name is `<start_dmgr>`. The `-background` parameter is an optional parameter that specifies that the generated script will run in the background when you execute it.

-J-<java_option>
Specifies options to pass through to the Java interpreter.

-help
Prints a usage statement.

-? Prints a usage statement.

Usage scenario

The following examples demonstrate correct syntax:

```
startManager

startManager -script (produces the start_dmgr.sh or .bat file)

startManager -trace (produces the startmanager.log file)
```

stopManager command

The **stopManager** command reads the configuration file for the Network Deployment manager process. It sends a Java Management Extensions (JMX) command to the manager telling it to shut down. By default, the **stopManager** command waits for the manager to complete the shutdown process before it returns control to the command line. There is a -nowait option to return immediately, as well as other options to control the behavior of the **stopManager** command. For more information about where to run this command, see the Using command tools article.

If you are using the Windows platform and the you have the deployment manager running as a Windows service, the **stopManager** command will start the associated Windows service and it will be responsible for starting the deployment manager.

Syntax

The command syntax is as follows:

```
stopManager [options]
```

Parameters

The following options are available for the **stopManager** command:

-nowait
Tells the **stopManager** command not to wait for successful shutdown of the deployment manager process.

-quiet
Suppresses the progress information that the **stopManager** command prints in normal mode.

-logfile <fileName>
Specifies the location of the log file to which information is written.

-profileName
Defines the profile of the Application Server process in a multi-profile installation. The -profileName option is not required for running in a single profile environment. The default for this option is the default profile.

-replacelog
Replaces the log file instead of appending to the current log.

-trace
Generates trace information to a file for debugging purposes.

-timeout <seconds>
Specifies the waiting time for the manager to complete shutdown before timing out and returning an error.

-statusport <portNumber>
Specifies that an administrator can set the port number for server status callback.

-conntype <type>
Specifies the Java Management Extensions (JMX) connector type to use for connecting to the deployment manager. Valid types are Simple Object Access Protocol (SOAP) or Remote Method Invocation (RMI).

-port <portNumber>
Specifies the deployment manager JMX port to use explicitly, so that you can avoid reading the configuration files to obtain information.

-username <name>
Specifies the user name for authentication if security is enabled in the deployment manager. Acts the same as the -user option.

-user <name>
Specifies the user name for authentication if security is enabled in the deployment manager. Acts the same as the -username option.

-password <password>
Specifies the password for authentication if security is enabled in the deployment manager.

Note: If you are running in a secure environment but have not provided a user ID and password, you receive the following error message:

```
ADMN0022E: Access denied for the stop operation on Server MBean due
to insufficient or empty credentials.
```

To solve this problem, provide the user ID and password information.

-help
Prints a usage statement.

-? Prints a usage statement.

Usage scenario

The following examples demonstrate correct syntax:

```
stopManager

stopManager -nowait

stopManager -trace (produces the stopmanager.log file)
```

startNode command

The **startNode** command reads the configuration file for the node agent process and constructs a **launch** command. Depending on the options that you specify, the **startNode** command creates a new Java virtual machine (JVM) API to run the agent process, or writes the launch command data to a file. For more information about where to run this command, see the Using command tools article.

If you are using the Windows platform and the you have the node agent running as a Windows service, the **startNode** command will start the associated Windows service and it will be responsible for starting the node agent.

Syntax

The command syntax is as follows:

```
startNode [options]
```

Parameters

The following options are available for the **startNode** command:

-nowait
Tells the **startNode** command not to wait for successful initialization of the node agent process.

-quiet
Suppresses the progress information that the **startNode** command prints in normal mode.

-logfile <fileName>
Specifies the location of the log file to which information gets written.

-profileName
Defines the profile of the Application Server process in a multi-profile installation. The -profileName option is not required for running in a single profile environment. The default for this option is the default profile.

-replacelog
Replaces the log file instead of appending to the current log.

-trace
Generates trace information into a file for debugging purposes.

-timeout <seconds>
Specifies the waiting time before node agent initialization times out and returns an error.

-statusport <portNumber>
Specifies that an administrator can set the port number for node agent status callback.

-script [<script fileName>] -background
Generates a launch script with the **startNode** command instead of launching the node agent process directly. The launch script name is an optional argument. If you do not provide the launch script name, the default script file name is `start_<nodeName>`, based on the name of the node. The `-background` parameter is an optional parameter that specifies that the generated script will run in the background when you execute it.

-J-<java_option>
Specifies options to pass through to the Java interpreter.

-help
Prints a usage statement.

-? Prints a usage statement.

Usage scenario

The following examples demonstrate correct syntax:

```
startNode

startNode -script (produces the start_node.bat or .sh file)

startNode -trace (produces the startnode.log file)
```

stopNode command

The **stopNode** command reads the configuration file for the Network Deployment node agent process and sends a Java Management Extensions (JMX) command telling the node agent to shut down. By default, the **stopNode** command waits for the node agent to complete shutdown before it returns control to the command line. There is a -nowait option to return immediately, as well as other options to control the behavior of the **stopNode** command. For more information about where to run this command, see the Using command tools article.

If you are using the Windows platform and the you have the node agent running as a Windows service, the **stopNode** command will start the associated Windows service and it will be responsible for starting the node agent.

Syntax

The command syntax is as follows:

```
stopNode [options]
```

Parameters

The following options are available for the **stopNode** command:

-nowait
Tells the **stopNode** command not to wait for successful shutdown of the node agent process.

-quiet
Suppresses the progress information that the **stopNode** command prints in normal mode.

-logfile <fileNname>
Specifies the location of the log file to which information gets written.

-profileName
Defines the profile of the Application Server process in a multi-profile installation. The -profileName option is not required for running in a single profile environment. The default for this option is the default profile.

-replacelog
Replaces the log file instead of appending to the current log.

-trace
Generates trace information into a file for debugging purposes.

-timeout <seconds>
Specifies the waiting time for the agent to shut down before timing out and returning an error.

-statusport <portNumber>
Specifies that an administrator can set the port number for server status callback.

-stopservers
Stops all application servers on the node before stopping the node agent.

-conntype <type>
Specifies the Java Management Extensions (JMX) connector type to use for connecting to the deployment manager. Valid types are Simple Object Access Protocol (SOAP) or Remote Method Invocation (RMI).

-port <portNumber>
Specifies the node agent JMX port to use explicitly, so that you can avoid reading configuration files to obtain the information.

-username <name>
Specifies the user name for authentication if security is enabled in the node agent. Acts the same as the -user option.

-user <name>
Specifies the user name for authentication if security is enabled in the node agent. Acts the same as the -username option.

-password <password>
Specifies the password for authentication if security is enabled in the node agent.

Note: If you are running in a secure environment but have not provided a user ID and password, you receive the following error message:

```
ADMN0022E: Access denied for the stop operation on Server MBean due
to insufficient or empty credentials.
```

To solve this problem, provide the user ID and password information.

-help
Prints a usage statement.

Note: When requesting help for the usage statement for the **stopNode** command, a reference to the **stopServer** command displays. All of the options displayed for this usage statement apply to the **stopNode** command.

-? Prints a usage statement.

Note: When requesting help for the usage statement for the **stopNode** command, a reference to the **stopServer** command displays. All of the options displayed for this usage statement apply to the **stopNode** command.

Usage scenario

The following examples demonstrate correct syntax:

```
stopNode

stopNode -nowait

stopNode -trace (produces the stopnode.log file)
```

addNode command

The **addNode** command incorporates a WebSphere Application Server installation into a cell. For more information about where to run this command, see the Using command tools article. Depending on the size and location of the new node you incorporate into the cell, this command can take a few minutes to complete.

The node agent server is automatically started as part of the **addNode** command unless you specify the `-noagent` option. If you recycle the system that hosts an application server node, and did not set up the node agent to act as an operating system daemon, you must issue a **startNode** command to start the node agent before starting any application servers.

The following items are new in V6:

- Ports generated for the node agent are unique for all the profiles in the installation. For development purposes, you can create multiple profiles on the same installation and add them to one or more cells without worrying about ports conflicts.
- If you want to specify the ports that the node agent uses, specify it is a file with the file name passed with the -portprops option. The format of the file is key=value pairs, one on each line, with the key being the same as the port name in the serverindex.xml file.
- If you want to use a number of sequential ports, the -startingport option works the same as it does in V5.x. This means that port conflicts with other profiles will not be detected.

Syntax

The command syntax is as follows:

```
addNode dmgr_host [dmgr_port] [-conntype type] [-includeapps]
[-startingport portnumber] [-portprops qualified_filename]
[-nodeagentshortname name] [-nodegroupname name] [-includebuses name]
[-registerservice] [-servicename name] [-servicepassword password]
[-coregroupname name] [-noagent] [-statusport port] [-quiet] [-nowait]
[-logfile filename] [-replacelog] [-trace] [-username uid]
[-password pwd] [-help]
```

The dmgr_host argument is required. All of the other arguments are optional. The default port number is 8879 for the default Simple Object Access Protocol (SOAP) port of the deployment manager. SOAP is the default Java Management Extensions (JMX) connector type for the command. If you have multiple WebSphere Application Server installations or multiple profiles, the SOAP port may be different than 8879. Examine the deployment manager SystemOut.log to see the current ports in use.

Parameters

The following options are available for the **addNode** command:

-conntype <type>
Specifies the JMX connector type to use for connecting to the deployment manager. Valid types are SOAP or RMI, which stands for Remote Method Invocation.

-includeapps
By default the **addNode** command does not carry over applications from the stand-alone servers on the new node to the cell. In general, you should install applications using the deployment manager. The -includeapps option tells the **addNode** command to carry over the applications from a node. If the application already exists in the cell, a warning is printed and the application does not install in the cell.

The applications will be mapped to the server that you federated using the **addNode** command. When the **addNode** command operation completes, the applications will run on that server when the server is started. Since these applications are part of the network deployment cell, you can map them to other servers and clusters in the cell using the administrative console. See the Mapping modules to servers article for more information.

By default, during application installation, application binaries are extracted in the *install_root*/installedApps/cellName directory. After the **addNode** command, the cell name of the configuration on the node that you added changes from the base cell name to the deployment manager cell name. The application binaries are located where they were before the **addNode** command ran, for example, *install_root*/installedApps/old_cellName.

If the application was installed by explicitly specifying the location for binaries as the following example:

```
${INSTALL_ROOT}/${CELL}
```

where the variable ${CELL}, specifies the current cell name, then when the **addNode** command runs, the binaries are moved to the following directory:

```
${INSTALL_ROOT}/currentCellName
```

Federating the node to a cell using the **addNode** command does not merge any cell level configuration, including virtual host information. If the virtual host and aliases for the new cell do not match WebSphere Application Server, you cannot access the applications running on the servers. You have to manually add all the virtual host and host aliases to the new cell, using the administrative console running on the deployment manager.

-profileName
Defines the profile of the Application Server process in a multi-profile installation. The -profileName option is not required for running in a single profile environment. The default for this option is the default profile.

-user <name> or -username <name>
Specifies the user name for authentication if security is enabled. Acts the same as the -user option. The user name that you choose must be a pre-existing user name.

-nowait
Tells the **addNode** command not to wait for successful initialization of the launched node agent process.

-quiet
Suppresses the progress information that the **addNode** command prints in normal mode.

-logfile <filename>
Specifies the location of the log file to which information gets written. By default, the log file is called addNode.log and is created in the `logs` directory of the profile for the node being added.

-trace
Generates additional trace information in the log file for debugging purposes.

-replacelog
Replaces the log file instead of appending to the current log. By default, the **addNode** command appends to the existing trace file. This option causes the **addNode** command to overwrite the trace file.

-noagent
Tells the **addNode** command not to launch the node agent process for the new node.

-password <password>
Specifies the password for authentication if security is enabled. The password that you choose must be one that is associated with a pre-existing user name.

-startingport <portNumber>
Supports the specification of a port number to use as the base port number for all node agent ports created during the **addNode** command. With this support you can control which ports are defined for these servers, rather than using the default port values. The starting port number is incremented to calculate the port number for every node agent port configured during the **addNode** command.

-registerservice
(Windows only) Registers the node agent as a Windows service.

-servicename <user>
(Windows only) Use the given user name as the Windows service user.

-servicepassword <password>
(Windows password) Use the given password as the Windows service password.

-portprops <filename>
Passes the name of the file that contains key-value pairs of explicit ports that you want the new node agent to use. For example, to set your SOAP and RMI ports to 3000 and 3001, create a file with the following two lines and pass it as the parameter:

```
SOAP_CONNECTOR_ADDRESS=3000
BOOTSTRAP_ADDRESS=3001
```

-coregroupname <name>
The name of the core group in which to add this node. If you do not specify this option, the node will be added to the DefaultCoreGroup.

-nodegroupname <name>
The name of the node group in which to add this node. If you do not specify, the node is added to the DefaultNodeGroup.

-includebuses
Copies the buses from the node to be federated to the cell.

-nodeagentshortname <name>
The shortname to use for the new node agent.

-help
Prints a usage statement.

-? Prints a usage statement.

Usage scenario

The following examples demonstrate correct syntax:

```
addNode testhost 8879 (adds an Application Server to the deployment manager)

addNode deploymgr 8879 -trace (produces the addNode.log file)

addNode host25 8879 -nowait (does not wait for a node agent process)
```

where 8879 is the default port.

Best practices for adding nodes using command line tools

Use the **addNode** command to add a standalone node into a cell. The **addNode** command does the following:

- Copies the base WebSphere Application Server cell configuration to a new cell structure. This new cell structure matches the structure of deployment manager.
- Creates a new node agent definition for the node that the cell incorporates.
- Sends commands to the deployment manager to add the documents from the new node to the cell repository.
- Performs the first configuration synchronization for the new node, and verifies that this node is synchronized with the cell.
- Launches the node agent process for the new node.
- Updates the setupCmdLine.bat or setupCmdline.sh files and the wsadmin.properties file to point to the new cell.
- After federating the node, the **addNode** command backs up the `plugin-cfg.xml` file from the `<install_root>/config/cells` directory to the `config/backup/base/cells` directory. The **addNode** command regenerates a new `plugin-cfg.xml` file at the Deployment Manger and the nodeSync operation copies the files to the node level.

  For information about port numbers, see port number settings in WebSphere Application Server versions.

Tips for using the **addNode** command:

- Do not put WebSphere Application Server Jar files on the generic `CLASSPATH` variable (default class path) for the overall system.
- **Unix/Linux users:** Some Unix or Linux systems create an association between the host name of the machine and the loopback address -- 127.0.0.1 (Red Hat installations do this by default). In addition, the `/etc/nsswitch.conf` file is set up to use the `/etc/hosts` path before trying to look up the server using a name server. This setup can cause failures when trying to add or administrate nodes when the deployment manager or application server is running on the Red Hat system or an Unix/Linux system with the same setup.

  If your deployment manager or your application server run on the Red Hat system, or an Unix/Linux system with the same setup, perform the following operations to ensure that you can successfully add and administer nodes:
  - Remove the 127.0.0.1 mapping to the local host in the `/etc/hosts` path.
  - Edit the `/etc/nsswitch.conf` file so that the hosts line reads:

    ```
    hosts:  dns files
    ```
- By default, applications that are installed on the node will not copy to the cell. If you install an application after using the **addNode** command, the application will install on the cell. By specifying the `-includeapps` option, you force the **addNode** command to copy applications from the node to the cell. Applications with duplicate names will not copy to the cell.
- Cell-level documents are not merged. Any changes that you make to the standalone cell-level documents before using the **addNode** command must be repeated on the new cell. For example, virtual hosts.

serverStatus command

Use the **serverStatus** command to obtain the status of one or all of the servers configured on a node. For more information about where to run this command, see the Using command tools article.

Syntax

The command syntax is as follows:

```
serverStatus <server>|-all [options]
```

The first argument is required. The argument is either the name of the server for which status is desired, or the -all keyword which requests status for all servers defined on the node.

Parameters

The following options are available for the **serverStatus** command:

-quiet
Suppresses the progress information that the **serverStatus** command prints in normal mode.

-logfile <fileName>
Specifies the location of the log file to which information gets written.

-profileName
Defines the profile of the Application Server process in a multi-profile installation. The -profileName option is not required for running in a single profile environment. The default for this option is the default profile.

-replacelog
Replaces the log file instead of appending to the current log.

-trace
Generates trace information into a file for debugging purposes.

-username <name>
Specifies the user name for authentication if security is enabled. Acts the same as the -user option.

-user <name>
Specifies the user name for authentication if security is enabled. Acts the same as the -username option.

-password <password>
Specifies the password for authentication if security is enabled.

-help
Prints a usage statement.

-? Prints a usage statement.

Usage scenario

The following examples demonstrate correct syntax:

```
serverStatus server1

serverStatus -all (returns status for all defined servers)

serverStatus -trace (produces the serverStatus.log file)
```

removeNode command

The **removeNode** command returns a node from a Network Deployment distributed administration cell to a base WebSphere Application Server installation. For more information about where to run this command, see the Using command tools article.

The **removeNode** command only removes the node-specific configuration from the cell. This command does not uninstall any applications that were installed as the result of executing an **addNode** command. Such applications can subsequently deploy on additional servers in the Network Deployment cell. As a consequence, an **addNode** command with the -includeapps option executed after a **removeNode** command does not move the applications into the cell because they already exist from the first **addNode** command. The resulting application servers added on the node do not contain any applications. To deal with this situation, add the node and use the deployment manager to manage the applications. Add the applications to the servers on the node after it is incorporated into the cell.

The **removeNode** command does the following:

- Stops all of the running server processes in the node, including the node agent process.
- Removes the configuration documents for the node from the cell repository by sending commands to the deployment manager.
- Copies the original application server cell configuration into the active configuration.

Depending on the size and location of the new node you remove from the cell, this command can take a few minutes to complete.

Syntax

The command syntax is as follows:

```
removeNode [options]
```

All arguments are optional.

Parameters

The following options are available for the **removeNode** command:

-quiet
Suppresses the progress information that the **removeNode** command prints in normal mode.

-logfile <fileName>
Specifies the location of the log file to which information is written.

-profileName
Defines the profile of the Application Server process in a multi-profile installation. The -profileName option is not required for running in a single profile environment. The default for this option is the default profile.

-replacelog
Replaces the log file instead of appending to the current log.

-trace
Generates trace information into a file for debugging purposes.

-statusport <portNumber>
Specifies that an administrator can set the port number for the node agent status callback.

-username <name>
Specifies the user name for authentication if security is enabled. Acts the same as the -user option.

-user <name>
Specifies the user name for authentication if security is enabled. Acts the same as the -username option.

-password <password>
Specifies the password for authentication if security is enabled.

-force
Cleans up the local node configuration regardless of whether you can reach the deployment manager for cell repository cleanup. After using the `-force` parameter, you may need to use the **cleanupNode** command on the deployment manager.

-help
Prints a usage statement.

-? Prints a usage statement.

Usage scenario

The following examples demonstrate correct syntax:

```
removeNode -quiet

removeNode -trace (produces the removeNode.log file)
```

cleanupNode command

The **cleanupNode** command cleans up a node configuration from the cell repository. Only use this command to clean up a node if you have a node defined in the cell configuration, but the node no longer exists. For more information about where to run this command, see the Using command tools article.

Syntax

The command syntax is as follows:

```
cleanupNode <node name> <deploymgr host> <deploymgr port> [options]
```

where the first argument is required.

Parameters

The following options are available for the **cleanupNode** command:

-quiet
Suppresses the progress information that the **cleanupNode** command prints in normal mode.

-trace
Generates trace information into a file for debugging purposes.

-profileName
Defines the profile of the Application Server process in a multi-profile installation. The -profileName option is not required for running in a single profile environment. The default for this option is the default profile.

Usage scenario

The following examples demonstrate correct syntax:

```
cleanupNode myNode
cleanupNode myNode -trace
```

syncNode command

The **syncNode** command forces a configuration synchronization to occur between the node and the deployment manager for the cell in which the node is configured.

The node agent server runs a configuration synchronization service that keeps the node configuration synchronized with the master cell configuration. If the node agent is unable to run because of a problem in the node configuration, you can use the **syncNode** command to perform a synchronization when the deployment manager is not running in order to force the node configuration back in sync with the cell configuration.

For more information about where to run this command, see the Using command tools article.

Syntax

The command syntax is as follows:

```
syncNode <deploymgr host> <deploymgr port> [options]
```

where the `<deploymgr host>` argument is required.

Parameters

The following options are available for the **syncNode** command:

-stopservers
Tells the **syncNode** command to stop all servers on the node, including the node agent, before performing configuration synchronization with the cell.

-restart
Tells the **syncNode** command to launch the node agent process after configuration synchronization completes.

-nowait
Tells the **syncNode** command not to wait for successful initialization of the launched node agent process.

-quiet
Suppresses the progress information that the **syncNode** command prints in normal mode.

-logfile <fileName>
Specifies the location of the log file to which information gets written.

-profileName
Defines the profile of the Application Server process in a multi-profile installation. The -profileName option is not required for running in a single profile environment. The default for this option is the default profile.

-replacelog
Replaces the log file instead of appending to the current log.

-trace
Generates trace information into a file for debugging purposes.

-timeout <seconds>
Specifies the waiting time before node agent initialization times out and returns an error.

-statusport <portnumber>
Specifies that an administrator can set the port number for node agent status callback.

-username <name>
Specifies the user name for authentication if security is enabled. Acts the same as the -user option.

-user <name>
Specifies the user name for authentication if security is enabled. Acts the same as the -username option.

-password <password>
Specifies the password for authentication if security is enabled.

-conntype <type>
Specifies the Java Management Extensions (JMX) connector type to use for connecting to the deployment manager. Valid types are Simple Object Access Protocol (SOAP) or Remote Method Invocation (RMI).

-help
Prints a usage statement.

-? Prints a usage statement.

Usage scenario

The following examples demonstrate correct syntax:

```
syncNode testhost 8879

syncNode deploymgr 8879 -trace (produces the syncNode.log file)

syncNode host25 4444 -stopservers -restart (assumes that the deployment manager JMX port is 4444)
```

backupConfig command

The **backupConfig** command is a simple utility to back up the configuration of your node to a file. By default, all servers on the node stop before the backup is made so that partially synchronized information is not saved. For more information about where to run this command, see the Using command tools article. If you do not have root authority, you must specify a path for the backup file in a location where you have write permission. The backup file will be in zip format and a `.zip` extension is recommended.

Syntax

The command syntax is as follows:

```
backupConfig <backup_file> [options]
```

where *backup_file* specifies the file to which the backup is written. If you do not specify one, a unique name is generated.

Parameters

The following options are available for the **backupConfig** command:

-nostop
Tells the **backupConfig** command not to stop the servers before backing up the configuration.

-quiet
Suppresses the progress information that the **backupConfig** command prints in normal mode.

-logfile <fileName>
Specifies the location of the log file to which information gets written.

-profileName
Defines the profile of the Application Server process in a multi-profile installation. The -profileName option is not required for running in a single profile environment. The default for this option is the default profile.

-replacelog
Replaces the log file instead of appending to the current log.

-trace
Generates trace information into the log file for debugging purposes.

-username <name>
Specifies the user name for authentication if security is enabled in the server. Acts the same as the -user option.

-user <name>
Specifies the user name for authentication if security is enabled in the server. Acts the same as the -username option.

-password <password>
Specifies the password for authentication if security is enabled in the server.

-help
Prints a usage statement.

-? Prints a usage statement.

Usage scenario

The following example demonstrates correct syntax:

```
backupConfig
```

This example creates a new file that includes the current date. For example: `WebSphereConfig_2003-04-22.zip`

```
backupConfig myBackup.zip -nostop
```

This example creates a file called `myBackup.zip`, and does not stop any servers before beginning the backup process.

restoreConfig command

The **restoreConfig** command is a simple utility to restore the configuration of your node after backing up the configuration using the **backupConfig** command. By default, all servers on the node stop before the configuration restores so that a node synchronization does not occur during the restoration. If the configuration directory already exists, it is renamed before the restoration occurs. For more information about where to run this command, see the Using command tools article.

For AIX only, if you are using a logical directory for `was_install/config`, the **restoreConfig** command will not work.

Syntax

The command syntax is as follows:

```
restoreConfig <backup_file> [options]
```

where *backup_file* specifies the file to be restored. If you do not specify one, the command will not run.

Parameters

The following options are available for the **restoreConfig** command:

-nowait
Tells the **restoreConfig** command not to stop the servers before restoring the configuration.

-quiet
Suppresses the progress information that the **restoreConfig** command prints in normal mode.

-location <directory_name>
Specifies the directory where the backup file is restored. The location defaults to the `install_root/config` directory.

-logfile <fileName>
Specifies the location of the log file to which information gets written.

-profileName
Defines the profile of the Application Server process in a multi-profile installation. The -profileName option is not required for running in a single profile environment. The default for this option is the default profile.

-replacelog
Replaces the log file instead of appending to the current log.

-trace
Generates trace information into the log file for debugging purposes.

-username <name>
Specifies the user name for authentication if security is enabled in the server. Acts the same as the -user option.

-user <name>
Specifies the user name for authentication if security is enabled in the server. Acts the same as the -username option.

-password <password>
Specifies the password for authentication if security is enabled in the server.

-help
Prints a usage statement.

-? Prints a usage statement.

You can use the **restoreConfig** command to recover an application server if it fails. Perform the following steps:

1. Locate the automatic migration backup in the `install_root/temp` directory. For example: `MigrationBackup.Thu-Aug-28-10.15045-2003.zip`
2. Restore the configuration with the **restoreConfig** command. For example: `restoreConfig install_root/temp/MigrationBackup.Thu-Aug-28-10.15045-2003.zip`

Usage scenario

The following example demonstrates correct syntax:

```
restoreConfig WebSphereConfig_2003-04-22.zip
```

The following example restores the given file to the `/tmp` directory and does not stop any servers before beginning the restoration:

```
restoreConfig WebSphereConfig_2003-04-22.zip -location /tmp -nostop
```

Be aware that if you restore the configuration to a directory that is different from the directory that was backed up when you performed the **backupConfig** command, you may need to manually update some of the paths in the configuration directory.

EARExpander command

Use the **EARExpander** command to expand an enterprise archive file (EAR) into a directory to run the application in that EAR file. You can collapse a directory containing application files into a single EAR file.

You can type `EARExpander` with no arguments to learn more about its options. For more information about where to run this command, see the Using command tools article.

Syntax

The command syntax is as follows:

```
EarExpander -ear earName -operationDir dirName -operation <expand | collapse> [-expansionFlags <all|war>]
```

Parameters

The following options are available for the **EARExpander** command:

-ear
Specifies the name of the input EAR file for the expand operation or the name of the output EAR file for the collapse operation.

-operationDir
Specifies the directory where the EAR file is expanded or specifies the directory from where files are collapsed.

-operation <expand | collapse>
The `expand` value expands an EAR file into a directory structure required by the WebSphere Application Server run time. The `collapse` value creates an EAR file from an expanded directory structure.

-expansionFlags <all | war>
(Optional) The `all` value expands all files from all of the modules. The `war` value only expands the files from Web archive file (WAR) modules.

-profileName
Defines the profile of the Application Server process in a multi-profile installation. The -profileName option is not required for running in a single profile environment. The default for this option is the default profile.

Usage scenario

The following examples demonstrate correct syntax:

```
EARExpander -ear C:\WebSphere\AppServer\installableApps\DefaultApplication.ear
-operationDir  C:\MyApps -operation expand -expansionFlags war

EARExpander -ear C:\backup\DefaultApplication.ear
-operationDir C:\MyAppsDefaultApplication.ear -operation collapse
```

GenPluginCfg command

This topic describes the command-line syntax for the GenPluginCfg command. This command is used to regenerate the WebSphere Web server plug-in configuration file, plugin-cfg.xml. For more information about where to run this command, see the Using command tools article.

CAUTION:
Regenerating the plug-in configuration can overwrite manual configuration changes that you might want to preserve. Before performing this task, understand its implications as described in "Communicating with Web servers" on page 57.

To regenerate the plug-in configuration, you can either click on **Servers > Web Servers** in the administrative console, select a Web server and then click Generate Plug-in, or you can issue the following command:

```
GenPluginCfg.sh|bat
```

Both methods for regenerating the plug-in configuration create a `plugin-cfg.xml` file in ASCII format, which is the proper format for execution in a distributed environment.

You can use the -profileName option to define the profile of the Application Server process in a multi-profile installation. The -profileName option is not required for running in a single profile environment. The default for this option is the default profile.

Syntax

The command syntax is as follows:

```
GenPluginCfg [[-option.name optionValue]...]
```

When the GenPluginCfg command is issued with the option -webserver.name webservrName, wsadmin generates a plug-in configuration file for the Web server. This settings in this generated configuration file are based on the list of applications that are deployed on the Web server. When this command is issued without the option -webserver.name webservrName, the plug-in configuration file is generated based on topology.

Parameters

The following options are available for the **startServer** command:

-config.root configroot_dir
: Defaults to environment variable CONFIG_ROOT.

-profileName
: Defines the profile of the Application Server process in a multi-profile installation. The -profileName option is not required for running in a single profile environment. The default for this option is the default profile.

-cell.name cell
: Defaults to environment variable WAS_CELL.

-node.name node
: Defaults to environment variable WAS_NODE.

-webserver.name webserver1
: Required for creating plug-in configuration file for a given Web server.

-propagate yes/no
: Applicable only when the option webserver.name is specified. Defaults to no.

-cluster.name cluster1,cluster2 | ALL
: Optional list of clusters. Ignored when the option webserver.name is specified.

-server.name server1,server2
: Optional list of servers. Required for single server plug-in generation. Ignored when the option webserver.name is specified.

-output.file.name file_name
: Defaults to the configroot_dir/plugin-cfg.xml file. Ignored when the option webserver.name is specified.

-destination.root root
: Installation root of the machine configuration is used on. Ignored when the option webserver.name is specified.

-destination.operating.system windows/unix
: Operating system of the machine configuration is used on. Ignored when the option webserver.name is specified.

-debug yes/no
: Defaults to no.

-help
Prints a usage statement.

-? Prints a usage statement.

Usage scenario

To generate a plug-in configuration for all of the clusters in a cell:

```
GenPluginCfg -cell.name NetworkDeploymentCell
```

To generate a plug-in configuration for a single server:

```
GenPluginCfg -cell.name BaseApplicationServerCell -node.name appServerNode -server.name appServerName
```

To generate a plug-in configuration file for a Web server:

```
GenPluginCfg -cell.name BaseApplicationServerCell -node.name webserverNode -webserver.name webserverName
```

Chapter 5. Starting and stopping quick reference

This topic describes how to start and stop the main operations in your application serving environment. It also provides a quick guide to accessing the main tools that are provided with this product.

- Use commands to start and stop servers.

Quick reference: Issuing commands to start and stop servers

These examples are for starting and stopping the default profile on a server. Otherwise, you might need to be in the `install_root/profiles/profile_name/bin`directory to start and stop the server.

Application server

Go to the *install_root* /bin directory of a WebSphere Application Server or Network Deployment installation and run the following command. See “startServer command” on page 669 for details and variations

```
startServer server
```

where *server* is the application server that you want to start.

Stopping the servers

Use the same command as to start, except substitute stop for start. For example, to stop an application server, issue the command:

```
stopServer server
```

- Use administrative clients and tools.

Quick reference: Opening the administrative console

To open the console, enter this Web address in your Web browser:

```
http://your_fully_qualified_server_name:9060/ibm/console
```

Depending on your configuration, your Web address might differ. Other factors can affect your ability to access the console. See “Starting and stopping the administrative console” on page 171 for details, as needed.

  - To launch a scripting client, see “Starting the wsadmin scripting client” on page 250.
  - To learn about all available administrative clients, see Chapter 4, “Using the administrative clients,” on page 171.
  - For performance monitoring, see ″Monitoring performance with Tivoli Performance Viewer (TPV)″ in the information center.

  See the administrator commands that are listed in the **Reference** section of the information center.

- Use development and deployment tools. Use the following tools to edit deployment descriptors. A deployment descriptor is an Extensible Markup Language (XML) file that describes how to deploy a module or application by specifying configuration and container options. The tools are available for use on distributed operating systems.

  Assembly tools

  The assembly tools and Rational Web Developer provide a graphical interface for developing code artifacts, assembling the code artifacts into various archives (modules), and configuring related Java 2 Platform, Enterprise Edition (J2EE) Version 1.2, 1.3 or 1.4-compliant deployment descriptors.

  See ″Starting an assembly tool″ in the information center.

  Application Client Resource Configuration Tool (ACRCT)

  Use the ACRCT to configure deployment descriptors for client applications. See “Deploying J2EE application clients on workstation platforms” on page 874.

Text editor

It is not recommended because it has no built-in error checking or validation, but you can edit deployment descriptors with any text editor with which you can edit XML files.

- Use installation and customization tools. Use the following tools to find planning information, start the product installation, and perform customization and other activities after installation.

  Launchpad

  A graphical interface for launching the product installation. It also provides links to information you might need for installation.

  See ″Using the launchpad to start the installation″ in the information center.

  First Steps

  A desktop GUI from which you can start or stop the Application Server. It also provides access to the administrative console.

  See “firststeps command” on page 33.

  Profile creation tool

  The installation places the product binary files on a machine and creates a default profile.

- Use troubleshooting tools - see ″Working with troubleshooting tools″ in the information center.

Chapter 6. Class loading

Class loaders are part of the Java virtual machine (JVM) code and are responsible for finding and loading class files. Class loaders enable applications that are deployed on servers to access repositories of available classes and resources. Application developers and deployers must consider the location of class and resource files, and the class loaders used to access those files, to make the files available to deployed applications. Class loaders affect the packaging of applications and the run-time behavior of packaged applications of deployed applications.

This article describes how to configure class loaders for application files or modules that are installed on an application server.

To better understand class loaders in WebSphere Application Server, read “Class loaders.” The article “Class loading: Resources for learning” on page 702 refers to additional sources.

Configure class loaders for application files or modules that are installed on an application server using the administrative console. You configure class loaders to ensure that deployed application files and modules can access the classes and resources that they need to run successfully.

1. If an installed application module uses a resource, create a resource provider that specifies the directory name of the resource drivers. Do not specify the resource Java archive (JAR) file names. All JAR files in the specified directory are added into the class path of the WebSphere Application Server extensions class loader. If a resource driver requires a native library (.DLL or .so file), specify the name of the directory that contains the library in the native path of the resource configuration.
2. Specify class-loader values for an application server.
3. Specify class-loader values for an installed enterprise application.
4. Specify the class-loader mode for an installed Web module.
5. If your deployed application uses shared library files, associate the shared library files with your application. Use a library reference to associate a shared library file with your application.
   a. If you have not done so already, define a shared library instance for each library file that your applications need.
   b. Define a library reference instance for each shared library that your application uses.
6. **Optional:** Configure class preloading.

Class loaders

Class loaders are part of the Java virtual machine (JVM) code and are responsible for finding and loading class files. Class loaders enable applications that are deployed on servers to access repositories of available classes and resources. Application developers and deployers must consider the location of class and resource files, and the class loaders used to access those files, to make the files available to deployed applications.

The run-time environment of WebSphere Application Server uses the following class loaders to find and load new classes for an application in the following order:

1. The bootstrap, extensions, and CLASSPATH class loaders created by the Java virtual machine

   The bootstrap class loader uses the boot class path (typically classes in `jre/lib`) to find and load classes. The extensions class loader uses the system property java.ext.dirs (typically `jre/lib/ext`) to find and load classes. The CLASSPATH class loader uses the CLASSPATH environment variable to find and load classes.

   The CLASSPATH class loader contains the Java 2 Platform, Enterprise Edition (J2EE) application programming interfaces (APIs) of the WebSphere Application Server product in the `j2ee.jar` file. Because the J2EE APIs are in this class loader, you can add libraries that depend on the J2EE APIs to the class path system property to extend a server class path. However, a preferred method of extending a server class path is to add a shared library.

2. A WebSphere-specific extensions class loader

   The WebSphere Application Server extensions class loader loads the WebSphere Application Server run-time and J2EE classes that are required at run time. The extensions class loader uses a ws.ext.dirs system property to determine the path that is used to load classes. Each directory in the `ws.ext.dirs` class path and every Java archive (JAR) file or ZIP file in these directories is added to the class path used by this class loader.

   The WebSphere Application Server extensions class loader also loads resource provider classes into a server if an application module installed on the server refers to a resource that is associated with the provider and if the provider specifies the directory name of the resource drivers.
3. One or more application module class loaders that load elements of enterprise applications running in the server

   The application elements can be Web modules, enterprise bean (EJB) modules, resource adapters archives (RAR files), and dependency JAR files. Application class loaders follow J2EE class-loading rules to load classes and JAR files from an enterprise application. The WebSphere Application Server run time enables you to associate a shared library class path with an application.

Each class loader is a child of the previous class loader. That is, the application module class loaders are children of the WebSphere-specific extensions class loader, which is a child of the CLASSPATH Java class loader. Whenever a class needs to be loaded, the class loader usually delegates the request to its parent class loader. If none of the parent class loaders can find the class, the original class loader attempts to load the class. Requests can only go to a parent class loader; they cannot go to a child class loader. If the WebSphere Application Server class loader is requested to find a class in a J2EE module, it cannot go to the application module class loader to find that class and a ClassNotFoundException error occurs. After a class is loaded by a class loader, any new classes that it tries to load reuse the same class loader or go up the precedence list until the class is found.

Class preloading

The first time that a WebSphere Application Server process starts, the name of each run-time class that is loaded and the name of the JAR file that contains the class are written to a preload file. The names of non-runtime classes such as custom services, resource classes such as `db2java.zip`, classes on the JVM class path, and application classes are not written to the preload file. Subsequent startups of the process use the preload file to start the process more quickly.

Preload files have the `.preload` extension. WebSphere Application Server processes that have preload files include the following:

Process	Preload file name
Application server	*`cell_name.node_name.server_name`*`.preload`
`startserver`	`WsServerLauncher.preload`
`launchClient`	`launchClient.preload`

Running the `startserver server1` command causes the `startserver` command to use a `WsServerLauncher.preload` file and the server to use a *`cell_name.node_name`*`.server1.preload` file. Later, running a command such as `startserver server1 -script`, where the -script option creates a new script, uses the *`cell_name.node_name`*`.server1.preload` file only.

Preload files, by default, are installed in the *`install_root`* directory.

New classes required during the startup of a process are added to the preload file. Any classes that are removed from a process are ignored during subsequent startups. Although it is not necessary, an administrator can delete the preload file and force a refresh that removes the ignored classes from the file.

Class-loader isolation policies

The number and function of the application module class loaders depend on the class-loader policies that are specified in the server configuration. Class loaders provide multiple options for isolating applications and modules to enable different application packaging schemes to run on an application server.

Two class-loader policies control the isolation of applications and modules:

Application class-loader policy

Application class loaders consist of EJB modules, dependency JAR files, resource adapters, and shared libraries. Depending on the application class-loader policy, an application class loader can be shared by multiple applications (Single) or unique for each application (Multiple). The application class-loader policy controls the isolation of applications that are running in the system. When set to `Single`, applications are not isolated. When set to `Multiple`, applications are isolated from each other.

WAR class-loader policy

By default, Web module class loaders load the contents of the `WEB-INF/classes` and `WEB-INF/lib` directories. The application class loader is the parent of the Web module class loader. You can change the default behavior by changing the Web application archive (WAR) class-loader policy of the application.

The WAR class-loader policy controls the isolation of Web modules. If this policy is set to `Application`, then the Web module contents also are loaded by the application class loader (in addition to the EJB files, RAR files, dependency JAR files, and shared libraries). If the policy is set to `Module`, then each Web module receives its own class loader whose parent is the application class loader.

Note: WebSphere Application Server class loaders never load application client modules.

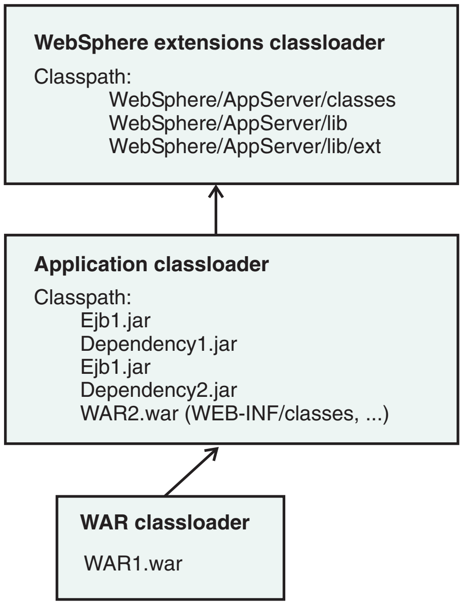
For each application server in the system, you can set the application class-loader policy to `Single` or `Multiple`. When the application class-loader policy is set to `Single`, then a single application class loader loads all EJB modules, dependency JAR files, and shared libraries in the system. When the application class-loader policy is set to `Multiple`, then each application receives its own class loader that is used for loading the EJB modules, dependency JAR files, and shared libraries for that application.

This application class loader can load the Web modules for each application if the class-loader policy of that WAR module is also set to `Application`. If the class-loader policy of the WAR module is set to `Application`, then the application loader loads the WAR module classes. If the WAR class-loader policy is set to `Module`, then each WAR module receives its own class loader.

The following example shows that when the application class-loader policy is set to `Single`, a single application class loader loads all of the EJB modules, dependency JAR files, and shared libraries of all applications on the server. The single application class loader can also load Web modules if an application has its WAR class-loader policy set to `Application`. Applications that have a WAR class-loader policy set to `Module` use a separate class loader for Web modules.

```
Application class-loader policy: Single

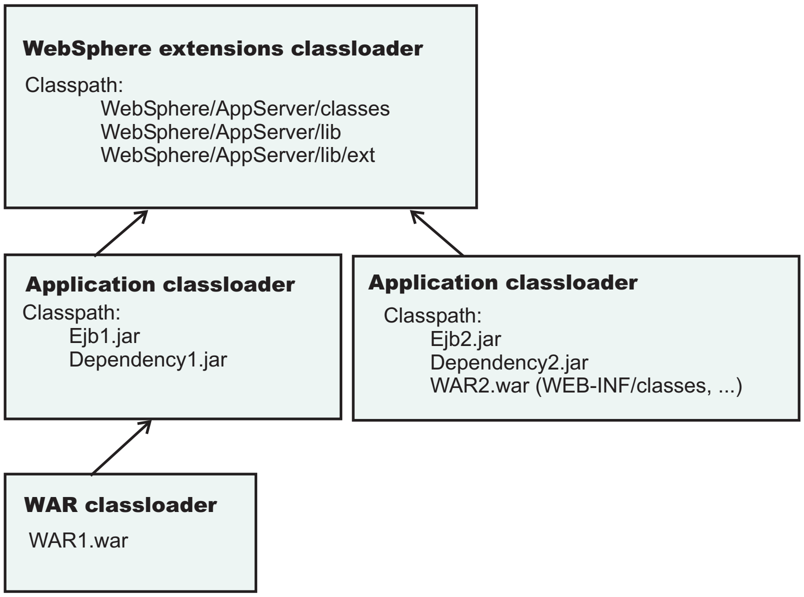
Application 1
 Module:  EJB1.jar
 Module: WAR1.war
   MANIFEST Class-Path: Dependency1.jar
  WAR Classloader Policy = Module
Application 2
 Module:   EJB2.jar
  MANIFEST Class-Path: Dependency2.jar
 Module: WAR2.war
  WAR Classloader Policy = Application
```



The following example shows that when the application class-loader policy of an application server is set to `Multiple`, each application on the server has its own class loader. An application class loader also loads its Web modules if the application WAR class-loader policy is set to `Application`. If the policy is set to `Module`, then a Web module uses its own class loader.

```
Application class-loader policy: Multiple

Application 1
 Module:  EJB1.jar
 Module: WAR1.war
  MANIFEST Class-Path: Dependency1.jar
  WAR Classloader Policy = Module
Application 2
 Module:   EJB2.jar
  MANIFEST Class-Path: Dependency2.jar
 Module: WAR2.war
  WAR Classloader Policy = Application
```



Class-loader modes

Two values for a class-loader mode are supported:

Parent First
The `Parent First` class-loader mode causes the class loader to delegate the loading of classes to its parent class loader before attempting to load the class from its local class path. This value is the default for the class-loader policy and for standard JVM class loaders.

Parent Last
The `Parent Last` class-loader mode causes the class loader to attempt to load classes from its local class path before delegating the class loading to its parent. Using this policy, an application class loader can override and provide its own version of a class that exists in the parent class loader.

The following settings determine the mode of a class loader:

- If the application class-loader policy of an application server is `Single`, the application class-loader policy of an application server defines the mode for an application class loader.
- If the application class-loader policy of an application server is `Multiple`, the class-loader mode of an application defines the mode for an application class loader.
- If the WAR class-loader policy of an application is `Module`, the WAR class-loader policy of a Web module defines the mode for a WAR class loader.

Configuring class loaders of a server

You can configure the application class loaders for an application server. Class loaders enable applications that are deployed on the application server to access repositories of available classes and resources.

This article assumes that an administrator created an application server on a WebSphere Application Server product.

Configure the class loaders of an application server to set class-loader policy and mode values which affect all applications that are deployed on the server. Use the administrative console to configure the class loaders.

1. Click **Servers > Application Servers >***server_name* to access the settings page for an application server.
2. Specify the application class-loader policy for the application server. The application class-loader policy controls the isolation of applications that run in the system (on the server). An application class loader groups enterprise bean (EJB) modules, shared libraries, resource adapter archives (RAR files), and dependency Java archive (JAR) files associated to an application. Dependency JAR files are JAR files that contain code which can be used by both enterprise beans and servlets. The application class-loader policy controls whether an application class loader can be shared by multiple applications or is unique for each application. Use the settings page for the application server to specify the application class-loader policy for the server:

Option	Description
Single	Applications are not isolated from each other. Uses a single application class loader to load all of the EJB modules, shared libraries, and dependency JAR files in the system.
Multiple	Applications are isolated from each other. Gives each application its own class loader to load the EJB modules, shared libraries, and dependency JAR files of that application.

3. Specify the application class-loader mode for the application server. The application class loading mode specifies the class-loader mode when the application class-loader policy is `Single`. On the settings page for the application server, select either of the following values:

Option	Description
Parent first	Causes the class loader to delegate the loading of classes to its parent class loader before attempting to load the class from its local class path. `Parent first` is the default value for class loading mode.
Parent last	Causes the class loader to attempt to load classes from its local class path before delegating the class loading to its parent. Using this policy, an application class loader can override and provide its own version of a class that exists in the parent class loader.

4. Specify the class-loader mode for the class loader.
   a. On the settings page for the application server, click **Java and Process Management > Class loader** to access the Class loader page.
   b. On the Class loader page, click **New** to access the settings page for a class loader.
   c. On the settings page for a class loader, specify the class-loader mode. The `Parent First` value causes the class loader to delegate the loading of classes to its parent class loader before attempting to load the class from its local class path. The `Parent Last` value causes the class loader to attempt to load classes from its local class path before delegating the class loading to its parent.
   d. Click **OK**.

   An identifier is assigned to a class-loader instance. The instance is added to the collection of class loaders shown on the Class loader page.

Save the changes to the administrative configuration.

Class loader collection

Use this page to manage class-loader instances on an application server. A class loader determines whether an application class loader or a parent class loader finds and loads Java class files for an application.

To view this administrative console page, click **Servers > Application Servers >***server_name* **> Java and Process Management > Class loader**.

Class loader ID

Provides a string that is unique to the server identifying the class-loader instance. The product assigns the identifier.

Class loader mode

Specifies the class-loader mode when the application class-loader policy for the application server is `Single`.

You specify a policy of `Single` on the settings page for the application server, accessed by clicking **Servers > Application Servers >***server_name*. When the policy is `Single`, applications are not isolated from each other. A single application class loader contains all of the EJB modules, dependency JAR files, and shared libraries in the system.

The `Parent First` value causes the class loader to delegate the loading of classes to its parent class loader before attempting to load the class from its local class path. The `Parent Last` value causes the class loader to attempt to load classes from its local class path before delegating the class loading to its parent. Specifying the `Parent Last` value enables an application class loader to override and provide its own version of a class that exists in the parent class loader.

Class loader settings

Use this page to configure a class loader for applications that reside on an application server.

To view this administrative console page, click **Servers > Application Servers >***server_name* **> Java and Process Management > Class loader >***class_loader_ID*.

Class loader ID

Provides a string that is unique to the server identifying the class-loader instance. The product assigns the identifier.

Data type	String

Class loader mode

Specifies the class-loader mode when the application class-loader policy for the application server is `Single`.

You specify a policy of `Single` on the settings page for the application server, accessed by clicking **Servers > Application Servers >***server_name*. When the policy is `Single`, applications are not isolated from each other. A single application class loader contains all of the EJB modules, dependency JAR files, and shared libraries in the system.

The `Parent First` value causes the class loader to delegate the loading of classes to its parent class loader before attempting to load the class from its local class path.

The `Parent Last` value causes the class loader to attempt to load classes from its local class path before delegating the class loading to its parent. Specifying the `Parent Last` value enables an application class loader to override and provide its own version of a class that exists in the parent class loader.

Data type	String
Default	Parent First

Configuring application class loaders

You can set values that control the class-loading behavior of an installed enterprise application. Class loaders enable an application to access repositories of available classes and resources.

This article assumes that you installed an application on an application server.

Configure the class loaders of an enterprise application to set class-loader policy and mode values for this application.

An application class loader groups enterprise bean (EJB) modules, shared libraries, resource adapter archives (RAR files), and dependency Java archive (JAR) files associated to an application. Dependency JAR files are JAR files that contain code which can be used by both enterprise beans and servlets.

An application class loader is the parent of a Web application archive (WAR) class loader. By default, a Web module has its own WAR class loader to load the contents of the Web module. The WAR class-loader policy value of an application class loader determines whether the WAR class loader or the application class loader is used to load the contents of the Web module.

Use the administrative console to configure the class loaders.

1. Click **Applications > Enterprise Applications >***application_name* to access the settings page for an enterprise application.

2. Specify the class-loader mode for the application. The application class-loader mode specifies whether the class loader searches in the parent class loader or in the application class loader first to load a class. The default is to search in the parent class loader before searching in the application class loader to load a class. Select either of the following values for **Class loader mode**:

Option	Description
Parent First	Causes the class loader to search in the parent class loader first to load a class. This value is the standard for Development Kit class loaders and WebSphere Application Server class loaders.
Parent Last	Causes the class loader to search in the application class loader first to load a class. By specifying `Parent Last`, your application can override classes contained in the parent class loader. **Tip:** Specifying the `Parent Last` value might result in LinkageErrors or ClassCastException messages if you have mixed use of overridden classes and non-overridden classes.

3. Specify whether to use a single or multiple class loaders to load Web application archives (WAR files) of your application. By default, Web modules have their own WAR class loader to load the contents of the `WEB-INF/classes` and `WEB-INF/lib` directories. The default WAR class loader value is `Module`, which uses a separate class loader to load each WAR file. Setting the value to `Application` causes the application class loader to load the Web module contents as well as the EJB modules, shared libraries, RAR files, and dependency JAR files associated to the application. The application class loader is the parent of the WAR class loader. Select either of the following values for **WAR class loader policy**:

Option	Description
Module	Uses a different class loader for each WAR file.
Application	Uses a single class loader to load all of the WAR files in your application.

4. Specify whether to enable class reloading when application files are updated. By default, class reloading is not enabled. See the description for **Enable class reloading** in “Enterprise application settings” on page 723 for details on enabling and disabling reloading. You might specify different values for EJB modules and for Web modules such as servlets and JavaServer page (JSP) files.
5. Specify the number of seconds to scan the application’s file system for updated files. The value specified for **Reloading interval** takes effect only if class reloading is enabled. The default is the value of the reloading interval attribute in the IBM extension (`META-INF/ibm-application-ext.xmi`) file of the enterprise application (EAR file). You might specify different values for EJB modules and for Web modules such as servlets and JSP files.

   To enable reloading, specify an integer value that is greater than zero (for example, 1 to 2147483647).

   To disable reloading, specify zero (0).
6. Click **OK**.

Save the changes to the administrative configuration.

Configuring Web module class loaders

You can set values that control the class-loading behavior of an installed Web module.

This article assumes that you installed a Web module on an application server.

Configure the class-loader mode value of an installed Web module. By default, a Web module has its own Web application archive (WAR) class loader to load the contents of the Web module, which are in the `WEB-INF/classes` and `WEB-INF/lib` directories.

An application class loader is the parent of a WAR class loader. The WAR class-loader policy value of an application class loader determines whether the WAR class loader or the application class loader is used to load the contents of the Web module. The default WAR class loader policy value is `Module`. If the policy is set to `Module`, then each Web module receives its own class loader whose parent is the application class loader. If the policy is set to `Application` on the settings page of an enterprise application, then the application class loader loads the Web module contents as well as the enterprise bean (EJB) modules, shared libraries, resource adapter archives (RAR files), and dependency Java archive (JAR) files associated to an application. Thus, the configuration of the parent application class loader affects the WAR class loader.

Use the administrative console to configure the application and WAR class loaders.

1. If you have not done so already, configure the application class loader. Settings such as **WAR class loader policy**, **Enable class reloading**, and **Reloading interval** can affect Web module class loading. If **WAR class loader policy** is set to `Module`, then the Web module receives its own class loader and the WAR class-loader policy of the Web module defines the mode for a WAR class loader. If the policy is set to `Application`, then the application class loader loads the Web module contents.
2. Click **Applications** > **Enterprise Application** >*application_name* > **Web modules** >*Web_module_name* to access the settings page for a deployed Web module.
3. Specify the class-loader mode for the installed Web module. The Web module class-loader mode specifies whether the class loader searches in the parent application class loader or in the WAR class loader first to load a class. The default is to search in the parent application class loader before searching in the WAR class loader to load a class. Select either of the following values for **Class loader mode**:

Option	Description
Parent first	Causes the class loader to search in the parent application class loader first to load a class. This is the standard for Development Kit class loaders and WebSphere Application Server class loaders. **Tip:** If classes and resources needed by the Web module cannot be accessed by the application class loader, but can be accessed by the WAR class loader, specify `Parent last`. If the application class loader cannot find a class, the class loader delegates the request to find the class to its parent, the WebSphere Application Server extensions class loader. If the WebSphere Application Server extensions class loader cannot find the class, the class loader delegates the request to its parent, the bootstrap, extensions, and CLASSPATH class loaders created by the Java virtual machine. Requests can only go to a parent class loader; they cannot go to a child class loader. Thus, if `Parent first` is specified, the WAR class loader never receives a request to load a class.
Parent last	Causes the class loader to search in the WAR class loader first to load a class. By specifying `Parent last`, your WAR class loader can override classes contained in the parent application class loader. **Tip:** Specifying the `Parent last` value might result in LinkageErrors or ClassCastException messages if you have mixed use of overridden classes and non-overridden classes.

4. Click **OK**.

Save the changes to the administrative configuration.

Configuring class preloading

Class preloading affects how quickly a WebSphere Application Server process starts.

The first time that a WebSphere Application Server process starts up, the name of each class that is loaded and the name of the JAR file that contains the class are written to a preload file. Subsequent startups of the process use the preload file to start the process more quickly.

No configuring of class preloading is necessary.

However, an administrator can disable or enable preloading explicitly. By default, class preloading is enabled for WebSphere Application Server processes. To change the configuration for class preloading, an administrator sets new values for system properties.

- Disable class preloading. Set the Java virtual machine (JVM) system property ibm.websphere.preload.classes to `false`.
  1. In the administrative console, click **Servers > Application Servers >***server_name* **> Java and Process Management > Process Definition > Java Virtual Machine** to access the Java Virtual Machine page.
  2. On the Java Virtual Machine page, specify `-Dibm.websphere.preload.classes=false` for **Generic JVM arguments**.
  3. Click **OK**.
  4. Save your administrative configuration.
  5. Stop the application server and then restart the application server.
- Enable class preloading again. If you disabled class preloading, you can enable it again by doing either of the following:
  – Set the JVM system property to `true`. On the Java Virtual Machine page, specify `-Dibm.websphere.preload.classes=true` for **Generic JVM arguments**.
  – Remove the JVM system property that was created to disable class preloading. On the Java Virtual Machine page, remove the value `-Dibm.websphere.preload.classes=false` specified for **Generic JVM arguments**.

  After you change the JVM system property, click **OK**, save your administrative configuration, stop the application server, and then restart the application server.
- Regenerate a class preload file. Delete the `.preload` file for the WebSphere Application Server process. When the process next starts up, a new class preload file is generated for the process.

Class loading: Resources for learning

Use the following links to find relevant supplemental information about class loaders. The information resides on IBM and non-IBM Internet sites, whose sponsors control the technical accuracy of the information.

These links are provided for convenience. Often, the information is not specific to the IBM WebSphere Application Server product, but is useful all or in part for understanding the product. When possible, links are provided to technical papers and Redbooks that supplement the broad coverage of the release documentation with in-depth examinations of particular product areas.

Refer to the information center for links to information applicable to WebSphere Application Server generally, such as lists of IBM technical papers, Redbooks and samples.

For current information available from IBM Support on known problems and their resolution, see the IBM Support page. IBM Support has documents that can save you time gathering information that is needed to resolve this problem. Before opening a PMR, see the IBM Support page.

Chapter 7. Deploying and administering applications

Deploying an application file consists of installing the application file on a server configured to hold installable modules.

Before installing an enterprise application or other installable module on an application server, you must develop and assemble the module and configure the target server. Before choosing a server as a target for the module, ensure that the node version for the server is compatible with your module

During installation, you can configure the module enough to enable it to run on the server. After installation, you can configure the module further, start or stop the application, and otherwise manage its activity.

- Install application files on an application server.
- Edit the administrative configuration for an application.
- Start and stop the application.
- Export applications.
- Export DDL files.
- Update an application or module.
- Uninstall applications.
- Remove a file from an application or module.

After making changes to administrative configurations of your applications in the administrative console, ensure that you save the changes.

Enterprise (J2EE) applications

Enterprise applications (or J2EE applications) are applications that conform to the Java 2 Platform, Enterprise Edition, specification.

Enterprise applications can consist of the following:

- Zero or more EJB modules
- Zero or more Web modules
- Zero or more connector modules (packaged in RAR files)
- Zero or more application client modules
- Additional JAR files containing dependent classes or other components required by the application
- Any combination of the above

A J2EE application is represented by, and packaged in, an enterprise archive (EAR) file.

System applications

A *system application* is a J2EE enterprise application that is central to a WebSphere Application Server product.

Examples of system applications include *adminconsole* and *filetransfer*.

Because a system application is an important part of a WebSphere Application Server product, a system application is deployed when the product is installed and is updated only through a product fix or upgrade. Users cannot change the metadata for a system application such as its J2EE bindings or J2EE extensions, unless the metadata assigns users and groups for security purposes. Non-security related metadata requiring a change must be updated through a product fix or upgrade.

System applications are not shown in the list of installed applications on the console Enterprise Applications page, or through wsadmin and Java application programming interfaces, to prevent users from accidentally stopping, updating or removing the system applications.

Note that J2EE Samples are not system applications even though they are provided as part of a WebSphere Application Server product. Similarly, applications that support changes to their metadata are not system applications.

Installing application files

As part of deploying an application, you install application files on a server configured to hold installable modules.

Before you can install your application files on an application server, you must configure the target application server. As part of configuring the server, determine whether your application files can be installed to your deployment targets.

Also, before you install the files, assemble modules as needed.

Installable modules include enterprise archive (EAR), enterprise bean (EJB), Web archive (WAR), and resource adapter (connector or RAR) files. Complete the following steps to install your files.

1. Determine which method to use to install your application files. WebSphere Application Server provides several ways to install modules.
2. Install the application files using
   - Administrative console
   - wsadmin scripts
   - Java administrative programs that use JMX APIs
   - Java programs that define a J2EE DeploymentManager object in accordance with J2EE Deployment API Specification (JSR-88)
3. Start the deployed application files using
   - Administrative console
   - wsadmin startApplication
   - Java programs that use ApplicationManager or AppManagement MBeans
   - Java programs that define a J2EE DeploymentManager object in accordance with J2EE Deployment API Specification (JSR-88)

Save the changes to your administrative configuration.

Next, test the application. For example, point a Web browser at the URL for a deployed application and examine the performance of the application. If the application does not perform as desired, update the application, then save and test it again.

Installable module versions

The contents of a module affect whether you can install the module on a WebSphere Application Server Version 6.0 and later (6.x) deployment target, or must install the module on a Version 5.0 and later (5.x) deployment target.

Installable application modules

You can install an application, enterprise bean (EJB) module or Web module developed for a Version 5.x product on a 5.x or 6.x deployment target, provided the module--

- Does not support Java 2 Platform, Enterprise Edition (J2EE) 1.4;
- Does not call any 6.x runtime application programming interfaces (APIs); and
- Does not use any 6.x product features.

If the module supports J2EE 1.4, calls a 6.x API or uses a 6.x feature, then you must install the module on a 6.x deployment target.

Selecting options such as **Pre-compile JSP**, **Use Binary Configuration**, **Deploy Web services** or **Deploy enterprise beans** during application installation to a 6.x server or a 6.x deployment manager indicates that the application uses 6.x product features. You cannot deploy such applications on a 5.x deployment target. You must deploy such applications on a 6.x deployment target.

Similarly, you must deploy an application that uses J2EE 1.4 features such as Java Authorization Contract for Containers (JACC) provided by an application server on a 6.x deployment target.

Installable RAR files

You can install a standalone resource adapter (connector) module, or RAR file, developed for a Version 5.x product to a 5.x or 6.x deployment target, provided the module does not call any 6.x runtime APIs. If the module calls a 6.x API, then you must install the module on a 6.x deployment target.

Deployment targets

A *5.x deployment target* is a server on a WebSphere Application Server Version 5 product.

A *6.x deployment target* is a server on a WebSphere Application Server Version 6 product.

Table 6. Compatible deployment target versions for 5.x and 6.x modules

Module type	Module Java support	Module calls 6.x runtime APIs or uses 6.x features?	Client versions that can install module	Deployment target versions
Application, EJB, Web, or client	J2EE 1.3	No	5.x or 6.x	5.x or 6.x
Application, EJB, Web, or client	J2EE 1.3	Yes	6.x	6.x
Application, EJB, Web, or client	J2EE 1.4	Yes or No	6.x	6.x
Resource adapter	JCA 1.0	No	5.x or 6.x	5.x or 6.x
Resource adapter	JCA 1.0	Yes	6.x	6.x
Resource adapter	JCA 1.5	Yes or No	6.x	6.x

Ways to install applications or modules

WebSphere Application Server provides several ways to install application files on a server.

Installable files include enterprise archive (EAR), enterprise bean (EJB), Web archive (WAR), resource adapter (connector or RAR), and application client modules.

Table 7. Ways to install application files

Option	Method	Modules	Comments	Starting after install

Table 7. Ways to install application files (continued)

Administrative console install wizard See “Installing application files with the console” on page 709.	Click **Applications > Install New Application** in the console navigation tree and follow instructions in the wizard.	All EAR, EJB, WAR, RAR, and application client files	Provides one of the easier ways to install application files. See “Preparing for application installation settings” on page 714 for guidance. For applications that do not require changes to the default bindings, select the **Generate Default Bindings** option and then, on the Summary panel, click **Finish**.	Click **Start** on the Enterprise Applications page accessed by clicking **Applications > Enterprise Applications** in the console navigation tree.
wsadmin scripts	Invoke AdminApp object *install* commands in a script or at a command prompt.	All EAR, EJB, WAR, RAR, and application client files	″Getting started with scripting″ in the information center provides an overview of wsadmin.	• Invoke the AdminApp *startApplication* command. • Invoke the *startApplication* method on an ApplicationManager MBean using AdminControl. .
Java application programming interfaces	Install programs by completing the steps in ″Managing applications through programming″ in the information center.	All EAR files	Use MBeans to install the application.	Start the application by calling the *startApplication* method on a proxy.
WebSphere rapid deployment Refer to articles under **Rapid deployment of J2EE applications** in the information center.	Briefly, do the following: 1. Update your J2EE application files. 2. Set up the rapid deployment environment. 3. Create a free-form project. 4. Launch a rapid deployment session. 5. Drop your updated application files into the free-form project.	All J2EE modules, including EAR files and standalone EJB, WAR, RAR, and application client files	WebSphere rapid deployment offers the following advantages: • You do not need to assemble your J2EE application files prior to deployment. • You do not need to use other installation tools mentioned in this table to deploy the files.	Use any of the above options to start the application. Clicking **Start** on the Enterprise Applications page is the easiest option.

Table 7. Ways to install application files (continued)

Java programs	Code programs that use J2EE DeploymentManager (JSR-88) methods.	All J2EE modules, including EAR files and standalone EJB, WAR, RAR, and application client files	• Uses J2EE Application Deployment Specification (JSR-88). • Can customize modules using DConfigBeans.	Call the J2EE DeploymentManager (JSR-88) method *start* in a program to start the deployed modules when the module's running environment initializes.

Installing application files with the console

Installing application files consists of placing assembled enterprise application, Web, enterprise bean (EJB), or other installable modules on a server or cluster configured to hold the files. Installed files that start and run properly are considered *deployed*.

Before installing enterprise application files, ensure that you are installing your application files onto a compatible deployment target. If the deployment target is not compatible, select a different target.

To install new enterprise application files to a WebSphere Application Server configuration, you can use the administrative console, the wsadmin tool, or Java programs that call J2EE DeploymentManager (JSR-88) methods. This article describes how to use the administrative console to install an application, EJB component, or Web module.

Important: After you start performing the steps below, click **Cancel** to exit if you decide not to install the application. Do not simply move to another administrative console page without first clicking **Cancel** on an application installation page.

1. Click **Applications > Install New Application** in the console navigation tree. The first of two Preparing for application installation pages is displayed.
2. On the first Preparing for application installation page:
   a. Specify the full path name of the source enterprise application file (`.ear` file otherwise known as an *EAR file*). The EAR file that you are installing can be either on the client machine (the machine that runs the Web browser) or on the server machine (the machine to which the client is connected). If you specify an EAR file on the client machine, then the administrative console uploads the EAR file to the machine on which the console is running and proceeds with application installation. You can also specify a standalone Web application archive (WAR) or Java archive (JAR) file for installation.
   b. If you are installing a standalone WAR file, specify the context root.
   c. Click **Next**.
3. On the second Preparing for application installation page:
   a. Select whether to generate default bindings. Using the default bindings causes any incomplete bindings in the application to be filled in with default values. Existing bindings are not altered. You can customize default values used in generating default bindings. For example, you can specify a Java Naming and Directory Interface (JNDI) prefix for EJB files in EJB modules, default data source and connection factory settings for EJB modules, virtual host for Web modules, and so on. "Preparing for application installation settings" on page 714 describes available customizations and provides sample bindings.
   b. Click **Next**. If security warnings are displayed, click **Continue**. The Install New Application pages are displayed. If you chose to generate default bindings, you can proceed to the Summary step (last step below). "Example: Installing an EAR file using the default bindings" on page 719 provides sample steps.
4. On the **Step: Select installation options** panel, provide values for the following settings specific to WebSphere Application Server. Default values are used if you do not specify a value.

a. For **Pre-compile JSP**, specify whether to precompile JavaServer page (JSP) files as a part of installation. The default is not to precompile JSP files. Install onto a 6.x deployment target. If you select **Pre-compile JSP** and try installing your application onto a 5.x deployment target, the installation is rejected. For this option, install only onto a 6.x deployment target.

b. For **Directory to install application**, specify the directory to which the application EAR file will be installed. The default value is the value of APP_INSTALL_ROOT/*cell_name*, where the APP_INSTALL_ROOT variable is `install_root/installedApps`; for example, `C:\WebSphere\AppServer\profiles\profile _name\installedApps\cell_name`.

c. For **Distribute application**, specify whether WebSphere Application Server expands or deletes application binaries in the installation destination. The default is to enable application distribution. As a result, when you save changes in the console, application binaries for newly installed applications are expanded to the directory specified. The binaries are also deleted when you uninstall and save changes to the configuration. If you disable this option, then you must ensure that the application binaries are expanded appropriately in the destination directories of all nodes where the application is expected to run.

d. For **Use Binary Configuration**, specify whether the application server uses the binding, extensions, and deployment descriptors located with the application deployment document, the `deployment.xml` file (default), or those located in the EAR file. The default is not to use the binary configuration. If you select **Use Binary Configuration**, your application files must be installed onto a 6.x deployment target. The files cannot be installed onto a 5.x deployment target.

e. For **Deploy enterprise beans**, specify whether the EJBDeploy tool runs during application installation. The tool generates code needed to run EJB files. You must enable this setting in the following situations:

   - The EAR file was assembled using an assembly tool such as Rational Web Developer or Application Server Toolkit (AST) and the EJBDeploy tool was not run during assembly.
   - The EAR file was not assembled using an assembly tool.
   - The EAR file was assembled using versions of the Application Assembly Tool (AAT) previous to Version 5.

   Enabling this setting might cause the installation program to run for several minutes. Also, install onto a 6.x deployment target. If you select **Deploy enterprise beans** and try installing your application onto a 5.x deployment target, the installation is rejected. For this option, install only onto a 6.x deployment target.

f. For **Application name**, name the application. Application names must be unique within a cell and cannot contain characters that are not allowed in object names.

g. For **Create MBeans for resources**, specify whether to create MBeans for various resources (such as servlets or JSP files) within an application when the application is started. The default is to create MBean instances.

h. For **Enable class reloading**, specify whether to enable class reloading when application files are updated. The default is not to enable class reloading. For EJB modules or any non-Web modules, enabling class reloading sets reloadEnabled to `true` in the `deployment.xml` file for the application. If an application's class definition changes, the application server run time stops and starts the application to reload application classes.

   For Web modules such as servlets and JSP files, a Web container reloads a Web module only when the IBM extension reloadingEnabled in the `ibm-web-ext.xmi` file is set to `true`. You can set reloadingEnabled to `true` when editing the extended deployment descriptors of your Web module in an assembly tool.

   To disable reloading of a Web module, set the IBM extension reloadingEnabled in the `ibm-web-ext.xmi` file to `false`. Or, if the Web module has the IBM extension reloadingEnabled in the `ibm-web-ext.xmi` file set to `true`, enable class loading, and set the **Reload interval** property to zero (0).

i. For **Reload interval in seconds**, specify the number of seconds to scan the application's file system for updated files. The default is the value of the reload interval attribute in the IBM extension (`META-INF/ibm-application-ext.xmi`) file of the EAR file. To enable reloading, specify a value greater than zero (for example, 1 to 2147483647). To disable reloading, specify zero (0).

The reload interval specified here takes effect only if class reloading is enabled.

j. For **Deploy Web services**, specify whether the Web services deploy tool `wsdeploy` runs during application installation. The tool generates code needed to run applications using Web services. The default is not to run the `wsdeploy` tool. You must enable this setting if the EAR file contains modules using Web services and has not previously had the `wsdeploy` tool run on it, either from the **Deploy** menu choice of an assembly tool or from a command line. Note that if you select **Deploy** and try installing your application onto a 5.x deployment target, the installation is rejected. For this option, install only onto a 6.x deployment target.

k. For **Validate Input off/warn/fail,** specify whether WebSphere Application Server examines the application references specified during application installation or updating and, if validation is enabled, warns you of incorrect references or fails the operation. An application typically refers to resources using data sources for container managed persistence (CMP) beans or using resource references or resource environment references defined in deployment descriptors. The validation checks whether the resource referred to by the application is defined in the scope of the deployment target of that application. Select **off** for no resource validation, **warn** for warning messages about incorrect resource references, or **fail** to stop operations that fail as a result of incorrect resource references.

l. For **Process embedded configuration**, specify whether the embedded configuration should be processed. An embedded configuration consists of files such as `resource.xml` and `variables.xml`. When selected or `true`, the embedded configuration is loaded to the application scope from the `.ear` file. If the `.ear` file does not contain an embedded configuration, the default is `false`. If the `.ear` file contains an embedded configuration, the default is `true`.

5. On the **Step: Map modules to servers** panel, for every module select a target server or cluster from the **Clusters and Servers** list. Select the check box beside **Module** to select all of the application modules or select individual modules. Ensure that you are installing your application onto an appropriate deployment target. You can specify Web servers as targets that route requests to the application. The plug-in configuration file `plugin-cfg.xml` for each Web server is generated based on the applications which are routed through it. If you want a Web server to serve the application, use the **Ctrl** key to select an application server or cluster and the Web server together in order to have the plug-in configuration file `plugin-cfg.xml` for that Web server generated based on the applications which are routed through it.
6. If your application uses EJB modules, on the **Step: Provide JNDI Names for Beans** panel, specify a JNDI name for each enterprise bean in every EJB module. You must specify a JNDI name for every enterprise bean defined in the application. For example, for the EJB module `MyBean.jar`, specify `MyBean`.
7. If your application uses EJB modules that contain Container Managed Persistence (CMP) beans that are based on the EJB 1.x specification, for **Step: Provide default datasource mapping for modules containing 1.x entity beans**, specify a JNDI name for the default data source for the EJB modules. The default data source for the EJB modules is optional if data sources are specified for individual CMP beans.
8. If your application has CMP beans that are based on the EJB 1.x specification, for **Step: Map datasources for all 1.x CMP**, specify a JNDI name for data sources to be used for each of the 1.x CMP beans. The data source attribute is optional for individual CMP beans if a default data source is specified for the EJB module that contains CMP beans. If neither a default data source for the EJB module nor a data source for individual CMP beans are specified, then a validation error displays after you click **Finish** and the installation is cancelled.
9. If your application defines EJB references, for **Step: Map EJB references to beans**, specify JNDI names for enterprise beans that represent the logical names specified in EJB references. Each EJB reference defined in the application must be bound to an EJB file before clicking **Finish** on the Summary panel.

10. If your application defines resource references, for **Step: Map resource references to resources**, specify JNDI names for the resources that represent the logical names defined in resource references. You can optionally specify login configuration name and authentication properties for the resource. After specifying authentication properties, click **OK** to save the values and return to the mapping step. Each resource reference defined in the application must be bound to a resource defined in your WebSphere Application Server configuration before clicking on **Finish** on the Summary panel.
11. If your application uses Web modules, for **Step: Map virtual hosts for web modules**, select a virtual host from the list that should map to a Web module defined in the application. The port number specified in the virtual host definition is used in the URL that is used to access artifacts such as servlets and JSP files in the Web module. Each Web module must have a virtual host to which it maps. Not specifying all needed virtual hosts will result in a validation error displaying after you click **Finish** on the Summary panel.
12. If the application has security roles defined in its deployment descriptor then, for **Step: Map security roles to users/groups**, specify users and groups that are mapped to each of the security roles. Select **Role** to select all of the roles or select individual roles. For each role, you can specify if predefined users such as **Everyone** or **All authenticated users** are mapped to it. To select specific users or groups from the user registry:
    a. Select a role and click **Lookup users** or **Lookup groups**.
    b. On the Lookup users/groups panel displayed, enter search criteria to extract a list of users or groups from the user registry.
    c. Select individual users or groups from the results displayed.
    d. Click **OK** to map the selected users or groups to the role selected on the **Step: Map security roles to users/groups** panel.
13. If the application has Run As roles defined in its deployment descriptor, for **Step: Map RunAs roles to user**, specify the Run As user name and password for every Run As role. Run As roles are used by enterprise beans that must run as a particular role while interacting with another enterprise bean. Select **Role** to select all of the roles or select individual roles. After selecting a role, enter values for the user name, password, and verify password and click **Apply**.
14. If your application contains EJB 1.x CMP beans that do not have method permissions defined for some of the EJB methods, for **Step: Ensure all unprotected 1.x methods have the correct level of protection**, specify if you want to leave such methods unprotected or assign protection with deny all access.
15. If your application contains message driven enterprise beans, for **Step: Provide Listener Ports or activation specification JNDI name for messaging beans**, provide a listener port name or an activation specification JNDI name for every message driven bean. A listener port name must be provided when using the JMS providers: Version 5 default messaging, WebSphere MQ, or generic. An activation specification must be provided when the application's resources are configured using the default messaging provider or any generic J2C resource adapter that supports inbound messaging. If neither is specified, then a validation error is displayed after you click **Finish** on the Summary panel. Also, if the module containing the message driven bean is deployed on a 5.x deployment target and a listener port is not specified, then a validation error is displayed after you click **Next**.
16. If your application uses EJB modules that contain CMP beans that are based on the EJB 2.x specification, for **Step: Provide default datasource mapping for modules containing 2.x entity beans**, specify a JNDI name for the default data source and the type of resource authorization to be used for the default data source for the EJB modules. You can optionally specify a login configuration name and authentication properties for the data source. When creating authentication properties, you must click **OK** to save the values and return to the mapping step. The default data source for EJB modules is optional if data sources are specified for individual CMP beans.
17. If your application has CMP beans that are based on the EJB 2.x specification, on the **Step: Map datasources for all 2.x CMP** panel, for each of the 2.x CMP beans specify a JNDI name and the type of resource authorization for data sources to be used. You can optionally specify a login

configuration name and authentication properties for the data source. When creating authentication properties, you must click **OK** to save the values and return to the mapping step. The data source attribute is optional for individual CMP beans if a default data source is specified for the EJB module that contains CMP beans. If neither a default data source for the EJB module nor a data source for individual CMP beans are specified, then a validation error is displayed after you click **Finish** and installation is cancelled.

18. If your application contains EJB 2.x CMP beans that do not have method permissions defined in the deployment descriptors for some of the EJB methods, on the **Step: Ensure all unprotected 2.x methods have the correct level of protection** panel, specify whether you want to assign a specific role to the unprotected methods, add the methods to the exclude list, or mark them as unchecked. Methods added to the exclude list are marked as uncallable. For methods marked unchecked no authorization check is performed prior to their invocation.
19. If the **Deploy enterprise beans** setting is enabled on the **Select installation options** panel, then you can specify options for the EJBDeploy tool on the **Step: Provide options to perform the EJB Deploy** panel. On this panel, you can specify extra class paths, RMIC options, database types, and database schema names to be used while running the EJBDeploy tool. The tool is run on the EAR file during installation after you click **Finish**.
20. If your application contains resource environment references, for **Step: Map resource environment references to resources**, specify JNDI names of resources that map to the logical names defined in resource environment references. If each resource environment reference does not have a resource associated with it, after you click **Finish** a validation error is displayed.
21. If your application defines **Run-As Identity** as *System Identity*, for **Step: Replace RunAs System to RunAs Roles**, you can optionally change it to *Run-As role* and specify a user name and password for the Run As role specified. Selecting *System Identity* implies that the invocation is done using the WebSphere Application Server security server ID and should be used with caution as this ID has more privileges.
22. If your application has resource references that map to resources that have an Oracle database doing backend processing, for **Step: Specify the isolation level for Oracle type provider**, specify or correct the isolation level to be used for such resources when used by the application. Oracle databases support ReadCommitted and Serializable isolation levels only.
23. If your application uses message driven beans, for **Step: Build message destination to administered objects**, specify the JNDI name of the J2C administered object to bind the message destination reference to the message driven beans.
24. If your application contains an embedded `.rar` file, for **Step: Map JCA resources to resources**, specify the name and JNDI name of each J2C connection factory, J2C administered object and J2C activation specification.
25. If your application contains an embedded `.rar` file, its activationSpec property has the value `Destination`, and its introspected type is `javax.jms.Destination`, for **Step: Bind J2CActivationSpec to Destination Jndi name**, specify the jndiName value for each activation bound to it.
26. If your application has EJB modules for which deployment code has been generated for multiple backend databases using an assembly tool, for **Step: Select a backend ID**, specify the backend ID representing the backend database to be used when the EJB module runs.
27. On the Summary panel, verify the cell, node, and server onto which the application modules will install:
    a. Beside **Cell/Node/Server**, click **Click here**.
    b. Verify the settings.
    c. Click **Finish**.

Several messages are displayed, indicating whether your application file is installing successfully.

If you receive an OutOfMemory exception and the source application file does not install, your system might not have enough memory or your application might have too many modules in it to install successfully onto the server. If lack of system memory is not the cause of the exception, package your application again so the `.ear` file has fewer modules. If lack of system memory and the number of modules are not the cause of the exception, check the options you specified on the Java Virtual Machine page of the application server running the administrative console. Then, try installing the application file again.

Windows During installation certain application files are extracted in the directory represented by the configuration session and, when the configuration is saved, these files are saved in the WebSphere Application Server configuration repository. On Windows machines, there is a limit of 256 characters for file paths. Therefore, the application installation might fail if the path for application files in the configuration session or in the configuration repository exceeds the limit of 256 characters. You might see FileNotFound exceptions with *path name too long* in the message. To overcome such problems, make application names and module URI names shorter in length, which helps reduce the file path length. Then, try installing the application file again.

After the application file installs successfully, do the following:

1. Associate any shared libraries that the application needs to the application.
2. Save the changes to your configuration. The application is registered with the administrative configuration and application files are copied to the target directory, which is `install_root/installedApps/cell_name` by default or the directory that you designate. For a single-server installation, application files are copied to the destination directory when the changes are saved.
3. Start the application.
4. Test the application. For example, point a Web browser at the URL for the deployed application and examine the performance of the application. If necessary, update the application.

Preparing for application installation settings

Use this page to install an application (EAR file) or module (JAR or WAR file).

To view this administrative console page, click **Applications > Install New Application**.

Follow the steps on this page to install an application or module. You must complete, at minimum, the first step; you must complete some or all of the later steps, depending on whether you are installing an application, EJB module, or Web module.

Path:

Specifies the fully qualified path to the `.ear`, `.jar`, or `.war` file for the enterprise application.

Use **Local file system** if the browser and application files are on the same machine (whether or not the server is on that machine, too).

Use **Remote file system** if the application file resides on any node in the current cell context. Only `.ear`, `.jar`, or `.war` files are shown during the browsing.

During application installation, application files typically are uploaded from a client machine running the browser to the server machine running the administrative console, where they are deployed. In such cases, use the Web browser running the administrative console to select EAR, WAR, or JAR modules to upload to the server machine.

In some cases, however, the application files reside on the file system of any of the nodes in a cell. To have the application server install these files, use the **Remote file system** option.

Also use the **Remote file system** option to specify an application file already residing on the machine running the application server. For example, the field value on a Windows machine might be `C:\WebSphere\AppServer\installableApps\test.ear`. If you are installing a stand-alone WAR module, then specify the context root as well.

After the application file is transferred, the **Remote file system** value shows the path of the temporary location on the server machine.

Context root:

Specifies the context root of the Web application (WAR).

This field is used only to install a stand-alone WAR file. The context root is combined with the defined servlet mapping (from the WAR file) to compose the full URL that users type to access the servlet. For example, if the context root is `/gettingstarted` and the servlet mapping is `MySession`, then the URL is `http://host:port/gettingstarted/MySession`.

Generate Default Bindings:

Specifies whether to generate default bindings. If you place a check mark in the check box, then any incomplete bindings in the application are filled in with default values. Existing bindings are not altered.

By choosing this option, you can directly jump to the Summary step and install the application if none of the steps have a red asterisk (*) next to them. A red asterisk denotes that the step has incomplete data and requires a valid value. On the Summary panel, verify the cell, node and server on which the application is installed.

Bindings are generated as follows:
- EJB JNDI names are generated of the form *prefix*/*ejb-name*. The default prefix is `ejb`, but can be overridden. The *ejb-name* is as specified in the deployment descriptors `<ejb-name>` tag.
- EJB references are bound as follows: If an `<ejb-link>` is found, it is honored. Otherwise, if a unique enterprise bean is found with a matching home (or local home) interface as the referenced bean, the reference is resolved automatically.
- Resource reference bindings are derived from the `<res-ref-name>` tag. Note that this action assumes that the `java:comp/env` name is the same as the resource global JNDI name.
- Connection factory bindings (for EJB 2.0 JAR files) are generated based on the JNDI name and authorization information provided. This action results in default connection factory settings for each EJB 2.0 JAR file in the application being installed. No bean-level connection factory bindings are generated.
- Data source bindings (for EJB 1.1 JAR files) are generated based on the JNDI name, data source user name password options. This results in default data source settings for each EJB JAR file. No bean-level data source bindings are generated.
- For EJB2.1 or EJB2.0 message-driven beans deployed as JCA 1.5-compliant resources, the JNDI names corresponding to activationSpec instances are generated in the form eis/*MDB_ejb-name*. Message Destination references are bound as follows: if a `<message-destination-link>` is found then the JNDI name is set to ejs/*message-destination-link*Name. Otherwise the JNDI name is set to eis/*message-destination-ref*Name.
- For EJB 2.0 message-driven beans deployed against a listener ports, the listener ports are derived from the MDB `<ejb-name>` tag with the string `Port` appended.
- For `.war` files, the virtual host is set as `default_host` unless otherwise specified.

The default strategy suffices for most applications or at least for most bindings in most applications. However, it does not work if:
- You want to explicitly control the global JNDI names of one or more EJB files.
- You need tighter control of data source bindings for container-managed persistence (CMP) beans. That is, you have multiple data sources and need more than one global data source.

- You must map resource references to global resource JNDI names that are different from the `java:comp/env` name.

In such cases, you can change the behavior with an XML document (a custom strategy). Use the **Specific bindings file** field to specify a custom strategy and see the field's help for examples.

Prefixes:

Specifies prefixes to use for generated JNDI names.

Override:

Specifies whether generated bindings are to override existing bindings.

If **Override existing bindings** is selected, the existing bindings are overridden by the generated ones.

Connection Factory Bindings:

Specifies the default data source JNDI name.

If **Default connection factory bindings** is selected, specify the JNDI name for the default data source to be used with the bindings. Also specify the resource authorization.

Virtual Host:

Specifies the virtual host for the Web module.

Specific bindings file:

Specifies a bindings file that overrides the default binding.

Change the behavior of the default binding with an XML document (a custom strategy). Custom strategies extend the default strategy so you only need to customize those areas where the default strategy is insufficient. Thus, you only need to describe how you want to change the bindings generated by the default strategy; you do not have to define bindings for the entire application.

Brief examples of how to override various aspects of the default bindings generator follow:

Controlling an EJB JNDI name

```
<?xml version="1.0"?>
<!DOCTYPE dfltbndngs SYSTEM "dfltbndngs.dtd">
<dfltbndngs>
  <module-bindings>
    <ejb-jar-binding>
      <jar-name>helloEjb.jar</jar-name>
      <ejb-bindings>
        <ejb-binding>
         <ejb-name>HelloEjb</ejb-name>
         <jndi-name>com/acme/ejb/HelloHome</jndi-name>
        </ejb-binding>
      </ejb-bindings>
    </ejb-jar-binding>
  </module-bindings>
</dfltbndngs>
```

Note: Ensure that the setting for `<ejb-name>` matches the `ejb-name` entry in the EJB JAR deployment descriptor. Here the setting is `<ejb-name>HelloEjb</ejb-name>`.

Setting the connection factory binding for an EJB JAR file

```
<!DOCTYPE dfltbndngs SYSTEM "dfltbndngs.dtd">
<dfltbndngs>
  <module-bindings>
    <ejb-jar-binding>
      <jar-name>yourEjb20.jar</jar-name>
      <connection-factory>
        <jndi-name>eis/jdbc/YourData_CMP</jndi-name>
        <res-auth>Container</res-auth>
      </connection-factory>
    </ejb-jar-binding>
  </module-bindings>
</dfltbndngs>
```

Setting the connection factory binding for an EJB file

```
<?xml version="1.0">
<!DOCTYPE dfltbndngs SYSTEM "dfltbndngs.dtd">
<dfltbndngs>
  <module-bindings>
    <ejb-jar-binding>
      <jar-name>yourEjb20.jar</jar-name>
      <ejb-bindings>
        <ejb-binding>
          <ejb-name>YourCmp20</ejb-name>
          <connection-factory>
           <jndi-name>eis/jdbc/YourData_CMP</jndi-name>
           <res-auth>PerConnFact</res-auth>
          </connection-factory>
        </ejb-binding>
      </ejb-bindings>
    </ejb-jar-binding>
 </module-bindings>
</dfltbndngs>
```

Note: Ensure that the setting for `<ejb-name>` matches the `ejb-name` tag in the deployment descriptor. Here the setting is `<ejb-name>YourCmp20</ejb-name>`.

Setting the message destination reference JNDI for a specific enterprise bean

Example XML extract in a custom strategy file for setting message-destination-refs for a specific enterprise bean.

```
<?xml version="1.0">
 <!DOCTYPE dfltbndngs SYSTEM "dfltbndngs.dtd">
 <dfltbndngs>
  <module-bindings>
   <ejb-jar-binding>
    <jar-name>yourEjb21.jar</jar-name>
    <ejb-bindings>
     <ejb-binding>
      <ejb-name>YourSession21</ejb-name>
      <message-destination-ref-bindings>
       <message-destination-ref-binding>
        <message-destination-ref-name>jdbc/MyDataSrc</message-destination-ref-name>
        <jndi-name>eis/somAO</jndi-name>
       </message-destination-ref-binding>
      </message-destination-ref-bindings>
     </ejb-binding>
    </ejb-bindings>
   </ejb-jar-binding>
  </module-bindings>
 </dfltbndngs>
```

Note: Ensure that the setting for `<ejb-name>` matches the `ejb-name` tag in the deployment descriptor. Here the setting is `<ejb-name>YourSession21</ejb-name>`. Also ensure that the setting for `<message-destination-ref-name>` matches the `message-destination-ref-name` tag in the deployment descriptor. Here the setting is <message-destination-ref-name>jdbc/MyDataSrc</message-destination-ref-name>.

Overriding a resource reference binding from a WAR, EJB JAR file, or J2EE client JAR file

Example code for overriding a resource reference binding from a WAR file follows. Use similar code to override a resource reference binding from an enterprise bean (EJB) JAR file or a J2EE client JAR file.

```
<?xml version="1.0"?>
<!DOCTYPE dfltbndngs SYSTEM "dfltbndngs.dtd">
<dfltbndngs>
  <module-bindings>
    <war-binding>
      <jar-name>hello.war</jar-name>
      <resource-ref-bindings>
        <resource-ref-binding>
          <resource-ref-name>jdbc/MyDataSrc</resource-ref-name>
          <jndi-name>war/override/dataSource</jndi-name>
        </resource-ref-binding>
      </resource-ref-bindings>
    </war-binding>
  </module-bindings>
</dfltbndngs>
```

Note: Ensure that the setting for <resource-ref-name> matches the resource-ref tag in the deployment descriptor. Here the setting is <resource-ref-name>jdbc/MyDataSrc</resource-ref-name>.

Overriding the JNDI name for a message-driven bean deployed as a JCA 1.5-compliant resource

Example XML extract in a custom strategy file for overriding the JMS activationSpec JNDI name for an EJB 2.1 or EJB 2.0 message-driven bean deployed as a JCA 1.5-compliant resource.

```
<?xml version="1.0"?>
 <!DOCTYPE dfltbndngs SYSTEM "dfltbndngs.dtd">
  <dfltbndngs>
  <module-bindings>
   <ejb-jar-binding>
     <jar-name>YourEjbJar.jar</jar-name>
     <ejb-bindings>
      <ejb-binding>
        <ejb-name>YourMDB</ejb-name>
        <activationspec-jndi-name>activationSpecJNDI</activationspec-jndi-name>
      </ejb-binding>
     </ejb-bindings>
   </ejb-jar-binding>
  </module-bindings>
 </dfltbndngs>
```

Overriding the JMS listener port name for an EJB 2.0 message-driven bean

Example XML extract in a custom strategy file for overriding the JMS listener port name for an EJB 2.0 message-driven bean deployed against a listener port.

```
<?xml version="1.0"?>
<!DOCTYPE dfltbndngs SYSTEM "dfltbndngs.dtd">
<dfltbndngs>
  <module-bindings>
    <ejb-jar-binding>
      <jar-name>YourEjbJar.jar</jar-name>
      <ejb-bindings>
        <ejb-binding>
          <ejb-name>YourMDB</ejb-name>
          <listener-port>yourMdbListPort</listener-port>
        </ejb-binding>
      </ejb-bindings>
    </ejb-jar-binding>
  </module-bindings>
</dfltbndngs>
```

Overriding an EJB reference binding from an EJB JAR, WAR file, or EJB file

Example code for overriding an EJB reference binding from an EJB JAR file follows. Use similar code to override an EJB reference binding from a WAR file or an EJB file.

```
<?xml version="1.0"?>
<!DOCTYPE dfltbndngs SYSTEM "dfltbndngs.dtd">
<dfltbndngs>
  <module-bindings>
    <ejb-jar-binding>
      <jar-name>YourEjbJar.jar</jar-name>
      <ejb-ref-bindings>
        <ejb-ref-binding>
          <ejb-ref-name>YourEjb</ejb-ref-name>
          <jndi-name>YourEjb/JNDI</jndi-name>
        </ejb-ref-binding>
      </ejb-ref-bindings>
    </ejb-jar-binding>
  </module-bindings>
</dfltbndngs>
```

Example: Installing an EAR file using the default bindings

If application bindings were not specified for all enterprise beans or resources in an application during application development or assembly, you can select to generate default bindings. After application installation, you can modify the bindings as needed using the administrative console.

An example of a simple `.ear` file installation using the default bindings follows:

1. Go to the Preparing for application install pages.

   Click **Applications > Install New Application** in the console navigation tree.
2. For **Path to the new application**, specify the full path name of the `.ear` file.

   For this example, the base file name is `my_appl.ear` and the file resides on a server at `C:\sample_apps`.
3. Now that a value is given for **Specify path**, on the first Preparing for application installation page, click **Next**.
4. On the second Preparing for application installation page, select **Generate Default Bindings** and click **Next**.

   Using the default bindings causes any incomplete bindings in the application to be filled in with default values. Existing bindings are not changed. By choosing this option, you can skip many of the steps on the Install New Application page and go directly to the Summary step.
5. If application security warnings are displayed, read the warnings and click **Continue**.
6. On the Install New Application page, click on **Summary**, the last step.
7. On the Summary panel, verify the cell, node, and server onto which the application files will install.
   a. Beside the **Cell/Node/Server** option, click **Click here**.
   b. On the **Map modules to servers** panel, select the server onto which the application files will install from the **Clusters and Servers** list, click **Module** to select all of the application modules, and click **Next**.

      Note that on the **Map modules to servers** panel, you can map modules to other servers such as Web servers. If you want a Web server to serve the application, use the **Ctrl** key to select an application server or cluster and the Web server together in order to have the plug-in configuration file `plugin-cfg.xml` for that Web server generated based on the applications which are routed through it.

   Because `my_appl.ear` does not require any additional settings to complete an installation, the Summary panel is displayed again.

8. On the Summary panel, click **Finish**.

Examine the application installation progress messages. If the application installs successfully, save your administrative configuration. You can now see the name of your application in the list of deployed applications on the Enterprise Applications page accessed by clicking **Applications > Enterprise Applications** in the console navigation tree.

If the application does not install successfully, read the messages to identify why the installation failed. Correct problems with the application as needed and try installing the application again.

Installing J2EE modules with JSR-88

You can install Java 2 Platform, Enterprise Edition (J2EE) modules on an application server provided by a WebSphere Application Server product using the J2EE Deployment API Specification (JSR-88).

JSR-88 defines standard application programming interfaces (APIs) to enable deployment of J2EE applications and stand-alone modules to J2EE product platforms. The J2EE Deployment Specification Version 1.1 is available at http://java.sun.com/j2ee/tools/deployment/reference/docs/index.html as part of the J2EE 1.4 Application Server Developer Release.

Read about JSR-88 and APIs used to manage applications at http://java.sun.com/j2ee/tools/deployment/.

JSR-88 defines a contract between a tool provider and a platform that enables tools from multiple vendors to configure, deploy and manage applications on any J2EE product platform. The tool provider typically supplies software tools and an integrated development environment (IDE) for developing and assembly of J2EE application modules. The J2EE platform provides application management functions that deploy, undeploy, start, stop, and otherwise manage J2EE applications.

WebSphere Application Server is a J2EE 1.4 specification-compliant platform that implements the JSR-88 APIs. Complete the following steps to deploy (install) J2EE modules on an application server provided by the WebSphere Application Server platform.

1. Code a Java program that can access the JSR-88 DeploymentManager class for WebSphere Application Server.
   a. Write code that finds the JAR manifest file key J2EE-DeploymentFactory-Implementation-Class. Under JSR-88, your code finds the DeploymentFactory using the JAR manifest file key J2EE-DeploymentFactory-Implementation-Class. For WebSphere Application Server, the application management JAR file containing this key and providing support is *install_root*/lib/wjmxapp.jar. After your code finds the DeploymentFactory, the deployment tool can create an instance of the WebSphere DeploymentFactory and register the instance with its DeploymentFactoryManager. For example:

```
import javax.enterprise.deploy.shared.factories.DeploymentFactoryManager;
import javax.enterprise.deploy.spi.DeploymentManager;
import javax.enterprise.deploy.spi.factories.DeploymentFactory;
import java.util.jar.JarFile;

// Get the DeploymentFactory implementation class from the MANIFEST.MF file.
JarFile wjmxappJar = new JarFile(new File(wasHome + "/lib/wjmxapp.jar"));
java.util.jar.Manifest manifestFile = wjmxappJar.getManifest();
Attributes attributes = manifestFile.getMainAttributes();
String key = "J2EE-DeploymentFactory-Implementation-Class";
String className = attributes.getValue(key);
// Get an instance of the DeploymentFactoryManager
DeploymentFactoryManager dfm = DeploymentFactoryManager.getInstance();

// Create an instance of the WebSphere Application Server DeploymentFactory.
Class deploymentFactory = Class.forName(className);
DeploymentFactory deploymentFactoryInstance =
   (DeploymentFactory) deploymentFactory.newInstance();
```

```
// Register the DeploymentFactory instance with the DeploymentFactoryManager.
dfm.registerDeploymentFactory(deploymentFactoryInstance);

// Provide WebSphere Application Server URL, user ID, and password.
// For more information, see the step that follows.
wsDM = dfm.getDeploymentManager(
   "deployer:WebSphere:myserver:8880", null, null);
```

   b. Write code that accesses the DeploymentManager instance for WebSphere Application Server. The WebSphere Application Server URL for deployment has the format

      `"deployer:WebSphere:`*`host`*`:`*`port`*`"`

      The example in the previous step, "`deployer:WebSphere:myserver:8880`", tries to connect to host *myserver* at port *8880* using the SOAP connector, which is the default.

      The URL for deployment can have an optional parameter *connectorType*. For example, to use the RMI connector to access *myserver*, code the URL as follows:

      `"deployer:WebSphere:myserver:2809?connectorType=RMI"`

2. **Optional:** Code a Java program that can customize or deploy J2EE applications or modules using the JSR-88 support provided by WebSphere Application Server.
3. Start the deployed J2EE applications or standalone J2EE modules using the JSR-88 API used to start applications or modules.

Test the deployed applications or modules. For example, point a Web browser at the URL for a deployed application and examine the performance of the application. If necessary, update the application.

Customizing modules using DConfigBeans

You can configure J2EE applications or stand-alone modules during deployment using the DConfigBean class in the Java 2 Platform, Enterprise Edition (J2EE) Deployment API Specification (JSR-88).

This article assumes that you are deploying (installing) J2EE modules on an application server provided by the WebSphere Application Server platform using the WebSphere Application Server support for JSR-88.

Read about the JSR-88 specification and using the DConfigBean class at http://java.sun.com/j2ee/tools/deployment/.

The DConfigBean class in JSR-88 provides JavaBeans-based support for platform-specific configuration of J2EE applications and modules during deployment. Your code can inspect DConfigBean instances to get platform-specific configuration attributes. The DConfigBean instances provided by WebSphere Application Server contain a single attribute which has an array of java.util.Hashtable objects. The hashtable entries contain configuration attributes, for which your code can get and set values.

1. Write code that installs J2EE modules on an application server using JSR-88.
2. Write code that accesses DConfigBeans generated by WebSphere Application Server during JSR-88 deployment. You (or a deployer) can then customize the accessed DConfigBeans instances. The following pseudocode shows how a J2EE tool provider can get DConfigBean instance attributes generated by WebSphere Application Server during JSR-88 deployment and set values for the attributes:

   ```
   import javax.enterprise.deploy.model.*;
   import javax.enterprise.deploy.spi.*;
   {
   DeploymentConfiguration dConfig = ___; // Get from DeploymentManager
   DDBeanRoot ddRoot = ___;               // Provided by J2EE tool

   // Obtain root bean.
   DConfigBeanRoot dcRoot = dConfig.getDConfigBeanRoot(dr);

   // Configure DConfigBean.
   configureDCBean (dcRoot);
   ```

```
   }

   // Get children from DConfigBeanRoot and configure each child.
   method configureDCBean (DConfigBean dcBean)
   {
      // Get DConfigBean attributes for a given archive.
      BeanInfo bInfo = Introspector.getBeanInfo(dcBean.getClass());
      IndexedPropertyDescriptor ipDesc =
         (IndexedPropertyDescriptor)bInfo.getPropertyDescriptors()[0];

      // Get the 0th table.
      int index = 0;
      Hashtable tbl = (Hashtable)
         ipDesc.getIndexedReadMethod().invoke
            (dcBean, new Object[]{new Integer(index)});

      while (tbl != null)
      {
         // Iterate over the hashtable and set values for attributes.

         // Set the table back into the DCBean.
         ipDesc.getIndexedWriteMethod().invoke
            (dcBean, new Object[]{new Integer(index), tbl});

         // Get the next entry in the indexed property
         tbl = (Hashtable)
            ipDesc.getIndexedReadMethod().invoke
               (dcBean, new Object[]{new Integer(++index)});
      }
   }
```

Enterprise application collection

Use this page to view and manage enterprise applications.

This page lists installed J2EE enterprise applications. System applications, which are central to the product, are not shown in the list because users cannot edit them. Examples of system applications include *adminconsole* and *filetransfer*.

To view this administrative console page, click **Applications > Enterprise Applications**.

To view the values specified for an application's configuration, click the application name in the list. The displayed application settings page shows the values specified. On the settings page, you can change existing configuration values and link to additional console pages that assist you in configuring the application.

To manage an installed J2EE enterprise application, enable the **Select** check box beside the application name in the list and click a button:

Button	Resulting action
Start	Attempts to run the application. After the application starts up successfully, the state of the application changes to *Started* if the application starts up on all deployment targets, else the state changes to *Partial Started*.
Stop	Attempts to stop the processing of the application. After the application stops successfully, the state of the application changes to *Stopped* if the application stops on all deployment targets, else the state changes to *Partial Stopped*.
Install	Opens a wizard that helps you deploy an application or a module such as a `.jar`, `.war` or `.rar` file onto a server.

Button	Resulting action
Uninstall	Deletes the application from the WebSphere Application Server configuration repository and deletes the application binaries from the file system of all nodes where the application modules are installed after the configuration is saved.
Update	Opens a wizard that helps you update application files deployed on a server. You can update the full application, a single module, a single file, or part of the application. If a new file or module has the same name as a file or module already existing on the server, the new file or module replaces the existing file or module. If the new file or module does not exist on the server, it is added to the deployed application.
Remove File	Deletes a file of the deployed application or module. **Remove File** deletes a file from the WebSphere Application Server configuration repository and from the file system of all nodes where the file is installed.
Export	Accesses the Export Application EAR files page, which you use to export an enterprise application to an EAR file at a location of your choice. Use the **Export** action to back up a deployed application and to preserve its binding information.
Export DDL	Accesses the Export Application DDL files page, which you use to export DDL files (`Table.ddl`) in the EJB modules of an enterprise application to a location of your choice.

Name

Specifies the name of the installed (or deployed) application. Application names must be unique within a cell and cannot contain characters that are not allowed in object names.

Status

Indicates whether the application deployed on the application server is started, stopped, or unavailable.

➡	**Started**	Application is running.
⇨	**Partial Start**	Application is in the process of changing from a *Stopped* state to a *Started* state. Application is starting to run but is not fully running yet.
✖	**Stopped**	Application is not running.
⇨	**Partial Stop**	Application is in the process of changing from a *Started* state to a *Stopped* state. Application has not stopped running yet.
⊘	**Unavailable**	Status cannot be determined. An application with an unavailable status might, in fact, be running but have an unavailable status because the server running the administrative console cannot communicate with the server running the application.
?	**Not applicable**	Application does not provide information as to whether it is running.

Enterprise application settings

Use this page to configure an enterprise application.

To view this administrative console page, click **Applications > Enterprise Applications** >*application_name*.

Name

Specifies a logical name for the application. Application names must be unique within a cell and cannot contain characters that are not allowed in object names.

Data type	String

Application binaries

Specifies the directory to which the application EAR file will be installed. The default value is the value of `APP_INSTALL_ROOT/`*`cell_name`*, where the `APP_INSTALL_ROOT` variable is *`install_root`*`/installedApps`; for example, `C:\WebSphere\AppServer\profiles\`*`profile _name`*`\installedApps\`*`cell_name`*.

You can specify an absolute path or use a pathmap variable such as `${MY_APPS}`. You can use a pathmap variable in any installation. A WebSphere Application Server variable `${CELL}` that denotes the current cell name can also be in the pathmap variable; for example, `${MY_APP}/${CELL}`.

You can define WebSphere Application Server variables on the WebSphere Variables page of the administrative console, accessed by clicking **Environment > WebSphere Variables**.

Data type	String
Units	Full path name

Use metadata from binaries

Specifies whether the application server uses the binding, extensions, and deployment descriptors located with the application deployment document, the `deployment.xml` file (default), or those located in the enterprise application resource (EAR) file.

This **Use metadata from binaries** setting is the same as the **Use Binary Configuration** field on the application installation and update wizards. Select this setting for applications installed on 6.x deployment targets only. This setting is not valid for applications installed on 5.x deployment targets.

Data type	Boolean
Default	false

Enable distribution

Specifies whether WebSphere Application Server expands or deletes application binaries in the installation destination. The default is to enable application distribution. Application binaries for installed applications are expanded to the directory specified. The binaries are also deleted when you uninstall and save changes to the configuration. If you disable this option, then you must ensure that the application binaries are expanded appropriately in the destination directories of all nodes where the application runs.

This **Enable distribution** setting is the same as the **Distribute application** field on the application installation and update wizards.

Data type	Boolean
Default	true

Validation

Specifies whether WebSphere Application Server examines the application references specified during application installation or updating and, if validation is enabled, warns the users of incorrect references or fails the operation.

An application typically refers to resources using data sources for container managed persistence (CMP) beans or using resource references or resource environment references defined in deployment descriptors. The validation checks whether the resource referred to by the application is defined in the scope of the deployment target of that application.

The resource can be defined on the server, its node, cell or the cluster if the server belongs to a cluster. Select **off** for no resource validation, **warn** for warning messages about incorrect resource references, or **fail** to stop operations that fail as a result of incorrect resource references.

This **Validation** setting is the same as the **Validate Input off/warn/fail** field on the application installation and update wizards.

Data type	String
Default	warn

Class loader mode

Specifies whether the class loader searches in the parent class loader or in the application class loader first to load a class. The standard for development kit class loaders and WebSphere Application Server class loaders is `Parent First`. By specifying `Parent Last`, your application can override classes contained in the parent class loader, but this action can potentially result in ClassCastException or LinkageErrors if you have mixed use of overridden classes and non-overridden classes.

The options are `Parent First` and `Parent Last`. The default is to search in the parent class loader before searching in the application class loader to load a class.

Data type	String
Default	Parent First

WAR class loader policy

Specifies whether to use a single class loader to load all WAR files of this application or to use a different class loader for each WAR file.

The options are `Application` and `Module`. The default is to use a separate class loader to load each WAR file.

Data type	String
Default	Module

Enable class reloading

Specifies whether to enable class reloading when application files are updated.

For EJB modules or any non-Web modules, selecting **Enable class reloading** sets reloadEnabled to `true` in the `deployment.xml` file for the application. If an application's class definition changes, the application server run time stops and starts the application to reload application classes.

For Web modules such as servlets and JavaServer page (JSP) files, a Web container reloads a Web module only when the IBM extension reloadingEnabled in the `ibm-web-ext.xmi` file is set to `true`. You can set reloadingEnabled to `true` when editing your Web module's extended deployment descriptors in an assembly tool.

To enable reloading of a Web module, where you also want reloading of EJB and non-Web modules enabled:

1. Set the IBM extension reloadingEnabled in the `ibm-web-ext.xmi` file to `true`.
2. Select this **Enable class reloading** property.
3. Set the **Reloading interval** property to a value greater than zero (for example, 1 to 2147483647).

To enable reloading of a Web module only, and not enable reloading of EJB or non-Web modules:

1. Set the IBM extension reloadingEnabled in the `ibm-web-ext.xmi` file to `true`.
2. Set the IBM extension reload interval attribute in the `ibm-web-ext.xmi` file to a value greater than zero (for example, 1 to 2147483647).
3. Do not select this **Enable class reloading** property.

To disable reloading of a Web module, set the IBM extension reloadingEnabled in the `ibm-web-ext.xmi` file to `false`. Or, if the Web module has the IBM extension reloadingEnabled in the `ibm-web-ext.xmi` file set to `true`, to disable reloading using the administrative console:

1. Select this **Enable class reloading** property.
2. Set the **Reloading interval** property to zero (0).

Data type	Boolean
Default	false

Reloading interval

Specifies the number of seconds to scan the application's file system for updated files. The default is the value of the reloading interval attribute in the IBM extension (`META-INF/ibm-application-ext.xmi`) file of the EAR file.

This **Reloading interval** setting is the same as the **Reload interval in seconds** field on the application installation and update wizards.

To enable reloading, specify a value greater than zero (for example, 1 to 2147483647). To disable reloading, specify zero (0).

The reloading interval specified here overrides the value specified in the IBM extensions for each non-Web module in the EAR file (which in turn overrides the reload interval specified in the IBM extensions for the application in the EAR file). The reloading interval attribute takes effect only if class reloading is enabled.

The range is from 0 to 2147483647.

Data type	Integer
Units	Seconds
Default	3

Starting weight

Specifies the order in which applications are started when the server starts. The application with the lowest starting weight is started first.

Data type	Integer
Default	1
Range	0 to 2147483647

Background application

Specifies whether the application must initialize fully before the server starts.

The default setting of `false` indicates that server startup will not complete until the application starts.

A setting of `true` informs WebSphere Application Server that the application might start on a background thread and thus server startup might continue without waiting for the application to start. Thus, the application might not be ready for use when the application server starts.

This setting applies only if the application is run on a Version 6 application server.

Data type	Boolean
Default	false

Create MBeans for resources

Specifies whether to create MBean files for various resources (such as servlets or JSP files) within an application when the application starts. The default is to create MBean files.

Data type	Boolean
Default	true

Configuring an application

You can change the configuration of an application or module deployed on a server.

You can change the contents of and deployment descriptors for an application or module before deployment, such as in an assembly tool. However, this article assumes that the module is already deployed on a server.

Changing an application or module configuration consists of one or more of the following:
- Changing the settings of the application or module.
- Removing a file from an application or module.
- Updating the application or its modules.

This article describes how to change the settings of an application or module using the administrative console.

- Change the settings of the application or module on the settings page for the enterprise application.
  1. Click **Applications > Enterprise Applications >***application_name* in the console navigation tree.
  2. Change the values for settings as needed. The settings page help provides detailed information on the settings and allowed values. When you installed the application or module, you specified most, if not all, of the settings values. After installation, the settings on this page that you are likely to change include the following:

Enable class reloading and **Reloading interval**	These settings control whether classes are reloaded when application files are updated. For enterprise bean (EJB) modules or any non-Web modules, enabling class reloading causes the application server run time to stop and start the application to reload application classes. For Web modules such as servlets and JavaServer page (JSP) files, a Web container reloads a Web module only when the IBM extension reloadingEnabled in the `ibm-web-ext.xmi` file is set to `true`. Refer to the settings page help for detailed information on enabling or disabling class reloading.
Starting weight	If your application starts automatically when its server starts, this value controls how quickly the application starts. **Starting weight** specifies the order in which applications are started when the server starts. The application with the lowest starting weight is started first.
Background application	If your application starts automatically when its server starts, **Background application** specifies whether the application must initialize fully before its server is considered started. Background applications can be initialized on an independent thread, thus allowing the server startup to complete without waiting for the application. This setting applies only if the application is run on a Version 6 (or later) application server.

  3. Click **OK**.
- Map each module of your application to a target server. Specify the application servers or Web servers onto which to install modules of your application.
- Change application bindings or other settings of the application or module.
  1. Click **Applications > Enterprise Applications >***application_name* **>** *property_or_item_name* in the console navigation tree. From the application settings page, you can access console pages for further configuring of the application or module.
     – Session management

- Libraries or library references
- Target mappings
- Deployment descriptors
- Publish WSDL files
- Provide JMS and EJB endpoint URL information
- Provide HTTP endpoint URL information
- Map security roles to users/groups
- Provide JNDI Names for Beans. For more information, refer to “Task overview: Using enterprise beans in applications” on page 817.
- Map resource references to resources
- Map EJB references to beans. For more information, refer to “Task overview: Using enterprise beans in applications” on page 817.
- Map data sources for all 2.x CMP beans
- Provide default data source mapping for modules containing 2.x entity beans. For more information, refer to “Creating and configuring a data source using the administrative console” on page 1171.
- Map virtual hosts for web modules. For more information, refer to ″Configuring virtual hosts″ in the information center.
- Map modules to servers
- Web modules
- EJB modules
- Connector modules

2. Change the values for settings as needed, and click **OK**.

- **Optional:** Configure the application so it does not start automatically when the server starts. By default, an installed application starts when the server on which the application resides starts. You can configure the target mapping for the application so the application does not start automatically when the server starts. To start the application, you must then start it manually.
- If the installed application or module uses a resource adapter archive (RAR file), ensure that the **Classpath** setting for the RAR file enables the RAR file to find the classes and resources that it needs. Examine the **Classpath** setting on the console Resource adapter settings page.

The application or module configuration is changed. The application or standalone Web module is restarted so the changes take effect.

Save changes to your administrative configuration.

Application bindings

Before an application that is installed on an application server can start, all enterprise bean (EJB) references and resource references defined in the application must be bound to the actual artifacts (enterprise beans or resources) defined in the application server.

When defining bindings, you specify Java Naming and Directory Interface (JNDI) names for the referenceable and referenced artifacts in an application. An example referenceable artifact is an EJB defined in an application. An example referenced artifact is an EJB or a resource reference used by the application. Binding definitions are stored in the `ibm-`*`xxx`*`-bnd.xmi` files of an application. The *xxx* can be `ejb-jar`, `web`, `application` or `application-client`.

Times when bindings can be defined

You can define bindings at the following times:

- During application development

  An application developer can create binding definitions in `ibm-`*`xxx`*`-bnd.xmi` files using a tool such as an IBM Rational developer tool. The developer then gives an enterprise application (`.ear` file) complete with bindings to a deployer. When assembling the application and then installing it onto a server supported by WebSphere Application Server, the deployer does not modify or override the bindings or generate default bindings unless changes to the bindings are necessary for successful deployment of the application.

- During application assembly

  An application assembler can define bindings when modifying deployment descriptors of an application. Bindings are specified in the **WebSphere Bindings** section of a deployment descriptor editor. Modifying the deployment descriptors might change the binding definitions in the `ibm-`*`xxx`*`-bnd.xmi` files created when assembling an application. After defining the bindings, the deployer can install the application onto a server supported by WebSphere Application Server without selecting to override the bindings or generate default bindings unless changes to the bindings are necessary for successful deployment of the application.
- During application installation

  An application deployer or server administrator can modify the bindings when installing the application onto a server supported by WebSphere Application Server using the administrative console. New binding definitions can be specified on the install wizard pages.

  If the deployer or administrator selects to override any existing bindings or to generate default bindings during application installation, default bindings are assigned to the application and new bindings might need to be specified using the console.

  Selecting **Generate Default Bindings** during application installation causes any incomplete bindings in the application to be filled in with default values. Existing bindings are not changed.

  Note: Bindings can be defined or overridden during application installation for all modules except application clients. For clients, you must define bindings for application client modules during assembly and store the bindings in the `ibm-application-client-bnd.xmi` file.
- During configuration of an installed application

  After an application is installed onto a server supported by WebSphere Application Server, an application deployer or server administrator can modify the bindings by changing values in administrative console pages such as those accessed from the settings page for the enterprise application.

Required bindings

Before an application can be successfully deployed, bindings must be defined for references to the following artifacts:

EJB JNDI names

For each enterprise bean (EJB), you must specify a JNDI name. The name is used to bind an entry in the global JNDI name space for the EJB home object. An example JNDI name for a *Product* EJB in a *Store* application might be `store/ejb/Product`. The binding definition is stored in the `META-INF/ibm-ejb-jar-bnd.xmi` file.

If a deployer chooses to generate default bindings when installing the application, the install wizard assigns EJB JNDI names having the form *`prefix/EJB_name`* to incomplete bindings. The default prefix is `ejb`, but can be overridden. The *EJB_name* is as specified in the deployment descriptor `<ejb-name>` tag.

During and after application installation, EJB JNDI names can be specified on the Provide JNDI Names for Beans panel. After installation, click **Applications > Enterprise Applications >***application_name* **> Provide JNDI Names for Beans** in the administrative console.

Data sources for entity beans

Entity beans such as container-managed persistence (CMP) beans store persistent data in data stores. With CMP beans, an EJB container manages the persistent state of the beans. You specify which data store a bean uses by binding an EJB module or an individual EJB to a data source. Binding an EJB module to a data source causes all entity beans in that module to use the same data source for persistence.

An example JNDI name for a *Store* data source in a *Store* application might be `store/jdbc/store`. The binding definition is stored in IBM binding files such as `ibm-ejb-jar-bnd.xmi`. A deployer can also specify whether authentication is handled at the container or application level.

If a deployer chooses to generate default bindings when installing the application, the install wizard generates the following for incomplete bindings:

- For EJB 2.x `.jar` files, connection factory bindings based on the JNDI name and authorization information specified
- For EJB 1.1 `.jar` files, data source bindings based on the JNDI name, data source user name and password specified

The generated bindings provide default connection factory settings for each EJB 2.x `.jar` file and default data source settings for each EJB 1.1 `.jar` file in the application being installed. No bean-level connection factory bindings or data source bindings are generated.

During and after application installation, data sources can be mapped to 2.x entity beans on the Map data sources for all 2.x CMP beans panel and on the Provide default data source mapping for modules containing 2.x entity beans panel. After installation, click **Applications > Enterprise Applications >***application_name* in the administrative console, then select **Map data sources for all 2.x CMP beans** or **Provide default data source mapping for modules containing 2.x entity beans**. Data sources can be mapped to 1.x entity beans on the Map data sources for all 1.x CMP beans panel and on the Provide default data source mapping for modules containing 1.x entity beans panel. After installation, access console pages similar to those for 2.x CMP beans, except click links for 1.x CMP beans.

Backend ID for EJB modules

If an EJB `.jar` file that defines CMP beans contains mappings for multiple backend databases, specify the appropriate backend ID that determines which persister classes are loaded at run time.

Specify the backend ID during application installation. You cannot select a backend ID after the application is installed onto a server.

EJB references

An enterprise bean (EJB) reference is a logical name used to locate the home interface of an enterprise bean. EJB references are specified during deployment. At run time, EJB references are bound to the physical location (global JNDI name) of the enterprise beans in the target operational environment. EJB references are made available in the `java:comp/env/ejb` Java naming subcontext.

For each EJB reference, you must specify a JNDI name. An example JNDI name for a *Supplier* EJB reference in a *Store* application might be `store/ejb/Supplier`. The binding definition is stored in IBM binding files such as `ibm-ejb-jar-bnd.xmi`. When the referenced EJB is also deployed in the same application server, you can specify a server-scoped JNDI name. But if the referenced EJB is deployed on a different application server or if `ejb-ref` is defined in an application client module, then you should specify the global cell-scoped JNDI name.

If a deployer chooses to generate default bindings when installing the application, the install wizard binds EJB references as follows: If an `<ejb-link>` is found, it is honored. If the `ejb-name` of an EJB defined in the application matches the `ejb-ref` name, then that EJB is chosen. Otherwise, if a unique EJB is found with a matching home (or local home) interface as the referenced bean, the reference is resolved automatically.

During and after application installation, EJB reference JNDI names can be specified on the Map EJB references to beans panel. After installation, click **Applications > Enterprise Applications >***application_name* **> Map EJB references to beans** in the administrative console.

Resource references

A resource reference is a logical name used to locate an external resource for an application. Resource references are specified during deployment. At run time, the references are bound to the physical location (global JNDI name) of the resource in the target operational environment.

Resource references are made available as follows:

Resource reference type	Subcontext declared in
Java DataBase Connectivity (JDBC) data source	`java:comp/env/jdbc`
JMS connection factory	`java:comp/env/jms`
JavaMail connection factory	`java:comp/env/mail`
Uniform Resource Locator (URL) connection factory	`java:comp/env/url`

For each resource reference, you must specify a JNDI name. If a deployer chooses to generate default bindings when installing the application, the install wizard generates resource reference bindings derived from the `<res-ref-name>` tag, assuming that the `java:comp/env` name is the same as the resource global JNDI name.

During application installation, resource reference JNDI names can be specified on the Map resource references to references panel. Specify JNDI names for the resources that represent the logical names defined in resource references. You can optionally specify login configuration name and authentication properties for the resource. After specifying authentication properties, click **OK** to save the values and return to the mapping step. Each resource reference defined in an application must be bound to a resource defined in your WebSphere Application Server configuration. After installation, click **Applications > Enterprise Applications >***application_name* **> Map resource references to resources** in the administrative console to access the Map resource references to references panel.

Virtual host bindings for Web modules

You must bind each Web module to a specific virtual host. The binding informs a Web server plug-in that all requests that match the virtual host must be handled by the Web application. An example virtual host to be bound to a *Store* Web application might be `store_host`. The binding definition is stored in IBM binding files such as `WEB-INF/ibm-web-bnd.xmi`.

If a deployer chooses to generate default bindings when installing the application, the install wizard sets the virtual host to `default_host` for each `.war` file.

During and after application installation, you can map a virtual host to a Web module defined in your application. On the Map virtual hosts for Web modules panel, specify a virtual host. The port number specified in the virtual host definition is used in the URL that is used to access artifacts such as servlets and JSP files in the Web module. For example, an external URL for a Web artifact such as a JSP file is `http://`*`host_name`*`:`*`virtual_host_port`*`/`*`context_root`*`/`*`jsp_path`*. After installation, click **Applications > Enterprise Applications >***application_name* **> Map virtual hosts for Web modules** in the administrative console.

Message-driven beans

For each message-driven bean, you must specify a queue or topic to which the bean will listen. A message-driven bean is invoked by a Java Messaging Service (JMS) listener when a message arrives on the input queue that the listener is monitoring. A deployer specifies a listener port or JNDI name of an activation spec as defined in a connector module (`.rar` file) under **WebSphere Bindings** on the **Beans** page of an assembly tool EJB deployment descriptor editor. An example JNDI name for a listener port to be used by a `Store` application might be `StoreMdbListener`. The binding definition is stored in IBM bindings files such as `ibm-ejb-jar-bnd.xmi`.

If a deployer chooses to generate default bindings when installing the application, the install wizard assigns JNDI names to incomplete bindings.

- For EJB 2.x message-driven beans deployed as JCA 1.5-compliant resources, the install wizard assigns JNDI names corresponding to activationSpec instances in the form `eis/MDB_ejb-name`.
- For EJB 2.x message-driven beans deployed against listener ports, the listener ports are derived from the message-driven bean `<ejb-name>` tag with the string `Port` appended.

During application installation using the administrative console, you can specify a listener port name or an activation specification JNDI name for every message-driven bean on the panel **Provide Listener Ports or activation specification JNDI name for messaging beans**. A listener port name must be provided when using the JMS providers: Version 5 default messaging, WebSphere MQ, or generic. An activation specification must be provided when the application's resources are configured using the default messaging provider or any generic J2C resource adapter that supports inbound messaging. If neither is specified, then a validation error is displayed after you click **Finish** on the Summary panel. Also, if the module containing the message-driven bean is deployed on a 5.x deployment target and a listener port is not specified, then a validation error is displayed after you click **Next**.

After application installation, you can specify JNDI names and configure message-driven beans on console pages under **Resources > JMS Providers** or under **Resources > Resource Adapters**. For more information, refer to ″Using asynchronous messaging″ in the information center.

Message destination references

A message destination reference is a logical name used to locate an enterprise bean in an EJB module that acts as a message destination. Message destination references exist only in J2EE 1.4 artifacts such as--

- J2EE 1.4 application clients
- EJB 2.1 projects
- 2.4 Web applications

If multiple message destination references are associated with a single message destination link, then a single JNDI name for an enterprise bean that maps to the message destination link, and in turn to all of the linked message destination references, is collected during deployment. At run time, the message destination references are bound to the administered message destinations in the target operational environment.

If a deployer chooses to generate default bindings when installing the application, the install wizard assigns JNDI names to incomplete message destination references as follows: If a message destination reference has a `<message-destination-link>`, then the JNDI name is set to `ejs/message-destination-linkName`. Otherwise, the JNDI name is set to `eis/message-destination-refName`.

Other bindings that might be needed

Depending on the references in and artifacts used by your application, you might need to define bindings for references and artifacts not listed in this article.

Mapping modules to servers

Each module of a deployed application must be mapped to one or more target servers. The target server can be an application server or Web server.

You can map modules of an application or standalone Web module to one or more target servers during or after application installation using the console. This article assumes that the module is already installed on a server and that you want to change the mappings.

Before you change a mapping, check the deployment targets. You must specify an appropriate deployment target for a module. Modules that use Version 6.x features cannot be installed onto a Version 5.x target server.

During application installation, different deployment targets might have been specified.

You use the Map modules to servers panel of the administrative console to view and change mappings. This panel is displayed during application installation using the console and, after the application is installed, can be accessed from the settings page for an enterprise application.

On the Map modules to servers panel, specify target servers where you want to install the modules contained in your application. Modules can be installed on the same application server or dispersed among several application servers. Also, specify the Web servers as targets that will serve as routers for requests to your application. The plug-in configuration file `plugin-cfg.xml` for each Web server is generated based on the applications which are routed through it.

1. Click **Applications > Enterprise Applications >***application_name* **> Map modules to servers** in the console navigation tree. The Selecting servers - Map modules to servers panel is displayed.
2. Examine the list of mappings. Ensure that each **Module** entry is mapped to the desired target(s), identified under **Server**.
3. Change a mapping as needed.
   a. Select each module that you want mapped to the same target(s). In the list of mappings, place a check mark in the **Select** check boxes beside the modules.
   b. From the **Clusters and Servers** drop-down list, select one or more targets. Use the **Ctrl** key to select multiple targets. For example, to have a Web server serve your application, use the **Ctrl** key to select an application server and the Web server together in order to have the plug-in configuration file `plugin-cfg.xml` for that Web server generated based on the applications which are routed through it.
   c. Click **Apply**.
4. Repeat steps 2 and 3 until each module maps to the desired target(s).
5. Click **OK**.

The application or module configurations are changed. The application or standalone Web module is restarted so the changes take effect.

Save changes to your administrative configuration.

Starting and stopping applications

You can start an application that is not running (has a status of *Stopped*) or stop an application that is running (has a status of *Started*).

This article assumes that the application is installed on a server. By default, the application starts automatically when the server starts.

You can start and stop applications manually using the following:

- Administrative console
- wsadmin `startApplication` and `stopApplication` commands
- Java programs that use ApplicationManager or AppManagement MBeans

This article describes how to use the administrative console to start or stop an application.

1. Go to the Enterprise Applications page. Click **Applications > Enterprise Applications** in the console navigation tree.
2. Select the check box for the application you want started or stopped.
3. Click a button:

Option	Description
Start	Runs the application and changes the state of the application to *Started*. The status is changed to *partially started* if not all servers on which the application is deployed are running.
Stop	Stops the processing of the application and changes the state of the application to *Stopped*.

To restart a running application, select the application you want to restart, click **Stop** and then click **Start**.

The status of the application changes and a message stating that the application started or stopped displays at the top the page.

You can configure an application so it does not start automatically when the server on which it resides starts. You then start the application manually using options described in this article.

If you want your application to start automatically when its server starts, you can adjust values that control how quickly the application or its server starts:

1. Go the settings page for your enterprise application. Click **Applications** > **Enterprise Applications** >*application_name*.
2. Specify a different value for **Starting weight**.

   This setting specifies the order in which applications are started when the server starts. The default value is `1` in a range from 0 to 2147483647. The application with the lowest starting weight is started first.
3. Specify a different value for **Background application**.

   This setting specifies whether the application must initialize fully before its server starts. The default value of `false` prevents the server from starting completely until the application starts. To reduce the amount of time it takes to start the server, you can set the value to `true` and have the application start on a background thread, thus allowing server startup to continue without waiting for the application
4. Save the changes to the application configuration.

Disabling automatic starting of applications

By default, an installed application starts automatically when the server on which the application resides starts. You can disable the automatic starting of the application, and later enable the automatic starting again.

This article assumes that the enterprise application is installed on an application server and that the application starts automatically when the server starts.

You might want an application to run only after you start it manually and not to run every time after the server starts. The target mapping for an application controls whether an application starts automatically when the server starts or requires you to start the application manually.

1. Go to the Target Mapping settings page for your application. Click **Applications** > **Enterprise Applications** >*application_name* > **Target Mappings** >*target_name*. The *target_name* is the server on which the application resides. You use the Target Mapping settings page to map an installed application or module to a server.
2. Clear the **Enabled** check box.
3. Click **OK**.
4. Save changes to the administrative configuration.

The application does not start when its server starts. You must start the application manually.

To enable automatic starting of the application, select the **Enabled** check box on the Target Mappings settings page for the application, click **OK**, and then save changes to the configuration.

Target mapping collection

Use this page to view mappings of deployed applications or modules to servers.

To view this administrative console page, click **Applications** > **Enterprise Applications** >*application_name* > **Target Mappings**.

Target

States the name of the target server to which the application or module maps. You specify the target on the Map modules to servers page accessed from the settings for an application.

Node

Specifies the node name if the target is a server.

Version

Specifies the version level of the target. The target can be a 5.x deployment target or a 6.x deployment target.

A *5.x deployment target* is a server on a WebSphere Application Server Version 5 product.

A *6.x deployment target* is a server on a WebSphere Application Server Version 6 product.

An application, enterprise bean (EJB) module, Web module or application client module developed for a WebSphere Application Server Version 5.x product can reside on a 5.x or 6.x deployment target, provided the module--

- Does not support Java 2 Platform, Enterprise Edition (J2EE) 1.4;
- Does not call any 6.x run-time application programming interfaces (APIs); and
- Does not use any 6.x product features.

Similarly, a resource adapter (connector) module, or RAR file, developed for a Version 5.x product can reside on a 5.x or 6.x node, provided the module does not support Java Cryptography Architecture (JCA) 1.5 and does not call any 6.x run-time application programming interfaces (APIs). If the module supports JCA 1.5 or calls a 6.x API, then the module must reside on a 6.x node.

Status

Indicates whether the status of the target server is started, stopped or unavailable.

Target mapping settings

Use this page to map a deployed application or module to a server.

To view this administrative console page, click **Applications** > **Enterprise Applications** >*application_name* > **Target Mappings** >*target_name*.

Target:

States the name of the target server to which the application or module maps. You specify the target on the Map modules to servers page accessed from the settings for an application.

Data type	String

Enabled:

Indicates whether the application modules installed on the target server are started (or enabled) when the server starts. This sets the initial state of application modules. A `true` value indicates that the corresponding modules are enabled and thus are accessible when the server starts. A `false` value indicates that the corresponding modules are not enabled and thus are not accessible when the server starts.

Data type	Boolean
Default	true

Exporting applications

You can export an enterprise application to a location of your choice.

Exporting applications enables you to back up your applications and preserve binding information for the applications. You might export your applications before updating installed applications or migrating to a later version of the WebSphere Application Server product.

1. Click **Applications > Enterprise Applications** in the console navigation tree to access the Enterprise Applications page.
2. Select the check box beside the application and click **Export**.
3. On the Export Application EAR Files page, click on the link to download the exported EAR file.
4. Use the browser dialogue to specify a location at which to save the exported EAR file.
5. Click **Back** to return to the Enterprise Applications page.

The file containing binding information is exported to the specified node and directory, and has the name *enterprise_application_name*.ear.

Exporting DDL files

You can export data definition language (DDL) files in the enterprise bean (EJB) modules of an application.

Exporting DDL (`Table.ddl`) files in the EJB modules of an application downloads the DDL files to a location of your choice.

1. Click **Applications > Enterprise Applications** in the administrative console navigation tree to access the Enterprise Applications page.
2. Place a check mark in the check box beside the application and click **Export DDL**. If the application has no DDL files in any of its EJB modules, then the message *No DDL files were found* is displayed at the top of the page. If the application has DDL files in its EJB modules, then a page listing DDL files in the format *`application_name.ear`*`/`*`_module`*`.jar_Table.ddl` is displayed.
3. Click on a file in the list and specify the location to which to download the file.

   Tip: Mozilla browsers might display the contents of the `Table.ddl` file instead of saving the file to disk. To save the file, edit the **Helper Application** preference settings of the Mozilla browser by adding a new type for DDL and specifying that you want to save DDL files to disk. That is, set `MIME type = ddl` and `Extension = ddl`.

The DDL file is downloaded to the specified location.

Updating applications

You can update application files deployed on a server.

Refer to “Ways to update application files” on page 739 and decide how to update your application files. You can update enterprise applications or modules using the administrative console or a wsadmin tool. Both ways provide identical updating capabilities. Further, in some situations, you can update applications or modules without restarting the application server.

Note that Version 6 supports Java 2 Platform, Enterprise Edition (J2EE) 1.4 enterprise applications and modules. If you are deploying J2EE 1.4 modules, ensure that the target server and its node support Version 6. The administrative console Server collection pages show the versions for servers. You can deploy J2EE 1.4 modules to Version 6.x servers only. You cannot deploy J2EE 1.4 modules to servers on Version 5.x nodes. Refer to “Installable module versions” on page 706 for details.

This article describes how to update deployed applications or modules using the administrative console.

Updating consists of adding a new file or module to an installed application, or replacing or removing an installed application, file or module. After replacement of a full application, the old application is uninstalled. After replacement of a module, file or partial application, the old installed module, file or partial application is removed from the installed application.

1. Update your application or modules and reassemble them using an assembly tool. Typical tasks include adding or editing assembly properties, adding or importing modules into an application, and adding enterprise beans, Web components, and files.
2. Back up the installed application.
   a. Go to the Enterprise Applications page of the administrative console. Click **Applications > Enterprise Applications** in the console navigation tree.
   b. Export the application to an EAR file. Select the application you want uninstalled and click **Export**. Exporting the application preserves the binding information.
3. With the application selected on the Enterprise Applications page, click **Update**. The Preparing for application update page is displayed.
4. Under **Specify the EAR, WAR or JAR module to upload and install**:
   a. Ensure that **Application name** refers to the application to be updated.
   b. Under **Update options**, select the installed application, module, or file that you want to update. The online help Preparing for application update settings provides detailed information on the options. Briefly, the options are as follows:

      Full application

      Replaces the installed (old) application with the updated (new) application on the server. If you select **Full application**, specify the path for the new `.ear` file. The path provides the location of the new `.ear` file before installation.

      Single module

      Adds a new module to, or replaces a module in, the installed application. Specify the path for the new Web module (`.war`), EJB module (`.jar`), or resource adapter module (`.rar`). The path provides the location of the new module before installation.

      To replace a module, the value for **Relative path to module** (or module URI) must match the path of the module to be updated in the installed application.

      To add a new module to the installed application, the value for **Relative path to module** must *not* match the path of a module in the installed application. The value specifies the desired path for the new module.

      If you are installing a standalone Web module, specify a value for **Context root**.

      Single file

      Adds a new file to, or replaces a file in, the installed application. Specify the path for the new file. The path provides the location of the new file before installation.

      To replace a file, the value for **Relative path to file** must match the path of the file to be updated in the installed application.

      To add a new file to the installed application, the value for **Relative path to file** must *not* match the path of a file in the installed application. The value specifies the desired path for the new file.

      The relative path to a file from the root of the application is the concatenation of the module path and the file path within the module. For example, if the file is `com/mycompany/abc.class` within the module `foo.jar`, then the relative file path is `foo.jar/com/mycompany/abc.class`.

      Partial application

      Updates multiple files of an installed application by uploading a compressed file. Depending on the contents of the compressed file, a single use of this option can replace files in, add new files to, and delete files from the installed application. Each entry in the compressed file is treated as a single file and the path of the file from the root of the compressed file is treated as the relative path of the file in the installed application.

Specify a valid compressed file format such as `.zip` or `.gzip`. The path provides the location of the compressed file before installation. This option unzips the compressed file into the installed application directory.

To replace a file, a file in the compressed file must have the same relative path as the file to be updated in the installed application.

To add a new file to the installed application, a file in the compressed file must have a different relative path than the files in the installed application.

To remove a file from the installed application, specify metadata in the compressed file using a file named `META-INF/ibm-partialapp-delete.props` at any archive scope. The `ibm-partialapp-delete.props` file must be an ASCII file that lists files to be deleted in that archive with one entry for each line. The entry can contain a string pattern such as a regular expression that identifies multiple files. The file paths for the files to be deleted must be relative to the archive path that has the `META-INF/ibm-partialapp-delete.props` file. Refer to Preparing for application update settings for more information.

After you select an option, specify a path. Use **Local file system** if the browser and application files are on the same machine (whether or not the server is on that machine, too). Use **Remote file system** if the application file resides on any node in the current cell context. Only `.ear`, `.jar`, or `.war` files are shown during the browsing.

During application updating, application files typically are uploaded from a client machine running the browser to the server machine running the administrative console, where they are deployed. In such cases, use the Web browser running the administrative console to select EAR, WAR, or JAR modules to upload to the server machine.

In some cases, however, the application files reside on the file system of any of the nodes in a cell. To have the application server install these files, use the **Remote file system** option.

Also use the **Remote file system** option to specify an application file already residing on the machine running the application server. For example, the field value on a Windows machine might be `C:\WebSphere\AppServer\installableApps\test.ear`. If you are installing a standalone WAR module, then specify the context root as well.

After the application file is transferred, the **Remote file system** value shows the path of the temporary location on the server machine.

5. If you selected the **Full application** or **Single module** option:
   a. Click **Next** to display a wizard for updating application files.
   b. Complete the steps in the update wizard. This update wizard, which is similar to the installation wizard, provides fields for specifying or editing application binding information. Refer to information on installing applications and on the settings page for application installation for guidance. Note that the installation steps have the merged binding information from the new version and the old version. If the new version has bindings for application artifacts such as EJB JNDI names, EJB references or resource references, then those bindings will be part of the merged binding information. If new bindings are not present, then bindings are taken from the installed (old) version. If bindings are not present in the old version and if the default binding generation option is enabled, then the default bindings will be part of the merged binding information. You can select whether to ignore bindings in the old version or ones in the new version.
6. Click **Finish**.
7. If you did not use the Map modules to servers page of the update wizard, after updating the application, map the installed application or module to servers. Use the Map modules to servers page accessed from the Enterprise Applications page.
   a. Go to the Map modules to servers page. Click **Applications > Enterprise Applications >***application_name* **> Map modules to servers**.

b. Specify the application server where you want to install modules contained in your application and click **OK**. You can deploy J2EE 1.4 modules to servers on Version 6.x nodes only.

After the application file or module installs successfully, do the following:

1. Save the changes to your configuration.

   When you update a full application in the single server (base) product, after you save the changes, the old version of the application is uninstalled and the new version is installed into the configuration. The application binaries for the old version are deleted from the destination directory and the new binaries are copied to the directory.
2. Examine the values specified for **Reload Enabled** and **Reload Interval** on the settings page for your enterprise application.

   If reloading of application files is enabled and the reload interval is greater than zero (0), the application's files are reloaded after the application is updated. For Web modules such as servlets and JavaServer page (JSP) files, a Web container reloads a Web module only when the IBM extension reloadingEnabled in the `ibm-web-ext.xmi` file is also set to `true`. You can set reloadingEnabled to `true` when editing your Web module's extended deployment descriptors in an assembly tool.
3. If needed, restart the application manually so the changes take effect.

   If the application is updated while it is running, WebSphere Application Server automatically stops the application or only its changed components, updates the application logic, and restarts the stopped application or its components.
4. If the application you are updating is deployed on a server that has its application class loader policy set to `Single`, restart the server.

Ways to update application files

You can update application files deployed on a server in several ways.

Table 8. Ways to update application files

Option	Method	Comments	Starting after update
Administrative console update wizard See "Updating applications" on page 736.	Briefly, do the following: 1. Go to the Enterprise Applications page. Click **Applications > Enterprise Applications** in the console navigation tree. 2. Select the application to update and click **Update**. 3. On the Preparing for application update page, identify the application, module or files to update and click **Next**. 4. Complete steps in the update wizard and click **Finish**.	On the Preparing for application update page: • Use **Full application** to update an `.ear` file. • Use **Single module** to update a `.war`, enterprise bean `.jar`, or connector `.rar` file. • Use **Single file** to update a file other than an `.ear`, `.war`, EJB `.jar`, or `.rar` file. • Use **Partial application** to update or remove multiple files.	On the Enterprise Applications page, select the updated application and click **Start**.
wsadmin scripts	Invoke AdminApp object *install* commands with the *-update* option in a script or at a command prompt.	″Getting started with scripting″ in the information center provides an overview of wsadmin.	Invoke the wsadmin *startApplication* command.

Table 8. Ways to update application files (continued)

Java application programming interfaces. See ″Using administrative programs (JMX)″ in the information center.	Update deployed applications by completing the steps in ″Managing applications through programming″ in the information center.	Update an application in the following ways: • Update the entire application • Add to, update or delete multiple files in an application • Add a module to an application • Update a module in an application • Delete a module in an application • Add a file to an application • Update a file in an application • Delete a file in an application	Start the application by either of the following methods: • On the Enterprise Applications page, select the updated application and click **Start**. • Invoke the wsadmin *startApplication* command.
WebSphere rapid deployment Refer to articles under **Rapid deployment of J2EE applications** in this information center.	Briefly, do the following: 1. Update your J2EE application files. 2. Set up the rapid deployment environment. 3. Create a free-form project. 4. Launch a rapid deployment session. 5. Drop your updated application files into the free-form project.	WebSphere rapid deployment offers the following advantages: • You do not need to assemble your J2EE application files prior to deployment. • You do not need to use other installation tools mentioned in this table to deploy the files.	Use any of the above options to start the application. Clicking **Start** on the Enterprise Applications page is the easiest option.
Hot deployment and dynamic reloading	Briefly, do the following: 1. Update your application (`.ear`), Web module (`.war`), enterprise bean `.jar` or HTTP plug-in configuration file. 2. Follow instructions in Hot deployment and dynamic reloading to update your file.	If you are new to WebSphere Application Server, use the administrative console to update applications. That option is easier. Hot deployment and dynamic reloading is more difficult to complete. You must directly manipulate the application or module file on the server where the application is deployed.	Use any of the above options to start the application. Clicking **Start** on the Enterprise Applications page is the easiest option.

You can update `.ear`, enterprise bean `.jar`, Web module `.war`, connector `.rar`, application client `.jar`, and any other files used by an installed application.

If the application is updated while it is running, WebSphere Application Server automatically stops the application, updates the application logic and restarts the application. If the application does not start automatically, start it manually using one of the **Starting** options.

Preparing for application update settings

Use this page to update enterprise applications, modules or files already installed on a server.

To view this administrative console page, do the following:
1. Click **Applications > Enterprise Applications**.
2. Select the installed application or module that you want to update.
3. Click **Update**.

Clicking **Update** displays a page that helps you update application files deployed in the cell. You can update the full application, a single module, a single file, or part of the application. If a new file or module has the same relative path as a file or module already existing on the server, the new file or module replaces the existing file or module. If the new file or module does not exist on the server, it is added to the deployed application.

Application name

Specifies the name of the installed (or deployed) application that you selected on the Enterprise Applications page.

Full application

Under **Update options**, specifies to replace the application already installed on the server with a new (updated) enterprise application `.ear` file.

After selecting this option, specify whether the `.ear` file is on a local or remote file system and the full path name of the application. The path provides the location of the updated `.ear` file before installation.

Use **Local file system** if the browser and the updated files or modules are on the same machine, whether or not the server is on that machine too. **Local file system** is available for all update options.

Use **Remote file system** if the application file resides on any node in the current cell context. Only `.ear`, `.jar`, or `.war` files are shown during the browsing. Also use the **Remote file system** option to specify an application file already residing on the machine running the application server. For example, the field value on a Windows machine might be `C:\WebSphere\AppServer\installableApps\test.ear`.

Note: During application installation, application files typically are uploaded from a client machine running the browser to the server machine running the administrative console, where they are deployed. In such cases, use the Web browser running the administrative console to select `.ear`, `.war`, or `.jar` modules to upload to the server machine. In some cases, however, the application files reside on the file system of any of the nodes in a cell. To have the application server install these files, use the **Remote file system** option.

After specifying the required information on the `.ear` file, click **Next** to display a wizard for updating application files. The update wizard, which is similar to the installation wizard, provides fields for specifying or editing application binding information. Complete the steps in the update wizard as needed.

When the full application is updated, the old application is uninstalled and the new application is installed. When the configuration changes are saved, the application files are expanded on the node where application will run. If the application is running on the node while it is updated, then the application is stopped, application files are updated, and application is started.

Single module

Under **Update options**, specifies to replace a module in or add a module to an installed application. The module can be a Web module (`.war` file), enterprise bean module (EJB `.jar` file), or resource adapter module (connector `.rar` file).

After selecting this option, specify whether the module is on a local or remote file system and the full path name of the module. The path provides the location of the updated module before installation. For information on **Local file system** and **Remote file system**, refer to the description of **Full application** above.

To replace a module, the value for **Relative path to module** (module URI) must match the path of the module to be updated in the installed application.

To add a new module to the installed application, the value for **Relative path to module** must *not* match the path of a module in the installed application. The value specifies the desired path for the new module.

If you are installing a standalone Web module, specify a value for **Context root**. The context root is combined with the defined servlet mapping (from the `.war` file) to compose the full URL that users type to access the servlet. For example, if the context root is `/gettingstarted` and the servlet mapping is `MySession`, then the URL is `http://host:port/gettingstarted/MySession`.

After specifying the required information on the module, click **Next** to display a wizard for updating application files. The update wizard, which is similar to the installation wizard, provides fields for specifying or editing module binding information. Complete the steps in the update wizard as needed.

After a single module is added or updated, when configuration changes are saved, the new or updated module is stored in the deployed application in the WebSphere Application Server configuration repository. When these changes are synchronized with the node, the module is added or updated to the node's file system. If the application is running on the node when the module is added or updated, then one of the following occurs:

- For updates to a Web module, the running Web module is stopped, Web module files are updated, and then the Web module is started.
- For module additions, the added module is started on the application servers where the application is running after it is expanded on the node. An application restart is not necessary.
- If the class loader policy for the application is set to `Single` so that all modules share a class loader, then the entire application is stopped and restarted for module level changes.
- If the security provider configured with WebSphere Application Server does not support dynamic updates, then the entire application is stopped and restarted for module level changes.
- For all other updates to a module, the entire application is stopped, the module files are updated, then the entire application is started.

Single file

Under **Update options**, specifies to replace a file in or add a file to an installed application.

Use this option to update a file used by the application that is not an `.ear`, `.war`, `.rar` or, in some instances, a `.jar` file. You can use this option to add or update .jar files that are not defined as modules in the application. To update an `.ear`, file use the **Full application** option. To update a `.war` file, `.rar` file , or `.jar` file that is defined as a module in the application, use the **Single module** option.

After selecting this option, specify whether the file is on a local or remote file system and the full path name of the file. The path provides the location of the updated file before installation. For information on **Local file system** and **Remote file system**, refer to the description of **Full application** above.

Next, specify a value for **Relative path to file**. The relative path of the file must start from the root of the `.ear` file. For example, if the file is located at `com/company/greeting.class` in module `hello.jar`, specify a relative path of `hello.jar/com/company/greeting.class`.

To replace a file, the value for **Relative path to file** must match the path of the file to be updated in the installed application.

To add a new file to the installed application, the value for **Relative path to file** must *not* match the path of a file in the installed application. The value specifies the desired path for the new file.

After a single file is added or updated, when configuration changes are saved, the new or updated file is stored in the deployed application in the WebSphere Application Server configuration repository. When these changes are synchronized with the node, the file is added or updated to the node's file system. If the application is running on the node when the file is added or updated, then one of the following occurs:

- For files added or updated at application scope or in non-Web modules, the entire application is stopped, the file is added or updated, and then the entire application is restarted.
- For files added or updated to Web module metadata (`META-INF` or `WEB-INF` directory), the running Web module is stopped, the Web module file is added or updated, and then the Web module is started.
- For all other files in Web modules, the file is added or updated on the node's file system without stopping the application or any of its components.

Partial application

Under **Update options**, specifies to update multiple files of an installed application by uploading a compressed file. Depending on the contents of the compressed file, a single use of this option can replace files in, add new files to, and delete files from the installed application. Each entry in the compressed file is treated as a single file and the path of the file from the root of the compressed file is treated as the relative path of the file in the installed application.

After selecting this option, specify whether the compressed file is on a local or remote file system and the full path name of the compressed file. You will likely use **Local file system** because you are uploading a compressed file and remote browsing only works for `.ear`, `.war` or `.jar` files. Specify a valid compressed file format such as `.zip` or `.gzip`. The path provides the location of the compressed file before installation. This option unzips the compressed file into the installed application directory.

Use **Local file system** if the browser and the updated files or modules are on the same machine, whether or not the server is on that machine too. **Local file system** is available for all update options.

To replace a file, a file in the compressed file must have the same relative path as the file to be updated in the installed application.

To add a new file to the installed application, a file in the compressed file must have a different relative path than the files in the installed application.

The relative path of a file in the installed application is formed by concatenation of the relative path of the module (if the file is inside a module) and the relative path of the file from the root of the module separated by `/`.

To remove a file from the installed application, specify metadata in the compressed file using a file named `META-INF/ibm-partialapp-delete.props` at any archive scope. The `ibm-partialapp-delete.props` file must be an ASCII file that lists files to be deleted in that archive with one entry for each line. The entry can contain a string pattern such as a regular expression that identifies multiple files. The file paths for the files to be deleted must be relative to the archive path that has the `META-INF/ibm-partialapp-delete.props` file.

Level of files to delete	**Metadata .props file to include in compressed file**
Application	Include `META-INF/ibm-partialapp-delete.props` in the compressed file. In the metadata `.props` file, list files to be deleted. File paths are relative to the location of the `META-INF/ibm-partialapp-delete.props` file. For example, to delete a file named `utils/config.xmi` from the root of the `my.ear` file, include the line `utils/config.xmi` in the `META-INF/ibm-partialapp-delete.props` file.
Module	Include *`module_uri`*`/META-INF/ibm-partialapp-delete.props` in the compressed file. To delete one file from a module, include the file path relative to the module in the metadata `.props` file. For example, to delete `a/b/c.jsp` from the `my.jar` module, include `a/b/c.class` in `my.jar/META-INF/ibm-partialapp-delete.props` file in the compressed file. To delete multiple files within a module, list the files to be deleted in the metadata `.props` file with one entry on each line. For example, to delete all JavaServer Pages (`.jsp` files) from the `my.war` file, include the line `.*jsp` in the `my.war/META-INF/ibm-partialapp-delete.props` file. The line uses a regular expression, `.*jsp`, to identify all `.jsp` files in `my.war`.

You can use a single partial application file to add, delete and update multiple files.

After a partial application update, when configuration changes are saved, the new or updated application file is stored in the deployed application in the WebSphere Application Server configuration repository. When these changes are synchronized with the node, the files are added or updated to the node's file system. Because the partial application option updates multiple files, the application components that are restarted are determined using individual files in the partial application.

An example of entries in a partial application compressed file follows:

```
util.jar
META-INF/ibm-partialapp-delete.props
foo.jar/com/mycomp/xyz.class
xyz.war/welcome.jsp
xyz.war/WEB-INF/web.xml
webmod.war/META-INF/ibm-partialapp-delete.props
```

For this example, the `META-INF/ibm-partialapp-delete.props` file contains the `.*.dat` and `tools/test.jar` files. The `webmod.war/META-INF/ibm-partialapp-delete.props` file contains the `com/test/.*.jsp` and `WEB-INF/test.xmi` files.

The partial application update option does the following:

- Adds or replaces `util.jar` in the deployed application.
- Adds or replaces `com/mycomp/xyz.class` inside the `foo.jar` file of the deployed application.
- Deletes `*.dat` files from the application, but not from any modules.
- Deletes `tools/test.jar` from the application.
- Adds or replaces `welcome.jsp` inside the `xyz.war` module of the deployed application.
- Replaces `WEB-INF/web.xml` inside the `xyz.war` module of the deployed application.
- Deletes `com/test/*.jsp` from the `webmod.war` module.
- Deletes `WEB-INF/test.xmi` from the `webmod.war` module.

Hot deployment and dynamic reloading

You can make various changes to applications and their modules without having to stop the server and start it again. Making these types of changes is known as *hot deployment and dynamic reloading*.

This article assumes that your application files are deployed on a server and you want to upgrade the files.

Hot deployment is the process of adding new components (such as WAR files, EJB Jar files, enterprise Java beans, servlets, and JSP files) to a running server without having to stop the application server process and start it again.

Dynamic reloading is the ability to change an existing component without needing to restart the server in order for the change to take effect. Dynamic reloading involves:

- Changes to the implementation of a component of an application, such as changing the implementation of a servlet
- Changes to the settings of the application, such as changing the deployment descriptor for a Web module

As opposed to the changes made to a deployed application described in “Updating applications” on page 736, changes made using hot deployment or dynamic reloading do not use the administrative console or a wsadmin scripting command. You must directly manipulate the application files on the server where the application is deployed.

If the application you are updating is deployed on a server that has its application class loader policy set to `Single`, you might not be able to dynamically reload your application. At minimum, you must restart the server after updating your application.

1. Locate your expanded application files. The application files are in the directory you specified when installing the application or, if you did not specify a custom target directory, are in the default target directory, *install_root*/installedApps/*cell_name*. Your EAR file, `${APP_INSTALL_ROOT}/`*`cell_name`*`/`*`application_name`*`.ear`, points to the target directory. The `variables.xml` file for the node defines ${APP_INSTALL_ROOT}. It is important to locate the expanded application files because, as part of installing applications, a WebSphere application server unjars

portions of the EAR file onto the file system of the computer that will run the application. These expanded files are what the server looks at when running your application. If you cannot locate the expanded application files, look at the binariesURL attribute in the `deployment.xml` file for your application. The attribute designates the location the run time uses to find the application files. For the remainder of this information on hot deployment and dynamic reloading, *application_root* represents the root directory of the expanded application files.

2. Locate application metadata files. The metadata files include the deployment descriptors (web.xml, application.xml, ejb-jar.xml, and the like), the bindings files (`ibm-web-bnd.xmi`, `ibm-app-bnd.xmi`, and the like), and the extensions files (`ibm-web-ext.xmi`, `ibm-app-ext.xmi`, and the like). Metadata XML files for an application can be loaded from one of two locations. The metadata files can be loaded from the same location as the application binary files (such as *application_root*/META-INF) or they can be loaded from the WebSphere configuration tree, ${CONFIG_ROOT}/cells/*cell_name*/applications /*application_EAR_name*/deployments/*application_name*/. The value of the useMetadataFromBinary flag specified during application installation controls which location is used. If specified, the metadata files are loaded from the same location as the application binary files. If not specified, the metadata files are loaded from the application deployment folder in the configuration tree. For the remainder of this information, *metadata_root* represents the location of the metadata files for the specified application or module.
3. **Optional:** Examine the values specified for **Enable class reloading** and **Reloading interval** on the settings page for your enterprise application. If reloading of application files is enabled and the reload interval is greater than zero (0), the application files are reloaded after the application is updated. For Web modules such as servlets and JavaServer page (JSP) files, a Web container reloads a Web module only when the IBM extension reloadingEnabled in the `ibm-web-ext.xmi` file is also set to `true`. You can set reloadingEnabled to `true` when editing your Web module's extended deployment descriptors in an assembly tool.
4. Change or add the following components or modules as needed:
   - Application files
   - WAR files
   - EJB Jar files
   - HTTP plug-in configuration files
5. For changes to take effect, you might need to start, stop, or restart an application. "Starting and stopping applications" on page 733 provides information on using the administrative console to start, stop, or restart an application. ″Starting applications with scripting″ and ″Stopping applications with scripting″ provide information on using the wsadmin scripting tool.

Changing or adding application files

You can change or add application files on application servers without having to stop the server and start it again.

There are several changes that you can make to deployed application files without stopping the server and starting it again. You can use the update wizard of the administrative console to make the changes without having to stop and restart the server. This article describes how to make the following changes by manipulating an application file on the server where the application is deployed:

- Updating an existing application on a running server, providing a new enterprise application (EAR file)
- Adding a new application to a running server
- Removing an existing application from a running server
- Changing or adding files to existing enterprise bean (EJB) or Web modules
- Changing the `application.xml` file for an application
- Changing the `ibm-app-ext.xmi` file for an application
- Changing the `ibm-app-bnd.xmi` file for an application
- Changing a non-module Jar file contained in the EAR file

Updating an existing application on a running server (providing a new EAR file)

Reinstall an updated application using the administrative console or the wsadmin `$AdminApp install` command with the `-update` option.

Both reinstallation methods enable you to update an existing application using any of the other steps listed in this file, including changing classes, adding modules, removing modules, changing modules, or changing metadata files. The application reinstallation methods detect the changes in your application and prompt you for additional binding data that might be needed to install the application. The reinstallation process automatically stops and restarts your application on the appropriate servers.

Hot deployment	Yes
Dynamic reloading	Yes

Adding a new application to a running server

Install an application using the administrative console or the wsadmin `install` command.

Hot deployment	Yes
Dynamic reloading	No

Removing an existing application from a running server

Stop the application and then uninstall it from the server. Use the administrative console to stop the application and then uninstall it. Or run the wasadmin `stopApplication` command and then the `uninstall` command.

Hot deployment	Yes
Dynamic reloading	No

Changing or adding files to existing EJB or Web modules

1. Update the application files in the *application_root* location.
2. Restart the application. Use the administrative console to restart the application. Or run the wasadmin `stopApplication` and `startApplication` commands.

Hot deployment	Yes
Dynamic reloading	No

Changing the application.xml file for an application

Restart the application. Automatic reloading will not detect the change. Use the administrative console to restart the application. Or run the wasadmin `stopApplication` and `startApplication` commands.

Hot deployment	Not applicable
Dynamic reloading	Yes

Changing the ibm-app-ext.xmi file for an application

Restart the application. Automatic reloading will not detect the change. Use the administrative console to restart the application. Or run the wasadmin `stopApplication` and `startApplication` commands.

Hot deployment	Not applicable
Dynamic reloading	Yes

Changing the ibm-app-bnd.xmi file for an application

Restart the application. Automatic reloading will not detect the change. Use the administrative console to restart the application. Or run the wasadmin `stopApplication` and `startApplication` commands.

Hot deployment	Not applicable
Dynamic reloading	Yes

Changing a non-module Jar file contained in the EAR file

1. Update the non-module Jar file in the *application_root* location.
2. If automatic reloading is not enabled, restart the application. Use the administrative console to restart the application. Or run the wasadmin `stopApplication` and `startApplication` commands.

   If automatic reloading is enabled, you do not need to take further action. Automatic reloading will detect the change.

Hot deployment	Yes
Dynamic reloading	Yes

Changing or adding WAR files

You can change Web application archives (WAR files) on application servers without having to stop the server and start it again.

There are several changes that you can make to WAR files without stopping the server and starting it again. You can use the update wizard of the administrative console to make the changes without having to stop and restart the server. This article describes how to make the following changes by manipulating a WAR file on the server where the application is deployed:
- Changing an existing JavaServer Pages (JSP) file
- Adding a new JSP file to an existing application
- Changing an existing servlet class (editing and recompiling)
- Changing a dependent class of an existing servlet class
- Adding a new servlet using the Invoker (Serve Servlets by class name) facility or adding a dependent class to an existing application
- Adding a new servlet, including a new definition of the servlet in the `web.xml` deployment descriptor for the application
- Changing the `web.xml` file of a WAR file
- Changing the `ibm-web-ext.xmi` file of a WAR file
- Changing the `ibm-web-bnd.xmi` file of a WAR file

Changing an existing JSP file

Place the changed JSP file directly in the *application_root*/*module_name* directory or the appropriate subdirectory. The change will be automatically detected and the JSP will be recompiled and reloaded.

Hot deployment	Not applicable
Dynamic reloading	Yes

Adding a new JSP file to an existing application

Place the new JSP file directly in the *application_root*/*module_name* directory or the appropriate subdirectory. The new file will be automatically detected and compiled on the first request to the page.

Hot deployment	Yes
Dynamic reloading	Yes

Changing an existing servlet class (editing and recompiling)

1. Place the new version of the servlet `.class` file directly in the *application_root/module_name*/`WEB-INF/classes` directory. If the `.class` file is part of a Jar file, you can place the new version of the Jar file directly in *application_root/module_name*/`WEB-INF/lib`. In either case, the change will be detected, the Web application will be shut down and reinitialized, picking up the new class.
2. If automatic reloading is not enabled, restart the application. Use the administrative console to restart the application. Or run the wasadmin `stopApplication` and `startApplication` commands.

   If automatic reloading is enabled, you do not need to take further action. Automatic reloading will detect the change.

Hot deployment	Not applicable
Dynamic reloading	Yes

Changing a dependent class of an existing servlet class

1. Place the new version of the dependent `.class` file directly in the *application_root/module_name*/`WEB-INF/classes` directory. If the `.class` file is part of a Jar file, you can place the new version of the Jar file directly in *application_root/module_name*/`WEB-INF/lib`. In either case, the change will be detected, the Web application will be shut down and reinitialized, picking up the new class.
2. If automatic reloading is not enabled, restart the application. Use the administrative console to restart the application. Or run the wasadmin `stopApplication` and `startApplication` commands.

   If automatic reloading is enabled, you do not need to take further action. Automatic reloading will detect the change.

Hot deployment	Not applicable
Dynamic reloading	Yes

Adding a new servlet using the Invoker (Serve Servlets by class name) facility or adding a dependent class to an existing application

1. Place the new `.class` file directly in the *application_root/module_name*/`WEB-INF/classes` directory. If the `.class` file is part of a Jar file, you can place the new version of the Jar file directly in *application_root/module_name*/`WEB-INF/lib`. In either case, the change will be detected, the Web application will be shut down and reinitialized, picking up the new class.

   This case is treated the same as changing an existing class. The difference is that adding the servlet or class does not immediately cause the Web application to reload because the class has never been loaded before. The class simply becomes available for execution.
2. If automatic reloading is not enabled, restart the application. Use the administrative console to restart the application. Or run the wasadmin `stopApplication` and `startApplication` commands.

   If automatic reloading is enabled, you do not need to take further action. Automatic reloading will detect the change.

Hot deployment	Yes
Dynamic reloading	Not applicable

Adding a new servlet, including a new definition of the servlet in the web.xml deployment descriptor for the application

1. Place the new `.class` file directly in the *application_root/module_name*/`WEB-INF/classes` directory. If the ".class" file is part of a Jar file, you can place the new version of the Jar file directly in *application_root/module_name*/`WEB-INF/lib`.

   You can edit the `web.xml` file in place or copy it into the *application_root/module_name*/`WEB-INF/classes` directory. The new `.class` file will not trigger a reloading of the application.
2. Restart the application. Use the administrative console to restart the application. Or run the wasadmin `stopApplication` and `startApplication` commands. After the application restarts, the new servlet is available for service.

Hot deployment	Yes
Dynamic reloading	Not applicable

Changing the web.xml file of a WAR file

1. Edit the `web.xml` file in place or copy it into the *`metadata_root`*/*`module_name`*/`WEB-INF` directory.
2. Restart the application. Use the administrative console to restart the application. Or run the wasadmin `stopApplication` and `startApplication` commands.

Hot deployment	Yes
Dynamic reloading	Yes

Changing the ibm-web-ext.xmi file of a WAR file

Edit the extension settings as needed. You can change all of the extension settings. The only warning is if you set the reloadInterval property to zero (`0`) or the reloadEnabled property to `false`, the application no longer automatically detects changes to class files. Both of these changes disable the automatic reloading function. The only way to re-enable automatic reloading is to change the appropriate property and restart the application. See other task descriptions in this file for information on restarting an application.

Hot deployment	Not applicable
Dynamic reloading	Yes

Changing the ibm-web-bnd.xmi file of a WAR file

1. Edit the bindings as needed. You can change all of the values but ensure that the entities you are binding to are present in the configuration of the server.
2. Restart the application. Use the administrative console to restart the application. Or run the wasadmin `stopApplication` and `startApplication` commands.

Hot deployment	Not applicable
Dynamic reloading	Yes

Changing or adding EJB Jar files

You can change enterprise bean (EJB) Jar files on application servers without having to stop the server and start it again.

There are several changes that you can make to EJB Jar files without stopping the server and starting it again. You can use the update wizard of the administrative console to make the changes without having to stop and restart the server. This article describes how to make the following changes by manipulating an EJB file on the server where the application is deployed:

- Changing the `ejb-jar.xml` file of an EJB Jar file
- Changing the `ibm-ejb-jar-ext.xmi` or `ibm-ejb-jar-bnd.xmi` file of an EJB Jar file
- Changing the `Table.ddl` file for an EJB Jar file
- Changing the `Map.mapxmi` or `Schema.dbxmi` file for an EJB Jar file
- Updating the implementation class for an EJB file or a dependent class of the implementation class for an EJB file
- Updating the Home/Remote interface class for an EJB file
- Adding a new EJB file to an existing EJB Jar file

Changing the ejb-jar.xml file of an EJB Jar file

Restart the application. Automatic reloading will not detect the change. Use the administrative console to restart the application. Or run the wasadmin `stopApplication` and `startApplication` commands.

Hot deployment	Not applicable
Dynamic reloading	Yes

Change the ibm-ejb-jar-ext.xmi or ibm-ejb-jar-bnd.xmi file of an EJB Jar file

Restart the application. Automatic reloading will not detect the change. Use the administrative console to restart the application. Or run the wasadmin `stopApplication` and `startApplication` commands.

Hot deployment	Not applicable
Dynamic reloading	Yes

Changing the Table.ddl file for an EJB Jar file

Rerun the DDL file on the user database server. Changing the `Table.ddl` file has no effect on the application server and is a change to the database table schema for the EJB files.

Hot deployment	Not applicable
Dynamic reloading	Not applicable

Changing the Map.mapxmi or Schema.dbxmi file for an EJB Jar file

1. Change the `Map.mapxmi` or `Schema.dbxmi` file for an EJB Jar file.
2. Regenerate the deployed code artifacts for the EJB file.
3. Apply the new EJB Jar file to the server.
4. Restart the application. Use the administrative console to restart the application. Or run the wasadmin `stopApplication` and `startApplication` commands.

Hot deployment	Not applicable
Dynamic reloading	Yes

Updating the implementation class for an EJB file or a dependent class of the implementation class for an EJB file

1. Update the class file in the *application_root*/*module_name*`.jar` file.
2. If automatic reloading is enabled, you do not need to take further action. Automatic reloading will detect the change.

   If automatic reloading is not enabled, restart the application of which the EJB file is a member. If the updated module is used by other modules in other applications, restart those applications as well. Use the administrative console to restart the application. Or run the wasadmin `stopApplication` and `startApplication` commands.

Hot deployment	Not applicable
Dynamic reloading	Yes

Updating the Home/Remote interface class for an EJB file

1. Update the interface class of the EJB file.
2. Regenerate the deployed code artifacts for the EJB file.
3. Apply the new EJB Jar file to the server.
4. If automatic reloading is enabled, you do not need to take further action. Automatic reloading will detect the change.

   If automatic reloading is not enabled, restart the application of which the EJB file is a member. Use the administrative console to restart the application. Or run the wasadmin `stopApplication` and `startApplication` commands.

Hot deployment	Not applicable
Dynamic reloading	Yes

Adding a new EJB file to an existing EJB Jar file

1. Apply the new or updated Jar file to the *application_root* location.
2. If automatic reloading is enabled, you do not need to take further action. Automatic reloading will detect the change.

   If automatic reloading is not enabled, restart the application. Use the administrative console to restart the application. Or run the wasadmin `stopApplication` and `startApplication` commands.

Hot deployment	Yes
Dynamic reloading	Yes

Changing the HTTP plug-in configuration

You can change the HTTP plug-in configuration without having to stop the server and start it again.

There are several change that you can make to the HTTP plug-in configuration without stopping the server and starting it again. This file describes--

- Changing the `application.xml` file to change the context root of a Web application archive (WAR file)
- Changing the `web.xml` file to add, remove, or modify a servlet mapping
- Changing the `server.xml` file to add, remove, or modify an HTTP transport or changing the `virtualhost.xml` file to add or remove a virtual host or to add, remove, or modify a virtual host alias

Changing the application.xml file to change the context root of a WAR file

1. Change the `application.xml` file.
2. If the plug-in configuration property Automatically propagate plug-in configuration file is selected for this plug-in, it is automatically regenerated whenever the `application.xml` file changes. (See for information on how to set this property.) You can also run the `GenPluginCfg.bat/sh` script, or issue a wsadmin command to regenerate the plug-in configuration file.

Hot deployment	Yes
Dynamic reloading	No

Changing the web.xml file to add, remove, or modify a servlet mapping

1. Change the `web.xml` file.
2. If the plug-in configuration property Automatically propagate plug-in configuration file is selected for this plug-in, it is automatically regenerated whenever the web.xml file changes. (See for information on how to set this property.) You can also run the `GenPluginCfg.bat/sh` script, or issue a wsadmin command to regenerate the plug-in configuration file.

   If the Web application has file serving enabled or has a servlet mapping of `/`, the plug-in configuration does not have to be regenerated. In all other cases a regeneration is required.

Hot deployment	Yes
Dynamic reloading	Yes

Changing the server.xml file to add, remove, or modify an HTTP transport or changing the virtualhost.xml file to add or remove a virtual host or to add, remove, or modify a virtual host alias

1. Change the `server.xml` file to add, remove, or modify an HTTP transport or change the `virtualhost.xml` file to add or remove a virtual host or to add, remove, or modify a virtual host alias.
2. If the plug-in configuration property **Automatically propagate plug-in configuration file** is selected for this plug-in, it is automatically regenerated whenever the `server.xml` file changes. (See for information on how to set this property.) You can also run the `GenPluginCfg.bat/sh` script, or issue a wsadmin command to regenerate the plug-in configuration file.

Hot deployment	Yes
Dynamic reloading	Yes

Uninstalling applications

After an application no longer is needed, you can uninstall it.

Uninstalling an application deletes the application from the WebSphere Application Server configuration repository and it deletes the application binaries from the file system of all nodes where the application modules are installed.

1. Click **Applications > Enterprise Applications** in the administrative console navigation tree to access the Enterprise Applications page.
2. If you need to retain a copy of the application, back up the application.
   a. Select the application you want uninstalled.
   b. Click **Export**.

   The application is exported to an enterprise application (`.ear` file), preserving the binding information.
3. Uninstall the application.
   a. Select the application you want uninstalled.
   b. Click **Uninstall**.
4. Save changes made to the administrative configuration.

In the single-server product, application binaries are deleted after you save the changes.

Removing a file

After a file is no longer needed, you can remove the file from an application or module deployed on a server.

Removing a file deletes the file from the WebSphere Application Server configuration repository and it deletes the file from the file system of all nodes where the file is installed.

- Remove a file from an application.
  1. Go to the Enterprise Applications page. Click **Applications > Enterprise Applications** in the console navigation tree.
  2. Select the application that contains a file you want removed.
  3. Click **Remove File**. The Remove a file from an application page is displayed
  4. Select the URI of the file that you want removed from the application.
  5. Select **Export before removing file** to back up the application.
  6. Specify the location to which you want the file exported.
  7. Click **Back** to return to the Enterprise Applications page.
- Remove a file from a module.
  1. Go to the settings page for the application. Click **Applications > Enterprise Applications** >*application_name* in the console navigation tree.
  2. Under **Related Items**, click **Web modules**, **EJB Modules**, or **Connector Modules**.
  3. Select the module from which you want to delete a file.
  4. Click **Remove File**. The Remove a file from a module page is displayed.
  5. Select the URI of the file that you want removed from the module.
  6. Optional: Back up the application. Select the application name and then specify the location to which you want the file exported.

7. Click **OK** to remove the file.

The file is exported to the designated location and removed from the application or module. The application or standalone Web module that had a file removed is restarted so the changes take effect.

Save the changes to your administrative configuration. In the single-server product, application binaries are deleted after you save the changes.

Deploying and administering applications: Resources for learning

Use the following links to find relevant supplemental information about deploying and administering applications using the administrative console. The information resides on IBM and non-IBM Internet sites, whose sponsors control the technical accuracy of the information.

These links are provided for convenience. Often, the information is not specific to the IBM WebSphere Application Server product, but is useful all or in part for understanding the product. When possible, links are provided to technical papers and Redbooks that supplement the broad coverage of the release documentation with in-depth examinations of particular product areas.

Refer to the information center for links to information applicable to WebSphere Application Server generally, such as lists of IBM technical papers, Redbooks and samples.

Web applications

Task overview: Developing and deploying Web applications

A developer creates the files comprising a Web application, and then assembles the Web application components into a Web module. Next, the deployer (typically the developer in a unit-testing environment or the administrator in a production environment) installs the Web application on the server.

1. **(Optional)** Migrate existing Web applications to run in the new version of WebSphere.
2. Design the Web application and develop its code artifacts: Servlets, JavaServer Pages (JSP) files, and static files, as for example, images and Hyper Text Markup Language (HTML) files. See the ″Resources for learning″ article for links to design documentation.

3. Develop the Web application, using WebSphere Application Server extensions to enhance its functionality.
4. Assemble the Web application into a Web module using an assembly tool. Web module assembly properties might include the ability to:
   - Configure servlet page lists.
   - Configure servlet filters.
   - Serve servlets by class name.
   - Enable file serving.
5. Deploy the Web module or application module that contains the Web application.

   Following deployment, you might find it handy to use the tool that enables batch compiling of the JSP files for quicker initial response times.
6. **(Optional)** Troubleshoot your Web application.
7. **(Optional)** Modify the default Web container configuration in the application server in which you deployed the Web module or application module containing the Web application.
8. **(Optional)** Manage the deployed Web application.

Web applications

A Web application is comprised of one or more related servlets, JavaServer Pages technology (JSP files), and Hyper Text Markup Language (HTML) files that you can manage as a unit.

The files in a Web application are related in that they work together to perform a business logic function. For example, one of the WebSphere Application Server samples is a *Simple Greeting* Web application. This application, comprised of a servlet and Web pages, greets new users when the application is accessed.

The Web application is a concept supported by the Java Servlet Specification. Web applications are typically packaged as `.war` files.

web.xml file

The `web.xml` file provides configuration and deployment information for the Web components that comprise a Web application. Examples of Web components are servlet parameters, servlet and JavaServer Pages (JSP) definitions, and Uniform Resource Locators (URL) mappings.

The Java Servlet 2.4 specification defines the `web.xml` deployment descriptor file in terms of an XML schema document. For backwards compatibility of applications written to the Java Servlet 2.2 Specification, Web containers are also required to support the Java Servlet 2.2 specification. For backwards compatibility of applications written to the Java Servlet 2.3 specification, Web containers are also required to support the Java Servlet 2.3 specification.

Location

The `web.xml` file must reside in the `WEB-INF` directory under the context of the hierarchy of directories that exist for a Web application. For example, if the application is `client.war`, then the `web.xml` file is placed in the *install_root*/*client war*/`WEB-INF` directory.

Usage notes

- Is this file read-only?

  No
- Is this file updated by a product component?

  This file is updated by the Application Server Toolkit.
- If so, what triggers its update?

  The Application Server Toolkit updates the `web.xml` file when you assemble Web components into a Web module, or when you modify the properties of the Web components or the Web module.
- How and when are the contents of this file used?

WebSphere Application Server functions use information in this file during the configuration and deployment phases of Web application development.

Default Application

The IBM WebSphere Application Server provides a default configuration that allows administrators to easily verify that the Application Server is running. When the product is installed, it includes an application server called *server1* and an enterprise application called *Default Application*.

Default Application contains a Web Module called *DefaultWebApplication* and an enterprise bean JAR file called *Increment*. The *Default Application* provides a number of servlets, described below. These servlets are available in the product.

For additional code examples, visit the Samples Gallery. Learn how to locate and install the Samples Gallery by viewing the Samples Gallery reference page.

The URL for accessing Samples is: `http://localhost:9080/WSsamples/`

Snoop

Use the Snoop servlet to retrieve information about a servlet request. This servlet returns the following information:

- Servlet initialization parameters
- Servlet context initialization parameters
- URL invocation request parameters
- Perferred client locale
- Context path
- User principal
- Request headers and their values
- Request parameter names and their values
- HTTPS protocol information
- Servlet request attributes and their values
- HTTP session information
- Session attributes and their values

The Snoop servlet includes security configuration so that when WebSphere Security is enabled, clients must supply a user ID and password to execute the servlet.

The URL for the Snoop servlet is: `http://localhost:9080/snoop/`.

HelloHTML

Use the HelloHTML pervasive servlet to exercise the PageList support provided by the WebSphere Web container. This servlet extends the PageListServlet, which provides APIs that allow servlets to call other Web resources by name or, when using the *Client Type detection* support, by type.

You can invoke the Hello servlet from an HTML browser, speech client, or most Wireless Application Protocol (WAP) enabled browsers using the URL: `http://localhost:9080/HelloHTML.jsp`.

HitCount

Use the HitCount Demonstration application to demonstrate how to increment a counter using a variety of methods, including:

- A servlet instance variable
- An HTTP session
- An enterprise bean

You can instruct the servlet to execute any of these methods within a transaction that you can commit or roll back. If the transaction is committed, the counter is incremented. If the transaction is rolled back, the counter is not incremented.

The enterprise bean method uses a Container- Managed Persistence enterprise bean that persists the counter value to a Cloudscape database. This enterprise bean is configured to use the Default Datasource, which is set to the DefaultDB database.

When using the enterprise bean method, you can instruct the servlet to look up the enterprise bean, either in the WebSphere global namespace, or in the namespace local to the application.

The URL for the HitCount application is: `http://localhost:9080/HitCount.jsp`.

Servlets

Servlets are Java programs that use the Java Servlet Application Programming Interface (API). You must package servlets in a Web archive (WAR) file or Web module for deployment to the application server. *Servlets* run on a Java-enabled Web server and extend the capabilities of a Web server, similar to the way applets run on a browser and extend the capabilities of a browser.

Servlets can support dynamic Web page content, provide database access, serve multiple clients at one time, and filter data.

For the purposes of WebSphere Application Server, discussions of servlets focus on Hyper Text Transfer Protocol (HTTP) servlets, which serve Web-based clients.

With the introduction of Java Servlet 2.4 specification, you can define servlets as welcome files. Non servlet resources are served only when the FileServingEnabled attribute is set to true. Serving welcome files is connected to serving static content, therefore fileServing enabled is set in the Web module.

JavaServer Pages

JavaServer Pages (JSP) are application components coded to the JavaServer Pages Specification. JavaServer Pages enable the separation of the Hypertext Markup Language (HTML) code from the business logic in Web pages so that HTML programmers and Java programmers can more easily collaborate in creating and maintaining pages.

JSP files support a division of roles:

HTML authors
Develop JSP files that access databases and reusable Java components, such as servlets and beans.

Java programmers
Create the reusable Java components and provide the HTML authors with the component names and attributes.

Database administrators
Provide the HTML authors with the name of the database access and table information.

WebSphere Application Server 6.0 supports the JSP 2.0 specification. The sub-topics below discuss WebSphere Application Server's JSP 2.0 implementation, focusing on configuration, tools and extensions.

JSP engine:

The WebSphere Application Server JavaServer Pages (JSP) engine is the implementation of the JavaServer Pages Specification.

WebSphere Application Server 6.0 supports the JSP 2.0 specification.

The JSP engine

- Validates JSP source, both classic and XML styles
- Translates JSP source to Java classes
- Compiles Java classes, reporting any errors
- Generates Java classes for any tag files that are used by the JSP
- Interfaces with the Web container to load JSP class files
- Supports JSP batch compilation, JSP compilation during application installation, and JSP compilation during the build process of customer applications, through an Ant task.
- Loads class files, and manage life-cycle (reloading, unloading as necessary)
- Supports debugging of JavaServer Pages files through support for JSR 45 (Debugging Support for Other Languages)

JSP engine configuration parameters: In WebSphere Application Server, you can configure the JavaServer Pages (JSP) engine for optimal performance in a production server environment and for the needs of developers in a development environment. The configuration parameters are described below.

The JSP engine parameters are case sensitive. If the value specified for a parameter is comprised of two or more words separated by spaces, you must add quotation marks around the value. Some parameters affect the Java source that is generated for a JSP or tag file. These parameters are identified by the statement ″This parameter requires regeneration of Java source.″ This statement indicates that if the configuration parameter is modified, the new value for the parameter does not have any effect until the JSP files are retranslated and the Java sources are recompiled.

- **compileWithAssert**

  Specifies whether the generated Java classes should contain support for the Developer Kit, Java Technology Edition 1.4 Assertion facility. The effect of setting this parameter to true is that the –source 1.4 option is passed to the Java compiler. The default for this parameter is `false`. This parameter requires regeneration of Java source.
- **classdebuginfo**

  Indicates whether the compiler includes debugging information in the generated class file. When you set this parameter to true, the –g option is passed to the Java compiler. The default for this parameter is `false`. This parameter requires regeneration of Java source.
- **deprecation**

  Specifies whether the compiler generates deprecation warnings when compiling the generated Java source. When you set this parameter to true, the -deprecation option is passed to the Java compiler. The default for this parameter is `false`. This parameter requires regeneration of Java source.
- **disableJspRuntimeCompilation**

  If this option is set to true, the JSP engine at runtime does not translate and compile JSP files; the JSP engine loads only precompiled class files. JSP source files do not need to be present in order to load class files. When this option is set to true, you can install an application without JSP source, but the application must have precompiled class files. There is a Web container custom property with the same name that is used to determine the behavior of all Web modules installed in a server. If both the Web container custom property and the JSP engine option are set, the JSP engine option takes precedence. The default for this parameter is `false`.
- **extendedDocumentRoot**

  To allow a JSP file resource to be shared across Web application archives, specify a comma delimited list of directories and/or Java Archive (JAR) files as search paths to be used if the requested resource cannot be located in the Web application archive's public document tree. If the JSP file is located inside a JAR file and reloadEnabled is true, the timestamp of the JAR file is used for isOutDated checks for recompile purposes. The default for this parameter is null.

- **ieClassID**

  Indicates the Java plug-in COM class ID for Internet Explorer. The `<jsp:plugin>` tags use this value. The default classid is `clsid:8AD9C840-044E-11D1-B3E9-00805F499D93`. This parameter requires regeneration of Java source.
- **javaEncoding**

  Specifies the encoding that is used when the `.java` file is generated, and when it is compiled by the Java compiler. Set this parameter when the page encoding of your JSP pages is not UTF-8 compatible. When javaEncoding is set, the encoding is passed to the Java compiler through the -encoding argument. Note that encoding is not supported by Jikes. The default is UTF-8. This parameter requires regeneration of Java source.
- **jspCompileClasspath**

  This parameter tells the JSP engine to use a small class path for the Java compilation phase. The small class path speeds up the compilation process. This small class path is not used by default because it includes only a subset of WebSphere JAR files and excludes many WebSphere JAR files that contain WebSphere public APIs.

  If your JSP files do not use WebSphere public APIs within scriptlets, you can enable the small class path by using the jspCompileClasspath parameter with no value. If your JSP files do use WebSphere public APIs within scriptlets, then add those additional JAR files to the jspCompileClasspath option. The entries are separated by spaces, and are assumed to be relative to the WebSphere Application Server installation root.

  1. A space-separated list of JAR files, relative to the WebSphere installation directory. This instructs the JSP engine to use the small class path, with the additional named JAR files.

  2. No value at all. This instructs the JSP engine to use the small class path, without any additional user-defined JAR files. See the example in ″Configuring JSP engine parameters″ in the information center.

  The entire WebSphere class path is used by default. This parameter requires regeneration of Java source.
- **jsp.file.extensions**

  For JSP files with extensions other than the four standard extensions, *.jsp, *.jspx, *.jsw, and *.jsv, you can configure this the extensions using this parameter. These extensions are added to the standard extensions. The preferred method for doing this is to create a `<jsp-property-group>`in web.xml, and add a `<url-pattern>` tag for each extension.

  The JSP engine can handle a list of file extensions that is separated by a colon or semi-colon. For example, *.ext1;*.ext2:*.extn
- **keepgenerated**

  Indicates that the Java files generated by the JSP compiler during the translation phase of the processing are retained. The default for this parameter is `false`. This parameter requires regeneration of Java source.
- **keepGeneratedclassfiles**

  Indicates that the class files generated by the JSP compiler during the translation phase of the processing are retained. The default for this parameter is `true`. This parameter requires regeneration of Java source.
- **reloadEnabled**

  Determines whether or not a JSP file is translated and compiled at runtime if the JSP file or its dependencies (see trackDependencies) are modified. If reloadEnabled is false, a JSP file is still compiled, if necessary, on the first request to it unless the parameter disableJspRuntimeCompilation is true. The default for this parameter is `false`.

If this JSP engine parameter is not specified, the equivalent Web container parameter for Web module class reloading is used. However, for an application whose deployment descriptor is at the Servlet 2.2 level, the default is true. This is done for the support of applications being migrated from WebSphere Application Server Version 4.x.

- **reloadInterval**

  If reloading is enabled, reloadInterval determines the delay between checks to see if a JSP file is outdated. For example, if reloadInterval is 5, the JSP engine checks to see if a JSP file is outdated only when the last such check was done more than 5 seconds prior to the current request for the JSP file. The larger the reloadInterval, the less frequently the JSP engine checks for the need to reload a JSP file. If this JSP engine parameter is not specified, the equivalent Web container parameter for Web module class reloading is used. However, for an application whose deployment descriptor is at the Servlet 2.2 level, the default is 5 seconds. This is done for the support of applications being migrated from WebSphere Application Server Version 4.x.

- **scratchdir**

  Specifies the directory where the generated class files are created. The system property com.ibm.websphere.servlet.temp.dir is used to set the scratchdir option on a server-wide basis. The JSP engine scratchdir parameter takes precedence over the system property com.ibm.websphere.servlet.temp.dir. The default for this parameter is `{WAS_ROOT}/profiles/profilename/temp`. This parameter requires regeneration of Java source.

- **trackDependencies**

  If reloading is enabled, trackDependencies determines whether the JSP engine tracks modifications to the requested JavaServer Pages files dependencies as well as to the JSP file itself. The dependencies tracked by the JSP engine are :

  1. files statically included in the JSP file
  2. tag files referenced in the JSP file (excluding tag files that are in JARs)
  3. TLD files referenced in the JSP file (excluding TLDs that are in JARs)

  The default is `false`.

- **useFullPackageNames**

  If useFullPackageNames is true, the JSP engine generates and loads JSP classes using full package names. The default is to generate all JSP classes in the same package. (For more information, see Packages and directories for generated files). The JSP engine's class loader knows how to load JSP classes when they are all in the same package.

  The default method of generating all JSP classes in the same package has the benefit of generating smaller file-system paths. Full package names has the benefit of enabling the configuration of precompiled JSP class files as servlets in the `web.xml` file without the use of the jsp-file attribute, resulting in a single class loader, the Web application's class loader, that is used to load all such JSP classes. Similarly, when the JSP engine's configuration attributes useFullPackageNames and disableJspRuntimeCompilation are both true, a single class loader is used to load all JSP classes, even if the JSP files are not configured as servlets in the `web.xml` file.

  When useFullPackageNames is set to true, the batch compiler generates a file called `generated_web.xml` in the Web module's `WEB-INF` directory. This file contains servlet configuration information for each JSP file that was successfully translated and compiled. The information can optionally be copied into the Web module's `web.xml` file so that the JSP files are loaded as servlets by the Web container. Note that if a JSP file is configured as a servlet in this way, no reloading of the JSP file is done at runtime if the JSP file is modified. This is because the JSP file is treated as a regular servlet and requests for it do not pass through the JSP engine. This parameter requires regeneration of Java source.

- **useImplicitTagLibs**

  The JSP engine implicitly recognizes tsx and jsx as tag library prefixes for tag libraries supplied by the JSP engine. If tsx or jsx are used as prefixes for a customer‘s tag library, the customer‘s tag library overrides the implicit tag library. However, the implicit tag library is still cached by the JSP engine. Explicitly setting this parameter to false tells the engine not to cache the implicit tag library, and save resources. The default for this parameter is `true`.

- **useJikes**

Specifies whether Jikes is used for compiling Java sources. NOTE: Jikes is not shipped with WebSphere Application Server. The default for this parameter is `false`. This parameter requires regeneration of Java source.

- **usePageTagPool**

  *Enables or disables the reuse of custom tag handlers on an individual JavaServer Pages basis. The default for this parameter is `false`. This parameter requires regeneration of Java source.
- **useThreadTagPool**

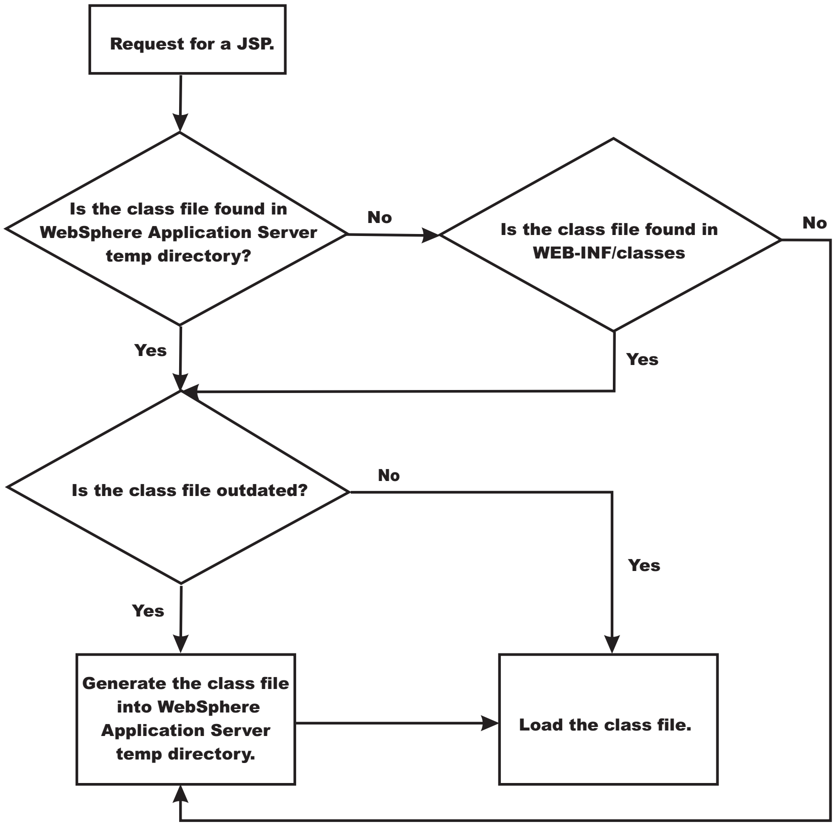
  *When thread-level tag handler pooling is used, tag handlers may be reused among separate occurrences of a custom action across all JSP pages in a single Web module across separate requests. The default for this parameter is `false`. This parameter requires regeneration of Java source.
- **verbose**

  Indicates that the compiler generates verbose output when compiling the generated Java source code. The effect of setting this parameter to true is that the -verbose option is passed to the Java compiler. The default for this parameter is `false`. This parameter requires regeneration of Java source.

*Enabling custom tag handler reuse might reveal problems in the tag handler code with regard to the tag's ability to be reused. A custom tag handler should always do two things:

- The release method of the tag handler should reset its state and release any private resources that it might have used. The JSP engine ensures the release method is called before the tag handler is garbage collected.
- In the doEndTag method, all instance states associated with this instance must be reset.

JSP class file generation: At runtime, the WebSphere Application Server JavaServer Pages (JSP) engine loads JSP class files from either the WebSphere Application Server `temp` directory or a Web module's `WEB-INF/classes` directory. The WebSphere Application Server `temp` directory is typically `{WAS_ROOT}/profiles/profilename/temp`. The JSP engine first searches for a class file in the `temp` directory and then it searches in the Web module's `WEB-INF/classes` directory. Figure 1 shows the processing logic of the JSP engine at runtime.



Request for a JSP.
Is the class file found in WebSphere Application Server temp directory?
No
Is the class file found in WEB-INF/classes
No
Yes
Yes
Is the class file outdated?
No
Yes
Yes
Generate the class file into WebSphere Application Server temp directory.
Load the class file.

The batch compiler supports the generation of class files in both the WebSphere Application Server `temp` directory and a Web module's `WEB-INF/classes` directory, depending on the type of batch compiler target. In addition, the batch compiler enables the generation of class files into any directory on the filesystem, outside of the target application. Generating class files into a Web module's `WEB-INF/classes` directory enables you to deploy the Web module as a self-contained Web archive (WAR) file, or a WAR file inside an enterprise archive (EAR) file. The following table shows the batch compiler's behavior when compiling class files.

	ear.path or war.path supplied	enterpriseApp.name supplied
compileToDir not supplied; *compileToWebInf* not supplied, or is true	The class files are compiled into the Web module's `WEB-INF/classes` directory.	The class files are compiled into the Web module's `WEB-INF/classes` directory.
compileToDir not supplied; *compileToWebInf* is false	The class files are compiled into the Web module's `WEB-INF/classes` directory.	The class files are compiled into the WebSphere temp directory, usually `{WAS_ROOT}/profiles/profilename/temp`.
compileToDir is supplied; *compileToWebInf* not supplied, or is either true or false	The class files are compiled into the directory indicated by *compileToDir*.	The class files are compiled into the directory indicated by *compileToDir*.

Packages and directories for generated .java and .class files:

By default, the .java files for all JavaServer Pages (JSP) files are generated with the package statement, `package com.ibm._jsp;`. The JSP engine's class loader knows how to load JSP classes when they are all in the same package. The .java files are located in the filesystem within a directory structure mirroring the JSP source directory structure.

If the JSP engine configuration parameter **useFullPackageNames** is set to true, the .java files are generated with the package statement

```
Package _ibmjsp.<directory structure in which the jsp is located>;
```

The usage of full package names enables the configuration of a JSP as a servlet in the `web.xml` file. See "JSP class loading" on page 766 for more information. The table below gives examples of packages and directory structures for generated .java and .class files.

	Java package		**Location of .java or .class files in file system**	
JSP file	**default**	**useFullPackage Names=true**	**default**	**useFullPackage Names=true**
/myJsp.jsp	com.ibm._jsp	_ibmjsp	/	/_ibmjsp
/jspFiles/jspOne.jsp	com.ibm._jsp	_ibmjsp.jspFiles	/jspFiles	/_ibmjsp/jspFiles
/dir with spaces/jspTwo.jsp	com.ibm._jsp	_ibmjsp.dir_20_with _20_spaces	/dir with spaces	/_ibmjsp/dir_20_with _20_spaces

Generated .java files: When the JSP engine's **keepgenerated** configuration parameter is set to true, the `.java` file that is generated for JavaServer Pages (JSP) is retained. This file contains information that is useful in debugging.

Dependency information

In the `.java` file, immediately following the class declaration, an array of dependent files is defined, if the source JSP has any dependencies. There are three types of files that are tracked as dependencies:

1. Files that are statically included in the JSP

2. Tag files that are used by the JSP, but only tag files that are not in Java Archive (JAR) files
3. TLD files that are used by the JSP, but only TLDs that are not in JAR files

This array is always generated, but the JSP engine uses it, in determining whether a JSP needs to be recompiled, only when the trackDependencies parameter is set to true.

In the example below, three JSP fragments, one TLD and one tag file are dependencies of the JSP jsp1.jsp. There are three parts to each array entry:

1. The path to the dependency, relative to the Web module‘s context root. For example: `/dir1/frag1.jspf`
2. The long value representing the time the file was last modified. For example: 1082407108000
3. The String representation of the long value. For example: Mon Apr 19 16:38:28 EDT 2004

```
public final class _jsp1 extends com.ibm.ws.jsp.runtime.HttpJspBase
  implements com.ibm.ws.jsp.runtime.JspClassInformation {

  private static String[] _jspx_dependants;
  static {
  _jspx_dependants = new String[5];
  _jspx_dependants[0] = "/Banner.jspf^1082407108000^Mon Apr 19 16:38:28 EDT 2004";
  _jspx_dependants[1] = "/Footer.jspf^1077657462000^Tue Feb 24 16:17:42 EST 2004";
  _jspx_dependants[2] = "/dir1/frag1.jspf^1035396680000^Wed Oct 23 14:11:20 EDT 2002";
  _jspx_dependants[3] = "/utility.tld^1080069938000^Tue Mar 23 14:25:38 EST 2004";
  _jspx_dependants[4] = "/WEB-INF/tags/top.tag^1065440490000^Mon Oct 06 07:41:30 EDT 2003";
  }
```

Version, JSP engine options, and WEB.XML information

The generated .java source contains a comment that lists information about the file which is located at the bottom of the generated file. This information includes:

- The date and time the `.java` file was generated
- The version, build number and build date of the WebSphere Application Server on which the `.java` file was generated
- The values of the JSP engine configuration parameters that were in effect when the file was generated
- The values of any `<jsp-config>` elements in the `web.xml` file that pertained to the source JSP file.

JSP class loading:

You can configure a JavaServer Pages (JSP) class to be loaded by either the JSP engine‘s class loader or by the Web module‘s class loader.

By default, a JSP class is loaded by a unique instance of the JSP engine‘s class loader. The JSP engine‘s class loader enables runtime reloading of a JSP class when the JSP source or one of its dependents is modified. This allows you to reload a single JSP class when necessary, without affecting any other loaded JSP classes.

JSP classes are loaded by the Web module‘s class loader under either of the following scenarios.

1. 1. The JSP engine configuration parameter useFullPackageNames is set to true, and the JSP file is configured as a servlet in the `web.xml` file using the <servlet-class> scenario in the table below.
2. 2. The JSP engine configuration parameters useFullPackageNames and disableJspRuntimeCompilation are both set to true. In this case, you do not need to configure a JSP file does as a servlet in the `web.xml` file.

Configuring JSP files as Servlets

You can configure a JSP file as a servlet in the `web.xml` file. There are two ways to do this. They are described in the table below.

Before you configure a JSP file as a servlet, consider the following.

1. Reloading capability - If runtime reloading of JavaServer Pages files is desired, requests for JavaServer Pages files must be handled by the JSP engine. The <servlet-class> scenario in the table below disables runtime JSP file reloading, while the <jsp-file> scenario is compatible with reloading.
2. Reducing the number of class loaders - If you do not require runtime reloading of modified JSP pages and you want to reduce the number of class loader instances, then you can use the <servlet-class> scenario in the table below. Similarly, scenario 2 in section 1 above can be used without having to configure a JSP file as a servlet.

Scenario	Example	compatible with runtime reloading	multiple class loaders used?	useFullPackage Names

<jsp-file>	<servlet> <servlet-name>jspOne</servlet-name> <jsp-file>jspOne.jsp</jsp-file> </servlet>	Yes	Yes	Can be true or false
<servlet-class>	<servlet> <servlet-name>jspTwo</servlet-name> <servlet-class>_ibmjsp.jspTwo</servlet-class> </servlet>	No	No	Must be true

The JSP batch compiler tool helps you configure JavaServer Pages files as servlets. When useFullPackageNames is true, the JSP batch compiler generates <servlet> and <servlet-mapping> elements for each JSP file that it successfully translates and compiles. The elements are written to a web.xml fragment file named generated_web.xml which is located in the binaries WEB-INF directory of a Web module processed by the JSP file batch compiler (this directory is located within the deployed application‘s ear file). You can copy and paste all or some of these elements into the web.xml file to configure JavaServer Pages files as servlets.

Take note of the location of the web.xml that is used by the application server. In WebSphere Application Server 6.0, application specific configuration is obtained from either the application binaries (the application‘s ear file) or from the configuration repository. If an application is deployed into WebSphere Application Server with the flag Use Binary Configuration set to true, then the WEB-INF/web.xml file is looked for in a Web module’s binaries directory, not in the configuration repository. Below are examples of these two locations.

1. An example of a configuration repository directory is
   {WAS_ROOT}/profiles/profilename/config/cells/cellname/applications/enterpriseappname/deployments/deployedname/webmodulename
2. An example of an application binaries directory is:
   {WAS_ROOT}/profiles/profilename/installedApps/nodename/EnterpriseAppName/WebModuleName/

If the JSP batch compiler is executed on a pre-deployed application then the web.xml file is in the Web module‘s WEB-INF directory.

Configuring JSP runtime reloading: JSP files can be translated and compiled at runtime when the JSP file or its dependencies are modified. This is known as JSP reloading. JSP reloading is enabled through the **reloadEnabled** JSP engine parameter in the WEB-INF/ibm-web-ext.xmi file:

```
<jspAttributes xmi:id="JSPAttribute_1" name="reloadEnabled" value="true"/>
```

The following table contains the recommended reload settings for production and development environments.

	Recommended settings	
Configuration Attribute	**Production Environment**	**Development Environment**
reloadEnabled	false	true
reloadInterval	n/a (ignored if reloadEnabled is false)	approximately 5 seconds
trackDependencies	n/a (ignored if reloadEnabled is false)	true Alternatively, set this to false to improve response time if dependencies are not changing

disableJspRuntimeCompilation	true - Alternatively, set this to false if JSPs are not pre-compiled and therefore need to be compiled on the first request.	false

If the **reloadEnabled** parameter is set to true, a JSP file is reloaded at runtime if the JSP file and its class file do not have the same timestamp. In addition, if **trackDependencies** is set to true then the JSP file is reloaded if the timestamp of any of its dependencies has changed since the JSP class file was last generated. If the **reloadEnabled** parameter is set to false, a JSP file is still compiled if necessary on the first request to it unless the parameter **disableJspRuntimeCompilation** is true. For example, when **disableJspRuntimeCompilation** is false and **reloadEnabled** is false, a JSP file is compiled on the first request if the class file is outdated. It would not compiled on subsequent requests even if the JSP source file is modified or the class file is deleted unless **reloadEnabled** is true

Reload interval

The reload interval is set through the **reloadInterval** JSP engine parameter:

```
<jspAttributes xmi:id="JSPAttribute_1" name="reloadInterval" value="5"/>
```

If reloading is enabled, the **reloadInterval** parameter value determines the delay between checks to see if a JSP file is outdated. For example, if **reloadInterval** is 5, the JSP engine checks to see if a JSP file is outdated only when the last such check was done more than five seconds prior to the current request for the JSP file. Once the **reloadInterval** is exceeded, reload checking is performed and the reload interval timer is reset to 0 for that JSP file. The larger the **reloadInterval**, the less frequently the JSP engine checks for the need to reload a JSP file.

Dependency tracking

Dependency tracking is set through the **trackDependencies** JSP engine parameter:

```
<jspAttributes xmi:id="JSPAttribute_1" name="trackDependencies" value="true"/>
```

If reloading is enabled, the **trackDependencies** parameter value determines whether the JSP engine tracks modifications to the requested JSP file dependencies as well as to the JSP file itself. The three types of dependencies tracked by the JSP engine are:

- files statically included in the JSP file
- tag files that are referenced in the JSP file (excluding tag files that are in JAR files)
- TLDs that are referenced in the JSP file (excluding TLDs that are in JAR files)

Dependency tracking information is always included in the generated class file even if **trackDependencies** is false. The information is not used by the JSP engine or batch compiler unless the **trackDependencies** parameter is true. This means that you can enable dependency tracking without having to recompile JSP files.

For example, the `toplevel.jsp` file statically includes the `footer.jspf` file. When the `toplevel.jsp` file is compiled, the path to the `footer.jspf` file and its timestamp are stored in the `toplevel.jsp`'s class file. As a result, the `footer.jspf` file is modified and the `toplevel.jsp` file is requested. Now that the reload interval for the `toplevel.jsp` file has been exceeded, the JSP engine compares the timestamp stored in the class file with the `footer.jspf` file timestamp on disk. Because the timestamps are different, the `toplevel.jsp` file is compiled, picking up the modification to the `footer.jspf` file. In order for dependency tracking to work, the **trackDependencies** value must be set to true at the time a JSP file is requested at runtime or is processed by the batch compiler.

Disabling compilation

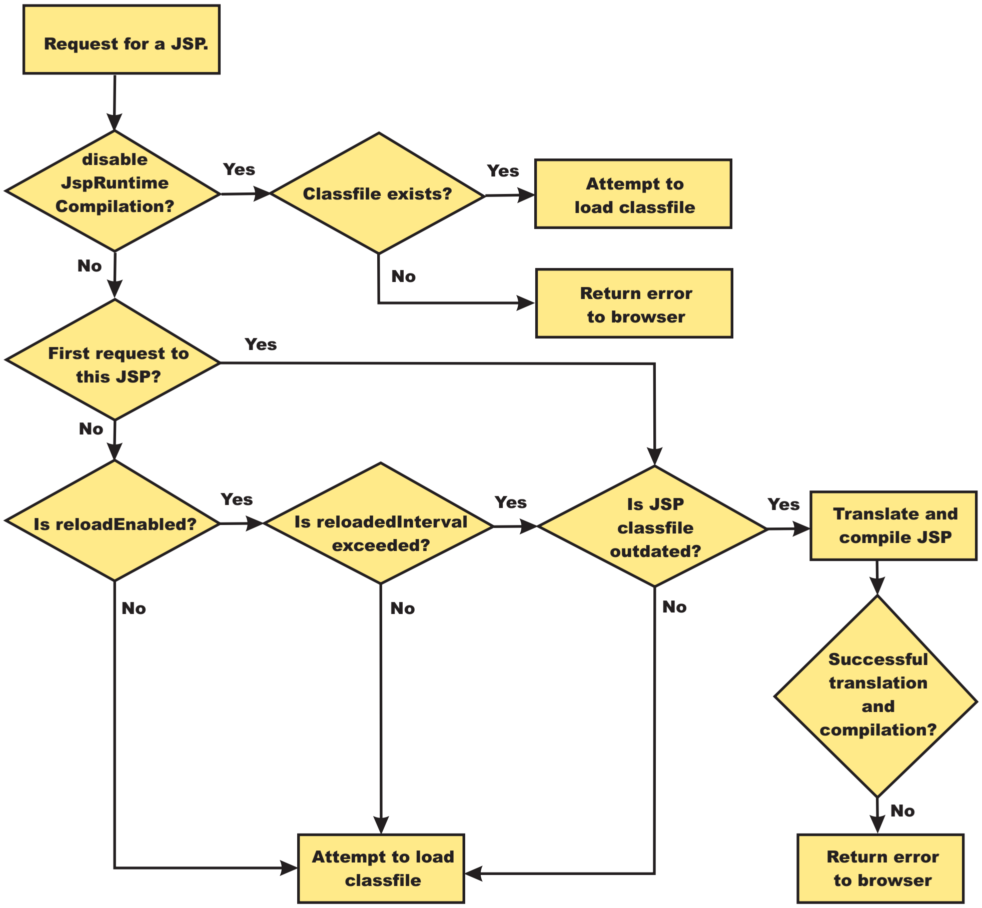
Disablement of runtime compilation of JavaServer Pages is set via the disableJspRuntimeCompilation JSP engine parameter:

```
<jspAttributes xmi:id="JSPAttribute_1" name="disableJspRuntimeCompilation" value="true"/>
```

If the **disableJspRuntimeCompilation** parameter is set to true, the JSP engine at runtime does not translate and compile JSP files; the JSP engine loads only precompiled class files. JSP source files do not need to be present in order for the class files to be loaded. With this option set to true, an application can be installed without JSP source, but must have precompiled class files. There is a Web container custom property of the same name that can be used to determine the behavior of all web modules installed in a server. If both the Web container custom property and the JSP engine option are set, the JSP engine option takes precedence. Setting the **disableJspRuntimeCompilation** parameter to true automatically sets **reloadEnabled** to false.

Reload processing sequence

The processing sequence pertaining to JSP file reloading when **trackDependencies** is false is shown in Figure 1.

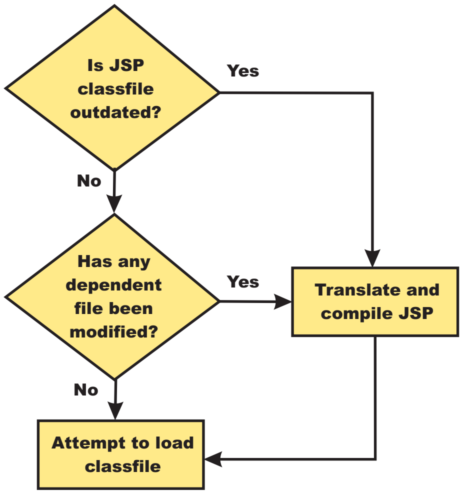


Request for a JSP.
disable JspRuntime Compilation?
Yes
Classfile exists?
Yes
Attempt to load classfile
No
No
Return error to browser
First request to this JSP?
Yes
No
Is reloadEnabled?
Yes
Is reloadedInterval exceeded?
Yes
Is JSP classfile outdated?
Yes
Translate and compile JSP
No
No
No
Successful translation and compilation?
No
Attempt to load classfile
Return error to browser

Figure 1. Reload processing sequence when **trackDependencies** *is false.*

When **trackDependencies** is true, the JSP engine does additional file system processing to determine if any of a JSP file's dependencies have changed since the JSP file was last translated and compiled.

Figure 2 shows the additional processes that are performed on the 'No' path of flow chart labeled "is JSP class file outdated?". You can see that the path taken when disableJspRuntimeCompilation is true is the most efficient path.



Is JSP classfile outdated?
Yes
No
Has any dependent file been modified?
Yes
Translate and compile JSP
No
Attempt to load classfile

Figure 2. Additional reload processing performed when **trackDependencies** *is true.*

Disabling JavaServer Pages run-time compilation: By default, the JavaServer Pages (JSP) engine translates a requested JSP file, compiles the `.java` file, and loads the compiled servlet into the run-time environment. You can change the JSP engine default behaviour by indicating a JSP file should never be translated or compiled at run-time, even when a `.class` file does not exist.

If run-time compilation is disabled, you must precompile the JSP files, which provides the following advantages:

- Reduces compilation related disk operations.
- Minimizes disk storage requirements necessary for handling temporary `.java` files generated during a run-time compilation.
- Allows you to not include the JSP source files in the application.
- Allows verification that a JSP file compiled successfully before deploying and installing the application in WebSphere Application Server.

You can disable run-time JSP file compilation on a global or an individual Web application basis:

- To disable the translation and compilation of JSP files for all Web applications, set the Web container custom property `disableJspRuntimeCompilation` to `true`.

  Set this property through the Web container `Custom properties` panel in the administrative console. To view this administrative console page, click:

  Servers > **Application servers** > *server_name* > **Web container settings** >
  Web container > **Custom properties** > *property_name*

  Valid values for this setting are `true` or `false`. If this property is set to `true`, then translation and compilation of the JSP files is disabled at run time for all Web applications.
- To disable the translation and compilation of JSP files for a specific Web application, set the JSP engine initialization parameter `disableJspRuntimeCompilation` to `true`. This setting, if enabled, determines the run-time behavior of the JSP engine and overrides the Web container custom property setting.

  Set this parameter through the `JavaServer Pages attribute assembly settings` panel as described in the "Assembling applications" topic in the information center.

  Valid values for this setting are `true` or `false`. If this parameter is set to `true`, then, for that specific Web application, translation and compilation of the JSP files is disabled at run time, and the JSP engine only loads precompiled files.

- If neither the Web container custom property nor the JSP parameter is set, the first request for a JSP file results in the translation and compilation of the JSP file when the `.class` file does not exist or is outdated. Subsequent requests for the file also result in translations and compilations, but only if the following conditions are met:
  - Translations are required because the `.class` file is outdated.
  - Reloading is enabled for the Web module.
  - Reload interval is exceeded.

If you disable run-time compilation and a request arrives for a JSP file that does not have a matching `.class` file, the JSP engine returns HTTP error 500 (Internal server error) to the browser. In this case, an exception is written to the System Out (SYSOUT) and First Failure Data Capture (FFDC) logs.

If a JSP file has a matching `.class` file but that file is out of date, the JSP engine still loads the `.class` file into memory.

JSP batch compilation:

As an IBM enhancement to JavaServer Pages (JSP) support, IBM WebSphere Application Server provides a batch JSP compiler that allows JSP page compilation before application deployment. The batch compiler validates the syntax of JSP pages, translates the JSP pages into Java source files, and compiles the Java source files into Java Servlet class files. The batch compiler also validates tag files and generates their Java implementation classes.

Batch compilation of JSP pages in a predeployed application simplifies the deployment process and improves the runtime performance of JSP page by eliminating first-request compilations. The batch compiler also operates on enterprise applications that have been deployed into WebSphere Application Server.

The JSP batch compiler works on Web modules that support Servlet 2.2 and up through Servlet 2.4 The batch compiler works on JSP pages written to the JSP 2.0 specification or previous specifications back to JSP 1.0. It recognizes a Servlet 2.4 deployment descriptor, `web.xml`, and can use any jsp-config elements that it may contain. In a Servlet 2.3 (JSP 1.2) or Servlet 2.2 (JSP 1.1) deployment descriptor the batch compiler recognizes and uses any taglib elements that the descriptor may contain.

Batch compiling makes the first request for a JSP page much faster because the JSP page is already translated and compiled into a servlet. Batch compiling is also useful as a fast way to resynchronize all of the JSP pages for an application.

The batch compiler supports the generation of class files in both the WebSphere Application Server `temp` directory and a Web module's `WEB-INF/classes` directory, depending on the type of batch compiler target. In addition, the batch compiler enables generation of class files into any directory on the filesystem, outside the target application. Generating class files into a Web module's `WEB-INF/classes` directory enables the Web module to be deployed as a self-contained WAR file, or a WAR inside an EAR.

JSP batch compiler tool: The batch compiler validates the syntax of JSP pages, translates the JSP pages into Java source files, and compiles the Java source files into Java Servlet class files. The batch compiler also validates tag files and generates their Java implementation classes. Use this function to batch compile your JSP files and thereby enable faster responses to the initial client requests for the JSP files on your production Web server.

The batch compiler can be executed against compressed or expanded enterprise archive (EAR) files and Web application archive (WAR) files, as well as enterprise applications and Web modules that have been deployed into WebSphere Application Server. When the target is a deployed enterprise application, the server does not need to be running to execute the batch compiler. If the batch compiler is executed while the target sever is running, the server is not aware of an updated class file and does not load that class file unless the enterprise application is restarted. When the target is a compressed EAR file or WAR file, the batch compiler must expand it before executing.

Processing of Web modules

The batch compiler operates on one Web module at a time. If the target is either an EAR file or an installed enterprise application that contains more than one Web module, the batch compiler operates on each Web module individually. This is done because JSP pages are configured on a Web module basis, through the Web module's web.xml deployment descriptor file. Within a Web module, the batch compiler processes one directory at a time. It validates and translates each JSP page individually, and then invokes the Java compiler for the entire group of generated Java sources files in that directory. If one JSP page fails during the Java compilation phase, the Java compiler might not create class files for most or all of the JSP pages that successfully compiled in that directory.

JSP file extensions

The batch compiler uses four things to determine what file extensions it should process:

1. Standard JSP file extensions
   - *.jsp
   - *.jspx
   - *.jsw
   - *.jsv
2. The url-pattern property of the jsp-property-group elements in the deployment descriptor file in Servlet 2.4 Web modules
3. The **jsp.file.extensions** JSP engine configuration parameter (for pre-Servlet 2.4 Web modules)
4. The batch compiler configuration parameter **jsp.file.extensions**

The standard extensions are always used by the batch compiler. If the Web module contains a Servlet 2.4 deployment descriptor, the batch compiler also processes any url-patterns found within the jsp-config element. If the batch compiler target contains the JSP engine configuration parameter **jsp.file.extensions**, then those extensions are also processed. If the batch compiler configuration parameter **jsp.file.extensions** is present, the extensions given are also processed and will override the JSP engine configuration parameter **jsp.file.extensions**.

It is a good idea to give JSP 'fragments' an extension that is not processed by the batch compiler. Statically-included fragments that do not stand alone generate translation or compilation errors if processed. The JSP 2.0 Specification suggests that you use the extension `.jspf` for such files.

Batch compiler command

Both a Windows batch file, `JspBatchCompiler.bat` and Unix shell script `JspBatchCompiler.sh` for running the batch compiler from the command line are found in the `{WAS_ROOT}/bin` directory. An Ant task (described in the topic Batch Compiler Ant Task) is also available for executing the batch compiler using Ant.

The batch compiler target is the only required parameter. The target is one of -ear.path, -war.path or -enterpriseapp.name.

```
JspBatchCompiler -ear.path | -war.path | -enterpriseapp.name <name>
   [-response.file <filename>]
   [-webmodule.name <name>]
   [-filename <jsp name | directory name>
   [-recurse <true | false>]
   [-config.root <path>]
   [-cell.name <name>]
   [-node.name <name>]
   [-server.name <name>]
   [-profileName <name>]
   [-extractToDir <path>]
   [-compileToDir <path>]
   [-compileToWebInf <true | false>]
   [-translate <true | false>]
   [-compile <true | false>]
   [-removeTempDir <true | false>]
   [-forceCompilation <true | false>]
   [-useFullPackageNames <true | false>]
   [-trackDependencies <true | false>]
   [-createDebugClassfiles <true | false>]
   [-keepgenerated <true | false>]
   [-keepGeneratedclassfiles <true | false>]
   [-usePageTagPool <true | false>]
   [-useThreadTagPool <true | false>]
   [-classloader.parentFirst <true | false>]
   [-classloader.singleWarClassloader <true | false>]
   [-additional.classpath <classpath to additional JAR files and classes>]
   [-jspCompileClasspath <classpath to Websphere Application Server public API JAR files;
         or no value at all>]
   [-verbose <true | false>]
   [-deprecation <true | false>]
   [-javaEncoding <encoding>
   [-compileWithAssert <true | false>]
   [-compilerOptions <space-separated list of java compiler options>]
   [-useJikes <true | false>]
   [-jsp.file.extensions <file extensions to process>]
   [-log.level <SEVERE | WARNING | INFO | CONFIG | FINE | FINER | FINEST | OFF>]

**See batchcompiler.properties.default in {WAS_ROOT}/bin for more information.**
**See JspCBuild.xml in {WAS_ROOT}/bin for information about the public WebSphere Ant task JspC.**
```

The batch compiler is aware of three groups of configuration parameters:

1. JSP engine configuration parameters for a Web module.

   See the topic, “JSP engine configuration parameters” on page 760.

2. Batch compiler response file configuration parameters.

   These are the parameters that are found in a batch compiler response file. See -response.file, below.

3. Batch compiler command line configuration parameters.

   These are the parameters entered on the command line when running the batch compiler.

The batch compiler looks at all three groups of configuration parameters in order to determine which value for a parameter is used when compiling JSP pages. When resolving the value for a given parameter, the precedence is:

1. If the parameter is found on the command line, its value is used.
2. If the parameter is not found on the command line, the batch compiler looks for the parameter in a response file named on the command line.
3. If no response file is named, or if the parameter is not found therein, the batch compiler looks for the parameter in the Web module’s JSP engine configuration parameters.

If a configuration parameter is not found among these three groups, then a default value is used. The default values for the configuration parameters are given below along with the description of the parameters.

With one exception, these parameters are not case sensitive; -profileName is case sensitive. If the values specified for these arguments are comprised of two or more words separated by spaces, you must add quotation marks around the values.

The batch compiler does not create, or set the values of, equivalent JSP engine parameters. This means that if a JSP page in a deployed Web module is modified and is recompiled by the JSP engine at runtime, the JSP engine's configuration parameters will determine the engine's behavior. For example, if you use the batch compiler to compile a Web module and you use the -useFullPackageNames true option, the JSP files will be compiled to support that option. But the JSP engine parameter useFullPackageNames must also be set to true in order for the JSP Runtime to be able to load the compiled JSP pages. If JSP pages are modified in a deployed Web module, then the engine's parameters should be set to the same values used in batch compilation.

To use the JSP batch compiler, enter the following command on a single line at an operating system command prompt:

where:

- **ear.path | war.path | enterpriseapp.name**

  Represents the full path to a single compressed or expanded enterprise application archive (EAR) file or Web application archive (WAR) file, or the name of the deployed enterprise application that you want to compile. For example:
  - `JspBatchCompiler -ear.path c:\myproject\sampleApp.ear`
  - `JspBatchCompiler -war.path c:\myWars\examples.war`
  - `JspBatchCompiler -enterpriseapp.name myEnterpriseApp -webmodule.name my.war -filename /aDir/main.jsp`
- **response.file**

  Specifies the path to a file that contains configuration parameters used by the batch compiler. The *response.file* is used only if it is given on the command-line; it is ignored if it is present in a response file. A template response file, batchcompiler.properties.default, is found in {WAS_ROOT}/bin. Copy this template to create your own response files containing defaults for the parameters in which you are interested. All the required and optional parameters (except response.file) can be configured in a response file.

  Example: JspBatchCompiler -response.file c:\myproject\batchc.props

  Default : null
- **webmodule.name**

  Represents the name of the specific Web module that you want to batch compile. If this argument is not set, all Web modules in the enterprise application are compiled. This parameter is used only when *ear.path* or *enterpriseapp.name* is given. This parameter is useful when JSP pages in a specific Web module within a deployed enterprise application need to be regenerated, because all Shared Library dependencies will be picked up.

  Example: JspBatchCompiler -enterpriseApp.name sampleApp -webmodule.name myWebModule.war

  Default: All Web modules in an EAR file or enterprise application are compiled if this parameter is not given.
- **filename**

  Represents the name of a single JSP file that you want to compile. If this argument is not set, all files in the Web module are compiled. Alternatively, if *filename* is set to the name of a directory, only the JSP files in that directory and that directory's child directories are complied. The name is relative to the context root of the Web module.

  Example 1: If you want to compile the file, `myTest.jsp`, and it is found in `/subdir/myJSPs`, you would enter `-filename /subdir/myJSPs/myTest.jsp`.

  Example 2: If you want to compile all JSP files in `/subdir/myJSPs` and its child directories, you would enter `-filename subdir/myJSPs`.

  Default: All JSP files in the Web module are compiled. Entering `-filename /` is equivalent to the default.
- **recurse**

Determines whether subdirectories beneath the target directory are processed. This parameter is used only when the *filename* parameter is given. Set value to `false` to process only the directory named *filename* parameter; and not its subdirectories.

Example: JspBatchCompiler -enterpriseApp.name sampleApp -filename /subdir1 -recurse false.

Default: true; All directories beneath the target directory are processed.

- **config.root**

  Specifies the location of the WebSpehere Application Server configuration directory. This parameter is used only when *enterpriseapp.name* is given.

  Default: `{WAS_ROOT}/profiles/profilename/config`
- **cell.name**

  Specifies the name of the cell in which the application is deployed. This parameter is used only when *enterpriseapp.name* is given.

  Default: The default is obtained from the profile script that is used. The symbolic name of this variable is WAS_CELL.
- **node.name**

  Specifies the name of the node in which the application is deployed. This parameter is used only when *enterpriseapp.name* is given.

  Default: The default is obtained from the profile script that is used. The symbolic name of this variable is WAS_NODE.
- **server.name**

  Represents the name of the server in which the application is deployed. This parameter is used only when *enterpriseapp.name* is given.

  Default: server1
- **profileName**

  Specifies the name of the profile you want to use. This parameter is used only when `enterpriseapp.name` is given.

  Example: JspBatchCompiler -enterpriseApp.name sampleApp -profileName AppServer-3

  Default: The default profile is used. This is obtained from the file `setupCmdLine.[bat/sh]` in `{WAS_ROOT}/bin`. The symbolic name is DEFAULT_PROFILE_SCRIPT.
- **extractToDir**

  Specifies the directory into which predeployed enterprise archive (EAR) files and Web application archive (WAR) files will be extracted before the batch compiler operates on them. This parameter is ignored when *enterpriseapp.name* is given. The extractToDir parameter is used as described in the table below.

  Example: JspBatchCompiler -ear.path c:\myproject\sampleApp.ear -extractToDir c:\myTempDir.

  Use-case: You must extract a compressed archive before it is batch compiled. You can also extract an expanded archive to a new directory as well. In both cases, extraction leaves the original archive untouched, which may be useful while development is underway.

  Default values:

	Expanded archive	Compressed archive
extractToDir supplied	The batch compiler extracts the archive to extractToDir before operating on it. If a file or directory of the same name as the archive already exists in the extractToDir, the batch compiler removes the archive completely before extracting that archive. If the batch compiler exits with no errors, it compresses the archive in place in the extractToDir, even if the original EAR file or WAR file was expanded. If errors are encountered during compilation, the EAR file or WAR file is left in the expanded state even if the original EAR file or WAR file was compressed.	

extractToDir not supplied	The batch compiler operates on the EAR file or WAR file in place (does not extract it to another directory) and the archive remains expanded after the batch compiler finishes.	The batch compiler extracts the archive to the directory returned by the JVM property ″java.io.tmpdir″. The rest of the behavior described above, when extractToDir is supplied, is the same in this case.

The default is `server1`.

- **compileToDir**

  Specifies the directory into which JSP pages are translated into Java source files and compiled into class files. This directory can be anywhere on the filesystem, but the batch compiler's default behavior is usually adequate. The batch compiler's behavior when compiling class files is described in the table below

  Example:: JspBatchCompiler -enterpriseApp.name sampleApp -compileToDir c:\myTargetDir

  Use-case: This parameter enables you to generate the Java and class files into a directory outside of the target, which may be useful if you want to compare the newly generated files with their previous versions which remain untouched within the target.

  Default values:

	ear.path or war.path supplied	enterpriseApp.name supplied
compileToDir not supplied; compileToWebInf not supplied, or is true	The class files are compiled into the Web module's `WEB-INF/classes` directory	The class files are compiled into the Web module's `WEB-INF/classes` directory.
compileToDir not supplied; compileToWebInf is false	The class files are compiled into the Web module's `WEB-INF/classes` directory.	The class files are compiled into the WebSphere temp directory (usually `{WAS_ROOT}/temp`).
compileToDir is supplied; compileToWebInf not supplied, or is either true or false	The class files are compiled into the directory indicated by compileToDir.	The class files are compiled into the directory indicated by compileToDir.

- **compileToWebInf**

  Specifies whether the target directory for the compiled JSP class files should be the Web module's `WEB-INF/classes directory`. This parameter is used only when *enterpriseApp.name* is given, and it is overridden by *compileToDir* if *compileToDir* is given.

  The batch compiler's default behavior is to compile to the Web module's `WEB-INF/classes` directory. The batch compiler's behavior when compiling class files is described in the table above.

  Example: JspBatchCompiler -enterpriseApp.name sampleApp -compileToWebInf false.

  Use-case: Set this parameter to false when enterpriseApp.name is supplied and you want the class files to be compiled to the WebSphere Application Server temp directory instead of the Web module's `WEB-INF/classes` directory. Recommendation: if this parameter is set to false, set forceCompilation to true if there are any JSP class files in the `WEB-INF/classes` directory.

  Default: true; see the table above.

- **forceCompilation**

  Specifies whether the batch compiler is forced to recompile all JSP resources regardless or whether the JSP page is outdated.

  Example: JspBatchCompiler -ear.path c:\myproject\sampleApp.ear -forceCompilation true.

  Use-case: Especially useful when creating an archive for deployment, to make sure all JSP classes are up to date.

  Default: false

- **useFullPackageNames**

  Specifies whether the batch compiler generates full package names for JSP classes. The default is to generate all JSP classes in the same package. The JSP engine's class loader knows how to load JSP classes when they are all in the same package. The default has the benefit of generating smaller file-system paths. Full package names have the benefit of enabling the configuration of precompiled JSP class files as servlets in the `web.xml` file without use of the `jsp-file` attribute, resulting in a single class loader (the Web application's class loader) being used to load all such JSP classes. Similarly, when the JSP engine's configuration attributes **useFullPackageNames** and **disableJspRuntimeCompilation** are both true, a single class loader is used to load all JSP classes, even if the JSP pages are not configured as servlets in the`web.xml` file.

When useFullPackageNames is set to true, the batch compiler generates a file called `generated_web.xml` in the Web module's `WEB-INF` directory. This file contains servlet configuration information for each JSP page that is successfully translated and compiled. The information can optionally be copied into the Web module's `web.xml` file so that the JSP pages are loaded as servlets by the Web container. Note that if a JSP page is configured as a servlet in this way, no reloading of the JSP page is done at runtime if the JSP page is modified. This is because the JSP page is treated as a regular servlet and requests for it do not pass through the JSP engine.

Example: JspBatchCompiler –enterpriseApp.name sampleApp –useFullPackageNames true

Use-case: Enables JSP classes to be loaded by a single class loader.

Default: false

- **removeTempDir**

  Specifies whether the Web module's temp directory is removed. The batch compiler by default generates JSP class files into a Web module's `WEB-INF/classes` directory. JSP class files are generated into the `temp` directory at runtime if a JSP page is modified and JSP reloading is enabled. By batch compiling all the JSP pages in a Web module and also removing the `temp` directory, disk resources are preserved. You can only use the removeTempDir parameter when -enterpriseApp.name is given.

  Example: JspBatchCompiler -enterpriseApp.name sampleApp -removeTempDir true.

  Use-case: Free up disk space by clearing out a Web application's `temp` directory.

  Default: false

- **translate**

  Specifies whether JSP pages are translated and compiled. Set translate to false if you do not want JSP pages to be translated and compiled. You must use this option in conjunction with `-removeTempDir` to tell the batch compiler to remove only the `temp` directory and to do no further processing.

  Example: JspBatchCompiler -enterpriseApp.name sampleApp -translate false -removeTempDir true.

  Use-case: Free up disk space by clearing out a Web application's `temp` directory, without invoking JSP processing.

  Default: true

- **compile**

  Specifies whether JSP pages go through the Java compilation phase. Set compile to `false` if you do not want JSP pages to go through the Java compilation phase.

  Example: JspBatchCompiler -enterpriseApp.name sampleApp -compile false

  Use-case: If you only want JSP pages to be syntax-checked, set -compile to false. You can set -keepgenerated to true if you want to see the `.java` files that are generated during the translation phase.

  Default: true

- **trackDependencies**

  Specifies whether the batch compiler recompiles a JSP page when any of its dependencies have changed, even if the JSP page itself has not changed. Tracking dependencies incurs a significant runtime performance penalty because the JSP Engine checks the filesystem on every request to a JSP page to see if any of its dependencies have changed. The dependencies tracked by WebSphere Application Server are :

  1. Files statically included in the JSP page
  2. Tag files used by the JSP page (excluding tag files that are in JAR files)
  3. TLD files used by the JSP page (excluding TLD files that are in JAR files)

Example: JspBatchCompiler -ear.path c:\myproject\sampleApp.ear -trackDependencies true.

Use-case: Useful in a development environment.

Default: false

- **createDebugClassfiles**

  Specifies whether the batch compiler generates class files that contain SMAP information, as per JSR 45, **Debugging support for Other Languages**.

  Example: JspBatchCompiler -enterpriseApp.name sampleApp -createDebugClassfiles true

  Use-case: Use this parameter when you want to be able to debug JSP pages in your JSR 45-compliant IDE.

  Default: false

- **keepgenerated**

  Specifies whether the batch compiler saves or erases the generated Java source files created during the translation phase.

  If set to `true`, WebSphere Application Server saves the generated `.java` files used for compilation on your server. By default, this argument is set to `false` and the `.java` files are erased after the class files have compiled.

  Example: JspBatchCompiler -ear.path c:\myproject\sampleApp.ear -keepgenerated true

  Use-case: Use this parameter when you want to review the Java code generated by the batch compiler.

  Default: false

- **keepGeneratedclassfiles**

  Specifies whether the batch compiler saves or erases the class files generated during the compilation of Java source files.

  Example: JspBatchCompiler -ear.path c:\myproject\sampleApp.ear -keepGeneratedclassfiles false -keepgenerated false

  Use-case: Set this parameter to false if you only want to see if there are any translation or compilation errors in your JSP pages. If paired with -keepgenerated false, this parameter results in all generated files being removed before the batch compiler completes.

  Default: true

- **usePageTagPool**

  Enables or disables the reuse of custom tag handlers on an individual JSP page basis.

  Example: JspBatchCompiler -ear.path c:\myproject\sampleApp.ear -usePageTagPool true

  Use-case: Use this parameter to enable JSP-page-based reuse of tag handlers.

  Default: false

- **useThreadTagPool**

  Enables or disables the reuse of custom tag handlers on a per request thread basis per Web module.

  Example: JspBatchCompiler -ear.path c:\myproject\sampleApp.ear -useThreadTagPool true

  Use-case: Use this parameter to enable Web module-based reuse of tag handlers.

  Default: false

- **classloader.parentFirst**

  Specifies the search order for loading classes by instructing the batch compiler to search the parent class loader prior to application class loader. This parameter is only used when *ear.path* or *enterpriseApp.name* is given.

  Example: JspBatchCompiler -ear.path c:\myproject\sampleApp.ear -classloader.parentFirst false

  Use-case: Set this parameter to false when your Web module contains a JAR file that is also found in the server lib directory, and you want your Web module's JAR file to be picked up first.

  Default: true

- **classloader.singleWarClassloader**

Specifies whether to use one class loader per enterprise archive (EAR) file or one class loader per Web application archive (WAR) file. Used only when *ear.path* or *enterpriseApp.name* is given.

Example: JspBatchCompiler -ear.path c:\myproject\sampleApp.ear -classloader.singleWarClassloader true

Use-case: Set this parameter to true when a Web module depends on JAR files and classes in another Web module in the same enterprise application.

Default: false; One class loader is created per WAR file with no visibility of classes in other Web modules.

- **additional.classpath**

  Specifies additional class path entries to be used when parsing and compiling JSP pages. This parameter is used only when `war.path` is given. When `war.path` is the target, WebSphere Shared Libraries are not picked up by the batch compiler. Therefore, if your WAR file relies on, for example, a JAR file that is configured in WebSphere Application Server as a shared library, then use this option to point to that JAR file. In addition, if you give `war.path` and also use the `-extractToDir` parameter, then any JAR files that are in the WAR file's manifest class-path is not added to the class path (since the WAR file has now been extracted by itself outside the EAR file in which it resides). Use `-additional.classpath` in this case to point to the necessary JAR files. Add the full path to needed resources, separated by your system-dependent path separator.

  Example: JspBatchCompiler -war.path c:\myproject\examples.war -additional.classpath c:\myJars\someJar.jar;c:\myClasses

  Use-case: Use this parameter to add to the class path JAR files and classes outside of your WAR file. At runtime, these same JAR files and classes have to be made available through the standard WebSphere Application Server configuration mechanisms.

  Default: null

- **jspCompileClasspath**

  This option instructs the batch compiler to use a small class path for the Java compilation phase. The small class path greatly speeds up the compilation process. This small class path is not used by default because it includes only a subset of WebSphere Application Server JAR files. The small class path excludes many WebSphere Application Server JAR files, among which are those that contain WebSphere public APIs.

  If your JSP pages do not use any WebSphere public APIs within scriptlets you can enable the small class path by using the jspCompileClasspath parameter with no value, as in Example 1 below.

  If your JSP pages do use WebSphere public APIs within scriptlets, then add those additional JAR files to the jspCompileClasspath option, as in Example 2 below.

  The entries are separated by spaces, and are assumed to be relative to the WebSphere Application Server installation root.

  Example 1: If no public APIs are needed in JSP pages: JspBatchCompiler -enterpriseApp.name sampleApp -jspCompileClasspath

  Example 2: public APIs from the `admin.jar` file needed in JSP pages: JspBatchCompiler -enterpriseApp.name sampleApp –jspCompileClasspath ″lib/admin.jar″

  Use-case: Use this parameter to speed up the Java compilation step of JSP page processing.

  Default: The entire WebSphere Application Server class path is used by default.

- **verbose**

  Specifies whether the batch compiler should generate verbose output while compiling the generated sources.

  Example: JspBatchCompiler -war.path c:\myproject\examples.war -verbose true

  Use-case: Set this parameter to true when you want to see Java compiler class loading and other messages.

  Default: false

- **deprecation**

Indicates the compiler should generate deprecation warnings while compiling the generated sources.

Example: JspBatchCompiler -war.path c:\myproject\examples.war -deprecation true

Use-case: Set this parameter to true when you want to see Java compiler deprecation messages.

Default: false

- **javaEncoding**

  Specifies the encoding that will be used when the .java file is generated, and when it is compiled by the Java compiler. When -javaEncoding is set, that encoding is passed to the java compiler via the -encoding argument. Note that encoding is not supported by Jikes.

  Example: JspBatchCompiler -war.path c:\myproject\examples.war -javaEncoding Shift-JIS

  Use-case: Set this parameter when the page encoding of your JSP pages is not UTF-8 compatible.

  Default value: UTF-8.

- **compileWithAssert**

  Tells the batch compiler to enable assertions. If compileWithAssert is true, the batch compiler will pass the –source 1.4 option to the javac compiler. If compileWithAssert is false, no option is sent to the javac compiler. The default behavior of javac is to compile code normally even if the word assert is used as regular identifier.

  Example: JspBatchCompiler -war.path c:\myproject\examples.war -compileWithAssert true

  Use-case: Set this parameter to true when you want you use the assertion facility in your JSP pages and you want to be able to turn on assertions at runtime.

  Default value: false

- **compilerOptions**

  Specifies a list of strings to be passed on the Java compiler command. This is a space-separated list of the form ″arg1 arg2 argn″.

  Example: JspBatchCompiler -war.path c:\myproject\examples.war -compilerOptions ″ -bootclasspath <path>″

  Use-case: Use this parameter if you need Java compiler arguments other than verbose, deprecation and Assert facility support.

  Default: null

- **useJikes**

  Specifies whether Jikes should be used for compiling Java sources. NOTE: Jikes is not shipped with WebSphere Application Server.

  Example: JspBatchCompiler -ear.path c:\myproject\sampleApp.ear -useJikes true

  Use-case: Set this parameter to true in order for the batch compiler to use Jikes as the Java compiler.

  Default value: false

- **jsp.file.extensions**

  Specifies the file extensions to be processed by the batch compiler. This is a semicolon- or colon-separated list of the form ″*.ext1;*.ext2:*.extn″. Note that this parameter is not necessary for Servlet 2.4 Web applications because the url-pattern property of the jsp-property-group elements in the deployment descriptor can be used to identify extensions that should be treated as JSP pages.

  Example: JspBatchCompiler -enterpriseApp.name sampleApp -jsp.file.extensions *jspz;*.jspt

  Use-case: Use this parameter to add additional extensions to the be processed by the batch compiler.

  Default: null; See the section, "JSP batch compiler tool" on page 771, for additional information.

- **log.level**

  Specifies the level of logging that is directed to the console during batch compilation. Values are SEVERE | WARNING | INFO | CONFIG | FINE | FINER | FINEST | OFF

  Example: JspBatchCompiler -enterpriseApp.name sampleApp -log.level FINEST

  Use-case: Set this parameter higher or lower to control logging output. FINEST generates the most output useful for debugging.

Default: CONFIG

Batch compiler ant task:

The ant task **JspC** exposes all the batch compiler configuration options. It executes the batch compiler under the covers. It is backward compatible with the WebSphere Application Server 5.x version of the **JspC** ant task. The following table lists all the ant task attribute and their batch compiler equivalents.

JspC attribute	Equivalent batch complier parameter
earPath	-ear.path
warPath	-war.path
src Same as warPath, for backward compatiblity	-war.path
enterpriseAppName	-enterpriseapp.name
responseFile	-response.file
webmoduleName	-webmodule.name
fileName	-filename -config.root
configRoot	-config.root
cellName	-cell.name
nodeName	-node.name
serverName	-server.name
profileName	-profileName
extractToDir	-extractToDir
compileToDir same as compileToDir, for backward compatibility	-compileToDir -compileToDir
compileToWebInf	-compileToWebInf
jspCompileClasspath	-jspCompileClasspath
compilerOptions	-compilerOptions
recurse	-recurse
removeTempDir	-removeTempDir
translate	-translate
compile	-compile
forceCompilation	-forceCompilation
useFullPackageNames	-useFullPackageNames
trackDependencies	-trackDependencies
createDebugClassfiles	-createDebugClassfiles
keepgenerated	-keepgenerated
keepGeneratedclassfiles	-keepGeneratedclassfiles
usePageTagPool	-usePageTagPool
useThreadTagPool	-useThreadTagPool
classloaderParentFirst	-classloader.parentFirst
classloaderSingleWarClassloader	-classloader.singleWarClassloader
additionalClasspath	-additional.classpath

classpath same as additionalClasspath, for backward compatibility	-additional.classpath
verbose	-verbose
deprecation	-deprecation
javaEncoding	-javaEncoding
compileWithAssert	-compileWithAssert
useJikes	-useJikes
jspFileExtensions	-jsp.file.extensions
logLevel	-log.level
wasHome	none
Classpathref	none

Below is an example of a build script with multiple targets, each with different attributes. The following commands are used to execute the script:

On Windows:

```
ws_ant -Dwas.home=%WAS_HOME% -Dear.path=%EAR_PATH% -Dextract.dir=%EXTRACT_DIR%
ws_ant jspc2 -Dwas.home=%WAS_HOME% -Dapp.name=%APP_NAME% -Dwebmodule.name=%MOD_NAME%
ws_ant jspc3 -Dwas.home=%WAS_HOME% -Dapp.name=%APP_NAME% -Dwebmodule.name=%MOD_NAME% -Ddir.name=%DIR_NAME%
```

On Unix:

```
ws_ant -Dwas.home=$WAS_HOME -Dear.path=$EAR_PATH -Dextract.dir=$EXTRACT_DIR
ws_ant jspc2 -Dwas.home=$WAS_HOME -Dapp.name=$APP_NAME -Dwebmodule.name=$MOD_NAME
ws_ant jspc3 -Dwas.home=$WAS_HOME -Dapp.name=$APP_NAME -Dwebmodule.name=$MOD_NAME -Ddir.name=$DIR_NAME
```

Example build.xml Using the JspC Task

```
<project name="JSP Precompile" default="jspc1" basedir=".">
 <taskdef name="wsjspc" classname="com.ibm.websphere.ant.tasks.JspC"/>
 <target name="jspc1" description="example using  a path to an EAR, and extracting the EAR to a directory">
  <wsjspc wasHome="${was.home}"
            earpath="${ear.path}"
            forcecompilation="true"
            extractToDir="${extract.dir}"
            useThreadTagPool="true"
            keepgenerated="true"
            jspCompileClasspath=""

  />
 </target>
 <target name="jspc2" description="example using an enterprise app and webmodule">
  <wsjspc wasHome="${was.home}"
            enterpriseAppName="${app.name}"
            webmoduleName="${webmodule.name}"
            removeTempDir="true"
            forcecompilation="true"
            keepgenerated="true"
            jspCompileClasspath=""

  />
 </target>
 <target name="jspc3" description="example using an enterprise app, webmodule and specific directory">
  <wsjspc wasHome="${was.home}"
            enterpriseAppName="${app.name}"
            webmoduleName="${webmodule.name}"
            fileName="${dir.name}"
            recurse="false"
```

```
           forcecompilation="true"
           keepgenerated="true"
           jspCompileClasspath=""

  />
 </target>
</project>
```

Batch compiler class path:

The batch compiler builds its class path as shown in the table below. When the batch compiler target is a Web archive (WAR) file and `war.path` is supplied, the configuration *additional.classpath* parameter is used to give extra class path information.

	Batch compiler target		
Location added to class path	enterpriseapp.name	ear.path	war.path
WebSphere Application Server JAR files and classes	yes	yes	yes
JAR files listed in manifest class path for a Web module	yes	yes	yes, when the target WAR is inside an EAR and *–extractToDir* is not used; otherwise, no.
Shared libraries	yes	no	no
Web module JAR files and classes	yes	yes	yes
additional.classpath parameter to batch compiler	no	no	yes
jspCompileClassPath parameter	When this parameter is used, the only change to the information above is that a subset of WebSphere Application Server JAR files and classes is used for Java compilation. All JAR files and classes, that are given in the value for the *jspCompileClassPath* parameter are also added to the class path for Java compilation.		

Global tag libraries:

JavaServer Pages (JSP) tag libraries contain classes for common tasks such as processing forms and accessing databases from JSP files.

Tag libraries encapsulate, as simple tags, core functionality common to many Web applications. The Java Standard Tag Library (JSTL) supports common programming tasks such as iteration and conditional processing, and provides tags for:
- manipulating XML documents
- supporting internationalization
- using Structured Query Language (SQL)

Tag libraries also introduce the concept of an expression language to simplify page development, and include a version of the JSP expression language.

A tag library has two parts - a Tag Library Descriptor (TLD) file and a Java archive (JAR) file.

tsx:dbconnect tag JavaServer Pages syntax: Use the <tsx:dbconnect> tag to specify information needed to make a connection to a database through Java DataBase Connectivity (JDBC) or Open Database Connectivity (ODBC) technology.

The <tsx:dbconnect> syntax does not establish the connection. Use the <tsx:dbquery> and <tsx:dbmodify> syntax instead to reference a <tsx:dbconnect> tag in the same JavaServer Pages (JSP) file to establish the connection.

When the JSP file compiles into a servlet, the Java processor adds the Java coding for the <tsx:dbconnect> syntax to the servlet service() method, which means a new database connection is created for each request for the JSP file.

This section describes the syntax of the <tsx:dbconnect> tag.

```
<tsx:dbconnect id="connection_id"
    userid="db_user" passwd="user_password"
    url="jdbc:subprotocol:database"
    driver="database_driver_name"
    jndiname="JNDI_context/logical_name">
</tsx:dbconnect>
```

where:

- **id**

  Represents a required identifier. The scope is the JSP file. This identifier is referenced by the connection attribute of a <tsx:dbquery> tag.
- **userid**

  Represents an optional attribute that specifies a valid user ID for the database that you want to access. Specify this attribute to add the attribute and its value to the request object.

  Although the userid attribute is optional, you must provide the user ID. See <tsx:userid> and <tsx:passwd> for an alternative to hard coding this information in the JSP file.
- **passwd**

  Represents an optional attribute that specifies the user password for the userid attribute. (This attribute is not optional if the userid attribute is specified.) If you specify this attribute, the attribute and its value are added to the request object.

  Although the passwd attribute is optional, you must provide the password. See <tsx:userid> and <tsx:passwd> for an alternative to hard coding this attribute in the JSP file.
- **url** and **driver**

  Respresents a required attribute if you want to establish a database connection. You must provide the URL and driver.

  The application server supports connection to JDBC databases and ODBC databases.
  - For a JDBC database, the URL consists of the following colon-separated elements: jdbc, the subprotocol name, and the name of the database to access. An example for a connection to the Sample database included with IBM DB2 is:

    ```
    url="jdbc:db2:sample"
    driver="COM.ibm.db2.jdbc.app.DB2Driver"
    ```
  - For an ODBC database, use the Sun JDBC-to-ODBC bridge driver included in their Java2 Software Developers Kit (SDK) or another vendor's ODBC driver.

    The url attribute specifies the location of the database. The driver attribute specifies the name of the driver to use in establishing the database connection.

    If the database is an ODBC database, you can use an ODBC driver or the Sun JDBC-to-ODBC bridge. If you want to use an ODBC driver, refer to the driver documentation for instructions on specifying the database location with the url attribute and the driver name.

    If you use the bridge, the url syntax is `jdbc:odbc:`*`database`*. An example follows:

    ```
    url="jdbc:odbc:autos"
    driver="sun.jdbc.odbc.JdbcOdbcDriver"
    ```

    Note: To enable the application server to access the ODBC database, use the ODBC Data Source Administrator to add the ODBC data source to the System DSN configuration. To access the ODBC Administrator, click the ODBC icon on the Windows NT Control Panel.
- **jndiname**

  Represents an optional attribute that identifies a valid context in the application server Java Naming and Directory Interface (JNDI) naming context and the logical name of the data source in that context. The Web administrator configures the context using an administrative client such as the WebSphere Administrative Console.

If you specify the jndiname attribute, the JSP processor ignores the driver and url attributes on the <tsx:dbconnect> tag.

An empty element (such as <url></url>) is valid.

dbquery tag JavaServer Pages syntax: Use the <tsx:dbquery> tag to establish a connection to a database, submit database queries, and return the results set.

The <tsx:dbquery> tag does the following:

1. References a <tsx:dbconnect> tag in the same JavaServer Pages (JSP) file and uses the information the tag provides to determine the database URL and driver. You can also obtain the user ID and password from the <tsx:dbconnect> tag if those values are provided in the <tsx:dbconnect> tag.
2. Establishes a new connection
3. Retrieves and caches data in the results object.
4. Closes the connection and releases the connection resource.

This section describes the syntax of the <tsx:dbquery> tag.

```
<%-- SELECT commands and (optional) JSP syntax can be placed within the tsx:dbquery. --%>
<%-- Any other syntax, including HTML comments, are not valid. --%>
<tsx:dbquery id="query_id" connection="connection_id" limit="value" >
</tsx:dbquery>
```

where:

- **id**

  Represents the identifier of this query. The scope is the JSP file. Use `id` to reference the query. For example, from the <tsx:getProperty> tag, use `id` to display the query results.

  The `id` is a tsx reference to the bean and can be used to retrieve the bean from the page contect. For example, if id is named mySingleDBBean, instead of using:
  - if (mySingleDBBean.getValue(″UISEAM″,0).startsWith(″N″))

  use:
  - com.ibm.ws.webcontainer.jsp.tsx.db.QueryResults bean = (com.ibm.ws.webcontainer.jsp.tsx.db.QueryResults)pageContext. findAttribute(″mySingleDBBean″); if (bean.getValue(″UISEAM″,0).startsWith(″N″)). . .

  The bean properties are dynamic and the property names are the names of the columns in the results set. If you want different column names, use the SQL keyword for specifying an alias on the SELECT command. In the following example, the database table contains columns named FNAME and LNAME, but the SELECT statement uses the `AS` keyword to map those column names to FirstName and LastName in the results set:

  ```
  Select FNAME, LNAME AS FirstName, LastName from Employee where FNAME='Jim'
  ```
- **connection**

  Represents the identifier of a <tsx:dbconnect> tag in this JSP file. The <tsx:dbconnect> tag provides the database URL, driver name, and optionally, the user ID and password for the connection.
- **limit**

  Represents an optional attribute that constrains the maximum number of records returned by a query. If this attribute is not specified, no limit is used. In such a case, the effective limit is determined by the number of records and the system caching capability.
- SELECT command and JSP syntax

  Represents the only valid SQL command, SELECT. The <tsx:dbquery> tag must return a results set. Refer to your database documentation for information about the SELECT command. See other articles in this section for a description of JSP syntax for variable data and inline Java code.

dbmodify tag JavaServer Pages syntax: The <tsx:dbmodify> tag establishes a connection to a database and then adds records to a database table.

The <tsx:dbmodify> tag does the following:

1. References a <tsx:dbconnect> tag in the same JavaServer Pages (JSP) file and uses the information provided by that tag to determine the database URL and driver.

   Note: You can also obtain the user ID and password from the <tsx:dbconnect> tag if those values are provided in the <tsx:dbconnect> tag.
2. Establishes a new connection.
3. Updates a table in the database.
4. Closes the connection and releases the connection resource.

This section describes the syntax of the <tsx:dbmodify> tag.

```
<%-- Any valid database update commands can be placed within the DBMODIFY tag. -->
<%-- Any other syntax, including HTML comments, are not valid. -->
<tsx:dbmodify connection="connection_id">
</tsx:dbmodify>
```

where:

- **connection**

  Represents the identifier of a <tsx:dbconnect> tag in this JSP file. The <tsx:dbconnect> tag provides the database URL, driver name, and (optionally) the user ID and password for the connection.
- Database commands

  Represents valid database commands. Refer to your database documentation for details

tsx:getProperty tag JavaServer Pages syntax and examples: The `<tsx:getProperty>` tag gets the value of a bean to display in a JavaServer Pages (JSP) file.

This IBM extension of the Sun JSP <jsp:getProperty> tag implements all of the <jsp:getProperty> function and adds the ability to introspect a database bean created using the IBM extension <tsx:dbquery> or <tsx:dbmodify>.

Note: You cannot assign the value from this tag to a variable. The value, generated as output from this tag, displays in the browser window.

This section describes the syntax of the `<tsx:getProperty>` tag:

```
<tsx:getProperty name="bean_name"
  property="property_name" />
```

where:

- **name**

  Represents the name of the bean declared by the `id` attribute of a <tsx:dbquery> syntax within the JSP file. See <tsx:dbquery> for an explanation. The value of this attribute is case-sensitive.
- **property**

  Represents the property of the bean to access for substitution. The value of the attribute is case-sensitive and is the locale-independent name of the property.

Tag example:

```
<tsx:getProperty name="userProfile" property="username" />
```

tsx:userid and tsx:passwd tag JavaServer Pages syntax: With the <tsx:userid> and <tsx:passwd> tags, you do not have to hard code a user ID and password in the <tsx:dbconnect> tag.

Use the <tsx:userid> and <tsx:passwd> tags to accept user input for the values and then add that data to the request object. You can access the request object with a JavaServer Pages (JSP) file, such as the *JSPEmployee.jsp* example that requests the database connection.

You must use <tsx:userid> and <tsx:passwd> tags within a <tsx:dbconnect> tag.

This section describes the syntax of the <tsx:userid> and <tsx:passwd> tags.

```
<tsx:dbconnect id="connection_id"
    <font color="red"><userid></font>
    <tsx:getProperty name="request" property=request.getParameter("userid") />
    <font color="red"></userid></font>
    <font color="red"><passwd></font>
    <tsx:getProperty name="request" property=request.getParameter("passwd") />
    <font color="red"></passwd></font>
    url="protocol:database_name:database_table"
    driver="JDBC_driver_name">
</tsx:dbconnect>
```

where:

- **<tsx:getProperty>**

  Represents the syntax as a mechanism for embedding variable data.
- **userid**

  Represents a reference to the request parameter that contains the user ID. You must add the parameter to the request object that passes to this JSP file. You can set the attribute and its value in the request object, using an HTML form or a URL query string to pass the user-specified request parameters.
- **passwd**

  Represents a reference to the request parameter that contains the password. Add the parameter to the request object that passes to this JSP file. You can set the attribute and its value in the request object, using an HTML form or a URL query string, to pass user-specified values.

tsx:repeat tag JavaServer Pages syntax: The <tsx:getProperty> tag repeats a block of HTML tagging.

Use the <tsx:repeat> syntax to iterate over a database query results set. The <tsx:repeat> syntax iterates from the start value to the end value until one of the following conditions is met:

- The end value is reached.
- An exception is thrown.

If an exception of the types **ArrayIndexOutOfBoundsException** or **NoSuchElementException** is created before a block completes, output is written only for the iterations up to and not including the iteration during which the exception was created. All other exceptions results in no output being written for that tag instance.

This section describes the syntax of the `<tsx:repeat>` tag:

```
<tsx:repeat index="name" start="starting_index" end="ending_index">
</tsx:repeat>
```

where:

- **index**

  Represents an optional name used to identify the index of this repeat block. The scope of the index is NESTED. Its type must be integer.
- **start**

  Represents an optional starting index value for this repeat block. The default is `0`.
- **end**

  Represents an optional ending index value for this repeat block. The maximum value is `2,147,483,647`.

  If the value of the end attribute is less than the value of the start attribute, the end attribute is ignored.

Example: Combining tsx:repeat and tsx:getProperty JavaServer Pages tags: The following code snippet shows you how to code these tags:

```
<tsx:repeat>
<tr>
    <td><tsx:getProperty name="empqs" property="EMPNO" />
    <tsx:getProperty name="empqs" property="FIRSTNME" />
    <tsx:getProperty name="empqs" property="WORKDEPT" />
    <tsx:getProperty name="empqs" property="EDLEVEL" />
    </td>
</tr>
</tsx:repeat>
```

Example: tsx:dbmodify tag syntax: In the following example, a new employee record is added to a database. The values of the fields are based on user input from this JavaServer Pages (JSP) file and referenced in the database commands using the <tsx:getProperty> tag.

```
<tsx:dbmodify connection="conn" >
insert into EMPLOYEE
    (EMPNO,FIRSTNME,MIDINIT,LASTNAME,WORKDEPT,EDLEVEL)
values
('<tsx:getProperty name="request" property=request.getParameter("EMPNO") />',
'<tsx:getProperty name="request" property=request.getParameter("FIRSTNME") />',
'<tsx:getProperty name="request" property=request.getParameter("MIDINIT") />',
'<tsx:getProperty name="request" property=request.getParameter("LASTNAME") />',
'<tsx:getProperty name="request" property=request.getParameter("WORKDEPT") />',
<tsx:getProperty name="request" property=request.getParameter("EDLEVEL") />)
</tsx:dbmodify>
```

Example: Using tsx:repeat JavaServer Pages tag to iterate over a results set: The <tsx:repeat> tag iterates over a results set. The results set is contained within a bean. The bean can be a static bean, for example, a bean created by using the IBM WebSphere Studio database wizard, or a dynamically generated bean, for example, a bean generated by the <tsx:dbquery> syntax. The following table is a graphic representation of the contents of a bean called, *myBean*:

	col1	col2	col3
row0	friends	Romans	countrymen
row1	bacon	lettuce	tomato
row2	May	June	July

Some observations about the bean:

- The column names in the database table become the property names of the bean. The <tsx:dbquery> section describes a technique for mapping the column names to different property names.
- The bean properties are indexed. For example, `myBean.get(Col1(row2))` returns `May`.
- The query results are in the rows. The <tsx:repeat> tag iterates over the rows, beginning at the start row.

The following table compares using the <tsx:repeat> tag to iterate over a static bean, versus a dynamically generated bean:

Static Bean Example	<tsx:repeat> Bean Example

myBean.class
`// Code to get a connection`
 	
`// Code to get the data`
`   Select * from myTable;`
 	
`// Code to close the connection`
 	
JSP file
`<tsx:repeat index=abc>`
`  <tsx:getProperty name="myBean"`
`    property="col1(abc)" />`
`</tsx:repeat>`
 	
Notes:
• The bean (myBean.class) is a static bean.
• The method to access the bean properties is myBean.get(*property*(*index*)).
• You can omit the property index, in which case the index of the enclosing <tsx:repeat> tag is used. You can also omit the index on the <tsx:repeat> tag.
• The <tsx:repeat> tag iterates over the bean properties row by row, beginning with the start row.
	JSP file
	`<tsx:dbconnect id="conn"`
	`userid="alice"passwd="test"`
	`url="jdbc:db2:sample"`
	`driver="COM.ibm.db2.jdbc.app.DB2Driver">`
	`</tsx:dbconnect >`
	
	`<tsx:dbquery id="dynamic"`
	` connection="conn" >`
	`  Select * from myTable;`
	`</tsx:dbquery>`
	
	`<tsx:repeat index=abc>`
	`  <tsx:getProperty name="dynamic"`
	`    property="col1(abc)" />`
	`</tsx:repeat>`
	
	Notes:
	• The bean (dynamic) is generated by the <tsx:dbquery> tag and does not exist until the syntax executes.
	• The method to access the bean properties is dynamic.getValue("*property*", *index*).
	• You can omit the property index, in which case the index of the enclosing <tsx:repeat> tag is used. You can also omit the index on the <tsx:repeat> tag.
	• The <tsx:repeat> tag syntax iterates over the bean properties row by row, beginning with the start row.

Implicit and explicit indexing

Examples 1, 2, and 3 show how to use the <tsx:repeat> tag. The examples produce the same output if all indexed properties have 300 or fewer elements. If there are more than 300 elements, Examples 1 and 2 display all elements, while Example 3 shows only the first 300 elements.

Example 1 shows *implicit indexing* with the default start and default end index. The bean with the smallest number of indexed properties restricts the number of times the loop repeats.

```
<table>
<tsx:repeat>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property="city" />
  </tr></td>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property="address" />
  </tr></td>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property="telephone" />
  </tr></td>
</tsx:repeat>
</table>
```

Example 2 shows indexing, starting index, and ending index:

```
<table>
<tsx:repeat index=myIndex start=0 end=2147483647>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property=city(myIndex) />
  </tr></td>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property=address(myIndex) />
  </tr></td>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property=telephone(myIndex) />
</tr></td>
</tsx:repeat>
</table>
```

Example 3 shows *explicit indexing* and ending index with implicit starting index. Although the index attribute is specified, you can still implicitly index the indexed property city because the (`myIndex`) tag is not required.

```
<table>
<tsx:repeat index=myIndex end=299>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property="city" /t>
  </tr></td>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property="address(myIndex)" />
  </tr></td>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property="telephone(myIndex)" />
  </tr></td>
</tsx:repeat>
</table>
```

Nesting <tsx:repeat> blocks

You can nest <tsx:repeat> blocks. Each block is separately indexed. This capability is useful for interleaving properties on two beans, or properties that have subproperties. In the example, two <tsx:repeat> blocks are nested to display the list of songs on each compact disc in the user's shopping cart.

```
<tsx:repeat index=cdindex>
  <h1><tsx:getProperty name="shoppingCart" property=cds.title /></h1>
  <table>
  <tsx:repeat>
    <tr><td><tsx:getProperty name="shoppingCart" property=cds(cdindex).playlist />
    </td></tr>
  </tsx:repeat>
  </table>
 </tsx:repeat>
```

Web modules

A Web module represents a Web application. A Web module is created by assembling servlets, JavaServer Pages (JSP) files, and static content such as Hype rText Markup Language (HTML) pages into a single deployable unit. Web modules are stored in Web archive (WAR) files, which are standard Java archive files.

A Web module contains:

- One or more servlets, JSP files, and HTML files.
- A deployment descriptor, stored in an Extensible Markup Language (XML) file.

  The file, named `web.xml`, declares the contents of the module. It contains information about the structure and external dependencies of Web components in the module and describes how the components are used at run time.

You can create Web modules as stand-alone applications, or you can combine Web modules with other modules to create Java 2 Platform, Enterprise Edition (J2EE) applications. You install and run a Web module in the Web container of an application server.

Troubleshooting tips for Web application deployment

Deployment of a Web application is successful if you can access the application by typing a Uniform Resource Locator (URL) in a browser, or if you can access the application by following a link.

If you cannot access your application, follow these steps to eliminate some common errors that can occur during migration or deployment.

Web module does not run in WebSphere Application Server Version 5 or 6.

Symptom	Your Web module does not run when you migrate it to Version 5 or 6

Problem In Version 4.x, the classpath setting that affected visibility was *Module Visibility Mode*. In Versions 5 and 6, you must use class loader policies to set visibility.

Recommended response Reassemble an existing module, or change the visibility settings in the class loader policies.

Welcome page is not visible.

Symptom You cannot access an application with a Web path of:

```
/webapp/myapp
```

Problem The default welcome page for a Web application is assumed to be *index.html*. You cannot access the default page of the *myapp* application unless it is named *index.html*.

Recommended response To identify a different welcome page, modify the properties of the Web module during assembly. See the article ″Assembling Web applications″ for more information.

HTML files are not found.

Symptom Your Web application ran successfully on prior versions, but now you encounter errors that the welcome page (typically *index.html*), or referenced HTML files are not found:

```
Error 404: File not found: Banner.html
Error 404: File not found: HomeContent.html
```

Problem For security and consistency reasons, Web application URLs are now case-sensitive on all operating systems.

Suppose the content of the index page is as follows:

```
<!DOCTYPE HTML PUBLIC "-//W3C//DTD HTML 5.0 Frameset//EN">
<HTML>
<TITLE>
Insurance Home Page
</TITLE>
   <frameset   rows="18,80">
   <frame      src="Banner.html"          name="BannerFrame"  SCROLLING=NO>
   <frame      src="HomeContent.html"     name="HomeContentFrame">
   </frameset>
</HTML>
```

However the actual file names in the `\WebSphere\AppServer\installedApps\...` directory where the application is deployed are:

```
banner.html
homecontent.html
```

Recommended response To correct this problem, modify the *index.html* file to change the names *Banner.html* and *HomeContent.html* to *banner.html* and *homecontent.html* to match the names of the files in the deployed application.

For current information available from IBM Support on known problems and their resolution, see the IBM Support page.

IBM Support has documents that can save you time gathering information needed to resolve this problem. Before opening a PMR, see the IBM Support page.

Web applications: Resources for learning

Use the following links to find relevant supplemental information about Web applications. The information resides on IBM and non-IBM Internet sites, whose sponsors control the technical accuracy of the information.

These links are provided for convenience. Often, the information is not specific to the IBM WebSphere Application Server product, but is useful all or in part for understanding the product. When possible, links are provided to technical papers and Redbooks that supplement the broad coverage of the release documentation with in-depth examinations of particular product areas.

Task overview: Managing HTTP sessions

IBM WebSphere Application Server provides a service for managing HTTP sessions: Session Manager. The key activities for session management are summarized below.

Before you begin these steps, make sure you are familiar with the programming model for accessing HTTP session support in the applications following the Servlet 2.4 API.

1. Plan your approach to session management, which could include session tracking and session recovery.
2. Create or modify your own applications to use session support to maintain sessions on behalf of Web applications.
3. Assemble your application. See ″Assembling applications″ in the information center.
4. Deploy your application.
5. Ensure the administrator appropriately configures session management in the administrative domain.
6. Adjust configuration settings and perform other tuning activities for optimal use of sessions in your environment.

Sessions

A session is a series of requests to a servlet, originating from the same user at the same browser.

Sessions allow applications running in a Web container to keep track of individual users.

For example, a servlet might use sessions to provide ″shopping carts″ to online shoppers. Suppose the servlet is designed to record the items each shopper indicates he or she wants to purchase from the Web site. It is important that the servlet be able to associate incoming requests with particular shoppers. Otherwise, the servlet might mistakenly add Shopper_1’s choices to the cart of Shopper_2.

A servlet distinguishes users by their unique session IDs. The session ID arrives with each request. If the user’s browser is cookie-enabled, the session ID is stored as a cookie. As an alternative, the session ID can be conveyed to the servlet by URL rewriting, in which the session ID is appended to the URL of the servlet or JavaServer Pages (JSP) file from which the user is making requests. For requests over HTTPS or Secure Sockets Layer (SSL), Another alternative is to use SSL information to identify the session.

Session security support

You can integrate HTTP sessions and security in WebSphere Application Server. When security integration is enabled in the session management facility and a session is accessed in a protected resource, you can access that session only in protected resources from then on. You cannot mix secured and unsecured resources accessing sessions when security integration is turned on. Security integration in the session management facility is not supported in form-based login with SWAM.

Security integration rules for HTTP sessions

Only authenticated users can access sessions created in secured pages and are created under the identity of the authenticated user. Only this authenticated user can access these sessions in other secured pages. To protect these sessions from unauthorized users, you cannot access them from an unsecured page.

Programmatic details and scenarios

WebSphere Application Server maintains the security of individual sessions.

An identity or user name, readable by the com.ibm.websphere.servlet.session.IBMSession interface, is associated with a session. An unauthenticated identity is denoted by the user name `anonymous`. WebSphere Application Server includes the com.ibm.websphere.servlet.session.UnauthorizedSessionRequestException class, which is used when a session is requested without the necessary credentials.

The session management facility uses the WebSphere Application Server security infrastructure to determine the authenticated identity associated with a client HTTP request that either retrieves or creates a session. WebSphere Application Server security determines identity using certificates, LPTA, and other methods.

After obtaining the identity of the current request, the session management facility determines whether to return the session requested using a getSession call.

The following table lists possible scenarios in which security integration is enabled with outcomes dependent on whether the HTTP request is authenticated and whether a valid session ID and user name was passed to the session management facility.

	Unauthenticated HTTP request is used to retrieve a session	**HTTP request is authenticated, with an identity of ″FRED″ used to retrieve a session**
No session ID was passed in for this request, or the ID is for a session that is no longer valid	A new session is created. The user name is `anonymous`	A new session is created. The user name is `FRED`
A session ID for a valid session is passed in. The current session user name is ″anonymous″	The session is returned.	The session is returned. session management changes the user name to `FRED`
A session ID for a valid session is passed in. The current session user name is `FRED`	The session is not returned. An UnauthorizedSessionRequestException error is created*	The session is returned.
A session ID for a valid session is passed in. The current session user name is `BOB`	The session is not returned. An UnauthorizedSessionRequestException error is created*	The session is not returned. An UnauthorizedSessionRequestException error is created*

* A com.ibm.websphere.servlet.session.UnauthorizedSessionRequestException error is created to the servlet.

Session management support

WebSphere Application Server provides facilities, grouped under the heading *Session Management*, that support the javax.servlet.http.HttpSession interface described in the Servlet API specification.

In accordance with the Servlet 2.3 API specification, the session management facility supports session scoping by Web modules. Only servlets in the same Web module can access the data associated with a particular session. Multiple requests from the same browser, each specifying a unique Web application, result in multiple sessions with a shared session ID. You can invalidate any of the sessions that share a session ID without affecting the other sessions.

You can configure a session timeout for each Web application. A Web application timeout value of 0 (the default value) means that the invalidation timeout value from the Session Management facility is used.

When an HTTP client interacts with a servlet, the state information associated with a series of client requests is represented as an HTTP session and identified by a session ID. Session Management is responsible for managing HTTP sessions, providing storage for session data, allocating session IDs, and tracking the session ID associated with each client request through the use of cookies or URL rewriting techniques. Session Management can store session-related information in several ways:

- In application server memory (the default). This information cannot be shared with other application servers.
- In a database. This storage option is known as *database persistent sessions*.
- In another WebSphere Application Server instance. This storage option is known as *memory-to-memory sessions*.

The last two options are referred to as *distributed sessions*. Distributed sessions are essential for using HTTP sessions for failover facility. When an application server receives a request associated with a session ID that it currently does not have in memory, it can obtain the required session state by accessing the external store (database or memory-to-memory). If distributed session support is not enabled, an application server cannot access session information for HTTP requests that are sent to servers other than the one where the session was originally created. Session Management implements caching optimizations to minimize the overhead of accessing the external store, especially when consecutive requests are routed to the same application server.

Storing session states in an external store also provides a degree of fault tolerance. If an application server goes offline, the state of its current sessions is still available in the external store. This availability enables other application servers to continue processing subsequent client requests associated with that session.

Saving session states to an external location does not completely guarantee their preservation in case of a server failure. For example, if a server fails while it is modifying the state of a session, some information is lost and subsequent processing using that session can be affected. However, this situation represents a very small period of time when there is a risk of losing session information.

The drawback to saving session states in an external store is that accessing the session state in an external location can use valuable system resources. session management can improve system performance by caching the session data at the server level. Multiple consecutive requests that are directed to the same server can find the required state data in the cache, reducing the number of times that the actual session state is accessed in external store and consequently reducing the overhead associated with external location access.

Session tracking options

There are several options for session tracking, depending on what sort of tracking method you want to use:

- Session tracking with cookies
- Session tracking with URL rewriting
- Session tracking with Secure Sockets Layer (SSL) information

Session tracking with cookies: Tracking sessions with cookies is the default. No special programming is required to track sessions with cookies.

Session tracking with URL rewriting: An application that uses URL rewriting to track sessions must adhere to certain programming guidelines. The application developer needs to do the following:
- Program servlets to encode URLs
- Supply a servlet or JavaServer Pages (JSP) file as an entry point to the application

Using URL rewriting also requires that you enable URL rewriting in the session management facility.

Note: In certain cases, clients cannot accept cookies. Therefore, you cannot use cookies as a session tracking mechanism. Applications can use URL rewriting as a substitute.

Program session servlets to encode URLs

Depending on whether the servlet is returning URLs to the browser or redirecting them, include either the encodeURL method or the encodeRedirectURL method in the servlet code. Examples demonstrating what to replace in your current servlet code follow.

Rewrite URLs to return to the browser

Suppose you currently have this statement:

```
out.println("<a href=\"/store/catalog\">catalog<a>");
```

Change the servlet to call the encodeURL method before sending the URL to the output stream:

```
out.println("<a href=\"");
out.println(response.encodeURL ("/store/catalog"));
out.println("\">catalog</a>");
```

Rewrite URLs to redirect

Suppose you currently have the following statement:

```
response.sendRedirect ("http://myhost/store/catalog");
```

Change the servlet to call the encodeRedirectURL method before sending the URL to the output stream:

```
response.sendRedirect (response.encodeRedirectURL ("http://myhost/store/catalog"));
```

The encodeURL method and encodeRedirectURL method are part of the HttpServletResponse object. These calls check to see if URL rewriting is configured before encoding the URL. If it is not configured, the calls return the original URL.

If both cookies and URL rewriting are enabled and the response.encodeURL method or encodeRedirectURL method is called, the URL is encoded, even if the browser making the HTTP request processed the session cookie.

You can also configure session support to enable protocol switch rewriting. When this option is enabled, the product encodes the URL with the session ID for switching between HTTP and HTTPS protocols.

Supply a servlet or JSP file as an entry point

The entry point to an application, such as the initial screen presented, may not require the use of sessions. However, if the application in general requires session support (meaning some part of it, such as a servlet, requires session support), then after a session is created, all URLs are encoded to perpetuate the session ID for the servlet (or other application component) requiring the session support.

The following example shows how you can embed Java code within a JSP file:

```
<%
response.encodeURL ("/store/catalog");
%>
```

Session tracking with SSL information: No special programming is required to track sessions with Secure Sockets Layer (SSL) information.

To use SSL information, turn on **Enable SSL ID tracking** in the session management property page. Because the SSL session ID is negotiated between the Web browser and HTTP server, this ID cannot survive an HTTP server failure. However, the failure of an application server does not affect the SSL session ID if an external HTTP server is present between WebSphere Application Server and the browser.

SSL tracking is supported for the IBM HTTP Server and iPlanet Web servers only. You can control the lifetime of an SSL session ID by configuring options in the Web server. For example, in the IBM HTTP Server, set the configuration variable SSLV3TIMEOUT to provide an adequate lifetime for the SSL session ID. An interval that is too short can cause a premature termination of a session. Also, some Web browsers might have their own timers that affect the lifetime of the SSL session ID. These Web browsers may not leave the SSL session ID active long enough to serve as a useful mechanism for session tracking. The internal HTTP Server of WebSphere Application Server also supports SSL tracking.

When using the SSL session ID as the session tracking mechanism in a cloned environment, use either cookies or URL rewriting to maintain session affinity. The cookie or rewritten URL contains session affinity information that enables the Web server to properly route a session back to the same server for each request.

Session recovery support

For session recovery support, WebSphere Application Server provides distributed session support in the form of database sessions. Use session recovery support under the following conditions:

- When the user’s session data must be maintained across a server restart
- When the user’s session data is too valuable to lose through an unexpected server failure

All the attributes set in a session must implement java.io.Serializable if the session requires external storage. In general, consider making all objects held by a session serialized, even if immediate plans do not call for session recovery support. If the Web site grows, and session recovery support becomes necessary, the transition occurs transparently to the application if the sessions only hold serialized objects. If not, a switch to session recovery support requires coding changes to make the session contents serialized.

Distributed environment settings:

Use this page to specify a type for saving a session in a distributed environment.

To view this administrative console page, click **Servers** > **Application servers** > *server_name* > **Web container settings** > **Session management** > **Distributed environment settings**.

Distributed sessions:

Specifies the type of distributed environment to be used for saving sessions.

None
Specifies that the session management facility discards the session data when the server shuts down.

Database

Specifies that the session management facility stores session information in the data source specified by the data source connection settings. Click **Database** to change these data source settings.

Memory-to-memory replication

Specifies that the session management facility stores the session information in a data source in memory. The session information is copied to other session management facilities for failure recovery.

Clustered session support

A clustered environment supports load balancing, where the workload is distributed among the application servers that compose the cluster. In a cluster environment, the same Web application must exist on each of the servers that can access the session. You can accomplish this setup by installing an application onto a cluster definition. Each of the servers in the group can then access the Web application

In a clustered environment, the session management facility requires an affinity mechanism so that all requests for a particular session are directed to the same application server instance in the cluster. This requirement conforms to the Servlet 2.3 specification in that multiple requests for a session cannot coexist in multiple application servers. One such solution provided by IBM WebSphere Application Server is *session affinity* in a cluster; this solution is available as part of the WebSphere Application Server plug-ins for Web servers. It also provides for better performance because the sessions are cached in memory. In clustered environments other than WebSphere Application Server clusters, you must use an affinity mechanism (for example, IBM WebSphere Edge Server affinity).

If one of the servers in the cluster fails, it is possible for the request to reroute to another server in the cluster. If distributed sessions support is enabled, the new server can access session data from the database or another WebSphere Application Server instance. You can retrieve the session data only if a new server has access to an external location from which it can retrieve the session.

Tuning session management

WebSphere Application Server session support has features for tuning session performance and operating characteristics, particularly when sessions are configured in a distributed environment. These options support the administrator flexibility in determining the performance and failover characteristics for their environment.

The table summarizes the features, including whether they apply to sessions tracked in memory, in a database, with memory-to-memory replication, or all. Click a feature for details about the feature. Some features are easily manipulated using administrative settings; others require code or database changes.

Feature or option	Goal	Applies to sessions in memory, database, or memory-to-memory
Write frequency	Minimize database write operations.	Database and Memory-to-Memory
Session affinity	Access the session in the same application server instance.	All
Multirow schema	Fully utilize database capacities.	Database
Base in-memory session pool size	Fully utilize system capacity without overburdening system.	All
Write contents	Allow flexibility in determining what session data to write	Database and Memory-to-Memory
Scheduled invalidation	Minimize contention between session requests and invalidation of sessions by the Session Management facility. Minimize write operations to database for updates to last access time only.	Database and Memory-to-Memory

Feature or option	Goal	Applies to sessions in memory, database, or memory-to-memory
Tablespace and row size	Increase efficiency of write operations to database.	Database (DB2 only)

Base in-memory session pool size: The base in-memory session pool size number has different meanings, depending on session support configuration:

- With in-memory sessions, session access is optimized for up to this number of sessions.

General memory requirements for the hardware system, and the usage characteristics of the e-business site, determines the optimum value.

Note that increasing the base in-memory session pool size can necessitate increasing the heap sizes of the Java processes for the corresponding WebSphere Application Servers.

Overflow in non-distributed sessions

By default, the number of sessions maintained in memory is specified by base in-memory session pool size. If you do not wish to place a limit on the number of sessions maintained in memory and allow overflow, set overflow to *true*.

Allowing an unlimited amount of sessions can potentially exhaust system memory and even allow for system sabotage. Someone could write a malicious program that continually hits your site and creates sessions, but ignores any cookies or encoded URLs and never utilizes the same session from one HTTP request to the next.

When overflow is disallowed, the Session Management facility still returns a session with the HttpServletRequest getSession(true) method when the memory limit is reached, and this is an invalid session that is not saved.

With the WebSphere Application Server extension to HttpSession, com.ibm.websphere.servlet.session.IBMSession, an isOverflow method returns *true* if the session is such an invalid session. An application can check this status and react accordingly.

Tuning parameter settings:

Use this page to set tuning parameters for distributed sessions.

To view this administrative console page, click **Servers > Application servers >***server_name***> Web container settings > Session management >Distributed environment settings >Custom tuning parameters**.

Tuning level:

Specifies that the session management facility provides certain predefined settings that affect performance.

Select one of these predefined settings or customize a setting. To customize a setting, select one of the predefined settings that comes closest to the setting desired, click **Custom settings**, make your changes, and then click **OK**.

Very high (optimize for performance)

Write frequency	Time based
Write interval	300 seconds

Write contents	Only updated attributes
Schedule sessions cleanup	true
First time of day default	0
Second time of day default	2

High

Write frequency	Time based
Write interval	300 seconds
Write contents	All session attributes
Schedule sessions cleanup	false

Medium

Write frequency	End of servlet service
Write contents	Only updated attributes
Schedule sessions cleanup	false

Low (optimize for failover)

Write frequency	End of servlet service
Write contents	All session attributes
Schedule sessions cleanup	false

Custom settings

Write frequency default	Time based
Write interval default	10 seconds
Write contents default	All session attributes
Schedule sessions cleanup default	false

Tuning parameter custom settings:

Use this page to customize tuning parameters for distributed sessions.

To view this administrative console page, click **Servers** > **Application servers** > *server_name***Web container settings** > **Session management** > **Distributed environment settings** > **Custom tuning parameters** > **Custom settings**.

Write frequency:

Specifies when the session is written to the persistent store.

End of servlet service
A session writes to a database or another WebSphere Application Server instance after the servlet completes execution.

Manual update
A programmatic sync on the IBMSession object is required to write the session data to the database or another WebSphere Application Server instance.

Time based
Session data writes to the database or another WebSphere Application Server instance based on the specified Write interval value. Default: 10 seconds

Write contents:

Specifies whether updated attributes are only written to the external location or all of the session attributes are written to the external location, regardless of whether or not they changed. The external location can be either a database or another application server instance.

Only updated attributes	Only updated attributes are written to the persistent store.
All session attribute	All attributes are written to the persistent store.

Schedule sessions cleanup:

Specifies when to clean the invalid sessions from a database or another application server instance.

Specify distributed sessions cleanup schedule	Enables the scheduled invalidation process for cleaning up the invalidated HTTP sessions from the external location. Enable this option to reduce the number of updates to a database or another application server instance required to keep the HTTP sessions alive. When this option is not enabled, the invalidator process runs every few minutes to remove invalidated HTTP sessions. When this option is enabled, specify the two hours of a day for the process to clean up the invalidated sessions in the external location. Specify the times when there is the least activity in the application servers. An external location can be either a database or another application server instance.
First Time of Day (0 - 23)	Indicates the first hour during which the invalidated sessions are cleared from the external location. Specify this value as a positive integer between 0 and 23. This value is valid only when schedule invalidation is enabled.
Second Time of Day (0 - 23)	Indicates the second hour during which the invalidated sessions are cleared from the external location. Specify this value as a positive integer between 0 and 23. This value is valid only when schedule invalidation is enabled.

Best practices for using HTTP Sessions

- **Enable Security integration for securing HTTP sessions**

  HTTP sessions are identified by session IDs. A session ID is a pseudo-random number generated at the runtime. Session hijacking is a known attack HTTP sessions and can be prevented if all the requests going over the network are enforced to be over a secure connection (meaning, HTTPS). But not every configuration in a customer environment enforces this constraint because of the performance impact of SSL connections. Due to this relaxed mode, HTTP session is vulnerable to hijacking and because of this vulnerability, WebSphere Application Server has the option to tightly integrate HTTP sessions and WebSphere Application Server security. Enable security in WebSphere Application Server so that the sessions are protected in a manner that only users who created the sessions are allowed to access them.
- **Release HttpSession objects using `javax.servlet.http.HttpSession.invalidate()` when finished.**

  HttpSession objects live inside the Web container until:
  - The application explicitly and programmatically releases it using the javax.servlet.http.HttpSession.invalidate method; quite often, programmatic invalidation is part of an application logout function.
  - WebSphere Application Server destroys the allocated HttpSession when it expires (default = 1800 seconds or 30 minutes). The WebSphere Application Server can only maintain a certain number of HTTP sessions in memory based on session management settings. In case of distributed sessions,

when maximum cache limit is reached in memory, the session management facility removes the least recently used (LRU) one from cache to make room for a session.

.

- **Avoid trying to save and reuse the HttpSession object outside of each servlet or JSP file.**

  The HttpSession object is a function of the HttpRequest (you can get it only through the req.getSession method), and a copy of it is valid only for the life of the service method of the servlet or JSP file. You *cannot* cache the HttpSession object and refer to it outside the scope of a servlet or JSP file.
- **Implement the java.io.Serializable interface when developing new objects to be stored in the HTTP session.**

  This action allows the object to properly serialize when using distributed sessions. Without this extension, the object cannot serialize correctly and throws an error. An example of this follows:

  ```
  public class MyObject implements java.io.Serializable {...}
  ```

  Make sure all instance variable objects that are not marked transient are serializable.
- **The HTTPSession API does not dictate transactional behavior for sessions.**

  Distributed HTTPSession support does not guarantee transactional integrity of an attribute in a failover scenario or when session affinity is broken. Use transactional aware resources like enterprise Java beans to guarantee the transaction integrity required by your application.
- **Ensure the Java objects you add to a session are in the correct class path.**

  If you add Java objects to a session, place the class files for those objects in the correct class path (the application class path if utilizing sharing across Web modules in an enterprise application, or the Web module class path if using the Servlet 2.2-complaint session sharing) or in the directory containing other servlets used in WebSphere Application Server. In the case of session clustering, this action applies to every node in the cluster.

  Because the HttpSession object is shared among servlets that the user might access, consider adopting a site-wide naming convention to avoid conflicts.
- **Avoid storing large object graphs in the HttpSession object.**

  In most applications each servlet only requires a fraction of the total session data. However, by storing the data in the HttpSession object as one large object, an application forces WebSphere Application Server to process all of it each time.
- **Utilize Session Affinity to help achieve higher cache hits in the WebSphere Application Server.**

  WebSphere Application Server has functionality in the HTTP Server plug-in to help with session affinity. The plug-in reads the cookie data (or encoded URL) from the browser and helps direct the request to the appropriate application or clone based on the assigned session key. This functionality increases use of the in-memory cache and reduces hits to the database or another WebSphere Application Server instance
- **Maximize use of session affinity and avoid breaking affinity.**

  Using session affinity properly can enhance the performance of the WebSphere Application Server. Session affinity in the WebSphere Application Server environment is a way to maximize the in-memory cache of session objects and reduce the amount of reads to the database or another WebSphere Application Server instance. Session affinity works by caching the session objects in the server instance of the application with which a user is interacting. If the application is deployed in multiple servers of a server group, the application can direct the user to any one of the servers. If the users starts on server1 and then comes in on server2 a little later, the server must write all of the session information to the external location so that the server instance in which server2 is running can read the database. You can avoid this database read using session affinity. With session affinity, the user starts on server1 for the first request; then for every successive request, the user is directed back to server1. Server1 has to look only at the cache to get the session information; server1 never has to make a call to the session database to get the information.

  You can improve performance by not breaking session affinity. Some suggestions to help avoid breaking session affinity are:
  - Combine all Web applications into a single application server instance, if possible, and use modeling or cloning to provide failover support.

  - Create the session for the frame page, but do not create sessions for the pages within the frame when using multi-frame JSP files. (See discussion later in this topic.)
- **When using multi-framed pages, follow these guidelines:**
  - Create a session in only one frame or before accessing any frame sets. For example, assuming there is no session already associated with the browser and a user accesses a multi-framed JSP file, the browser issues concurrent requests for the JSP files. Because the requests are not part of any session, the JSP files end up creating multiple sessions and all of the cookies are sent back to the browser. The browser honors only the last cookie that arrives. Therefore, only the client can retrieve the session associated with the last cookie. Creating a session before accessing multi-framed pages that utilize JSP files is recommended.
  - By default, JSP files get a HTTPSession using `request.getSession(true)` method. So by default JSP files create a new session if none exists for the client. Each JSP page in the browser is requesting a new session, but only one session is used per browser instance. A developer can use `<% @ page session="false" %>` to turn off the automatic session creation from the JSP files that do not access the session. Then if the page needs access to the session information, the developer can use `<%HttpSession session = javax.servlet.http.HttpServletRequest.getSession(false); %>` to get the already existing session that was created by the original session creating JSP file. This action helps prevent breaking session affinity on the initial loading of the frame pages.
  - Update session data using only one frame. When using framesets, requests come into the HTTP server concurrently. Modifying session data within only one frame so that session changes are not overwritten by session changes in concurrent frameset is recommended.
  - Avoid using multi-framed JSP files where the frames point to different Web applications. This action results in losing the session created by another Web application because the JSESSIONID cookie from the first Web application gets overwritten by the JSESSIONID created by the second Web application.
- **Secure all of the pages (not just some) when applying security to servlets or JSP files that use sessions with security integration enabled, .**

  When it comes to security and sessions, it is all or nothing. It does not make sense to protect access to session state only part of the time. When security integration is enabled in the session management facility, all resources from which a session is created or accessed must be either secured or unsecured. You cannot mix secured and unsecured resources.

  The problem with securing only a couple of pages is that sessions created in secured pages are created under the identity of the authenticated user. Only the same user can access sessions in other secured pages. To protect these sessions from use by unauthorized users, you cannot access these sessions from an unsecured page. When a request from an unsecured page occurs, access is denied and an `UnauthorizedSessionRequestException` error is created. (`UnauthorizedSessionRequestException` is a runtime exception; it is logged for you.)
- **Use manual update and either the sync() method or time-based write in applications that read session data, and update infrequently.**

  With END_OF_SERVICE as write frequency, when an application uses sessions and anytime data is read from or written to that session, the LastAccess time field updates. If database sessions are used, a new write to the database is produced. This activity is a performance hit that you can avoid using the Manual Update option and having the record written back to the database only when data values update, not on every read or write of the record.

  To use manual update, turn it on in the session management service. (See the tables above for location information.) Additionally, the application code must use the `com.ibm.websphere.servlet.session.IBMSession` class instead of the generic HttpSession. Within the IBMSession object there is a sync method. This method tells the WebSphere Application Server to write the data in the session object to the database. This activity helps the developer to improve overall performance by having the session information persist only when necessary.

  Note: An alternative to using the manual updates is to utilize the timed updates to persist data at different time intervals. This action provides similar results as the manual update scheme.
- Implement the following suggestions to achieve high performance:

  - If your applications do not change the session data frequently, use Manual Update and the sync function (or timed interval update) to efficiently persist session information.
  - Keep the amount of data stored in the session as small as possible. With the ease of using sessions to hold data, sometimes too much data is stored in the session objects. Determine a proper balance of data storage and performance to effectively use sessions.
  - If using database sessions, use a dedicated database for the session database. Avoid using the application database. This helps to avoid contention for JDBC connections and allows for better database performance.
  - If using memory-to-memory sessions, employ partitioning (either group or single replica) as your clusters grow in size and scaling decreases.
  - Verify that you have the latest fix packs for the WebSphere Application Server.
- Utilize the following tools to help monitor session performance.
  - Run the com.ibm.servlet.personalization.sessiontracking.IBMTrackerDebug servlet. - To run this servlet, you must have the servlet invoker running in the Web application you want to run this from. Or, you can explicitly configure this servlet in the application you want to run.
  - Use the WebSphere Application Server Resource Analyzer which comes with WebSphere Application Server to monitor active sessions and statistics for the WebSphere Application Server environment.
  - Use database tracking tools such as ″Monitoring″ in DB2. (See the respective documentation for the database system used.)

Managing HTTP sessions: Resources for learning

Use the following links to find relevant supplemental information about HTTP sessions. The information resides on IBM and non-IBM Internet sites, whose sponsors control the technical accuracy of the information.

These links are provided for convenience. Often, the information is not specific to the WebSphere Application Server product, but is useful all or in part for understanding the product. When possible, links are provided to technical papers and Redbooks that supplement the broad coverage of the release documentation with in-depth examinations of particular product areas.

Modifying the default Web container configuration

The Web container is created initially with default properties values suitable for simple Web applications. However, these values might not be appropriate for more complex Web applications.

Your application is considered complex if it requires any of the following features:
- Virtual host
- Servlet caching
- Special client request loads
- Persistent HTTP session support
- Special HTTP transport settings

- Transaction class mappings

Make the following configuration changes if you have a complex application:

1. In the administrative console, click **Servers** > **Application servers** >*server_name*. Then under Web container settings, click on one of the following:
   a. **Web container**, if your Web application requires a virtual host, other than the default_host, or requires servlet caching.
   b. **Web container transport chains**, if you need to reconfigure your HTTP connections.
   c. **Session management**, if your application requires persistent HTTP session support.
2. If your application handles special client request loads, in the administrative console, click **Servers** > **Application servers** >*server_name*. Then under Additional Properties, click **Thread Pools** to modify your thread pool settings.
3. If your application requires global settings for internal servlets for WAR files packaged by third-party tools, iIn the administrative console, click **Servers** > **Application servers** >*server_name* > **Web container settings** > **Web container**. Then under Additional Properties, click **Custom Properties** and enter the appropriate custom property.

Web container

A Web container handles requests for servlets, JavaServer Pages (JSP) files, and other types of files that include server-side code. The Web container creates servlet instances, loads and unloads servlets, creates and manages request and response objects, and performs other servlet management tasks.

The Web server plug-ins, provided by the WebSphere Application Server, help supported Web servers pass servlet requests to Web containers.

Web container settings

Use this page to configure the Web container settings.

To view this administrative console page, click **Servers** > **Application servers** > *server_instance* > **Web container settings** > **Web container**.

Default virtual host:

Specifies a virtual host that enables a single host machine to resemble multiple host machines. Resources associated with one virtual host cannot share data with resources associated with another virtual host, even if the virtual hosts share the same physical machine.

Select a virtual host option:

default_host
The product provides a default virtual host with some common aliases, such as the machine IP address, short host name, and fully qualified host name. The alias comprises the first part of the path for accessing a resource such as a servlet. For example, it is `localhost:9080` in the request `http://localhost:9080/myServlet`.

admin_host
This is another name for the application server; also known as *server1* in the base installation. This process supports the use of the administrative console.

Enable servlet caching:

Specifies that if a servlet is invoked once and it generates output to be cached, a cache entry is created containing not only the output, but also side effects of the invocation. These side effects can include calls to other servlets or Java Server Pages (JSP) files, as well as metadata about the entry, including timeout and entry priority information.

Web module deployment settings

Use this page to configure an instance of Web module deployment.

To view this administrative console page, click **Applications** > **Enterprise Application** > *application_instance* > **Web modules** > *Web_module_instance*.

URI:

Specifies a URI that, when resolved relative to the application URL, specifies the location of the module archive contents on a file system. The URI must match the ModuleRef URI in the deployment descriptor of an application if the module was packaged as part of a deployed application or enterprise archive (EAR) file.

Alternate deployment descriptor:

Specifies the file name for an alternative deployment descriptor file to use instead of the original deployment descriptor file in the module JAR file.

This file is the *post-assembly* version of the deployment descriptor file. You can edit the original deployment descriptor file to resolve dependencies and security information. Specifying the use of the alternative deployment descriptor keeps the original deployment descriptor file intact.

The value of the *Alternate deployment descriptor* property must be the full path name of the deployment descriptor file, relative to the module root directory. By convention, the file is in the `ALT-INF` directory. If this property is not specified, the deployment descriptor file is read from the module JAR file.

Starting weight:

Specifies the order in which modules are started. Lower weighted modules are started before higher weighted modules.

Class loader mode:

Specifies whether the class loader should search in the parent class loader or in the application class loader first to load a class. The standard for JDK class loaders and WebSphere class loaders is Parent First. By specifying Parent Last, your application can override classes contained in the parent class loader, but this action can potentially result in ClassCastException or LinkageErrors if you have mixed use of overriden classes and non-overriden classes.

The options are Parent First and Parent Last. The default is to search in the parent class loader before searching in the application class loader to load a class.

Data type	String
Default	Parent First

Web container custom properties

Use this page to configure arbitrary name-value pairs of data, where the name is a property key and the value is a string value that you can use to set internal system configuration properties. Defining a new property enables you to configure a setting beyond that which is available in the administrative console.

To view this administrative console page, click **Servers > Application servers >***server_name* **> Web container settings > Web container > Custom properties**.

HTTP Transport custom properties can also be set at the Web container level. See HTTP transport custom properties for a description of these properties.

Name:

Specifies the name or key for the property.

Value:

Specifies the value that is paired with the specified name.

Data type	String

Description:

Specifies information about the name-value pair.

Data type	String

Global settings for internal servlets

Web application archive (WAR) files that are packaged using third-party tools cannot specify behavior for the services that are exposed by the Web container internal servlets. You can globally enable and disable internal servlets for all Web applications at the Web container level by creating name-value pairs such as:

Name	Value
fileServingEnabled	true
directoryBrowsingEnabled	true
serveServletsByClassnameEnabled	true

Settings that are defined in an assembly tool take precedence over the global settings that are set through the custom properties at the Web container level.

Web application deployment extensions continue to hold configuration information for the services that are provided by the internal servlets, and take precedence over the global settings that are set through the custom properties at the Web container level.

UTF-8 encoded URLs

The UTF-8 encoded URL feature, which provides UTF-8 encoded Uniform Resource Locators (URLs) to support the double-byte characters in URLs is enabled by default. You can prevent the Web container from explicitly decoding URLs in UTF-8 and have them use the ISO-8859 standard as per the current HTTP specification by using the following name-value pair:

Name	Value
DecodeUrlAsUTF8	false

Global configuration of servlet listeners

The servlet specification supports applications registering listeners for servlet-related events on an individual application basis through the `web.xml` descriptor. However, using the listeners custom property, a server can listen to servlet events across Web applications. To implement global listening, a listener is registered at the Web container level and is propagated to all of the installed and new Web applications. This global behavior of internal servlet listeners is controlled by the listeners custom property by using the following name-value pair format:

Name	Value
listeners	*listener_class*

The values for this property is a string specifying a comma separated list of listener classes. The listener supplied must implement standard listener classes from the Java Servlet API or IBM listener extension classes.

Binary Large Object (BLOB) data type for Oracle databases

The *UseOracleBLOB* custom property creates the HTTP session database table using the Binary Large Object (BLOB) data type for the medium column. This property increases performance of persistent sessions when Oracle databases are used. Due to an Oracle restriction, BLOB support requires use of the Oracle's oci database driver for more than 4000 bytes of data. You must also ensure that a new sessions table is created before the server is restarted by dropping your old sessions table or by changing the datasource definition to reference a database that does not contain a sessions table. To create a sessions table using the BLOB data type, use the following name-vaule pair:

Name	Value
UseOracleBLOB	true

Detecting Session Data Crossover

The *DebugSessionCrossover* custom property enables code to perform additional checks to verify that only the session associated with the request is accessed or referenced. Messages are logged if any discrepancies are detected. To enable session data crossover detection, use the following name-vaule pair:

Name	Value
DebugSessionCrossover	true

See article, ″Problems creating or using HTTP sessions″, for additional information.

Optimizing web services client to Web container communication

To improve performance, there is an optimized communication path between a Web services client application and a Web container that are located in the same application server process. Requests from the Web services client that are normally sent to the Web container using a network connection are delivered directly to the Web container using an optimized local path. The local path is available because the Web services client application and the Web container are running in the same process. This optimized communication path is disabled by default. Before enabling this property, make sure that wild cards are not specified for the Web container ports. Use specific ports for the web container when the optimized communication path is enabled. To enable the optimized communication path, use the following name-value pair:

Name	Value
enableInProcessConnections	true

See article, "Web services client to Web container optimized communication" on page 168, for additional information.

Transaction class mapping file entries

Following is the syntax for entries in a transaction class mapping file:

```
TransClassMap host:port uritemplate tclass
```

where:

host Is the value compared against the hostname of the HOST: header of the request. This value can be a wildcard '*'.

Note: A value of '*' for the host:port value is acceptable and is equivalent to '*:*'.

port Is the value compared against the port of the request. This value can be a wildcard '*'.

uritemplate
Is the value compared against the URI of the request. Any query string will not be used in the comparison. This value can be a wildcard '*', or end in a wildcard.

tclass Is the Workload Manager Transaction Class name that will be used in the creation of the enclave.

Examples:

```
TransClassMap www.ibm.com:80 /webap1/myservlet TCLASS1

TransClassMap www.ibm.com:* /webap1/myservlet TCLASS2

TransClassMap *:443 * TCLASS3

TransClassMap *:* /webap1/myservlet TCLASS4

TransClassMap www.ibm.com:* /webap2/* TCLASS5

TransClassMap * /myservlet TCLASS6

TransClassMap * * TCLASS6
```

Configuring session management by level

When you configure session management at the Web container level, all applications and the respective Web modules in the Web container normally inherit that configuration, setting up a basic default configuration for the applications and Web modules below it.

However, you can set up different configurations individually for specific applications and Web modules that vary from the Web container default. These different configurations override the default for these applications and Web modules only.

Note: When you overwrite the default session management settings on the application level, all the Web modules below that application inherit this new setting unless they too are set to overwrite these settings.

1. Open the Administrative console.
2. Select the level that this configuration applies to:
   - For the web container level:
     a. Click **Servers** > **Application Servers**.
     b. Select a server from the list of application servers.
     c. Under Additional Properties, click **Web Container**.
   - For the enterprise application level:
     a. Click **Applications** > **Applications**.
     b. Select an applications from the list of applications.
   - For the Web module level:
     a. Click **Applications** > **Enterprise Applications**.
     b. Select an applications from the list of applications.

   c. Under Related Items, click **Web Modules**.
   d. Select a Web module from the list of Web modules defined for this application.
3. Under **Additional Properties**, click **Session Management**.
4. Make whatever changes you need to manage sessions
5. If you are working on the Web module or application level and want these settings to override the inherited Session Management settings, under **General Properties**, select **Overwrite**.
6. Click **Apply** and **Save**.

Configuring session tracking

To configure session tracking, complete the following:

1. Go to the appropriate level of Session Management.
2. Specify which session tracking mechanism you want to pass the session ID between the browser and the servlet:
   - To track sessions with cookies, click **Enable Cookies**.

     To change the cookie settings, click **Modify**.
   - To track sessions with URL rewriting, click **Enable URL Rewriting**.

     If you want to enable protocol switch rewriting, click **Enable protocol switch rewriting.**
   - To track sessions with SSL information, click **Enable SSL ID tracking**.
3. Click **Apply**.
4. Click **Save**.
5. Define the session recovery characteristics.

Serializing access to session data

The Servlet API supports concurrent access to a session in a given server instance. WebSphere Application Server provides an option to prevent the concurrent access to a session in a given server instance so that concurrent modification of a session does not occur in a given server instance. This prevention is achieved by synchronizing the requests based on session. When this feature is turned on, a session is obtained for the request before invoking the servlet and requests are synchronized by locking the session for the servlet execution time. Note that synchronization is based on the memory copy of session. So this feature cannot serialize requests across servers based on session when session affinity fails.

Restriction: Use this feature only when concurrent modification of the same session data is possible and is not desirable by the application. This feature has overhead of serializing the requests based on a session.

Do the following to synchronize session access:

1. Select the level of Session Management on which you want to serialize session access.
2. Under Serialize Session access, click **Allow serial access**.
3. In the Maximum wait time box, type the amount of time, in milliseconds, a servlet waits on a session before continuing execution. The default is 120000 milliseconds or two minutes.
4. Select **Allow access on timeout** if you want the servlet to gain access to the session and continue normal execution even if the session is still locked by another servlet. If you do not select this box, the servlet execution will abort when the session request times out.
5. Click **Apply**.
6. Click **Save**.

Session management settings

Use this page to manage HTTP session support. This support includes specifying a session tracking mechanism, setting maximum in-memory session count, controlling overflow, and configuring session timeout.

To view this administrative console page, click **Servers** > **Application servers** > *server_name* > **Web container settings** > **Session management**.

Override session management:

Specifies whether or not these session management settings take precedence over those normally inherited from a higher level for the current application or web module.

By default, web modules inherit session management settings from the application level above it, and applications inherit session management settings from the Web container level above it.

Session tracking mechanism:

Specifies a mechanism for HTTP session management.

Mechanism	Function	Default
Enable SSL ID Tracking	Specifies that session tracking uses Secure Sockets Layer (SSL) information as a session ID. Enabling SSL tracking takes precedence over cookie-based session tracking and URL rewriting. There are two parameters available if you enable SSL ID tracking: SSLV3Timeout and Secure Authentication Service (SAS). SSLV3Timeout specifies the time interval after which SSL sessions are renegotiated. This is a high setting and modification does not provide any significant impact on performance. The SAS parameter establishes an SSL connection only if it goes out of the Java Virtual Machine (JVM) to another JVM. If all the beans are co-located within the same JVM, the SSL used by SAS does not hinder performance. These are set by editing the `sas.server.properties` and `sas.client.props` files located in the *product_installation_root*\properties directory, where *product_installation_root* is the directory where WebSphere Application Server is installed.	9600 seconds

Enable cookies

Specifies that session tracking uses cookies to carry session IDs. If cookies are enabled, session tracking recognizes session IDs that arrive as cookies and tries to use cookies for sending session IDs. If cookies are not enabled, session tracking uses Uniform Resource Identifier (URL) rewriting instead of cookies (if URL rewriting is enabled).

Enabling cookies takes precedence over URL rewriting. Do not disable cookies in the session management facility of the application server that is running the administrative application because this action causes the administrative application not to function after a restart of the server. As an alternative, run the administrative application in a separate process from your applications.

Click **Modify** to change these settings.

Enable URL rewriting

Specifies that the session management facility uses rewritten URLs to carry the session IDs. If URL rewriting is enabled, the session management facility recognizes session IDs that arrive in the URL if the encodeURL method is called in the servlet.

Enable protocol switch rewriting

Specifies that the session ID is added to a URL when the URL requires a switch from HTTP to HTTPS or from HTTPS to HTTP. If rewriting is enabled, the session ID is required to go between HTTP and HTTPS.

Maximum in-memory session count:

Specifies the maximum number of sessions to maintain in memory.

The meaning differs depending on whether you are using in-memory or distributed sessions. For in-memory sessions, this value specifies the number of sessions in the base session table. Use the Allow overflow property to specify whether to limit sessions to this number for the entire session management facility or to allow additional sessions to be stored in secondary tables. For distributed sessions, this value specifies the size of the memory cache for sessions. When the session cache has reached its maximum size and a new session is requested, the session management facility removes the least recently used session from the cache to make room for the new one.

Allow overflow:

Specifies that the number of sessions in memory can exceed the value specified by the Max in-memory session count property. This option is valid only in non-distributed sessions mode.

Session timeout:

Specifies how long a session can go unused before it is no longer valid. Specify either `Set timeout` or `No timeout`. Specify the value in minutes greater than or equal to two.

The value specified in a web module deployment descriptor file takes precedence over the administrative console settings. However, the value of this setting is used as a default when the session timeout is not specified in a web module deployment descriptor. Note that to preserve performance, the invalidation timer is not accurate to the second. When the write frequency is time based, ensure that this value is least twice as large as the write interval.

Security integration:

Specifies that when security integration is enabled, the session management facility associates the identity of users with their HTTP sessions

Serialize session access:

Specifies that concurrent session access in a given server is not allowed.

Maximum wait time
Specifies the maximum amount of time a servlet request waits on an HTTP session before continuing execution. This parameter is optional and expressed in seconds. The default is 120 seconds, or 2 minutes. Under normal conditions, a servlet request waiting for access to an HTTP session gets notified by the request that currently owns the given HTTP session when the request finishes.

Allow access on timeout
Specifies whether the servlet is executed normally or aborted in the event of a timeout. If this box is checked, the servlet executes normally. If this box is not checked, the servlet execution aborts and error logs are generated.

Cookie settings

Use this page to configure cookie settings for session management.

To view this administrative console page, click **Servers** > **Application servers** > *server_name* > **Web container settings** > **Session management** > **Enable cookies**.

Cookie name:

Specifies a unique name for the session management cookie. The servlet specification requires the name JSESSIONID. However, for flexibility this value can be configured.

Restrict cookies to HTTP sessions:

Specifies that the session cookies include the secure field. Enabling the feature restricts the exchange of cookies to HTTPS sessions only.

Cookie domain:

Specifies the domain field of a session tracking cookie. This value controls whether or not a browser sends a cookie to particular servers. For example, if you specify a particular domain, session cookies are sent to hosts in that domain. The default domain is the server.

Cookie path:

Specifies that a cookie is sent to the URL designated in the path. Specify any string representing a path on the server. ″/″ indicates root directory. Specify a value to restrict the paths to which the cookie will be sent. By restricting paths, you prevent the cookie from going to certain URLs on the server. If you specify the root directory, the cookie is sent no matter which path on the given server is accessed.

Cookie maximum age:

Specifies the amount of time that the cookie lives on the client browser. Specify that the cookie lives only as long as the current browser session, or to a maximum age. If you choose the maximum age option, specify the age in seconds. This value corresponds to the Time to Live (TTL) value described in the Cookie specification.

Default is the current browser session which is equivalent to setting the value to -1.

Session management custom properties

Custom properties for session management:

CloneSeparatorChange
Use this property to maintain session affinity. The clone ID of the server is appended to session identifier separated by colon. On some Wireless Application Protocol (WAP) devices, a colon is not allowed. Set this property to ″true″ to change clone separator to a plus sign (+).

HttpSessionCloneId
Use this property to change the clone ID of the cluster member. Within a cluster, this name must be unique to maintain session affinity. When set, this name overwrites the default name generated by WebSphere Application Server. Default clone ID length: 8 or 9.

HttpSessionIdLength
Use this property to configure the session identifier length. Do not use an extremely low value; using a low value results in reduced number of combinations possible, thereby increasing risk of guessing the session identifier. In a cluster, all cluster members should be configured with same ID length. Allowed range: 8 to 128. Default length: 23.

HttpSessionReaperPollInterval
Use this property to set a wake-up interval for the process that removes invalid sessions. Default is based on maximum inactive interval set in session management. Allowed value: integer.

NoAdditionalSessionInfo
Set this value to ″true″ to force removal of information that is not needed in session identifiers. In WebSphere Application Server base edition,a clone ID of -1 is never used; therefore, a clone ID is not included in base edition when this is set. Also, cache ID is not used with nonpersistent sessions; so the cache ID is not included with nonpersistent sessions when this value is set.

SessionIdentifierMaxLength
Use this value to set maximum length that a session identifier can grow. In a cluster, because of fail-over when a request goes to new cluster member, session management appends a new clone ID to the existing clone ID. In a large cluster, if for some reason servers are failing more often, then it is possible that the session identifier length can be more than expected reducing room for URL. So this property helps to find out the condition and take appropriate action to address servers fail-over. When this is specified, message is logged when specified maximum length is reached. Allowed value: integer.

SessionRewriteIdentifier
Use this property to change the key used with URL rewriting. Default key: jsessionid.

Configuring session tracking for Wireless Application Protocol (WAP) devices

Most Wireless Application Protocol (WAP) devices do not support cookies. The preferred way to track sessions for WAP devices is to use URL rewriting. However on most WAP devices, the maximum allowed URL length is 128 characters. With URL rewriting, a session indentifier is added to the URL itself, effectively decreasing the space available for the actual URL and the number of parameters that can be sent on a request.

To reduce the length of session identifier, you can configure key (jsessionid), session ID length and clone ID. To make these configuration changes, complete the following:

1. Open the Administrative console.
2. Click **Servers** > **Application Servers**.
3. Select a server from the list of application servers.
4. Under Additional Properties, click **Web Container**
5. Under Additional Properties, click **Custom Properties**.
6. Add the appropriate properties from the following list:
   - HttpSessionIdLength
   - SessionRewriteIdentifier
   - HttpSessionCloneId
   - CloneSeparatorChange
   - NoAdditionalSessionInfo
   - SessionIdentifierMaxLength
7. Click **Apply** and **Save**.

Configuring for database session persistence

To configure the session management facility for database session persistence, complete the following:

1. Create and configure a JDBC provider.
2. Create a data source pointing to an existing database, using the JDBC provider that you defined. **Resources > JDBC Providers >** *JDBC_provider* **> Data Sources > New**. The data source should be non-JTA, for example, non-XA enabled. Note the JNDI name of the data source.
3. Verify that the correct database is listed for the value of the **databaseName** property under **Data Sources >** *datasource_name* **> Custom Properties**. If necessary, contact your database administrator to verify the correct database name.
4. Go to the appropriate level of Session Management.
5. Click **Distributed Environment Settings**
6. Select and click **Database**.
7. Specify the Data Source JNDI name from step 2.
8. Specify the database user ID and password for accessing the database.
9. Retype the password for confirmation.
10. Configure a table space and page sizes for DB2 session databases.
11. Switch to a multirow schema.
12. Click **OK**.
13. If you want to change the tuning parameters, click **Custom Tuning Parameters** and select a setting or customize one.
14. Click **Apply**.
15. Click **Save**.

Switching to a multirow schema

By default, a single session maps to a single row in the database table used to hold sessions. With this setup, there are hard limits to the amount of user-defined, application-specific data that WebSphere Application Server can access.

1. Modify the Session Management facility properties to switch from single to multirow schema.
2. Manually drop the database table or delete all the rows in the database table that the product uses to maintain HttpSession objects.

   To drop the table:

   a. Determine which data source configuration Session Management is using.

b. In the data source configuration, look up the database name.
c. Use the database facilities to connect to the database.
d. Drop the SESSIONS table.

Configuring tablespace and page sizes for DB2 session databases

If you are using DB2 for session persistence, you can increase the page size to optimize performance for writing large amounts of data to the database. Page sizes of 8K, 16K, and 32K are supported.

To use a page size other than the default (4K), do the following:

1. If the SESSIONS table already exists, drop it from the DB2 database.
2. Create a new DB2 buffer pool and table space, specifying the same page size (8K, 16K or 32K) for both, and assign the new buffer pool to this table space.

   ```
   DB2 Connect to session
   DB2 CREATE BUFFERPOOL sessionBP SIZE 1000 PAGESIZE 8K
   DB2 Connect reset
   DB2 Connect to session
   DB2 CREATE TABLESPACE sessionTS PAGESIZE 8K MANAGED BY SYSTEM
       USING ('D:\DB2\NODE0000\SQL00005\sessionTS.0') BUFFERPOOL sessionBP
   DB2 Connect reset
   ```

   Refer to DB2 product documentation for details.
3. Configure the correct table space name and page size in the Session Management facility. Page size is referred to as *row size* on the Session Management page.)

When the product is restarted, the Session Management facility creates the new SESSIONS table in the specified tablespace based on the indicated page size.

Database settings

Use this page to specify the settings for database session support.

To view this administrative console page, click **Servers** > **Application servers** > *server_name* > **Web container settings** > **Session management** > **Distributed environment settings** > **Database**.

Datasource JNDI name:

Specifies the datasource description.

The JNDI name of the non-XA enabled data source from which session management obtains database connections. For example, if the JNDI name of the datasource is ″jdbc/sessions″, specify ″jdbc/sessions.″ The data source represents a pool of database connections and a configuration for that pool (such as the pool size). The data source must already exist as a configured resource in the environment.

User ID:

Specifies the user ID for database access.

Password:

Specifies the password for database access.

DB2 row size:

Specifies the table space page size configured for the sessions table, if using a DB2 database. Possible values are 4, 8, 16, and 32 kilobytes (KB). The default row size is 4KB.

The default row size is 4KB. In DB2, it can be updated to a larger value. This can help database performance in some environments. When this value is other than 4, you must specify table space name to use this property. For 4KB pages, the table space name is optional.

Table space name:

Specifies that table space to be used for the sessions table.

This value is required when the DB2 page size is other than 4KB.

Use multi row schema:

Specifies that each instance of application data be placed in a separate row in the database, allowing larger amounts of data to be stored for each session. This action can yield better performance in certain usage scenarios. If using multirow schema is not enabled, instances of application data can be placed in the same row.

Multirow schema considerations

WebSphere Application Server supports the use of a multirow schema option in which each piece of application specific data is stored in a separate row of the database. With this setup, the total amount of data you can place in a session is now bound only by the database capacities. The only practical limit that remains is the size of the session attribute object.

The multirow schema potentially has performance benefits in certain usage scenarios, such as when larger amounts of data are stored in the session but only small amounts are specifically accessed during a given servlet processing of an HTTP request. In such a scenario, avoiding unneeded Java object serialization is beneficial to performance.

Understand that switching between multirow and single row is not a trivial proposition.

In addition to allowing larger session records, using multirow schema can yield performance benefits. However, it requires a little work to switch from single-row to multirow schema, as shown in the instructions below.

Coding considerations and test environment

Consider configuring direct single-row usage to one database and multirow usage to another database while you verify which option suits your application needs. (Do this in code by switching the data source used; then monitor performance.)

Programming issue	Application scenario
Reasons to use single-row	• You can read or write all values with just one record read and write. • This takes up less space in a database because you are guaranteed that each session is only one record long.
Reasons **not** to use single-row	2-megabyte limit of stored data per session.
Reasons to use multirow	• The application can store an unlimited amount of data; that is, you are limited only by the size of the database and a 2-megabyte-per-record limit. • The application can read individual fields instead of the whole record. When large amounts of data are stored in the session but only small amounts are specifically accessed during servlet processing of an HTTP request, multirow sessions can improve performance by avoiding unneeded Java object serialization.

Programming issue	Application scenario
Reasons **not** to use multirow	If data is small in size, you probably do not want the extra overhead of multiple row reads when you can store everything in one row.

In the case of multirow usage, design your application data objects not to have references to each other, to prevent circular references. For example, suppose you are storing two objects A and B in the session using HttpSession.put(..) method, and A contains a reference to B. In the multirow case, because objects are stored in different rows of the database, when objects A and B are retrieved later, the object graph between A and B is different than stored. A and B behave as independent objects.

EJB applications

Task overview: Using enterprise beans in applications

1. Design a J2EE application and the enterprise beans that it needs. For links to design information that is specific to enterprise beans, see “Data access : Resources for learning” on page 1154 and “Messaging: Resources for learning” on page 1251.
2. Develop any enterprise beans that your application will use. See ″Developing enterprise beans″ in the information center.
3. Prepare for assembly. For your EJB 2.x-compliant entity beans, decide on an appropriate access intent policy.
4. Assemble the beans into one or more EJB modules using the assembly tool. See ″Assembling EJB modules″ in the information center for more information. This process includes setting security, see ″Securing enterprise bean applications″. For your EJB 2.x-compliant entity beans, you might also want to designate container-managed persistence (CMP) sequence groups. See ″Setting the run time for CMP sequence groups″ in the information center.
5. Assemble the modules into a J2EE application using the assembly tool. See ″Assembling applications″ in the information center.
6. For a given application server, update the EJB container configuration if needed for the application to be deployed, and determine if you want to batch commands or defer commands for container managed persistence. See ″Setting the run time for batched commands with JVM arguments″ and ″Setting the run time for deferred create with JVM arguments″ in the information center.
7. Deploy the application in an application server.
8. Test the modules.
   - As needed, debug problems with the container.
   - Debug access problems.
9. Assemble the production application using the assembly tools. See ″Assembling applications″ in the information center
10. Deploy the application to a production environment.
11. Manage the application:
    a. Manage installed EJB modules. After an application has been installed, you can manage its EJB modules individually through the Assembly Service Toolkit.
    b. Manage other aspects of the J2EE application.
12. Update the module and redeploy it using the assembly tools. See ″Assembling applications″ in the information center.
13. Tune the performance of the application. See ″Best practices for developing enterprise beans″ in the information center.

Enterprise beans

An enterprise bean is a Java component that can be combined with other resources to create J2EE applications. There are three types of enterprise beans, *entity* beans, *session* beans, and *message-driven* beans.

All beans reside in EJB containers, which provide an interface between the beans and the application server on which they reside.

Entity beans store permanent data, so they require connections to a form of persistent storage. This storage might be a database, an existing legacy application, a file, or another type of persistent storage.

Session beans typically contain the high-level and mid-level business logic for an application. Each method on a session bean typically performs a particular high-level operation. For example, submitting an order or transferring money between accounts. Session beans often invoke methods on entity beans in the course of their business logic.

Session beans can be either *stateful* or *stateless*. A stateful bean instance is intended for use by a single client during its lifetime, where the client performs a series of method calls that are related to each other in time for that client. One example is a ″shopping cart″ where the client adds items to the cart over the course of an online shopping session. In contrast, a stateless bean instance is typically used by many clients during its lifetime, so stateless beans are appropriate for business logic operations that can be completed in the span of a single method invocation. Stateful beans should be used only where absolutely necessary -- using stateless beans improves the ability to debug, maintain, and scale the application.

Message-driven beans enable asynchronous message servicing.

- The EJB container and a Java Message Service (JMS) provider work together to process messages. When a message arrives from another application component through JMS, the EJB container forwards it through an onMessage() call to a message-driven bean instance, which then processes the message. In other respects, message-driven beans are similar to stateless session beans.
- The EJB container and a Java Connector Architecture (JCA) resource adapter work together to process messages from an enterprise information system (EIS). When a message arrives from an EIS, the resource adapter receives the message and forwards it to a message-driven bean, which then processes the message. The message-driven bean is provided services such as transaction support by the EJB container in the same way that other enterprise beans are provided service.

Beans that require data access use *data sources*, which are administrative resources that define pools of connections to persistent storage mechanisms.

For more information about enterprise beans, see ″Resources for learning.″

EJB modules

An EJB module is used to assemble one or more enterprise beans into a single deployable unit. An EJB module is stored in a standard Java archive (JAR) file.

An EJB module contains the following:

- One or more deployable enterprise beans.
- A deployment descriptor, stored in an Extensible Markup Language (XML) file. This file declares the contents of the module, defines the structure and external dependencies of the beans in the module, and describes how the beans are to be used at run time.

You can deploy an EJB module as a stand alone application, or combine it with other EJB modules or with Web modules to create a J2EE application. An EJB module is installed and run in an enterprise bean container.

For more information about EJB modules, see ″Resources for learning.″

EJB containers

An Enterprise JavaBeans (EJB) container provides a run-time environment for enterprise beans within the application server. The container handles all aspects of an enterprise bean's operation within the application server and acts as an intermediary between the user-written business logic within the bean and the rest of the application server environment.

One or more EJB modules, each containing one or more enterprise beans, can be installed in a single container.

The EJB container provides many services to the enterprise bean, including the following:

- Beginning, committing, and rolling back transactions as necessary.
- Maintaining pools of enterprise bean instances ready for incoming requests and moving these instances between the inactive pools and an active state, ensuring that threading conditions within the bean are satisfied.
- Most importantly, automatically synchronizing data in an entity bean's instance variables with corresponding data items stored in persistent storage.

By dynamically maintaining a set of active bean instances and synchronizing bean state with persistent storage when beans are moved into and out of active state, the container makes it possible for an application to manage many more bean instances than could otherwise simultaneously be held in the application server's memory. In this respect, an EJB container provides services similar to virtual memory within an operating system.

Between transactions, the state of an entity bean can be cached. The EJB container supports option A, B, and C caching.

By default, an EJB container runs in the **quick start** mode. The EJB container startup logic delays the loading and processing of all EJB types *except* Message Driven Beans (because they must exist before messages are posted for them), Startup Beans (which must be processed at server startup time), and those EJB types that you specify to initialize at server start. For more information about disabling quick start for EJB types, see ″Changing enterprise bean types to initialize at application start time using the Application Server Toolkit″ in the information center.

All other EJB initialization is delayed until the first use of the EJB type. When using Local Interfaces, the first use is when you perform an *InitialContext.lookup()* method for the type. For Remote Interfaces, it is when you call the first method on an EJB or its Home.

For more information about EJB containers, see ″Resources for learning.″

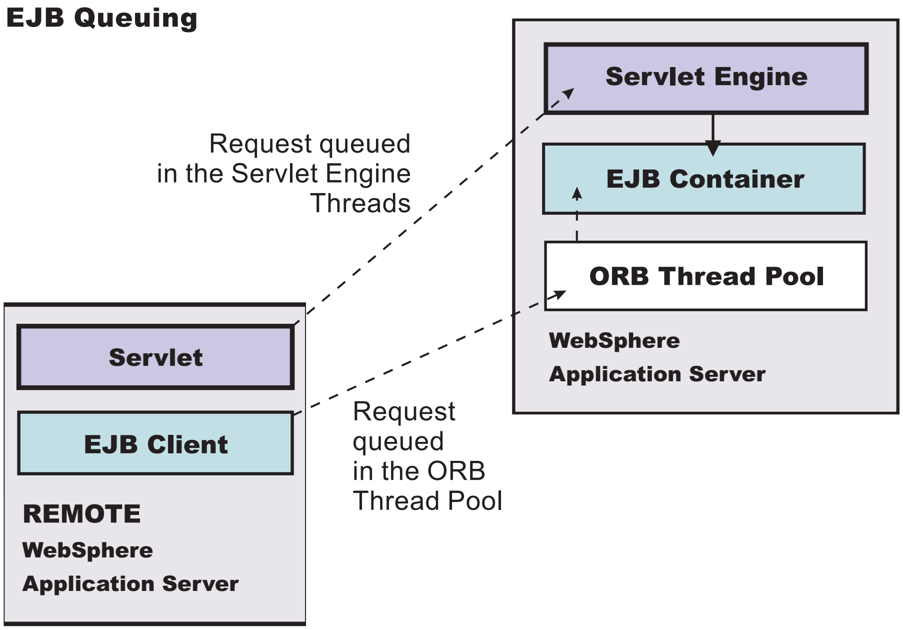
EJB method Invocation Queuing

Method invocations to enterprise beans are only queued for remote clients, making the method call. An example of a remote client is an enterprise Java bean (EJB) client running in a separate Java virtual machine (JVM) (another address space) from the enterprise bean. In contrast, no queuing occurs if the EJB client, either a servlet or another enterprise bean, is installed in the same JVM on which the EJB method runs and on the same thread of execution as the EJB client.

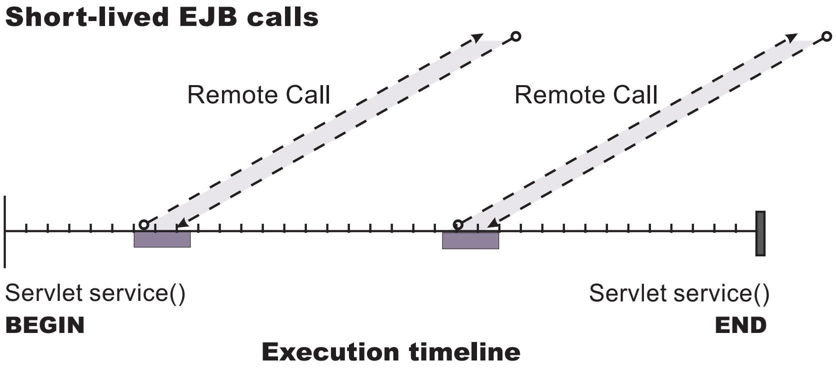
Remote enterprise beans communicate by using the Remote Method Invocation over Internet Inter-ORB Protocol (RMI-IIOP). Method invocations initiated over RMI-IIOP are processed by a server-side object request broker (ORB). The thread pool acts as a queue for incoming requests. However, if a remote method request is issued and there are no more available threads in the thread pool, a new thread is created. After the method request completes the thread is destroyed. Therefore, when the ORB is used to process remote method requests, the EJB container is an open queue, due to the use of unbounded threads. The following illustration depicts the two queuing options of enterprise beans.

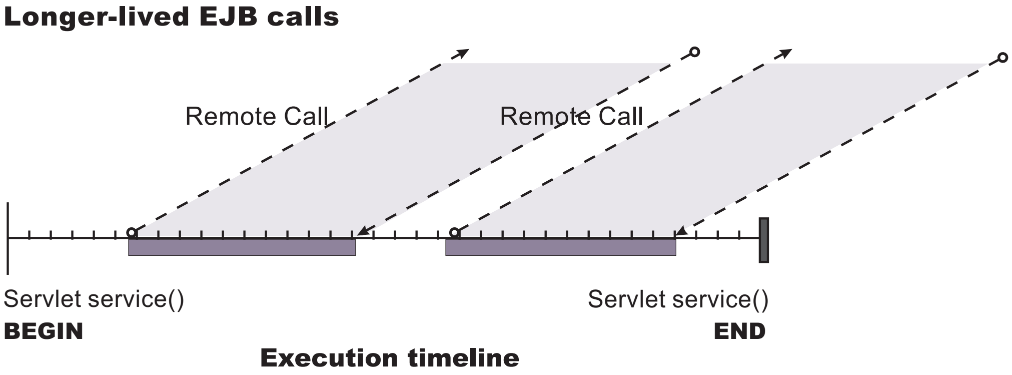


The following are two tips for queueing enterprise beans:

- **Analyze the calling patterns of the EJB client.**

  When configuring the thread pool, it is important to understand the calling patterns of the EJB client. If a servlet is making a small number of calls to remote enterprise beans and each method call is relatively quick, consider setting the number of threads in the ORB thread pool to a value lower than the Web container thread pool size value.





The degree to which the ORB thread pool value needs increasing is a function of the number of simultaneous servlets, that is, clients, calling enterprise beans and the duration of each method call. If the method calls are longer or the applications spend a lot of time in the ORB, consider making the ORB thread pool size equal to the Web container size. If the servlet makes only short-lived or quick calls to the ORB, servlets can potentially reuse the same ORB thread. In this case, the ORB thread pool can be small, perhaps even one-half of the thread pool size setting of the Web container.

- **Monitor the percentage of configured threads in use**.

  Tivoli Performance Viewer shows a metric called *percent maxed*, which is used to determine how often the configured threads are used. A value that is consistently in the double-digits, indicates a possible bottleneck a the ORB. Increase the number of threads.

See also ″Queuing network″ in the information center.

Using access intent policies

Apply access intent policies to methods of CMP entity beans.

Access intent policies

An access intent policy is a named set of properties (access intents) that governs data access for Enterprise JavaBeans (EJB) persistence. You can assign policies to an entity bean and to individual methods on an entity bean's home, remote, or local interfaces during assembly. You can set access intents only within EJB Version 2.x-compliant modules for entity beans with CMP Version 2.x.

This product supplies a number of access intent policies that specify permutations of read intent and concurrency control; the pessimistic/update policy can be qualified further. The selected policy determines the appropriate isolation level and locking strategy used by the run time environment.

Access intent policies are specifically designed to supplant the use of isolation level and access intent method-level modifiers found in the extended deployment descriptor for EJB version 1.1 enterprise beans. You cannot specify isolation level and read-only modifiers for EJB version 2.x enterprise beans.

Access intent policies configured on an entity basis define the default access intent for that entity. The default access intent controls the entity unless you specify a different access intent policy based on either method-level configuration or application profiling.

Note: Method level access intent has been deprecated for Version 6.

You can use application profiling or method level access intent policies to control access intent more precisely. Method-level access intent policies are named and defined at the module level. A module can have one or many such policies. Policies are assigned, and apply, to individual methods of the declared interfaces of entity beans and their associated home interfaces. A method-based policy is acted upon by the combination of the EJB container and persistence manager when the method causes the entity to load.

For entity beans that are backed by tables with nullable columns, use an optimistic policy with caution. Nullable columns are automatically excluded from overqualified updates at deployment time; concurrent changes to a nullable field might result in lost updates. When used with the IBM Rational Application Developer product, this product provides support for selecting a subset of the non-nullable columns that are to be reflected in the overqualified update statement that is generated in the deployment code to support optimistic policies.

Concurrency control:

Concurrency control is the management of contention for data resources. A concurrency control scheme is considered *pessimistic* when it locks a given resource early in the data-access transaction and does not release it until the transaction is closed. A concurrency control scheme is considered *optimistic* when locks are acquired and released over a very short period of time at the end of a transaction.

The objective of optimistic concurrency is to minimize the time over which a given resource would be unavailable for use by other transactions. This is especially important with long-running transactions, which under a pessimistic scheme would lock up a resource for unacceptably long periods of time.

Under an optimistic scheme, locks are obtained immediately before a read operation and released immediately afterwards. Update locks are obtained immediately before an update operation and held until the end of the transaction.

To enable optimistic concurrency, this product uses an *overqualified update scheme* to test whether the underlying data source has been updated by another transaction since the beginning of the current transaction. With this scheme, the columns marked for update and their original values are added explicitly through a WHERE clause in the UPDATE statement so that the statement fails if the underlying column values have been changed. As a result, this scheme can provide column-level concurrency control; pessimistic schemes can control concurrency at the row level only.

Optimistic schemes typically perform this type of test only at the end of a transaction. If the underlying columns have not been updated since the beginning of the transaction, pending updates to container-managed persistence fields are committed and the locks are released. If locks cannot be acquired or if some other transaction has updated the columns since the beginning of the current transaction, the transaction is rolled back: All work performed within the transaction is lost.

Pessimistic and optimistic concurrency schemes require different transaction isolation levels. Enterprise beans that participate in the same transaction and require different concurrency control schemes cannot operate on the same underlying data connection.

Whether or not to use optimistic concurrency depends on the type of transaction. Transactions with a high penalty for failure might be better managed with a pessimistic scheme. (A high-penalty transaction is one for which recovery would be risky or resource-intensive.) For low-penalty transactions, it is often worth the risk of failure to gain efficiency through the use of an optimistic scheme. In general, optimistic concurrency is more efficient when update collisions are expected to be infrequent; pessimistic concurrency is more efficient when update collisions are expected to occur often.

Read-ahead hints:

Read-ahead schemes enable applications to minimize the number of database round trips by retrieving a working set of container-managed persistence (CMP) beans for the transaction within one query. Read-ahead involves activating the requested CMP beans and caching the data for their related beans, which ensures that data is present for the beans that are most likely to be needed next by an application. A *read-ahead hint* is a representation of the related beans that are to be read. It is associated with the *findByPrimaryKey* method for the requested bean type, which must be an EJB 2.x-compliant CMP entity bean.

A read-ahead hint takes the form of a character string. You do not have to provide the string; the wizard generates it for you based on CMRs defined for the bean. The following example is provided as supplemental information only. Suppose a CMP bean type A has a finder method that returns instances of bean A. A read-ahead hint for this method is specified using the following notation: `RelB.RelC; RelD`

Interpret the preceding notation as follows:
- Bean type A has a CMR with bean types B and D.
- Bean type B has a CMR with bean type C.

For each bean of type A that is retrieved from the database, its directly-related B and D beans and its indirectly-related C beans are also retrieved. The order of the retrieved bean data columns in each row of the result set is the same as their order in the read-ahead hint: an A bean, a B bean (or null), a C bean (or null), a D bean (or null). For hints in which the same relationship is mentioned more than once (for example, `RelB.RelC;RelB.RelE`), a bean's data columns appear only once, at the position it first appears in the hint.

The tokens shown in the notation (*RelB* and so on) must be CMR field names for the relationships as defined in the deployment descriptor for the bean. In indirect relationships such as `RelB.RelC`, *RelC* is a CMR field name defined in the deployment descriptor for bean type B.

A single read-ahead hint cannot refer to the same bean type in more than one relationship. For example, if a Department bean has a relationship *employees* with the Employee bean and also has a relationship *manager* with the Employee bean, the read-ahead hint cannot specify both *employees* and *manager*.

For more information about how to set read-ahead hints, see the documentation for the Rational Application Developer product.

Some things to consider

When developing your read-ahead hints, you should keep the following in mind:

- Read ahead on long or complex paths can result in a query that is too complex to be useful. Read ahead on root or leaf inheritance mappings need particular care. You should add up the number of tables that are involved in the preload and then consider whether a join that complex is really a reasonable query on your target database.
- Read ahead does NOT work in the following cases:
  - preload paths across M:N relationships
  - preload paths across recursive enterprise bean relationships or recursive fk relationships
  - where multiple instances of the same table occur on the same path (whether through a recursive relationship or not).
  - when readAhead contains a table join. Different access intents can result in requiring a select for update statement. Check the matrix on the JDBC driver and select for update support to see if readAhead is enabled.

Configuring read-read consistency checking with the assembly tools

Read-read consistency checking only applies to LifeTimeInCache beans whose data is read from another transaction. For the Access Intents that are for *repeatable read* (RR), this means the product checks that the data is consistent with that in the data store, and ensures that no one updates it after the checking. For the Access Intents that are for *read committed* (RC), this means the product checks that the data is consistent at the point of checking, it does **not** guarantee that the data does not change after the checking. This makes the behavior of the LifeTimeInCache bean the same as non-LifeTimeInCache beans.

To perform this checking, you need to configure CMP entity beans with read-read consistency checking. You can do this using the Application Server Toolkit.

1. Start the Application Server Toolkit. See ″Starting an assembly tool″ in the information center
2. In the Project Explorer view of the J2EE perspective, right-click the **Deployment Descriptor: EJB Module Name** under the EJB module for the bean instance, then select **Open With > Deployment Descriptor Editor**. A property dialog notebook for the EJB project is displayed in the property pane.
3. Select the **Access** tab. The Add Access Intent window appears. There are two areas of the panel that deal with adding access intent:
   - Default Access Intent for Entities 2.x (Bean Level)
   - Access Intent for Entities 2.x (Method Level)
4. Select the Bean or Method level. Another access intent window appears where you can set the properties you wish to use.

5. Use the dropdown list to select the Access intent name.
6. **Optional:** Enter a description.
7. Check the **Persistence Option** box.
8. Check the **Verify Read Only Data** box.
9. Use the dropdown list to select your choice for read-read consistency checking. You have three options:

   NONE No read-read checking is done.

   AT_TRAN_BEGIN
   During ejbLoad, if the data is from cache, check the database to ensure that the data of the bean has not changed since the last load (with proper locking based on access intent's concurrency control attribute.)

   AT_TRAN_END
   At the end of transaction, if the bean is not changed and did not load by the current transaction, check the database to ensure that the data of the bean has not changed from last load (with proper locking based on access intent's concurrency control attribute.) If the data has changed, fail the transaction.
10. Select **Finish**.

Examples: read-read consistency checking:
Usage Scenario

Read-read consistency checking only applies to LifeTimeInCache beans whose data is read from another transaction. For the Access Intents that are for *repeatable read* (RR), this means the product checks that the data is consistent with that in the data store, and ensures that no one updates it after the checking. For the Access Intents that are for *read committed* (RC), this means the product checks that the data is consistent at the point of checking, it does **not** guarantee that the data does not change after the checking. This makes the behavior of the LifeTimeInCache bean the same as non-LifeTimeInCache beans.

You have three options for setting consistency checking, as shown in the following scenarios concerning the calculation of interest in ″Ann's″ bank account. In each case, the data store is shared by this EJB CMP application (to calculate the interest) and other applications, such as EJB BMP, JDBC, or legacy applications. Also in each case, the EJB Account is configured as a "long-lifetime" bean.

NONE

- The server is started.
- User1 in Transaction 1 calls Account.findByPrimaryKey(″10001″), account data for Ann is read from the database, with a balance of $100.
- Ann's record is cached by the persistence manager (PM) on the server.
- User 2 writes a JDBC call and changes the balance to $120.
- User3 in Transaction 2 calls Account.findByPrimaryKey() for account ″10001″, Ann's data is read from cache, with a balance of $100.
- Calculate Ann's interest, but the result might not be correct because of the data integrity issue.

Read-read checking AT_TRAN_BEGIN

- The server is started.
- User1 in Transaction 1 calls Account.findByPrimaryKey(″10001″), account data for Ann is read from the database, with a balance of $100.
- Ann's record is cached by the persistence manager (PM) on the server.
- User 2 writes a JDBC call and changes the balance to $120.
- User3 in Transaction 2 calls Account.findByPrimaryKey() for account ″10001″, Ann's data is read from cache, with a balance of $100.

- PM performs read-read check on Ann’s account and finds that the balance of 100 is changed. It issues a database query to retrieve balance of $120, and Ann‘s data in the cache is refreshed.
- Calculate Ann‘s interest, proceed with the transaction because data integrity is protected.

Read-read checking AT_TRAN_END

- The server is started.
- User1 in Transaction 1 calls Account.findByPrimaryKey(″10001″), account data for Ann is read from the database, with a balance of $100.
- Ann‘s record is cached by the persistence manager (PM) on the server.
- User 2 writes a JDBC call and changes the balance to $120.
- User 3 in Transaction 2 calls Account.findByPrimaryKey() for account ″10001″, Ann‘s data is read from database, with balance of $100.
- Calculate Ann‘s interest.
- During end of transaction 2, PM performs read-read check on Ann’s account and finds that the balance of 100 is changed.
- PM rolls back the transaction and invalidates the cache. The transaction fails and again data integrity is protected.

Access intent service

Access intent is a WebSphere Application Server run-time service that enables you to more precisely manage an application’s persistence. The access intent service defines a set of declarative annotations used by the Enterprise JavaBeans (EJB) container and its agents to make performance optimizations for entity bean access. These annotations are organized into sets called *access intent policies*.

Access intent policies contain a set of annotations considered as hints by the EJB container and its agents. Most access intent policies are hints representing high-level abstractions that can be mapped to a specific back end resource manager. It is the responsibility of the EJB persistence machinery to ensure the necessary concurrency control, connection, and cache management when carrying out the persistence details. The EJB persistence manager can use access intent hints to make better performance decisions when carrying out its assigned task. A smaller number of access intents are hints to the EJB container, influencing the management of EJB collections.

Although it is recommended that you always configure bean level access intent for your applications, if you find it necessary you can apply access intent policies to methods within the scope of an EJB module. In such cases the policy becomes the default access intent for all requests upon the configured methods.

You can also apply access intent policies to beans within the scope of application profiles. Consequently, you can configure beans with multiple and opposing access intent policies. The application profiling documentation explains in more detail how to configure an application to apply a particular access intent policy to a bean for one request, then apply another access intent policy to the same bean for a different request.

Access intent design considerations

Use the access intent service to solve clear performance problems. Identify usage patterns that lead to poor application performance and apply appropriate access intent policies.

Refrain from over-tuning an application. You can introduce errors by incorrectly using the access intent service. For example, misuse of the wsPessimisticUpdate-NoCollision policy can result in lost updates; inappropriately setting the collection increment value can introduce performance issues; and problem determination is more difficult when an application is confusingly configured with multiple access intent policies. Clarity and simplicity should be your guiding principles when using the access intent service. This is even more important when applying access intent polices within the scope of application profiles (a feature of WebSphere Business Integration Server Foundation).

Even though access intent policies can be configured on any method of an entity bean, some attributes of a policy can only be leveraged by the run-time environment under certain conditions. For example, concurrency and access intent are only used for CMP entity beans when the ejbLoad() method is driven to open a connection to, and read data from, a given resource; that data is cached and used to drive the proper queries during invocation of the ejbStore() method. Read-ahead hints are only used during the execution of a finder for a bean. Finally, the collection increment and resource manager prefetch increment are only used on multi-object finders. Configuring policies on methods that will not use the policy is not an error (only certain attributes of any policy are used, even when the policy is appropriately applied to a method). However, configuring policies unnecessarily throughout an application obscures the design of the application and complicates the maintenance of the application.

Applying access intent policies to methods

You apply an access intent policy to a method, or set of methods, in an application's entity beans through the assembly tools. See ″Assembling applications″ in the information center.

Note: Method level access intent is deprecated in Version 6.0.

1. Start the Application Server Toolkit. See ″Starting an assembly tool″ in the information center.
2. **Optional:** Open the J2EE perspective to work with J2EE projects. Click **Window > Open Perspective > Other > J2EE**.
3. **Optional:** Open the Project Explorer view. Click **Window > Show View > Project Explorer**. Another helpful view is the Navigator view (**Window > Show View > Navigator**).
4. Create a new application EAR file or edit an existing one.

   For example, to change attributes of an existing application, use the import wizard to import an EAR file. To start the import wizard:

   a. Select **File > Import > EAR file > Next**
   b. Select the EAR file.
   c. Create a WebSphere Application Server v6.0 type of Server Runtime. Select **New** to open the New Server Runtime Wizard and follow the instructions.
   d. In the *Target server* field, select *WebSphere Application Server v6.0* type of Server Runtime.
   e. Select **Finish**
5. In the Project Explorer view of the J2EE perspective, right-click the **Deployment Descriptor: EJB Module Name** under the EJB module for the bean instance, then select **Open With > Deployment Descriptor Editor**. A property dialog notebook for the EJB project is displayed in the property pane.
6. Select the **Access** tab.
7. On the right side of the **Access Intent for Entities 2.x (Method Level)** panel, select **Add**. The **Add Access Intent** panel displays.
8. Specify the **Name** for your new intent policy.
9. Select the **Access intent name** from the drop-down list.
10. Enter a **Description** to help you remember what this policy does.
11. **Optional:** Select **Read Ahead Hint**. A single access intent read ahead hint might not refer to the same bean type in more than one relationship. For example, if a **Department** enterprise bean has a relationship *employees* with the **Employee** enterprise bean, and also has a relationship *manager* with the **Employee** enterprise bean, then a read ahead hint cannot specify both *employees* and *manager*.
12. Click **Next**. The next **Add Access Intent** panel displays, with optional attributes.
13. **Optional:** Decide whether or not to overwrite these optional access intent attributes. Click on those you want to change.
14. Click **Next**. The next **Add Access Intent** panel, with a list of Enterprise Beans, displays.
15. Select one or more Enterprise Beans from the list.

Note: If you selected **Read Ahead Hint** in an earlier step, you can only select **ONE** bean at this step.

16. Click **Next**. The next **Add Access Intent** panel, with a list of methods, displays.
17. Select the methods you want to use.
18. If you *DID NOT* select **Read Ahead Hint** in an earlier step, click **Finish**. If you *DID* select the Read Ahead Hint option, you can click **Next** to specify your Read Ahead Hint for the specified bean. The next **Add Access Intent** panel, with a list of EJB preload paths, displays.
19. Edit the EJB preload path by selecting relationship roles from the **Relationship roles:** window.
20. Click **Finish**. A new entry is created in the **Access Intent for Entities 2.x (Method Level)** panel

Access intent exceptions

The following exceptions are thrown in response to the application of access intent policies:

com.ibm.ws.ejbpersistence.utilpm.PersistenceManagerException

If the method that drives the ejbLoad() method is configured to be read-only but updates are then made within the transaction that loaded the bean's state, an exception is thrown during invocation of the ejbStore() method, and the transaction is rolled back. Likewise, the ejbRemove() method cannot succeed in a transaction that is set as read-only. If an update hint is applied to methods of entity beans with bean-managed persistence, the same behavior and exception results. The forwarded exception object contains the message string `PMGR1103E: update instance level read only bean` *`beanName`*

This exception is also thrown if the applied access intent policy cannot be honored because a finder, ejbSelect, or container-managed relationship (CMR) accessor method returns an inherently read-only result. The forwarded exception object contains the message string `PMGR1001: No such DataAccessSpec -` *`methodName`*

The most common occurrence of this error is when a custom finder that contains a read-only EJB Query Language (EJB QL) statement is called with an applied access intent of `wsPessimisticUpdate` or `wsPessimisticUpdate-Exclusive`. These policies require the use of a USE AND KEEP UPDATE LOCKS clause on the SQL SELECT statement to be executed, but a read-only query cannot support USE AND KEEP UPDATE LOCKS. Other examples of read-only queries include joins; the use of ORDER BY, GROUP BY, and DISTINCT keywords.

To eliminate the exception, edit the EJB query so that it does not return an inherently read-only result or change the access intent policy being applied.

- If an update access is required, change the applied access intent setting to `wsPessimisticUpdate-WeakestLockAtLoad` or `wsOptimisticUpdate`.
- If update access is not truly required, use `wsPessimisticRead` or `wsOptimisticRead`.
- If connection sharing between entity beans is required, use `wsPessimisticUpdate-WeakestLockAtLoad` or `wsPessimisticRead`.

com.ibm.websphere.ejb.container.CollectionCannotBeFurtherAccessed

If a lazy collection is driven after it is no longer in scope, and beyond what has already been locally buffered, a CollectionCannotBeFurtherAccessed exception is thrown.

com.ibm.ws.exception.RuntimeWarning

If an application is configured incorrectly, a run-time warning exception is thrown as the application starts; startup is ended. You can validate an application's configuration by choosing the verify function. Some examples of misconfiguration include:

- A method configured with two different access intent policies
- A method configured with an undefined access intent policy

Access intent assembly settings

Access intent policies contain data-access settings for use by the persistence manager. Default access intent policies are configured on the entity bean.

These settings are applicable only for EJB 2.x-compliant entity beans that are packaged in EJB 2.x-compliant modules. Connection sharing between beans with bean-managed persistence and those with container-managed persistence is possible if they all use the same access intent policy.

Name:

Specifies a name for a mapping between an access intent policy and one or more methods.

Description:

Contains text that describes the mapping.

Methods - Name:

Specifies the name of an enterprise bean method, or the asterisk character (*). The asterisk is used to denote all of the methods of an enterprise bean's remote and home interfaces.

Methods - Enterprise bean:

Specifies which enterprise bean contains the methods indicated in the Name setting.

Methods - Type:

Used to distinguish between a method with the same signature that is defined in both the home and remote interface. Use `Unspecified` if an access intent policy applies to all methods of the bean.

Data type	String
Range	Valid values are `Home`, `Remote`,`Local`, `LocalHome` or `Unspecified`

Methods - Parameters:

Contains a list of fully qualified Java type names of the method parameters. This setting is used to identify a single method among multiple methods with an overloaded method name.

Applied access intent:

Specifies how the container must manage data access for persistence. Configurable both as a default access intent for an entity and as part of a method-level access intent policy.

Data type	String
Range	Valid settings are `wsPessimisticUpdate`, `wsPessimisticUpdate-NoCollision`, `wsPessimisticUpdate-Exclusive`, `wsPessimisticUpdate-WeakestLockAtLoad`, `wsPessimisticRead`, `wsOptimisticUpdate`, or `wsOptimisticRead`. Only `wsPessimisticRead` and `wsOptimisticRead` are valid when class-level caching is enabled in the EJB container.

This product supports lazy collections. For each segment of a collection, iterating through the collection (*next()*) does not trigger a remote method call to retrieve the next remote reference. Two policies (`wsPessimisticUpdate` and `wsPessimisticUpdate-Exclusive`) are extremely lazy; the collection increment size is set to 1 to avoid overlocking the application. The other policies have a collection increment size of 25.

Additional information about valid settings follows:

Profile name	Concurrency control	Access type	Transaction isolation
wsPessimisticRead (Note 1)	pessimistic	read	For Oracle, read committed. Otherwise, repeatable read
wsPessimisticUpdate (Note 2)	pessimistic	update	For Oracle, read committed. Otherwise, repeatable read
wsPessimisticUpdate-Exclusive (Note 3)	pessimistic	update	serializable
wsPessimisticUpdate-NoCollision (Note 4)	pessimistic	update	read committed
wsPessimisticUpdate-WeakestLockAtLoad (Note 5)	pessimistic	update	Repeatable read
wsOptimisticRead	optimistic	read	read committed
wsOptimisticUpdate (Note 6)	optimistic	update	read committed

Notes:
1. Read locks are held for the duration of the transaction.
2. The generated SELECT FOR UPDATE query grabs locks at the beginning of the transaction.
3. SELECT FOR UPDATE is generated; locks are held for the duration of the transaction.
4. Generated overqualified-update query forces failure if CMP column values have changed since the beginning of the transaction.

Access intent best practices

This topic outlines issues to consider when applying access intent policies to Enterprise JavaBeans (EJB) methods.

- **Take care when applying `wsPessimisticUpdate-NoCollision`.** This policy does not ensure data integrity. No database locks are held, so concurrent transactions can overwrite each other's updates. Use this policy only if you can be sure that only one transaction will attempt to update persistent store at any given time.

Frequently asked questions: Access intent

I have not applied any access intent policies at all. My application runs just fine with a DB2 database, but it fails with an Oracle database with the following message: *com.ibm.ws.ejbpersistence.utilpm.PersistenceManagerException: PMGR1001E: No such DataAccessSpec :FindAllCustomers. The backend datastore does not support the SQLStatement needed by this AccessIntent: (pessimistic update-weakestLockAtLoad)(collections: transaction/25) (resource manager prefetch: 0) (AccessIntentImpl@d23690a)*. Why?

If you have not configured access intent, all of your data is accessed under the default access intent policy (`wsPessimisticUpdate-WeakestLockAtLoad`). On DB2 databases, the weakest lock is a shared one, and the query runs without a USE AND KEEP UPDATE LOCKS clause. On Oracle databases, however, the weakest lock is an update lock; this means that the SQL query must contain a USE AND KEEP UPDATE LOCKS clause. However, not every SQL statement necessarily supports USE AND KEEP UPDATE LOCKS; for example, if the query is being run against multiple tables in a join, USE AND KEEP UPDATE LOCKS is not supported. To avoid this problem, try either of the following:

- Modify your SQL query or reconfigure your application so that an update lock is supported
- Apply an access intent policy that supports optimistic concurrency

I am calling a finder method and I get an InconsistentAccessIntentException at run time. Why?

This can occur when you use method-level access intent policies to apply more control over how a bean instance is loaded. This exception indicates that the entity bean was previously loaded in the same transaction. This could happen if you called a multifinder method that returned the bean instance with access intent policy X applied; you are now trying to load the second bean again by calling its findByPrimaryKey method with access intent Y applied. Both methods must have the same access intent policy applied.

Likewise, if the entity was loaded once in the transaction using an access intent policy configured on a finder, you might have called a container-managed relationship (CMR) accessor method that returned the entity bean configured to load using that entity's default access intent.

To avoid this problem, ensure that your code does not load the same bean instance twice within the same transaction with different access intent policies applied. Avoid the use of method-level access intent unless absolutely necessary.

I have two beans in a container-managed relationship. I call findByPrimaryKey() on the first bean and then call getBean2( ), a CMR accessor method, on the returned instance. At that point, I get an InconsistentAccessIntentException. Why?

You are probably using read-ahead. When you loaded the first bean, you caused the second bean to be loaded under the access intent policy applied to the finder method for the first bean. However, you have configured your CMR accessor method from the first bean to the second with a different access intent policy. CMR accessor methods are really finder methods in disguise; the run-time environment behaves as if you were trying to change the access intent for an instance you have already read from persistent store.

To avoid this problem, beans configured in a read-ahead hint are all driven to load with the same access intent policy as the bean to which the read-ahead hint is applied.

I have a bean with a one-to-many relationship to a second bean. The first bean has a pessimistic-update intent policy applied. When I try to add an instance of the second bean to the first bean's collection, I get an UpdateCannotProceedWithIntegrityException. Why?

The second bean probably has a read intent policy applied. When you add the second bean to the first bean's collection, you are not updating the first bean's state, you are implicitly modifying the second bean's state. (The second bean contains a foreign key to the first bean, which is modified.)

To avoid this problem, ensure that both ends of the relationship have an update intent policy applied if you expect to change the relationship at run time.

Managing EJB containers

Each application server can have a single EJB container; one is created automatically for you when the application server is created. The following steps are to be performed only as needed to improve performance after the EJB application has been deployed.

1. Adjust EJB container settings.
2. Adjust EJB cache settings.

If adjustments do not improve performance, consider adjusting access intent policies for entity beans, reassembling the module, and redeploying the module in the application.

EJB container settings

Use this page to configure and manage the EJB container of this application server.

To view this administrative console page, click **Servers > Application Servers >** *serverName* **> EJB Container Settings** > **EJB container**.

Passivation directory:

Specifies the directory into which the container saves the persistent state of passivated stateful session beans.

Stateful session beans with an activation policy of TRANSACTION are passivated at the end of the transaction in which they are enlisted, and stateful session beans with an activation policy of ONCE (default) are passivated when the number of active bean instances becomes greater than the cache size specified in the container configuration. When a stateful bean is passivated, the container serializes the bean instance to a file in the passivation directory and discards the instance from the bean cache. If, at a later time, a request arrives for the passivated bean instance, the container retrieves it from the passivation directory, deserializes it, returns it to the cache, and dispatches the request to it. If any step fails (for example, if the bean instance is no longer in the passivation directory), the method invocation fails.

Inactive pool cleanup interval:

Specifies the interval at which the container examines the pools of available bean instances to determine if some instances can be deleted to reduce memory usage.

Data type	Integer
Units	Milliseconds
Range	0 to 2 147 483 674

Default datasource JNDI name:

Specifies the JNDI name of a data source to use if no data source is specified during application deployment. This setting is not applicable for EJB 2.x-compliant CMP beans.

Servlets and enterprise beans use *data sources* to obtain these connections. When configuring a container, you can specify a default data source for the container. This data source becomes the default data source used by any entity beans installed in the container that use container-managed persistence (CMP).

The default data source for a container is secure. When specifying it, you must provide a user ID and password for accessing the data source.

Specifying a default data source is optional if each CMP entity bean in the container has a data source specified in its configuration. If a default data source is not specified and a CMP entity bean is installed in the container without specifying a data source for that bean, applications cannot use that CMP entity bean.

Enable stateful session bean failover using memory-to-memory replication:

Specifies that failover is enabled for *all* stateful session beans installed in this EJB container.

This checkbox is disabled until you define a replication domain. This selection has a hyperlink to help you configure the replication settings. If no replication domains are configured, the link takes you to a panel where you can create one. If at least one domain is configured, the link takes you to a panel where you can select the replication settings to be used by the EJB container.

Data type	Checkbox
Default	Unselected
Range	Selected or unselected.

Initial state:

Specifies the execution state requested when the server first starts.

Data type	String
Default	Started
Range	Valid values are `Started` and `Stopped`

EJB container system properties

In addition to the settings accessible from the administrative console, you can set the following system property by command-line scripting:

com.ibm.websphere.ejbcontainer.poolSize

Specifies the size of the pool for the specified bean type. This property applies to stateless, message-driven and entity beans. If you do not specify a default value, the container defaults of 50 and 500 are used.

Set the pool size for a given entity bean as follows:

```
beantype=min,max[:beantype=min,max...]
```

beantype is the J2EE name of the bean, formed by concatenating the application name, the **#** character, the module name, the **#** character, and the name of the bean (that is, the string assigned to the `<ejb-name>` field in the bean's deployment descriptor). *min* and *max* are the minimum and maximum pool sizes, respectively, for that bean type. Do not specify the square brackets shown in the previous prototype; they denote optional additional bean types that you can specify after the first. Each bean-type specification is delimited by a colon (:).

Use an asterisk (*) as the value of *beantype* to indicate that all bean types are to use those values unless overridden by an exact bean-type specification somewhere else in the string, as follows:

```
*=30,100
```

To specify that a default value be used, omit either *min* or *max* but retain the comma (,) between the two values, as follows (split for publication):

```
SMApp#PerfModule#TunerBean=54,
   :SMApp#SMModule#TypeBean=100,200
```

You can specify the bean types in any order within the string.

com.ibm.websphere.ejbcontainer.allowEarlyInsert

Note: This property is applicable to CMP 1.1 beans only.

By default, the EJB Container creates the entity bean representation in the database only after the method ejbPostCreate(...) is called. However, some applications may rely on method ejbCreate(...) to have created the entity bean in the database. For such a requirement, setting the JVM property *com.ibm.websphere.ejbcontainer.allowEarlyInsert* to **true** overrides the default behavior.

Changing enterprise bean types to initialize at application start time using the Application Server Toolkit

By default, the WebSphere Application Server's Enterprise JavaBeans (EJB) Container delays the initialization (loading and processing) of most EJB types until they are needed during runtime. This helps to speed up the application start time.

EJB types can, however, be forced to initialize at application start time by setting a flag within the bean's deployment descriptor. If this flag is set to **true** then the bean is initialized at application start time.

1. Start the Application Server Toolkit. See ″Starting an assembly tool″ in the information center.
2. Select **EJB Deployment Descriptor**.
3. In the property pane, select the **WebSphere Extensions** tab.
4. Check the box labeled **Start EJB at Application Start**.
5. Select **OK**.

Changing enterprise bean types to initialize at application start time using the administrative console

By default, the WebSphere Application Server's Enterprise JavaBeans (EJB) Container delays the initialization (loading and processing) of most EJB types until they are needed during runtime. This helps to speed up the application start time.

All EJB types within a server can, however, be forced to initialize at application start time by setting a system property within the administrative console. If the value of this property is set to **true** then all beans within the server are initialized at each application's start time.

1. Open the administrative console.
2. Select **Servers**.
3. Select **Application Servers**.
4. Select the server you want to configure.
5. In the Server Infrastructure area, select **Java and Process Management**.
6. In the Server Infrastructure area, select **Process Definition**.
7. In the Additional Properties area, select **Java Virtual Machine**.
8. In the Additional Properties area, select **Custom Properties**.
9. Select the **New** box.
10. In the **Name** entry field, type *com.ibm.websphere.ejbcontainer.initializeEJBsAtStartup*.
11. In the **Value** entry field, type *true*. Entering *true* causes all Enterprise JavaBeans to initialize when your application starts. Entering *false* causes initialization of all beans to be delayed.

    Note: Setting com.ibm.websphere.ejbcontainer.initializeEJBsAtStartup to either true or false takes precedence over any *Start EJB at Application Start* settings made on individual EJB types (see "Changing enterprise bean types to initialize at application start time using the Application Server Toolkit" on page 833).
12. Select **OK**.

EJB cache settings

Use this page to configure and manage the cache for a specific EJB container. To determine the cache absolute limit, multiply the number of enterprise beans active in any given transaction by the total number of concurrent transactions expected. Then, add the number of active session bean instances. You can use the Tivoli Performance Viewer to view bean performance information.

To view this administrative console page, click **Servers > Application Servers >** *serverName* **> EJB Container Settings > EJB cache settings**.

Cleanup interval:

Specifies the interval at which the container attempts to remove unused items from the cache in order to reduce the total number of items to the value of the cache size.

The cache manager tries to maintain some unallocated entries that can be allocated quickly as needed. A background thread attempts to free some entries while maintaining some unallocated entries. If the thread runs while the application server is idle, when the application server needs to allocate new cache entries, it does not pay the performance cost of removing entries from the cache. In general, increase this parameter as the cache size increases.

Data type	Integer
Units	Milliseconds
Range	0 to 2 147 483 674
Default	3000

Cache size:

Specifies the number of buckets in the active instance list within the EJB container.

A bucket can contain more than one active enterprise bean instance, but performance is maximized if each bucket in the table has a minimum number of instances assigned to it. When the number of active instances within the container exceeds the number of buckets, that is, the cache size, the container periodically attempts to reduce the number of active instances in the table by passivating some of the active instances. For the best balance of performance and memory, set this value to the maximum number of active instances expected during a typical workload.

Data type	Integer
Units	Buckets in the hash table
Range	Greater than 0. The container selects the next largest prime number equal to or greater than the specified value.
Default	2053

Container interoperability

Container interoperability describes the ability of WebSphere Application Server clients and servers at different versions to successfully negotiate differences in native Enterprise JavaBeans (EJB) finder methods support and Java 2 Platform, Enterprise Edition (J2EE) compliance.

The product uses interoperable versions of some class types to enable interoperability. However, older 4.0.x client and application server versions do not support the interoperability classes, which makes them uninteroperable with versions that use the classes. The system property *com.ibm.websphere.container.portable* remedies this situation by enabling newer versions of the application server to turn off the interoperability classes. This lets a more recent application server return class types that are interoperable with an older client.

Depending on the value of com.ibm.websphere.container.portable, application servers at versions 5 and later, and 4.0.3 and later, return different classes for the following:

- Enumerations and collections returned by EJB 1.1 finder methods
- EJBMetaData
- Handles to:
  - Entity beans
  - Session beans
  - Home interfaces

If the property is set to `false`, application servers return the old class types, to enable interoperability with 4.0.2 and earlier. If the property is set to `true`, application servers return the new classes.

The following tables show interoperability characteristics for various version combinations of application servers and clients as well as default property values for each combination.

Interoperability of Version 4.0.x client with Version 5 (and later) application server

Ideally, all 4.0.x clients that use Version 5 or later application servers should be at Version 4.0.3 or later.

Version 5 and later application servers return the interoperability class types by default (`true`). This can cause interoperability problems for distributed clients at versions 4.0.1 or 4.0.2. In particular, problems can occur with collections and enumerations returned by Enterprise JavaBeans Version 1.1 finder methods.

Although it is strongly discouraged, you can set com.ibm.websphere.container.portable to `false` on a Version 5 and later application server. This causes the application server to return the old class types, providing interoperability with clients at Version 4.0.2 and earlier. This is discouraged because:

- The Version 5 application server instance would become non-J2EE 1.3 (and later) compliant with regard to handles, home interface handles, and EJBMetaData.
- EJB 1.x finder methods return collection and enumeration objects that do not originate from ejbportable.jar.
- Interoperability restrictions still exist with the property set to `false`.
- Version 5 and later client handles to entity beans and home interfaces do not work across domains for the server you set to `false`.

  If you would like to use updated Handle classes in EJB 2.x-compliant beans but have one of the older clients (versions 4.0.2 and earlier) installed, set the system property com.ibm.websphere.container.portable.finder to `false`. With this setting in place, the Version 5 and later application server uses the updated handles but returns the enumerations and collections that were used in the earlier clients.

Interoperability of client at Version 4.0.2 and earlier with Version 5 (and later) application server

Client at Version 4.0.2 and earlier, using this function	Application server at Version 5 and later, property true (default)	Application server at Version 5 and later, property false
EJBMetaData	Does not work	Works for 4.0.2 client
Handle to session bean	Does not work	Works
Handle to entity bean	Does not work	Does not work across cells
Enumeration returned by EJB 1.x finder method	Does not work	Works
Collection returned by EJB 1.x finder method	Does not work	Works
Handle to home interface	Does not work	Does not work across cells

If you would like to use updated Handle classes in EJB 2.x-compliant beans but have one of the older clients (versions 4.0.2 and earlier) installed, set the system property com.ibm.websphere.container.portable.finder to `false`. With this setting in place, the Version 5 and later server uses the new Handle classes but returns the older enumeration and collection classes.

Interoperability of client at Version 4.0.3 and later with Version 5 and later application server

Clients at Version 4.0.3 and later work well with Version 5 and later application servers. However, if you set the com.ibm.websphere.container.portable to `false`, client handles to entity beans and home interfaces do not work across domains for the server you set to `false`.

Client at Version 4.0.3 and later, using this function	Application server at Version 5 and later, property true (default)	Application server at Version 5 and later, property false
EJBMetaData	Works	Works
Handle to session bean	Works	Works
Handle to entity bean	Works	Does not work across cells
Enumeration returned by EJB 1.x finder method	Works	Works
Collection returned by EJB 1.x finder method	Works	Works
Handle to home interface	Works	Does not work across cells

Interoperability of Version 5 and later client with Version 4.0.x application server

Clients at Version 5 and later work well with Version 4.0.3 application servers if you set com.ibm.websphere.container.portable to `true`. Client handles to entity beans and home interfaces do not work across domains for any Version 4.0.3 server with com.ibm.websphere.container.portable at the default value, `false`. Version 5 client handles to application servers at Version 4.0.2 and earlier also have restrictions.

Client at Version 5 and later, using this function	Application server at Version 4.0.3, property true	Application server at Version 4.0.3, property false (default)	Application server at Version 4.0.2 or earlier
EJBMetaData	Works	Works	Works for 4.0.2 server only
Handle to session bean	Works	Works	Works
Handle to entity bean	Works	Does not work across domains	Does not work across domains
Enumeration returned by EJB 1.x finder method	Works	Works	Works
Collection returned by EJB 1.x finder method	Works	Works	Works
Handle to home interface	Works	Does not work across domains	Does not work across domains

Interoperability of zSeries Version 4.0.x client with Version 5 and later application server

The only valid configuration for container interoperability with zSeries Version 4.0.x clients is the default configuration for the Version 5 application server.

Interoperability of Version 5 and later client with zSeries Version 4.0.x application server

Version 5 clients should work with a zSeries Version 4.0.x application server with the correct interoperability fixes described in the zSeries documentation. The interoperability characteristics should be the same as for a Version 4.0.3 distributed application server with the property set to `true`.

Client at Version 5 and later, using this function	zSeries application server at Version 4.0.x
EJBMetaData	Works
Handle to session bean	Works
Handle to entity bean	Works
Enumeration returned by EJB 1.x finder method	Works
Collection returned by EJB 1.x finder method	Works
Handle to home interface	Works

Deploying EJB modules

When you deploy an EJB module, you install that module on a server that has been configured to support deployed modules.

Assemble one or more EJB modules, assemble one or more Web modules, and assemble them into a J2EE application. See ″Assembling EJB modules″, ″Assembling Web applications″, and ″Assembling applications″ in the information center.

1. Prepare the deployment environment.

2. Update the configuration for each EJB module as needed for the deployment environment. See ″Preparing to host applications″ in the information center.
3. Deploy the application.

If you specify that EJB deploy be run during application installation and the installation fails with a NameNotFoundException message, ensure that the input JAR or EAR file does not contain source files. Either remove the source files or include all dependent classes and resource files on the class path. If there are source files in the input JAR or EAR file, the EJB deployment tools runs a rebuild before generating the deployment code.

If the module deploys successfully, test and debug the module.

EJB module collection

Use this page to manage the EJB modules deployed in a specific application.

To view this administrative console page, click **Applications > Enterprise Applications >** *applicationName* **> EJB modules**. Click the check boxes to select one or more of the EJB modules in your collection.

Remove: Removes a module from the deployed application. The module is deleted from the application in the WebSphere Application Server configuration repository and also from all the nodes where the application is installed and running (or expected to run). If the application is running on a node when the module file is deleted from the node as a result of configuration synchronization then the application is stopped, the module file is deleted from the node's file system, and then the application is restarted.

Update: Opens a wizard that helps you update module in an application. If a module has the same URI as a module already existing in the application, the new module replaces the existing module. If the new module does not exist in the application, it is added to the deployed application. If the application is running on a node when the module file is updated on the node as a result of configuration synchronization then the application is stopped, the module file is updated on the node's file system, and then the application is restarted.

Remove File: Deletes a file from a module of a deployed application. The file is also deleted from all the nodes where the module is installed after configuration is synchronized with nodes. If the application is running on a node when the module file is updated on the node as a result of configuration synchronization then the application is stopped, the module file is updated on the node's file system, and then the application is restarted.

URI:

When resolved relative to the application URL, this specifies the location of the module's archive contents on a file system. The URI matches the <ejb> or <web> tag in the <module> tag of the application deployment descriptor.

There are three buttons on this panel.

Remove
removes the EJB Module

Remove File
removes the specified file from the EJB Module

Update
updates the module or the application. With Update, you can add, remove, or replace modules

EJB module settings

Use this page to configure and manage a specific deployed EJB module.

Note: You cannot start or stop an individual EJB module for modification. You must start or stop the appropriate application entirely.

To view this administrative console page, click **Applications** > **Enterprise Applications** > *applicationName* > **EJB modules** > *moduleName*.

URI:

When resolved relative to the application URL, this specifies the location of the module archive contents on a file system. The URI must match the URI of a ModuleRef URI in the deployment descriptor of the deployed application (EAR).

Alternate DD:

Specifies a deployment descriptor to be used at run time instead of the one installed in the module.

Starting weight:

Specifies the order in which modules are started when the server starts. The module with the lowest starting weight is started first.

Data type	Integer
Default	5000
Range	Greater than 0

Client applications

Using application clients

An application client module is a Java Archive (JAR) file that contains a client for accessing a Java application. Complete the following steps for developing different types of application clients.

1. Decide on a type of application client.
2. Develop the application client code.
   a. Develop ActiveX application client code.
   b. Develop J2EE application client code.
   c. Develop pluggable application client code.
   d. Develop thin application client code.

View the WebSphere Application Server Clients Samples Gallery for more information. To access these samples, install WebSphere Application Server Clients, and retrieve the samples from your local file system as the following command indicates:

```
<install_root>/samples/index.html
```

Application Client for WebSphere Application Server

In a traditional client-server environment, the client requests a service and the server fulfills the request. Multiple clients use a single server. Clients can also access several different servers. This model persists for Java clients except that now these requests use a client run-time environment.

In this model, the client application requires a servlet to communicate with the enterprise bean, and the servlet must reside on the same machine as the WebSphere Application Server.

The Application Client for WebSphere Application Server Version 6 (Application Client) consists of the following client applications:

- J2EE application client application (Uses services provided by the J2EE Client Container)
- Thin application client application (Does not use services provided by the J2EE Client Container)
- Applet application client application
- ActiveX to EJB Bridge application client application

The Application Client is packaged with the following components:

- Java Runtime Environment (JRE) (or an optional full Software Development Kit) that IBM provides
- WebSphere Application Server run time for J2EE application client applications or Thin application client applications.
- An ActiveX to EJB Bridge run time for ActiveX to EJB Bridge application client applications (only for Windows)
- IBM plug-in for Java platforms for Applet client applications (Windows only).

Note: The Pluggable application client is a kind of Thin application client. However, the Pluggable application client uses a Sun JRE and Software Development Kit instead of the JRE and Software Development Kit that IBM provides.

The *ActiveX application client* model, uses the Java Native Interface (JNI) architecture to programmatically access the Java virtual machine (JVM) API. Therefore the JVM code exists in the same process space as the ActiveX application (Visual Basic, VBScript, or Active Server Pages (ASP) files) and remains attached to the process until that process terminates.

In the *Applet client* model, a Java applet embeds in a HyperText Markup Language (HTML) document residing on a remote client machine from the WebSphere Application Server. With this type of client, the user accesses an enterprise bean in the WebSphere Application Server through the Java applet in the HTML document.

The *J2EE application client* is a Java application program that accesses enterprise beans, Java DataBase Connectivity (JDBC) APIs, and Java Message Service message queues. The J2EE application client program runs on client machines. This program follows the same Java programming model as other Java programs; however, the J2EE application client depends on the Application Client run time to configure its execution environment, and uses the Java Naming and Directory Interface (JNDI) name space to access resources.

The *Pluggable and Thin application clients* provide a lightweight Java client programming model. These clients are useful in situations where a Java client application exists but the application needs enhancements to use enterprise beans, or where the client application requires a thinner, more lightweight environment than the one offered by the J2EE application client. The difference between the Thin application client and the Pluggable application client is that the Thin application client includes a Java virtual machine (JVM) API, and the Pluggable application client requires the user to provide this code. The Pluggable application client uses the Sun Java Development Kit, and the Thin application client uses the IBM Developer Kit for the Java platform.

The J2EE application client programming model provides the benefits of the J2EE platform for the Java client application. Use the J2EE application client to develop, assemble, deploy and launch a client application. The tooling provided with the WebSphere platform supports the seamless integration of these stages to help the developer create a client application from start to finish.

When you develop a client application using and adhering to the J2EE platform, you can put the client application code from one J2EE platform implementation to another. The client application package can require redeployment using each J2EE platform deployment tool, but the code that comprises the client application remains the same.

The Application Client run time supplies a container that provides access to system services for the client application code. The client application code must contain a main method. The Application Client run time invokes this main method after the environment initializes and runs until the Java virtual machine code terminates.

The J2EE platform supports the Application Client use of *nicknames* or *short names*, defined within the client application deployment descriptor. These deployment descriptors identify enterprise beans or local resources (JDBC, Java Message Service (JMS), JavaMail and URL APIs) for simplified resolution through JNDI. This simplified resolution to the enterprise bean reference and local resource reference also eliminates changes to the client application code, when the underlying object or resource either changes or moves to a different server. When these changes occur, the Application Client can require redeployment.

The Application Client also provides initialization of the run-time environment for the client application. The deployment descriptor defines this unique initialization for each client application. The Application Client run time also provides support for security authentication to enterprise beans and local resources.

The Application Client uses the Java Remote Method Invocation-Internet InterORB Protocol (RMI-IIOP). Using this protocol enables the client application to access enterprise bean references and to use Common Object Request Broker Architecture (CORBA) services provided by the J2EE platform implementation. Use of the RMI-IIOP protocol and the accessibility of CORBA services assist users in developing a client application that requires access to both enterprise bean references and CORBA object references.

When you combine the J2EE and CORBA environments or programming models in one client application, you must understand the differences between the two programming models to use and manage each appropriately.

View the Samples gallery for more information about the Application Client.

Application client functions: Use the following table to identify the available functions in the different types of clients.

Available functions	**ActiveX client**	**Applet client**	**J2EE client**	**Pluggable client**	**Thin client**
Provides all the benefits of a J2EE platform	Yes	No	Yes	No	No
Portable across all J2EE platforms	No	No	Yes	No	No
Provides the necessary run-time support for communication between a client and a server	Yes	Yes	Yes	Yes	Yes
Supports the use of nicknames in the deployment descriptor files. **Note:** Although you can edit deployment descriptor files, do not use the administrative console to modify them.	Yes	No	Yes	No	No
Supports use of the RMI-IIOP protocol	Yes	Yes	Yes	Yes	Yes
Browser-based application	No	Yes	No	No	No
Enables development of client applications that can access enterprise bean references and CORBA object references	Yes	Yes	Yes	Yes	Yes

Enables the initialization of the client application run-time environment	Yes	No	Yes	No	No
Supports security authentication to enterprise beans	Yes	Limited	Yes	Yes	Yes
Supports security authentication to local resources	Yes	No	Yes	No	No
Requires distribution of application to client machines	Yes	No	Yes	Yes	Yes
Enables access to enterprise beans and other Java classes through Visual Basic, VBScript, and Active Server Pages (ASP) code	Yes	No	No	No	No
Provides a lightweight client suitable for download	No	Yes	No	Yes	Yes
Enables access JNDI APIs for enterprise bean resolution	Yes	Yes	Yes	Yes	Yes
Runs on client machines that use the Sun Java Runtime Environment	No	No	No	Yes	No
Supports CORBA services (using CORBA services can render the application client code nonportable)	No	No	Yes	No	No

ActiveX application clients:

WebSphere Application Server provides an ActiveX to EJB bridge that enables ActiveX programs to access enterprise beans through a set of ActiveX automation objects.

The bridge accomplishes this access by loading the Java virtual machine (JVM) into any ActiveX automation container such as Visual Basic, VBScript, and Active Server Pages (ASP).

There are two main environments in which the ActiveX to EJB bridge runs:
- **Client applications**, such as Visual Basic and VBScript, are programs that a user starts from the command line, desktop icon, or Start menu shortcut.
- **Client services**, such as Active Server Pages, are programs started by some automated means like the Services control panel applet.

The ActiveX to EJB bridge uses the Java Native Interface (JNI) architecture to programmatically access the JVM code. Therefore the JVM code exists in the same process space as the ActiveX application (Visual Basic, VBScript, or ASP) and remains attached to the process until that process terminates. To create JVM code, an ActiveX client program calls the XJBInit() method of the XJB.JClassFactory object. For more information about creating JVM code for an ActiveX program, see ″ActiveX to EJB bridge, initializing JVM code’ in the information center.

After an ActiveX client program has initialized the JVM code, the program calls several methods to create a proxy object for the Java class. When accessing a Java class or object, the real Java object exists in the JVM code; the automation container contains the proxy for that Java object. The ActiveX program can use the proxy object to access the Java class, object fields, and methods. For more information about using Java proxy objects, see ″Example: Developing an ActiveX application client to enterprise beans″. For more information about calling methods and access fields, see ″Example: Calling Java methods in the ActiveX to enterprise beans″ and ″Java field programming tips″ in the information center.

The client program performs primitive data type conversion through the COM IDispatch interface (use of the IUnknown interface is not directly supported). Primitive data types are automatically converted between native automation types and Java types. All other types are handled automatically by the proxy objects For more information about data type conversion, see ″ActiveX to Java primitive data type conversion values″ in the information center.

Any exceptions thrown in Java code are encapsulated and thrown again as a COM error, from which the ActiveX program can determine the actual Java exceptions. For more information about handling exceptions, see ActiveX to EJB bridge, handling errors.

The ActiveX to EJB bridge supports both free-threaded and apartment-threaded access and implements the free threaded marshaler (FTM) to work in a hybrid environment such as Active Server Pages. For more information about the support for threading, see ″Threading tips″ for ActiveX to EJB bridge, using threading.

Applet clients:

The applet client provides a browser-based Java run time capable of interacting with enterprise beans directly, instead of indirectly through a servlet.

This client is designed to support users who want a browser-based Java client application programming environment that provides a richer and more robust environment than the one offered by the **Applet > Servlet > enterprise bean** model.

The programming model for this client is a hybrid of the Java application thin client and a servlet client. When accessing enterprise beans from this client, the applet can consider the enterprise bean object references as CORBA object references.

No tooling support exists for this client to develop, assemble or deploy the applet. You are responsible for developing the applet, generating the necessary client bindings for the enterprise beans and CORBA objects, and bundling these pieces together to install or download to the client machine. The Java applet client provides the necessary run time to support communication between the client and the server. The applet client run time is provided through the Java applet browser plug-in that you install on the client machine.

Generate client-side bindings using an assembly tool such as the Application Server Toolkit (AST) or Rational Web Developer. See ″Assembly tools″ in the information center for additional information. An applet can utilize these bindings, or you can generate client-side bindings using the **rmic** command. This command is part of the IBM Developer Kit, Java edition that is installed with the WebSphere Application Server.

The applet client uses the RMI-IIOP protocol. Using this protocol enables the applet to access enterprise bean references and CORBA object references, but the applet is restricted in using some supported CORBA services.

If you combine the enterprise bean and CORBA environments in one applet, you must understand the differences between the two programming models, and you must use and manage each model appropriately.

The applet environment restricts access to external resources from the browser run-time environment. You can make some of these resources available to the applet by setting the correct security policy settings in the WebSphere Application Server `client.policy` file. If given the correct set of permissions, the applet client must explicitly create the connection to the resource using the appropriate API. This client does not perform initialization of any service that the client applet can need. For example, the client application is responsible for the initialization of the naming service, either through the CosNaming, or the Java Naming and Directory Interface (JNDI) APIs.

J2EE application clients:

The J2EE application client programming model provides the benefits of the Java 2 Platform for WebSphere Application Server Enterprise product.

The J2EE platform offers the ability to seamlessly develop, assemble, deploy and launch a client application. The tooling provided with the WebSphere platform supports the seamless integration of these stages to help the developer create a client application from start to finish.

When you develop a client application using and adhering to the J2EE platform, you can put the client application code from one J2EE platform implementation to another. The client application package can require redeployment using each J2EE platform deployment tool, but the code that comprises the client application does not change.

The J2EE application client run time supplies a container that provides access to system services for the application client code. The J2EE application client code must contain a main method. The J2EE application client run time invokes this main method after the environment initializes and runs until the Java virtual machine application terminates.

Application clients can use *nicknames* or *short names*, defined within the client application deployment descriptor with the J2EE platform. These deployment descriptors identify enterprise beans or local resources (JDBC data sources, J2C connection factories, Java Message Service (JMS), JavaMail and URL APIs) for simplified resolution through JNDI use. This simplified resolution to the enterprise bean reference and local resource reference also eliminates changes to the application client code, when the underlying object or resource either changes or moves to a different server. When these changes occur, the application client can require redeployment. Although you can edit deployment descriptor files, do not use the administrative console to modify them.

The J2EE application client also provides initialization of the run-time environment for the client application. The deployment descriptor defines this unique initialization for each client application. The J2EE application client run time also provides support for security authentication to the enterprise beans and local resources.

The J2EE application client uses the Java Remote Method Invocation technology run over Internet Inter-Orb Protocol (RMI-IIOP). Using this protocol enables the client application to access enterprise bean references and to use Common Object Request Broker Architecture (CORBA) services provided by the J2EE platform implementation. Use of the RMI-IIOP protocol and the accessibility of CORBA services assist users in developing a client application that requires access to both enterprise bean references and CORBA object references.

When you combine the J2EE and the CORBA WebSphere Application Server Enterprise environments or programming models in one client application, you must understand the differences between the two programming models to use and manage each appropriately.

Pluggable application clients:

The Pluggable application client provides a lightweight, downloadable Java application run time capable of interacting with enterprise beans.

The Pluggable application client requires that you have previously installed the Sun Java Runtime Environment (JRE) files. In all other aspects, the Pluggable application client, and the Thin application client are similar.

Note: The Pluggable application client is only available on the Windows platform.

This client is designed to support those users who want a lightweight Java client application programming environment, without the overhead of the J2EE platform on the client machine. The programming model for this client is heavily influenced by the CORBA programming model, but supports access to enterprise beans.

When accessing enterprise beans from this client, the client application can consider the enterprise beans object references as CORBA object references.

Tooling does not exist on the client; however, tooling does exists on the server. You are responsible for developing the client application, generating the necessary client bindings for the enterprise bean and CORBA objects, and after bundling these pieces together, installing them on the client machine.

The Pluggable application client provides the necessary run time to support the communication needs between the client and the server.

The Pluggable application client uses the RMI-IIOP protocol. Using this protocol enables the client application to access enterprise bean references and CORBA object references and use any supported CORBA services. Using the RMI-IIOP protocol along with the accessibility of CORBA services can assist a user in developing a client application that needs to access both enterprise bean references and CORBA object references.

When you combine the J2EE and CORBA environments in one client application, you must understand the differences between the two programming models to use and manage each appropriately.

The Pluggable application client run time provides the necessary support for the client application for object resolution, security, Reliability Availability and Serviceability (RAS), and other services. However, this client does not support a container that provides easy access to these services. For example, no support exists for using *nicknames* for enterprise beans or local resource resolution. When resolving to an enterprise bean (using either the Java Naming and Directory Interface (JNDI) API or CosNaming) sources, the client application must know the location of the name server and the fully qualified name used when the reference was bound into the name space.

When resolving to a local resource, the client application cannot resolve to the resource through a JNDI lookup. Instead the client application must explicitly create the connection to the resource using the appropriate API (JDBC, Java Message Service (JMS), and so on). This client does not perform initialization of any of the services that the client application might require. For example, the client application is responsible for the initialization of the naming service, either through CosNaming or JNDI APIs.

The Pluggable application client offers access to most of the available client services in the J2EE application client. However, you cannot access the services in the Pluggable application client as easily as you can in the J2EE application client. The J2EE client has the advantage of performing a simple Java Naming and Directory Interface (JNDI) name space lookup to access the desired service or resource. The Pluggable application client must code explicitly for each resource in the client application. For example, looking up an enterprise bean Home object requires the following code in a J2EE application client:

```
        java.lang.Object ejbHome =  initialContext.lookup("java:/comp/env/ejb/MyEJBHome"
);
    MyEJBHome = (MyEJBHome)javax.rmi.PortableRemoteObject.narrow(ejbHome,
MyEJBHome.class);
```

However, you need more explicit code in a Pluggable application client for Java:

```
        java.lang.Object ejbHome =  initialContext.lookup("the/fully/qualified
/path/to/actual/home/in/namespace/MyEJBHome");
    MyEJBHome = (MyEJBHome)javax.rmi.PortableRemoteObject.narrow(ejbHome,
MyEJBHome.class);
```

In this example, the J2EE application client accesses a logical name from the `java:/comp` name space. The J2EE client run time resolves that name to the physical location and returns the reference to the client application. The pluggable client must know the fully qualified physical location of the enterprise bean Home object in the name space. If this location changes, the pluggable client application must also change the value placed on the lookup() statement.

In the J2EE client, the client application is protected from these changes because it uses the logical name. A change can require a redeployment of the EAR file, but the actual client application code remains the same.

The Pluggable application client is a traditional Java application that contains a *main* function. The WebSphere Pluggable application client provides run-time support for accessing remote enterprise beans, and provides the implementation for various services (security, Workload Management (WLM), and others). This client can also access CORBA objects and CORBA-based services. When using both environments in one client application, you need to understand the differences between the enterprise bean and the CORBA programming models to manage both environments.

For instance, the CORBA programming model requires the CORBA CosNaming name service for object resolution in a name space. The enterprise beans programming model requires the JNDI name service. The client application must initialize and properly manage these two naming services.

Another difference applies to the enterprise bean model. Use the Java Naming and Directory Interface (JNDI) implementation in the enterprise bean model to initialize the Object Request Broker (ORB). The client application is unaware that an ORB is present. The CORBA model, however, requires the client application to explicitly initialize the ORB through the `ORB.init()` static method.

The Pluggable application client provides a batch command that you can use to set the CLASSPATH and JAVA_HOME environment variables to enable the Pluggable application client run time.

Thin application clients:

The thin application client provides a lightweight, downloadable Java application run time capable of interacting with enterprise beans.

This client is designed to support those users who want a lightweight Java client application programming environment, without the overhead of the J2EE platform on the client machine. The programming model for this client is heavily influenced by the CORBA programming model, but supports access to enterprise beans.

When accessing enterprise beans from this client, the client application can consider the enterprise beans object references as CORBA object references.

Tooling does not exist on the client, it exists on the server. You are responsible for developing the client application, generating the necessary client bindings for the enterprise bean and CORBA objects, and bundling these pieces together to install on the client machine.

The thin application client provides the necessary run-time to support the communication needs between the client and the server.

The thin application client uses the RMI-IIOP protocol. Using this protocol enables the client application to access not only enterprise bean references and CORBA object references, but also allows the client application to use any supported CORBA services. Using the RMI-IIOP protocol along with the accessibility of CORBA services can assist a user in developing a client application that needs to access both enterprise bean references and CORBA object references.

When you combine the J2EE and CORBA environments in one client application, you must understand the differences between the two programming models, to use and manage each appropriately.

The thin application client run time provides the necessary support for the client application for object resolution, security, Reliability Availability and Servicability (RAS), and other services. However, this client does not support a container that provides easy access to these services. For example, no support exists for using *nicknames* for enterprise beans or local resource resolution. When resolving to an enterprise bean (using either Java Naming and Directory Interface (JNDI) or CosNaming) sources, the client application must know the location of the name server and the fully qualified name used when the reference was bound into the name space. When resolving to a local resource, the client application cannot resolve to the resource through a JNDI lookup. Instead the client application must explicitly create the connection to the resource using the appropriate API (JDBC, Java Message Service (JMS), and so on). This client does not perform initialization of any of the services that the client application might require. For example, the client application is responsible for the initialization of the naming service, either through CosNaming or JNDI APIs.

The thin application client offers access to most of the available client services in the J2EE application client. However, you cannot access the services in the thin client as easily as you can in the J2EE application client. The J2EE client has the advantage of performing a simple Java Naming and Directory Interface (JNDI) name space lookup to access the desired service or resource. The thin client must code explicitly for each resource in the client application. For example, looking up an enterprise bean Home requires the following code in a J2EE application client:

```
        java.lang.Object ejbHome =  initialContext.lookup("java:/comp/env/ejb/MyEJBHome");
    MyEJBHome = (MyEJBHome)javax.rmi.PortableRemoteObject.narrow(ejbHome,  MyEJBHome.class);
```

However, you need more explicit code in a Java thin application client:

```
        java.lang.Object ejbHome =
initialContext.lookup("the/fully/qualified/path/to/actual/home/in/namespace/MyEJBHome");
    MyEJBHome = (MyEJBHome)javax.rmi.PortableRemoteObject.narrow(ejbHome,  MyEJBHome.class);
```

In this example, the J2EE application client accesses a logical name from the `java:/comp` name space. The J2EE client run time resolves that name to the physical location and returns the reference to the client application. The thin client must know the fully qualified physical location of the enterprise bean Home in the name space. If this location changes, the thin client application must also change the value placed on the lookup() statement.

In the J2EE client, the client application is protected from these changes because it uses the logical name. A change might require a redeployment of the EAR file, but the actual client application code remains the same.

The thin application client is a traditional Java application that contains a *main* function. The WebSphere thin application client provides run-time support for accessing remote enterprise beans, and provides the implementation for various services (security, Workload Management (WLM), and others). This client can also access CORBA objects and CORBA based services. When using both environments in one client application, you need to understand the differences between the enterprise bean and CORBA programming models to manage both environments.

For instance, the CORBA programming model requires the CORBA CosNaming name service for object resolution in a name space. The enterprise beans programming model requires the JNDI name service. The client application must initialize and properly manage these two naming services.

Another difference applies to the enterprise bean model. Use the Java Naming and Directory Interface (JNDI) implementation in the enterprise bean model to initialize the Object Request Broker (ORB). The client application is unaware that an ORB is present. The CORBA model, however, requires the client application to explicitly initialize the ORB through the `ORB.init()` static method.

The thin application client provides a batch command that you can use to set the CLASSPATH and JAVA_HOME environment variables to enable the thin application client run time.

Application client troubleshooting tips

This section provides some debugging tips for resolving common Java 2 Platform Enterprise Edition (J2EE) application client problems. To use this troubleshooting guide, review the trace entries for one of the J2EE application client exceptions, and then locate the exception in the guide. Some of the errors in the guide are samples, and the actual error you receive can be different than what is shown here. You might find it useful to rerun the `launchClient` command specifying the `-CCverbose=true` option. This option provides additional information when the J2EE application client run time is initializing

Error: java.lang.NoClassDefFoundError

Explanation
This exception is thrown when Java code cannot load the specified class.

Possible causes
- Invalid or non-existent class
- Class path problem
- Manifest problem

Recommended response
Check to determine if the specified class exists in a Java Archive (JAR) file within your Enterprise Archive (EAR) file. If it does, make sure the path for the class is correct. For example, if you get the exception:

```
java.lang.NoClassDefFoundError:
WebSphereSamples.HelloEJB.HelloHome
```

verify that the HelloHome class exists in one of the JAR files in your EAR file. If it exists, verify that the path for the class is WebSphereSamples.HelloEJB.

If both the class and path are correct, then it is a class path issue. Most likely, you do not have the failing class JAR file specified in the client JAR file manifest. To verify this situation, perform the following steps:
1. Open your EAR file with the Application Server Toolkit or the Rational Web Developer assembly tool, and select the Application Client.
2. Add the names of the other JAR files in the EAR file to the Classpath field.

This exception is generally caused by a missing Enterprise Java Beans (EJB) module name from the Classpath field.

If you have multiple JAR files to enter in the Classpath field, be sure to separate the JAR names with spaces.

If you still have the problem, you have a situation where a class is loaded from the file system instead of the EAR file. This error is difficult to debug because the offending class is not the one specified in the exception. Instead, another class is loaded from the file system before the one specified in the exception. To correct this error, review the class paths specified with the -CCclasspath option and the class paths configured with the Application Client Resource Configuration Tool. Look for classes that also exist in the EAR file. You must resolve the situation where one of the classes is found on the file system instead of in the `.ear` file. Remove entries from the classpaths, or include the `.jar` files and classes in the `.ear` file instead of referencing them from the file system.

If you use the -CCclasspath parameter or resource classpaths in the Application Client Resource Configuration Tool, and you have configured multiple JAR files or classes, verify they are separated with the correct character for your operating system. Unlike the Classpath field, these class path fields use platform-specific separator characters, usually a colon (on UNIX platforms) or a semi-colon (on Windows systems).
Note: The system class path is not used by the Application Client run time if you use the launchClient batch or shell files. In this case, the system class path would not cause this problem. However, if you load the launchClient class directly, you do have to search through the system class path as well.

Error: com.ibm.websphere.naming.CannotInstantiateObjectException: Exception occurred while attempting to get an instance of the object for the specified reference object. [Root exception is javax.naming.NameNotFoundException: xxxxxxxxxx]

Explanation

This exception occurs when you perform a lookup on an object that is not installed on the host server. Your program can look up the name in the local client Java Naming and Directory Interface (JNDI) name space, but received a NameNotFoundException exception because it is not located on the host server. One typical example is looking up an EJB component that is not installed on the host server that you access. This exception might also occur if the JNDI name you configured in your Application Client module does not match the actual JNDI name of the resource on the host server.

Possible causes

- Incorrect host server invoked
- Resource is not defined
- Resource is not installed
- Application server is not started
- Invalid JNDI configuration

Recommended response

If you are accessing the wrong host server, run the `launchClient` command again with the -CCBootstrapHost parameter specifying the correct host server name. If you are accessing the correct host server, use the product `dumpnamespace` command line tool to see a listing of the host server JNDI name space. If you do not see the failing object name, the resource is either not installed on the host server or the appropriate application server is not started. If you determine the resource is already installed and started, your JNDI name in your client application does not match the global JNDI name on the host server. Use the Application Server Toolkit to compare the JNDI bindings value of the failing object name in the client application to the JNDI bindings value of the object in the host server application. The values must match.

Error: javax.naming.ServiceUnavailableException: A communication failure occurred while attempting to obtain an initial context using the provider url: ″iiop://[invalidhostname]″. Make sure that the host and port information is correct and that the server identified by the provider URL is a running name server. If no port number is specified, the default port number 2809 is used. Other possible causes include the network environment or workstation network configuration. Root exception is org.omg.CORBA.INTERNAL: JORB0050E: In Profile.getIPAddress(), InetAddress.getByName[invalidhostname] threw an UnknownHostException. minor code: 4942F5B6 completed: Maybe

Explanation

This exception occurs when you specify an invalid host server name.

Possible causes

- Incorrect host server invoked
- Invalid host server name

Recommended response

Run the `launchClient` command again and specify the correct name of your host server with the -CCBootstrapHost parameter.

Error: javax.naming.CommunicationException: Could not obtain an initial context due to a communication failure. Since no provider URL was specified, either the bootrap host and port of an existing ORB was used, or a new ORB instance was created and initialized with the default bootstrap host of ″localhost″ and the default bootstrap port of 2809. Make sure the ORB bootstrap host and port resolve to a running name server. Root exception is org.omg.CORBA.COMM_FAILURE: WRITE_ERROR_SEND_1 minor code: 49421050 completed: No

Explanation

This exception occurs when you run the `launchClient` command to a host server that does not have the Application Server started. You also receive this exception when you specify an invalid host server name. This situation might occur if you do not specify a host server name when you run the launchClient tool. The default behavior is for the launchClient tool to run to the local host, because WebSphere Application Server does not know the name of your host server. This default behavior only works when you are running the client on the same machine with WebSphere Application Server is installed.

Possible causes

- Incorrect host server invoked
- Invalid host server name
- Invalid reference to `localhost`
- Application server is not started
- Invalid bootstrap port

Recommended response

If you are not running to the correct host server, run the `launchClient` command again and specify the name of your host server with the `-CCBootstrapHost` parameter. Otherwise, start the Application Server on the host server and run the `launchClient` command again.

Error: javax.naming.NameNotFoundException: Name comp/env/ejb not found in context ″java:″

Explanation

This exception is thrown when the Java code cannot locate the specified name in the local JNDI name space.

Possible causes

- No binding information for the specified name
- Binding information for the specified name is incorrect
- Wrong class loader was used to load one of the program classes
- A resource reference does not include any client configuration information

Recommended response

Open the EAR file with the Application Server Toolkit, and check the bindings for the failing name. Ensure this information is correct. If you are using Resource References, open the EAR file with the Application Client Resource Configuration Tool, and verify that the Resource Reference has client configuration information and the name of the Resource Reference exactly matches the JNDI name of the client configuration. If the values are correct, you might have a class loader error.

Error: java.lang.ClassCastException: Unable to load class: org.omg.stub.WebSphereSamples.HelloEJB._HelloHome_Stub at com.ibm.rmi.javax.rmi.PortableRemoteObject.narrow(portableRemoteObject.java:269)

Explanation

This exception occurs when the application program attempts to narrow to the EJB home class and the class loaders cannot find the EJB client side bindings.

Possible causes

- The files, *_Stub.class and _Tie.class, are not in the EJB `.jar` file
- Class loader could not find the classes

Recommended response

Look at the EJB `.jar` file located in the `.ear` file and verify the class contains the Enterprise Java Beans (EJB) client side bindings. These are class files with file names that end in `_Stub` and `_Tie`. If the binding classes are in the EJB `.jar` file, then you might have a class loader error.

Error: WSCL0210E: The Enterprise archive file [EAR file name] could not be found. com.ibm.websphere.client.applicationclient.ClientContainerException: com.ibm.etools.archive.exception.OpenFailureException

Explanation

This error occurs when the application client run time cannot read the Enterprise Archive (EAR) file.

Possible causes

The most likely cause of this error is that the system cannot find the EAR file cannot be found in the path specified on the `launchClient` command.

Recommended response

Verify that the path and file name specified on the `launchclient` command are correct. If you are running on the Windows operating system and the path and file name are correct, use a short version of the path and file name (8 character file name and 3 character extension).

The launchClient command appears to hang and does not return to the command line when the client application has finished.

Explanation

When running your application client using the `launchClient` command the WebSphere Application Server run time might need to display the security login dialog. To display this dialog, WebSphere Application Server run time creates an Abstract Window Toolkit (AWT) thread. When your application returns from its main method to the application client run time, the application client run time attempts to return to the operating system and end the Java virtual machine (JVM) code. However, since there is an AWT thread, the JVM code will not end until `System.exit` is called.

Possible causes

The JVM code does not end because there is an AWT thread. Java code requires that `System.exit()` be called to end AWT threads.

Recommended response

- Modify your application to call `System.exit(0)` as the last statement.
- Use the `-CCexitVM=true` parameter when you call the `launchClient` command.

For current information available from IBM Support on known problems and their resolution, see the IBM customer support page.

IBM Support has documents that can save you time gathering information needed to resolve this problem. Before opening a PMR, see the IBM customer support page.

Running application clients

The J2EE specification requires support for a client container that runs stand-alone Java applications (known as J2EE application clients) and provides J2EE services to the applications. J2EE services include naming, security, and resource connections.

You are ready to run your application client using this tool after you have:
1. Written the application client program.
2. Assembled and installed an application module (`.ear` file) in the application server run time.
3. Deployed the application using the Application Client Resource Configuration Tool (ACRCT).

This task only applies to J2EE application clients.
1. Open a command window and invoke the following script to launch J2EE application clients using the launchClient shell:

   ```
   install_root/bin/launchClient.bat
   ```

   The launchClient batch command starts the application client run time, which:
   - Initializes the client run time.
   - Loads the class that you designated as the main class with an assembly tool. See ″Starting an assembly tool″ in the information center.
   - Runs the main method of the application client program.

   When your program terminates, the application client run time cleans up the environment and the Java virtual machine (JVM) code ends.
2. Pass parameters to the `launchClient` command or to your application client program as well. The `launchClient` command allows you to do both. The `launchClient` command requires that the first parameter is either:
   - An EAR file specifying the application client to launch.
   - A request for `launchClient` usage information.

   The following example illustrates the command line invocation syntax for the launchClient tool (shown here on 2 lines for publication):

   ```
   launchClient [-profileName pName | -JVMOptions options | -help | -?] <userapp>
    [-CC<name>=<value>] [app args]
   ```

   where
   - *userapp.ear* is the path and the name of the EAR file that contains the application client.
   - *-CC<name>=<value>* is the client container name-value pair parameter. See the client container parameters section, for supported name-value pair arguments.
   - *app args* are arguments that pass to the application client.
   - *-profileName* defines the profile of the Application Server process in a multi-profile installation. The -profileName option is not required for running in a single profile environment or in an Application Clients installation. The default is **default_profile**.
   - *-JVMOptions* is a valid Java standard or non-standard option string. Insert quotation marks around the string.
   - *-help, -?* prints the usage information.

   All other parameters intended for the `launchClient` command must begin with the -CC prefix.

   Parameters that are not EAR files, or usage requests, or that do not begin with the -CC prefix, are ignored by the application client run time, and are passed directly to the application client program.

   The `launchClient` command retrieves parameters from three places:
   - The command line
   - A properties file
   - System properties

The parameters are resolved in the order listed above, with command line values having the highest priority and system properties the lowest. Using this prioritization you can set and override default values.

3. Specify the server name. By default, the **launchClient** command uses the localhost for the `BootstrapHost` property value. This setting is effective for testing your application client when it is installed on the same computer as the server. However, in other cases override this value with the name of your server.

   You can override the `BootstrapHost` value by invoking `launchClient` command with the following parameters:

   ```
   launchClient myapp.ear -CCBootstrapHost=abc.midwest.mycompany.com
   ```

   You can also override the default by specifying the value in a properties file and passing the file name to the launchClient shell.

   Security is controlled by the server. You do not need to configure security on the client because the client assumes that security is enabled. If server security is not enabled, then the server ignores the security request, and the application client functions as expected.

You can store launchClient values in a properties file, which is a good method for distributing default values. You can then override one or more values on the command line. The format of the file is one `launchClient -CC` parameter per line without the `-CC` prefix. For example:

```
 verbose=true classpath=c:\mydir\util.jar;c:\mydir\harness.jar;c:\production\G19
\global.jar BootstrapHost=abc.westcoast.mycompany.com tracefile=c:\WebSphere\mylog.txt
```

launchClient tool

This section describes the Java 2 Platform Enterprise Edition (J2EE) command line syntax for the launchClient tool for WebSphere Application Server.

The following example illustrates the command line invocation syntax for the launchClient tool (shown here on 2 lines for publication):

```
launchClient [-profileName pName | -JVMOptions options | -help | -?]
  <userapp> [-CC<name>=<value>] [app args]
```

where

- *userapp.ear* is the path and the name of the EAR file that contains the application client.
- *-CC<name>=<value>* is the client container name-value pair parameter. See the client container parameters section, for supported name-value pair arguments.
- *app args* are arguments that pass to the application client.
- *-profileName* defines the profile of the Application Server process in a multi-profile installation. The -profileName option is not required for running in a single profile environment or in an Application Clients installation. The default is **default_profile**.
- *-JVMOptions* is a valid Java standard or nonstandard option string. Insert quotation marks around the string.
- *-help, -?* prints the usage information.

The first parameter must be `-help`, `-?` or contain no parameter at all. The `-profileName pName` and `-JVMOptions` options are optional parameters. If used, they must appear before the *<userapp>* parameter. All other parameters are optional and can appear in any order after the *<userapp>* parameter. The J2EE Application client run time ignores any optional parameters that do not begin with a `-CC` prefix and passes those parameters to the application client.

Client container parameters

Supported arguments include:

-CCsoapConnectorPort
The Simple Object Access Protocol (SOAP) connector port. If you do not specify this argument, the WebSphere Application Server default value is used.

-CCverbose
This option displays additional information messages. The default is `false`.

-CCclasspath
A class path value. When you launch an application, the system class path is used. If you want to access classes that are not in the EAR file or part of the system class paths, specify the appropriate class path here. Multiple paths can be concatenated.

-CCjar
The name of the client Java Archive (JAR) file that resides within the EAR file for the application you wish to launch. Use this argument when you have multiple client JAR files in the EAR file.

-CCadminConnectorHost
Specifies the host name of the server from which configuration information is retrieved. The default is the value of the `-CCBootstrapHost` parameter or the value, `localhost`, if the `-CCBootstrapHost` parameter is not specified.

-CCadminConnectorPort
Indicates the port number for the administrative client function to use. The default value is `8880` for SOAP connections and `2809` for Remote Method Invocation (RMI) connections.

-CCadminConnectorType
Specifies how the administrative client connects to the server. Specify `RMI` to use the RMI connection type, or specify `SOAP` to use the SOAP connection type. The default value is `SOAP`.

-CCadminConnectorUser
Administrative clients use this user name when a server requires authentication. If the connection type is SOAP, and security is enabled on the server, this parameter is required. The SOAP connector does not prompt for authentication.

-CCadminConnectorPassword
The password for the user name that the `-CCadminConnectorUser` parameter specifies.

-CCaltDD
The name of an alternate deployment descriptor file. This parameter is used with the `-CCjar` parameter to specify the deployment descriptor to use. Use this argument when a client JAR file is configured with more than one deployment descriptor. Set the value to `null` to use the client JAR file standard deployment descriptor.

-CCBootstrapHost
The name of the host server you want to connect to initially. The format is:
`your_server_of_choice.com`

-CCBootstrapPort
The server port number. If you do not specify this argument, the WebSphere Application Server default value is `used`.

-CCproviderURL
Provides bootstrap server information that the initial context factory can use to obtain an initial context. WebSphere Application Server initial context factory can use either a Common Object Request Broker Architecture (CORBA) object URL or an Internet Inter-ORB Protocol (IIOP) URL. CORBA object URLs are more flexible than IIOP URLs and are the recommended URL format to use. This value can contain more than one bootstrap server address. This feature can be used when attempting to obtain an initial context from a server cluster. You can specify bootstrap server addresses, for all servers in the cluster, in the URL. The operation will succeed if at least one of the servers is running, eliminating a single point of failure. The address list does not process in a particular order. For naming operations, this value overrides the `-CCBootstrapHost` and `-CCBootstrapPort` parameters. A CORBA object URL specifying multiple systems is illustrated in the following example:

```
-CCproviderURL=corbaloc:iiop:myserver.mycompany.com:9810,:mybackupserver.mycompany.com:2809
```

This value is mapped to the `java.naming.provider.url` system property.

-CCinitonly
Use this option to initialize application client run time for ActiveX application clients without launching the client application. The default is `false`.

-CCtrace
Use this option to obtain debug trace information. You might need this information when reporting a problem to IBM customer support. The default is `false` For more information, read the topic "Enabling trace" in the *Troubleshooting and support* PDF.

-CCtracefile
Indicates the name of the file to which trace information is written. The default is to write output to the console.

-CCpropfile
Indicates the name of a properties file that contains launchClient properties. Specify the properties without the `-CC` prefix in the file. For example: `verbose=true`.

-CCsecurityManager
Enables and runs the WebSphere Application Server with a security manager. The default is `disable`.

-CCsecurityMgrClass
Indicates the fully qualified name of a class that implements a security manager. Only use this argument if the `-CCsecurityManager` parameter is set to `enable`. The default is `java.lang.SecurityManager`.

-CCsecurityMgrPolicy
Indicates the name of a security manager policy file. Only use this argument if the `-CCsecurityManager` parameter is set to enable. When you enable this parameter, the `java.security.policy` system property is set. The default is `<`*`install_root`*`>/ properties/client.policy`.

-CCD
Use this option to have the WebSphere Application Server set the specified system property during initialization. Do not use the equals (=) character after the `-CCD`. For example: `-CCDcom.ibm.test.property=testvalue`. You can specify multiple `-CCD` parameters. The general format of this parameter is `-CCD<property key>=<property value>`.

-CCexitVM
Use this option to have the WebSphere Application Server call the `System.exit()` method after the client application completes. The default is `false`.

-CCdumpJavaNameSpace
Prints out the Java portion of the Java Naming and Directory Interface (JNDI) name space for WebSphere Application Server. The `true` value uses the short format that prints out the binding name and the type of the object bound at that location. The `long` value uses the long format that prints out the binding name, bound object type, local object, type and string representation of the local object, for example, IORs and string values. The default value is `false`.

-CCtraceMode
Specifies the trace format to use for tracing. If the valid value, `basic`, is not specified the default is advanced. Basic tracing format is a more compact form of tracing. For more information on basic and advanced trace formatting, read the topic "Interpreting trace output" in the *Troubleshooting and support* PDF.

-CCclassLoaderMode
Specifies the class loader mode. If PARENT_LAST is specified, the class loader loads classes from the local class path before delegating the class loading to its parent. The classes loaded for the following are affected:

- Classes defined for the J2EE application client

- Resources defined in the J2EE application
- Classes specified on the manifest of the J2EE client JAR file
- Classes specified using the -CCclasspath option

If PARENT_LAST is not specified, then the default mode, PARENT_FIRST, causes the class loader to delegate the loading of classes to its parent class loader before attempting to load the class from its local class path.

The following examples demonstrate correct syntax.

On the Windows operating system:

```
launchClient c:\earfiles\myapp.ear -CCBootstrapHost=myWASServer -CCverbose=true
app_parm1 app_parm2
```

On the UNIX operating system:

```
./launchClient.sh /usr/earfiles/myapp.ear -CCBootstrapHost=myWASServer -CCverbose=true
app_parm1 app_parm2
```

Specifying the directory for an expanded EAR file:

Each time the launchClient tool is called, it extracts the Enterprise Archive (EAR) file to a random directory name in the temporary directory on your hard drive. Then the tool sets up the thread ClassLoader to use the extracted EAR file directory and JAR files included in the `Manifest.mf` client Java Archive (JAR) file. In a normal J2EE Java client, these files are automatically cleaned up after the application exits. This cleanup occurs when the client container shutdown hook is called. To avoid extracting the EAR file (and removing the temporary directory) each time the launchClient tool is called, complete the following steps:

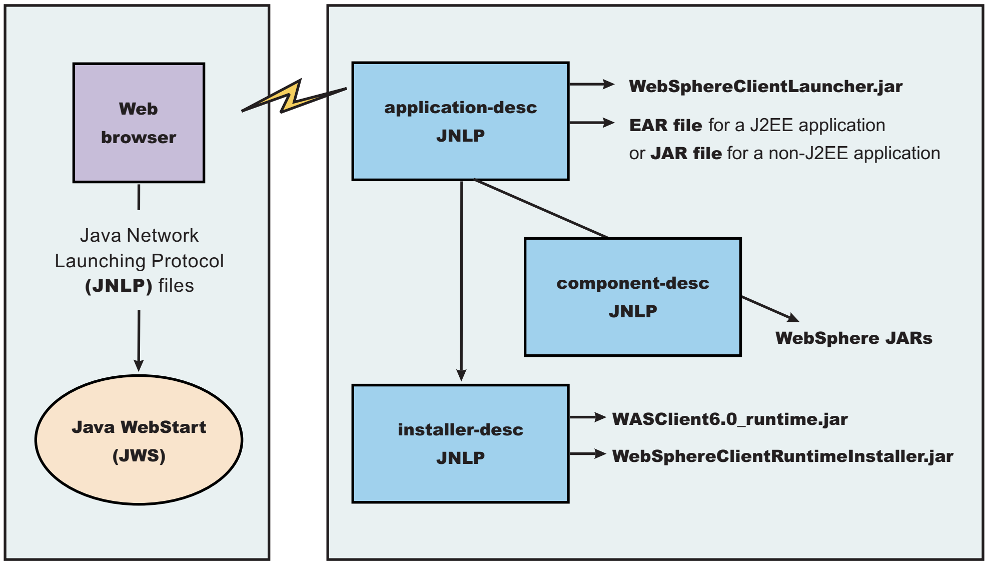
1. Specify a directory to extract the EAR file by setting the `com.ibm.websphere.client.applicationclient.archivedir` Java system property. If the directory does not exist or is empty, the EAR file is extracted normally. If the EAR file was previously extracted, the launchClient tool reuses the directory.
2. Delete the directory before running the launchClient tool again, if you need to update your EAR file. When you call the `launchClient` command, it extracts the new EAR file to the directory. If you do not delete the directory or change the system property value to point to a different directory, the launchClient tool reuses the currently extracted EAR file and does not use your changed EAR file. When specifying the `com.ibm.websphere.client.applicationclient.archivedir` property, make sure that the directory you specify is unique for each EAR file you use. For example, do not point the `MyEar1.ear` and the `MyEar2.ear` files to the same directory.

Java Web Start architecture for deploying application clients

Java Web Start is an application-deployment technology that includes the portability of applets, the maintainability of servlets and JavaServer Pages (JSP) file technology, and the simplicity of mark-up languages such as XML and HTML. It is a Java application that allows full-featured Java 2 client applications to be launched, deployed and updated from a standard Web server. Upon launching Java Web Start for the first time, you might download new client applications from the Web. Each time you launch JWS thereafter, you can initiate applications either through a link on a Web page or (in Windows) from desktop icons or the Start menu. You can deploy applications quickly using Java Web Start, cache applications on the client machine, and launch applications remotely offline. Additionally, because Java Web Start is built from the J2EE infrastructure, the technology inherits the complete security architecture of the J2EE platform.

The technology underlying Java Web Start is the Java Network Launching Protocol & API (JNLP). Java Web Start is a JNLP client and it reads and parses a JNLP descriptor file (JNLP file). Base on the JNLP descriptor, it downloads appropriate pieces of a client application and any of its dependencies. If any of the pieces of the application are already cached on the client machine, then those components are not downloaded again, unless they have been updated on the server machine. After you download and cache the client application, JWS launches it natively on the client machine.

The following diagram shows an overview of launching a client application, include the Application Client for WebSphere Application Server, Version 6 as a dependent resource, using Java Web Start.



Web browser
Java Network Launching Protocol (JNLP) files
Java WebStart (JWS)
application-desc JNLP
WebSphereClientLauncher.jar
EAR file for a J2EE application or JAR file for a non-J2EE application
component-desc JNLP
WebSphere JARs
installer-desc JNLP
WASClient6.0_runtime.jar
WebSphereClientRuntimeInstaller.jar

The Web browser running on a client machine connects to a Web application located on a server machine. The client application JNLP descriptor file is downloaded and processed by Java Web Start on the client machine.

In this diagram, there are three JNLP descriptor files:

- Client application JNLP descriptor (application-desc in the diagram)
- Application Clients run-time installer JNLP descriptor (installer-desc in the diagram)
- Application Clients run-time library component JNLP descriptor (component-desc in the diagram)

Each of these JNLP descriptor files, the client application (JAR or EAR) and the dependent resource JAR files are packaged as Web applications in an EAR file. This EAR file is deployed to an Application server. The client machine with JWS installed uses a Web browser to connect to the url of the client application JNLP descriptor file to download and run the client application.

Using Java Web Start product version 1.4.2 or later is highly recommended. The following operating systems support running J2EE application client applications and or Thin application client applications using Java Web Start:

- Red Hat Enterprise Linux for Intel, Version 3.0
- SuSE Linux Enterprise Server, Versions 8 and 9
- Windows 2000 Professional, Windows 2000 Professional, Windows Advance Server, and Windows 2000 Advance Server
- AIX, Versions 5.1, 5.2, and 5.3
- Solaris, Versions 8 and 9
- HP-UX 11i

You can use Java Web Start on the Java 2 Standard Edition Developer Kits that IBM provides, packaged in Application Client for WebSphere Application Server, Version 6; Java Web Start on Sun Microsystems J2SE Software Development Kit or J2SE Java Runtime Environment 1.4.2, which you can download from the Sun Microsystems Web site for Windows, Linux and Solaris operating systems, or the Java Web Start on HP SDK or RTE for Java 2 version 1.4.2, which you can download from the HP Web site.

Using Java Web Start

Before you begin this task, see the following topics to understand Java Web Start technology and its components:

- “Java Web Start architecture for deploying application clients” on page 856
- “Client application Java Network Launcher Protocol deployment descriptor file”
- “ClientLauncher class” on page 861

Note: You can use Java Web Start on Java 2 Standard Edition Developer Kits that IBM provides, packaged in the Application Client for WebSphere Application Server, Version 6; Java Web Start on Sun Microsystems J2SE Software Development Kit or J2SE Java Runtime Environment 1.4.2, which you can download from the Sun Microsystems Web site for Windows, Linux and Solaris operating systems, or the Java Web Start on HP SDK or RTE for Java 2 version 1.4.2, which you can download from the HP Web site.

1. Prepare the Application Clients run-time dependency component for JWS.
2. Prepare the Application Clients run-time library component for JWS.
3. **Optional:** Run the Java Web Start sample.

   Note: **Problem**: When you run Web services clients from Java Web Start using a Mozilla browser, you might get errors if the client argument contains quotations in the jnlp.jsp file. For example, the following argument (shown here on 2 lines for publication))results in an error:

   ```
   <argument>-url="wsejb:/com.ibm.wssvt.tc.pli.ejb.WSMultiProtocolHome?jndiName=com/ibm
     /wssvt/tc/pli/ejb/WSMultiProtocolHome&"</argument>
   ```

   Error: The following errors display in the Java Web Start console:

   ```
   Client caught exception getting the InsuranceWebServicesPort
   using the URL
   "wsejb:/com.ibm.wssvt.tc.pli.ejb.WSMultiProtocolHome?jndiName=
       com/ibm/wssvt/tc/pli/ejb/WSMultiProtocolHome&"
   java.net.MalformedURLException: no protocol:
    "wsejb:/com.ibm.wssvt.tc.pli.ejb.WSMultiProtocolHome?jndiName=
       com/ibm/wssvt/tc/pli/ejb/WSMultiProtocolHome&"
    at java.net.URL.<init>(URL.java(Compiled Code))
    at java.net.URL.<init>(URL.java(Compiled Code))
    at java.net.URL.<init>(URL.java:411)
    at com.ibm.wssvt.tc.pli.webservice.InsuranceWebServicesClient.getInsuranceServicesClientURL(
       InsuranceWebServicesClient.java:231)
    at com.ibm.wssvt.tc.pli.webservice.InsuranceWebServicesClient.main(
       InsuranceWebServicesClient.java:748)
    at sun.reflect.NativeMethodAccessorImpl.invoke0(Native Method)
    at sun.reflect.NativeMethodAccessorImpl.invoke(NativeMethodAccessorImpl.java:85)
    at sun.reflect.NativeMethodAccessorImpl.invoke(NativeMethodAccessorImpl.java:58)
    at sun.reflect.DelegatingMethodAccessorImpl.invoke(DelegatingMethodAccessorImpl.java:60)
    at java.lang.reflect.Method.invoke(Method.java:391)
    at com.ibm.websphere.client.applicationclient.launchClient.createContainerAndLaunchApp(
       launchClient.java:649)
   ```

   Solution: Update the jnlp.jsp file to remove the quotation marks (″ ″) from the argument. Use the following example argument (shown here on 2 lines for publication) to correct the errors:

   ```
   <argument>-url=wsejb:/com.ibm.wssvt.tc.pli.ejb.WSMultiProtocolHome?jndiName=
     com/ibm/wssvt/tc/pli/ejb/WSMultiProtocolHome&</argument>
   ```

   Now rerun the client from Java Web Start.

Client application Java Network Launcher Protocol deployment descriptor file: The deployment descriptor file is the main Java Network Launcher Protocol (JNLP) descriptor file for the client application. The client application has an Application Clients run-time dependency that provides the Java 2 Runtime Environment from IBM, Application Clients run-time properties, the SSL KeyStore and TrustStore file, and the Application Clients run-time library JAR files (optional for Thin Application client applications). If the Application Clients run-time dependency is not met, it is downloaded and installed in Java Web Start (JWS), as described by the Application Clients run-time installer JNLP descriptor file.

```
<j2se version="WASclient6.0" href="/WebSphereClientRuntimeWeb/Runtime/jnlp.jsp"/>
```

It must also include the `WebSphereClientLauncher.jar` file, which contains the launcher class, com.ibm.websphere.client.launcher.ClientLauncher, that completes one of the following actions:

- If it is a J2EE Application client application (that is the resources for the application contain an EAR file with a client application), then the launcher class starts a second Java Virtual Machine (JVM) using the JRE provided by the Application Clients run-time dependency and launches the J2EE Application client application which is packaged in the EAR file.

  The EAR file must be specified as a JAR resource so that it can be downloaded to JWS and specified in the system property, `com.ibm.websphere.client.launcher.ear`. See the following example for details:

  ```
  <resources>
  <j2se version="WASclient6.0" href="/WebSphereClientRuntimeWeb/Runtime/jnlp.jsp"/>
  <jar href="Launcher/WebSphereClientLauncher.jar" main="true"/>
  <jar href="lib/j2eeclient.ear"/>
  <property name="com.ibm.websphere.client.launcher.ear" value="j2eeclient.ear"/>
  </resources>
  ```

- If it is a Thin Application client application, then the launcher class uses the current JVM from the Application Clients run-time dependency and invokes the Thin Application client application main method.

  The Thin Application client application JAR file must be specified as a JAR resource so that it can be download to JWS and the name of the class containing main method entry point is specified in the system property, `com.ibm.websphere.launcher.main`.

  ```
  <resources>
  <j2se version="WASclient6.0" href="/WebSphereClientRuntimeWeb/Runtime/jnlp.jsp"/>
      <extension name="WebSphere Runtime"
          href="/WebSphereClientRuntimeWeb/Runtime/WebSphereJars/jnlp.jsp"/>
      <jar href="Launcher/WebSphereClientLauncher.jar" main="true"/>
      <jar href="lib/thinclient.jar"/>
      <property name="com.ibm.websphere.client.launcher.main"
                       value="myapp.sample.thinclient.ThinClientMain"/>

  </resources>
  ```

  Unlike the J2EE Application client application, the Thin Application client application is not loading the Application Clients run-time library JAR files from the Application Clients run-time dependency. It is downloaded from the server directly as it is for the Thin Application client application JAR file. An Application Clients run-time library component JNLP descriptor is used for specifying the Application Clients run-time library JAR files resources, as shown in the following example:

  ```
  <extension name="WebSphere Runtime"
            href="/WebSphereClientRuntimeWeb/Runtime/WebSphereJars/jnlp.jsp"/>
  ```
