How to send your comments.	xi
Chapter 1. Overview and new features for securing applications and their environment	1
What is new for security specialists	1
Identity management capabilities	6
Security planning overview	16
Chapter 2. How do I secure applications and their environments?	25
Chapter 3. Task overview: Securing resources	27
Chapter 4. Setting up and enabling security	29
Migrating, coexisting, and interoperating – Security considerations	29
Interoperating with previous product versions	30
Migrating custom user registries	31
Migrating trust association interceptors	34
Migrating Common Object Request Broker Architecture programmatic login to Java Authentication and Authorization Service (CORBA and JAAS)	36
Migrating from the CustomLoginServlet class to servlet filters	39
Migrating Java 2 security policy	40
Migrating Java thin clients that use the password encoding algorithm	42
Enabling security	43
Administrative security.	47
Application security.	61
Java 2 security	61
Enabling security for the realm	72
Testing security after enabling it	82
Securing specific application servers	82
Server-level security settings	84
Chapter 5. Authenticating users	87
Selecting a registry or repository	87
User registries and repositories	89
Configuring local operating system registries	90
Configuring Lightweight Directory Access Protocol user registries	92
Configuring standalone custom registries	111
Managing the realm in a federated repository configuration.	115
Local operating system registries	165
Standalone Lightweight Directory Access Protocol registries	166
Federated repositories	169
Authentication mechanisms	170
Portlet URL security	172
Lightweight Third Party Authentication	176
Trust associations	177
Single sign-on	181
Security attribute propagation	188
UserRegistry interface methods	202
Authentication protocol for EJB security	209
Supported authentication protocols	212
Common Secure Interoperability Version 2 features	213
Identity assertion	213
Identity assertions with trust validation	214
Message layer authentication	215

Configuring the Lightweight Third Party Authentication mechanism	216
Authentication mechanisms and expiration	217
Generating Lightweight Third Party Authentication keys	220
Exporting Lightweight Third Party Authentication keys.	221
Importing Lightweight Third Party Authentication keys.	221
Disabling automatic generation of Lightweight Third Party Authentication keys.	222
Managing LTPA keys from multiple WebSphere Application Server cells	223
Activating Lightweight Third Party Authentication key versions	223
Integrating third-party HTTP reverse proxy servers	224
Trust association settings	225
Trust association interceptor collection	225
Trust association interceptor settings	225
Implementing single sign-on to minimize Web user authentications	226
Configuring single sign-on capability with SPNEGO TAI	229
Configuring single sign-on capability with Enterprise Identity Mapping	250
Configuring single sign-on capability with Lotus Domino	262
Configuring single sign-on capability with Tivoli Access Manager or WebSEAL	265
Propagating security attributes among application servers	279
Configuring the authentication cache	282
Security cache properties	282
Configuring IIOp authentication	283
Configuring Common Secure Interoperability Version 2 inbound authentication	283
Configuring Common Secure Interoperability Version 2 outbound authentication	287
Example: Common Secure Interoperability Version 2 scenarios	291
Configuring RMI over IIOp.	297
Configuring inbound transports	298
Configuring outbound transports	302
Performing identity mapping for authorization across servers in different realms	305
Common Secure Interoperability Version 2 and Security Authentication Service client configuration	319
Java Authentication and Authorization Service	324
Java Authentication and Authorization Service authorization	324
Using the Java Authentication and Authorization Service programming model for Web authentication	326
Chapter 6. Authorizing access to resources	329
Authorization technology	329
Administrative roles and naming service authorization	330
Role-based authorization	334
Administrative roles	336
Enterprise bean component security	339
Authorization providers	339
Delegations	351
Programmatic login	353
Authorizing access to J2EE resources using Tivoli Access Manager	360
Using the default authorization provider	361
Enabling an external JACC provider	364
Authorizing access to administrative roles	382
Administrative user roles settings and CORBA naming service user settings	383
Administrative group roles and CORBA naming service groups	385
Assigning users to naming roles	387
Propagating administrative role changes to Tivoli Access Manager	387
The migrateEAR utility for Tivoli Access Manager	388
Chapter 7. Securing communications	391
Secure communications using Secure Sockets Layer	391
Secure Sockets Layer configurations	397

Keystore configurations	402
Dynamic outbound selection of Secure Sockets Layer configurations	405
Central management of Secure Sockets Layer configurations	407
Secure Sockets Layer node, application server, and cluster isolation	408
Default self-signed certificate configuration	413
Dynamic configuration updates	423
Management scope configurations	424
Certificate management using iKeyman	425
Certificate management	426
Creating a Secure Sockets Layer configuration	429
SSL certificate and key management	432
SSL configurations for selected scopes	433
SSL configurations collection	434
SSL configuration settings	435
Creating a custom trust manager configuration	436
Creating a custom key manager	442
Associating a Secure Sockets Layer configuration dynamically with an outbound protocol and remote secure endpoint	448
Quality of protection (QoP) settings	457
ssl.client.props client configuration file	458
Creating a keystore configuration	465
Changing a keystore password	466
Recreating the .kdb keystore internal password record	466
Configuring a hardware cryptographic keystore	467
Managing keystore configurations remotely	468
Key stores and certificates collection	468
Key store settings	469
Key managers collection	470
Key managers settings	471
Creating a self-signed certificate	472
Replacing an existing self-signed certificate	472
Creating a certificate authority request	473
Certificate request settings	474
Personal certificates collection	475
Personal certificates settings	476
Personal certificate requests collection	478
Personal certificate requests settings	479
Extract certificate request	480
Receiving a certificate issued by a certificate authority	480
Replace a certificate	483
Extracting a signer certificate from a personal certificate	484
Extract certificate	484
Extract signer certificate	485
Retrieving signers using the retrieveSigners utility at the client	485
Changing the signer auto-exchange prompt at the client	486
Importing a signer certificate from a truststore to a z/OS keyring	487
Exporting a signer certificate from WebSphere Application Server for z/OS to a truststore	488
Importing a signer certificate from a truststore to a z/OS keyring	489
Exporting a signer certificate from WebSphere Application Server for z/OS to a truststore	490
Retrieving signers from a remote SSL port	491
Retrieve from port	492
Adding a signer certificate to a keystore	493
Add signer certificate	493
Signer certificates collection	494
Signer certificate settings	494
Exchanging signer certificates	495

Key stores and certificates exchange signers	496
Configuring certificate expiration monitoring	496
Manage certificate expiration settings.	497
Notifications	499
Notifications settings	499
Key management for cryptographic uses	500
Creating a key set configuration.	501
Active key history collection	503
Add key alias reference settings	503
Key sets collection	504
Key sets settings	504
Creating a key set group configuration	506
Example: Retrieving the generated keys from a key set group	507
Example: Developing a key or key pair generation class for automated key generation	508
Key set groups collection	511
Key set groups settings	511
Chapter 8. Developing extensions to the WebSphere security infrastructure	515
Developing standalone custom registries	515
Creating a classes subdirectory in your profile for custom classes	516
Example: Standalone custom registries	517
Result.java file	517
UserRegistry.java files	518
Implementing custom password encryption	525
Developing applications that use programmatic security	525
Protecting system resources and APIs (Java 2 security)	526
Developing with programmatic security APIs for Web applications	547
Developing with programmatic APIs for EJB applications	551
Customizing Web application login.	555
Example: Form login	556
Developing servlet filters for form login processing	559
Customizing application login with Java Authentication and Authorization Service	563
Developing programmatic logins with the Java Authentication and Authorization Service	563
Configuring programmatic logins for Java Authentication and Authorization Service	567
Customizing an application login to perform an identity assertion	586
Customization of a server-side Java Authentication and Authorization Service authentication and login configuration	588
Enabling identity assertion with trust validation	606
Secure transports with JSSE and JCE programming interfaces	607
Configuring Federal Information Processing Standard Java Secure Socket Extension files	611
Implementing tokens for security attribute propagation	613
Implementing a custom propagation token	613
Implementing a custom authorization token	622
Implementing a custom single sign-on token	630
Implementing a custom authentication token	640
Propagating a custom Java serializable object	649
Developing a custom interceptor for trust associations	652
Trust association interceptor support for Subject creation	656
Plug point for custom password encryption	658
Enabling custom password encryption	660
Chapter 9. Configuring security with scripting	663
Enabling and disabling administrative security using scripting	663
Enabling and disabling Java 2 security using scripting	665
Enabling authentication in the file transfer service using scripting	665
Propagating security policy of installed applications to a JACC provider using wsadmin scripting	666

Configuring the JACC provider for Tivoli Access Manager using the wsadmin utility	667
Disabling embedded Tivoli Access Manager client using wsadmin	669
Creating an SSL configuration at the node scope using scripting.	670
Creating self-signed certificates using scripting	672
Automating SSL configurations using scripting	673
Updating default key store passwords using scripting	676
Commands for the IdMgrConfig group of the AdminTask object	676
Commands for the IdMgrRepositoryConfig group of the AdminTask object	681
Commands for the IdMgrRealmConfig group of the AdminTask object.	770

Commands for the DescriptivePropCommands group of the AdminTask object	820
Commands for the TrustManagerCommands group of the AdminTask object	823
Commands for the keyManagerCommands group of the AdminTask object	827
Commands for the SSLConfigGroupCommands group of the AdminTask object	831
Commands for the DynamicSSLConfigSelections group of the AdminTask object.	836
Commands for the ManagementScopeCommands group of the AdminTask object	840
Commands for the WSCertExpMonitorCommands group of the AdminTask object	844
Commands for the KeySetGroupCommands group of the AdminTask object	850
Commands for the KeySetCommands group of the AdminTask object.	856
Commands for the KeyReferenceCommands group of the AdminTask object	862
Commands for the securityEnablement group of the AdminTask object	866
Commands for the CertificateRequestCommands group of the AdminTask object	872
Commands for the SignerCertificateCommands group of the AdminTask object	876
Commands for the PersonalCertificateCommands group of the AdminTask object	882
Commands for the SPNEGO TAI group of the AdminTask object.	892
Commands for the AuthorizationGroupCommands group of the AdminTask object	899
Commands for the ChannelFrameworkManagement group of the AdminTask object	913
Chapter 10. Granting authority to a profile using the i5/OS command line	919
Chapter 11. Revoking authority to a profile using the i5/OS command line	921
Chapter 12. Web applications	923
Securing Web applications using an assembly tool.	923
Security constraints	925
Security settings	925
Security role references.	926
Securing applications during assembly and deployment	927
Assigning users and groups to roles	928
Updating and redeploying secured applications	936
Deploying secured applications	937
Chapter 13. SIP applications	939
Securing SIP applications	939
Configuring security for the SIP container	939
Chapter 14. EJB applications	943
Securing enterprise bean applications	943
Configuring security for EJB 2.1 message-driven beans	945
Chapter 15. Client applications	947
Accessing secure resources using SSL and applet clients	947
Applet client security requirements.	947

Chapter 16. Web services	949
Configuring HTTP outbound transport level security with the administrative console.	949
HTTP SSL Configuration collection	949
Configuring HTTP outbound transport level security with an assembly tool	950
Configuring HTTP outbound transport-level security using Java properties	951
Transport level security	951
HTTP basic authentication.	952
Configuring HTTP basic authentication with the administrative console	952
HTTP basic authentication collection	953
Configuring HTTP basic authentication with an assembly tool.	953
Configuring HTTP basic authentication programmatically	954
Configuring additional HTTP transport properties using the JVM custom property panel in the administrative console	954
Configuring additional HTTP transport properties with an assembly tool	955
Configuring additional HTTP transport properties using the wsadmin command-line tool	957
Provide HTTP endpoint URL information	958
Specify endpoint URL prefixes for Web services.	958
Select default HTTP URL prefix.	958
Select custom HTTP URL prefix	959
Publish WSDL zip files settings	959
Securing Web services for Version 6 and later applications based on WS-Security	959
What is new for securing Web services	964
Web services security enhancements	979
High-level architecture for Web services security	983
Overview of platform configuration and default bindings	985
Security model mixture	988
Security considerations for Web services	989
Migrating Version 5.x applications with Web services security to Version 6.1 applications.	991
Default implementations of the Web services security service provider programming interfaces	1004
Default configuration	1007
Basic Security Profile compliance.	1013
Configuring an application for Web services security with an assembly tool	1014
Configuring trust anchors for the generator binding on the application level	1108
Configuring the collection certificate store for the generator binding on the application level	1113
Username token element.	1122
Nonce, a randomly generated token.	1123
Custom security token propagation	1124
rrdSecurity.props file	1124
Configuring the token generator on the application level	1125
Configuring the key locator for the generator binding on the application level.	1142
Configuring the key information for the generator binding on the application level	1148
Configuring the signing information for the generator binding on the application level.	1160
Configuring the encryption information for the generator binding on the application level	1176
Configuring trust anchors for the consumer binding on the application level	1188
Configuring the collection certificate store for the consumer binding on the application level	1189
Binary security token	1191
Configuring token consumer on the application level.	1191
Configuring the key locator for the consumer binding on the application level	1203
Configuring the key information for the consumer binding on the application level	1204
Configuring the signing information for the consumer binding on the application level	1207
Configuring the encryption information for the consumer binding on the application level	1211
Hardware cryptographic device support for Web Services Security	1213
Retrieving tokens from the JAAS Subject in a server application	1216
Retrieving tokens from the JAAS Subject in an application	1217
Configuring trust anchors on the server or cell level	1217
Configuring the collection certificate store for the server or cell-level bindings	1218

Distributed nonce caching	1220
Configuring a nonce on the server or cell level	1221
Configuring token generators on the server or cell level	1222
Configuring the key locator on the server or cell level	1234
Configuring the key information for the generator binding on the server or cell level	1236
Configuring the signing information for the generator binding on the server or cell level	1238
Configuring the encryption information for the generator binding on the server or cell level	1241
Configuring trusted ID evaluators on the server or cell level	1242
Configuring token consumers on the server or cell level	1246
Configuring the key information for the consumer binding on the server or cell level	1254
Configuring the signing information for the consumer binding on the server or cell level	1255
Configuring the encryption information for the consumer binding on the server or cell level	1258

How to send your comments

Your feedback is important in helping to provide the most accurate and highest quality information.

- To send comments on articles in the WebSphere Application Server Information Center
 1. Display the article in your Web browser and scroll to the end of the article.
 2. Click on the **Feedback** link at the bottom of the article, and a separate window containing an e-mail form appears.
 3. Fill out the e-mail form as instructed, and click on **Submit feedback** .
- To send comments on PDF books, you can e-mail your comments to: **wasdoc@us.ibm.com** or fax them to 919-254-0206.

Be sure to include the document name and number, the WebSphere Application Server version you are using, and, if applicable, the specific page, table, or figure number on which you are commenting.

When you send information to IBM, you grant IBM a nonexclusive right to use or distribute the information in any way it believes appropriate without incurring any obligation to you.

Chapter 1. Overview and new features for securing applications and their environment

Use the links provided in this topic to learn more about the security infrastructure.

“What is new for security specialists”

This topic provides an overview of new and changed features in security.

Security

This topic describes how IBM WebSphere Application Server provides security infrastructure and mechanisms to protect sensitive Java 2 Platform, Enterprise Edition (J2EE) resources and administrative resources and to address enterprise end-to-end security requirements on authentication, resource access control, data integrity, confidentiality, privacy, and secure interoperability.

“Security planning overview” on page 16

Several communication links are provided from a browser on the Internet, through Web servers and product servers, to the enterprise data at the back-end. This topic examines some typical configurations and common security practices. WebSphere Application Server security is built on a layered security architecture. This section also examines the security protection offered by each security layer and common security practice for good quality of protection in end-to-end security.

Samples

The Samples Gallery offers:

- **Login - Form Login**

The Form Login Sample demonstrates a very simple example of how to use the login facilities for WebSphere Application Server to implement and configure login applications. The Sample uses the Java 2 Platform, Enterprise Edition (J2EE) form-based login technology to customize the look and feel of the login screens. It uses servlet filters to log the user information and the date information. The Sample finishes the session by using the form-based logout function, an IBM extension to the J2EE specification.

- **Login - JAAS Login**

The JAAS Login Sample demonstrates how to use the Java Authentication and Authorization Service (JAAS) with WebSphere Application Server. The Sample uses server-side login with JAAS to authenticate a real user to the WebSphere security run time. Based upon a successful login, the WebSphere security run time uses the authenticated Subject to perform authorization checks on a protected stateless session enterprise bean. If the Sample runs successfully, it displays all the principals and public credentials of the authenticated user.

What is new for security specialists

This version contains many new and changed features for those who are responsible for securing applications and the application serving environment.

New in Version 6.1! indicates new features or changes implemented at the Version 6.1 level. Unmarked items are Version 6.0 improvements that apply also to Version 6.1, which should interest anyone migrating to Version 6.1 from Version 5.x.

Deprecated and removed features describes features that are being replaced or removed in this or future releases.

Ease of use

Administrative security enabled out of box

New in Version 6.1! Access to the administrative system and its data is now protected by default. When creating a profile, whether during or after installation, you will be prompted whether to keep the default. The default is for administrative security to be enabled with the file based user repository as the user registry. The file based repository is implemented using virtual member manager. For information about this option, see “Managing the realm in a federated repository configuration” on page 115.

Simplified security configuration and administration

Rest assured that if you are migrating from a prior product version, the existing security configuration will be preserved.

New in Version 6.1!

- Simplified administrative console security panels
- New security wizard
- Security configuration reporting tool

Automatically generated server IDs

New in Version 6.1! This version distinguishes between the user identities for administrators who manage the environment and server identities for authenticating server to server communications. In most cases, server identities are automatically generated and are not stored in a repository. You can change the ID if you like.

You no longer need to specify a server user ID and password during security configuration, unless using a mixed cell environment. To maintain backwards compatibility, you must specify the server user ID.

Simplified WebSphere® key and certificate management

See “Local operating system settings” on page 91.

New in Version 6.1! Simplified WebSphere key and certificate management has been added to:

- Allow you to use the key management tools from the console
- Make it easier to configure Secure Sockets Layer (SSL) attributes
- Manage Web server and plug-in certificates from the console
- Use the TrustManager to automatically trust hosts or signers
- Make it easier to refresh an expiring certificate

Federate various repositories, so you can manage them as one

New in Version 6.1! Inclusion of virtual member manager in this release provides a single model for managing organizational entities. You can configure a realm that consists of identities in the file-based repository that is built into the system, in one or more external repositories, or in both the built-in, file-based repository and in one or more external repositories.

Currently most WebSphere Application Server applications have their own models and components for managing organizational entities, and they provide different levels of security. Most applications are dependent on specific types and brands of repositories, assume a specific schema for the data in those repositories, and are not able to use repositories with existing data. Virtual member manager helps these applications by providing them a common model, secure access to various brands and types of repositories, and the ability to use repositories with existing data. The single model includes a set of organizational entity types and their properties, a repository-independent application programming interface (API) and a Service Provider Programming Interface (SPI) for plugging in repositories. XPath is chosen as the search language in the API and SPI.

For more information, see “Federated repositories” on page 169.

Standards support and interoperability

SPNEGO support for single sign-on authentication through Windows desktop

New in Version 6.1! The Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) protocol allows flowing Kerberos tokens from web browsers such as Mozilla FireFox or Microsoft Internet Explorer. This enables seamless single-sign-on experiences on Windows desktops with web browsers that support SPNEGO.

See “Configuring SPNEGO TAI in WebSphere Application Server” on page 233.

Interoperability with other vendors on WS-Security

New in Version 6.1! The product now supports the WS-I Basic Security Profile 1.0, which promotes interoperability by addressing the most common problems encountered from implementation experience to date.

See Web Services-Interoperability Basic Profile.

JCA 1.5 support

WebSphere Application Server Version 6.0.x supports the J2EE Connector architecture (JCA) Version 1.5 specification, which provides new features such as the inbound resource adapter. For more information, see J2EE Connector Architecture resource adapters.

From a security perspective, WebSphere Application Server Version 6.0.x provides an enhanced custom principal and credential mapping programming interface and custom mapping properties at the resource reference level. The custom Java Authentication and Authorization Service (JAAS) login module, which was developed for JCA principal and credential mapping for WebSphere Application Server Version 5.x, is still supported.

Web services security

A pluggable architecture increases the extensibility of Web services security. The implementation includes many of the features that are described in the Organization for the Advancement of Structured Information Standards (OASIS) Web Services Security Version 1 standard. As part of this standard, WebSphere Application Server supports custom, pluggable tokens that are used for signing and encryption, pluggable signing and encryption algorithms, pluggable key locators for locating a key that is used for digital signature or encryption, signing or encrypting elements in a SOAP message, and specifying the order of the signing or encryption processes.

See “What is new for securing Web services” on page 964.

Messaging security

For security changes pertaining to service integration, search the information center for key word: cjr0420

When administrative security is enabled, the default behavior is for a secure bus to use secure transport protocols. To connect to a secure bus, a user must explicitly be granted the bus connector role. The default bootstrap endpoint is enhanced to use BootstrapSecureMessaging rather than BootstrapBasicMessaging.

For additional details, search the information center for keyword: cjr0009

Web authentication improvements

Separate Web authentication and authorization

New in Version 6.1! Now, Web authentication can be performed with or without Web authorization, and Web client’s authenticated identity is available whether or not Web authorization is required. An authenticated identity is persisted both for protected and unprotected resources. Without the separation of Web authentication and Web authorization, a Web authenticated identity is not available when Web authorization is not required, and programmatic security can not work independently without container declarative security.

Enhanced control over Web authentication behavior

New in Version 6.1! WebSphere Application Server provides enhanced control over the authentication behavior for a Web client. Depending upon the option that you select, WebSphere Application Server can retain the authentication data for future use. Also, when you use certificate authentication and authentication fails, you can enable the Application Server to challenge the Web client for a user ID and password.

For more information, see “Authentication mechanisms” on page 170.

Portlet URL security

New in Version 6.1! The product enables direct access to portlet Uniform Resource Locators (URLs), just like servlets. For security purposes, portlets are treated similar to servlets. Most portlet security uses the underlying servlet security mechanism. However, portlet security information resides in the `portlet.xml` file, while the servlet and JavaServer Pages files reside in the `web.xml` file. Also, when you make access decisions for portlets, the security information, if any, in the `web.xml` file is combined with the security information in the `portlet.xml` file. Portlet security must support both programmatic security, that is `isUserInRole`, and declarative security

For more information, see “Portlet URL security” on page 172.

Web authentication using the Java Authentication and Authorization Service programming model

WebSphere Application Server Version 6.0.x enables you to use the Java Authentication and Authorization Service (JAAS) programming model to perform Web authentication in your application code. To use this function, you must create your own JAAS login configuration by cloning the `WEB_INBOUND` login configuration and define a `cookie=true` login option. After a successful login using your login configuration, the Web login session is tracked by single sign-on (SSO) token cookies. This option replaces the `SSOAuthenticator` interface, which was deprecated in WebSphere Application Server Version 4.

For more information, see “Java Authentication and Authorization Service authorization” on page 324.

Expanded capabilities

Larger variety of administrative roles

New in Version 6.1! Even more administrative roles are defined to provide degrees of authority that are needed to perform certain administrative functions from either the Web-based administrative console or the system management scripting interface. The newest roles are `Deployer` and `AdminSecurityManager`, available through administrative scripting (`wsadmin`).

For more information, see “Administrative roles” on page 336.

Fine grained administrative role authorization

New in Version 6.1! In prior releases, users granted administrative roles could administer all of the resource instances under the cell. Now the product is more fine-grained, meaning that access can be granted to each user per resource instance.

For more information, see “Fine-grained administrative security” on page 48.

Hardware cryptographic device support for Web services security

New in Version 6.1! Web services security now supports the use of cryptographic hardware devices in two different ways. The hardware cryptographic device can be used to accelerate the cryptographic operations. Also, cryptographic keys can be stored on the hardware cryptographic device and never leave the device.

See “Hardware cryptographic device support for Web Services Security” on page 1213.

Custom password encryption

A plug point for custom password encryption must be created to encrypt and decrypt all passwords in WebSphere Application Server that are currently encoded or decoded using Base64-encoding. The implementation class of this plug point has the responsibility for managing keys, determining the encryption algorithm to use, and for protecting the master secret.

For more information, see the Technote <http://www.ibm.com/support/docview.wss?rs=180&uid=swg21210244>.

Enhanced LDAP support

In addition to support for multiple Lightweight Directory Access Protocol (LDAP) directory services binding and failover, you can dynamically update LDAP binding information without first stopping and restarting application servers.

For more information, see <http://www-1.ibm.com/support/docview.wss?rs=180&uid=swg21210243>.

Programming interfaces for implementing identity assertion with trust validation

If you want an application or system provider to perform an identity assertion with trust validation, it can be accomplished by use of the Java Authentication and Authorization Service (JAAS) login framework, where trust validation is performed in one login module and credential creation in another. These two custom login modules are used to create a JAAS login configuration that performs a login to an identity assertion.

For more information, see “Identity assertions with trust validation” on page 214.

Java 2 security manager

WebSphere Application Server Version 6.0.x provides you with greater control over the permissions granted to applications for manipulating non-system threads. You can permit applications to manipulate non-system threads using the `was.policy` file. However, these thread control permissions are disabled by default.

For more information, see “Configuring the `was.policy` file” on page 535.

SSL channel framework

The Secure Sockets Layer channel framework incorporates the new IBMJSSE2 implementation and separates the security function of Java Secure Sockets Extension (JSSE) from the network communication function.

See Transport chains.

Identity management capabilities

Today’s security infrastructure is identity driven. Secure business applications ask two key questions: who are you, and what can you access? IBM offers a complete solution for identity management across the enterprise. Learn about the identity management capabilities provided by WebSphere Application Server in conjunction with other WebSphere products and Tivoli.

For an identity management primer, refer to the identity management white paper, Help improve security and lower costs with repeatable identity management solutions. The paper describes the:

- Business landscape that makes identity management increasingly important
- Benefits of deploying an identity-driven infrastructure
- Basic functions to expect within an identity-driven infrastructure

- Known patterns into which business operations fall
- Tivoli software that provides solutions for addressing the patterns

WebSphere Application Server includes virtual member manager, for the primary purpose of providing out of box security and an additional user registry option: the federated, file-based repository. See “Federated repositories” on page 169 for details. Virtual member manager provides additional identity management capabilities. So do many Tivoli products that extend and complement the solid base for identity management now provided by the WebSphere platform.

As described later, the IBM portfolio supports the following identity management capabilities.

- Offer single sign on for your users’ convenience
- Control access to Web applications
- Administer identities
- Provision users
- Federate disparate sources of identity data
- Provide standard directory services to applications
- Use strong authentication
- Control and manage access to Web applications, Web services, and your Service Oriented Architecture (SOA)
- Ensure regulatory compliance
- Secure your business portal
- Provide instance based access control for business rules
- Secure work flows containing people interactions
- Secure integration with other business applications
- Government solutions

Products that work in conjunction with WebSphere Application Server to provide a full range of identity management capabilities include, but are not limited to:

- Tivoli products for identity management
- WebSphere Process Server
- WebSphere Portal

Offer single sign on for your users’ convenience

With WebSphere Application Server, Web users can authenticate once when accessing Web resources across multiple application servers. Choices for securely negotiating and authenticating HTTP requests for secured resources include trust association interceptor (TAI) that uses the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO), or using Tivoli Access Manager WebSEAL or Tivoli Access Manager plug-in for Web servers as reverse proxy servers to provide access management and single sign-on (SSO) capability. See “Implementing single sign-on to minimize Web user authentications” on page 226 for details.

Add Tivoli Access Manager for e-business to achieve Web SSO and secure session management across e-communities, to securely extend your business processes to business partners and business affiliates. You can enable a flexible SSO to Web-based applications that can span multiple sites or domains with a range of SSO options, to help eliminate help-desk calls and other security problems associated with multiple passwords. By integrating with other SSO providers (such as Kerberos from a Microsoft domain logon, and client/server SSO solutions) Access Manager goes beyond ‘reduced sign-on’ to help implement a single authentication for the user across all system interactions.

Upgrade to Tivoli Federated Identity Manager to achieve standardized cross-domain SSO. The product supports a number of SSO federated identity and Web Services security standards, including Liberty Alliance specifications, SAML, WS-Federation, WS-Security and WS-Trust. This

enables the company or the provider to interoperate and get SSO benefits from partners who implement any of these standards. Single Sign On (SSO) simplifies sign on for third-party users who typically have a primary relationship with their home organization. A federated business model enables a company to obtain trusted information about a third-party identity (such as customer, supplier, or a client employee) from that user's home organization without having to create, enroll, or manage a new account.

Reduce help-desk calls and other security problems associated with multiple passwords, using Tivoli Access Manager for e-business. Achieve a flexible SSO to Web-based applications that can span multiple sites or domains with a range of SSO options. By integrating with other SSO providers (such as Kerberos from a Microsoft domain logon, and client/server SSO solutions) Access Manager goes beyond 'reduced sign-on' to help implement a single authentication for the user across all system interactions.

Enhance user experience and reduced help desk costs, with one less password to remember. Use Tivoli Access Manager for e-business to achieve Microsoft desktop single sign on. Windows users can be automatically authenticated to applications protected by Access Manager for e-business.

Improve end-user experience through Single Sign On (SSO) implemented by Tivoli Federated Identity Manager.

Reduce administrative cost by delivering rapid enrollment and personalized access to end-users at their convenience with integrated self-care. The Tivoli Access Manager for e-business Self-Registration capability enables end-users to quickly self-enroll to the Enterprise Web environment without requiring manual intervention or lengthy procedures.

Administer identities

WebSphere Application Server provides fine-grained administration.

Use these products in conjunction with WebSphere Application Server for additional capabilities.

Achieve centralized administration of both access control and data protection policies across mainframe and distributed servers with Tivoli Access Manager for Business Integration. An authorized administrator can perform Web-based administration remotely without visiting a system or deploying a special administration client.

Define and manage a centralized authentication, access, and audit policy for a broad range of business initiatives with Tivoli Access Manager for e-business. Initiative include employee, customer and partner portals, CRM systems, e-procurement, cross-company single sign-on (SSO) projects, and outsourcing projects.

Manage users and groups, including dynamic and nested groups. Achieve dynamic group support with Tivoli Access Manager for e-business. An upper limit on static groups makes dynamic groups the only option in some cases, while dynamic groups may be preferred in other environments. Integrates with existing data management environments.

Use Tivoli Access Manager for e-business to achieve integrated security management for critical WebSphere applications leveraging IMS, CICS and DB2 transactions on mainframe and non-mainframe platforms.

Reduce administrative cost by delivering rapid enrollment and personalized access to end-users at their convenience with integrated self-care. The Tivoli Access Manager for e-business Self-Registration capability enables end-users to quickly self-enroll to the Enterprise Web environment without requiring manual intervention or lengthy procedures.

Use the Web Portal Manager of Tivoli Access Manager for Operating Systems for easier, graphically based management.

Access Control Lists (ACLs) help you pro-actively prevent security breaches across your enterprise, using Tivoli Access Manager for Operating Systems.

Scale to tens of millions of entries, as well as groups of hundreds of thousands of members with Tivoli Directory Server.

Enhance directory security with the password strength features of Tivoli Directory Server. Enable the pre-expiration of passwords, the definition of password rules, maintenance of password history and failed attempt account in correlation with ACL protection.

Manage organizations and entities. Lower overhead costs by automatically managing accounts, credentials, and access rights throughout the user life cycle with workflow provided by Tivoli Identity Manager.

Reduce help-desk costs and ease the burden of daily administration on help-desk and IT staff with the self-service interfaces of Tivoli Identity Manager. Enable users to perform password resets, password synchronization, and modification to personal information without administrative intervention.

Use Tivoli Identity Manager to cut elapsed turn-on time for new accounts; improve productivity by allowing end users to rapidly reset and synchronize their own passwords; and decrease errors by automating user submission and approval requests.

Take advantage of the various products' APIs to integrate and customize your identity management solution.

Provision users

Use these products in conjunction with WebSphere Application Server for additional capabilities.

Quickly connect users to appropriate resources while reducing administration workload, with Tivoli Identity Manager. Embedded provisioning engine and universal integration tools automate the implementation of administrative requests on the environment, and provide universal connectors for extending the management model to support new and custom environments.

Demonstrate enforcement of internal controls to auditors and eliminate orphan or over privileged accounts. Use Tivoli Identity Manager closed loop user provisioning to detect and correct discrepancies between approved account access and local privileges.

Implement and modify provisioning policies more quickly and accurately. Use Tivoli Identity Manager to simulate the impact of provisioning policy on user accounts before committing changes.

Centralize the definition of users and provisioning of user services with the centralized administration of Tivoli Identity Manager. Role and rule-based delegated administration enables grouping of users according to business needs and delegation of administrative privileges along organizational and geographical boundaries.

Tivoli Identity Manager provisioning is integrated with access and identity. Access to Web applications and other applications can be determined by one user profile. The product interacts directly with users and with two external types of systems: identity sources and access control mechanisms. The identity systems deliver authoritative information about the users that need accounts. The provisioning system communicates directly with access control systems to create accounts, supply user information and passwords and define the entitlements of the account.

Pair Tivoli Identity Manager with WebSphere Process Server to achieve identity-based workflow. Streamlined automated workflow can decrease errors and inconsistency in business processes. Intelligent approval routing automates the submission and approval processes for access requests and changes to user information.

Federate disparate sources of identity data

Federated identity is a technology for brokering identities between companies or business units. Federated identity management is the set of business agreements, technical agreements and policy agreements that enable companies to partner to lower their overall identity management costs and improve user experience. It leverages the concept of a portable identity - the idea that

your identity is not bound to a specific credential - to simplify the administration of users in a federated business relationship. Federation simplifies integration because there is a common way to share identities between companies and manage user sessions. Identity Federation services within a Service Oriented Architecture (SOA) ensure that users have simplified access and single sign on to the composite application environment.

Use these products in conjunction with WebSphere Application Server for additional capabilities.

Use Tivoli Access Manager for e-business to provide first-point-of-contact and session management that typically are prerequisites to federation with IBM Tivoli Federated Identity Manager.

Connect to disparate data sources with Tivoli Directory Integrator as an enterprise directory.

Ensure data availability and to maximize server response time, using Tivoli Directory Server to achieve single-master multiple replication, multiple-master replication, cascaded, gateway and partial replication.

Simplify the administration and the lifecycle management of user identities and obtain a simple, loosely-coupled model for managing identity and access to resources that span companies or security domains with the open standards and specifications support of Tivoli Federated Identity Manager, including Liberty, SAML, WS-Federation, WS-Security and WS-Trust. Works with standards based, off-the-shelf products.

Reduce administration and provisioning costs related to managing identities for third-party users, with Tivoli Federated Identity Manager. Rather than having to enroll third-party users into a company's internal identity systems, federated identity management enables IT service providers to offload the cost of user administration to their business partner companies. Because the business partner company acts like an identity provider, the service provider does not have to take on the burden of user administration costs such as user enrollment, account management, password management, password reset, help desk, or customer care costs.

Simplify integration with a common way to share identities between companies and manage user sessions. Tivoli Federated Identity Manager facilitates "straight through processing" techniques because the identity provider does not have to replicate or stage business processes on behalf of a service provider. By employing Tivoli Access Manager for e-business (included with FIM), FIM is able to provide integrated session management, significantly facilitating inter-company transactions. With a federated identity model, identity providers have an opportunity to streamline inter-company transactions, thereby reducing costs, and simplifying integration.

Obtain great flexibility for synchronization, using Tivoli Directory Integrator.

Simplify integration between your company and your partners' Web sites and business applications, including simplified session management with Tivoli Federated Identity Manager.

Provide standard directory services to applications

WebSphere Application Server supports a variety of registry and repository choices, including Lightweight Directory Access Protocol (LDAP) directories. See "Selecting a registry or repository" on page 87.

Use these products in conjunction with WebSphere Application Server for additional capabilities.

Obtain rapid time to value and save development costs with Tivoli Access Manager for Business Integration for application-level data protection for WebSphere MQ-based applications. Implement comprehensive security without writing complex security code, or modifying or recompiling existing applications.

Store credentials in Novell eDirectory with Tivoli Access Manager for Business Integration.

Achieve integration with over 70 ISV offerings, with Tivoli Access Manager for e-business. Offerings including Siebel CRM, SAP, PeopleSoft and Portal solutions from WebSphere, Plumtree, and others. Enterprises benefit from a common security model (authentication, access control, Single Sign On and audit) across the e-business, ISV and legacy applications. This reduces costly

integrations and delivers rapid time to value in solution deployment because enterprises can standardize on a single identity and access management platform.

Deploy the security architecture of your choice due to the multiple directory support of Tivoli Access Manager for e-business.

Synchronize and exchange information between applications or directory sources with Tivoli Directory Integrator.

Manage data across a variety of repositories providing the consistent directory infrastructure needed for a wide variety of applications, including security and provisioning, with Tivoli Directory Integrator.

Leverages existing investments in directory and identity repositories, platforms, and operating systems with Tivoli Directory Integrator.

Avoid the time-consuming design of schemata, which can slow the deployment of the LDAP directory. Tivoli Directory Server provides comprehensive, extensible, and dynamically updatable schema.

Manage users and groups, including dynamic and nested groups. Achieve dynamic group support with Tivoli Access Manager for e-business. An upper limit on static groups makes dynamic groups the only option in some cases, while dynamic groups may be preferred in other environments. Integrates with existing data management environments.

Use Tivoli Access Manager for e-business to achieve integrated security management for critical WebSphere applications leveraging IMS, CICS and DB2 transactions on mainframe and non-mainframe platforms.

Reduce administrative cost by delivering rapid enrollment and personalized access to end-users at their convenience with integrated self-care. The Tivoli Access Manager for e-business Self-Registration capability enables end-users to quickly self-enroll to the Enterprise Web environment without requiring manual intervention or lengthy procedures.

Use strong authentication

- With Tivoli Access Manager, WebSphere Application Server supports integration with smart cards and tokens. See “Configuring single sign-on capability with Tivoli Access Manager or WebSEAL” on page 265.

Control and manage access to Web applications, Web services, and Service Oriented Architecture

WebSphere Application Server provides a solid base for protecting Web applications and Web services in a Service Oriented Architecture. See “Securing Web services for Version 6 and later applications based on WS-Security” on page 959.

Use these products in conjunction with WebSphere Application Server for additional capabilities.

Web applications

Leverage a common security policy model with Tivoli Access Manager for e-business to with the Tivoli Access Manager.

Achieve highly secure e-business with Tivoli Access Manager for e-business, which provides flexible deployment that supports proxies, plug-ins, and agents.

Enhance application and database security with Tivoli Access Manager for Operating Systems. Restricts ability to switch user IDs. Prevents deliberate or accidental loss of application data, tampering with log files, and prevents unauthorized assumption of application administrative IDs.

Eliminate many user-access problems, while still using the standard UNIX authentication mechanisms, with Tivoli Access Manager for Operating Systems. Login Policy Enforcement tracks the UNIX login process and applies policies that prevent unauthorized access, such as the number of permitted failed login attempts before the user is locked out.

Ensure application speed and user experience are not impeded by access control decision speed with the multi-threaded architecture enabled by Tivoli Access Manager for Operating Systems.

Prevent password theft with Tivoli Access Manager for Operating Systems.

Ensure security and consistent policy on your most sensitive systems with the centralized control and local autonomy provided by Tivoli Identity Manager.

Defend against the top security threat that enterprises face: misbehavior by internal users and employees with Tivoli Access Manager for Operating Systems.

Ramp up quickly to effective security with Tivoli Access Manager for Operating Systems. Fast Track Policy Modules are pre-written, customizable, best-practice policies.

Achieve centralized administration of security policy across the enterprise with Tivoli Access Manager for Operating Systems.

Create the authoritative data spaces needed to expose only trustworthy data to advanced software applications such as Web services, with Tivoli Directory Integrator.

Authorization services also help application developers use standard development tools such as Eclipse or Rational by providing a standards-based API interfaces.

Web services

Integrates seamlessly with a wide variety of repositories and technologies and enables integration with new and existing Web Services in the enterprise through the standards & Web Services support of Tivoli Directory Integrator.

Extend the reach of the directory to web services with Tivoli Directory Server. Expose the directory and deliver it to web services through XML coding. An enterprise's customers could, for example, make changes to directory data such as phone numbers or street addresses themselves over the Internet rather than calling in to customer service.

Simplify administration of security in cross-enterprise business processes by delivering "security as services" with Tivoli Federated Identity Manager.

Simplify the administration and the lifecycle management of user identities and obtain a simple, loosely-coupled model for managing identity and access to resources that span companies or security domains with the open standards and specifications support of Tivoli Federated Identity Manager, including Liberty, SAML, WS-Federation, WS-Security and WS-Trust.

SOA

SOA Management: Securing Web Services discusses the challenges of security in a Service Oriented Architecture (SOA). The security environment is still disjointedly hard wired into organizational silos segmented into network security, perimeter security, desktop security, server security and application security. Point solutions solve a partial need but they don't work in unison. Hence, they can't appreciably lower system risk, improve platform integrity, or mitigate the risk of broadening access. SOA adoption introduces new and unforeseen challenges with security integration, identity and security management.

- Multiple Application Platforms (WebSphere, Microsoft or SAP)
- Multiple Security Domains (internal, external, business unit silos, extranet)
- Multiple Security Credentials (Kerberos, SAML, WS-Security, RACF)
- Multiple Protocols (SOAP, HTTP/S, JMS, MQ)
- Lack of "thread of identity" across the services context

Composite Applications must deal with the challenges of independent security and identity silos. The security solution needs to secure end user interactions as well service interactions (application to application). Security management needs to provide unified customer views for the composite application. The "thread" of user identity needs to be preserved end to end for auditing and compliance purposes.

Deliver policy-based integrated security management for SOA Web Services with Tivoli Federated Identity Manager.

Authorization services provided by Tivoli products in the Tivoli identity management solution ensure that SOA components can apply consistent authorization policies for Web, HTTP, and Java resources, Web Services, SOAP (WSDL resources), MQ (Queues and Queue Managers) and even core infrastructure platforms such as UNIX and Linux Servers.

Authorization services in an SOA ensures that a common authorization abstraction model enables application platforms such as WebSphere, MS .NET, BEA and SAP to apply fine-grained authorization for these resource types.

Tivoli Access Manager for e-business implements a centralized policy service for SOA elements enabling business owners to delegate authorization decisions to a Policy server deployed in the SOA environment.

As SOA transactions originate across various channels and protocols it is important to have the centralized session management service of Tivoli Access Manager for e-business to enable various SOA components to have a "common view" of the current user session, for single sign on, single sign off, auditing and reporting, and so on.

Ensure regulatory compliance

Use these products in conjunction with WebSphere Application Server for additional capabilities.

Demonstrate specific compliance with the defined security policy Tivoli Access Manager for Business Integration by obtaining message-level audit function and audit record generation.

Maintain confidentiality of message data and allow for verification of data integrity with Tivoli Access Manager for Business Integration. Securing messages both while they are being processed by WebSphere MQ and while they travel from system to system reduces exposure of data from internal employees or vendors. It can be used as part of a HIPAA compliance solution.

Obtain a central point for reporting on security events and sample reports with Tivoli Access Manager for e-business. An audit and reporting service collects audit data from multiple enforcement points, as well as from other platforms and security applications.

Achieve easier, extended auditing and reporting capabilities with Tivoli Access Manager for e-business. Audit records are written in standard XML format. An information-gathering tool allows secure, centralized collection and reporting of audit, log, statistics, and such across the extended enterprise.

Tivoli Access Manager for Operating Systems combines full-fledged intrusion prevention—host-based firewall, application and platform protection, user tracking and controls—with robust auditing and compliance checking.

Obtain mainframe-class security and auditing in a lightweight, easy-to-use product with Tivoli Access Manager for Operating Systems.

Document compliance with government regulations, corporate policy and other security mandates using the persistent universal auditing of Tivoli Access Manager for Operating Systems.

Obtain extended auditing capabilities with Tivoli Access Manager for Operating Systems. Configurable audit events can track sensitive access attempts, provide security-related information on user activity, and can send events to a centralized event management console. Verify access policy through secure logging of security events.

Improve business compliance by helping to reduce security exposure with Tivoli Federated Identity Manager.

Address policy compliance needs, using Tivoli Identity Manager to produce centralized reports on security policy, access rights, and audit events to quickly respond to internal audits and regulatory mandates.

Quickly produce reports for internal audits and ensuring regulatory compliance, with Tivoli Identity Manager auditing and reporting mechanisms.

Enforces privacy policies across your IT infrastructure with Tivoli Privacy Manager for e-business.

Monitor access to personal information and generate detailed audit logs with Tivoli Privacy Manager for e-business.

Automatically generate reports detailing compliance to corporate policies with Tivoli Privacy Manager for e-business.

Help privacy officers, legal counsel and IT staff work together to build privacy rules that integrate policy into practices, without knowledge of IT systems in order to author policies. This is provided by Tivoli Privacy Manager for e-business.

Update policies in the future with minimal impact to the environment, using Tivoli Privacy Manager for e-business. Monitor and record users' privacy preferences on a separate system from individual applications. You can author one policy and deploy it everywhere there are monitored systems, as a cost-effective alternative to modifying or rewriting existing applications in order to incorporate preferences across applications.

Comply with internal audits and regulatory reviews with Tivoli Privacy Manager for e-business. It generates enterprise-wide reports showing policies deployed, enforcement locations and audit trails that detail the management of personal information according to privacy policies.

Control policies, storage locations, audit logs, preferences and consent across the enterprise with Tivoli Privacy Manager for e-business.

Rapidly develop and customize e-business monitors for applications, middleware data repositories and other systems that persistently store privacy-sensitive information with Tivoli Privacy Manager for e-business. Monitors for LDAP and Siebel 7 are included to allow monitoring, enforcement and auditing for LDAP and Siebel 7 applications.

Use Tivoli Security Compliance Manager to automate scans of servers and desktop systems, which can help reduce the cost and time associated with manual security checks.

Provide detailed reports to security officers and compliance auditors so they can take the appropriate steps to make individual systems and departments compliant, with Tivoli Security Compliance Manager.

Improve business operations and increase efficiencies through automation and centralization with Tivoli Security Compliance Manager.

Mediate security policy violations and risks using Tivoli Security Compliance Manager in conjunction with Tivoli automated security management tools.

Automate compliance tasks, monitor correspondence, reduce human error, and tame compliance costs with Tivoli Security Compliance Manager.

Use Tivoli Security Compliance Manager to ensure consistent security audits across the organization, reducing human error.

Reduce the cost and time associated with manual security checks, using the automated scans of server and desktop systems with Tivoli Security Compliance Manager.

Identify software security vulnerabilities prior to costly damage being inflicted by security incidents, using the security vulnerability scans of Tivoli Security Compliance Manager.

Quickly produce reports for audits and ensuring regulatory compliance with the reporting mechanisms of Tivoli Security Compliance Manager.

Manage and secure your business environments from your existing hardware and operating system platforms with Tivoli Access Manager for e-business.

Secure your business portal

Use Portal in conjunction with WebSphere Application Server to satisfy customers, reduce service costs, and enable customer profiles.

- Portal includes personalization features to be able to respond to end users based on identity (and things derived from identity, such as group memberships and user profile attribute values) and context using rules.
- Portal has its own access control for protecting Portal resources (pages and portlets) that are not visible in a securable way in a URL. This access control is based on user identity and group memberships.
- Portal has a basic user interface for user self-registration and self-care after creation. It also features basic User and Group administration interfaces, not intended to replace the management interfaces of the directory server, or to be as function-rich as TIM.

Provide instance based access control for business rules

Use these products in conjunction with WebSphere Application Server for additional capabilities.

Enact rules-enabled authorization checks with WebSphere Process Server. Its rules technology for conditions enables administrators to create rules depending on the role of an invoker, for example. Although it currently does not allow for checking on role and subject information specifically, developers can use a workaround. A Java code snippet can be used to retrieve this information and feed it into the rule condition.

Dramatically improve both how quickly your applications are deployed and how quickly they adapt, achieving rules based authorization with Tivoli Access Manager for e-business. Change access-influencing policy parameters without having to rewrite and recompile applications.

Reduce administrative costs with Tivoli Identity Manager. Role and rule-based delegated administration enables grouping of users according to business needs and delegation of administrative privileges along organizational and geographical boundaries.

Streamlined automated workflow can decrease errors and inconsistency in business processes. Tivoli Identity Manager automates the submission and approval processes for access requests and changes to user information.

Secure work flows containing people interactions

The staff resolution capabilities of WebSphere Process Choreographer, part of WebSphere Process Server, provide role-based staff assignment and are compatible with various directory services.

- WebSphere Application Server Enterprise Process Choreographer: Staff Resolution Architecture
- WebSphere Application Server Enterprise Process Choreographer: Displaying work items in the Web client
- Working with WebSphere Business Integration Server Foundation Process Choreographer

Secure integration with other business applications

Use these products in conjunction with WebSphere Application Server for additional capabilities.

Leverage your J2EE investment and enable applications to be managed as part of a consistent, policy-driven strategy with Tivoli Access Manager for e-business. The product supports J2EE, Java 2 and JAAS environments, with no plug-in required, no proprietary coding needed and no pre- or post-compile necessary.

Use Tivoli Federated Identity Manager to expand the business reach of service providers creating revenue generating opportunities.

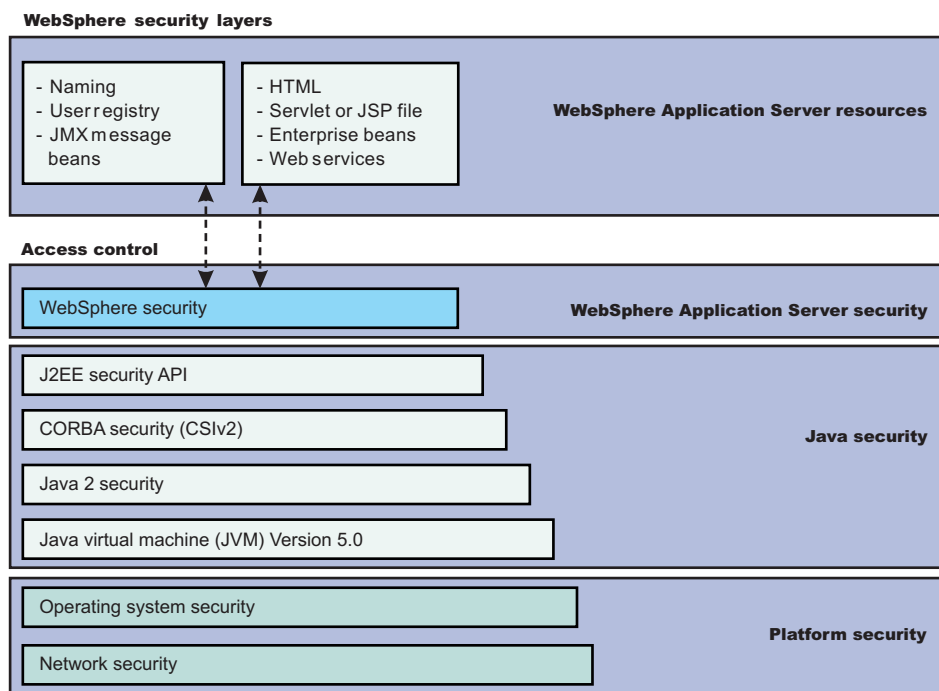

For information about Identity and Privacy Strategies Methodologies and Best Practices, see the related information link below:

Security planning overview

When you access information on the Internet, you connect through Web servers and product servers to the enterprise data at the back end. This section examines some typical configurations and common security practices. WebSphere Application Server security is built on a layered security architecture as shown in the following figure. This section also examines the security protection that is offered by each security layer and common security practice for good quality of protection in end-to-end security. The following figure illustrates the building blocks that comprise the operating environment for security within WebSphere Application Server:

The following information describes each of the components of WebSphere Application Server security, Java security, and Platform security that are illustrated in the previous figure.

WebSphere Application Server security

WebSphere security

WebSphere Application Server security enforces security policies and services in a unified manner on access to Web resources, enterprise beans, and JMX administrative resources. It consists of WebSphere Application Server security technologies and features to support the needs of a secure enterprise environment.

Java security

Java 2 Platform, Enterprise Edition (J2EE) security application programming interface (API)

The security collaborator enforces Java 2 Platform, Enterprise Edition (J2EE)-based security policies and supports J2EE security APIs.

CORBA security (CSlv2)

Any calls made among secure Object Request Brokers (ORB) are invoked over the Common Security Interoperability Version 2 (CSlv2) security protocol that sets up the

security context and the necessary quality of protection. After the session is established, the call is passed up to the enterprise bean layer.

V6.0.x

For backward compatibility, WebSphere Application Server supports the Secure Authentication Service (SAS) security protocol, which was used in prior releases of WebSphere Application Server and other IBM products.

Java 2 security

The Java 2 Security model offers fine-grained access control to system resources including file system, system property, socket connection, threading, class loading, and so on. Application code must explicitly grant the required permission to access a protected resource.

Java Virtual Machine (JVM) 5.0

The JVM security model provides a layer of security above the operating system layer. For example, JVM security protects the memory from unrestricted access, creates exceptions when errors occur within a thread, and defines array types.

Platform security

Operating system security

The security infrastructure of the underlying operating system provides certain security services for WebSphere Application Server. These services include the file system security support that secures sensitive files in the product installation for WebSphere Application Server. The system administrator can configure the product to obtain authentication information directly from the operating system user registry.

Network security

The Network Security layers provide transport level authentication and message integrity and confidentiality. You can configure the communication between separate application servers to use Secure Sockets Layer (SSL). Additionally, you can use IP Security and Virtual Private Network (VPN) for added message protection.

WebSphere Application Server Network Deployment installation

Important: A node agent instance exists on every computer node.

Each product application server consists of a Web container, an Enterprise Java Beans (EJB) container, and the administrative subsystem.

The WebSphere Application Server deployment manager contains only WebSphere Application Server administrative code and the administrative console.

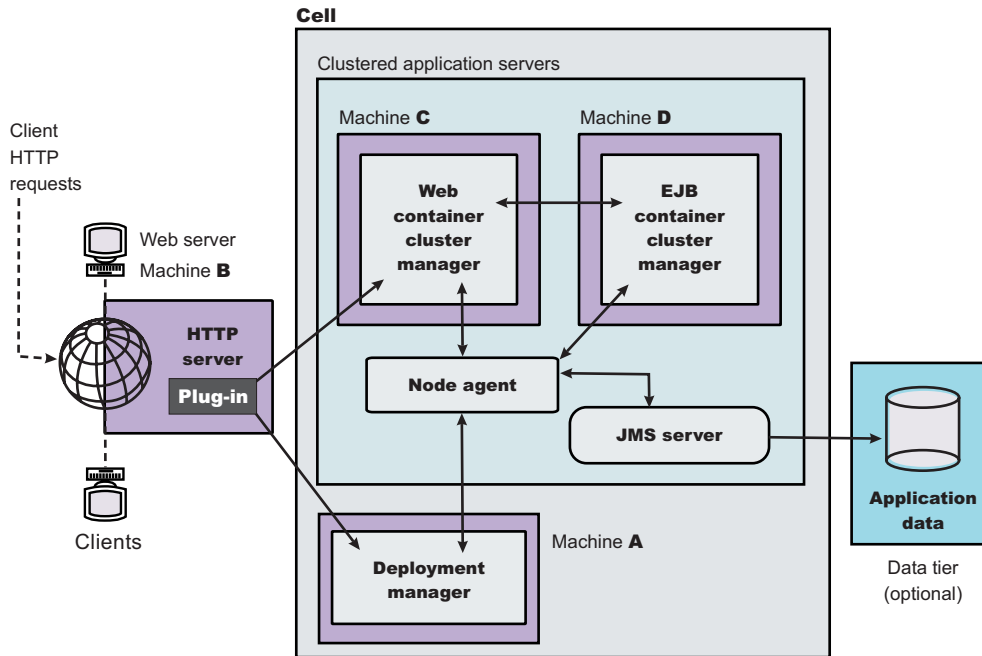

The administrative console is a special J2EE Web application that provides the interface for performing administrative functions. WebSphere Application Server configuration data is stored in XML descriptor files, which must be protected by operating system security. Passwords and other sensitive configuration data can be modified using the administrative console. However, you must protect these passwords and sensitive data. For more information, see “Encoding password in files” on page 1425.

The administrative console Web application has a setup data constraint that requires access to the administrative console servlets and JavaServer Pages (JSP) files only through an SSL connection when administrative security is enabled.

In WebSphere Application Server Version 6.0.x and earlier, the administrator console HTTPS port was configured to use `DummyServerKeyFile.jks` and `DummyServerTrustFile.jks` with the default self-signed certificate. The dummy certificates and keys must be replaced immediately after WebSphere Application Server installation; the keys are common in all of the installation and are therefore insecure. WebSphere Application Server Version 6.1 provides integrated certificate and key management, which generate distinct

private key and self-signed certificate with embedded server host name to enable host name verification. WebSphere Application Server Version 6.1 also enables integration with external certificate (CA) authority to use CA-issued certificates. The WebSphere Application Servers Version 6.1 installation process provides an option to enable administrative security during installation. As a result, a WebSphere Application Server process is secured immediately after installation.

The following figure shows a typical multiple-tier business computing environment.

Administrative security

V6.0.x WebSphere Application Servers interact with each other through CSv2 and Secure Authentication Services (SAS) security protocols as well as the HTTP and HTTPS protocols.

Important: SAS is supported only between Version 6.0.x and previous version servers that have been federated in a Version 6.1 cell.

You can configure these protocols to use Secure Sockets Layer (SSL) when you enable WebSphere Application Server administrative security. The WebSphere Application Server administrative subsystem in every server uses SOAP, Java Management Extensions (JMX) connectors and Remote Method Invocation over the Internet Inter-ORB Protocol (RMI/IIOP) JMX connectors to pass administrative commands and configuration data. When administrative security is disabled, the SOAP JMX connector uses the HTTP protocol and the RMI/IIOP connector uses the TCP/IP protocol. When administrative security is enabled, the SOAP JMX connector always uses the HTTPS protocol. When administrative security is enabled, you can configure the RMI/IIOP JMX connector to either use SSL or to use TCP/IP. It is recommended that you enable administrative security and enable SSL to protect the sensitive configuration data.

When administrative security is enabled, you can disable application security at each individual application server by clearing the **Enable administrative security** option at the server level. For more information, see “Securing specific application servers” on page 82. Disabling application server security does not affect the administrative subsystem in that application server, which is controlled by the security configuration only. Both administrative subsystem and application code in an application server share the optional per server security protocol configuration.

Security for J2EE resources

Security for J2EE resources is provided by the Web container and the EJB container. Each container provides two kinds of security: declarative security and programmatic security.

In declarative security, an application security structure includes network message integrity and confidentiality, authentication requirements, security roles, and access control. Access control is expressed in a form that is external to the application. In particular, the deployment descriptor is the primary vehicle for declarative security in the J2EE platform. WebSphere Application Server maintains J2EE security policy, including information that is derived from the deployment descriptor and specified by deployers and administrators in a set of XML descriptor files. At runtime, the container uses the security policy that is defined in the XML descriptor files to enforce data constraints and access control.

When declarative security alone is not sufficient to express the security model of an application, you might use programmatic security to make access decisions. When administrative security is enabled and application server security is not disabled at the server level, J2EE applications security is enforced. When the security policy is specified for a Web resource, the Web container performs access control when the resource is requested by a Web client. The Web container challenges the Web client for authentication data if none is present according to the specified authentication method, ensures that the data constraints are met, and determines whether the authenticated user has the required security role. The Web security collaborator enforces role-based access control by using an access manager implementation. An access manager makes authorization decisions that are based on security policy derived from the deployment descriptor. An authenticated user principal can access the requested servlet or JSP file if the user principal has one of the required security roles. Servlets and JSP files can use the `HttpServletRequest` methods, `isUserInRole` and `getUserPrincipal`.

When administrative security and application security are enabled, and the application server level application security is not disabled, the EJB container enforces access control on EJB method invocation.

The authentication occurs regardless of whether method permission is defined for the specific EJB method. The EJB security collaborator enforces role-based access control by using an access manager implementation. An access manager makes authorization decisions that are based on security policy derived from the deployment descriptor. An authenticated user principal can access the requested EJB method if it has one of the required security roles. EJB code can use the `EJBContext` methods, `isCallerInRole` and `getCallerPrincipal`. Use the J2EE role-based access control to protect valuable business data from access by unauthorized users through the Internet and the intranet. Refer to “Securing Web applications using an assembly tool” on page 923, and “Securing enterprise bean applications” on page 943.

Role-based security

WebSphere Application Server extends the security, role-based access control to administrative resources including the JMX system management subsystem, user registries, and Java Naming and Directory Interface (JNDI) name space. WebSphere administrative subsystem defines four administrative security roles:

Monitor role

A monitor can view the configuration information and status but cannot make any changes.

Operator role

An operator can trigger run-time state changes, such as start an application server or stop an application but cannot make configuration changes.

Configurator role

A configurator can modify the configuration information but cannot change the state of the runtime.

Administrator role

An operator as well as a configurator, which additionally can modify sensitive security configuration

and security policy such as setting server IDs and passwords, enable or disable administrative security and Java 2 security, and map users and groups to the administrator role.

iscadmins

The `iscadmins` role has administrator privileges for managing users and groups from within the administrative console only.

WebSphere Application Server defines two additional roles that are available when you use `wsadmin` scripting only

Deployer

A deployer can perform both configuration actions and run-time operations on applications.

AdminSecurityManager

An administrative security manager can map users to administrative roles. Also, when fine grained admin security is used, users granted this role can manage authorization groups.

A user with the configurator role can perform most administrative work including installing new applications and application servers. Certain configuration tasks exist that a configurator does not have sufficient authority to do when administrative security is enabled, including modifying a WebSphere Application Server identity and password, Lightweight Third-Party Authentication (LTPA) password and keys, and assigning users to administrative security roles. Those sensitive configuration tasks require the administrative role because the server ID is mapped to the administrator role.

Enable WebSphere Application Server administrative security to protect administrative subsystem integrity. Application server security can be selectively disabled if no sensitive information is available to protect. For securing administrative security, refer to “Authorizing access to administrative roles” on page 382 and “Assigning users and groups to roles” on page 928.

Java 2 security permissions

WebSphere Application Server uses the Java 2 security model to create a secure environment to run application code. Java 2 security provides a fine-grained and policy-based access control to protect system resources such as files, system properties, opening socket connections, loading libraries, and so on. The J2EE Version 1.4 specification defines a typical set of Java 2 security permissions that Web and EJB components expect to have. These permissions are shown in the following table.

Table 1. J2EE security permissions set for Web components

Security Permission	Target	Action
<code>java.lang.RuntimePermission</code>	<code>loadLibrary</code>	
<code>java.lang.RuntimePermission</code>	<code>queuePrintJob</code>	
<code>java.net.SocketPermission</code>	*	connect
<code>java.io.FilePermission</code>	*	read, write
<code>java.util.PropertyPermission</code>	*	read

Table 2. J2EE security permissions set for EJB components

Security Permission	Target	Action
<code>java.lang.RuntimePermission</code>	<code>queuePrintJob</code>	
<code>java.net.SocketPermission</code>	*	connect
<code>java.util.PropertyPermission</code>	*	read

The WebSphere Application Server Java 2 security default policies are based on the J2EE Version 1.4 specification. The specification grants Web components read and write file access permission to any file in

the file system, which might be too broad. The WebSphere Application Server default policy gives Web components read and write permission to the subdirectory and the subtree where the Web module is installed. The default Java 2 security policies for all Java virtual machines and WebSphere Application Server processes are contained in the following policy files:

/QIBM/ProdData/Java400/jdk15/lib/security/java.policy

Used as the default policy for the Java virtual machine (JVM).

\${USER_INSTALL_ROOT}/properties/server.policy

This file is used as the default policy for all product server processes.

To simplify policy management, WebSphere Application Server policy is based on resource type rather than code base (location). The following files are the default policy files for a WebSphere Application Server subsystem. These policy files, which are an extension of the WebSphere Application Server runtime, are referred to as *Service Provider Programming Interfaces (SPI)*, and shared by multiple J2EE applications:

profile_root/config/cells/cell_name/nodes/node_name/spi.policy

Used for embedded resources defined in the `resources.xml` file, such as the Java Message Service (JMS), JavaMail, and JDBC drivers.

profile_root/config/cells/cell_name/nodes/node_name/library.policy

Used by the shared library that is defined by the WebSphere Application Server administrative console.

profile_root/config/cells/cell_name/nodes/node_name/app.policy

Used as the default policy for J2EE applications.

In general, applications do not require more permissions to run than those recommended by the J2EE specification to be portable among various application servers. However, some applications might require more permissions. WebSphere Application Server supports the packaging of a `was.policy` file with each application to grant extra permissions to that application.

Attention: Grant extra permissions to an application only after careful consideration because of the potential of compromising the system integrity.

Loading libraries into WebSphere Application Server does allow applications to leave the Java sandbox. WebSphere Application Server uses a permission filtering policy file to alert you when an application installation fails because of additional permission requirements. For example, it is recommended that you not give the `java.lang.RuntimePermission exitVM` permission to an application so that application code cannot terminate WebSphere Application Server.

The filtering policy is defined by the filtermask in the `profile_root/config/cells/cell_name/filter.policy` file. Moreover, WebSphere Application Server also performs run-time permission filtering that is based on the run-time filtering policy to ensure that application code is not granted a permission that is considered harmful to system integrity.

Therefore, many applications developed for prior releases of WebSphere Application Server might not be Java 2 security ready. To quickly migrate those applications to the latest version of WebSphere Application Server, you might temporarily give those applications the `java.security.AllPermission` permission in the `was.policy` file. Test those applications to ensure that they run in an environment where Java 2 security is active. For example, identify which extra permissions, if any, are required, and grant only those permissions to a particular application. Not granting the `AllPermission` permission to applications can reduce the risk of compromising system integrity. For more information on migrating applications, refer to “Migrating Java 2 security policy” on page 40.

The WebSphere Application Server runtime uses Java 2 security to protect sensitive run-time functions. Applications that are granted the `AllPermission` permission not only have access to sensitive system

resources, but also WebSphere Application Server run-time resources and can potentially cause damage to both. In cases where an application can be trusted as safe, WebSphere Application Server does support having Java 2 security disabled on a per application server basis. You can enforce Java 2 security by default in the administrative console and clear the Java 2 security flag to disable it at the particular application server.

When you specify the **Enable administrative security** and **Use Java 2 security to restrict application access to local resources** options on the Secure administration, applications, and infrastructure panel of the administrative console, the information and other sensitive configuration data, are stored in a set of XML configuration files. Both role-based access control and Java 2 security permission-based access control are employed to protect the integrity of the configuration data. The example uses configuration data protection to illustrate how system integrity is maintained.

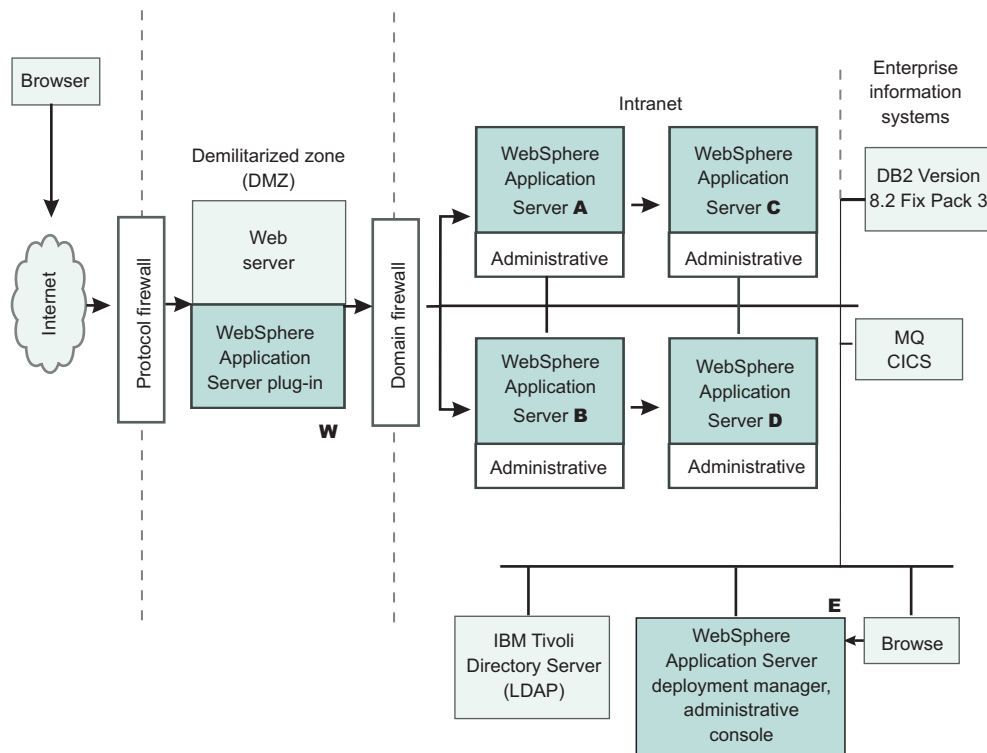

Attention: The **Enable global security** option in previous releases of WebSphere Application Server is the same as the **Enable administrative security** option in Version 6.1. Also, the **Enable Java 2 security** option in previous releases is the same as the **Use Java 2 security to restrict application access to local resources** option in Version 6.1.

- When Java 2 security is enforced, the application code cannot access the WebSphere Application Server run-time classes that manage the configuration data unless the code is granted the required WebSphere Application Server run-time permissions.
- When Java 2 security is enforced, application code cannot access the WebSphere Application Server configuration XML files unless the code is granted the required file read and write permission.
- The JMX administrative subsystem provides SOAP over HTTP or HTTPS and a RMI/IIOP remote interface to enable application programs to extract and to modify configuration files and data. When administrative security is enabled, an application program can modify the WebSphere Application Server configuration if the application program has presented valid authentication data and the security identity has the required security roles.
- If a user can disable Java 2 security, the user can also modify the WebSphere Application Server configuration, including the WebSphere Application Server security identity and authentication data with other sensitive data. Only users with the administrator security role can disable Java 2 security.
- Because WebSphere Application Server security identity is given to the administrator role, only users with the administrator role can disable administrative security, change server IDs and passwords, and map users and groups to administrative roles, and so on.

Other Runtime resources

Other WebSphere Application Server run-time resources are protected by a similar mechanism, as described previously. It is very important to enable WebSphere Application Server administrative security and to use Java 2 security to restrict application access to local resources. J2EE Specification defines several authentication methods for Web components: HTTP Basic Authentication, Form-Based Authentication, and HTTPS Client Certificate Authentication. When you use client certificate login, it is more convenient for the browser client if the Web resources have integral or confidential data constraint. If a browser uses HTTP to access the Web resource, the Web container automatically redirects the browser to the HTTPS port. The CSIV2 security protocol also supports client certificate authentication. You can also use SSL client authentication to set up secure communication among a selected set of servers based on a trust relationship.

If you start from the WebSphere Application Server plug-in at the Web server, you can configure SSL mutual authentication between it and the WebSphere Application Server HTTPS server. When using a certificate, you can restrict the WebSphere Application Server plug-in to communicate with only the selected two WebSphere Application Servers as shown in the following figure. Note that you can use self-signed certificates to reduce administration and cost.

For example, you want to restrict the HTTPS server in WebSphere Application Server **A** and in WebSphere Application Server **B** to accept secure socket connections only from the WebSphere Application Server plug-in **W**. To complete this task, you can generate three certificates using the IKEYMAN and the certificate management utilities. Also, you can use certificate **W** and trust certificate **A** and **B**. Configure the HTTPS server of WebSphere Application Server **A** to use certificate **A** and to trust certificate **W**. Configure the HTTPS server of WebSphere Application Server **B** to use certificate **B** and to trust certificate **W**. For more information on IKEYMAN, refer to .

The trust relationship that is depicted in the previous figure is shown in the following table.

Server	Key	Trust
WebSphere Application Server plug-in	W	A, B
WebSphere Application Server A	A	W
WebSphere Application Server B	B	W

The WebSphere Application Server Deployment Manager is a central point of administration. System management commands are sent from the deployment manager to each individual application server. When administrative security is enabled, you can configure WebSphere Application Servers to require SSL and mutual authentication.

You might want to restrict WebSphere Application Server **A** so that it can communicate with WebSphere Application Server **C** only and WebSphere Application Server **B** can communicate with WebSphere Application Server **D** only. All WebSphere Application Servers must be able to communicate with WebSphere Application Server deployment manager **E**; therefore, when using self-signed certificates, you might configure the CSiv2 and SOAP/HTTPS Key and trust relationship, as shown in the following table.

Server	Key	Trust
WebSphere Application Server A	A	C, E

Server	Key	Trust
WebSphere Application Server B	B	D, E
WebSphere Application Server C	C	A, E
WebSphere Application Server D	D	B, E
WebSphere Application Server Deployment Manager E	E	A, B, C, D

When WebSphere Application Server is configured to use Lightweight Directory Access Protocol (LDAP) user registry, you also can configure SSL with mutual authentication between every application server and the LDAP server with self-signed certificates so that a password is not visible when it is passed from WebSphere Application Server to the LDAP server.

In this example, the node agent processes are not discussed. Each node agent must communicate with application servers on the same node and with the deployment manager. Node agents also must communicate with LDAP servers when configured to use an LDAP user registry. It is reasonable to let the deployment manager and the node agents use the same certificate. Suppose application server **A** and **C** are on the same computer node. The node agent on that node needs to have certificates **A** and **C** in its trust store.

WebSphere Application Server does not provide a registry configuration or management utility. In addition, it does not dictate the registry password policy. It is recommended that you use the password policy recommended by your registry, including the password length and expiration period.

Before securing your WebSphere Application Server environment, determine which versions of WebSphere Application Server you are using, review the WebSphere Application Server security architecture, and review each of the following topics:

- “Authentication protocol for EJB security” on page 209
 - “Supported authentication protocols” on page 212
 - “Common Secure Interoperability Version 2 features” on page 213
 - “Identity assertion” on page 213
- “Authentication mechanisms” on page 170
 - “Lightweight Third Party Authentication” on page 176
 - “Trust associations” on page 177
 - “Single sign-on” on page 181
- “User registries and repositories” on page 89
 - “Local operating system registries” on page 165
 - “Standalone Lightweight Directory Access Protocol registries” on page 166
- “Java 2 security” on page 61
 - “Java 2 security policy files” on page 66
- “Java Authentication and Authorization Service” on page 324
 - “Programmatic login” on page 353
- J2EE connector security

 - “Administrative roles and naming service authorization” on page 330

Chapter 2. How do I secure applications and their environments?

Develop and deploy secure applications. These tasks involve securing your applications during development (optional, programmatic security), assembly (declarative security), and after deploying them on the application server.

Secure the application hosting environment. The counterpart of securing your applications before and after deployment is to secure the server hosting environment into which the applications are deployed.

Chapter 3. Task overview: Securing resources

WebSphere Application Server supports the Java 2 Platform, Enterprise Edition (J2EE) model for creating, assembling, securing, and deploying applications. Applications are often created, assembled, and deployed in different phases and by different teams.

You can secure resources in a J2EE environment by following the required high-level steps. Consult the J2EE specifications for complete details.

- Set up and enable security. You must address several issues prior to authenticating users, authorizing access to resources, securing applications, and securing communications. These security issues include migration, interoperability, and installation. After installing WebSphere Application Server, you must determine the proper level of security that is needed for your environment. For more information, see Chapter 4, “Setting up and enabling security,” on page 29.
- Authenticate users. The process of authenticating users involves a user registry and an authentication mechanism. Optionally, you can define trust between WebSphere Application Server and a proxy server, configure single sign-on capability, and specify how to propagate security attributes between application servers. For more information, see Chapter 5, “Authenticating users,” on page 87.
- Authorize access to resources. WebSphere Application Server provides many different methods for authorizing accessing resources. For example, you can assign roles to users and configure a built-in or external authorization provider. For more information, see Chapter 6, “Authorizing access to resources,” on page 329.
- Secure communications. WebSphere Application Server provides several methods to secure communication between a server and a client. For more information, see Chapter 7, “Securing communications,” on page 391.
- Develop extensions to the WebSphere security infrastructure. WebSphere Application Server provides various plug points so that you can extend the security infrastructure. For more information, see Chapter 8, “Developing extensions to the WebSphere security infrastructure,” on page 515.
- Secure various types of WebSphere applications. See **Securing WebSphere applications** for tasks involving developing, deploying, and administering secure applications, including Web applications, Web services, and many other types. This section highlights the security concerns and tasks that are specific to each type of application.
- Tune, harden, and maintain security configurations. After you have installed WebSphere Application Server, there are several considerations for tuning, strengthening, and maintaining your security configuration. For more information, see Chapter 21, “Tuning, hardening, and maintaining,” on page 1417.
- Troubleshoot security configurations. For more information, see Chapter 22, “Troubleshooting security configurations,” on page 1435.

Your applications and production environment are secured.

See *Security: Resources* for learning for more information on the WebSphere Application Server security architecture.

Chapter 4. Setting up and enabling security

You must address several issues prior to authenticating users, authorizing access to resources, securing applications, and securing communications. These security issues include migration, interoperability, and installation.

After installing WebSphere Application Server, you can determine the proper level of security that is needed for your environment. By default, administrative security is enabled and provides the authentication of users, the use of Secure Sockets Layer (SSL), and the choice of user account repository.

The following information is covered in this section:

Enable security for all your application servers or for specific application servers in your realm.

For more information, see either “Enabling security” on page 43 or “Securing specific application servers” on page 82.

After installing WebSphere Application Server and securing your environment, you must authenticate users. For more information, see Chapter 5, “Authenticating users,” on page 87.

Migrating, coexisting, and interoperating – Security considerations

Use this topic to migrate the security configuration of previous WebSphere Application Server releases and its applications to the new installation of WebSphere Application Server.

This information addresses the need to migrate your security configurations from a previous release of IBM WebSphere Application Server to WebSphere Application Server Version 6.1 or later. Complete the following steps to migrate your security configurations:

- If security is enabled in the previous release, obtain the administrative server ID and password of the previous release. This information is needed in order to run certain migration jobs.
- You can optionally disable security in the previous release before migrating the installation. No logon is required during the installation.

Follow the steps in Migrating product configurations.

The security configuration of previous WebSphere Application Server releases and its applications are migrated to the new installation of WebSphere Application Server Version 6.1.

If a custom user registry is used in the previous version, the migration process does not migrate the class files that are used by the standalone custom registry in the previous *app_server_root/classes* directory. Therefore, after migration, copy your custom user registry implementation classes to the *app_server_root/classes* directory.

If you upgrade from WebSphere Application Server, Version 5.x to WebSphere Application Server, Version 6.1, the data that is associated with Version 5.x trust associations is not automatically migrated to Version 6.1. To migrate trust associations, see “Migrating trust association interceptors” on page 34.

If the previous version instance is configured to enable secure connections using digital certificates that are signed by the Digital Certificate Manager (DCM) local certificate authority, those certificates must be renewed. For example, they must be renewed for the previous version instance, the WebSphere Application Server Version 6.1 profile, and all of the Secure Socket Layer-enabled clients and servers that connect to WebSphere Application Server. For more information, see SSL handshake failure using digital certificates signed by a Digital Certificate Manager (DCM) local certificate authority.

i5/OS *SYSTEM certificate stores for applications are deprecated in WebSphere Application Server Version 5. In WebSphere Application Server, you must migrate your applications to use Java keystores.

The `os400.security.password.validation.list.object` property is profile-dependent. If you are migrating from Version 5, see “Migrating Java thin clients that use the password encoding algorithm” on page 42 for instructions on how to migrate your client configuration.

Interoperating with previous product versions

IBM WebSphere Application Server inter-operates with the previous product versions. Use this topic to configure this behavior.

1. Configure WebSphere Application Server Version 6.1 with the same distributed user registry (that is, LDAP or Custom) that is configured with the previous version. Make sure that the same LDAP user registry is shared by all of the product versions.
 - a. In the administrative console, select **Security > Secure administration, applications, and infrastructure**.
 - b. Choose an available Realm definition and click **Configure**.
 - c. Enter a **Primary administrative user name**. This is the identity you use to login to the administrative console or to wsadmin. When inter-operating with a previous release, you must use the same server ID. In WebSphere Application Server Version 6.1, there are two choices for server ID. For previous releases, specify a server ID and password. However, if you choose to use the internal server ID, you must be able to override the generated value and to specify the server ID from a previous release.
 - d. Click either **Automatically generated server identity** or **Server identity that is stored in the user repository**.
 - e. If you select **Automatically generated server identity**, click **Authentication mechanisms and expiration** to change the identity to the one used by the previous release you are inter-operating with. Scroll down to the Cross-cell single sign-on section and enter the identity in **Internal server ID**.
 - f. If you select **Server identity that is stored in the user repository**, enter the **Server user id** and the associated **Password**.
 - g. Fill out the rest of the user registry settings and then click **OK**.
2. Configure the LTPA authentication mechanism. Automatic generation of the LTPA keys should be disabled. If not, keys used by a previous release are lost. Export the current LTPA keys from WebSphere Application Server Version 6.1 and import them into the previous release.
 - a. In the administrative console select **Security > Secure administration, applications, and infrastructure**.
 - b. Click **Authentication mechanisms and expiration**.
 - c. Click the **Key set groups** link, then click the key set group that displays in the Key set groups panel.
 - d. Clear the **Automatically generate keys** check box.
 - e. Click **OK**, then click **Authentication mechanisms and expiration** in the path at the top of the Key set groups panel.
 - f. Scroll down to the Cross-cell single sign-on section, and enter a password to use for encrypting the LTPA keys when adding them to the file.
 - g. Enter the password again to confirm the password.
 - h. Enter the **Fully qualified key file name** that contains the exported keys.
 - i. Click **Export keys**.
 - j. Follow the instructions provided in the previous release to import the exported LTPA keys into that configuration.

3. If you are using the default SSL configuration, extract all of the signer certificates from the WebSphere Application Server Version 6.1 common trust store. Otherwise, extract signers where necessary to import them into the previous release.
 - a. In the administrative console, click **Security > SSL certificate and key management**.
 - b. Click **Key stores and certificates**.
 - c. Click **CellDefaultTrustStore**.
 - d. Click **Signer certificates**.
 - e. Select one signer and click **Extract**.
 - f. Enter a unique path and filename for the signer (for example, c:\temp\signer1.arm).
 - g. Click **OK**. Repeat for all of the signers in the trust store.
 - h. Check other trust stores for other signers that might need to be shared with the other server. Repeat steps e through h to extract the other signers.
4. Add the exported signers to DummyServerTrustFile.jks and DummyClientTrustFile.jks in the /etc directory of the back-level product version. If the previous release is not using the dummy certificate, the signer certificate(s) from the previous release must be extracted and added into the WebSphere Application Server Version 6.1 release to enable SSL connectivity in both directions.
 - a. Open the key management utility, iKeyman, for that product version.
 - b. Start ikeyman.bat or ikeyman.sh from the \${USER_INSTALL_ROOT}/bin directory.
 - c. Select **Key Database File > Open**.
 - d. Open \${USER_INSTALL_ROOT}/etc/DummyServerTrustFile.jks.
 - e. Enter WebAS for the password.
 - f. Select **Add** and enter one of the files extracted in step 2. Continue until you have added all of the signers.
 - g. Repeat steps c through f for the DummyClientTrustFile.jks file.
5. Verify that the application uses the correct Java Naming and Directory Interface (JNDI) name and naming bootstrap port for performing a naming lookup.
6. Stop and restart all of the servers.

Migrating custom user registries

If you built your own custom user registry, consider the migration items listed below. If you have a custom user registry that was provided by a Security Solution Provider, you must contact that provider to ensure that you have the correct version of their custom user registry to support WebSphere Application Server.

In WebSphere Application Server, in addition to the UserRegistry interface, the custom user registry requires the Result object to handle user and group information. This file is already provided in the package and you are expected to use it for the getUsers, getGroups, and the getUsersForGroup methods.

You cannot use other WebSphere Application Server components, for example, data sources, to initialize the custom registry because other components, like the containers, are initialized after security and are not available during the registry initialization. A custom registry implementation is a pure custom implementation, independent of other WebSphere Application Server components.

The getCallerPrincipal enterprise bean method and the getUserPrincipal and getRemoteUser servlet methods return the security name instead of the display name. For more information, see the API documentation.

If the migration tool is used to migrate the WebSphere Application Server Version 5 configuration to WebSphere Application Server Version 6.0.x and later, this migration does not change your existing code. Because the WebSphere Application Server Version 5 custom registry works in WebSphere Application Server Version 6.0.x and later without any changes to the implementation, except when using data sources, you can use the Version 5-based custom registry after the migration without modifying the code.

Copy the files to the cell and to each of the nodes class paths and *profile_root/classes* directories.

In WebSphere Application Server Version 6.0.x and later, a case-insensitive authorization can occur when using an enabled custom user registry.

Setting this flag does not have any effect on the user names or passwords. Only the unique IDs that are returned from the registry are changed to lower-case before comparing them with the information in the authorization table, which is also converted to lowercase during runtime.

Before proceeding, look at the UserRegistry interface. See “Developing standalone custom registries” on page 515 for a description of each of these methods in detail.

The following steps go through all the changes that are required to move your WebSphere Application Server Version 4.x custom user registry that implemented the old `com.ibm.websphere.security.CustomRegistry` interface to the `com.ibm.websphere.security.UserRegistry` interface.

Note: The sample implementation file is used as an **example** when describing the following steps.

1. Change your implementation to UserRegistry instead of CustomRegistry. Change:

```
public class FileRegistrySample implements CustomRegistry
```

to:

```
public class FileRegistrySample implements UserRegistry
```

2. Create the `java.rmi.RemoteException` exception in the constructors:

```
public FileRegistrySample() throws java.rmi.RemoteException
```

3. Change the `mapCertificate` method to take a certificate chain instead of a single certificate. Change

```
public String mapCertificate(X509Certificate cert)
```

to:

```
public String mapCertificate(X509Certificate[]cert)
```

Having a certificate chain gives you the flexibility to act on the chain instead of one certificate. If you are interested only in the first certificate, take the first certificate in the chain before processing. In WebSphere Application Server Version 6.0.x and later, the `mapCertificate` method is called to map the user in a certificate to a valid user in the registry when certificates are used for authentication by the Web or the Java clients.

4. Remove the `getUsers` method.
5. Change the signature of the `getUsers(String)` method to return a `Result` object and accept an additional parameter (`int`). Change:

```
public List getUsers(String pattern)
```

to:

```
public Result getUsers(String pattern, int limit)
```

In your implementation, construct the `Result` object from the list of the users that is obtained from the user registry (whose number is limited to the value of the `limit` parameter) and call the `setHasMore` method on the `Result` object if the total number of users in the registry exceeds the `limit` value.

6. Change the signature of the `getUsersForGroup(String)` method to return a `Result` object and accept an additional parameter (`int`) and throw a new exception called `NotImplementedException` exception. Change the following code:

```
public List getUsersForGroup(String groupName)
    throws CustomRegistryException,
        EntryNotFoundException {
```

to:

```
public Result getUsersForGroup(String groupSecurityName, int limit)
    throws NotImplementedException,
        EntryNotFoundException,
        CustomRegistryException {
```

In WebSphere Application Server Version 6.0.x and later, this method is not called directly by the WebSphere Application Server security component. However, other components of WebSphere Application Server, like the WebSphere Business Integration Server Foundation process choreographer, use this method when staff assignments are modeled using groups. Because this implementation is supported in WebSphere Application Server Version 6.0.x and later, it is recommended that you change the implementation similar to the `getUsers` method as explained in step 5.

7. Remove the `getUniqueUserIds(String)` method.
8. Remove the `getGroups` method.
9. Change the signature of the `getGroups(String)` method to return a `Result` object and accept an additional parameter (`int`). Change the following code:

```
public List getGroups(String pattern)
```

to:

```
public Result getGroups(String pattern, int limit)
```

In your implementation, construct the `Result` object from the list of the groups that is obtained from the user registry whose number is limited to the value of the `limit` parameter. Call the `setHasMore` method on the `Result` object if the total number of groups in the registry exceeds the `limit` value.

10. Add the `createCredential` method. This method is not called at this time, so return as `null`.

```
public com.ibm.websphere.security.cred.WSCredential
    createCredential(String userSecurityName)
        throws CustomRegistryException,
            NotImplementedException,
            EntryNotFoundException {
    return null;
}
```

The first and second lines of the previous code example are split onto two lines for illustrative purposes only.

11. To build the WebSphere Application Server Version 6.0.x and later implementation, make sure you have the `sas.jar` and the `wssec.jar` files in your class path.

To set the files in your class path, use the following code as a sample and substitute your environment values for the variables that are used in the example:

```
javac -J-Djava.version=1.5 -classpath profile_root/lib/wssec.jar;
profile_root/lib/sas.jar FileRegistrySample.java
```

Type the previous lines as one continuous line.

To build the WebSphere Application Server Version 5 custom registry (`CustomRegistry`) in WebSphere Application Server Version 6.0.x and later, only the `sas.jar` file is required.

12. Copy the implementation classes to the product class path.

It is recommended that you copy these implementation classes to the `profile_root/classes` directory.

Make sure that you copy these classes to the cell and all the nodes. Without the classes in each of the node class paths, the nodes and the application servers in those nodes cannot start when security is on.

13. Use the administrative console to set up the custom registry.

Follow the instructions in “Configuring standalone custom registries” on page 111 to set up the custom registry, including the **ignore case for authorization** option. Make sure that you add the `WAS_UseDisplayName` properties if required.

WebSphere Application Server Version 4.x based custom user registry that implemented the old `com.ibm.websphere.security.CustomRegistry` interface is migrated to the `com.ibm.websphere.security.UserRegistry` interface.

If you are enabling security, see “Enabling security” on page 43 to complete the remaining steps. When completed, save the configuration and restart all the servers. Try accessing some Java 2 Platform, Enterprise Edition (J2EE) resources to verify that the custom registry migration is successful.

Migrating trust association interceptors

Use this topic to manually migrate trust associations.

Note: Data sources are not supported for use within a Trust Association Interceptor (TAI). Data sources are intended for use within J2EE applications and designed to operate within the EJB and Web containers. Trust Association Interceptors do not run within a container, and while data sources may function in the TAI environment, they are untested and not guaranteed to function properly.

The following topics are addressed in this document:

- Changes to the product-provided trust association interceptors
- Migrating product-provided trust association interceptors
- Changes to the custom trust association interceptors
- Migrating custom trust association interceptors

Changes to the product-provided trust association interceptors

For the product-provided implementation for the WebSEAL server, a new optional `com.ibm.websphere.security.webseal.ignoreProxy` property is added. If this property is set to `true` or `yes`, the implementation does not check for the proxy host names and the proxy ports to match any of the host names and ports that are listed in the `com.ibm.websphere.security.webseal.hostnames` and the `com.ibm.websphere.security.webseal.ports` property respectively. For example, if the VIA header contains the following information:

```
HTTP/1.1 Fred (Proxy), 1.1 Sam (Apache/1.1),  
HTTP/1.1 webseal1:7002, 1.1 webseal2:7001
```

and the `com.ibm.websphere.security.webseal.ignoreProxy` property is set to `true` or `yes`, the host name `Fred`, is not used when matching the host names. By default, this property is not set, which implies that any proxy host names and ports that are expected in the VIA header are listed in the host names and the ports properties to satisfy the `isTargetInterceptor` method.

The previous VIA header information was split onto two lines for illustrative purposes only.

For more information about the `com.ibm.websphere.security.webseal.ignoreProxy` property, see the article in the information center on configuring single signon using trust association interceptor ++.

Migrating product-provided trust association interceptors

The properties that are located in the `webseal.properties` and `trustedserver.properties` files are not migrated from previous versions of WebSphere Application Server. You must migrate the appropriate properties to WebSphere Application Server Version 6.0.x using the trust association panels in the administrative console. For more information, see Configuring trust association interceptors.

Changes to the custom trust association interceptors

If the custom interceptor extends the `com.ibm.websphere.security.WebSphereBaseTrustAssociationInterceptor` property, implement the following new method to initialize the interceptor:

```
public int init (java.util.Properties props);
```

WebSphere Application Server checks the return status before using the trust association implementation. Zero (0) is the default value for indicating that the interceptor is successfully initialized.

However, if a previous implementation of the trust association interceptor returns a different error status, you can either change your implementation to match the expectations or make one of the following changes:

Method 1:

Add the `com.ibm.websphere.security.trustassociation.initStatus` property in the trust association interceptor custom properties. Set the property to the value that indicates the interceptor is successfully initialized. All of the other possible values imply failure. In case of failure, the corresponding trust association interceptor is not used.

Method 2:

Add the `com.ibm.websphere.security.trustassociation.ignoreInitStatus` property in the trust association interceptor custom properties. Set the value of this property to `true`, which tells WebSphere Application Server to ignore the status of this method. If you add this property to the custom properties, WebSphere Application Server does not check the return status, which is similar to previous versions of WebSphere Application Server.

The `public int init (java.util.Properties props)` method replaces the `public int init (String propsFile)` method.

The `init(Properties)` method accepts a `java.util.Properties` object, which contains the set of properties that is required to initialize the interceptor. All of the properties set for an interceptor are sent to this method. The interceptor can then use these properties to initialize itself. For example, in the product-provided implementation for the WebSEAL server, this method reads the hosts and ports so that a request coming in can be verified to come from trusted hosts and ports. A return value of Zero (0) implies that the interceptor initialization is successful. Any other value implies that the initialization is not successful and the interceptor is not used.

The `init(String)` method still works if you want to use it instead of implementing the `init(Properties)` method. The only requirement is that you enter the file name containing the custom trust association properties using the **Custom Properties** link of the interceptor in the administrative console or by using scripts. You can enter the property using either of the following methods. The first method is used for backward compatibility with previous versions of WebSphere Application Server.

Method 1:

The same property names used in the previous release are used to obtain the file name. The file name is obtained by concatenating `.config` to the `com.ibm.websphere.security.trustassociation.types` property value. If the `myTAI.properties` file is located in the `profile_root/properties` directory, set the following properties:

- `com.ibm.websphere.security.trustassociation.types = myTAItype`
- `com.ibm.websphere.security.trustassociation.myTAItype.config = profile_root/properties/myTAI.properties`

Method 2:

You can set the `com.ibm.websphere.security.trustassociation.initPropsFile` property in the trust association custom properties to the location of the file. For example, set the following property:

```
com.ibm.websphere.security.trustassociation.initPropsFile=  
profile_root/properties/myTAI.properties
```

The previous line of code is split into two lines for illustrative purposes only. Type as one continuous line.

In a Network Deployment installation, where the location of the file name can vary for different nodes, use the variable `install_root` to refer to the WebSphere Application Server installation directory.

However, it is highly recommended that your implementation be changed to implement the `init(Properties)` method instead of relying on the `init (String propsfile)` method.

Migrating custom trust association interceptors

The trust associations from previous versions of WebSphere Application Server are not automatically migrated to WebSphere Application Server Version 6.0.x and later. You can manually migrate these trust associations using the following steps:

1. Recompile the implementation file, if necessary.

For more information, refer to the "Changes to the custom trust association interceptors" section previously discussed in this document.

- a. Enter QSH from a command line to start the QShell environment.
- b. Change to the directory that contains your Java source file.
- c. Enter the command to recompile the implementation file.

```
javac -Djava.version=1.5 -classpath
app_server_root/lib/wssec.jar:install_root/lib/j2ee.jar .java
```

Where *install_root* is the installation root.

2. Copy the custom trust association interceptor class files to a location in your product class path. Copy these class files into the *profile_root/classes* directory.

You must copy this class file to the *profile_root/classes* directory of each node and cell.

3. Start WebSphere Application Server.
4. Enable security to use the trust association interceptor. The properties that are located in your custom trust association properties file and in the `trustedserver.properties` file are not migrated from previous versions of WebSphere Application Server. You must migrate the appropriate properties to WebSphere Application Server Version 6.0.x and later using the trust association panels in the administrative console.

For more information, see [Configuring trust association interceptors](#).

Migrating Common Object Request Broker Architecture programmatic login to Java Authentication and Authorization Service (CORBA and JAAS)

Use this topic as an example of how to perform programmatic login using the CORBA-based programmatic login APIs.

This document outlines the deprecated Common Object Request Broker Architecture (CORBA) programmatic login APIs and the alternatives that are provided by JAAS. WebSphere Application Server fully supports the Java Authentication and Authorization Service (JAAS) as programmatic login application programming interfaces (API). Refer to the *Securing applications and their environment* PDF for more details on JAAS support.

The following list includes the deprecated CORBA programmatic login APIs.

- `profile_root/installedApps/sampleApp.ear/default_app.war/WEB-INF/classes/ServerSideAuthenticator.java`.
- **org.omg.SecurityLevel2.Credentials**. This API is included with the product, but it is not recommended that you use the API.

The APIs that are provided in WebSphere Application Server are a combination of standard JAAS APIs and a product implementation of standard JAAS interfaces.

The following information is only a summary; refer to the JAAS documentation for your platform located at: <http://www.ibm.com/developerworks/java/jdk/security/> .

- Programmatic login APIs:
 - `javax.security.auth.login.LoginContext`
 - `javax.security.auth.callback.CallbackHandler` interface: The WebSphere Application Server product provides the following implementation of the `javax.security.auth.callback.CallbackHandler` interface:
 - `com.ibm.websphere.security.auth.callback.WSCallbackHandlerImpl`**
Provides a non-prompt `CallbackHandler` handler when the application pushes basic authentication data (user ID, password, and security realm) or token data to product login modules. This API is recommended for server-side login.
 - `com.ibm.websphere.security.auth.callback.WSGUICallbackHandlerImpl`**
Provides a login prompt `CallbackHandler` handler to gather basic authentication data (user ID, password, and security realm). This API is recommended for client-side login.

If this API is used on the server side, the server is blocked for input.
 - `com.ibm.websphere.security.auth.callback.WSStdinCallbackHandlerImpl`**
Provides a stdin login prompt `CallbackHandler` handler to gather basic authentication data (user ID, password, and security realm). This API is recommended for client-side login.

Note: If this API is used on the server side, the server is blocked for input.
 - `javax.security.auth.callback.Callback` interface:
 - `javax.security.auth.callback.NameCallback`**
Provided by JAAS to pass the user name to the `LoginModules` interface.
 - `javax.security.auth.callback.PasswordCallback`**
Provided by JAAS to pass the password to the `LoginModules` interface.
 - `com.ibm.websphere.security.auth.callback.WSCredTokenCallbackImpl`**
Provided by the product to perform a token-based login. With this API, an application can pass a token-byte array to the `LoginModules` interface.
 - **`javax.security.auth.spi.LoginModule` interface**
WebSphere Application Server provides a `LoginModules` implementation for client and server-side login. Refer to the *Securing applications and their environment* PDF for details.
 - `javax.security.Subject`:
 - `com.ibm.websphere.security.auth.WSSubject`**
An extension provided by the product to invoke remote J2EE resources using the credentials in the `javax.security.Subject`
 - `com.ibm.websphere.security.cred.WSCredential`**
After a successful JAAS login with the WebSphere Application Server `LoginModules` interfaces, a `com.ibm.websphere.security.cred.WSCredential` credential is created and stored in the `Subject`.
 - `com.ibm.websphere.security.auth.WSPrincipal`**
An authenticated principal that is created and stored in a `Subject` that is authenticated by the WebSphere Application Server `LoginModules` interface.
1. Use the following as an example of how to perform programmatic login using the CORBA-based programmatic login APIs: The CORBA-based programmatic login APIs are replaced by JAAS login.

Note: The `LoginHelper` application programming interface (API) that is used in the following example is deprecated in WebSphere Application Server Version 6.1 and will be removed in a future release. It is recommended that you use the JAAS programmatic login APIs that are shown in the next step.

```
public class TestClient {
    ...
    private void performLogin() {
        // Get the ID and password of the user.
        String userid = customGetUserid();
        String password = customGetPassword();

        // Create a new security context to hold authentication data.
        LoginHelper loginHelper = new LoginHelper();
```

```

try {
// Provide the ID and password of the user for authentication.
org.omg.SecurityLevel2.Credentials credentials =
loginHelper.login(userid, password);

// Use the new credentials for all future invocations.
loginHelper.setInvocationCredentials(credentials);
// Retrieve the name of the user from the credentials
// so we can tell the user that login succeeded.

String username = loginHelper.getUserName(credentials);
System.out.println("Security context set for user: "+username);
} catch (org.omg.SecurityLevel2.LoginFailed e) {
// Handle the LoginFailed exception.
}
}
...
}

```

2. Use the following example to migrate the CORBA-based programmatic login APIs to the JAAS programmatic login APIs.

The following example assumes that the application code is granted for the required Java 2 security permissions. For more information, see the *Securing applications and their environment* PDF and the JAAS documentation located at <http://www.ibm.com/developerworks/java/jdk/security/>.

```

public class TestClient {
...
private void performLogin() {
// Create a new JAAS LoginContext.
javax.security.auth.login.LoginContext lc = null;

try {
// Use GUI prompt to gather the BasicAuth data.
lc = new javax.security.auth.login.LoginContext("WSLogin",
new com.ibm.websphere.security.auth.callback.WSGUICallbackHandlerImpl());

// create a LoginContext and specify a CallbackHandler implementation
// CallbackHandler implementation determine how authentication data is collected
// in this case, the authentication date is collected by login prompt
// and pass to the authentication mechanism implemented by the LoginModule.
} catch (javax.security.auth.login.LoginException e) {
System.err.println("ERROR: failed to instantiate a LoginContext and the exception: "
+ e.getMessage());
e.printStackTrace();

// may be javax.security.auth.AuthPermission "createLoginContext" is not granted
// to the application, or the JAAS Login Configuration is not defined.
}

if (lc != null)
try {
lc.login(); // perform login
javax.security.auth.Subject s = lc.getSubject();
// get the authenticated subject

// Invoke a J2EE resources using the authenticated subject
com.ibm.websphere.security.auth.WSSubject.doAs(s,
new java.security.PrivilegedAction() {
public Object run() {
try {
bankAccount.deposit(100.00); // where bankAccount is an protected EJB
} catch (Exception e) {
System.out.println("ERROR: error while accessing EJB resource, exception: "
+ e.getMessage());
e.printStackTrace();
}
}
return null;
}
});

// Retrieve the name of the principal from the Subject
// so we can tell the user that login succeeded,
// should only be one WSPPrincipal.

```

```

java.util.Set ps =
s.getPrincipals(com.ibm.websphere.security.auth.WSPPrincipal.class);
java.util.Iterator it = ps.iterator();
while (it.hasNext()) {
com.ibm.websphere.security.auth.WSPPrincipal p =
(com.ibm.websphere.security.auth.WSPPrincipal) it.next();
System.out.println("Principal: " + p.getName());
}
} catch (javax.security.auth.login.LoginException e) {
System.err.println("ERROR: login failed with exception: " + e.getMessage());
e.printStackTrace();

// login failed, might want to provide relogin logic
}
}
...
}

```

Migrating from the CustomLoginServlet class to servlet filters

Use this topic to allow migration in an application that uses form-based login and servlet filters without the use of the CustomLoginServlet class.

The CustomLoginServlet class is deprecated in WebSphere Application Server Version 5. Those applications using the CustomLoginServlet class to perform authentication now need to use form-based login. Using the form-based login mechanism, you can control the look and feel of the login screen. In form-based login, a login page is specified and displays when retrieving the user ID and password information. You also can specify an error page that displays when authentication fails.

If login and error pages are not enough to implement the CustomLoginServlet class, use servlet filters. Servlet filters can dynamically intercept requests and responses to transform or use the information that is contained in the requests or responses. One or more servlet filters attach to a servlet or a group of servlets. Servlet filters also can attach to JavaServer Pages (JSP) files and HTML pages. All the attached servlet filters are called before invoking the servlet.

Both form-based login and servlet filters are supported by any Servlet 2.3 specification-compliant Web container. A form login servlet performs the authentication and servlet filters can perform additional authentication, auditing, or logging tasks.

To perform pre-login and post-login actions using servlet filters, configure these servlet filters for either form login page or for /j_security_check URL. The j_security_check is posted by the form login page with the j_username parameter that contains the user name and the j_password parameter that contains the password. A servlet filter can use user name and password information to perform more authentication or meet other special needs.

1. Develop a form login page and error page for the application.
Refer to the *Securing applications and their environment* PDF for details.
2. Configure the form login page and the error page for the application as described in .
Refer to the *Securing applications and their environment* PDF for details.
3. Develop servlet filters if additional processing is required before and after form login authentication.
Refer to the *Securing applications and their environment* PDF for details.
4. Configure the servlet filters that are developed in the previous step for either the form login page URL or for the /j_security_check URL. Use an assembly tool or development tools like Rational Application Developer to configure filters. After configuring the servlet filters, the web-xml file contains two stanzas. The first stanza contains the servlet filter configuration, the servlet filter, and its implementation class. The second stanza contains the filter mapping section and a mapping of the servlet filter to the URL.
For more information, see the *Securing applications and their environment* PDF.

This migration results in an application that uses form-based login and servlet filters without the use of the CustomLoginServlet class.

The new application uses form-based login and servlet filters to replace the CustomLoginServlet class. Servlet filters also are used to perform additional authentication, auditing, and logging.

Migrating Java 2 security policy

Use this topic for guidance pertaining to migrating Java 2 security policy.

Previous WebSphere Application Server releases

WebSphere Application Server uses the Java 2 security manager in the server runtime to prevent enterprise applications from calling the System.exit and the System.setSecurityManager methods. These two Java application programming interfaces (API) have undesirable consequences if called by enterprise applications. The System.exit API, for example, causes the Java virtual machine (application server process) to exit prematurely, which is not a beneficial operation for an application server.

To support Java 2 security properly, all the server runtime must be marked as privileged (with doPrivileged API calls inserted in the correct places), and identify the default permission sets or policy. Application code is not privileged and subject to the permissions that are defined in the policy files. The doPrivileged instrumentation is important and necessary to support Java 2 security. Without it, the application code must be granted the permissions that are required by the server runtime. This situation is due to the design and algorithm that is used by Java 2 security to enforce permission checks. Refer to the Java 2 security check permission algorithm.

The following two permissions are enforced by the Java 2 security manager (hard coded) for WebSphere Application Server:

- java.lang.RuntimePermission(exitVM)
- java.lang.RuntimePermission(setSecurityManager)

Application code is denied access to these permissions regardless of what is in the Java 2 security policy. However, the server runtime is granted these permissions. All the other permission checks are not enforced.

Only two permissions are supported:

- java.net.SocketPermission
- java.net.NetPermission

However, not all the product server runtime is properly marked as privileged. You must grant the application code all the other permissions besides the two listed previously or the enterprise application can potentially fail to run. This Java 2 security policy for enterprise applications is liberal.

What changed

Java 2 Security is fully supported in WebSphere Application Server, which means all permissions are enforced. The default Java 2 security policy for enterprise application is the recommended permission set defined by the Java 2 Platform, Enterprise Edition (J2EE) Version 1.4 specification. Refer to the *profile_root/config/cells/cell_name/nodes/node_name/app.policy* file for the default Java 2 security policy granted to enterprise applications. This policy is much more stringent compared to previous releases.

All policy is declarative. The product security manager honors all policy declared in the policy files. There is an exception to this rule: enterprise applications are denied access to permissions declared in the *profile_root/config/cells/cell_name/filter.policy* file.

Note: The default Java 2 security policy for enterprise applications is much more stringent and all the permissions are enforced in WebSphere Application Server Version 6.0.x and later. The security

policy might fail because the application code does not have the necessary permissions granted where system resources, such as file I/O, can be programmatically accessed and are now subject to the permission checking.

In application code, do not use the `setSecurityManager` permission to set a security manager. When an application uses the `setSecurityManager` permission, there is a conflict with the internal security manager within WebSphere Application Server. If you must set a security manager in an application for RMI purposes, you also must enable the **Use Java 2 security to restrict application access to local resources** option on the Secure administration, applications, and infrastructure page within the WebSphere Application Server administrative console. WebSphere Application Server then registers a security manager. The application code can verify that this security manager is registered by using `System.getSecurityManager()` application programming interface (API).

Migrating system properties

The following system properties are used in previous releases in relation to Java 2 security:

- **java.security.policy.** The absolute path of the policy file (action required). This system property contains both system permissions (permissions granted to the Java virtual machine (JVM) and the product server runtime) and enterprise application permissions. Migrate the Java 2 security policy of the enterprise application to WebSphere Application Server Version 6.0.x. For Java 2 security policy migration, see the steps for migrating Java 2 security policy.
- **enableJava2Security.** Used to enable Java 2 security enforcement (no action required). This system property is deprecated; a flag in the WebSphere configuration application programming interface (API) is used to control whether to enable Java 2 security. Enable this option through the administrative console.
- **was.home.** Expanded to the installation directory of WebSphere Application Server (action might be required). This system property is deprecated; superseded by the `${user.install.root}` and `${was.install.root}` properties. If the directory contains instance-specific data then `${user.install.root}` is used; otherwise `${was.install.root}` is used. Use these properties interchangeably for the WebSphere Application Server or the Network Deployment environments. See the steps for migrating Java 2 security policy.

Migrating the Java 2 Security Policy

No easy way exists to migrate the Java policy file to WebSphere Application Server Version 6.0.x and later automatically because of a mixture of system permissions and application permissions in the same policy file. Manually copy the Java 2 security policy for enterprise applications to a `was.policy` or `app.policy` file. However, migrating the Java 2 security policy to a `was.policy` file is preferable because symbols or relative code base is used instead of an absolute code base. This process has many advantages. Grant the permissions that are defined in the `was.policy` to the specific enterprise application only, while permissions in the `app.policy` file apply to all the enterprise applications that run on the node where the `app.policy` file belongs.

Refer to the *Securing applications and their environment* PDF for more details on policy management.

The following example illustrates the migration of a Java 2 security policy from a previous release. The contents include the Java 2 security policy file for the `app1.ear` enterprise application and the system permissions, which are permissions that are granted to the Java virtual machine (JVM) and the product server runtime.

The default location for the Java 2 security policy file is `profile_root/properties/java.policy`. Default permissions are omitted for clarity:

```
// For product Samples
grant codeBase "file:${app_server_root}/installedApps/app1.ear/-" {
    permission java.security.SecurityPermission "printIdentity";
    permission java.io.FilePermission "${app_server_root}${/}temp${/}somefile.txt",
        "read";
};
```

For clarity of illustration, all the permissions are migrated as the application level permissions in this example. However, you can grant permissions at a more granular level at the component level (Web, enterprise beans, connector or utility Java archive (JAR) component level) or you can grant permissions to a particular component.

1. Ensure that Java 2 security is disabled on the application server.
2. Create a new `was.policy` file, if the file is not present, or update the `was.policy` file for migrated applications in the configuration repository with the following contents:

```
grant codeBase "file:${application}" {
    permission java.security.SecurityPermission "printIdentity";
    permission java.io.FilePermission "
        ${user.install.root}${/}temp${/}somefile.txt", "read";
};
```

The third and fourth lines in the previous code sample are presented on two lines for illustrative purposes only.

The `was.policy` file is located in the `profile_root/config/cells/cell_name/applications/app.ear/deployments/app/META-INF/` directory.

3. Use an assembly tool to attach the `was.policy` file to the enterprise archive (EAR) file. You also can use an assembly tool to validate the contents of the `was.policy` file. For more information, see the *Securing applications and their environment* PDF.
4. Validate that the enterprise application does not require additional permissions to the migrated Java 2 security permissions and the default permissions set declared in the `${user.install.root}/config/cells/cell_name/nodes/node_name/app.policy` file. This validation requires code review, code inspection, application documentation review, and sandbox testing of migrated enterprise applications with Java 2 security enabled in a preproduction environment. Refer to developer kit APIs protected by Java 2 security for information about which APIs are protected by Java 2 security. If you use third-party libraries, consult the vendor documentation for APIs that are protected by Java 2 security. Verify that the application is granted all the required permissions, or it might fail to run when Java 2 security is enabled.
5. Perform preproduction testing of the migrated enterprise application with Java 2 security enabled. Enable trace for the WebSphere Application Server Java 2 security manager in a preproduction testing environment with the following trace string: `com.ibm.ws.security.core.SecurityManager=all=enabled`. This trace function can be helpful in debugging the `AccessControlException` exception that is created when an application is not granted the required permission or some system code is not properly marked as privileged. The trace dumps the stack trace and permissions that are granted to the classes on the call stack when the exception is created.

For more information, see the *Securing applications and their environment* PDF.

Note: Because the Java 2 security policy is much more stringent compared with previous releases, the administrator or deployer must review their enterprise applications to see if extra permissions are required before enabling Java 2 security. If the enterprise applications are not granted the required permissions, they fail to run.

Migrating Java thin clients that use the password encoding algorithm

To migrate Java thin clients that are enabled for OS400 password encoding, use the following information to modify the Java client invocation so that the `os400.security.password` properties are no longer set on the invocation.

The password encoding feature offers the following encoding algorithms:

- XOR, which is the default
- OS400

In Version 5 and later, the value of the `os400.security.password.validation.list.object` property is dependant upon the property value passed to the thin client using the `JAVA_FLAGS` environment variable. The `JAVA_FLAGS` environment variable is set by the **setupClient** script. The **setupClient** script calls the **setupCmdLine** script, which is where the value for the `os400.security.password.validation.list.object` property is set. For example, if a Version 6.x Base Edition Java client is passed **-profileName default**, then the **setupClient** script calls the `profile_root/default/bin/setupCmdLine` file.

To migrate Java thin clients that are enabled for OS400 password encoding, modify the Java client invocation so that the `os400.security.password` properties are no longer set on the invocation. The following code sample does not contain the `os400.security.password` properties:

```
java -classpath $MY_CLIENT_CLASSES:app_server_root/classes/wsa400.jar:$WAS_CLASSPATH \  
  $CLIENTSAS $JAVA_FLAGS \  
  -Djava.naming.factory.initial=com.ibm.websphere.naming.WsnInitialContextFactory \  
  -Djava.naming.provider.url=iiop://server1:10151 \  
  MyClientClass $*
```

Perform the following steps if the following condition is true:

- If the passwords in the `sas.client.props` file for that profile are encoded with the OS400 password encoding algorithm
1. Replace all of the OS400 encoded passwords, which have {OS400} prefixes in the `sas.client.props` file for the Application Server profile, with the clear text values of the passwords.
 2. Encode the passwords using the **PropFilePasswordEncoder** Qshell command.
For more information, see “PropFilePasswordEncoder command reference” on page 1427.

Attention: You can configure a WebSphere Application Server profile to encode passwords with the XOR algorithm even though the profile is enabled to decode passwords that were encoded with either the OS400 algorithm or the XOR algorithm. If you encode these passwords with the XOR algorithm, then the passwords in the `sas.client.props` file are encoded with the XOR algorithm.

Enabling security

It is helpful to understand security from an infrastructure perspective so that you know the advantages of different authentication mechanisms, user registries, authentication protocols, and so on. Picking the right security components to meet your needs is a part of configuring security. The following sections help you make these decisions.

Read the following article before continuing with the security configuration:

- Security

After you understand the security components, you can proceed to configure security in WebSphere Application Server.

Note: For WebSphere Application Server Version 6.1, administrative security is enabled by default whenever a new profile is created, either during the initial install when you create a new profile or during post-install when you use the profile creation tooling. You can decide not to enable administrative security during profile creation time by instead enabling security post-profile creation using the administrative console.

1. Start the WebSphere Application Server administrative console.

Start the deployment manager and, in your browser, type in the address of your WebSphere Application Server Network Deployment server. By default, the console is located at `http://your_host.your_domain:9060/ibm/console`.

If security is currently disabled, you are prompted for a user ID. Log in with any user ID. However, if security is currently enabled, you are prompted for both a user ID and a password. Log in with a predefined administrative user ID and password.

2. Click **Security > Secure administration, applications, and infrastructure**. Use the Security Configuration Wizard, which is now available in WebSphere Application Server, Version 6.1, or configure security manually. The configuration order is not important. For more information on manual configuration, see `tsec_authusers.dita`.
3. Configure the user account repository. For more information, see “Selecting a registry or repository” on page 87. On the Secure administration, applications, and infrastructure panel, you can configure user account repositories such as federated repositories, local operating system, standalone Lightweight Directory Access Protocol (LDAP) registry, and standalone custom registry.

Note: You can choose to specify either a server ID and password for interoperability or enable a WebSphere Application Server 6.1 installation to automatically generate an internal server ID. For more information about automatically generating server IDs, see “Local operating system settings” on page 91.

One of the details common to all user registries or repositories is the *Primary administrative user name*. This ID is a member of the chosen repository, but also has special privileges in WebSphere Application Server. The privileges for this ID and the privileges that are associated with the administrative role ID are the same. The Primary administrative user name can access all of the protected administrative methods.

In standalone LDAP registries, verify that the Primary administrative user name is a member of the repository and not just the LDAP administrative role ID. The entry must be searchable.

The Primary administrative user name does **not** run WebSphere Application Server processes. Rather, the process ID runs the WebSphere Application Server processes.

In the default configuration, WebSphere Application Server processes run under the QEJBSVR system-provided user profile.

4. Select the **Set as current** option after you configure the user account repository. When you click **Apply** and the Enable administrative security option is set, a verification occurs to see if an administrative user ID has been configured and is present in the active user registry. The administrative user ID can be specified at the active user registry panel or from the console users link. If you do not configure an administrative ID for the active user registry, the validation fails.
5. **Optional:** You can configure and change your External Authorization provider to either WebSphere Authorization, SAF Authorization, or an external JACC provider. For more information, see and “Enabling an external JACC provider” on page 364. To change the Authorization provider, click **Security > Secure Administration, applications, and infrastructure > External Authorization providers**.
6. Configure the authentication mechanism.
Configure Lightweight Third-Party Authentication (LTPA), which is the default authentication mechanism, on the Authentication mechanisms and expiration panel. LTPA credentials can be forwarded to other machines. For security reasons, credential expire; however, you can configure the expiration dates on the console. LTPA credentials enable browsers to visit different product servers, which means you do not have to authenticate multiple times. For more information, see “Configuring the Lightweight Third Party Authentication mechanism” on page 216
If you want single sign-on (SSO) support, which provides the ability for browsers to visit different product servers without having to authenticate multiple times, see “Implementing single sign-on to minimize Web user authentications” on page 226. For form-based login, you must configure SSO when using LTPA.
7. **Optional:** Import and export the LTPA keys for cross-cell single Sign-on (SSO) between cells. For more information, see the following articles:

- “Exporting Lightweight Third Party Authentication keys” on page 221.
 - “Importing Lightweight Third Party Authentication keys” on page 221
8. Configure the authentication protocol for special security requirements from Java clients, if needed. You can configure Common Secure Interoperability Version 2 (CSlv2) through links on the Secure administration, applications, and infrastructure panel. The Security Authentication Service (SAS) protocol is provided for backwards compatibility with previous product releases, but is deprecated. Links to the SAS protocol panels display on the Secure administration, applications, and infrastructure panel if your environment contains servers that use previous versions of WebSphere Application Server and support the SAS protocol. For details on configuring CSlv2 or SAS, see the article, “Configuring RMI over IIOp” on page 297.

Important: SAS is supported only between Version 6.0.x and previous version servers that have been federated in a Version 6.1 cell.

Attention: V6.0.x IBM no longer ships or supports the Secure Authentication Service (SAS) IIOp security protocol. It is recommended that you use the Common Secure Interoperability version 2 (CSlv2) protocol.

9. Modify or create a default Secure Sockets Layer (SSL) configuration. This action protects the integrity of the messages sent across the Internet. The product provides a single location where you can specify SSL configurations that the various WebSphere Application Server features that use SSL can utilize, including the LDAP registry, Web container and the authentication protocol (CSlv2 and SAS). For more information, see “Creating a Secure Sockets Layer configuration” on page 429. After you modify a configuration or create a new configuration, specify it on the **SSL configurations** panel. To get to the SSL configurations panel, complete the following steps:
- Click **Security > SSL certificate and key management**.
 - Under Configuration settings, click **Manage endpoint security configurations > configuration_name**.
 - Under Related items, click **SSL configurations**.

You can either edit the DefaultSSLConfig file or create a new SSL configuration with a new alias name. If you create a new alias name for your new keystore and truststore files, change every location that references the DefaultSSLConfig SSL configuration alias. The following list specifies the locations of where the SSL configuration repertoire aliases are used in the WebSphere Application Server configuration.

For any transports that use the new network input/output channel chains, including HTTP and Java Message Service (JMS), you can modify the SSL configuration repertoire aliases in the following locations for each server:

- Click **Server > Application server > server_name**. Under Communications, click **Ports**. Locate a transport chain where SSL is enabled and click **View associated transports**. Click *transport_channel_name*. Under Transport Channels, click **SSL Inbound Channel (SSL_2)**.
- Click **System administration > Deployment manager**. Under Additional properties, click **Ports**. Locate a transport chain where SSL is enabled and click **View associated transports**. Click *transport_channel_name*. Under Transport Channels, click **SSL Inbound Channel (SSL_2)**.
- Click **System administration > Node agents > node_agent_name**. Under Additional properties, click **Ports**. Locate a transport chain where SSL is enabled and click **View associated transports**. Click *transport_channel_name*. Under Transport Channels, click **SSL Inbound Channel (SSL_2)**.

For the Object Request Broker (ORB) SSL transports, you can modify the SSL configuration repertoire aliases in the following locations. These configurations are for the server-level for WebSphere Application Server and WebSphere Application Server Express and the cell level for WebSphere Application Server Network Deployment.

- Click **Security > Secure administration, applications, and infrastructure**. Under RMI/IIOp security, click **CSlv2 inbound transport**.

- Click **Security > Secure administration, applications, and infrastructure**. Under RMI/IIOP security, click **CSlv2 outbound transport**.
- **V6.0.x** Click **Security > Secure administration, applications, and infrastructure**. Under RMI/IIOP security, click **SAS inbound transport**
- **V6.0.x** Click **Security > Secure administration, applications, and infrastructure**. Under RMI/IIOP security, click **SAS outbound transport**

For the ORB SSL transports on the server level for WebSphere Application Server Network Deployment, you can modify the SSL configuration repertoire aliases in the following locations:

- Click **Servers > Application servers > server_name**. Under Security, click **Server security > CSlv2 inbound transport**.
- Click **Servers > Application servers > server_name**. Under Security, click **Server security > CSlv2 outbound transport**.
- **V6.0.x** Click **Servers > Application servers > server_name**. Under Security, click **Server security > SAS inbound transport**.
- **V6.0.x** Click **Servers > Application servers > server_name**. Under Security, click **Server security > SAS outbound transport**.

For the SOAP Java Management Extensions (JMX) administrative transports, you can modify the SSL configurations repertoire aliases by clicking **Servers > Application servers > server_name**. Under Server infrastructure, click **Administration > Administration services**. Under Additional properties, click **JMX connectors > SOAPConnector**. Under Additional properties, click **Custom properties**. If you want to point the sslConfig property to a new alias, click **New** and type sslConfig in the name field, and its value in the Value field.

For additional SOAP JMX administrative transports for WebSphere Application Server Network Deployment, you can modify the SSL configuration repertoire aliases in the following locations:

- Click **System administration > Deployment manager**. Under Additional properties, click **Administration services**. Under Additional properties, click **JMX connectors > SOAPConnector**. Under Additional properties, click **Custom properties**. If you want to point the sslConfig property to a new alias, click **sslConfig** and select an alias in the Value field.
- Click **System administration > Node agents > node_agent_name**. Under Additional properties, click **Administration services**. Under Additional properties, click **JMX connectors > SOAPConnector**. Under Additional properties, click **Custom properties**. If you want to point the sslConfig property to a new alias, click **New** and type sslConfig in the name field, and its value in the Value field.

For the Lightweight Directory Access Protocol (LDAP) SSL transport, you can modify the SSL configuration repertoire aliases by clicking **Security > Secure administration, applications, and infrastructure**. Under User account repository, click the **Available realm definitions** drop-down list, and select **Standalone LDAP registry**.

10. Click **Security > Secure administration, applications, and infrastructure** to configure the rest of the security settings and enable security. For information about these settings, see “Secure administration, applications, and infrastructure settings” on page 73.
For additional information, see “Server and administrative security” on page 58.
11. Validate the completed security configuration by clicking **OK** or **Apply**. If problems occur, they display at the top of the console page in red type.
12. If there are no validation problems, click **Save** to save the settings to a file that the server uses when it restarts. Saving writes the settings to the configuration repository.

Important: If you do not click **Apply** or **OK** in the Secure administration, applications, and infrastructure panel before you click **Save**, your changes are not written to the repository. The server must be restarted for any changes to take effect when you start the administrative console.

The save action enables the deployment manager to use the changed settings after WebSphere Application Server is restarted. For more information, see “Enabling security for the realm” on page 72. A Deployment manager configuration differs from a stand-alone base application server. The configuration is stored temporarily in the deployment manager until it is synchronized with all of the node agents.

Also, verify that all of the node agents are up and running in the domain. Stop all application servers during this process. If any of the node agents are down, run a manual file synchronization utility from the node agent machine to synchronize the security configuration from the deployment manager. Otherwise, the malfunctioning node agent does not communicate with the deployment manager after security is enabled on the deployment manager.

13. Start the WebSphere Application Server administrative console.

Start the deployment manager and, in your browser, type in the address of your WebSphere Application Server Network Deployment server. By default, the console is located at `http://your_host.your_domain:9060/ibm/console`.

If security is currently disabled, log in with any user ID. If security is currently enabled, log in with a predefined administrative ID and password. This ID is typically the server user ID that is specified when you configured the user registry.

Administrative security

Administrative security determines whether security is used at all, the type of registry against which authentication takes place, and other values, many of which act as defaults. Proper planning is required because incorrectly enabling administrative security can lock you out of the administrative console or cause the server to end abnormally.

Administrative security can be thought of as a “big switch” that activates a wide variety of security settings for WebSphere Application Server. Values for these settings can be specified, but they will not take effect until administrative security is activated. The settings include the authentication of users, the use of Secure Sockets Layer (SSL), and the choice of user account repository. In particular, application security, including authentication and role-based authorization, is not enforced unless administrative security is active. Administrative security is enabled by default.

Administrative security represents the security configuration that is effective for the entire security domain. A *security domain* consists of all of the servers that are configured with the same user registry *realm* name. In some cases, the realm can be the machine name of a local operating system registry. In this case, all of the application servers must reside on the same physical machine. In other cases, the realm can be the machine name of a standalone Lightweight Directory Access Protocol (LDAP) registry.

A multiple node configuration is supported because you can access remotely user registries that support the LDAP protocol. Therefore, you can enable authentication from anywhere.

The basic requirement for a security domain is that the access ID that is returned by the registry or repository from one server within the security domain is the same access ID as that returned from the registry or repository on any other server within the same security domain. The *access ID* is the unique identification of a user and is used during authorization to determine if access is permitted to the resource.

The administrative security configuration applies to every server within the security domain.

Why turn on administrative security?

Turning on administrative security activates the settings that protect your server from unauthorized users. Administrative security is enabled by default during the profile creation time. There might be some environments where no security is needed such as a development system. On these systems you can elect to disable administrative security. However, in most environments you should keep unauthorized

users from accessing the administrative console and your business applications. Administrative security must be enabled to restrict access.

What does administrative security protect?

The configuration of administrative security for a security domain involves configuring the following technologies:

- Authentication of HTTP clients
- Authentication of IIOp clients
- Administrative console security
- Naming security
- Use of SSL transports
- Role-based authorization checks of servlets, enterprise beans, and mbeans
- Propagation of identities (RunAs)
- The common user registry
- The authentication mechanism
- Other security information that defines the behavior of a security domain includes:
 - The authentication protocol (Remote Method Invocation over the Internet Inter-ORB Protocol (RMI/IIOp) security)
 - Other miscellaneous attributes

Fine-grained administrative security

In releases prior to WebSphere Application Server version 6.1, users granted administrative roles could administer all of the resource instances under the cell. WebSphere Application Server is now more fine-grained, meaning that access can be granted to each user per resource instance.

For example, users can be granted configurator access to a specific instance of a resource only (an application, an application server or a node). Users cannot access any other resources outside of the resources assigned to them. The administrative roles are now per resource instance rather than to the entire cell. However, there is a cell-wide authorization group for backward compatibility. Users assigned to administrative roles in the cell-wide authorization group can still access all of the resources within the cell.

To achieve this instance-based security or fine-grained security, resources that require the same privileges are placed in a group called the *administrative authorization group* or *authorization group*. Users can be granted access to the authorization group by assigning to them the required administrative role.

Fine-grained administrative security can also be used in single-server environments. Various applications in the single server can be grouped and placed in different authorization groups. Therefore, there are different authorization constraints for different applications. Note that the server itself cannot be part of any authorization group.

The AdminSecurityManager role is available for wsadmin users. When using **wsadmin**, users granted this role can map users to administrative roles. Also, when fine grained admin security is used, users granted this role can manage authorization groups. See “Administrative roles and naming service authorization” on page 330 for detailed explanations of all administrative roles.

There are several administrative security commands that can be used to create authorization groups, map resources to authorization groups, and to assign users to administrative roles within the authorization groups. Following are some examples:

- **Create a new authorization group:**
`$AdminTask createAuthorizationGroup {-authorizationGroupName authGroup1}`
- **Deleting an authorization group:**

```
$AdminTask deleteAuthorizationGroup {-authorizationGroupName groupName}
```

- **Add resources to an authorization group:**

```
$AdminTask addResourceToAuthorizationGroup  
{-authorizationGroupName groupName -resourceName Application=appl}
```

- **Remove resources from an authorization group:**

```
$AdminTask removeResourceFromAuthorizationGroup  
{-authorizationGroupName groupName -resourceName Application=appl}
```

- **Add user IDs to roles in an authorization group:**

```
$AdminTask mapUsersToAdminRole {-authorizationGroupName groupName  
-roleName administrator -userids user1}
```

- **Add group IDs to roles in an authorization group:**

```
$AdminTask mapGroupsToAdminRole {-authorizationGroupName groupName  
-roleName administrator -groupids group1}
```

- **Remove user IDs from roles in an authorization group:**

```
AdminTask removeUsersFromAdminRole {-authorizationGroupName  
groupName -roleName administrator -userids user1}
```

- **Remove group IDs from roles in an authorization group:**

```
$AdminTask removeGroupsFromAdminRole {-authorizationGroupName  
groupName -roleName administrator -groupids group1}
```

Resources that can be added to an authorization group

You can add only resource instances of the following types to an authorization group:

- Cell
- Node
- ServerCluster
- Server
- Application
- NodeGroup

If a resource instance is not one of the types listed above, its parent resource will be used.

A resource instance can only belong to one authorization group. However, there is a containment relationship among resource instances. If a parent resource belongs to a different authorization group than that of its child resource instance, the child resource instance implicitly will belong to multiple authorization groups. You cannot add the same resource instance to more than one authorization group.

The following diagram shows the containment relationship among resource instances:

The privileges required for actions on resource instances depend on two factors:

- The authorization group of the administrative resource instance. If a user is granted access to an authorization group, all of the resource instances in that group will be included.
- The containment relationship of the resource instance. If a user is granted access to a parent resource instance, all of the children resource instances will be included.

The privileges required to access various administrative resource instances are shown in the following table:

Resource	Action	Required roles
Server	Start, stop, runtime operations	Server-operator, node-operator, cell-operator
Server	New, delete	Node-configurator, cell-configurator
Server	Edit configuration	Server-configurator, node-configurator, cell-configurator
Server	View configuration, runtime status	Server-monitor, node-monitor, cell-monitor
Node	Restart, stop, sync	Node-operator, Cell-operator
Node	Add, delete	Cell-configurator
Node	Edit configuration	Node-configurator, cell-configurator
Node	View configuration, runtime status	Node-monitor, cell-monitor
Cluster	Start, stop, runtime operations	Cluster-operator, cell-operator
Cluster	New, delete	Cell-configurator
Cluster	Edit configuration	Cluster-configurator, cell-configurator
Cluster	View configuration, runtime status	Cluster-monitor, cell-monitor
Cluster member	Start, stop, runtime operations	Server-operator, cluster-operator, node-operator, cell-operator
Cluster member	New, delete	Node-configurator, cell-configurator
Cluster member	Edit configuration	Server-configurator, cluster-configurator, node-configurator, cell-configurator
Cluster member	View configuration, runtime status	Server-monitor, cluster-monitor, node-monitor, cell-monitor
Application	Start, stop, runtime operations	Application-deployer, cell-operator
Application	Install, uninstall	Cell-configurator application-deployer
Application	Edit configuration	Application-deployer, cell-configurator
Application	View configuration, runtime status	Application-monitor, cell-monitor
Node, cluster	Add, delete	Cell-configurator

The *server-operator* role is the operator role of the authorization group to which the server instance is part of. Similarly, the *node-operator* role is in the operator role of the authorization group to which the node instance is part of.

Fine-grained administrative security is only available for wsadmin users. It is not available for administrative console users. To log in to the administrative console, a user should be granted a monitor role at the cell level at minimum. However, to login using wsadmin, a user should be granted a monitor role for any authorization group.

If you log in to the administrative console as a cell-level administrator, operator, monitor or configurator, you can perform all operations. However, if you want to use additional administrator roles (such as

deployer or AdminSecurityManager), or give users access only to specific authorization groups or permissions to non-cell authorization groups, you must use **wsadmin**.

Fine-grained administrative security in heterogeneous and single-server environments

Fine-grained administrative security can be used in heterogeneous or single-server environments with some restrictions.

Fine-grained administrative security in a heterogeneous environment

In WebSphere Application Server Version 6.0, heterogeneous systems are supported. Specifically, a deployment manager node can run in WebSphere Application Server Version 6.0, some nodes can run WebSphere Application Server Version 6.0, and other nodes can run WebSphere Application Server Version 5.x. In WebSphere Application Server Version 6.1, nodes are available for WebSphere Application Server Versions 5.x, 6.0, and Version 6.1.

Because all of the configurations that are done in deployment manager node are always of WebSphere Application Server Version 6.1 or higher, fine-grained administrative security can be enforced when configuring resources that belong to earlier releases. However, run-time code for versions lower than Version 6.1 cannot enforce fine-grained administrative security. Therefore, any resource instance that is not part of a WebSphere Application Server Version 6.1 node cannot be added to an authorization group.

Fine-grained administrative security in a heterogeneous environment has the following restrictions:

- Only nodes that are running WebSphere Application Server Version 6.1 can be part of an administrative authorization group.
- Only servers that are running in a WebSphere Application Server Version 6.1 node can be part of an administrative authorization group.
- Only applications that are targeted on servers running on WebSphere Application Server Version 6.1 can be part of an administrative authorization group.
- If a cluster spans nodes of multiple releases, it cannot be part of an administrative authorization group.
- If a cluster spans nodes of multiple releases, none of its members can be part of an administrative authorization group.
- If an application is targeted on a cluster that spans multiple releases, that application cannot be part of an administrative authorization group.

Fine-grained administrative security in a single-server environment

You can also use fine-grained administrative security in a single-server environment. Various applications in the single server can be grouped and placed in different authorization groups. Therefore, different authorization constraints might exist for different applications.

Life cycle of fine-grained administrative resource

An administrative resource that was once part of an authorization group continues to be part of that authorization group until one of the following events occurs:

- The administrative resource is removed from the authorization group. In this instance, the administrative resource belongs to the cell-level authorization group.
- The administrative resource is removed from the configuration. In this instance, the administrative resource does not exist in the configuration, but still exists in the authorization group. Remove this administrative resource from the authorization group.

After the administrative resource is removed from the authorization group, the administrative authorizer runtime must be notified by using the AuthorizationManager refreshAll MBean method.

The **refreshAll** command must be invoked after `AdminConfig.save()` and sync nodes. For example:

JACL:

```
// get AuthorizationGroup Mbean
wsadmin> set agBean [$AdminControl queryNames
Type=AuthorizationGroupManager,process=dmgr,*]
```

JYTHON:

```
// get AuthorizationGroup Mbean
wsadmin> set agBean [$AdminControl queryNames
Type=AuthorizationGroupManager,process=dmgr,*]
```

Fine-grained administrative security scenarios

The following scenarios describe the use of fine-grained administrative security, particularly the new deployment role.

Deployment role scenario 1

In the following scenario, there are four applications configured on server S1, as shown in the following table. Each application must be isolated so that the administrator of one application cannot modify another application. Assume that only user1 can manage application A1, user2 can manage applications A2 and A3, and only user3 can manage application A4.

Note: It is not recommended to have an application in one group and its target server in another group. However, that is not always possible. It is common to have many applications on one server. It is still sometimes necessary to isolate the administration of applications running on the same server.

One example is an Application Service Provider (ASP), where a single application server can have multiple vendor applications. In this instance the server administrator is responsible for installing all of the vendor applications. Once applications are installed, each vendor can manage their own application without interfering with other vendor's applications.

Application	Server	Node
A1	S1	N1
A2	S1	N1
A3	S1	N1
A4	S1	N1

We can configure authorization groups as shown in the diagram below:

In the diagram, application A1 is in authorization group G1, applications A2 and A3 are in authorization group G2, and application A4 is in authorization group G3.

A deployer role is assigned from authorization group G1 to user1, from authorization group G2 to user2, and from authorization group G3 to user3.

Consequently, user1 can perform all of the operations on application A1, user2 on applications A2 and A3, and user3 on application A4. Since all applications share the same server, we cannot put the same server on all authorization groups. Only a cell-level administrator can install an application. After the installation of an application is complete, the deployer of each application can modify their own. To start and stop the server, cell-level administrative authority is required. This type of scenario is useful in an ASP environment.

Deployment role scenario 2

In the following scenario, a group of applications require the same administrative roles to one server. In this example, applications A1 and A2 are related applications, and can be administrated by one set of administrators. They are running on the same server (S1). Applications A3 and A4 require a different set of administrators, and are running on servers S2 and S3 respectively.

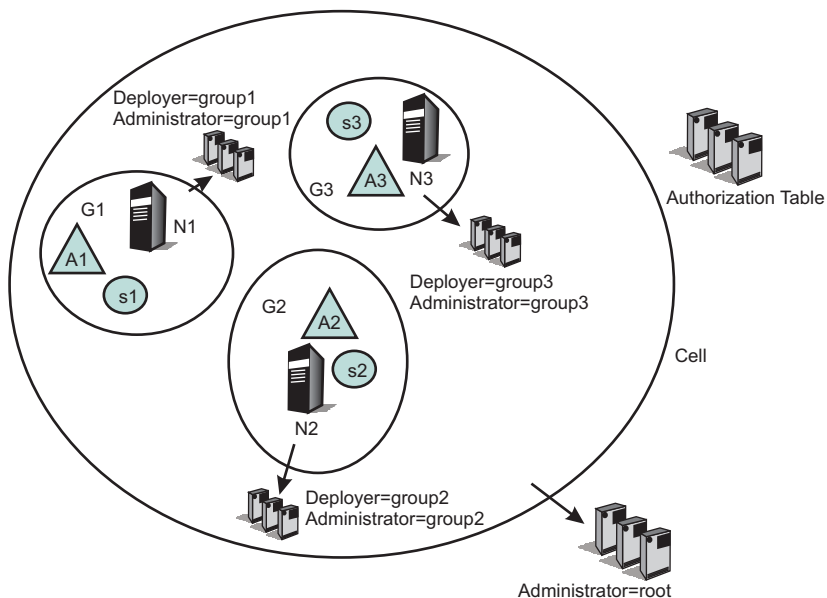

Application	Server	Node
A1	S1	N1
A2	S1	N1
A3	S2	N2
A4	S3	N3

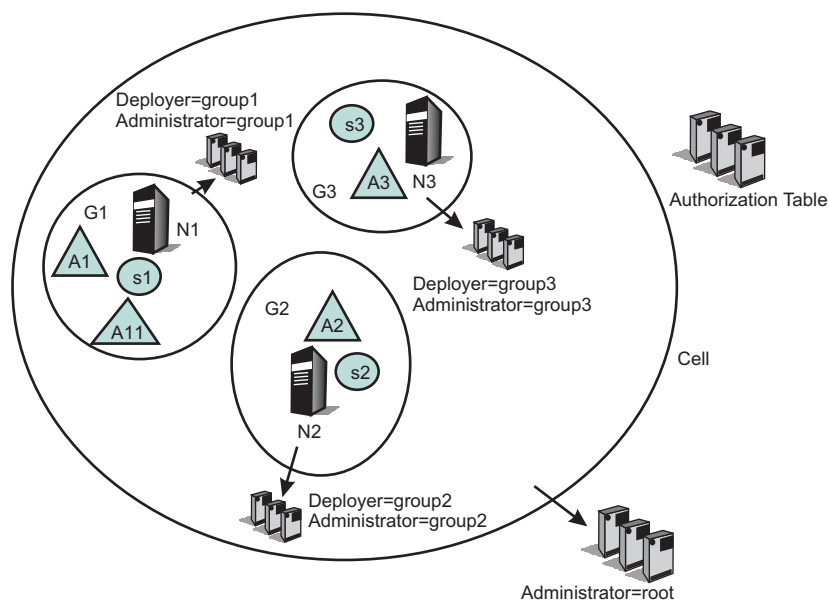

Scenarios that can be applied directly in customer environments

Each developer must be able to modify the configuration for their server, and they must be able to install their application onto that server. They also must be able to start and stop the server as well as the application on the server.

Developers also must be able to configure the server so that they can debug any problems they run into. They must have the ability to update or modify the application being developed. The administrative authorization group for this developer includes at least one server and any applications that the developer installs on that server.

In the following example, developers of authorization group G1 have a new application (A11). They can install and target that new application only on servers within authorization group G1. Also, they can place that new application in their authorization group (G1).

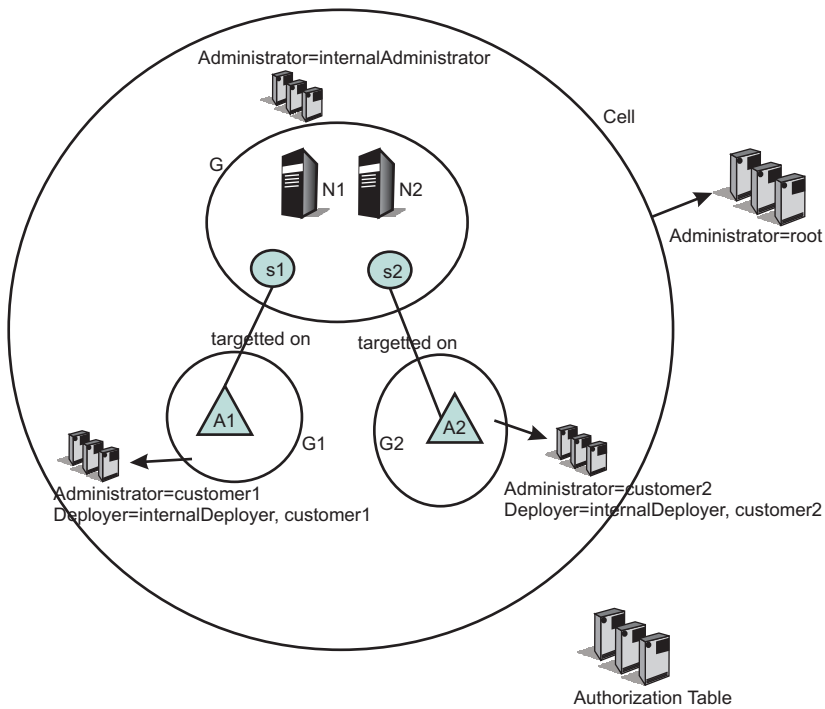

ASP environment scenario

In this scenario, the customer is an ASP. They have their own customers to whom they provide application serving function. They want to enable their customers to administer and monitor their applications, but not to see or administer applications for different customers. In this example, however, the ASP has internal staff administrators whose job it is to maintain the servers.

This internal ASP staff administrator might need to move an application from one server to another to ensure that an application remains available. The internal ASP staff administrator should be able to stop and start the servers and to change their configuration.

In contrast, the ASP customer administrator should not be able to stop or start servers. However, the ASP customer administrator should be able to update their applications running on those servers. The administrative authorization group for the internal ASP administrator can be the whole cell or can include a subset of servers, nodes, clusters and applications. The administrative authorization group for the customer administrator only includes those applications that the customer has paid to have served by this ASP.

The following diagram contains a scenario where two different customers have two different type of applications, and can manage their own applications. However, the servers and nodes on which the applications are running are isolated from their customers. The servers and nodes can only be maintained by the internal administrators. In addition, the customers cannot target their applications on a different server. This can only be performed by the internal administrator or internal deployers.

Regional organization scenario

In this scenario, the customer is a large global company. The company's nodes and servers are organized so as to provide application serving for different regions (or alternatively, different lines of business). They want representatives from the different regional areas to be able to monitor and administer the nodes and servers associated with that region. However, they do not want the regional administrator to be able to effect any node and server associated with a different region.

The administrative authorization group for each regional representative includes the nodes, servers, clusters and applications associated with that region.

For example, consider a company that provides multiple services, such as a financial institution that provides services like credit card accounts, brokerage accounts, banking accounts, or travel accounts. Each of these services can be separate applications, and the administrator for each of these applications must also be different. The following figure shows one way to configure such a system:

The following figure shows how the resources in such a system can be grouped to isolate administrators from each other:

Note that the nodes are not part of any authorization group. Therefore, a trade application administrator cannot stop a server on any of the nodes, and is prevented from stopping a travel application.

The same system can be configured in another way as shown below:

The following figure shows how the resources in such a system can be grouped to isolate administrators from each other:

Server and administrative security

The term *administrative security* refers to the security configuration that is effective for the entire security domain. A security domain consists of all the servers that are configured with the same user registry realm name. On the z/OS platform, the term *administrative security* refers to the security configuration that is effective for the WebSphere Application Server cell.

In some cases, the realm can be the machine name of a Local OS user registry. In this case, all application servers must reside on the same physical machine. In other cases, the realm can be the machine name of a Lightweight Directory Access Protocol (LDAP) user registry. Because LDAP is a distributed user registry, this allows for a multiple node configuration in a Network Deployment environment. The basic requirement for a security domain is that the access ID returned by the registry

from one server within the security domain is the same access ID that is returned from the registry on any other server within the same security domain. The access ID is the unique identification of a user and is used during authorization to determine if access is permitted to the resource.

Configuration of administrative security for a security domain consists of configuring the common user registry, the authentication mechanism, and other security information that defines the behavior of a security domain. The other security information that is configured includes the following components:

- Java 2 Security Manager
- Java Authentication and Authorization Service (JAAS)
- Java 2 Connector authentication data entries
- **V6.0.x** Common Secure Interoperability Version 2 (CSIv2) and Secure Authentication Service (SAS) authentication protocol (Remote Method Invocation over the Internet Inter-ORB Protocol (RMI/IOP) security)
- Other miscellaneous attributes.

You can override some portions of the configuration at the server level.

Where multiple nodes and multiple servers within a node are possible, you can configure certain attributes at a server level. The attributes that are configurable at a server level include security enablement for the server, Java 2 security manager enablement, and CSIv2/SAS authentication protocol (RMI/IOP security). You can disable security on individual application servers while administrative security is enabled, however, you cannot enable security on an individual application server while administrative security is disabled.

While application server security is disabled for user requests, administrative and naming security is still enabled for that application server so that the administrative and naming infrastructure remains secure. If cell security is enabled, but security for individual servers is disabled, J2EE applications are not authenticated or authorized. However, naming and administrative security is still enforced. Consequently, because naming services can be called from user applications, grant Everyone access to the naming functions that are required so that these functions accept unauthenticated requests. User code does not directly access administrative security except through the supported scripting tools.

Considering security specific to a multi-node or process Network Deployment environment

WebSphere Application Server Network Deployment supports centralized management of distributed nodes and application servers. This support inherently brings complexity, especially when security is included. Because everything is distributed, security plays an even larger role in ensuring that communications are appropriately secure between application servers and node agents, and between node agents (a node-specific configuration manager) and the deployment manager (a domain-wide, centralized configuration manager).

Because the processes are distributed, the authentication mechanism that must be used is Lightweight Third Party Authentication (LTPA). The LTPA tokens are encrypted, signed and forwardable to remote processes. However, the tokens have expirations. The SOAP connector which is the default connector, is used for administrative security and does not have retry logic for expired tokens. However, the protocol is stateless so a new token is created for each request if there is not sufficient time to run the request with the given time left in the token. An alternative connector is the RMI connector, which is stateful, and has some retry logic to correct expired tokens by resubmitting the requests after the error is detected. Also, because tokens have time-specific expiration, the synchronization of the system clocks are crucial to the proper operation of token-based validation. If the clocks are off by too much (approximately 10-15 minutes), you can encounter unrecoverable validation failures that can be avoided by having them in sync. Verify that the clock time, date, and time zones are all the same between systems. It is acceptable for nodes to be across time zones, provided that the times are correct within the time zones (for example, 5 PM CST = 6 PM EST, and so on).

Consider the following issues when using or planning for a Network Deployment environment.

- When attempting to run system management commands such as the **stopNode** command, explicitly specify administrative credentials to perform the operation. Most commands accept **-user** and **-password** parameters to specify the user ID and password, respectively. Specify the user ID and password of an administrative user; for example, a user who is a member of the console users with Operator or Administrator privileges or the administrative user ID that is configured in the user registry. An example of the **stopNode** command follows:
 - `stopNode -username user -password pass`
- Verify that the configuration at the node agents are always synchronized with the deployment manager prior to starting or restarting a node. To manually get the configuration synchronized, issue the **syncNode** command from each node that is not synchronized. To synchronize the configuration for node agents that are started, click **System Administration > Nodes**. Select all the started nodes, and then click **Synchronize**.
- Verify that the clocks on all systems are in sync including the time zone, time and date. If they are out of sync, the tokens expire immediately when they reach the target server due to the time differences.
- Verify that the LTPA token expiration period is long enough to complete your longest downstream request. Some credentials are cached and therefore the timeout does not always include the length of the request.
- The administrative connector that is used by default for system management is SOAP. SOAP is a stateless HTTP protocol. For most situations, this connector is sufficient. If you have a problem using the SOAP connector, you might want to change the default connector on all the servers from SOAP to RMI. The RMI connector uses Common Secure Interoperability Version 2 (CSIv2), a stateful, interoperable protocol, and can be configured to use identity assertion (downstream delegation), message-layer authentication (BasicAuth or Token), and client certificate authentication (for server trust isolation). To change the default connector on a given server, go to **Administration Services** under Additional properties for that server.
- An error message might occur within the administrative subsystem security. This error indicates that the sending process did not supply a credential to the receiving process. Typically the causes of this problem are:
 - The sending process has security disabled while the receiving process has security enabled. This setup typically indicates one of the two processes are not synchronized with the cell. Having security disabled for a specific application server does not have any effect on administrative security.
 - The clocks between the systems are not synchronized; this immediately makes the credential tokens not valid. Verify that the time, date, and time zones are consistent between the two machines. An error similar to the following might occur:

```
[9/18/02 16:48:23:859 CDT] 3b9cef35 RoleBasedAuth A CWSCJ0305I: Role based authorization check failed for security name <null>, accessId NO_CRED_NO_ACCESS_ID while invoking method propagateNotifications:[Ljavax.management.Notification; on resource NotificationService and module NotificationService.
```
- When getting the following error message, validate that the clocks are synchronized between all servers within the cell, and the configurations are synchronized between all nodes and the Deployment Manager. An error similar to the following might occur:

```
[9/18/02 16:48:22:859 CDT] 3bd06f34 LTPAServerObj E CWSCJ0372E: Validation of the token failed.
```

Proper understanding of the security interactions between distributed servers greatly reduces the problems that are encountered with secure communications. Security adds complexity because additional function must be managed. For security to work properly, it needs thorough consideration during the planning of your infrastructure.

When you have security problems that are related to the WebSphere Application Server Network Deployment environment, see Chapter 22, “Troubleshooting security configurations,” on page 1435 to find additional information about the problem. When trace is needed to solve a problem because servers are

distributed, it is often required to gather trace on all servers simultaneously while recreating the problem. This trace can be enabled dynamically or statically, depending on the type of problem that is occurring.

Application security

Application security enables security for the applications in your environment. This type of security provides application isolation and requirements for authenticating application users

In previous releases of WebSphere Application Server, when a user enabled global security, both administrative and application security were enabled. In WebSphere Application Server Version 6.1, the previous notion of global security is split into administrative security and application security, each of which you can enable separately.

As a result of this split, WebSphere Application Server clients must know whether application security is disabled at the target server. Administrative security is enabled, by default. Application security is disabled, by default. To enable application security, you must enable administrative security. Application security is in effect only when administrative security is enabled.

An Application Server Enablement Tag, which is specific to WebSphere Application Server, is imported into the Interoperable Object Reference (IOR) to indicate if application security is disabled for the server where the object lives. This tag is server-specific and enables clients to know when application security is disabled at the target server of its request.

For Web resources, when application security is enabled, authentication is prompted for lookups on the application server.

For enterprise bean resources, when application security is disabled, the client Common Secure Interoperability version 2 (CSIv2) code ignores the CSIv2 security tags for objects that are unknown system objects. When pure clients see that application security is disabled, these clients prompt for naming lookups, but do not prompt for enterprise bean operations.

Java 2 security

Java 2 security provides a policy-based, fine-grain access control mechanism that increases overall system integrity by checking for permissions before allowing access to certain protected system resources. Java 2 security guards access to system resources such as file I/O, sockets, and properties. Java 2 Platform, Enterprise Edition (J2EE) security guards access to Web resources such as servlets, JavaServer Pages (JSP) files and Enterprise JavaBeans (EJB) methods.

WebSphere Application Server security includes the following technologies:

- Java 2 Security Manager
- Java Authentication and Authorization Service (JAAS)
- Java 2 Connector authentication data entries
- **V6.0.x** Common Secure Interoperability Version 2 (CSIv2) or Security Authentication Service (SAS)

Important: SAS is supported only between Version 6.0.x and previous version servers that have been federated in a Version 6.1 cell.

- J2EE role-based authorization
- Secure Sockets Layer (SSL) configuration

Because Java 2 security is relatively new, many existing or even new applications might not be prepared for the very fine-grain access control programming model that Java 2 security is capable of enforcing. Administrators need to understand the possible consequences of enabling Java 2 security if applications are not prepared for Java 2 security. Java 2 security places some new requirements on application developers and administrators.

Important: Java 2 security only restricts Java programs that run in a Java virtual machine that has Java 2 security enabled. It does not protect system resources if Java 2 Security is disabled or if system resources are accessed from other programs or commands. Therefore, if you want to protect your system resources, you need to use operating system security.

Java 2 security for deployers and administrators

Although Java 2 security is supported, it is disabled by default. You can configure Java 2 security and administrative security independently of one another. Disabling administrative security does not disable Java 2 security automatically. You need to explicitly disable it.

If your applications, or third-party libraries are not ready, having Java 2 security enabled causes problems. You can identify these problems as Java 2 security `AccessControlExceptions` in the system log or trace files. If you are unsure about the Java 2 security readiness of your applications, disable Java 2 security initially to get your application installed and verify that it is working properly.

Implications exist if Java 2 security is enabled; deployers or administrators are required to make sure that all the applications are granted the required permissions; otherwise, applications might fail to run. By default, applications are granted the permissions that are recommended in the J2EE 1.4 Specification. For the details of default permissions granted to applications in the product, refer to the following policy files:

- `QIBM/ProdData/Java400/jdk15/lib/security/java.policy`
- `profile_root/properties/server.policy`
- `profile_root/config/cells/*cell_name/nodes/*node_name/app.policy`

The policy embodied by these policy files cannot be made more restrictive because the product might not have the necessary Java 2 security `doPrivileged` APIs in place. The restrictive policy is the default policy. You can grant additional permissions, but you cannot make the default more restrictive because `AccessControlExceptions` exceptions are generated from within WebSphere Application Server. The product does not support a more restrictive policy than the default that is defined in the policy files previously mentioned.

Several policy files are used to define the security policy for the Java process. These policy files are static (code base is defined in the policy file) and in the default policy format provided by the IBM Developer Kit, Java Technology Edition. For enterprise application resources and utility libraries, WebSphere Application Server provides dynamic policy support. The code base is dynamically calculated based on deployment information and permissions are granted based on template policy files during runtime. Refer to the “Java 2 security policy files” on page 66 for more information.

Important: Syntax errors in the policy files cause the application server process to fail. Edit these policy files carefully using the Policy Tool that is provided by the IBM Developer Kit, Java Technology Edition. See “Using PolicyTool to edit policy files” on page 528 for more information.

If an application is not prepared for Java 2 security, if the application provider does not provide a `was.policy` file as part of the application, or if the application provider does not communicate the expected permissions the application is likely to cause Java 2 security access control exceptions at runtime. It might not be obvious that an application is not prepared for Java 2 security. Several run-time debugging aids help troubleshoot applications that might have access control exceptions. See the Java 2 security debugging aids for more details. See “Handling applications that are not Java 2 security ready” on page 64 for information and strategies for dealing with such applications.

It is important to note when Java Security is enabled in the administrative security settings, the installed security manager does not currently check `modifyThread` and `modifyThreadGroup` permissions for non-system threads. Allowing Web and Enterprise JavaBeans (EJB) application code to create or modify a thread can have a negative impact on other components of the container and can affect the capability of the container to manage enterprise bean life cycles and transactions.

Java 2 security for application developers

Application developers must understand the permissions that are granted in the default WebSphere policy and the permission requirements of the SDK APIs that their application calls to know whether additional permissions are required. The Permissions in the Java 2 SDK reference in the resources section describes which APIs require which permission.

Application providers can assume that applications have the permissions granted in the default policy previously mentioned. Applications that access resources not covered by the default WebSphere policy are required to grant the additional Java 2 security permissions to the application.

While it is possible to grant the application additional permissions in one of the other dynamic WebSphere policy files or in one of the more traditional `java.policy` static policy files, the `was.policy` file, which is embedded in the EAR file ensures the additional permissions are scoped to the exact application that requires them. Scoping the permission beyond the application code that requires it can permit code that normally does not have permission to access particular resources.

If an application component is being developed, like a library that might actually be included in more than one `.ear` file, then the library developer needs to document the required Java 2 permissions that are required by the application assembler. There is no `was.policy` file for library-type components. The developer must communicate the required permissions through application programming interface (API) documentation or some other external documentation.

If the component library is shared by multiple enterprise applications, the permissions can be granted to all enterprise applications on the node in the `app.policy` file.

If the permission is only used internally by the component library and the application is never granted access to resources that are protected by the permission, it might be necessary to mark the code as **privileged**. Refer to the, `AccessControlException`, topic for more details. However, improperly inserting a `doPrivileged` call might open up security holes. Understand the implication of `doPrivileged` call to make a correct judgement.

The section on Dynamic policy files in “Java 2 security policy files” on page 66 describes how the permissions in the `was.policy` files are granted at runtime.

Developing an application to use with Java 2 security might be a new skill and impose a security awareness not previously required of application developers. Describing the Java 2 security model and the implications on application development is beyond the scope of this section. The following URL can help you get started: <http://java.sun.com/j2se/1.5.0/docs/guide/security/index.html>.

Debugging Aids

The WebSphere Application Server SYSOUT file and the `com.ibm.websphere.java2secman.norethrow` property are the two primary aids for debugging.

The WebSphere System Log or Trace Files

The `AccessControl` exception that is logged in the system log or trace files contains the permission violation that causes the exception, the exception call stack, and the permissions granted to each stack frame. This information is usually enough to determine the missing permission and the code requiring the permission.

The `com.ibm.websphere.java2secman.norethrow` property

When Java 2 security is enabled in WebSphere Application Server, the security manager component creates a `java.security.AccessControl` exception when a permission violation occurs. This exception, if not handled, often causes a run-time failure. This exception is also logged in the `SYSOUT` file.

However, when the Java virtual machine `com.ibm.websphere.java2secman.norethrow` property is set and has a value of `true`, the security manager does not create the `AccessControl` exception. This information is logged.

To set the `com.ibm.websphere.java2secman.norethrow` property for the server, go to the WebSphere Application Server administrative console and click **Servers > Application Servers > *server_name***. Under Server infrastructure, click **Java and Process Management > Process definition**. Under Additional properties, click **Java Virtual Machine > Custom Properties > New**. In the **Name** field, type `com.ibm.websphere.java2secman.norethrow`. In the **Value** field, type `true`.

To set the `com.ibm.websphere.java2secman.norethrow` property for the node agent, go to the WebSphere Application Server administrative console and click **System Administration > Node Agents > *node_agent_name***. Under Server infrastructure, click **Java and Process Management > Process Definition**. Under Additional properties, click **Java Virtual Machine > Custom Properties > New**. In the **Name** field, type `com.ibm.websphere.java2secman.norethrow`. In the **Value** field, type `true`.

To set the `com.ibm.websphere.java2secman.norethrow` property for the deployment manager, go to the WebSphere Application Server administrative console and click **System Administration > Deployment Manager**. Under Server infrastructure, click **Java and Process Management > Process Definition**. Under Additional Properties, click **Process Definition > Java Virtual Machine > Custom Properties > New**. In the **Name** field, type `com.ibm.websphere.java2secman.norethrow`. In the **Value** field, type `true`.

This property is intended for a sandbox or debug environment because it instructs the security manager not to create the `AccessControl` exception. Java 2 security is not enforced. Do not use this property in a production environment where a relaxed Java 2 security environment weakens the integrity that Java 2 security is intended to produce.

This property is valuable in a sandbox or test environment where the application can be thoroughly tested and where the system log or trace files can be inspected for `AccessControl` exceptions. Because this property does not create the `AccessControl` exception, it does not propagate the call stack and does not cause a failure. Without this property, you have to find and fix `AccessControl` exceptions one at a time.

Handling applications that are not Java 2 security ready

If the increased system integrity that Java 2 security provides is important, then contact the application provider to have the application support Java 2 security or at least communicate the required additional permissions beyond the default WebSphere Application Server policy that must be granted.

The easiest way to deal with such applications is to disable Java 2 security in WebSphere Application Server. The downside is that this solution applies to the entire system and the integrity of the system is not as strong as it might be. Disabling Java 2 security might not be acceptable depending on the organization security policies or risk tolerances.

Another approach is to leave Java 2 security enabled, but to grant either just enough additional permissions or grant all permissions to just the problematic application. Granting permissions however, might not be a trivial thing to do. If the application provider has not communicated the required permissions in some way, no easy way exists to determine what the required permissions are and granting all permissions might be the only choice. You minimize this risk by locating this application on a different node, which might help isolate it from certain resources. Grant the `java.security.AllPermission` permission in the `was.policy` file that is embedded in the application `.ear` file, for example:

```
grant codeBase "file:${application}" {  
    permission java.security.AllPermission;  
};
```

The server.policy file

The server.policy file is located in the *profile_root/properties* directory.

This policy defines the policy for the WebSphere Application Server classes. At present, all the server processes on the same installation share the same server.policy file. However, you can configure this file so that each server process can have a separate server.policy file. Define the policy file as the value of the java.security.policy Java system properties . For details of how to define Java system properties, refer to the Process definition section of the Manage application servers file.

The server.policy file is not a configuration file managed by the repository and the file replication service. Changes to this file are local and do not get replicated to other machines. Use the server.policy file to define Java 2 security policy for server resources. Use the app.policy file (per node) or the was.policy file (per enterprise application) to define Java 2 security policy for enterprise application resources.

The java.policy file

The file represents the default permissions that are granted to all classes. The policy of this file applies to all the processes launched by the Java Virtual Machine in the WebSphere Application Server.

The java.policy file is located in the /QIBM/ProdData/Java400/jdk15/lib/security/ directory. The policy file is used throughout the operating system. Do not edit the java.policy file.

Troubleshooting

Symptom:

Error message CWSCJ0314E: Current Java 2 security policy reported a potential violation of Java 2 security permission. Refer to Problem Determination Guide for further information.{0}Permission\:{1}Code\:{2}{3}Stack Trace\:{4}Code Base Location\:{5} Current Java 2 security policy reported a potential violation of Java 2 Security Permission. Refer to Problem Determination Guide for further information.{0}Permission\:{1}Code\:{2}{3}Stack Trace\:{4}Code Base Location\:{5}

Problem:

The Java security manager checkPermission method reported a security exception on the subject permission with debugging information. The reported information can be different with respect to the system configuration. This report is enabled by either configuring a Reliability Availability Service Ability (RAS) trace into debug mode or specifying a Java property.

See Enabling trace for information on how to configure RAS trace in debug mode.

Specify the following property in the JVM Settings panel from the administrative console:

java.security.debug. Valid values include:

access

Print all debug information including: required permission, code, stack, and code base location.

stack Print debug information including: required permission, code, and stack.

failure Print debug information including: required permission and code.

Recommended response:

The reported exception might be critical to the secure system. Turn on security trace to determine the potential code that might have violated the security policy. After the violating code is determined, verify if the attempted operation is permitted with respect to Java 2 security, by examining all applicable Java 2 security policy files and the application code.

If the application is running with Java Mail, this message might be benign. You can update the `was.policy` file to grant the following permissions to the application:

```
permission java.io.FilePermission "${user.home}{/}.mailcap", "read";
permission java.io.FilePermission "${user.home}{/}.mime.types", "read";
permission java.io.FilePermission "${java.home}{/}lib{/}mailcap", "read";
permission java.io.FilePermission "${java.home}{/}lib{/}mime.types", "read";
```

Problem:	An unexpected exception is caught when the code base location is determined.

Java 2 security policy files

The Java 2 Platform, Enterprise Edition (J2EE) Version 1.3 and later specifications have a well-defined programming model of responsibilities between the container providers and the application code. Using Java 2 security manager to help enforce this programming model is recommended. Certain operations are not supported in the application code because such operations interfere with the behavior and operation of the containers. The Java 2 security manager is used in the product to enforce responsibilities of the container and the application code.

This product provides support for policy file management. A number of policy files in the product are either static or dynamic. *Dynamic policy* is a template of permissions for a particular type of resource. No relative code base is defined in the dynamic policy template. The code base is dynamically calculated from the deployment and run-time data.

Static policy files

Policy file	Location
<code>java.policy</code>	<code>/QIBM/ProdData/Java400/jdk15/lib/security/java.policy</code> . The <code>java.policy</code> file is used throughout the system. Do not edit this file.
<code>server.policy</code>	<code>profile_root/properties/server.policy</code> . Default permissions are granted to all the product servers.
<code>client.policy</code>	<code>profile_root/properties/client.policy</code> . Default permissions are granted for all of the product client containers and applets on a node.

The static policy files are not managed by configuration and file replication services. Changes made in these files are local and are not replicated to other nodes in the Network Deployment cell.

Dynamic policy files

Policy file	Location
spi.policy	<p><i>profile_root/config/cells/cell_name</i> <i>/nodes/node_name/spi.policy</i></p> <p>This template is for the Service Provider Interface (SPI) or the third-party resources that are embedded in the product. Examples of SPI are the Java Message Service (JMS) in MQ Series and Java database connectivity (JDBC) drivers. The code base for the embedded resources are dynamically determined from the configuration (<i>resources.xml</i> file) and run-time data, and permissions that are defined in the <i>spi.policy</i> files are automatically applied to these resources and JAR files that are specified in the class path of a resource adapter. The default permission of the <i>spi.policy</i> file is <code>java.security.AllPermissions</code>.</p>
library.policy	<p><i>profile_root/config/cells/cell_name/nodes</i> <i>/node_name/library.policy</i></p> <p>This template is for the library (Java library classes). You can define a shared library to use in multiple product applications. The default permission of the <i>library.policy</i> file is empty.</p>
app.policy	<p><i>profile_root/config/cells/cell_name</i> <i>/nodes/node_name/app.policy</i></p> <p>The <i>app.policy</i> file defines the default permissions that are granted to all of the enterprise applications running on <i>node_name</i> in <i>cell_name</i>.</p>
was.policy	<p><i>profile_root/config/cells/cell_name</i> <i>/applications/ear_file_name/deployments/</i> <i>application_name/META-INF/was.policy</i></p> <p>This template is for application-specific permissions. The <i>was.policy</i> file is embedded in the enterprise archive (EAR) file.</p>
ra.xml	<p><i>rar_file_name/META-INF/was.policy.RAR.</i></p> <p>This file can have a permission specification that is defined in the <i>ra.xml</i> file. The <i>ra.xml</i> file is embedded in the RAR file.</p>

Grant entries that are specified in the *app.policy* and *was.policy* files must have a code base defined. If grant entries are specified without a code base, the policy files are not loaded properly and the application can fail. If the intent is to grant the permissions to all applications, use `file:${application}` as a code base in the grant entry.

Syntax of the policy file

A policy file contains several policy entries. The following example depicts each policy entry format:

```
grant [codebase <Codebase>] {
  permission <Permission>;
  permission <Permission>;
  permission <Permission>;
};
```

<CodeBase>: A URL.

For example, `"file:${java.home}/lib/tools.jar"`

When `[codebase <Codebase>]` is not specified, listed permissions are applied to everything.

If URL ends with a JAR file name, only the classes in the JAR file belong to the codebase.

If URL ends with `"/"`, only the class files in the specified directory belong to the codebase.

If URL ends with `"*"`, all JAR and class files in the specified directory belong to the codebase.

If URL ends with "-", all JAR and class files in the specified directory and its subdirectories belong to the codebase.

```
<Permissions>: Consists from
    Permission Type    : class name of the permission
    Target Name       : name specifying the target
    Actions           : actions allowed on target
For example,
    java.io.FilePermission "/tmp/xxx", "read,write"
```

Refer to developer kit specifications for the details of each permission.

Syntax of dynamic policy

You can define permissions for specific types of resources in dynamic policy files for an enterprise application. This action is achieved by using *product-reserved symbols*. The reserved symbol scope depends on where it is defined. If you define the permissions in the `app.policy` file, the symbol applies to all the resources on all of the enterprise applications that run on `node_name`. If you define the permissions in the `META-INF/was.policy` file, the symbol applies only to the specific enterprise application. Valid symbols for the code base are listed in the following table:

Symbol	Meaning
<code>file:\${application}</code>	Permissions apply to all the resources within the application
<code>file:\${jars}</code>	Permissions apply to all the utility Java archive (JAR) files within the application
<code>file:\${ejbComponent}</code>	Permissions apply to the Enterprise JavaBeans (EJB) resources within the application
<code>file:\${webComponent}</code>	Permissions apply to the Web resources within the application
<code>file:\${connectorComponent}</code>	Permissions apply to the connector resources within the application

You can specify the module name for a granular setting, except for these entries that are specified by the code base symbols. For example:

```
grant codeBase "file:DefaultWebApplication.war" {
    permission java.security.SecurityPermission "printIdentity";
};

grant codeBase "file:IncCMP11.jar" {
    permission java.io.FilePermission
"$${user.install.root}${/}bin${/}DefaultDB${/}-",
"read,write,delete";
};
```

The sixth and seventh lines in the previous code sample are one continuous line. You can use a relative code base only in the `META-INF/was.policy` file. Several product-reserved symbols are defined to associate the permission lists to a specific type of resources.

Symbol	Meaning
<code>file:\${application}</code>	Permissions apply to all the resources within the application
<code>file:\${jars}</code>	Permissions apply to all the utility JAR files within the application
<code>file:\${ejbComponent}</code>	Permissions apply to the enterprise beans resources within the application

Symbol	Meaning
file:\${webComponent}	Permissions apply to the Web resources within the application
file:\${connectorComponent}	Permissions apply to the connector resources both within the application and in the standalone connector resources.

Five embedded symbols are provided to specify the path and the name for the `java.io.FilePermission` permission. These symbols enable flexible permission specification. The absolute file path is fixed after the installation of the application.

Symbol	Meaning
\${app.installed.path}	Path where the application is installed
\${was.module.path}	Path where the module is installed
\${current.cell.name}	Current cell name
\${current.node.name}	Current node name
\${current.server.name}	Current server name

Attention: Do not use the `${was.module.path}` in the `${application}` entry.

Carefully determine where to add a new permission. An incorrectly specified permission causes an `AccessControlException` exception. Because dynamic policy resolves the code base at runtime, determining which policy file has a problem is difficult. Add a permission only to the necessary resources. For example, use `${ejbcomponent}`, and etc instead of `${application}`, and update the `was.policy` file instead of the `app.policy` file, if possible.

Static policy filtering

Limited static policy filtering support exists. If the `app.policy` file and the `was.policy` file have permissions that are defined in the `filter.policy` file with the `filterMask` keyword, the runtime removes the permissions from the applications and an audit message is logged. However, if the permissions that are defined in the `app.policy` and the `was.policy` files are compound permissions, for example, `java.security.AllPermission`, the permission is not removed, but a warning message is written to the log file. The policy filtering only supports Developer Kit permissions; the permissions package name begins with `java` or `javax`.

Run-time policy filtering support is provided to force stricter filtering. If the `app.policy` file and the `was.policy` file have permissions that are defined in the `filter.policy` file with the `runtimeFilterMask` keyword, the runtime removes the permissions from the applications no matter what permissions are granted to the application. For example, even if a `was.policy` file has the `java.security.AllPermission` permission granted to one of its modules, specified permissions such as the `runtimeFilterMask` permission are removed from the granted permission during runtime.

If the **Warn if applications are granted custom permissions** option on the Secure administration, applications, and infrastructure panel is enabled and if the `app.policy` file and the `was.policy` file contain custom permissions (non-Developer Kit permissions, where the permissions package name begins with `java` or `javax`), a warning message logs. The permission is not removed. If the `AllPermission` permission is listed in the `app.policy` file and the `was.policy` file, a warning message logs.

Policy file editing

Using the policy tool that is provided by the Developer Kit (`app_server_root/java/jre/bin/policytool`), to edit the previous policy files is recommended. For Network Deployment, extract the policy files from the

repository before editing. After the policy file is extracted, use the policy tool to edit the file. Check the modified policy files into the repository and synchronize them with other nodes.

If syntax errors exist in the policy files, the enterprise application or the server process might fail to start. Be cautious when editing these policy files. For example, if a policy has a trailing space in the policy permission target name, the policy fails to parse the permission properly in the IBM Developer Kit, Java Technology Edition Version 5. In the following example, note the space before the last quote: * \ "*\ " "

```
grant {
    permission javax.security.auth.PrivateCredentialPermission
        "javax.resource.spi.security.PasswordCredential * \ "*\ " ", "read";
};
```

If the permission is in a policy file that is loaded by the IBM Developer Kit, Java Technology Edition policy tool Version 5, the following message might display:

```
Errors have occurred while opening the policy configuration.
View the warning log for more information.
```

or the following message might display in a warning log:

```
Warning: Invalid argument(s) for constructor:
javax.security.auth.PrivateCredentialPermission.
```

To fix this problem, edit the permission and remove the trailing space. When the trailing space is removed, the permission loads properly. The following code sample shows the corrected permission:

```
grant {
    permission javax.security.auth.PrivateCredentialPermission
        "javax.resource.spi.security.PasswordCredential * \ "*\","read";
}
```

Troubleshooting

To debug the dynamic policy, choose one of three ways to generate the detail report of the `AccessControlException` exception.

- **Trace** (Configured by RAS trace). Enables traces with the trace specification:

Attention: The following command is one continuous line

```
com.ibm.ws.security.policy.*=all=enabled:
com.ibm.ws.security.core.SecurityManager=all=enabled
```

- **Trace** (Configured by property). Specifies a Java `java.security.debug` property. Valid values for the `java.security.debug` property are as follows:

- Access. Print all debug information including required permission, code, stack, and code base location.
- Stack. Print debug information including, required permission, code, and stack.
- Failure. Print debug information including required permission and code.

- **ffdc**. Enable `ffdc`, modify the `ffdcRun.properties` file by changing `Level=4` and `LAE=true`. Look for an `Access Violation` keyword in the log file.

Access control exception

The Java 2 security behavior is specified by its *security policy*. The security policy is an access-control matrix that specifies which system resources certain code bases can access and who must sign them. The Java 2 security policy is declarative and it is enforced by the `java.security.AccessController.checkPermission` method.

The following example depicts the algorithm for the `java.security.AccessController.checkPermission` method. For the complete algorithm, refer to the Java 2 security check permission algorithm in Resources for learning.

```

i = m;
while (i > 0) {
  if (caller i's domain does not have the permission)
    throw AccessControlException;
  else if (caller i is marked as privileged)
    return;
  i = i - 1;
};

```

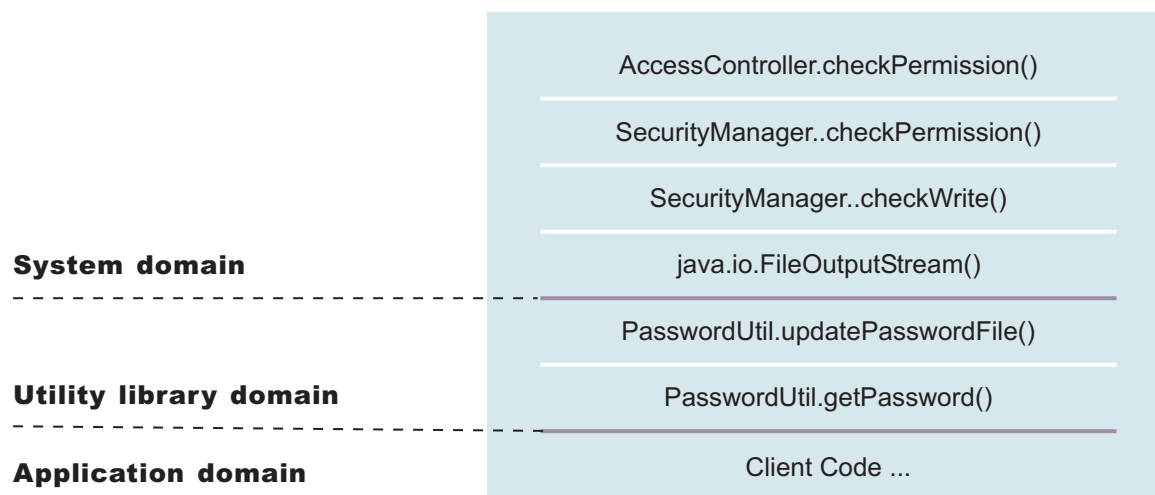

The algorithm requires that all the classes or callers on the call stack have the permissions when a `java.security.AccessController.checkPermission` method is performed or the request is denied and a `java.security.AccessControlException` exception is created. However, if the caller is marked as *privileged* and the class (caller) is granted these permissions, the algorithm returns and does not traverse the entire call stack. Subsequent classes (callers) do not need the required permission granted.

A `java.security.AccessControlException` exception is created when certain classes on the call stack are missing the required permissions during a `java.security.AccessController.checkPermission` method. Two possible resolutions to the `java.security.AccessControlException` exception are as follows:

- If the application is calling a Java 2 security-protected application programming interface (API), grant the required permission to the application Java 2 security policy. If the application is not calling a Java 2 security-protected API directly, the required permission results from the side-effect of the third-party APIs accessing Java 2 security-protected resources.
- If the application is granted the required permission, it gains more access than it needs. In this case, it is likely that the third party code that accesses the Java 2 security-protected resource is not properly marked as privileged.

Example call stack

This example of a call stack indicates where application code is using a third-party API utility library to update the password. The following example is presented to illustrate the point. The decision of where to mark the code as privileged is application-specific and is unique in every situation. This decision requires great depth of domain knowledge and security expertise to make the correct judgement. A number of well written publications and books are available on this topic. Referencing these materials for more detailed information is recommended.

You can use the `PasswordUtil` utility to change the password of a user. The utility types in the old password and the new password twice to ensure that the correct password is entered. If the old password matches the one stored in the password file, the new password is stored and the password file updates. Assume that none of the stack frame is marked as privileged. According to the

java.security.AccessController.checkPermission algorithm, the application fails unless all the classes on the call stack are granted write permission to the password file. The client application does not have permission to write to the password file directly and to update the password file at will.

However, if the PasswordUtil.updatePasswordFile method marks the code that accesses the password file as privileged, then the check permission algorithm does not check for the required permission from classes that call the PasswordUtil.updatePasswordFile method for the required permission as long as the **PasswordUtil** class is granted the permission. The client application can successfully update a password without granting the permission to write to the password file.

The ability to mark code privileged is very flexible and powerful. If this ability is used incorrectly, the overall security of the system can be compromised and security holes can be exposed. Use the ability to mark code privileged carefully.

Resolution to the java.security.AccessControlException exception

As described previously, you have two approaches to resolve a java.security.AccessControlException exception. Judge these exceptions individually to decide which of the following resolutions is best:

1. Grant the missing permission to the application.
2. Mark some code as privileged, after considering the issues and risks.

Enabling security for the realm

Use this topic to enable IBM WebSphere Application Server security. You must enable administrative security for all other security settings to function.

WebSphere Application Server uses cryptography to protect sensitive data and to ensure confidentiality and integrity of communications between WebSphere Application Server and other components in the network. Cryptography is also used by Web services security when certain security constraints are configured for the Web Services application.

1. Enable administrative security in WebSphere Application Server.
For more information, see “Enabling security” on page 43. It is important to click **Security > Secure administration, applications, and infrastructure**. Select an available realm definition from the list, and then click **Set as current**. Save the configuration to the repository. Verify that the validation that occurs after you click **OK** on the **Security > Secure administration, applications, and infrastructure** panel is successful before continuing. If the validation is not successful and you continue with these steps, you risk the server not starting. Re-configure the security settings until validation is successful.
2. Send a copy of the new configuration to all of the running node agents using the administrative console. If a node agent fails to get the security-enabled configuration, communication with the deployment manager fails, due to a lack of access. The node agent is not security-enabled. To force synchronize a specific node, complete the following steps from the administrative console:
 - a. Click **System administration > Nodes** and select the option next to all the nodes. You do not need to select the deployment manager node.
 - b. Click **Full resynchronize** to verify that the file synchronization has occurred. The message might indicate that the nodes already are synchronized. This message is OK. When synchronization is initiated, verify that the Synchronized status displays for all nodes.
3. Stop the deployment manager. Manually restart the deployment manager from the command line or service. To stop the deployment manager, click **System administration > Deployment manager** and click **Stop**. This action logs you out of the administrative console and stops the deployment manager process.
4. Restart the deployment manager process.
5. Restart the deployment manager process. To restart the deployment manager process, open the Qshell environment and locate the *app_server_root/bin* directory. The *app_server_root* variable refers to the *app_server_rootND/bin/* default directory. On the Qshell command line, type startManager.

After the deployment manager initialization is complete, go back into the administrative console to complete this task. Remember that security now is enabled in only the deployment manager. If you enabled single sign-on (SSO), specify the fully qualified domain name of your Web address, for example, `http://myhost.domain:port_number/ibm/console`. When you are prompted for a user ID and password, type the one that you defined as the administrator ID in the configured user registry.

6. If the deployment manager does not start after enabling security, disable security using a script and restart. Disable security by issuing the following command from the `DeploymentManager/bin` directory:

```
./wsadmin.sh -conntype NONE
```

At the prompt, enter `securityoff`.

7. Restart all node agents to make them security enabled. You must have restarted the deployment manager in a previous step before completing this step. If the node agent is security-enabled before the deployment manager is security-enabled, the deployment manager cannot query the node agent for status or give the node agent commands. To stop all node agents, complete the following steps:
 - a. Go to **System administration > Node agents** and select the option beside all node agents. Click **Restart**. A message similar to the following example is displayed at the top of the panel: The node agent on node NODE NAME was restarted successfully.
 - b. Alternatively, if you previously did not stop your application servers, restart all of the servers within any given node by clicking **System administration > Node agents** and by clicking the node agents where you want to restart all the servers. Click **Restart all Servers on Node**. This action restarts the node agent and any started application servers.
8. If any node agent fails to restart, perform a manual resynchronization of the configuration. This step consists of going to the physical node and running the client **syncNode** command. This client logs into the deployment manager and copies all of the configuration files to the node agent. This action ensures that the configuration is security-enabled. If the node agent is started, but is not communicating with the deployment manager, stop the node agent by issuing the **stopServer** command.

Secure administration, applications, and infrastructure settings

Use this page to configure administrative, application, and infrastructure security on a global level.

To view this administrative console page, click **Security > Secure administration, applications, and infrastructure**.

Security has some performance impacts on your applications. The performance impacts can vary depending upon the application workload characteristics. You must first determine that the needed level of security is enabled for your applications, and then measure the impact of security on the performance of your applications.

When security is configured, validate any changes to the user registry or authentication mechanism panels. Click **Apply** to validate the user registry settings. An attempt is made to authenticate the server ID or to validate the admin ID (if `internalServerID` is used) to the configured user registry. Validating the user registry settings after enabling administrative security can avoid problems when you restart the server for the first time.

Security configuration wizard:

Launches a wizard that enables you to configure the basic administrative and application security settings. This process restricts administrative tasks and applications to authorized users.

Using this wizard, you can configure application security, resource or Java 2 Connector (J2C) security, and a user registry. You can configure an existing registry and enable administrative, application, and resource security.

When you apply changes made by using the security configuration wizard, administrative security is turned on by default.

Security configuration report:

Launches a security configuration report that displays the core security settings of the application server. The report also displays the administrative users and groups and the CORBA naming roles.

A current limitation to the report is that it does not display application level security information. The report also does not display information on Java Message Service (JMS) security, bus security, or Web Services security.

Enable administrative security:

Specifies whether to enable administrative security for this application server domain. Administrative security requires users to authenticate before obtaining administrative control of the application server.

For more information, see “Administrative roles” on page 336.

When enabling security, set the authentication mechanism configuration and specify a valid user ID and password (or a valid admin ID when internalServerID feature is used) in the selected registry configuration.

Note: There is a difference between the user ID (which is normally called the admin ID), which identifies administrators who manage the environment, and a server ID, which is used for server-to-server communication. You do not need to enter a server ID and password when you are using the internal server ID feature. However, optionally, you can specify a server ID and password. To specify the server ID and password, complete the following steps:

1. Click **Security > Secure administration, applications, and infrastructure**.
2. Under User accounts repository, select the repository and click **Configure**.
3. Specify the server ID and password in the Server user identity section.

If your server does not restart after you enable administrative security, you can disable security. Go to your *app_server_root/bin* directory and run the `wsadmin -conntype NONE` command. At the `wsadmin>` prompt, enter `securityoff` and then type `exit` to return to a command prompt. Restart the server with security disabled to check any incorrect settings through the administrative console.

Default: Enabled

Enable application security:

Enables application-level security unless the option is overwritten at the server level.

Default: Disabled

Use Java 2 security to restrict application access to local resources:

Specifies whether to enable or disable Java 2 security permission checking. By default, access to local resources is not restricted. You can choose to disable Java 2 security, even when application security is enabled.

When the **Use Java 2 security to restrict application access to local resources** option is enabled and if an application requires more Java 2 security permissions than are granted in the default policy, the application might fail to run properly until the required permissions are granted in either the `app.policy` file or the `was.policy` file of the application. `AccessControl` exceptions are generated by applications that do

not have all the required permissions. See “Java 2 security” on page 61 for more information about Java 2 security.

Default: Disabled

Disabling security if you have server startup problems:

If your server does not restart after you enable administrative security, you can disable security. Go to your *profile_root/bin* directory and run the `wsadmin -conntype NONE` command. At the `wsadmin>` prompt, enter `securityoff` and then type `exit` to return to a command prompt. Restart the server with administrative security disabled to check any incorrect settings through the administrative console.

Warn if applications are granted custom permissions:

Specifies that during application deployment and application start, the security runtime issues a warning if applications are granted any custom permissions. Custom permissions are permissions that are defined by the user applications, not Java API permissions. Java API permissions are permissions in the `java.*` and `javax.*` packages.

The application server provides support for policy file management. A number of policy files are available in this product, some of them are static and some of them are dynamic. Dynamic policy is a template of permissions for a particular type of resource. No code base is defined and no relative code base is used in the dynamic policy template. The real code base is dynamically created from the configuration and run-time data. The `filter.policy` file contains a list of permissions that you do not want an application to have according to the J2EE 1.4 specification. For more information on permissions, see “Java 2 security policy files” on page 66.

Important: You cannot enable this option without enabling the **Use Java 2 security to restrict application access to local resources** option.

Default: Disabled

Restrict access to resource authentication data:

Enable this option to restrict application access to sensitive Java Connector Architecture (JCA) mapping authentication data.

Consider enabling this option when both of the following conditions are true:

- Java 2 security is enforced.
- The application code is granted the `accessRuntimeClasses WebSphereRuntimePermission` permission in the `was.policy` file found within the application enterprise archive (EAR) file. For example, the application code is granted the permission when the following line is found in your `was.policy` file:
`permission com.ibm.websphere.security.WebSphereRuntimePermission "accessRuntimeClasses";`

The **Restrict access to resource authentication data** option adds fine-grained Java 2 security permission checking to the default principal mapping of the `WSPrincipalMappingLoginModule` implementation. You must grant explicit permission to Java 2 Platform, Enterprise Edition (J2EE) applications that use the `WSPrincipalMappingLoginModule` implementation directly in the Java Authentication and Authorization Service (JAAS) login when **Use Java 2 security to restrict application access to local resources** and the **Restrict access to resource authentication data** options are enabled.

Default: Disabled

Current realm definition:

Specifies the current setting for the active user repository.

This field is read-only.

Available realm definitions:

Specifies the available user account repositories.

Use domain-qualified user names:

Specifies that user names that are returned by methods are qualified with the security domain in which they reside.

Default: Disabled

Active protocol:

Specifies the active authentication protocol for Remote Method Invocation over the Internet Inter-ORB Protocol (RMI IIOP) requests, when security is enabled.

An Object Management Group (OMG) protocol called Common Secure Interoperability Version 2 (CSIv2) supports increased vendor interoperability and additional features. If all of the servers in your security domain are Version 5.x and later servers, specify CSI as your protocol.

V6.0.x If some servers are Version 3.x or Version 4.x servers, specify CSI and SAS.

Important: SAS is supported only between Version 6.0.x and previous version servers that have been federated in a Version 6.1 cell.

Note: **V6.0.x** This field displays only when a Version 6.0.x and earlier server is detected in your environment.

Default: BOTH
Range: CSI and SAS, CSI

Specify extent of protection wizard settings

Use this security wizard page to determine whether to enable application security and restrict access to local resources. When you use the wizard, admin security is enabled by default.

To view this security wizard page, click **Security > Secure administration, applications, and infrastructure > Security configuration wizard**.

Enable application security:

Enables application-level security unless the option is overwritten at the server level.

Default: Disabled

Use Java 2 security to restrict application access to local resources:

Specifies whether to enable or disable Java 2 security permission checking. By default, access to local resources is not restricted. You can choose to disable Java 2 security, even when application security is enabled.

When the **Use Java 2 security to restrict application access to local resources** option is enabled and if an application requires more Java 2 security permissions than are granted in the default policy, the application might fail to run properly until the required permissions are granted in either the app.policy file or the was.policy file of the application. AccessControl exceptions are generated by applications that do not have all the required permissions. See “Java 2 security” on page 61 for more information about Java 2 security.

Default: Disabled

Custom properties: Security

Use this page to understand the predefined custom properties that are related to security.

To view this administrative console page, click **Security > Secure administration, applications, and infrastructure > Custom properties**. You can click **New** to add a new custom property and its associated value.

com.ibm.CSI.rmiInboundLoginConfig:

This property specifies the Java Authentication and Authorization Service (JAAS) login configuration that is used for Remote Method Invocation (RMI) requests that are received inbound.

By knowing the login configuration, you can plug in a custom login module that can handle specific cases for RMI logins.

Default system.RMI_INBOUND

com.ibm.CSI.rmiOutboundLoginConfig:

This property specifies the JAAS login configuration that is used for RMI requests that are sent outbound.

Primarily, this property prepares the propagated attributes in the Subject to be sent to the target server. However, you can plug in a custom login module to perform outbound mapping.

Default system.RMI_OUTBOUND

com.ibm.CSI.supportedTargetRealms:

This property enables credentials that are authenticated in the current realm to be sent to any realm that is specified in the Trusted target realms field. The Trusted target realms field is available on the CSiv2 outbound authentication panel. This property enables those realms to perform inbound mapping of the data from the current realm.

It is not recommended that you send authentication information to an unknown realm. Thus, this provides a way to specify that the alternate realms are trusted. To access the CSiv2 outbound authentication panel, complete the following steps:

1. Click **Security > Secure administration, applications, and infrastructure**.
2. Under RMI/IIOP security, click **CSiv2 outbound authentication**.

com.ibm.audit.auditPolicy:

This property is used by the auditing service that was introduced as a technical preview in Version 6. The auditing functionality is not available. Do not modify this property.

Default REQUIRED

com.ibm.audit.auditQueueSize:

This property is used by the auditing service that was introduced as a technical preview in Version 6. The auditing functionality is not available. Do not modify this property.

Default 5000

com.ibm.audit.auditServiceEnabled:

This property is used by the auditing service that was introduced as a technical preview in Version 6. The auditing functionality is not available. Do not modify this property.

Default false

com.ibm.audit.auditSpecification:

This property is used by the auditing service that was introduced as a technical preview in Version 6. The auditing functionality is not available. Do not modify this property.

Default J2EE=AUTHN=failure=enabled:J2EE=AUTHZ=failure=enabled

com.ibm.security.useFIPS:

Specifies that Federal Information Processing Standard (FIPS) algorithms are used. The application server uses the IBMJCEFIPS cryptographic provider instead of the IBMJCE cryptographic provider.

Default false

com.ibm.websphere.security.audit.auditEventFactory:

This property is used by the auditing service that was introduced as a technical preview in Version 6. The auditing functionality is not available. Do not modify this property.

Default J2EE=com.ibm.ws.security.audit.defaultAuditEventFactoryImpl

com.ibm.ws.security.defaultLoginConfig:

This property is the JAAS login configuration that is used for logins that do not fall under the WEB_INBOUND, RMI_OUTBOUND, or RMI_INBOUND login configuration categories.

Internal authentication and protocols that do not have specific JAAS plug points call the system login configuration that is referenced by com.ibm.ws.security.defaultLoginConfig configuration.

Default system.DEFAULT

com.ibm.ws.security.ssoInteropModeEnabled:

This property determines whether to send LtpaToken2 and LtpaToken cookies in the response to a Web request (interoperable).

When this property value is false, the application server just sends the new LtpaToken2 cookie which is stronger, but not interoperable with some other products and Application Server releases prior to Version 5.1.1. In most cases, the old LtpaToken cookie is not needed and you can set this property to false.

Default true

com.ibm.ws.security.webChallengeCustomSubjectNotFound:

This property determines the behavior of a single sign-on LtpaToken2 login.

When this property value is set to true, the token contains a custom cache key, and the custom Subject cannot be found, the token is used to log in directly as the custom information needs to be gathered again. A challenge occurs so that the user to login again. When this property value is set to false and the custom Subject is not found, the LtpaToken2 is used to login and gather all of the registry attributes. However, the token might not obtain any of the special attributes that downstream applications might expect.

Default true

com.ibm.ws.security.webInboundLoginConfig:

This property is the JAAS login configuration that is used for Web requests that are received inbound.

By knowing the login configuration, you can plug in a custom login module that can handle specific cases for Web logins.

Default system.WEB_INBOUND

com.ibm.ws.security.webInboundPropagationEnabled:

This property determines whether a received LtpaToken2 cookie should search for the propagated attributes locally before searching the original login server that is specified in the token. After the propagated attributes are received, the Subject is regenerated and the custom attributes are preserved.

You can configure the distributed replication service (DRS) to send the propagated attributes to front-end servers such that a local dynacache lookup can find the propagated attributes. Otherwise, an MBean request is sent to the original login server to retrieve these attributes.

Default true

com.ibm.wsspi.security.audit.auditServiceProvider:

This property is used by the auditing service that was introduced as a technical preview in Version 6. The auditing functionality is not available. Do not modify this property.

Default DEFAULT =
com.ibm.ws.security.audit.defaultAuditServiceProviderImpl

com.ibm.wsspi.security.ltpa.tokenFactory:

This property specifies the Lightweight Third Party Authentication (LTPA) token factories that can be used to validate the LTPA tokens.

Validation occurs in the order in which the token factories are specified because LTPA tokens do not have object identifiers (OIDs) that specify the token type. The Application Server validates the tokens using each token factory until validation is successful. The order that is specified for this property is the most likely order of the received tokens. Specify multiple token factories by separating them with a pipe (|) without spaces before or following the pipe.

Default `com.ibm.ws.security.ltpa.LTPATokenFactory |
com.ibm.ws.security.ltpa.LTPAToken2Factory |
com.ibm.ws.security.ltpa.AuthzPropTokenFactory`

com.ibm.wsspi.security.token.authenticationTokenFactory:

This property specifies the implementation that is used for an authentication token in the attribute propagation framework. The property provides an old LTPA token implementation for use as the authentication token.

Default `com.ibm.ws.security.ltpa.LTPATokenFactory`

com.ibm.wsspi.security.token.authorizationTokenFactory:

This property specifies the implementation that is used for an authorization token. This token factory encodes the authorization information.

Default `com.ibm.ws.security.ltpa.AuthzPropTokenFactory`

com.ibm.wsspi.security.token.propagationTokenFactory:

This property specifies the implementation that is used for a propagation token. This token factory encodes the propagation token information.

The propagation token is on the thread of execution and is not associated with any specific user Subjects. The token follows the invocation downstream wherever the process leads.

Default `com.ibm.ws.security.ltpa.AuthzPropTokenFactory`

com.ibm.wsspi.security.token.singleSignonTokenFactory:

This property specifies the implementation that is used for a Single Sign-on (SSO) token. This implementation is the cookie that is set when propagation is enabled regardless of the state of the `com.ibm.ws.security.ssoInteropModeEnabled` property.

By default, this implementation is the `LtpaToken2` cookie.

Default `com.ibm.ws.security.ltpa.LTPAToken2Factory`

security.enablePluggableAuthentication:

This property is no longer used. Instead, use `WEB_INBOUND` login configuration.

Complete the following steps to modify the `WEB_INBOUND` login configuration:

1. Click **Security > Secure administration, applications, and infrastructure**.
2. Under Java Authentication and Authorization Service, click **System logins**.

Default

true

Security custom property collection

Use this page to view and manage arbitrary name-value pairs of data, where the name is a property key and the value is a string value that can be used to set internal system configuration properties.

The administrative console contains several Custom Properties pages that work similarly. To view one of these administrative pages, click a **Custom Properties** link.

Name:

Specifies the name (or key) for the property.

Each property name must be unique. If the same name is used for multiple properties, the value specified for the first property that has that name is used.

Do not start your property names with `was.` because this prefix is reserved for properties that are predefined in the application server.

Value:

Specifies the value paired with the specified name.

Description:

Provides information about the name-value pair.

Security custom property settings

Use this page to configure arbitrary name-value pairs of data, where the name is a property key and the value is a string value that can be used to set internal system configuration properties. Defining a new property enables you to configure a setting beyond that which is available in the administrative console.

The administrative console contains several Custom property settings pages that work similarly. To view one of these administrative pages, click **Custom Properties > New**.

Name:

Specifies the name (or key) for the property.

Each property name must be unique. If the same name is used for multiple properties, the value specified for the first property that has that name is used.

Do not start your property names with `was.` because this prefix is reserved for properties that are predefined in WebSphere Application Server.

Data type

String

Value:

Specifies the value paired with the specified name.

Data type

String

Description:

Provides information about the name and value pair.

Data type String

Testing security after enabling it

Basic tests are available that show whether the fundamental security components are working properly. Use this task to validate your security configuration.

After configuring administrative security and restarting all of your servers in a secure mode, validate that security is properly enabled.

There are a few techniques that you can use to test the various security login types. For example, you can test the Web-based BasicAuth login, Web-based form login, and the Java client BasicAuth login.

Basic tests are available that show whether the fundamental security components are working properly. Complete the following steps to validate your security configuration:

1. After enabling security, verify that your system comes up in secure mode.
2. Test the Web-based BasicAuth with *Snoop*, by accessing the following URL: `http://hostname.domain:9080/snoop`. A login panel is displayed. If a login panel does not display, then a problem exists. If the panel appears, type in any valid user ID and password in your configured user registry.

Note: The Snoop servlet is only available in the domain if you included the **DefaultApplication** option when adding the application server to the cell. The **-includeapps** option for the **addNode** command migrates the **DefaultApplication** option to the cell. Otherwise, skip this step.

3. Test the Web-based form login by starting the administrative console: `http://hostname.domain:port_number/ibm/console`. A form-based login page is displayed. If a login page does not appear, try accessing the administrative console by typing `https://myhost.domain:9043/ibm/console`.

Type in the administrative user ID and password that are used for configuring your user registry when configuring security.

4. Test Test Java Client BasicAuth with *dumpNameSpace*.
Use the `app_server_root/bin/dumpNameSpace` file. A login panel appears. If a login panel does not appear, there is a problem. Type in any valid user ID and password in your configured user registry.
5. Test all of your applications in secure mode.
6. If all the tests pass, proceed with more rigorous testing of your secured applications. If you have any problems, review the output logs in the WebSphere Application Server `/logs/nodeagent` or WebSphere Application Server `/logs/server_name` directories, respectively. For more information on common problems, see Chapter 22, "Troubleshooting security configurations," on page 1435.

The results of these tests, if successful, indicate that security is fully enabled and working properly.

Securing specific application servers

You can customize security to some extent at the application server level. You can disable administrative security on an application server.

You can also modify Java 2 Security and some of the other security attributes that are found on the Secure administration, applications, and infrastructure panel. This panel provides access to the cell-level security settings. You cannot configure a different authentication mechanism or user registry on an individual server basis. This feature is limited to cell-level configuration only.

By default, server security inherits all of the values that are configured for cell-level security. To override the cell-level security configuration at the server level, click **Servers > Application Servers > server_name**. Under Security, click **Server Security** and click any of the following links:

- CSIV2 inbound authentication
- CSIV2 outbound authentication
- CSIV2 inbound transport
- CSIV2 outbound transport
- **V6.0.x** SAS inbound transport
- **V6.0.x** SAS outbound transport
- Server-level security

Note: SAS is supported only between Version 6.0.x and previous version servers that have been federated in a Version 6.1 cell.

After modifying the configuration in any of these panels and clicking **OK** or **Apply**, the security configuration for that panel or set of panels now overrides cell-level security. Other panels that are not overridden continue to be inherited at the cell-level. However, you can always revert back to the cell-level configuration at any time. You can revert back to the cell-level security configuration by clearing the check box next to any of the following options on the Server security panel:

- Security settings for this server override cell settings
 - RMI/IIOP security for this server overrides cell settings
 - SAS security for this server overrides cell settings
1. Start the administrative console for the deployment manager. To get to the administrative console, go to `http://host.domain:port_number/ibm/console`. If security is disabled, you can enter any ID. If security is enabled, you must enter a valid user ID and password, which is either the administrative ID that is configured for the user registry or a user ID that is entered as an administrative user. To add a user ID as an administrative user, click **System Administration > Console settings > Console users**.
 2. Configure cell-level security if you have not configured it previously. Go to “Enabling security” on page 43 for detailed steps. After security is configured, configure server-level security.
 3. To configure server-level security, click **Servers > Application Servers > server_name**. Under Security, click **Server security**. The status of the security level that is in use for this application server is displayed.

V6.0.x

- By default, you can see that your cell-level security configuration, Common Secure Interoperability (CSI), and SAS have not been overridden at the server level. CSI and SAS are authentication protocols for RMI/IIOP security requests. The server-level security panel lists attributes that are on the Secure administration, applications, and infrastructure panel and can be overridden at the server level. Not all of the attributes on the Secure administration, applications, and infrastructure panel can be overridden at the server level, including the user account repository.
4. To enable administrative security for this application server, go to the Server-level security panel, select the **Security settings for this server override cell settings** and the **Enable application security** options. By modifying the Server-level security panel, these settings override the settings for cell-level security.
 5. Click **Apply** and **Save**.
 6. To enable RMI/IIOP security for the application server, go to the Server-level security panel, select the **RMI/IIOP security for this server overrides cell settings** option and click **Apply**. If you select the **RMI/IIOP security for this server overrides cell settings** option, any changes that you make to the CSIV2 authentication or transport settings override the same settings on the cell level.

Typically, server-level security is used to disable user security for a specific application server. However, this can also be used to disable or enable the Java 2 security manager, and to configure the authentication requirements for RMI/IIOP requests both incoming and outgoing from this application server.

After you modify the configuration for a particular application server, you must restart the application server for the changes to become effective. To restart the application server, go to **Servers > Application servers** and click the server name that you recently modified. Click **Stop** and then **Start**.

If you disabled security for the application server, you can typically test a Web address that is protected when security is enabled.

One URL that usually is installed when the DefaultApplication during installation is the snoop application. If the DefaultApplication is installed on the application server, test that security is disabled by going to the following URL: `http://host.domain:9080/snoop`. If security is disabled, a prompt does not display. This URL is just one method of validating the configuration. Validate that the configuration is appropriate for your applications.

Server-level security settings

Use this page to enable server-level security and specify other server-level security configurations.

To view this administrative console page, complete the following steps:

1. Click **Servers > Application Servers > *server_name***.
2. Click **Server security**.

Security settings for this server override cell settings

Specifies that the settings on this panel override the settings on the Security > Security applications, administration, and infrastructure panel.

Enable application security

Specifies that server security is disabled, by default, when application security is enabled. Administrative (administrative console and wsadmin) and naming security remain enabled while application security is enabled, regardless of the status of this flag.

Default Disabled

Use Java 2 security to restrict application access to local resources

Specifies that the server enforces Java 2 security permission checking at the server level. When cleared, the Java 2 server-level security manager is not installed and all of the Java 2 security permission checking is disabled at the server level.

If your application policy file is not set up correctly, see “Configuring the was.policy file” on page 535 in the information center.

Default Disabled

Warn if applications are granted custom permissions

Specifies whether a warning is issued during application installation when an application requires a Java 2 permission that is normally not granted to an application.

The application server provides support for policy file management. A number of policy files are included in the application server. Some of these policy files are static and some of them are dynamic. Dynamic policy is a template of permissions for a particular type of resource. In dynamic policy files, the code bases are evaluated at runtime using the configuration data. You can add or remove permissions, as needed, for each code base.

However, do not add, remove, or modify the existing code bases. The real code base is dynamically created from the configuration and run-time data. The `filter.policy` file contains a list of permissions that an application does not have, according to the J2EE 1.4 Specification. For more information on permissions, see the documentation on the Java 2 security policy files.

Default Enabled

Restrict access to resource authentication data

Enable this option to restrict application access to sensitive Java Connector Architecture (JCA) mapping authentication data.

Default Disabled

Use domain-qualified user names

Specifies whether user IDs that are returned by `getUserPrincipal()` are qualified with the server level security domain within which they reside.

Default Disabled

Authentication cache timeout

Specifies the time period in which a Lightweight Third Party Authentication (LTPA) token expires.

Data type	Integer
Units	Minutes and seconds
Default	10 minutes and 0 seconds
Range	Greater than 30 seconds. Avoid setting Authentication cache timeout value to 30 seconds or less.

Active protocol

Specifies the active server level security authentication protocol when server level security is enabled.

You can use an Object Management Group (OMG) protocol called Common Secure Interoperability Version 2 (CSIv2) for more vendor interoperability and additional features. If all of the servers in your entire security domain are Version 5.0 servers, it is best to specify CSI as your protocol.

V6.0.x Specifying CSI and SAS causes you to have two interceptors invoking each request.

Important: SAS is supported only between Version 6.0.x and previous version servers that have been federated in a Version 6.1 cell.

This field displays if a version 6.0.x server exists in your environment.

Data type	String
Default	CSI and SAS
Range	CSI, CSI and SAS

RMI/IIOP security for this server overrides cell settings

Specifies that the Remote Method Invocation over Internet InterORB Protocol (RMI/IIOP) settings on this panel override the settings on the Security > Security applications, administration, and infrastructure panel.

Default Enabled

Chapter 5. Authenticating users

The process of authenticating users involves a user registry and an authentication mechanism. Optionally, you can define trust between WebSphere Application Server and a proxy server, configure single sign-on capability, and specify how to propagate security attributes between application servers.

The following security topics are covered in this section:

User registries

For information on local operating system, Lightweight Directory Access Protocol (LDAP), custom user registries, and user repositories such as virtual member manager, see “User registries and repositories” on page 89.

Authentication protocol for EJB security

For more information on the authentication protocols that are used for Enterprise JavaBeans (EJB) security, see “Authentication protocol for EJB security” on page 209.

Trust associations

For more information on trust associations, see “Trust associations” on page 177.

Single sign-on

For more information on single sign-on, see “Single sign-on” on page 181.

Security attribute propagation

For more information on propagation tokens, authorization tokens, single sign-on tokens, and authentication tokens, see “Security attribute propagation” on page 188.

The following information is covered in this section:

- Configure a user registry. For more information, see “Selecting a registry or repository.”
- Configure WebSEAL or a custom trust association interceptor. For more information see, “Integrating third-party HTTP reverse proxy servers” on page 224.
- Configure single sign-on. For more information, see “Implementing single sign-on to minimize Web user authentications” on page 226.
- Propagate security attributes. For more information, see “Propagating security attributes among application servers” on page 279.
- Configure the authentication cache. For more information, see “Configuring the authentication cache” on page 282.

After completing the configuring the authentication process, you must authorize access to resources. For more information, see Chapter 6, “Authorizing access to resources,” on page 329.

Selecting a registry or repository

Information about users and groups reside in a user registry. In WebSphere Application Server, a user registry authenticates a user and retrieves information about users and groups to perform security-related functions, including authentication and authorization.

Note: During profile creation, either during installation or post-installation, administrative security is enabled by default. You might decide not to enable security, but if the default is accepted, the file-based federated user repository is configured as the active user registry. You can use a different user registry before the profile is created.

Before configuring the user registry or repository, decide which user registry or repository to use. Though different types of registries and repositories are supported, all of the processes in WebSphere Application Server can use only one active registry.

Configuring the correct registry or repository is a prerequisite to assigning users and groups to roles for applications. When a user registry or repository is not configured, the local operating system registry is used by default. If your choice of user registry is not the local operating system registry, you need to first configure the registry or repository, which is normally done as part of enabling security, restart the servers, and then assign users and groups to roles for all your applications.

In addition to local operating system and LDAP registries, WebSphere Application Server also provides a plug-in to support any registry by using the custom registry feature. The custom registry feature enables you to configure any user registry that is not made available through the security configuration panels of the WebSphere Application Server.

The UserRegistry interface is used to implement both the custom registry and the federated repository options for the user account repository. The interface is very helpful in situations where the current user and group information exists in some other formats, for example, a database, and cannot move to local operating system or LDAP registries. In such a case, you can implement the UserRegistry interface so that WebSphere Application Server can use the existing registry for all the security-related operations. The process of implementing a custom registry is a software implementation effort and it is expected that the implementation does not depend on other WebSphere Application Server resources, for example, data sources, for its operation.

WebSphere Application Server supports the following types of user registries:

- Federated repository
- Local operating system
- Standalone Lightweight Directory Access Protocol (LDAP) registry
- Standalone custom registry

After the applications are assigned users and groups and you need to change the user registries, delete all the users and groups, including any RunAs role, from the applications, and reassign them after changing the registry through the administrative console or by using `wsadmin` scripting. The following **wsadmin** command, which uses Jacl, removes all of the users and groups from any application:

```
$AdminApp deleteUserAndGroupEntries yourAppName
```

where *yourAppName* is the name of the application. Backing up the old application is advised before performing this operation. However, if both of the following conditions are true, you might be able to switch the registries without having to delete the users and groups information:

- All of the user and group names, including the password for the RunAs role users, in all of the applications match in both user registries.
- The application bindings file does not contain the access IDs which are unique for each user registry even for the same user or group name.

By default, an application does not contain access IDs in the bindings file. These IDs are generated when the applications start. However, if you migrated an existing application from an earlier release, or if you used the `wsadmin` script to add access IDs for the applications to improve performance, you have to remove the existing user and group information and add the information after configuring the new user registry.

For more information on updating access IDs, see `updateAccess IDs` in the AdminApp object for scripted administration article.

Complete one of the following steps to configure your user registry:

- “Configuring local operating system registries” on page 90
- “Configuring Lightweight Directory Access Protocol user registries” on page 92
- “Configuring standalone custom registries” on page 111.

- “Managing the realm in a federated repository configuration” on page 115
1. If you are enabling security, make sure that you complete the remaining steps. Verify that the User account repository on the Secure administration, applications, and infrastructure panel is set to the appropriate registry or repository. As the final step, validate the user ID and the password by clicking **Apply** on the Secure administration, applications, and infrastructure panel. Save, stop and start all WebSphere Application Servers.
 2. For any changes in user registry panels to be effective, you must validate the changes by clicking **Apply** on the Secure administration, applications, and infrastructure panel. After validation, save the configuration and stop and start all WebSphere Application Servers, including the cells, nodes and all of the application servers. To avoid inconsistencies between the WebSphere Application Server processes, make sure that any changes to the registry or repository are done when all of the processes are running. If any of the processes are down, force synchronization to make sure that the process can start later.
If the server or servers start without any problems, the setup is correct.

User registries and repositories

Information about users and groups reside within a registry or repository.

WebSphere Application Server provides implementations that support multiple types of registries and repositories including the local operating system registry, a standalone Lightweight Directory Access Protocol (LDAP) registry, a standalone custom registry, and federated repositories.

With WebSphere Application Server, a user registry or a repository, such as virtual member manager, authenticates a user and retrieves information about users and groups to perform security-related functions including authentication and authorization.

With WebSphere Application Server, a user registry or repository is used for:

- Authenticating a user using basic authentication, identity assertion, or client certificates
- Retrieving information about users and groups to perform security-related administrative functions, such as mapping users and groups to security roles

Although WebSphere Application Server supports different types of user registries, only one user registry can be active. This active registry is shared by all of the product server processes.

After configuring the registry or repository, you must specify it as the active repository. Through the administration console, you can select an available realm definition for the registry or repository from the User account repository section of the Secure administration, applications, and administration panel. After selecting the registry or repository, first click **Set as current**, and then click **Apply**.

Note: WebSphere Application Server has implemented a user registry proxy by using the UserRegistry interface. However, the return values are little different from the interface. For example, `getUniqueId` returns the uniqueID with the realm name wrapped. You cannot use the return value to pass to `getUserSecurityName`, as shown in the following example:

```
// Retrieves the default InitialContext for this server.
javax.naming.InitialContext ctx = new javax.naming.InitialContext();

// Retrieves the local UserRegistry object.
com.ibm.websphere.security.UserRegistry reg =
    (com.ibm.websphere.security.UserRegistry) ctx.lookup("UserRegistry");

// Retrieves the registry uniqueID based on the userName that is specified
// in the NameCallback.
String uniqueid = reg.getUniqueId(userName);
// Strip the realm name and get real uniqueID
String uid = WSSecurityPropagationHelper.getUserFromUniqueID (uniqueID);
```

```
// Retrieves the security name from the user registry based on the uniqueID.  
String securityName = reg.getUserSecurityName(uid);
```

Configuring local operating system registries

Use these steps to configure local operating system registries.

For detailed information about using the local operating system user registry, see “Local operating system registries” on page 165. As installed, security is disabled for WebSphere Application Server. These steps set up security based on the local operating system user registry on which WebSphere Application Server is installed.

In WebSphere Application Server Version 6.1, you can use an internally-generated server ID because the Security WebSphere Common Configuration Model (WCCM) model contains a new tag, `internalServerId`. You do not need to specify a server user ID and a password during security configuration except in a mixed-cell environment. See “Administrative roles and naming service authorization” on page 330 for more detailed information about the new internal server ID.

Important: The local operating system is not a valid user account repository when you have a mixed cell environment that includes both z/OS platform and non-z/OS platform nodes.

The following steps are needed to perform this task initially when setting up security for the first time.

1. Click **Security > Secure administration, applications, and infrastructure**.
2. Under User account repository, select **Local operating system** and click **Configure**.
3. Enter a valid user name in the **Primary administrative user name** field. This value is the name of a user with administrative privileges that is defined in the registry. This user name is used to access the administrative console or used by `wsadmin`.
4. Click **Apply**.
5. Select either the **Automatically generated server identity** or **Server identity that is stored in the repository** option. If you select the **Server identity that is stored in the repository** option, enter the following information:

Server user ID or administrative user on a Version 6.0.x node

Specify the short name of the account that is chosen in the second step.

Server user password

Specify the password of the account that is chosen in the second step.

6. Enter a valid user profile name in the **Primary administrative user name** field.

The Primary administrative user name specifies the user profile to use when the server authenticates to the underlying operating system. This identity is also the user that has initial authority to access the administrative application through the administrative console. The administrative user ID is common to all user registries. The administrative ID is a member of the chosen registry and it has special privileges in WebSphere Application Server. However, it does not have any special privileges in the registry that it represents. In other words, you can select any valid user ID in the registry to use as the administrative user ID or server user ID.

For the **Primary administrative user name** field, you can specify any user profile that meets this criteria:

- The user profile has a status of `*ENABLED`.
- The user profile has a valid password.
- The user profile is not used as a group profile.

Important: A group profile is assigned a unique group ID number, which is not assigned to a regular user profile. Run the `DSPUSRPRF` Display User Profile command to determine if

the user profile you want to use as the Primary administrative user name has a defined group ID number. If the **Group ID** field is set to *NONE, you can use the user profile as the Primary administrative user name.

7. Click **OK**.

The administrative console does not validate the user ID and password when you click **OK**. Validation is only done when you click **OK** or **Apply** in the Secure administration, applications, and infrastructure panel. First, make sure that you select **Local operating system** as the available realm definition in the User account repository section, and click **Set as current**. If security was already enabled and you had changed either the user or the password information in this panel, make sure to go to the Secure administration, applications, and infrastructure panel and click **OK** or **Apply** to validate your changes. If your changes are not validated, the server might not start.

Important: Until you authorize other users to perform administrative functions, you can only access the administrative console with the server user ID and password that you specified. For more information, see “Authorizing access to administrative roles” on page 382.

For any changes in this panel to be effective, you need to save, stop, and start all the product servers, including deployment managers, nodes and application servers. If the server comes up without any problems, the setup is correct.

After completed these steps, you have configured WebSphere Application Server to use the local operating system registry to identify authorized users.

Complete any remaining steps for enabling security. For more information, see “Enabling security” on page 43.

Local operating system settings

Use this page to configure local operating system registry settings.

To view this administrative console page, complete the following steps:

1. Click **Security > Secure administration, applications, and infrastructure**.
2. Under User account repository, click the **Available realm definitions** drop-down list, select **Local operating system**.
3. Click **Configure**.

WebSphere Application Server Version 6.1 distinguishes between the user identities for administrators who manage the environment and server identities for authenticating server to server communications. In most cases, server identities are automatically generated and are not stored in a repository.

Primary administrative user name:

Specifies the name of a user with administrative privileges that is defined in your local operating system.

The user name is used to log on to the administrative console when administrative security is enabled.

Automatically generated server identity:

Enables the application server to generate the server identity that is used for internal process communication.

You can change this server identity on the Authentication mechanisms and expiration panel. To access the Authentication mechanisms and expiration panel, click **Security > Secure administration, applications, and infrastructure > Authentication mechanisms and expiration**. Change the value of the Internal server ID field.

Default: Disabled

Server identity that is stored in the repository:

Specifies a user identity in the repository that is used for internal process communication.

Default: Enabled

Local operating system wizard settings

Use this security wizard page to configure local operating system registry settings.

To view this security wizard page, complete the following steps:

1. Click **Security > Secure administration, applications, and infrastructure > Security configuration wizard**.
2. Select your protection settings and click **Next**.
3. Select the **Local operating system** option and click **Next**.

Primary administrative user name:

Specifies the name of a user with administrative privileges that is defined in your local operating system.

The user name is used to log on to the administrative console when administrative security is enabled.

Configuring Lightweight Directory Access Protocol user registries

To access a user registry using the Lightweight Directory Access Protocol (LDAP), you must know a valid user name (ID) and password, the server host and port of the registry server, the base distinguished name (DN) and, if necessary, the bind DN and the bind password. You can choose any valid user in the user registry that is searchable. You can use any user ID that has the administrative role to log in.

In some LDAP servers, administrative users cannot be searched and thus cannot be used, for example, when `cn=root` in Tivoli Access Manager. The user is referred to as a WebSphere Application Server security server ID, server ID, or server user ID in the documentation. A server ID user has special privileges when calling some protected internal methods.

Normally, the primary administrative user name is used to log into the administrative console if security is enabled. By default, security is enabled after installation.

When security is enabled in the product, the primary administrative user name and password are authenticated with the registry during the product startup. If authentication fails, the server does not start. It is important to choose an ID and password that do not expire or change often. If the product server user ID or password need to change in the registry, make sure that the changes are performed when all the product servers are up and running. When changes are to be made in the registry, review the article on “Standalone Lightweight Directory Access Protocol registries” on page 166 (LDAP) before beginning this task.

1. In the administrative console, click **Security > Secure administration, applications, and infrastructure**.
2. Under User account repository, click the **Available realm definitions** drop-down list, select **Standalone LDAP registry**, and click **Configure**.
3. Enter a valid user name in the **Primary administrative user name** field. You can either enter the complete distinguished name (DN) of the user or the short name of the user, as defined by the user filter in the Advanced LDAP settings panel. For example, enter the user ID for Netscape browsers. This ID is the security server ID, which is only used for WebSphere Application Server security and is not associated with the system process that runs the server. The server calls the local operating

system registry to authenticate and obtain privilege information about users by calling the native application programming interfaces (API) in that particular registry.

4. **Optional:** If you want to use the server ID that is stored in the repository, complete the following:
 - a. Select **Automatically generated server identity** to enable the application server to generate the server identity that is used for internal process communication. You can change this server identity on the Authentication mechanisms and expiration panel. To access the Authentication mechanisms and expiration panel, click **Security > Secure administration, applications, and infrastructure > Authentication mechanisms and expiration**. Change the value of the **Internal server ID** field.
 - b. Alternatively, specify a user identity in the repository that is used for internal process communication in the **Server identity that is stored in the repository** field.
 - c. Alternatively, specify the user ID that is used to run the application server for security purposes in the **Server user ID or administrative user on a Version 6.0.x node** field.
5. Select the type of LDAP server to use from the **Type** list. The type of LDAP server determines the default filters that are used by WebSphere Application Server. These default filters change the **Type** field to **Custom**, which indicates that custom filters are used. This action occurs after you click **OK** or **Apply** in the Advanced LDAP settings panel. Choose the **Custom** type from the list and modify the user and group filters to use other LDAP servers, if required.

IBM Tivoli Directory Server users can choose IBM Tivoli Directory Server as the directory type. Use the IBM Tivoli Directory Server directory type for better performance. For a list of supported LDAP servers, see the Supported hardware, software, and APIs Web site.

Attention: IBM SecureWay Directory Server has been renamed to IBM Tivoli Directory Server in WebSphere Application Server version 6.1.

6. Enter the fully qualified host name of the LDAP server in the **Host** field. You can enter either the IP address or domain name system (DNS) name.
7. Enter the LDAP server port number in the **Port** field. The host name and the port number represent the realm for this LDAP server in the WebSphere Application Server cell. So, if servers in different cells are communicating with each other using Lightweight Third Party Authentication (LTPA) tokens, these realms must match exactly in all the cells.

The default value is 389. If multiple WebSphere Application Servers are installed and configured to run in the same single sign-on domain, or if the WebSphere Application Server interoperates with a previous version of the WebSphere Application Server, then it is important that the port number match all configurations. For example, if the LDAP port is explicitly specified as 389 in a version 5.x configuration, and a WebSphere Application Server at version 6.0.x is going to interoperate with the version 5.x server, then verify that port 389 is specified explicitly for the version 6.0.x server.

8. Enter the base distinguished name (DN) in the **Base distinguished name** field. The base DN indicates the starting point for searches in this LDAP directory server. For example, for a user with a DN of cn=John Doe, ou=Rochester, o=IBM, c=US, specify the base DN as any of the following options assuming a suffix of c=us): ou=Rochester, o=IBM, c=us or o=IBM c=us or c=us. For authorization purposes, this field is case sensitive by default. Match the case in your directory server. If a token is received (for example, from another cell or Lotus Domino) the base DN in the server must match exactly the base DN from the other cell or Domino. If case sensitivity is not a consideration for authorization, enable the **Ignore case for authorization** option.

In WebSphere Application Server, the distinguished name is normalized according to the Lightweight Directory Access Protocol (LDAP) specification. Normalization consists of removing spaces in the base distinguished name before or after commas and equal symbols. An example of a non-normalized base distinguished name is o = ibm, c = us or o=ibm, c=us. An example of a normalized base distinguished name is o=ibm,c=us.

To interoperate between WebSphere Application Server Version 5 and later versions, you must enter a normalized base distinguished name in the **Base Distinguished Name** field. In WebSphere Application Server, Version 5.0.1 or later, the normalization occurs automatically during runtime.

This field is required for all LDAP directories except the Lotus Domino Directory. The **Base Distinguished Name** field is optional for the Domino server.

9. **Optional:** Enter the bind DN name in the **Bind distinguished name** field. The bind DN is required if anonymous binds are not possible on the LDAP server to obtain user and group information. If the LDAP server is set up to use anonymous binds, leave this field blank. If a name is not specified, the application server binds anonymously. See the **Base Distinguished Name** field description for examples of distinguished names.
10. **Optional:** Enter the password corresponding to the bind DN in the **Bind password** field.
11. **Optional:** Modify the Search time out value. This timeout value is the maximum amount of time that the LDAP server waits to send a response to the product client before stopping the request. The default is 120 seconds.
12. Ensure that the **Reuse connection** option is selected. This option specifies that the server should reuse the LDAP connection. Clear this option only in rare situations where a router is used to send requests to multiple LDAP servers and when the router does not support affinity. Leave this option selected for all other situations.
13. **Optional:** Verify that the **Ignore case for authorization** option is enabled. When you enable this option, the authorization check is case insensitive. Normally, an authorization check involves checking the complete DN of a user, which is unique in the LDAP server and is case sensitive. However, when you use either the IBM Directory Server or the Sun ONE (formerly iPlanet) Directory Server LDAP servers, you must enable this option because the group information that is obtained from the LDAP servers is not consistent in case. This inconsistency affects the authorization check only. Otherwise, this field is optional and can be enabled when a case sensitive authorization check is required. For example, you might select this option when you use certificates and the certificate contents do not match the case of the entry in the LDAP server.

You can also enable the **Ignore case for authorization** option when you are using single sign-on (SSO) between the product and Lotus Domino. The default is enabled.

14. **Optional:** Select the **SSL enabled** option if you want to use Secure Sockets Layer communications with the LDAP server.

If you select the **SSL enabled** option, you can select either the **Centrally managed** or the **Use specific SSL alias** option.

Centrally managed

Enables you to specify an SSL configuration for particular scope such as the cell, node, server, or cluster in one location. To use the **Centrally managed** option, you must specify the SSL configuration for the particular set of endpoints. The Manage endpoint security configurations and trust zones panel displays all of the inbound and outbound endpoints that use the SSL protocol. If you expand the Inbound or Outbound section of the panel and click the name of a node, you can specify an SSL configuration that is used for every endpoint on that node. For an LDAP registry, you can override the inherited SSL configuration by specifying an SSL configuration for LDAP. To specify an SSL configuration for LDAP, complete the following steps:

- a. Click **Security > SSL certificate and key management > Manage endpoint security configurations and trust zones**.
- b. Expand **Outbound > cell_name > Nodes > node_name > Servers > server_name > LDAP**.

Use specific SSL alias

Select the **Use specific SSL alias** option if you intend to select one of the SSL configurations in the menu below the option.

This configuration is used only when SSL is enabled for LDAP. The default is *DefaultSSLSettings*. To modify or create a new SSL configuration, complete the following steps:

- a. Click **Security > SSL certificate and key management**.

- b. Under Configuration settings, click **Manage endpoint security configurations**.
 - c. Select a Secure Sockets Layer (SSL) *configuration_name* for selected scopes, such as a cell, node, server, or cluster.
 - d. Under Related items, click **SSL configurations**.
 - e. Click **New**.
15. Click **OK** and either **Apply** or **Save** until you return to the Secure administration, applications, and infrastructure panel.

This set of steps is required to set up the LDAP user registry. This step is required as part of enabling security in the WebSphere Application Server.

1. If you are enabling security, complete the remaining steps as specified in “Enabling security for the realm” on page 72.
2. Save, stop, and restart all the product servers (deployment managers, nodes and Application Servers) for changes in this panel to take effect. If the server comes up without any problems the setup is correct.

Standalone LDAP registry settings

Use this page to configure Lightweight Directory Access Protocol (LDAP) settings when users and groups reside in an external LDAP directory.

To view this administrative console page, complete the following steps:

1. Click **Security > Secure administration, applications, and infrastructure**.
2. Under User account repository, click the **Available realm definitions** drop-down list, select **Standalone LDAP registry**, and click **Configure**.

When security is enabled and any of these properties change, go to the Secure administration, applications, and infrastructure panel and click **Apply** to validate the changes.

WebSphere Application Server Version 6.1 distinguishes between the user identities for administrators who manage the environment and server identities for authenticating server to server communications. In most cases, server identities are automatically generated and are not stored in a repository.

Primary administrative user name:

Specifies the name of a user with administrative privileges that is defined in your custom user registry.

The user name is used to log onto the administrative console when administrative security is enabled.

Automatically generated server identity:

Enables the application server to generate the server identity that is used for internal process communication.

You can change this server identity on the Authentication mechanisms and expiration panel. To access the Authentication mechanisms and expiration panel, click **Security > Secure administration, applications, and infrastructure > Authentication mechanisms and expiration**. Change the value of the Internal server ID field.

Default: Disabled

Server identity that is stored in the repository:

Specifies a user identity in the repository that is used for internal process communication.

Default: Enabled

Type of LDAP server:

Specifies the type of LDAP server to which you connect.

IBM SecureWay Directory Server is not supported.

Host:

Specifies the host ID (IP address or domain name service (DNS) name) of the LDAP server.

Port:

Specifies the host port of the LDAP server.

If multiple application servers are installed and configured to run in the same single sign-on domain or if the application server interoperates with a previous version, it is important that the port number match all configurations. For example, if the LDAP port is explicitly specified as 389 in a Version 4.0.x configuration, and a WebSphere Application Server at Version 5 is going to interoperate with the Version 4.0.x server, verify that port 389 is specified explicitly for the Version 5 server.

Default: 389
Type: Integer

Base distinguished name (DN):

Specifies the base distinguished name (DN) of the directory service, which indicates the starting point for LDAP searches of the directory service. In most cases, bind DN and bind password are needed. However, when anonymous bind can satisfy all of the required functions, bind DN and bind password are not needed.

For example, for a user with a DN of `cn=John Doe , ou=Rochester, o=IBM, c=US`, specify the Base DN as any of the following options: `ou=Rochester, o=IBM, c=US` or `o=IBM c=US` or `c=US`. For authorization purposes, this field is case sensitive. This specification implies that if a token is received, for example, from another cell or Lotus Domino, the base DN in the server must match the base DN from the other cell or Lotus Domino server exactly. If case sensitivity is not a consideration for authorization, enable the **Ignore case for authorization** option. This option is required for all Lightweight Directory Access Protocol (LDAP) directories, except for the Lotus Domino Directory, IBM Tivoli Directory Server V6.0, and Novell eDirectory, where this field is optional.

If you need to interoperate between the application server Version 5 and a Version 5.0.1 or later server, you must enter a normalized base DN. A normalized base DN does not contain spaces before or after commas and equal symbols. An example of a non-normalized base DN is `o = ibm, c = us` or `o=ibm, c=us`. An example of a normalized base DN is `o=ibm,c=us`. In WebSphere Application Server, Version 5.0.1 or later, the normalization occurs automatically during runtime.

Bind distinguished name (DN):

Specifies the DN for the application server to use when binding to the directory service.

If no name is specified, the application server binds anonymously. See the Base distinguished name (DN) field description for examples of distinguished names.

Bind password:

Specifies the password for the application server to use when binding to the directory service.

Search timeout:

Specifies the timeout value in seconds for an Lightweight Directory Access Protocol (LDAP) server to respond before stopping a request.

Default: 120

Reuse connection:

Specifies whether the server reuses the LDAP connection. Clear this option only in rare situations where a router is used to distribute requests to multiple LDAP servers and when the router does not support affinity.

Default: Enabled
Range: Enabled or Disabled

Important: Disabling the **Reuse connection** option causes the application server to create a new LDAP connection for every LDAP search request. This situation impacts system performance if your environment requires extensive LDAP calls. This option is provided because the router is not sending the request to the same LDAP server. The option is also used when the idle connection timeout value or firewall timeout value between the application server and LDAP is too small.

If you are using WebSphere Edge Server for LDAP failover, you must enable TCP resets with the Edge server. A TCP reset causes the connection to immediately closed and a backup server to failover. For more information, see "Sending TCP resets when server is down" at <http://www-3.ibm.com/software/webservers/appserv/doc/v50/ec/infocenter/edge/LBguide.htm#HDRRESETSERVER> and the Edge Server V2 - TCP Reset feature in PTF #2 described in: <ftp://ftp.software.ibm.com/software/websphere/edgeserver/info/doc/v20/en/updates.pdf>.

Ignore case for authorization:

Specifies that a case insensitive authorization check is performed when using the default authorization.

This option is required when IBM Tivoli Directory Server is selected as the LDAP directory server.

This option is required when Sun ONE Directory Server is selected as the LDAP directory server. For more information, see "Using specific directory servers as the LDAP server" in the documentation.

This option is optional and can be enabled when a case-sensitive authorization check is required. For example, use this option when the certificates and the certificate contents do not match the case that is used for the entry in the LDAP server. You can enable the **Ignore case for authorization** option when using single sign-on (SSO) between the application server and Lotus Domino.

Default: Enabled
Range: Enabled or Disabled

SSL enabled:

Specifies whether secure socket communication is enabled to the Lightweight Directory Access Protocol (LDAP) server.

When enabled, the LDAP Secure Sockets Layer (SSL) settings are used, if specified.

Centrally managed:

Specifies that the selection of an SSL configuration is based upon the outbound topology view for the Java Naming and Directory Interface (JNDI) platform.

Centrally managed configurations support one location to maintain SSL configurations rather than spreading them across the configuration documents.

Default: Enabled

Use specific SSL alias:

Specifies the SSL configuration alias to use for LDAP outbound SSL communications.

This option overrides the centrally managed configuration for the JNDI platform.

Standalone LDAP registry wizard settings

Use this security wizard page to provide the basic settings to connect the application server to an existing Lightweight Directory Access Protocol (LDAP) registry.

To view this security wizard page, click **Security > Secure administration, applications, and infrastructure > Security configuration wizard**. You can modify your LDAP registry configuration by completing the following steps:

1. Click **Security > Security administration, applications, and infrastructure**.
2. Under User account repository, click the **Available realm definitions** drop-down list, select **Standalone LDAP registry**, and click **Configure**.

Primary administrative user name:

Specifies the name of a user with administrative privileges that is defined in your custom user registry.

The user name is used to log onto the administrative console when administrative security is enabled.

Type of LDAP server:

Specifies the type of LDAP server to which you connect.

IBM SecureWay Directory Server is not supported.

Host:

Specifies the host ID (IP address or domain name service (DNS) name) of the LDAP server.

Port:

Specifies the host port of the LDAP server.

If multiple application servers are installed and configured to run in the same single sign-on domain or if the application server interoperates with a previous version, it is important that the port number match all configurations. For example, if the LDAP port is explicitly specified as 389 in a Version 4.0.x configuration, and a WebSphere Application Server at Version 5 is going to interoperate with the Version 4.0.x server, verify that port 389 is specified explicitly for the Version 5 server.

Default: 389
Type: Integer

Base distinguished name (DN):

Specifies the base distinguished name (DN) of the directory service, which indicates the starting point for LDAP searches of the directory service. In most cases, bind DN and bind password are needed. However, when anonymous bind can satisfy all of the required functions, bind DN and bind password are not needed.

For example, for a user with a DN of cn=John Doe , ou=Rochester, o=IBM, c=US, specify the Base DN as any of the following options: ou=Rochester, o=IBM, c=US or o=IBM, c=US or c=US. For authorization purposes, this field is case sensitive. This specification implies that if a token is received, for example, from another cell or Lotus Domino, the base DN in the server must match the base DN from the other cell or Lotus Domino server exactly.

If you need to interoperate between the application server Version 5 and a Version 5.0.1 or later server, you must enter a normalized base DN. A normalized base DN does not contain spaces before or after commas and equal symbols. An example of a non-normalized base DN is o = ibm, c = us or o=ibm, c=us. An example of a normalized base DN is o=ibm,c=us. In WebSphere Application Server, Version 5.0.1 or later, the normalization occurs automatically during run time.

Bind distinguished name (DN):

Specifies the DN for the application server to use when binding to the directory service.

If no name is specified, the application server binds anonymously. See the Base distinguished name (DN) field description for examples of distinguished names.

Bind password:

Specifies the password for the application server to use when binding to the directory service.

Advanced Lightweight Directory Access Protocol user registry settings

Use this page to configure the advanced Lightweight Directory Access Protocol (LDAP) user registry settings when users and groups reside in an external LDAP directory.

To view this administrative page, complete the following steps:

1. Click **Security > Secure administration, applications, and infrastructure**.
2. Under User account repository, click the **Available realm definitions** drop-down list, select **Standalone LDAP registry**, and click **Configure**.
3. Under Additional properties, click **Advanced Lightweight Directory Access Protocol (LDAP) user registry settings**.

Default values for all the user and group related filters are already completed in the appropriate fields. You can change these values depending on your requirements. These default values are based on the type of LDAP server that is selected in the Standalone LDAP registry settings panel. If this type changes, for example from Netscape to Secureway, the default filters automatically change. When the default filter values change, the LDAP server type changes to Custom to indicate that custom filters are used. When security is enabled and any of these properties change, go to the Secure administration, applications, and infrastructure panel and click **Apply** or **OK** to validate the changes.

User filter:

Specifies the LDAP user filter that searches the user registry for users.

This option is typically used for security role-to-user assignments and specifies the property by which to look up users in the directory service. For example, to look up users based on their user IDs, specify `(&(uid=%v)(objectclass=inetOrgPerson))`. For more information about this syntax, see the LDAP directory service documentation.

Data type: String

Group filter:

Specifies the LDAP group filter that searches the user registry for groups

This option is typically used for security role-to-group assignments and specifies the property by which to look up groups in the directory service. For more information about this syntax, see the LDAP directory service documentation.

Data type: String

User ID map:

Specifies the LDAP filter that maps the short name of a user to an LDAP entry.

Specifies the piece of information that represents users when users display. For example, to display entries of the object class = inetOrgPerson type by their IDs, specify `inetOrgPerson:uid`. This field takes multiple `objectclass:property` pairs delimited by a semicolon (;).

Data type: String

Group ID map:

Specifies the LDAP filter that maps the short name of a group to an LDAP entry.

Specifies the piece of information that represents groups when groups display. For example, to display groups by their names, specify `*:cn`. The asterisk (*) is a wildcard character that searches on any object class in this case. This field takes multiple `objectclass:property` pairs, delimited by a semicolon (;).

Data type: String

Group member ID map:

Specifies the LDAP filter that identifies user-to-group relationships.

For directory types SecureWay, and Domino, this field takes multiple `objectclass:property` pairs, delimited by a semicolon (;). In an `objectclass:property` pair, the object class value is the same object class that is defined in the group filter, and the property is the member attribute. If the object class value does not match the object class in the group filter, authorization might fail if groups are mapped to security roles. For more information about this syntax, see your LDAP directory service documentation.

For IBM Directory Server, Sun ONE, and Active Directory, this field takes multiple `group attribute:member attribute` pairs delimited by a semicolon (;). These pairs are used to find the group memberships of a user by enumerating all the group attributes that are possessed by a given user. For example, attribute pair `memberof:member` is used by Active Directory, and `ibm-allGroup:member` is used by IBM Directory Server. This field also specifies which property of an object class stores the list of members belonging to the group represented by the object class. For supported LDAP directory servers, see "Supported directory services".

Data type: String

Perform a nested group search:

Specifies a recursive nested group search.

Select this option if the Lightweight Directory Access Protocol (LDAP) server does not support recursive server-side group member searches and if recursive group member search is required. It is not recommended that you select this option to locate recursive group memberships for LDAP servers. Application server security leverages the recursive search functionality of the LDAP server to search a user's group memberships, including recursive group memberships. For example:

- IBM Directory Server is preconfigured by the application server security to recursively calculate a user's group memberships using the `ibm-allGroup` attribute.
- SunONE directory server is preconfigured to calculate nested group memberships using the `nsRole` attribute.

Data type: String

Certificate map mode:

Specifies whether to map X.509 certificates into an LDAP directory by EXACT_DN or CERTIFICATE_FILTER. Specify CERTIFICATE_FILTER to use the specified certificate filter for the mapping.

Data type: String

Certificate filter:

Specifies the filter certificate mapping property for the LDAP filter. The filter is used to map attributes in the client certificate to entries in the LDAP registry.

If more than one LDAP entry matches the filter specification at runtime, authentication fails because the result is an ambiguous match. The syntax or structure of this filter is:

`(&(uid=${SubjectCN})(objectclass=inetOrgPerson))`. The left side of the filter specification is an LDAP attribute that depends on the schema that your LDAP server is configured to use. The right side of the filter specification is one of the public attributes in your client certificate. The right side must begin with a dollar sign (\$) and open bracket ({} and end with a close bracket (}). You can use the following certificate attribute values on the right side of the filter specification. The case of the strings is important:

- `${UniqueKey}`
- `${PublicKey}`
- `${Issuer}`
- `${NotAfter}`
- `${NotBefore}`
- `${SerialNumber}`
- `${SigAlgName}`
- `${SigAlgOID}`
- `${SigAlgParams}`
- `${SubjectCN}`
- `${Version}`

Data type: String

Configuring Lightweight Directory Access Protocol search filters

Use this topic to configure the LDAP search filters. These steps are required to modify existing user and group filters for a particular LDAP directory type, and also to set up certificate filters to map certificates to entries in the LDAP server.

WebSphere Application Server uses Lightweight Directory Access Protocol (LDAP) filters to search and obtain information about users and groups from an LDAP directory server. A default set of filters is provided for each LDAP server that the product supports. You can modify these filters to fit your LDAP configuration. After the filters are modified and you click **OK** or **Apply** the directory type in the Standalone LDAP registry panel changes to custom, which indicates that custom filters are used. Also, you can develop filters to support any additional type of LDAP server. The effort to support additional LDAP directories is optional and other LDAP directory types are not supported. Complete the following steps in the administrative console.

1. Click **Security > Secure administration, applications, and infrastructure**.
2. Under User account repository, select **Standalone LDAP registry** and click **Configure**.
3. Under Additional properties, click **Advanced Lightweight Directory Access Protocol (LDAP) user registry settings**.
4. Modify the user filter, if necessary. The user filter is used for searching the registry for users and is typically used for the security role-to-user assignment. The filter is also used to authenticate a user with the attribute that is specified in the filter. The filter specifies the property that is used to look up users in the directory service.

In the following example, the property that is assigned to %v, which is the short name of the user, must be a unique key. Two LDAP entries with the same object class cannot have the same short name. To look up users based on their user IDs (uid) and to use the inetOrgPerson object class, specify the following syntax:

```
(&(uid=%v)(objectclass=inetOrgPerson)
```

For more information about this syntax, see the “Using specific directory servers as the LDAP server” on page 105 documentation.

5. Modify the group filter, if necessary. The group filter is used in searching the registry for groups and is typically used for the security role-to-group assignment. Also, the filter is used to specify the property by which to look up groups in the directory service.

In the following example, the property that is assigned to %v, which is the short name of the group, must be a unique key. Two LDAP entries with the same object class cannot have the same short name. To look up groups based on their common names (CN) and to use either the groupOfNames object class or the groupOfUniqueNames object class, specify the following syntax:

```
(&(cn=%v)(|(objectclass=groupOfNames)(objectclass=groupOfUniqueNames)))
```

For more information about this syntax, see the “Using specific directory servers as the LDAP server” on page 105 documentation.

6. Modify the user ID map, if necessary. This filter maps the short name of a user to an LDAP entry and specifies the piece of information that represents users when these users are displayed with their short names. For example, to display entries of object class = inetOrgPerson by their IDs, specify inetOrgPerson:uid. This field takes multiple objectclass:property pairs, delimited by a semicolon (;). To provide a consistent value for methods like the getCallerPrincipal method and the getUserPrincipal method, the short name that is obtained by using this filter is used. For example, the CN=Bob Smith, ou=austin.ibm.com, o=IBM, c=US user can log in using any attributes that are defined, for example, e-mail address, social security number, and so on, but when these methods are called, the bob user ID is returned no matter how the user logs in.
7. Modify the group ID map filter, if necessary. This filter maps the short name of a group to an LDAP entry and specifies the piece of information that represents groups when groups display. For example,

to display groups by their names, specify *:cn. The asterisk (*) is a wildcard character that searches on any object class in this case. This field takes multiple objectclass:property pairs, delimited by a semicolon (;).

8. Modify the group member ID map filter, if necessary. This filter identifies user-to-group memberships. For SecureWay, and Domino directory types, this field is used to query all the groups that match the specified object classes to see if the user is contained in the specified attribute. For example, to get all the users that belong to groups with the groupOfNames object class and the users that are contained in the member attributes, specify groupOfNames:member. This syntax, which is a property of an object class, stores the list of members that belong to the group that is represented by the object class. This field takes multiple objectclass:property pairs that are delimited by a semicolon (;). For more information about this syntax, see the “Using specific directory servers as the LDAP server” on page 105.

For the IBM Tivoli Directory Server, Sun ONE, and Active Directory, this field is used to query all users in a group with the information that is stored in the user object. For example, the memberof:member filter (for Active Directory) is used to get the memberof attribute of the user object to obtain all the groups to which the user belongs. The member attribute is used to get all the users in a group that use the Group object. Using the User object to obtain the group information improves performance.

9. Select the **Perform a nested group search** option if your LDAP server does not support recursive server-side searches.
10. Modify the Certificate map mode, if necessary. You can use the X.590 certificates for user authentication when LDAP is selected as the registry. This field is used to indicate whether to map the X.509 certificates into an LDAP directory user by **EXACT_DN** or **CERTIFICATE_FILTER**. If **EXACT_DN** is selected, the DN in the certificate must exactly match the user entry in the LDAP server, including case and spaces.

Select the **Ignore case for authorization** option on the Standalone LDAP registry settings to make the authorization case insensitive. To access the Standalone LDAP registry settings panel, complete the following steps:

- a. Click **Security > Secure administration, applications, and infrastructure**.
 - b. Under User account repository, click the **Available realm definitions** drop-down list, select **Standalone LDAP registry**.
11. If you select **CERTIFICATE_FILTER**, specify the LDAP filter for mapping attributes in the client certificate to entries in LDAP. If more than one LDAP entry matches the filter specification at run time, authentication fails because an ambiguous match results. The syntax or structure of this filter is: LDAP attribute=\${Client certificate attribute} (for example, uid=\${SubjectCN}).

The left side of the filter specification is an LDAP attribute that depends on the schema that your LDAP server is configured to use. The right side of the filter specification is one of the public attributes in your client certificate. Note that the right side must begin with a dollar sign (\$), open bracket ({), and end with a close bracket (}). Use the following certificate attribute values on the right side of the filter specification. The case of the strings is important.

- \${UniqueKey}
- \${PublicKey}
- \${Issuer}
- \${NotAfter}
- \${NotBefore}
- \${SerialNumber}
- \${SigAlgName}
- \${SigAlgOID}
- \${SigAlgParams}
- \${SubjectDN}
- \${Version}

To enable this field, select **CERTIFICATE_FILTER** for the certificate mapping.

12. Click **Apply**.

When any LDAP user or group filter is modified in the Advanced LDAP Settings panel click **Apply**. Clicking **OK** navigates you to the Standalone LDAP registry panel, which contains the previous LDAP directory type, rather than the custom LDAP directory type. Clicking **OK** or **Apply** in the Standalone LDAP registry panel saves the back-level LDAP directory type and the default filters of that directory. This action overwrites any changes to the filters that you made. To avoid overwriting changes, you can take either of the following actions:

- Click **Apply** in the Advanced Lightweight Directory Access Protocol (LDAP) user registry settings panel. Click **Security > Secure administration, applications, and infrastructure** and change the User account repository type to Standalone custom registry.
- Select **Custom** type from the Standalone LDAP registry panel. Click **Apply** and then change the filters by clicking the Advanced Lightweight Directory Access Protocol (LDAP) user registry settings panel. After you complete your changes, click **Apply** or **OK**.

The validation of the changes does not take place in this panel. Validation is done when you click **OK** or **Apply** on the Secure administration, applications, and infrastructure panel. If you are in the process of enabling security for the first time, complete the remaining steps and go to the Secure administration, applications, and infrastructure panel. Select **Standalone LDAP registry** as the user account repository. If security is already enabled and any information on this panel changes, go to the Secure administration, applications, and infrastructure panel and click **OK** or **Apply** to validate your changes. If your changes are not validated, the server might not start.

These steps result in the configuration of the LDAP search filters. These steps are required to modify existing user and group filters for a particular LDAP directory type. The steps are also used to set up certificate filters to map certificates to entries in the LDAP server.

1. Validate this setup by clicking **OK** or **Apply** on the Secure administration, applications, and infrastructure panel.
2. Save, stop, and start all the product servers, including the cell, nodes and all of the application servers for any changes in this panel to become effective.
3. After the server starts, go through all the security-related tasks (getting users, getting groups, and so on) to verify that the changes to the filters function.

Updating LDAP binding information

Use this information to dynamically update security LDAP binding information by switching to a different binding identity.

You can dynamically update Lightweight Directory Access Protocol (LDAP) binding information without first stopping and restarting WebSphere Application Server by using the **wsadmin** tool.

The `resetLdapBindInfo` method in `SecurityAdmin` MBean is used to dynamically update LDAP binding information at WebSphere Application Server security runtime, and it takes the bind distinguished name (DN) and bind password parameters as input. The `resetLdapBindInfo` method validates the bind information against the LDAP server. If validation passes, new binding information is stored in `security.xml`, and a copy of the information is placed in WebSphere Application Server security runtime.

The MBean method also synchronizes the binding information change in `security.xml` from cell to nodes.

If the new binding information is `null`, `null`, the `resetLdapBindInfo` method first extracts LDAP binding information, including bind DN, bind password, and target binding host from WebSphere Application Server security configuration in `security.xml`. It then pushes the binding information to WebSphere Application Server security runtime.

There are two ways to dynamically update WebSphere Application Server security LDAP binding information using the `SecurityAdmin` MBean through `wsadmin`:

- “Switching to a different binding identity” on page 105
- “Switching to a failover LDAP host” on page 105

Switching to a different binding identity:

To dynamically update security LDAP binding information by switching to a different binding identity:

1. In the administrative console, click **Security > Secure administration, applications, and infrastructure**.
2. Under User account repository, click the **Available realm definitions** drop-down list, select **Standalone LDAP registry**, and click **Configure**.
3. Create a new bind DN. It must have the same access authority as the current bind DN.
4. Run the SecurityAdmin MBean across all of the processes (deployment manager, nodes, and application servers) to validate the new binding information, to save it to `security.xml`, and to push the new binding information to the runtime.

The following is a sample Jacl file for step 4:

```
proc LDAPReBind {args} {
  global AdminConfig AdminControl ldapBindDn ldapBindPassword
  set ldapBindDn [lindex $args 0]
  set ldapBindPassword [lindex $args 1]
  set secMBeans [$AdminControl queryNames type=SecurityAdmin,*]
  set plist [list $ldapBindDn $ldapBindPassword]
  foreach secMBean $secMBeans {
    set result [$AdminControl invoke $secMBean resetLdapBindInfo $plist]
  }
}
```

Switching to a failover LDAP host:

To dynamically update security LDAP binding information by switching to a failover LDAP host:

1. In the administrative console, click **Security > Secure administration, applications, and infrastructure**.
2. Under User account repository, select **Standalone LDAP registry** and click **Configure**.
3. Change the password for bind DN on one LDAP server (it can be the primary or the backup).
4. Update the new bind DN password to WebSphere Application security runtime by calling `resetLdapBindInfo` with the bind DN and by using its new password as a parameter.
5. Use the new bind DN password for all of the other LDAP servers. The binding information is now consistent across WebSphere Application Server and the LDAP servers.

Note: If you call `resetLdapBindInfo` with `null`, `null` as input parameters, WebSphere Application Server security runtime completes the following steps:

- a. Reads the bind DN, bind password, and target LDAP hosts from `security.xml`.
- b. Refreshes the cached connection to the LDAP server.

If you configure security to use multiple LDAP servers, this MBean call forces WebSphere Application Server security to reconnect to the first available LDAP host in the list. For example, if three LDAP servers are configured in the order of L1, L2, and L3, the reconnection process always starts with the L1 server.

Using specific directory servers as the LDAP server

This article provides important information about the directory servers that are supported as Lightweight Directory Access Protocol (LDAP) servers in WebSphere Application Server.

Microsoft Active Directory forest is not supported in the user registry in this product.

For a list of supported LDAP servers, refer to the Supported hardware and software Web site.

It is expected that other LDAP servers follow the LDAP specification. Support is limited to these specific directory servers only. You can use any other directory server by using the custom directory type in the list and by filling in the filters that are required for that directory.

To improve performance for LDAP searches, the default filters for IBM Tivoli Directory Server, Sun ONE, and Active Directory are defined such that when you search for a user, the result contains all the relevant information about the user (user ID, groups, and so on). As a result, the product does not call the LDAP server multiple times. This definition is possible only in these directory types, which support searches where the complete user information is obtained.

If you use the IBM Directory Server, select the **Ignore case for authorization** option. This option is required because when the group information is obtained from the user object attributes, the case is not the same as when you get the group information directly. For the authorization to work in this case, perform a case insensitive check and verify the requirement for the **Ignore case for authorization** option.

- **Using Directory Services as the LDAP server**

Directory Services is provided with i5/OS Version 5 Release 3 and is a member of the IBM Tivoli Directory Server family of products and services. For i5/OS Version 5 Release 3 and later, specify IBM Tivoli Directory Server as the directory type when configuring the user registry to use Directory Services.

Support for groups that contain other groups or nested groups depends upon the specific versions of WebSphere Application Server and LDAP. For more information, see “Dynamic groups and nested group support” on page 167.

- **Using IBM Tivoli Directory Server as the LDAP server**

To use IBM Tivoli Directory Server, formerly IBM Directory Server, select **IBM Tivoli Directory Server** as the directory type.

The difference between these two types is group membership lookup. It is recommended that you choose the IBM Tivoli Directory Server for optimum performance during runtime. In the IBM Tivoli Directory Server, the group membership is an operational attribute. With this attribute, a group membership lookup is done by enumerating the `ibm-allGroups` attribute for the entry. All group memberships, including the static groups, dynamic groups, and nested groups, can be returned with the `ibm-allGroups` attribute.

WebSphere Application Server supports dynamic groups, nested groups, and static groups in IBM Tivoli Directory Server using the `ibm-allGroups` attribute. To utilize this attribute in a security authorization application, use a case-insensitive match so that attribute values returned by the `ibm-allGroups` attribute are all in uppercase.

Important: It is recommended that you do not install IBM Tivoli Directory Server Version 6.0 on the same machine that you install WebSphere Application Server Version 6.1. IBM Tivoli Directory Server Version 6.0 includes WebSphere Application Server Express Version 5.1.1, which the directory server uses for its administrative console. Install the Web Administration tool Version 6.0 and WebSphere Application Server Express Version 5.1.1, which are both bundled with IBM Tivoli Directory Server Version 6.0, on a different machine from WebSphere Application Server Version 6.1. You cannot use WebSphere Application Server Version 6.1 as the administrative console for IBM Tivoli Directory Server. If IBM Tivoli Directory Server Version 6.0 and WebSphere Application Server Version 6.1 are installed on the same machine, you might encounter port conflicts.

If you must install IBM Tivoli Directory Server Version 6.0 and WebSphere Application Server Version 6.1 on the same machine, consider the following information:

- During the IBM Tivoli Directory Server installation process, you must select both the **Web Administration tool** and **WebSphere Application Server Express Version 5.1.1**.
- Install WebSphere Application Server Version 6.1.

- When you install WebSphere Application Server Version 6.1, change the port number for the application server.
- You might need to adjust the WebSphere Application Server environment variables on WebSphere Application Server Version 6.1 for *WAS_HOME* and *WAS_INSTALL_ROOT* (or *APP_SERVER_ROOT* for i5/OS). To change the variables using the administrative console, click **Environment > WebSphere Variables**.

- **Using a Lotus Domino Enterprise Server as the LDAP server**

If you select the Lotus Domino Enterprise Server Version 6.5.4 or Version 7.0 and the attribute short name is not defined in the schema, you can take either of the following actions:

- Change the schema to add the short name attribute.
- Change the user ID map filter to replace the short name with any other defined attribute (preferably to UID). For example, change `person:shortname` to `person:uid`.

The userID map filter is changed to use the uid attribute instead of the shortname attribute as the current version of Lotus Domino does not create the shortname attribute by default. If you want to use the shortname attribute, define the attribute in the schema and change the userID map filter.

User ID Map : `person:shortname`

- **Using Sun ONE Directory Server as the LDAP server**

You can select **Sun ONE Directory Server** for your Sun ONE Directory Server system. In Sun ONE Directory Server, the object class is the default `groupOfUniqueName` when you create a group. For better performance, WebSphere Application Server uses the User object to locate the user group membership from the `nsRole` attribute. Create the group from the role. If you want to use the `groupOfUniqueName` attribute to search groups, specify your own filter setting. Roles unify entries. Roles are designed to be more efficient and easier to use for applications. For example, an application can locate the role of an entry by enumerating all the roles that are possessed by a given entry, rather than selecting a group and browsing through the members list. When using roles, you can create a group using a:

- Managed role
- Filtered role
- Nested role

All of these roles are computable by the `nsRole` attribute.

- **Using Microsoft Active Directory server as the LDAP server**

To use Microsoft Active Directory as the LDAP server for authentication with WebSphere Application Server you must take specific steps. By default, Microsoft Active Directory does not permit anonymous LDAP queries. To create LDAP queries or to browse the directory, an LDAP client must bind to the LDAP server using the distinguished name (DN) of an account that belongs to the administrator group of the Windows system. A group membership search in the Active Directory is done by enumerating the `memberof` attribute for a given user entry, rather than browsing through the member list in each group. If you change the default behavior to browse each group, you can change the **Group Member ID Map** field from `memberof:member` to `group:member`.

The following steps describe how to set up Microsoft Active Directory as your LDAP server.

1. Determine the full distinguished name (DN) and password of an account in the administrators group. For example, if the Active Directory administrator creates an account in the Users folder of the Active Directory Users and Computers Windows control panel and the DNS domain is `ibm.com`, the resulting DN has the following structure:

```
cn=<adminUsername>, cn=users, dc=ibm, dc=com
```
2. Determine the short name and password of any account in the Microsoft Active Directory.
3. Use the WebSphere Application Server administrative console to set up the information that is needed to use Microsoft Active Directory.

- a. Click **Security > Secure administration, applications, and infrastructure**.
- b. Under User account repository, select **Standalone LDAP registry** and click **Configure**.
- c. Set up LDAP with Active Directory as the type of LDAP server. Based on the information that is determined in the previous steps, you can specify the following values on the LDAP settings panel:

Primary administrative user name

Specify the name of a user with administrative privileges that is defined in the registry. This user name is used to access the administrative console or used by wsadmin.

Type Specify Active Directory

Host Specify the domain name service (DNS) name of the machine that is running Microsoft Active Directory.

Base distinguished name (DN)

Specify the domain components of the DN of the account that is chosen in the first step. For example: dc=ibm, dc=com

Bind distinguished name (DN)

Specify the full distinguished name of the account that is chosen in the first step. For example: cn=adminUsername, cn=users, dc=ibm, dc=com

Bind password

Specify the password of the account that is chosen in the first step.

- d. Click **OK** and **Save** to save the changes to the master configuration.
4. Click **Security > Secure administration, applications, and infrastructure**.
5. Under User account repository, click the **Available realm definitions** drop-down list, select **Standalone LDAP registry**, and click **Configure**.
6. Select either the **Automatically generated server identity** or **Server identity that is stored in the repository** option. If you select the **Server identity that is stored in the repository** option, enter the following information:

Server user ID or administrative user on a Version 6.0.x node

Specify the short name of the account that is chosen in the second step.

Server user password

Specify the password of the account that is chosen in the second step.

7. **Optional:** Set ObjectCategory as the filter in the Group member ID map field to improve LDAP performance.
 - a. Under Additional properties, click **Advanced Lightweight Directory Access Protocol (LDAP) user registry settings**.
 - b. Add ;objectCategory:group to the end of the Group member ID map field.
8. Click **OK** and **Save** to save the changes to the master configuration.
9. Stop and restart the administrative server so that the changes take effect.

Adding users to the Lightweight Directory Access Protocol user registry

You can use the Lightweight Directory Access Protocol (LDAP) user registry with any of the authentication mechanisms supported by WebSphere Application Server. Therefore, it is necessary to add users into the LDAP directory that you want to have authorization to access Application Server resources.

This information in this article is specific to the iSeries Directory Services product.

A variety of methods are available to add users. However, the easiest way is to create an LDAP Data Interchange Format (LDIF) file. The file contains the set of users to add into the directory. The file is used by the LDAP utilities, such as **idsldapmodify**. You can run these utilities from either the operating system or from a workstation. If you run these LDAP utilities from the operating system, your LDIF file must reside in the integrated file system.

Complete the following steps to add users to the LDAP user registry:

1. Create an LDIF file and save it in the integrated file system. Use either the Edit File (EDTF) utility or your workstation text editor to create the file. Save the file in the integrated file system either by mapping a drive or using the file transfer protocol (FTP).

For WebSphere Application Server and LDAP directory services, create entries in the directory that correspond to the ePerson schema definition.

A simple ePerson LDIF entry resembles the following example:

```
dn: cn=John Doe, ou=Rochester, o=IBM, c=US
objectclass: person
objectclass: inetOrgPerson
objectclass: top
objectclass: organizationalPerson
objectclass: ePerson
cn: John Doe
sn: Doe
uid: jdoe
userpassword: secretpass
```

This LDIF entry defines an ePerson for user John Doe. The user identification (uid) for John is set to jdoe and his password is set to secretpass. This entry resides within the Rochester organizational unit, which is within the IBM organization in the United States. Each of the ou, o, and c containing entries are defined before this ePerson entry is defined. You can define a series of LDIF entries in the same file to define Lightweight Third Party Authentication (LTPA) users for WebSphere Application Server.

If you do not specify a value for the userpassword attribute, the LDAP server attempts to authenticate LTPA users with the user profile for the local operating system that is identified by the uid attribute value. This action might be desirable if users have user profiles for the operating system and do not want to manage passwords in both the operating system user registry and the LDAP directory.

When you create an ePerson entry, make sure that the cn and uid attributes each have a unique value. Do not create two entries that have the same value for the cn and uid attributes.

Important: If you have a large user registry, login performance might be severely impacted if the Group Member ID Map property is left at its default value, which is both groupOfNames:member and groupOfUniqueNames:uniqueMember.

To address this performance problem, specify one of these object classes and not both. You must then exclusively use the selected object class to implement groups in the user registry.

2. Import the LDIF file entries into your directory on the server. Use the LDAP ldapadd utility in Qshell Interpreter (QSH) or from a workstation.

For more information on importing LDIF entries, see the Directory Services documentation in the iSeries Information Center:

- For V5R3

Locating a user's group memberships in Lightweight Directory Access Protocol

WebSphere Application Server security can be configured to search group memberships directly or indirectly. It can also be configured to search only a static group, or it can be configured to search static groups, recursive or nested groups, and dynamic groups for some Lightweight Directory Access Protocol (LDAP) servers.

- Evaluate group memberships from user object directly.
 - Several popular LDAP servers enable user objects to contain information about the groups to which they belong such as Microsoft Active Directory Server, or eDirectory. Some user group memberships can be computable attributes from the user object such as IBM Directory Server or Sun ONE directory server. In some LDAP servers, this attribute can be used to include a user's dynamic group memberships, nesting group memberships, and static group memberships to locate all the group memberships from a single attribute.

- For example, in IBM Directory Server all group memberships including the static groups, dynamic groups, and nested groups can be returned using the `ibm-allGroups` attribute. In Sun ONE, all roles, including managed roles, filtered roles, and nested roles, are calculated using the `nsRole` attribute. If an LDAP server has such an attribute in a User object to include dynamic groups, nested groups, and static groups, WebSphere Application Server security can be configured to use this attribute to support these groups.
- Evaluate group memberships from a Group object indirectly.
 - Some LDAP servers enable only Group objects, such as the Lotus Domino LDAP server to contain information about users. The LDAP server does not enable the User object to contain information about groups. For this type of LDAP server, group membership searches are performed by locating the user on the member list of groups. The member list evaluation is not currently used in the static group membership search for WebSphere Application Server.
- Use the direct method for searching group memberships if your LDAP server has an attribute in the User object to include group information. To use the direct method or the indirect method, enter the appropriate value in the Group Member ID map field on the Advanced LDAP Settings panel using the following methods.
 - `objectclass:attribute` pairs for the indirect method
 - `attribute:attribute` pairs for the direct method
- Use the sample entries of `attribute:attribute` pairs in Group member ID map fields. Note that the `groupMembership` attribute lists all the static groups for which a user is a member. This attribute is NOT updated whenever an object matches or does not match a dynamic group's filter. Please refer to the Novell eDirectory documentation for more information about the `groupMembership` attribute.
 - `ibm-allGroups:member` for IBM Directory server
 - `nsRole:nsRole` for Sun ONE directory, if groups are created with role inside Sun ONE
 - `memberOf:member` in Microsoft Active Directory Server
 - `groupMembership:member` for eDirectory
- Use the sample entries of `objectClass:attribute` pairs in the Group member ID map field.
 - `dominoGroup:member` for Lotus Domino
 - `groupOfNames:member` for eDirectory

While using the direct method, dynamic groups, recursive groups, and static groups can be returned as multiple values of a single attribute. For example, in IBM Directory Server all group memberships, including the static groups, dynamic groups, and nested groups, can be returned using the `ibm-allGroups` attribute. In Sun ONE, all roles, including managed roles, filtered roles, and nested roles, are calculated using the `nsRole` attribute. If an LDAP server can use the `nsRole` attribute, dynamic groups, nested groups, and static groups are all supported by WebSphere Application Server.

Some LDAP servers do not have recursive computing functionality. For example, although Microsoft Active Directory server has direct group search capability using the `memberOf` attribute, this attribute lists the groups beneath, which the group is directly nested only and does not contain the recursive list of nested predecessors. The Lotus Domino LDAP server only supports the indirect method to locate the group memberships for a user. You cannot obtain recursive group memberships from a Domino server directly. For LDAP servers without recursive searching capability, WebSphere Application Server security provides a recursive function that is enabled by clicking **Perform a Nested Group Search** in the Advanced LDAP user registry settings. Select this option only if your LDAP server does not provide recursive searches and you want a recursive search.

Configuring dynamic and nested group support for the SunONE or iPlanet Directory Server:

Configure dynamic and nested groups to simplify WebSphere Application Server security management and increase its effectiveness and flexibility.

To use dynamic and nested groups with WebSphere Application Server security, you must be running WebSphere Application Server Version 5.1.1 or later. Refer to “Dynamic and nested group support for the SunONE or iPlanet Directory Server” on page 167 for more information on this topic.

1. In the administrative console for WebSphere Application Server, click **Security > Secure administration, applications, and infrastructure**.
2. Under User account repository, click the **Available realm definitions** drop-down list, select **Standalone LDAP registry**, and click **Configure**.
3. Select SunONE for the type of LDAP server.
4. Select the **Ignore case for authorization** option.
5. Under Additional Properties, click **Advanced Lightweight Directory Access Protocol (LDAP) user registry settings**.
6. Change the Group filter setting to `&(cn=%v)(objectclass=ldapsubentry)`.
7. Change the Group member ID map setting to `nsRole:nsRole`.
8. Click **Apply** or **OK** to validate the changes.

Configuring dynamic and nested group support for the IBM Tivoli Directory Server:

Configure dynamic and nested groups to simplify WebSphere Application Server security management and increase its effectiveness and flexibility.

When creating groups, ensure that nested and dynamic group memberships work correctly.

1. In the administrative console for WebSphere Application Server, click **Security > Secure administration, applications, and infrastructure**.
2. Under User account repository, click **Standalone LDAP registry**, and click **Configure**.
3. Select IBM Tivoli Directory Server for the type of LDAP server.
4. Under Additional properties, click **Advanced Lightweight Directory Access Protocol (LDAP) user registry settings**.
5. Change the Group filter value to `&(cn=%v)(|(objectclass=groupOfNames)(objectclass=groupOfUniqueNames)(objectclass=groupOfURLs))`.
6. Change the Group member ID map value to `ibm-allGroups:member;ibm-allGroups:uniqueMember`.
7. Click **Apply** or **OK** to validate the changes.
8. Verify that Auxiliary object class field on the Add an LDAP entry panel for your IBM Tivoli Directory server has the appropriate value. When you create a nested group, the Auxiliary object class value is `ibm-nestedGroup`. When you create a dynamic group, the Auxiliary object class value is `ibm-dynamicGroup`.

Configuring standalone custom registries

Before you begin this task, implement and build the UserRegistry interface. For more information on developing standalone custom registries refer to “Developing standalone custom registries” on page 515. The following steps are required to configure standalone custom registries through the administrative console.

1. Click **Security > Secure administration, applications, and infrastructure**.
2. Under User account repositories, select **Standalone custom registry** and click **Configure**.
3. Enter a valid user name in the Primary administrative user name field. This ID is the security server ID, which is only used for WebSphere Application Server security and is not associated with the system process that runs the server. The server calls the local operating system registry to authenticate and obtain privilege information about users by calling the native APIs in that particular registry.

4. Enter the complete location of the dot-separated class name that implements the `com.ibm.websphere.security.UserRegistry` interface in the Custom registry class name field. For the sample, this file name is `com.ibm.websphere.security.FileRegistrySample`.
The file can be located in any directory in the integrated file system. However, it is recommended that the directory is not located in a product directory. Copy the custom trust association interceptor class files to the `profile_root/classes` directory.
This file exists in all the product processes. Thus, this file exists in the cell class path and in all of the node class paths.
Attention: The sample provided is intended to familiarize you with this feature. Do not use this sample in an actual production environment.
5. Add your custom registry class name to the class path. It is recommended that you add the Java Archive (JAR) file that contains your custom user registry implementation to the `app_server_root/classes` directory.
6. **Optional:** Select the **Ignore case for authorization** option for the authorization to perform a case insensitive check. Enabling this option is necessary only when your user registry is case insensitive and does not provide a consistent case when queried for users and groups.
7. Click **Apply** if you have any other additional properties to enter for the registry initialization.
8. **Optional:** Enter additional properties to initialize your implementation.
 - a. Click **Custom properties > New**.
 - b. Enter the property name and value.

For the sample, enter the following two properties. It is assumed that the `users.props` file and the `groups.props` file are in the `customer_sample` directory under the product installation directory. You can place these properties in any directory that you choose and reference their locations through custom properties. However, make sure that the directory has the appropriate access permissions.

Property name	Property value
usersFile	<code>\${USER_INSTALL_ROOT}/customer_sample /users.props</code>
groupsFile	<code>\${USER_INSTALL_ROOT}/customer_sample /groups.props</code>

Attention: The QEJBSVR user profile must have Execute (*X) authority for the directory that contains `user.props` and `groups.props` files. Additionally, QEJBSVR must have Read and Execute (*RX) authority for the `user.props` and `groups.props` files.

Samples of these two properties are available in `users.props` file and `groups.props` file.

The **Description**, **Required**, and **Validation Expression** fields are not used and can remain blank.

In a Network Deployment environment where multiple WebSphere Application Server processes exist, such as cell and multiple nodes in different machines, these properties are available for each process. Use the `USER_INSTALL_ROOT` relative name to locate any files, as this name expands to the product installation directory. If this name is not used, ensure that the files exist in the same location in all the nodes.

WebSphere Application Server version 4-based custom user registry is migrated to the custom user registry based on the `com.ibm.websphere.security.UserRegistry` interface.

- c. Click **Apply**.
- d. Repeat this step to add other additional properties.
9. Click **Security > Secure administration, applications, and infrastructure**.
10. Under User account repository, click the **Available realm definitions** drop-down list, select **Standalone custom registry**, and click **Configure**.
11. Select either the **Automatically generated server identity** or **Server identity that is stored in the repository** option. If you select the **Server identity that is stored in the repository** option, enter the following information:

Server user ID or administrative user on a Version 6.0.x node

Specify the short name of the account that is chosen in the second step.

Server user password

Specify the password of the account that is chosen in the second step.

12. Click **OK** and complete the required steps to turn on security.

This set of steps is required to set up the standalone custom registry and to enable security in WebSphere Application Server.

Note: The security component of WebSphere Application Server expands a selected list of variables when enabling security. See Variable settings for more detail.

1. Complete the remaining steps, if you are enabling security.
2. Validate the user and password. Save and synchronize in the cell environment.
3. After security is turned on, save, stop, and start all the product servers, including cell, nodes, and all of the application servers, for any changes to take effect. If the server comes up without any problems, the setup is correct.

Standalone custom registry settings

Use this page to configure the standalone custom registry.

To view this administrative console page, complete the following steps:

1. Click **Security > Secure administration, applications, and infrastructure**.
2. Under User account repository, click the **Available realm definitions** drop-down list, select **Standalone custom registry**, and click **Configure**.

After the properties are set in this panel, click **Apply**. Under Additional Properties, click **Custom properties** to include additional properties that the custom user registry requires.

Note: Custom properties might include information such as specifying lists of users or groups.

When security is enabled and any of these custom user registry settings change, go to the Secure administration, applications, and infrastructure panel and click **Apply** to validate the changes.

WebSphere Application Server Version 6.1 distinguishes between the user identities for administrators who manage the environment and server identities for authenticating server to server communications. In most cases, server identities are automatically generated and are not stored in a repository.

Primary administrative user name:

Specifies the name of a user with administrative privileges that is defined in your custom user registry.

The user name is used to log onto the administrative console when administrative security is enabled.

Automatically generated server identity:

Enables the application server to generate the server identity that is used for internal process communication.

You can change this server identity on the Authentication mechanisms and expiration panel. To access the Authentication mechanisms and expiration panel, click **Security > Secure administration, applications, and infrastructure > Authentication mechanisms and expiration**. Change the value of the Internal server ID field.

Default: Disabled

Server identity that is stored in the repository:

Specifies a user identity in the repository that is used for internal process communication.

Default: Enabled

Custom registry class name:

Specifies a dot-separated class name that implements the `com.ibm.websphere.security.UserRegistry` interface.

Put the custom registry class name in the class path. A suggested location is the `profile_root/classes` directory.

Data type: String

Default: `com.ibm.websphere.security.FileRegistrySample`

Ignore case for authorization:

Indicates that a case-insensitive authorization check is performed when you use the default authorization.

Default: Disabled

Range: Enabled or Disabled

Standalone custom registry wizard settings

Use this page to provide the basic settings to connect the application server to an existing standalone custom registry.

To view this security wizard page, complete the following steps:

1. Click **Security > Secure administration, applications, and infrastructure > Security configuration wizard**.
2. Select your protection settings and click **Next**.
3. Select the **Standalone custom registry** option and click **Next**.

You can modify your standalone custom registry configuration by completing the following steps:

1. Click **Security > Security administration, applications, and infrastructure**.
2. Under User account repository, click the **Available realm definitions** drop-down list, select **Standalone custom registry**, and click **Configure**.
3. Enter additional properties to initialize your implementation
 - Click **Custom properties > New**.
 - Enter the property name and value. For the sample, enter the following two properties. It is assumed that the `users.props` file and the `groups.props` file are in the `customer_sample` directory under the product installation directory. You can place these properties in any directory that you choose and reference their locations through Custom properties. However, make sure that the directory has the appropriate access permissions.

Property name	Property value
usersFile	<code>\${USER_INSTALL_ROOT}/customer_sample /users.props</code>
groupsFile	<code>\${USER_INSTALL_ROOT}/customer_sample /groups.props</code>

Samples of these two properties are available in `users.props` file and `groups.props` file.

The Description, Required, and Validation Expression fields are not used and can remain blank.

WebSphere Application Server Version 4 based custom user registry is migrated to the custom user registry based on the `com.ibm.websphere.security.UserRegistry` interface.

- Click **Apply**.

Primary administrative user name:

Specifies the name of a user with administrative privileges that is defined in your custom user registry.

The user name is used to log onto the administrative console when administrative security is enabled.

Custom registry class name:

Specifies a dot-separated class name that implements the `com.ibm.websphere.security.UserRegistry` interface.

Put the custom registry class name in the class path. A suggested location is the `profile_root/classes` directory.

Data type:	String
Default:	<code>com.ibm.websphere.security.FileRegistrySample</code>

Ignore case for authorization:

Indicates that a case-insensitive authorization check is performed when you use the default authorization.

Default:	Disabled
Range:	Enabled or Disabled

Managing the realm in a federated repository configuration

Follow this topic to manage the realm in a federated repository configuration.

The realm can consist of identities in:

- The file-based repository that is built into the system
- One or more external repositories
- Both the built-in, file-based repository and in one or more external repositories

Before you configure your realm, review [Limitations of federated repositories](#).

1. Configure your realm by using one of the following topics. You might be configuring your realm for the first time or changing an existing realm configuration.
 - “Using a single built-in, file-based repository in a new configuration under [Federated repositories](#)” on page 118
 - “Changing a federated repository configuration to include a single built-in, file-based repository only” on page 120
 - “Configuring a single, Lightweight Directory Access Protocol repository in a new configuration under [Federated repositories](#)” on page 121
 - “Changing a federated repository configuration to include a single, Lightweight Directory Access Protocol repository only” on page 122
 - “Configuring multiple Lightweight Directory Access Protocol repositories in a federated repository configuration” on page 123
 - “Configuring a single built-in, file-based repository and one or more Lightweight Directory Access Protocol repositories in a federated repository configuration” on page 124

2. Configure supported entity types using the steps described in “Configuring supported entity types in a federated repository configuration” on page 147. You must configure supported entity types before you can manage this account with Users and Groups. The Base entry for the default parent determines the repository location where entities of the specified type are placed on a create operation.
3. **Optional:** Use one or more of the following tasks to extend the capabilities of storing data and attributes in your realm:
 - a. Configure an entry mapping repository using the steps described in “Configuring an entry mapping repository in a federated repository configuration” on page 144. An entry mapping repository is used to store data for managing profiles on multiple repositories.
 - b. Configure a property extension repository using the steps described in “Configuring a property extension repository in a federated repository configuration” on page 132. A property extension repository is used to store attributes that cannot be stored in your Lightweight Directory Access Protocol (LDAP) server.
 - a. Set up a database repository using wsadmin commands as described in “Setting up an entry mapping repository, a property extension repository, or a database repository using wsadmin commands” on page 136
4. **Optional:** Use one or more of the following advanced user tasks to extend the capabilities of LDAP repositories in your realm:
 - “Increasing the performance of the federated repository configuration” on page 151
 - “Configuring Lightweight Directory Access Protocol entity types in a federated repository configuration” on page 155
 - “Configuring group attribute definition settings in a federated repository configuration” on page 158
5. **Optional:** Manage repositories that are configured in your system by following the steps described in “Managing repositories in a federated repository configuration” on page 149.
6. **Optional:** Add an external repository into your realm by following the steps described in “Adding an external repository in a federated repository configuration” on page 131.
1. After configuring the federated repositories, click **Security > Secure administration, applications, and infrastructure** to return to the Secure administration, applications, and infrastructure panel. Verify that Federated repositories is identified in the Current realm definition field. If Federated repositories is not identified, select **Federated repositories** from the Available realm definitions field and click **Set as current**. To verify the federated repositories configuration, click **Apply** on the Secure administration, applications, and infrastructure panel. If Federated repositories is not identified in the Current realm definition field, your federated repositories configuration is not used by WebSphere Application Server.
2. If you are enabling security, complete the remaining steps as specified in “Enabling security for the realm” on page 72. As the final step, validate this setup by clicking **Apply** in the Secure administration, applications, and infrastructure panel.
3. Save, stop, and restart all the product servers (deployment managers, nodes, and Application Servers) for changes in this panel to take effect. If the server comes up without any problems, the setup is correct.

Realm configuration settings

Use this page to manage the realm. The realm can consist of identities in the file-based repository that is built into the system, in one or more external repositories, or in both the built-in, file-based repository and one or more external repositories.

To view this administrative console page, complete the following steps:

1. In the administrative console, click **Security > Secure administration, applications, and infrastructure**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.

When you finish adding or updating your federated repository configuration, go to the **Security > Secure administration, applications, and infrastructure** panel and click **Apply** to validate the changes.

A single built-in, file-based repository is built into the system and included in the realm by default.

You can configure one or more Lightweight Directory Access Protocol (LDAP) repositories to store identities in the realm. Click **Add base entry to realm** to specify a repository configuration and a base entry into the realm. You can configure multiple different base entries into the same repository.

Click **Remove** to remove selected repositories from the realm. Repository configurations and contents are not destroyed. The following restrictions apply:

- The realm must always contain at least one base entry; therefore, you cannot remove every entry.
- If you plan to remove the built-in, file-based repository from the administrative realm, verify that at least one user in another member repository is a console user with administrative rights. Otherwise, you must disable security to regain access to the administrative console.

WebSphere Application Server Version 6.1 distinguishes between the user identities for administrators who manage the environment and server identities for authenticating server to server communications. In most cases, server identities are automatically generated and are not stored in a repository.

Ream name:

Specifies the name of the realm. You can change the realm name.

Primary administrative user name:

Specifies the name of the user with administrative privileges that is defined in the repository, for example, adminUser.

Automatically generated server identity:

Enables the application server to generate the server identity that is used for internal process communication.

You can change this server identity on the Authentication mechanisms and expiration panel. To access the Authentication mechanisms and expiration panel, click **Security > Secure administration, applications, and infrastructure > Authentication mechanisms and expiration**. Change the value of the Internal server ID field.

Default: Disabled

Server identity that is stored in the repository:

Specifies a user identity in the repository that is used for internal process communication.

Default: Enabled

Ignore case for authorization:

Specifies that a case-insensitive authorization check is performed.

If case sensitivity is not a consideration for authorization, enable the **Ignore case for authorization** option.

Base entry:

Specifies the base entry within the realm. This entry and its descendents are part of the realm.

Repository identifier:

Specifies a unique identifier for the repository. This identifier uniquely identifies the repository within the cell.

Repository type:

Specifies the repository type, such as File or LDAP.

Using a single built-in, file-based repository in a new configuration under Federated repositories

Follow this task to use a single built-in, file-based repository in a new configuration under Federated repositories.

To use the default configuration under Federated repositories that includes a single built-in, file-based repository only, you need to know the primary administrative user name of the user who manages WebSphere Application Server resources and user accounts.

Restriction: Client certificate login is not supported in a realm that includes a single built-in, file-based repository or a single built-in, file-based repository with other repositories.

1. In the administrative console, click **Security > Secure administration, applications, and infrastructure**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Leave the Realm name field value as defaultWIMFileBasedRealm.
4. Enter the name of the primary administrative user in the Primary administrative user name field, for example, adminUser.
5. Leave the **Ignore case for authorization** option enabled.
6. Click **OK**.
7. Provide an administrative user password. This panel displays only when a built-in, file-based repository is included in the realm. Otherwise, the panel does not display. If a built-in, file-based repository is included, complete the following steps:
 - a. Supply a password for the administrative user in the Password field.
 - b. Confirm the password of the primary administrative user in the Confirm password field.
 - c. Click **OK**.

After completing these steps, your new configuration under Federated repositories includes a single built-in, file-based repository only.

1. Before you can manage this account with Users and Groups, configure supported entity types as described in “Configuring supported entity types in a federated repository configuration” on page 147.
2. After configuring the federated repositories, click **Security > Secure administration, applications, and infrastructure** to return to the Secure administration, applications, and infrastructure panel. Verify that Federated repositories is identified in the Current realm definition field. If Federated repositories is not identified, select **Federated repositories** from the Available realm definitions field and click **Set as current**. To verify the federated repositories configuration, click **Apply** on the Secure administration, applications, and infrastructure panel. If Federated repositories is not identified in the Current realm definition field, your federated repositories configuration is not used by WebSphere Application Server.
3. If you are enabling security, complete the remaining steps, as specified in “Enabling security for the realm” on page 72. As the final step, validate this setup by clicking **Apply** in the Secure administration, applications, and infrastructure panel.
4. Save, stop, and restart all the product servers (deployment managers, nodes, and Application Servers) for changes in this panel to take effect. If the server comes up without any problems, the setup is correct.

Administrative user password settings:

Use this page to set a password for the administrative user who manages the product resources and user accounts.

To view this administrative console page, complete the following steps:

1. In the administrative console, click **Security > Secure administration, applications, and infrastructure**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. If your federated repository configuration includes a built-in, file-based repository, then the **Administrative user password** panel displays when changes are applied.

When you finish adding or updating your federated repository configuration, go to the **Security > Secure administration, applications, and infrastructure** panel and click **Apply** to validate the changes.

Password:

Specifies the password of the administrative user who manages the product resources and user accounts.

Confirm password:

Confirms the password of the administrative user who manages the product resources and user accounts.

Federated repository wizard settings:

Use this security wizard page to complete the basic requirements to connect the application server to a federated repository.

To view this security wizard page, complete the following steps

1. Click **Security > Secure administration, applications, and infrastructure > Security configuration wizard**.
2. Select your protection settings and click **Next**.
3. Select the **Federated repositories** option and click **Next**.

You can modify your federated repository configuration by completing the following steps:

1. Click **Security > Security administration, applications, and infrastructure**.
2. Under User account repository, select Federated repository and click **Configure**.

Note: This wizard is used for the initial configuration of a built-in, file-based repository. The user name and password do not have to be in the federated repository because they will be created. If you have previously configured federated repositories, do not use the Security configuration wizard to modify your configuration. Instead, modify your configuration using the Federated repositories selection under User account repository on the Secure administration, applications, and infrastructure panel.

Primary administrative user name:

Specifies the name of the user with administrative privileges that is defined in the repository, for example, adminUser.

Password:

Specifies the password of the administrative user who manages the product resources and user accounts.

Confirm password:

Confirms the password of the administrative user who manages the product resources and user accounts.

Changing a federated repository configuration to include a single built-in, file-based repository only

Follow this task to change your federated repository configuration to include a single built-in, file-based repository only.

To change your federated repository configuration to include a single built-in, file-based repository only, you need to know the primary administrative user name of the user who manages WebSphere Application Server resources and user accounts.

Restriction: Client certificate login is not supported in a realm that includes a single built-in, file-based repository or a single built-in, file-based repository with other repositories.

1. In the administrative console, click **Security > Secure administration, applications, and infrastructure**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Enter the name of the realm in the Realm name field. If the realm contains a single built-in, file-based repository only, you must specify defaultWIMFileBasedRealm as the realm name.
4. Enter the name of the primary administrative user in the Primary administrative user name field, for example, adminUser.
5. Enable the **Ignore case for authorization** option.
6. Click **Use built-in repository** if the built-in, file-based repository is not listed in the collection.
7. Select all repositories in the collection that are not of type File and click **Remove**.
8. Click **OK**.
9. Provide an administrative user password. This panel displays only when a built-in, file-based repository is included in the realm. Otherwise, it does not display. If a built-in, file-based repository is included, complete the following steps:
 - a. Supply a password for the primary administrative user in the Password field.
 - b. Confirm the password of the primary administrative user in the Confirm password field.
 - c. Click **OK**.

After completing these steps, your federated repository configuration, which includes a single built-in, file-based repository only, is configured.

1. Before you can manage this account with Users and Groups, configure supported entity types as described in “Configuring supported entity types in a federated repository configuration” on page 147.
2. After configuring the federated repositories, click **Security > Secure administration, applications, and infrastructure** to return to the Secure administration, applications, and infrastructure panel. Verify that Federated repositories is identified in the Current realm definition field. If Federated repositories is not identified, select **Federated repositories** from the Available realm definitions field and click **Set as current**. To verify the federated repositories configuration, click **Apply** on the Secure administration, applications, and infrastructure panel. If Federated repositories is not identified in the Current realm definition field, your federated repositories configuration is not used by WebSphere Application Server.
3. If you are enabling security, complete the remaining steps, as specified in “Enabling security for the realm” on page 72. As the final step, validate this setup by clicking **Apply** in the Secure administration, applications, and infrastructure panel.
4. Save, stop, and restart all the product servers (deployment managers, nodes, and Application Servers) for changes in this panel to take effect. If the server comes up without any problems, the setup is correct.

Configuring a single, Lightweight Directory Access Protocol repository in a new configuration under Federated repositories

Follow this task to configure a single, Lightweight Directory Access Protocol (LDAP) repository in a new configuration under Federated repositories.

To configure an LDAP repository in a new configuration under Federated repositories, you must know a valid user name (ID), the user password, the server host and port and, if necessary, the bind distinguished name (DN) and the bind password. You can choose any valid user in the repository that is searchable. In some LDAP servers, administrative users are not searchable and cannot be used (for example, `cn=root` in SecureWay). This user is referred to as the WebSphere Application Server *administrative user name* or *administrative ID* in the documentation. Being an administrative ID means a user has special privileges when calling some protected internal methods. Normally, this ID and password are used to log in to the administrative console after you turn on security. You can use other users to log in, if those users are part of the administrative roles.

1. In the administrative console, click **Security > Secure administration, applications, and infrastructure**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. On the Federated repositories panel, complete the following steps:
 - a. Enter the name of the realm in the Realm name field. You can change the existing realm name.
 - b. Enter the name of the primary administrative user in the Primary administrative user name field, for example, `adminUser`.
 - c. **Optional:** Select the **Ignore case for authorization** option. When you enable this option, the authorization check is case-insensitive. Normally, an authorization check involves checking the complete DN of a user, which is unique in the realm and is case-insensitive. Clear this option when all of the member repositories in the realm are case-sensitive.

Restriction: Some repositories contain data that is case-sensitive only, and some repositories contain data that is case-insensitive only. Do not include both case-sensitive and case-insensitive repositories in the realm. For example, do not include case-sensitive repositories in the realm with a built-in, file-based repository.

- d. Click **Add base entry to realm** to add a base entry that uniquely identifies the external repository in the realm. Then complete the steps in “Adding an external repository in a federated repository configuration” on page 131.
4. On the Federated repositories panel, complete the following steps:
 - a. Select the built-in, file-based repository in the collection, and click **Remove**.

Restriction: Before you remove the built-in, file-based repository from the administrative realm, verify that at least one user in another member repository is a console user with administrative rights. Otherwise, you must disable security to regain access to the administrative console.

- b. Click **OK**.

After completing these steps, your new configuration under Federated repositories includes a single, LDAP repository only.

1. Before you can manage this account with Users and Groups, configure supported entity types as described in “Configuring supported entity types in a federated repository configuration” on page 147.
2. After configuring the federated repositories, click **Security > Secure administration, applications, and infrastructure** to return to the Secure administration, applications, and infrastructure panel. Verify that Federated repositories is identified in the Current realm definition field. If Federated repositories is not identified, select **Federated repositories** from the Available realm definitions field and click **Set as current**. To verify the federated repositories configuration, click **Apply** on the Secure administration,

- applications, and infrastructure panel. If Federated repositories is not identified in the Current realm definition field, your federated repositories configuration is not used by WebSphere Application Server.
3. If you are enabling security, complete the remaining steps as specified in “Enabling security for the realm” on page 72. As the final step, validate this setup by clicking **Apply** in the Secure administration, applications, and infrastructure panel.
 4. Save, stop, and restart all the product servers (deployment managers, nodes and Application Servers) for changes in this panel to take effect. If the server comes up without any problems, the setup is correct.

Changing a federated repository configuration to include a single, Lightweight Directory Access Protocol repository only

Follow this task to change your federated repository configuration to include a single, Lightweight Directory Access Protocol repository (LDAP) repository only.

To configure an LDAP repository in a federated repository configuration, you must know a valid user name (ID), the user password, the server host and port and, if necessary, the bind distinguished name (DN) and the bind password. You can choose any valid user in the repository that is searchable. In some LDAP servers, administrative users are not searchable and cannot be used (for example, cn=root in SecureWay). This user is referred to as a WebSphere Application Server *administrative user name* or *administrative ID* in the documentation. Being an administrative ID means a user has special privileges when calling some protected internal methods. Normally, this ID and password are used to log into the administrative console after you turn on security. You can use other users to log in if those users are part of the administrative roles.

1. In the administrative console, click **Security > Secure administration, applications, and infrastructure**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Enter the name of the realm in the Realm name field. You can change the existing realm name.
4. Enter the name of the primary administrative user in the Primary administrative user name field, for example, adminUser.
5. **Optional:** Select the **Ignore case for authorization** option. When you enable this option, the authorization check is case-insensitive. Normally, an authorization check involves checking the complete DN of a user, which is unique in the realm and is case-insensitive. Clear this option when all of the member repositories in the realm are case-sensitive.

Restriction: Some repositories contain data that is case-sensitive only, and some repositories contain data that is case-insensitive only. Do not include both case-sensitive and case-insensitive repositories in the realm. For example, do not include case-sensitive repositories in the realm with a built-in, file-based repository.

6. **Optional:** Click **Add base entry to realm** if the LDAP repository that you need is not contained in the collection. Then complete the steps in “Adding an external repository in a federated repository configuration” on page 131.
7. On the Federated repositories panel, complete the following steps:
 - a. **Optional:** Select the repositories in the collection that you do not need in the realm and click **Remove**.

Restriction: The realm must always contain at least one base entry; therefore, you cannot remove every entry.
 - b. Click **OK**.

After completing these steps, your federated repository configuration, which includes a single LDAP repository only, is configured.

1. Before you can manage this account with Users and Groups, configure supported entity types as described in “Configuring supported entity types in a federated repository configuration” on page 147.

2. After configuring the federated repositories, click **Security > Secure administration, applications, and infrastructure** to return to the Secure administration, applications, and infrastructure panel. Verify that Federated repositories is identified in the Current realm definition field. If Federated repositories is not identified, select **Federated repositories** from the Available realm definitions field and click **Set as current**. To verify the federated repositories configuration, click **Apply** on the Secure administration, applications, and infrastructure panel. If Federated repositories is not identified in the Current realm definition field, your federated repositories configuration is not used by WebSphere Application Server.
3. If you are enabling security, complete the remaining steps as specified in “Enabling security for the realm” on page 72. As the final step, validate this setup by clicking **Apply** in the Secure administration, applications, and infrastructure panel.
4. Save, stop, and restart all the product servers (deployment managers, nodes, and Application Servers) for changes in this panel to take effect. If the server comes up without any problems, the setup is correct.

Configuring multiple Lightweight Directory Access Protocol repositories in a federated repository configuration

Follow this task to configure multiple Lightweight Directory Access Protocol (LDAP) repositories in a federated repository configuration.

To configure an LDAP repository in a federated repository configuration, you must know a valid user name (ID), the user password, the server host and port and, if necessary, the bind distinguished name (DN) and the bind password. You can choose any valid user in the repository that is searchable. In some LDAP servers, administrative users are not searchable and cannot be used (for example, cn=root in SecureWay). This user is referred to as a WebSphere Application Server *administrative user name* or *administrative ID* in the documentation. Being an administrative ID means a user has special privileges when calling some protected internal methods. Normally, this ID and password are used to log into the administrative console after you turn on security. You can use other users to log in if those users are part of the administrative roles.

1. In the administrative console, click **Security > Secure administration, applications, and infrastructure**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Enter the name of the realm in the Realm name field. You can change the existing realm name.
4. Enter the name of the primary administrative user in the Primary administrative user name field, for example, adminUser.
5. **Optional:** Select the **Ignore case for authorization** option. When you enable this option, the authorization check is case-insensitive. Normally, an authorization check involves checking the complete DN of a user, which is unique in the realm and is case-insensitive. Clear this option when all of the member repositories in the realm are case-sensitive.

Restriction: Some repositories contain data that is case-sensitive only, and some repositories contain data that is case-insensitive only. Do not include both case-sensitive and case-insensitive repositories in the realm. For example, do not include case-sensitive repositories in the realm with a built-in, file-based repository.

6. **Optional:** Click **Add base entry to realm** if the LDAP repository that you need is not listed in the collection. Then complete the steps in “Adding an external repository in a federated repository configuration” on page 131.
7. On the Federated repositories panel, complete the following steps:
 - a. **Optional:** Repeat step 6 if the LDAP repository that you need is not listed in the collection.
 - b. **Optional:** Select the repositories in the collection that you do not need in the realm and click **Remove**. The following restrictions apply:
 - The realm must always contain at least one base entry; therefore, you cannot remove every entry.

- If you plan to remove the built-in, file-based repository from the administrative realm, verify that at least one user in another member repository is a console user with administrative rights. Otherwise, you must disable security to regain access to the administrative console.
- c. Click **OK**.

After completing these steps, your federated repository configuration, which includes multiple LDAP repositories, is configured.

1. Before you can manage this account with Users and Groups, configure supported entity types as described in “Configuring supported entity types in a federated repository configuration” on page 147.
2. After configuring the federated repositories, click **Security > Secure administration, applications, and infrastructure** to return to the Secure administration, applications, and infrastructure panel. Verify that Federated repositories is identified in the Current realm definition field. If Federated repositories is not identified, select **Federated repositories** from the Available realm definitions field and click **Set as current**. To verify the federated repositories configuration, click **Apply** on the Secure administration, applications, and infrastructure panel. If Federated repositories is not identified in the Current realm definition field, your federated repositories configuration is not used by WebSphere Application Server.
3. If you are enabling security, complete the remaining steps as specified in “Enabling security for the realm” on page 72. As the final step, validate this setup by clicking **Apply** in the Secure administration, applications, and infrastructure panel.
4. Save, stop, and restart all the product servers (deployment managers, nodes, and Application Servers) for changes in this panel to take effect. If the server comes up without any problems, the setup is correct.

Configuring a single built-in, file-based repository and one or more Lightweight Directory Access Protocol repositories in a federated repository configuration

Follow this task to configure a single built-in, file-based repository and multiple Lightweight Directory Access Protocol (LDAP) repositories in a federated repository configuration.

To configure a built-in, file-based repository in a federated repository configuration, you must know the primary administrative user name of the user who manages WebSphere Application Server resources and user accounts.

To configure an LDAP repository in a federated repository configuration, you must know a valid user name (ID), the user password, the server host and port and, if necessary, the bind distinguished name (DN) and the bind password. You can choose any valid user in the repository that is searchable. In some LDAP servers, administrative users are not searchable and cannot be used (for example, cn=root in SecureWay). This user is referred to as a WebSphere Application Server *administrative user name* or *administrative ID* in the documentation. Being an administrative ID means a user has special privileges when calling some protected internal methods. Normally, this ID and password are used to log in to the administrative console after you turn on security. You can use other users to log in if those users are part of the administrative roles.

Restriction: Client certificate login is not supported in a realm that includes a single built-in, file-based repository or a single built-in, file-based repository with other repositories.

1. In the administrative console, click **Security > Secure administration, applications, and infrastructure**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Enter the name of the realm in the Realm name field. You can change the existing realm name.
4. Enter the name of the primary administrative user in the Primary administrative user name field, for example, adminUser.

Restriction: When you configure multiple repositories that includes a single built-in, file-based repository, the primary administrative user name must exist in the file-based repository. If

the primary administrative user name does not exist in the file-based repository, then the name is created in the file-based repository. The primary administrative user name cannot exist in other repositories.

5. Select the **Ignore case for authorization** option.

Attention: When the realm includes a built-in, file-based repository, you must enable the **Ignore case for authorization** option.

When you enable this option, the authorization check is case-insensitive. Normally, an authorization check involves checking the complete DN of a user, which is unique in the realm and is case-insensitive. Clear this option when all of the member repositories in the realm are case-sensitive.

Restriction: Some repositories contain data that is case-sensitive only, and some repositories contain data that is case-insensitive only. Do not include both case-sensitive and case-insensitive repositories in the realm. For example, do not include case-sensitive repositories in the realm with a built-in, file-based repository.

6. **Optional:** Click **Add base entry to realm** if the LDAP repository that you need is not contained in the collection. Then complete the steps in “Adding an external repository in a federated repository configuration” on page 131.
7. On the Federated repositories panel, complete the following steps:
 - a. **Optional:** Repeat step 6 if the LDAP repository that you need is not listed in the collection.
 - b. Click **Use built-in repository** if the built-in, file-based repository is not listed in the collection.
 - c. **Optional:** Select the repositories in the collection that you do not need in the realm and click **Remove**.

Restriction: The realm must always contain at least one base entry; therefore, you cannot remove every entry.

- d. Click **OK**.
8. Provide an administrative user password. This panel displays only when a built-in, file-based repository is included in the realm. Otherwise, the panel does not display. If a built-in, file-based repository is included, complete the following steps:
 - a. Supply a password for the administrative user in the Password field.
 - b. Confirm the password of the primary administrative user in the Confirm password field.
 - c. Click **OK**.

After completing these steps, your federated repository configuration, which includes a single built-in, file-based repository and one or more LDAP repositories, is configured.

1. Before you can manage this account with Users and Groups, configure supported entity types as described in “Configuring supported entity types in a federated repository configuration” on page 147.
2. After configuring the federated repositories, click **Security > Secure administration, applications, and infrastructure** to return to the Secure administration, applications, and infrastructure panel. Verify that Federated repositories is identified in the Current realm definition field. If Federated repositories is not identified, select **Federated repositories** from the Available realm definitions field and click **Set as current**. To verify the federated repositories configuration, click **Apply** on the Secure administration, applications, and infrastructure panel. If Federated repositories is not identified in the Current realm definition field, your federated repositories configuration is not used by WebSphere Application Server.
3. If you are enabling security, complete the remaining steps as specified in “Enabling security for the realm” on page 72. As the final step, validate this setup by clicking **Apply** in the Secure administration, applications, and infrastructure panel.
4. Save, stop, and restart all the product servers (deployment managers, nodes, and Application Servers) for changes in this panel to take effect. If the server comes up without any problems, the setup is correct.

Configuring Lightweight Directory Access Protocol in a federated repository configuration

Follow this topic to configure Lightweight Directory Access Protocol (LDAP) settings in a federated repository configuration.

You have chosen among various ways to configure LDAP:

- “Configuring a single, Lightweight Directory Access Protocol repository in a new configuration under Federated repositories” on page 121
- “Changing a federated repository configuration to include a single, Lightweight Directory Access Protocol repository only” on page 122
- “Configuring multiple Lightweight Directory Access Protocol repositories in a federated repository configuration” on page 123
- “Configuring a single built-in, file-based repository and one or more Lightweight Directory Access Protocol repositories in a federated repository configuration” on page 124
- “Managing repositories in a federated repository configuration” on page 149

At this point, you are viewing the LDAP repository configuration page of the administrative console.

1. Enter a unique identifier for the repository in the Repository identifier field. This identifier uniquely identifies the repository within the cell, for example: LDAP1.
2. Select the type of LDAP server that is used from the Directory type list. The type of LDAP server determines the default filters that are used by WebSphere Application Server.
IBM Tivoli Directory Server users can choose either IBM Tivoli Directory Server or SecureWay as the directory type. Use the IBM Tivoli Directory Server directory type for better performance. For a list of supported LDAP servers, see “Using specific directory servers as the LDAP server” on page 105.
3. Enter the fully qualified host name of the primary LDAP server in the Primary host name field. You can enter either the IP address or the domain name system (DNS) name.
4. Enter the server port of the LDAP directory in the Port field. The host name and the port number represent the realm for this LDAP server in a mixed version nodes cell. If servers in different cells are communicating with each other using Lightweight Third Party Authentication (LTPA) tokens, these realms must match exactly in all the cells.

The default value is 389, which is not a Secure Sockets Layer (SSL) connection. Use port 636 for a Secure Sockets Layer (SSL) connection. For some LDAP servers, you can specify a different port for a non-SSL or SSL connection. If you do not know the port to use, contact your LDAP server administrator.

If multiple WebSphere Application Servers are installed and configured to run in the same single sign-on domain, or if WebSphere Application Server interoperates with a previous version of WebSphere Application Server, then it is important that the port number match all configurations. For example, if the LDAP port is explicitly specified as 389 in a Version 5.x or 6.0.x configuration, and WebSphere Application Server at Version 6.1 is going to interoperate with the Version 5.x or 6.0.x server, then verify that port 389 is specified explicitly for the Version 6.1 server.

5. **Optional:** Enter the host name of the failover LDAP server in the Failover host name field. You can specify a secondary directory server to be used in the event that your primary directory server becomes unavailable. After switching to a secondary directory server, LDAP repository attempts to reconnect to the primary directory server every 15 minutes.
6. **Optional:** Enter the port of the failover LDAP server in the Port field and click **Add**. The default value is 389, which is not a Secure Sockets Layer (SSL) connection. Use port 636 for a Secure Sockets Layer (SSL) connection. For some LDAP servers, you can specify a different port for a non-SSL or SSL connection. If you do not know the port to use, contact your LDAP server administrator.
7. **Optional:** Select the type of *referral*. A referral is an entity that is used to redirect a client request to another LDAP server. A referral contains the names and locations of other objects. It is sent by the server to indicate that the information that the client requested can be found at another location, possibly at another server or several servers. The default value is ignore.

ignore

Referrals are ignored.

follow Referrals are followed automatically.

8. **Optional:** Enter the bind DN name in the Bind distinguished name field, for example, cn=root. The bind DN is required if anonymous binds are not possible on the LDAP server to obtain user and group information or for write operations. In most cases, bind DN and bind password are needed. However, when anonymous bind can satisfy all of the required functions, bind DN and bind password are not needed. If the LDAP server is set up to use anonymous binds, leave this field blank. If a name is not specified, the application server binds anonymously.
9. **Optional:** Enter the password that corresponds to the bind DN in the Bind password field.
10. **Optional:** Enter the property names to use to log into WebSphere Application Server in the Login properties field. This field takes multiple login properties, delimited by a semicolon (;). For example, uid;mail.

All login properties are searched during login. If multiple entries or no entries are found, an exception is thrown. For example, if you specify the login properties as uid;mail and the login ID as Bob, the search filter searches for uid=Bob or mail=Bob. When the search returns a single entry, then authentication can proceed. Otherwise, an exception is thrown.

11. **Optional:** Select the certificate map mode in the Certificate mapping field. You can use the X.590 certificates for user authentication when LDAP is selected as the repository. The Certificate mapping field is used to indicate whether to map the X.509 certificates into an LDAP directory user by EXACT_DN or CERTIFICATE_FILTER. If EXACT_DN is selected, the DN in the certificate must exactly match the user entry in the LDAP server, including case and spaces.
12. If you select **CERTIFICATE_FILTER** in the Certificate mapping field, specify the LDAP filter for mapping attributes in the client certificate to entries in LDAP.

If more than one LDAP entry matches the filter specification at run time, authentication fails because the result is an ambiguous match. The syntax or structure of this filter is:

```
LDAP attribute=${Client certificate attribute}
```

For example, uid=\${SubjectCN}.

The left side of the filter specification is an LDAP attribute that depends on the schema that your LDAP server is configured to use. The right side of the filter specification is one of the public attributes in your client certificate. The right side must begin with a dollar sign (\$) and open bracket ({} and end with a close bracket (}). You can use the following certificate attribute values on the right side of the filter specification. The case of the strings is important:

- \${UniqueKey}
- \${PublicKey}
- \${PublicKey}
- \${Issuer}
- \${NotAfter}
- \${NotBefore}
- \${SerialNumber}
- \${SigAlgName}
- \${SigAlgOID}
- \${SigAlgParams}
- \${SubjectCN}
- \${Version}

13. **Optional:** Select the **Require SSL communications** option if you want to use Secure Sockets Layer communications with the LDAP server.

If you select the **Require SSL communications** option, you can select either the **Centrally managed** or **Use specific SSL alias** option.

Centrally managed

Enables you to specify an SSL configuration for a particular scope, such as the cell, node, server, or cluster in one location. To use the Centrally managed option, you must specify the

SSL configuration for the particular set of endpoints. The Manage endpoint security configurations and trust zones panel displays all of the inbound and outbound endpoints that use the SSL protocol. If you expand the Inbound or Outbound section of the panel and click the name of a node, you can specify an SSL configuration that is used for every endpoint on that node. For an LDAP registry, you can override the inherited SSL configuration by specifying an SSL configuration for LDAP. To specify an SSL configuration for LDAP, complete the following steps:

- a. Click **Security > SSL certificate and key management > Manage endpoint security configurations and trust zones**.
- b. Expand **Outbound > cell_name > Nodes > node_name > Servers > server_name > LDAP**.

Use specific SSL alias

Select the **Use specific SSL alias** option if you intend to select one of the SSL configurations in the menu that follows the option.

This configuration is used only when SSL is enabled for LDAP. The default is *DefaultSSLSettings*. To modify or create a new SSL configuration, complete the following steps:

- a. Click **Security > SSL certificate and key management**.
- b. Under Configuration settings, click **Manage endpoint security configurations and trust zones > configuration_name**.
- c. Under Related items, click **SSL configurations**.

14. Click **OK**.

After completing these steps, your LDAP repository settings are configured.

Return to the appropriate task to complete the steps for your federated repository configuration:

- “Configuring a single, Lightweight Directory Access Protocol repository in a new configuration under Federated repositories” on page 121
- “Changing a federated repository configuration to include a single, Lightweight Directory Access Protocol repository only” on page 122
- “Configuring multiple Lightweight Directory Access Protocol repositories in a federated repository configuration” on page 123
- “Configuring a single built-in, file-based repository and one or more Lightweight Directory Access Protocol repositories in a federated repository configuration” on page 124
- “Managing repositories in a federated repository configuration” on page 149

Lightweight Directory Access Protocol repository configuration settings:

Use this page to configure secure access to a Lightweight Directory Access Protocol (LDAP) repository with optional failover servers.

To view this administrative console page, complete the following steps:

1. In the administrative console, click **Security > Secure administration, applications, and infrastructure**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Under Related items, click **Manage repositories**.
4. Click **Add** to specify a new external repository or select an external repository that is preconfigured.

When you finish adding or updating your federated repository configuration, go to the **Security > Secure administration, applications, and infrastructure** panel and click **Apply** to validate the changes.

Repository identifier:

Specifies a unique identifier for the LDAP repository. This identifier uniquely identifies the repository within the cell, for example: LDAP1.

Directory type:

Specifies the type of LDAP server to which you connect.

Expand the drop-down list to display a list of LDAP directory types.

Primary host name:

Specifies the host name of the primary LDAP server. This host name is either an IP address or a domain name service (DNS) name.

Port:

Specifies the LDAP server port.

The default value is 389, which is not a Secure Sockets Layer (SSL) connection. Use port 636 for a Secure Sockets Layer (SSL) connection. For some LDAP servers, you can specify a different port for a non-SSL or SSL connection. If you do not know the port to use, contact your LDAP server administrator.

Data type:	Integer	
Default:	389	
Range:	389, which is not a Secure Sockets Layer (SSL) connection	636, which is a Secure Sockets Layer (SSL) connection

Failover host name:

Specifies the host name of the failover LDAP server.

You can specify a secondary directory server to be used in the event that your primary directory server becomes unavailable. After switching to a secondary directory server, the LDAP repository attempts to reconnect to the primary directory server every 15 minutes.

Port:

Specifies the port of the failover LDAP server.

The default value is 389, which is not a Secure Sockets Layer (SSL) connection. Use port 636 for a Secure Sockets Layer (SSL) connection. For some LDAP servers, you can specify a different port for a non-SSL or SSL connection. If you do not know the port to use, contact your LDAP server administrator.

Data type:	Integer	
Range:	389, which is not a Secure Sockets Layer (SSL) connection	636, which is a Secure Sockets Layer (SSL) connection

Support referrals to other LDAP servers:

Specifies how referrals that are encountered by the LDAP server are handled.

A referral is an entity that is used to redirect a client request to another LDAP server. A referral contains the names and locations of other objects. It is sent by the server to indicate that the information that the client requested can be found at another location, possibly at another server or several servers. The default value is ignore.

Default: ignore
Range: **ignore** Referrals are ignored.
follow Referrals are followed automatically.

Bind distinguished name:

Specifies the distinguished name (DN) for the application server to use when binding to the LDAP repository.

If no name is specified, the application server binds anonymously. In most cases, bind DN and bind password are needed. However, when anonymous bind can satisfy all of the required functions, bind DN and bind password are not needed.

Bind password:

Specifies the password for the application server to use when binding to the LDAP repository.

Login properties:

Specifies the property names to use to log into the application server.

This field takes multiple login properties, delimited by a semicolon (;). For example, `uid;mail`. All login properties are searched during login. If multiple entries or no entries are found, an exception is thrown. For example, if you specify the login properties as `uid;mail` and the login ID as Bob, the search filter searches for `uid=Bob` or `mail=Bob`. When the search returns a single entry, then authentication can proceed. Otherwise, an exception is thrown.

Certificate mapping:

Specifies whether to map X.509 certificates into an LDAP directory by `EXACT_DN` or `CERTIFICATE_FILTER`. Specify `CERTIFICATE_FILTER` to use the specified certificate filter for the mapping.

Certificate filter:

Specifies the filter certificate mapping property for the LDAP filter. The filter is used to map attributes in the client certificate to entries in the LDAP repository.

If more than one LDAP entry matches the filter specification at run time, authentication fails because the result is an ambiguous match. The syntax or structure of this filter is:

```
LDAP attribute=${Client certificate attribute}
```

For example, `uid=${SubjectCN}`.

The left side of the filter specification is an LDAP attribute that depends on the schema that your LDAP server is configured to use. The right side of the filter specification is one of the public attributes in your client certificate. The right side must begin with a dollar sign (\$) and open bracket ({} and end with a close bracket (}). You can use the following certificate attribute values on the right side of the filter specification. The case of the strings is important:

- `${UniqueKey}`
- `${PublicKey}`
- `${PublicKey}`
- `${Issuer}`

- `${NotAfter}`
- `${NotBefore}`
- `${SerialNumber}`
- `${SigAlgName}`
- `${SigAlgOID}`
- `${SigAlgParams}`
- `${SubjectCN}`
- `${Version}`

Require SSL communications:

Specifies whether secure socket communication is enabled to the LDAP server.

When enabled, the Secure Sockets Layer (SSL) settings for LDAP are used, if specified.

Centrally managed:

Specifies that the selection of an SSL configuration is based upon the outbound topology view for the Java Naming and Directory Interface (JNDI) platform.

Centrally managed configurations support one location to maintain SSL configurations, rather than spreading them across the configuration documents.

Default:	Enabled
Range:	Enabled or Disabled

Use specific SSL alias:

Specifies the SSL configuration alias to use for LDAP outbound SSL communications.

This option overrides the centrally managed configuration for the JNDI platform.

Adding an external repository in a federated repository configuration

Follow this task to add an external repository into a federated repository configuration.

1. If the Lightweight Directory Access Protocol (LDAP) repository that you want to add to your federated repository configuration is previously configured, select the corresponding Repository on the Repository reference panel. To access the Repository reference panel, complete the following steps:
 - a. Click **Security > Secure administration, applications, and infrastructure**.
 - b. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
 - c. Click **Add base entry to realm**.
2. Enter a distinguished name for the realm base entry in the Distinguished name that uniquely identifies... field. This base entry must uniquely identify the external repository in the realm. If multiple repositories are included in the realm, use this field to define an additional distinguished name (DN) that uniquely identifies this set of entries within the realm. For example, repositories LDAP1 and LDAP2 might both use `o=ibm,c=us` as the base entry in the repository. Use the DN in this field to uniquely identify this set of entries in the realm. For example: `o=ibm,c=us` for LDAP1 and `o=ibm2,c=us` for LDAP2. The specified DN in this field maps to the LDAP DN of the base entry within the repository.
3. Enter the LDAP DN of the base entry within the repository in the Distinguished name of a base entry... field. The base entry indicates the starting point for searches in this LDAP directory server. This entry and its descendents are mapped to the subtree that is identified by this unique base name entry field. For example, for a user with a DN of `cn=John Doe, ou=Rochester, o=IBM, c=US`, specify the LDAP base entry as any of the following options:
`ou=Rochester, o=IBM, c=us` or `o=IBM, c=us` or `c=us`

In most cases, this LDAP DN is the same as the distinguished name for the realm base entry.

If this field is left blank, then the subtree defaults to the root of the LDAP repository. Consult your LDAP administrator to determine if your LDAP repository provides support to search from the root, or create users and groups under the root without defining a suffix beforehand.

In WebSphere Application Server, the distinguished name is normalized according to the LDAP specification. Normalization consists of removing spaces in the base distinguished name before or after commas and equal symbols. An example of a non-normalized base distinguished name is `o = ibm, c = us` or `o=ibm, c=us`. An example of a normalized base distinguished name is `o=ibm,c=us`.

4. If the LDAP repository that you want to add to your realm is not previously configured, complete the following steps:
 - a. Click **Add Repository** on the Repository reference panel to configure the LDAP repository. See step 1 to access the Repository reference panel.
 - b. Configure LDAP on the LDAP configuration panel, as described in “Configuring Lightweight Directory Access Protocol in a federated repository configuration” on page 126.
 - c. Select the new Repository on the Repository reference panel.
5. Click **OK**.

You have added a new or previously configured external repository into your federated repository configuration.

1. Before you can manage this account with Users and Groups, configure supported entity types as described in “Configuring supported entity types in a federated repository configuration” on page 147.
2. After configuring the federated repositories, click **Security > Secure administration, applications, and infrastructure** to return to the Secure administration, applications, and infrastructure panel. Verify that Federated repositories is identified in the Current realm definition field. If Federated repositories is not identified, select **Federated repositories** from the Available realm definitions field and click **Set as current**. To verify the federated repositories configuration, click **Apply** on the Secure administration, applications, and infrastructure panel. If Federated repositories is not identified in the Current realm definition field, your federated repositories configuration is not used by WebSphere Application Server.
3. If you are enabling security, complete the remaining steps as specified in “Enabling security for the realm” on page 72. As the final step, validate this setup by clicking **Apply** in the Secure administration, applications, and infrastructure panel.
4. Save, stop, and restart all the product servers (deployment managers, nodes and Application Servers) for changes in this panel to take effect. If the server comes up without any problems, the setup is correct.

Configuring a property extension repository in a federated repository configuration

Follow this task to configure a property extension repository to store attributes that cannot be stored in your Lightweight Directory Access Protocol (LDAP) server.

For security and business reasons, you might not want to not allow write operations to your repositories. However, applications calling the federated repository configuration might need to store additional properties for the entities. A federated repository configuration provides a *property extension repository*, which is a database regardless of the type of main profile repositories, for a property-level join configuration. For example, a company that uses an LDAP directory for its internal employees and a database for external customers and business partners might not allow write access to its LDAP and its database. The company can use the *property extension repository* in a federated repository configuration to store additional properties for the people in those repositories, excluding the user ID. When an application uses the federated repository configuration to retrieve an entry for a person, the federated repository configuration transparently joins the properties of the person that is retrieved from either the LDAP or the customer’s database with the properties of the person that is retrieved from the property extension repository into a single logical person entry.

When you configure a property extension repository, you can supply a valid data source, a direct connection configuration, or both. The system first tries to connect by way of the data source. If the data source is not available, then the system uses the direct access configuration.

Restriction: You cannot configure a property extension repository in a mixed-version deployment manager cell.

1. Configure the WebSphere Application Server data source. See “Configuring the WebSphere Application Server data source” on page 143.
2. If you are adding new properties (including properties that are stored in the property extension repository) to the schema, you must do the following before you create the property extension repository.
 - a. Open or create the `wimxmlextension.xml` file under the `<WAS61>\profiles\<propfile_name>\config\cells\<cell_name>\wim\model` directory.

Attention: Make sure the editor is on the deployment manager node.
 - b. Add the schema definition of the new property. The following sample `wimxmlextension.xml` file adds a new property called `ibm-otherEmail` to both the `Person` and `PersonAccount` entity types. This new property type is “String” and it is multiple-valued.

```
<sdo:datagraph xmlns:sdo="commonj.sdo"
  xmlns:wim="http://www.ibm.com/websphere/wim">
  <wim:schema>
    <wim:propertySchema nsURI="http://www.ibm.com/websphere/wim"
      dataType="String"
      multiValued="true" propertyName="ibm-otherEmail">
      <wim:applicableEntityTypeNames>Person</wim:applicableEntityTypeNames>
      <wim:applicableEntityTypeNames>PersonAccount
      </wim:applicableEntityTypeNames>
    </wim:propertySchema>
  </wim:schema>
</sdo:datagraph>
```

Available data types are defined in `com.ibm.websphere.wim.SchemaConstants`. For example:

```
/**
 * Instance Class: java.lang.String
 */
String DATA_TYPE_STRING = "String";
/**
 * Instance Class: int
 */
String DATA_TYPE_INT = "Int";
/**
 * Instance Class: java.lang.Object
 */
String DATA_TYPE_DATE = "Date";
/**
 * Instance Class: dobjava.lang.Object
 */
String DATA_TYPE_ANY_SIMPLE_TYPE = "AnySimpleType";
/**
 * Instance Class: java.lang.String
 */
String DATA_TYPE_ANY_URI = "AnyURI";
/**
 * Instance Class: java.lang.boolean
 */
String DATA_TYPE_BOOLEAN = "Boolean";
/**
 * Instance Class: long
 */
String DATA_TYPE_LONG = "Long";
/**
 * Instance Class: double
 */
```

```
String DATA_TYPE_DOUBLE = "Double";
/**
 * Instance Class: short
 */
String DATA_TYPE_SHORT = "Short";
```

- c. Add the new property to the property extension repository. Before running the `setupIdMgrPropertyExtensionRepositoryTables` command, add the new properties into `<WAS61>\profiles\<propfile_name>\config\cells\<cell_name>\wim\config\wimlaproperties.xml`.
 - d. Follow the example inside this file to define the new property definitions. The schema file for `wimlaproperties.xml` is `wimdbproperty.xsd` and is in the same directory. It can be used for reference.
 - e. Run the `setupIdMgrPropertyExtensionRepositoryTables` command to create the property extension repository and to add the new properties.
3. Set up the property extension repository using `wsadmin` by following the procedure discussed in "Setting up an entry mapping repository, a property extension repository, or a database repository using `wsadmin` commands" on page 136; ignore the "Before you begin" options.
 4. Configure the property extension repository by completing the following steps:
 - a. In the administrative console, click **Security > Secure administration, applications, and infrastructure**.
 - b. Under User account repository, select **Federated repositories**, and click **Configure**.
 - c. Click **Property extension repository**.
 - d. Supply the name of the data source in the Data source name field.
 - e. Select the type of database that is used for the property extension repository.
 - f. Supply the name of the Java database connectivity (JDBC) driver in the JDBC driver field.

Values include:

DB2 `COM.ibm.db2.jdbc.app.DB2Driver`

Oracle
`oracle.jdbc.driver.OracleDriver`

Informix
`com.informix.jdbc.IfxDriver`

Microsoft SQL Server
`com.microsoft.jdbc.sqlserver.SQLServerDriver`

Derby `org.apache.derby.jdbc.EmbeddedDriver`

DB2 for z/OS
`com.ibm.db2.jcc.DB2Driver`

DB2 for iSeries
`com.ibm.db2.jdbc.app.DB2Driver`

- g. Supply the database URL that is used to access the property extension repository with JDBC in the Database URL field. Use an alphanumeric text string that conforms to the standard JDBC URL syntax.

Values include:

DB2 `jdbc:db2:wim`

Oracle
`jdbc:oracle:thin:@<hostname>:1521:orcl`

Derby `jdbc:derby:c:\derby\wim`

Microsoft SQL Server
`jdbc:microsoft:sqlserver://<hostname>:1433;databaseName=wim;selectmethod=cursor;`

Informix

```
jdbc:informix-sqli://<hostname>:1526/wim:INFORMIXSERVER=<IFXServerName>;
```

- h. Supply the user name of the database administrator in the Database administrator user name field.
- i. Supply the password of the database administrator in the Password field.
- j. Specify the entity retrieval limit in the Entity retrieval limit field. The entity retrieval limit is the maximum number of entities that the system can retrieve from the property extension repository with a single database query. The default value is 200.
- k. Click **OK**.

After completing these steps, your federated repository configuration, which includes a property extension repository, is configured.

1. If you are enabling security, complete the remaining steps as specified in “Enabling security for the realm” on page 72. As the final step, validate this setup by clicking **Apply** in the Secure administration, applications, and infrastructure panel.
2. Save, stop, and restart all the product servers (deployment managers, nodes, and Application Servers) for changes in this panel to take effect. If the server comes up without any problems, the setup is correct.

Property extension repository settings:

Use this page to configure a property extension repository that is used to store attributes that cannot be stored in existing repositories.

To view this administrative console page, complete the following steps:

1. In the administrative console, click **Security > Secure administration, applications, and infrastructure**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Under Additional properties, click **Property extension repository**.

When you finish adding or updating your federated repository configuration, go to the **Security > Secure administration, applications, and infrastructure** panel and click **Apply** to validate the changes.

Data source name:

Specifies the Java Naming and Directory Interface (JNDI) name of the data source that is used to access the property extension repository.

Default: jdbc/wimDS

Database type:

Specifies the type of database that is used for the property extension repository.

Default: DB2

JDBC driver:

Specifies the Java Database Connectivity (JDBC) driver that is used to access the entry mapping repository.

Values include:

DB2 COM.ibm.db2.jdbc.app.DB2Driver

Oracle`oracle.jdbc.driver.OracleDriver`**Informix**`com.informix.jdbc.IfxDriver`**Microsoft SQL Server**`com.microsoft.jdbc.sqlserver.SQLServerDriver`**Derby**`org.apache.derby.jdbc.EmbeddedDriver`**DB2 for z/OS**`com.ibm.db2.jcc.DB2Driver`**DB2 for iSeries**`com.ibm.db2.jdbc.app.DB2Driver`*Database URL:*

Specifies the Web address for the property extension repository.

Values include:

DB2 `jdbc:db2:wim`**Oracle**`jdbc:oracle:thin:@<hostname>:1521:orcl`**Derby**`jdbc:derby:c:\derby\wim`**Microsoft SQL Server**`jdbc:microsoft:sqlserver://<hostname>:1433;databaseName=wim;selectmethod=cursor;`**Informix**`jdbc:informix-sqli://<hostname>:1526/wim:INFORMIXSERVER=<IFXServerName>;`*Database administrator user name:*

Specifies the user name of the database administrator that is used to access the property extension repository.

Password:

Specifies the password that is used to enable the database administrator to access the property extension repository.

Entity retrieval limit:

Specifies the maximum number of entities that the system can retrieve from the property extension repository with a single database query.

Data type:

Integer

Default:

200

Setting up an entry mapping repository, a property extension repository, or a database repository using wsadmin commands:

You can set up an entry mapping repository, a property extension repository, or a database repository using wsadmin commands.

If you are setting up an entry mapping repository, begin with the steps described in “Configuring an entry mapping repository in a federated repository configuration” on page 144.

If you are setting up a property extension repository, begin with the steps described in “Configuring a property extension repository in a federated repository configuration” on page 132.

Three types of repositories are currently supported: DB2 repository, property extension repository, and entry mapping repository. When a repository is created, use the appropriate wsadmin command to define the database schema and to populate the database property definitions.

1. Create an empty entry mapping repository as shown in the following examples:
 - a. For DB2, open a DB2 command window or command center and enter the following:

```
db2 create database <name> using codeset UTF-8 territory US
```
 - b. Enter the following database tuning commands:

```
db2 update database configuration for <name> using applheapsz 1024
db2 update database configuration for <name> using stmtheap 4096
db2 update database configuration for <name> using app_ct1_heap_sz 2048
db2 update database configuration for <name> using locklist 1024
db2 update database configuration for <name> using indexrec RESTART
db2 update database configuration for <name> using logfilsiz 1000
db2 update database configuration for <name> using logprimary 12
db2 update database configuration for <name> using logsecond 10
db2 update database configuration for <name> using sortheap 2048
db2set DB2_RR_TO_RS=yes
```
 - c. **Optional:** For Informix databases using dbaccess, enter the following command:

```
CREATE DATABASE <name> WITH BUFFERED LOG
```
 - d. **Optional:** For Oracle databases, the database should already exist during Oracle installation (for example, orcl).
2. Run the setupIdMgrDBTables command by doing the following:
 - a. Start WebSphere Application Server.
 - b. Open a command window and go to the <WAS>/Profiles/<PROFILE_NAME>bin directory.
 - c. Start wsadmin.
 - d. Type the necessary commands as described below.

The setupIdMgrDBTables command can be used to:

- Specify the arguments on the command line.
- Specify the arguments in a file.

For the commands below, the `-file` option enables you to specify a file in which some or all of the parameters are specified. To use the `-file` argument on the command line, enter the full path to the file. Parameters in the file must be specified in `key=value` pairs and each must be on its own line. If a parameter is specified on both the command line and in the file, the value on the command line takes precedence.

Note: If an argument is not properly specified on the command line or in the file, a message is returned which states that the argument was not properly specified. This might mean that the argument was not specified at all or was required for a given configuration but was not specified.

If the argument was not specified at all, check that the parameter is specified on the command line or in the file, and that it is properly spelled and has matching case.

If the argument was required for a given configuration but was not specified, it is possible that a value is not required solely by the command but is required for the type of database and configuration you are setting.

For example, if you set the `dn`, `wasAdminId`, or `wasAdminPassword` parameters, you must also specify the `dbDriver` parameter. Additionally, if the `dn`, `wasAdminId` or `wasAdminPassword` parameters are specified, and the `databaseType` is not a Cloudscape 10 Version 1 database, then the `dbAdminId` and `dbAdminPassword` parameters must also be specified.

The `setupIdMgrDBTables` command:

The `setupIdMgrDBTables` command sets up the database, which includes creating and populating the tables in the database. Required arguments are prefixed by a double start (**). Arguments are case-sensitive, both through the command line and the file.

Parameters:

****schemaLocation (String)**

The location of the `<WAS>/etc/wim/setup` directory.

dbPropXML (String)

The location of database repository property definition XML file.

****databaseType (String)**

The type of database. Supported databases are `db2`, `oracle`, `informix`, `cloudscape`, `sqlserver`, `db2zos`, and `db2iseries`.

****dbURL (String)**

The database URL for direct access mode. For example: `jdbc:db2:wim`.

dbDriver (String)

The name of the database driver. For example: `COM.ibm.db2.jdbc.app.DB2Driver`.

dbAdminId (String)

The database administrator ID for direct access mode. For example: `db2admin`.

Note: For a Cloudscape 10 Version 1 embedded database, `dbAdminId` is not required.

dbAdminPassword (String)

The password associated with the `dbAdminId`.

Note: For a Cloudscape 10 Version 1 embedded database, `dbAdminPassword` is not required.

dn (String)

The default organization `uniqueName` to replace. For example: `o=yourco`. If it is not set, `o=DefaultOrganization` is used.

wasAdminId (String)

The WebSphere Application Server admin user ID. The ID should be a short name, not a `uniqueName`. For example: `wasadmin`. After creation, the `uniqueName` is `uid=wasadmin, <defaultOrg>`.

wasAdminPassword (String)

The WebSphere Application Server admin user password. If `wasAdminId` is set, then this parameter is mandatory.

saltLength (Integer)

The salt length of the randomly generated salt for password hashing.

encryptionKey (String)

The password encryption key. Set the password encryption key to match the encryption key in the `wimconfig.xml` file for the repository. If the encryption key is not set, the default is used.

derbySystemHome (String)

The home location of the Cloudscape 10 Version 1 system if you are setting up a Cloudscape 10 Version 1 database.

reportSqlError (String)

Specifies whether to report SQL errors while setting up databases.

file (String)

The full path to a file containing the input parameters. Each input parameter must match a corresponding parameter as it would be typed on the command line, and it must be placed in a key=value pair. Each pair must be on a separate line.

The deleteIdMgrDBTables command:

The deleteIdMgrDBTables command deletes the tables in the database.

Parameters:

****schemaLocation (String)**

The location of the <WAS>/etc/wim/setup directory.

****databaseType (String)**

The type of database. Supported databases are db2, oracle, informix, cloudscape, sqlserver, db2zos, and db2iseries.

****dbURL (String)**

The database URL for direct access mode. For example: jdbc:db2:wim.

dbDriver (String)

The name of the database driver. For example: COM.ibm.db2.jdbc.app.DB2Driver.

dbAdminId (String)

The database administrator ID for direct access mode. For example: db2admin.

Note: For a Cloudscape 10 Version 1 embedded database, dbAdminId is not required.

dbAdminPassword (String)

The password associated with the dbAdminId.

Note: For a Cloudscape 10 Version 1 embedded database, dbAdminPassword is not required.

derbySystemHome (String)

The home location of the Cloudscape 10 Version 1 system if you are setting up a Cloudscape 10 Version 1 database.

reportSqlError (String)

Specifies whether to report SQL errors while setting up databases.

file (String)

The full path to a file containing the input parameters. Each input parameter must match a corresponding parameter as it would be typed on the command line, and it must be placed in a key=value pair. Each pair must be on a separate line.

The setupIdMgrPropertyExtensionRepositoryTables command:

The setupIdMgrPropertyExtensionRepositoryTables command sets up the property extension repository, which includes creating and populating the tables in the database.

Parameters:

****schemaLocation (String)**

The location of the <WAS>/etc/wim/setup directory.

laPropXML (String)

The location of the property extension repository definition XML file.

****databaseType (String)**

The type of database. Supported databases are db2, oracle, informix, cloudscape, sqlserver, db2zos, and db2iseries.

****dbURL (String)**

The database URL for direct access mode. For example: jdbc:db2:wim.

dbAdminId (String)

The database administrator ID for direct access mode. For example: db2admin.

Note: For a Cloudscape 10 Version 1 embedded database, dbAdminId is not required.

dbAdminPassword (String)

The password associated with the dbAdminId.

Note: For a Cloudscape 10 Version 1 embedded database, dbAdminPassword is not required.

derbySystemHome (String)

The home location of the Cloudscape 10 Version 1 system if you are setting up a Cloudscape 10 Version 1 database.

reportSqlError (String)

Specifies whether to report SQL errors while setting up databases.

file (String)

The full path to a file containing the input parameters. Each input parameter must match a corresponding parameter as it would be typed on the command line, and it must be placed in a key=value pair. Each pair must be on a separate line.

The deleteIdMgrPropertyExtensionRepositoryTables command:

The deleteIdMgrPropertyExtensionRepositoryTables command deletes the tables in the property extension database.

*Parameters:*****schemaLocation (String)**

The location of the <WAS>/etc/wim/setup directory.

****databaseType (String)**

The type of database. Supported databases are db2, oracle, informix, cloudscape, sqlserver, db2zos, and db2iseries.

****dbURL (String)**

The database URL for direct access mode. For example: jdbc:db2:wim.

dbDriver (String)

The name of the database driver. For example: COM.ibm.db2.jdbc.app.DB2Driver.

dbAdminId (String)

The database administrator ID for direct access mode. For example: db2admin.

Note: For a Cloudscape 10 Version 1 embedded database, dbAdminId is not required.

dbAdminPassword (String)

The password associated with the dbAdminId.

Note: For a Cloudscape 10 Version 1 embedded database, dbAdminPassword is not required.

derbySystemHome (String)

The home location of the Cloudscape 10 Version 1 system if you are setting up a Cloudscape 10 Version 1 database.

reportSqlError (String)

Specifies whether to report SQL errors while setting up databases.

file (String)

The full path to a file containing the input parameters. Each input parameter must match a corresponding parameter as it would be typed on the command line, and it must be placed in a key=value pair. Each pair must be on a separate line.

The setupIdMgrEntryMappingRepositoryTables command:

The setupIdMgrEntryMappingRepositoryTables command sets up the entry mapping repository, which includes creating and populating the tables of the repository.

Parameters:

****schemaLocation (String)**

The location of the <WAS>/etc/wim/setup directory.

****databaseType (String)**

The type of database. Supported databases are db2, oracle, informix, cloudscape, sqlserver, db2zos, and db2iseries.

****dbURL (String)**

The database URL for direct access mode. For example: jdbc:db2:wim.

dbDriver (String)

The name of the database driver. For example: COM.ibm.db2.jdbc.app.DB2Driver.

dbAdminId (String)

The database administrator ID for direct access mode. For example: db2admin.

Note: For a Cloudscape 10 Version 1 embedded database, dbAdminId is not required.

dbAdminPassword (String)

The password associated with the dbAdminId.

Note: For a Cloudscape 10 Version 1 embedded database, dbAdminPassword is not required.

derbySystemHome (String)

The home location of the Cloudscape 10 Version 1 system if you are setting up a Cloudscape 10 Version 1 database.

reportSqlError (String)

Specifies whether to report SQL errors while setting up databases.

file (String)

The full path to a file containing the input parameters. Each input parameter must match a corresponding parameter as it would be typed on the command line, and it must be placed in a key=value pair. Each pair must be on a separate line.

The deleteIdMgrEntryMappingRepositoryTables command:

The deleteIdMgrEntryMappingRepositoryTables command deletes the tables in the entry mapping repository.

Parameters:

****schemaLocation (String)**

The location of the <WAS>/etc/wim/setup directory.

****databaseType (String)**

The type of database. Supported databases are db2, oracle, informix, cloudscape, sqlserver, db2zos, and db2iseries.

****dbURL (String)**

The database URL for direct access mode. For example: jdbc:db2:wim.

dbDriver (String)

The name of the database driver. For example: COM.ibm.db2.jdbc.app.DB2Driver.

dbAdminId (String)

The database administrator ID for direct access mode. For example: db2admin.

Note: For a Cloudscape 10 Version 1 embedded database, dbAdminId is not required.

dbAdminPassword (String)

The password associated with the dbAdminId.

Note: For a Cloudscape 10 Version 1 embedded database, dbAdminPassword is not required.

derbySystemHome (String)

The home location of the Cloudscape 10 Version 1 system if you are setting up a Cloudscape 10 Version 1 database.

reportSqlError (String)

Specifies whether to report SQL errors while setting up databases.

file (String)

The full path to a file containing the input parameters. Each input parameter must match a corresponding parameter as it would be typed on the command line, and it must be placed in a key=value pair. Each pair must be on a separate line.

Sample command line usage:

To set up a database using the command line, enter the following:

```
$AdminTask setupIdMgrDBTables {-schemaLocation "C:\WAS7\etc\wim\setup" -dbPropXML
"C:\WAS7\etc\wim\setup\wimdbproperties.xml" -databaseType db2
-dbURL jdbc:db2:wim -dbAdminId db2admin
-dbDriver COM.ibm.db2.jdbc.app.DB2Driver -dbAdminPassword db2adminPwd
-reportSqlError true}
```

To delete database tables using the command line, enter the following:

```
$AdminTask deleteIdMgrDBTables {-schemaLocation "C:\WAS7\etc\wim\setup"
-databaseType db2 -dbURL jdbc:db2:wim -dbAdminId db2admin
-dbDriver COM.ibm.db2.jdbc.app.DB2Driver -dbAdminPassword db2adminPwd
-reportSqlError true}
```

To set up a property extension repository using the command line, enter the following:

```
$AdminTask setupIdMgrPropertyExtensionRepositoryTables {-schemaLocation
"C:\WAS7\etc\wim\setup"
-1aPropXML "C:\WAS7\etc\wim\setup\wim1aproperties.xml" -databaseType db2
-dbURL jdbc:db2:wim -dbAdminId db2admin -dbDriver COM.ibm.db2.jdbc.app.DB2Driver
-dbAdminPassword db2adminPwd -reportSqlError true}
```

To delete a property extension repository using the command line, enter the following:

```
$AdminTask deleteIdMgrPropertyExtensionRepositoryTables {-schemaLocation "C:\WAS7\etc\wim\setup "
-databaseType db2 -dbURL jdbc:db2:wim -dbAdminId db2admin -dbDriver
COM.ibm.db2.jdbc.app.DB2Driver -dbAdminPassword db2adminPwd -reportSqlError true}
```

To set up an entry mapping repository using the command line, enter the following:

```
$AdminTask setupIdMgrEntryMappingRepositoryTables {-schemaLocation "C:\WAS7\etc\wim\setup"  
-databaseType db2 -dbURL jdbc:db2:wim -dbAdminId db2admin -dbDriver  
COM.ibm.db2.jdbc.app.DB2Driver -dbAdminPassword db2adminPwd -reportSqlError true}
```

To delete an entry mapping repository using the command line, enter the following:

```
$AdminTask deleteIdMgrEntryMappingRepositoryTables {-schemaLocation "C:\WAS7\etc\wim\setup"  
-databaseType db2 -dbURL jdbc:db2:wim -dbAdminId db2admin -dbDriver  
COM.ibm.db2.jdbc.app.DB2Driver -dbAdminPassword db2adminPwd -reportSqlError true}
```

Sample CLI Usage using -file option:

To set up a database with the -file option using the example params.txt file below, enter the following:

```
$AdminTask setupIdMgrDBTables {-file C:\params.txt -dbPropXML  
"C:\OverrideDBPropParam\wimdbproperties.xml"}
```

Params.txt

```
schemaLocation=C:\WAS7\etc\wim\setup  
dbPropXML=C:\Program Files\IBM\WebSphere\AppServer\profiles\default  
\config\cells\mycell\wim\config\wimdbproperties.xml  
laPropXML=C:\Program Files\IBM\WebSphere\AppServer\profiles\default  
\config\cells\mycell\wim\config\wimlaproperties.xml  
databaseType=db2  
dbURL=jdbc:db2:wim  
dbDriver=COM.ibm.db2.jdbc.app.DB2Driver  
reportSqlError=true  
dn=o=db.com  
dbAdminId=db2admin  
dbAdminPassword=dbPassword  
wasAdminId=wasadmin  
wasAdminPassword=wasadmin1
```

To set up a database with the -file option using a file only, enter the following:

```
$AdminTask setupIdMgrDBTables {-file C:\params.txt}
```

Note: The use of a file only works if -file is the only parameter specified on the command line. If other parameters are specified then the file is completely ignored, and only the parameters on the command line are used to execute the command.

Configuring the WebSphere Application Server data source:

This section describes how to configure the data source service in WebSphere Application Server.

1. Start the WebSphere Application Server administrative console.
2. Click **Security -> Secure administration, applications and infrastructure**.
3. On the Configuration panel, expand Java Authentication and Authorization Service and click **J2C authentication data**.
4. Click **New** and enter the Alias, User ID and Password.
5. Click **Ok**.
6. Click **Resources -> JDBC -> JDBC Providers**.
7. In the Scope section, choose the **Node level**.
8. Click **New** to create a new JDBC driver.
9. Select the Database type, Provider type, Implementation type and Name.
10. Click **Next** and configure the database class path. Click **Next**.
11. On the Summary page, click **Finish**.
12. In the Additional properties section, click **Data sources**.

13. Click **New** to create a new data source. Enter the Data source name and the JNDI name, and choose the authentication alias from the drop-down list in Component-managed authentication alias. The JNDI name should match the datasourceName value set in wimconfig.xml. By default, it is jdbc/wimDS.

Note: For Cloudscape 10 Version 1 embedded databases, leave the Component-managed authentication alias field set to NONE.

14. Click **Next**.
15. Enter the Database name and deselect **Use this data source in container managed persistence (CMP)**. Click **Next**.
16. Under Component-managed authentication alias, select the authentication alias previously created. Click **Test Connection**. The message should indicate that the connection is successful. Ignore any warnings, and then click **Next**.
17. On the Summary page, click **Finish**.
18. Save the configurations, and restart WebSphere Application Server.

Configuring an entry mapping repository in a federated repository configuration

Follow this task to configure an entry mapping repository that is used to store data for managing profiles on multiple repositories.

An *entry-level join* means that the federated repository configuration uses multiple repositories simultaneously and recognizes the entries in the different repositories as entries representing distinct entities. For example, a company might have a Lightweight Directory Access Protocol (LDAP) directory that contains entries for its employees and a database that contains entries for business partners and customers. By configuring an entry mapping repository, a federated repository configuration can use both the LDAP and the database at the same time. The federated repository configuration hierarchy and constraints for identifiers provide the aggregated namespace for both of those repositories and prevent identifiers from colliding.

When you configure an entry mapping repository, you can supply a valid data source, a direct connection configuration, or both. The system first tries to connect by way of the data source. If the data source is not available, then the system uses the direct access configuration.

Restriction: You cannot configure an entry mapping repository in a mixed-version deployment manager cell.

1. Configure the WebSphere Application Server data source. See “Configuring the WebSphere Application Server data source” on page 143.
2. Set up the entry mapping repository using wsadmin. See “Setting up an entry mapping repository, a property extension repository, or a database repository using wsadmin commands” on page 136.
3. Configure the entry mapping repository into the federated repository by doing the following:
 - a. In the administrative console, click **Security > Secure administration, applications, and infrastructure**.
 - b. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
 - c. Click **Entry mapping repository**.
 - d. Supply the name of the data source in the Data source name field.
 - e. Select the type of database that is used for the property extension repository.
 - f. Supply the name of the Java database connectivity (JDBC) driver in the JDBC driver field.

Values include:

DB2 COM.ibm.db2.jdbc.app.DB2Driver

Oracle`oracle.jdbc.driver.OracleDriver`**Informix**`com.informix.jdbc.IfxDriver`**Microsoft SQL Server**`com.microsoft.jdbc.sqlserver.SQLServerDriver`**Derby** `org.apache.derby.jdbc.EmbeddedDriver`**DB2 for z/OS**`com.ibm.db2.jcc.DB2Driver`**DB2 for iSeries**`com.ibm.db2.jdbc.app.DB2Driver`

- g. Supply the database URL that is used to access the property extension repository with JDBC in the Database URL field. Use an alphanumeric text string that conforms to the standard JDBC URL syntax.

Values include:

DB2 `jdbc:db2:wim`

Oracle

`jdbc:oracle:thin:@<hostname>:1521:orcl`

Derby `jdbc:derby:c:\derby\wim`

Microsoft SQL Server

`jdbc:microsoft:sqlserver://<hostname>:1433;databaseName=wim;selectmethod=cursor;`

Informix

`jdbc:informix-sqli://<hostname>:1526/wim:INFORMIXSERVER=<IFXServerName>;`

- h. Supply the user name of the database administrator in the Database administrator user name field.
 i. Supply the password of the database administrator in the Password field.
 j. Click **OK**.

After completing these steps, your federated repository configuration, which includes an entry mapping repository, is configured.

1. After configuring the federated repositories, click **Security > Secure administration, applications, and infrastructure** to return to the Secure administration, applications, and infrastructure panel. Verify that Federated repositories is identified in the Current realm definition field. If Federated repositories is not identified, select **Federated repositories** from the Available realm definitions field and click **Set as current**. To verify the federated repositories configuration, click **Apply** on the Secure administration, applications, and infrastructure panel. If Federated repositories is not identified in the Current realm definition field, your federated repositories configuration is not used by WebSphere Application Server.
2. If you are enabling security, complete the remaining steps as specified in “Enabling security for the realm” on page 72. As the final step, validate this setup by clicking **Apply** in the Secure administration, applications, and infrastructure panel.
3. Save, stop, and restart all the product servers (deployment managers, nodes, and Application Servers) for changes in this panel to take effect. If the server comes up without any problems, the setup is correct.

Entry mapping repository settings:

Use this page to configure an entry mapping repository that is used to store data for managing profiles on multiple repositories.

To view this administrative console page, complete the following steps:

1. In the administrative console, click **Security > Secure administration, applications, and infrastructure**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Under Additional properties, click **Entry mapping repository**.

When you finish adding or updating your federated repository configuration, go to the **Security > Secure administration, applications, and infrastructure** panel and click **Apply** to validate the changes.

Data source name:

Specifies the Java Naming and Directory Interface (JNDI) name of the data source that is used to access the entry mapping repository.

Default: jdbc/wimDS

Database type:

Specifies the type of database that is used to access the entry mapping repository.

Default: DB2

JDBC driver:

Specifies the Java Database Connectivity (JDBC) driver that is used to access the entry mapping repository.

Values include:

DB2 com.ibm.db2.jdbc.app.DB2Driver

Oracle
oracle.jdbc.driver.OracleDriver

Informix
com.informix.jdbc.IfxDriver

Microsoft SQL Server
com.microsoft.jdbc.sqlserver.SQLServerDriver

Derby org.apache.derby.jdbc.EmbeddedDriver

DB2 for z/OS
com.ibm.db2.jcc.DB2Driver

DB2 for iSeries
com.ibm.db2.jdbc.app.DB2Driver

Database URL:

Specifies the Web address for the entry mapping repository.

Values include:

DB2 jdbc:db2:wim

Oracle
jdbc:oracle:thin:@<hostname>:1521:orcl

Derby jdbc:derby:c:\derby\wim

Microsoft SQL Server

```
jdbc:microsoft:sqlserver://<hostname>:1433;databaseName=wim;selectmethod=cursor;
```

Informix

```
jdbc:informix-sqli://<hostname>:1526/wim:INFORMIXSERVER=<IFXServerName>;
```

Database administrator user name:

Specifies the user name of the database administrator that is used to access the entry mapping repository.

Password:

Specifies the password that is used to enable the database administrator to access the entry mapping repository.

Configuring supported entity types in a federated repository configuration

Follow this task to configure supported entity types for user and group management.

You must configure the supported entity types before you can manage this account with Users and Groups in the administrative console. The supported entity types are Group, OrgContainer, and PersonAccount. A Group entity represents a simple collection of entities that might not have any relational context. An OrgContainer entity represents an organization, such as a company or an enterprise, a subsidiary, or an organizational unit, such as a division, a location, or a department. A PersonAccount entity represents a human being. You cannot add or delete the supported entity types, because these types are predefined.

The Base entry for the default parent determines the repository location where entities of the specified type are placed on write operations by user and group management.

Note: To manage users and groups, click **Users and Groups** in the console navigation tree. Click either **Manage Users** or **Manage Groups**.

1. In the administrative console, click **Security > Secure administration, applications, and infrastructure**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Click **Supported entity types** to view a list of predefined entity types.
4. Click the name of a predefined entity type to change its configuration.
5. Supply the distinguished name of a base entry in the repository in the Base entry for the default parent field. This entry determines the default location in the repository where entities of this type are placed on write operations by user and group management.
6. Supply the relative distinguished name (RDN) properties for the specified entity type in the Relative Distinguished Name properties field. Possible values are *cn* for Group, *uid* or *cn* for PersonAccount, and *o*, *ou*, *dc*, and *cn* for OrgContainer. Delimit multiple properties for the OrgContainer entity with a semicolon (;).

The following list outlines known requirements and limitations that apply to specific Lightweight Directory Access Protocol (LDAP) servers:

Using Microsoft Active Directory as the LDAP server

- Unless you modify the LDAP schema to use *uid*, you must specify *cn* in the Relative Distinguished Name (RDN) properties field for the PersonAccount entity type.
- Secure Sockets Layer communications must be enabled to create users with passwords. To select the **Require SSL communications** option, see the topic “Configuring Lightweight Directory Access Protocol in a federated repository configuration” on page 126.
- Typically the value of user is specified as the value in the Object classes field for the PersonAccount entity type and the value of group is specified as the value in the Object classes field for the Group entity type.

Using a Lotus Domino Enterprise Server as the LDAP server

- Typically, the value of cn is specified in the Relative Distinguished Name (RDN) properties field for the PersonAccount entity type. The value of uid is also acceptable.
- Typically, both inetOrgPerson and dominoPerson are used as values in the Object classes field for the PersonAccount entity type.

Using Sun ONE Directory Server as the LDAP server

- Typically, groupOfUniqueNames is specified as the value in the Object classes field for the Group entity type.

7. Click **OK**.

After completing these steps, your federated repository configuration, which uses supported entity types, is configured.

1. After configuring the federated repositories, click **Security > Secure administration, applications, and infrastructure** to return to the Secure administration, applications, and infrastructure panel. Verify that Federated repositories is identified in the Current realm definition field. If Federated repositories is not identified, select **Federated repositories** from the Available realm definitions field and click **Set as current**. To verify the federated repositories configuration, click **Apply** on the Secure administration, applications, and infrastructure panel. If Federated repositories is not identified in the Current realm definition field, your federated repositories configuration is not used by WebSphere Application Server.
2. If you are enabling security, complete the remaining steps as specified in “Enabling security for the realm” on page 72. As the final step, validate this setup by clicking **Apply** in the Secure administration, applications, and infrastructure panel.
3. Save, stop, and restart all the product servers (deployment managers, nodes, and Application Servers) for changes in this panel to take effect. If the server comes up without any problems, the setup is correct.

Supported entity types collection:

Use this page to list entity types that are supported by the member repositories or to select an entity type to view or change its configuration properties.

To view this administrative console page, complete the following steps:

1. In the administrative console, click **Security > Secure administration, applications, and infrastructure**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Under Additional properties, click **Supported entity types**.

You must configure the supported entity types before you can manage this account with Users and Groups in the administrative console. The Base entry for the default parent determines the repository location where entities of the specified type are placed on write operations by user and group management.

When you finish adding or updating your federated repository configuration, go to the **Security > Secure administration, applications, and infrastructure** panel and click **Apply** to validate the changes.

Related reference

“Lightweight Directory Access Protocol entity types settings” on page 157

Use this page to configure Lightweight Directory Access Protocol (LDAP) entity types that are supported by the member repositories.

Entity type:

Specifies the entity type name.

Base entry for the default parent:

Specifies the distinguished name of a base entry in the repository.

This entry determines the default location in the repository where entities of this type are placed on write operations by user and group management.

Relative Distinguished Name properties:

Specifies the relative distinguished name (RDN) properties for the specified entity type.

Possible values are `cn` for Group, `uid` or `cn` for PersonAccount, and `o`, `ou`, `dc`, and `cn` for OrgContainer. Delimit multiple properties for the OrgContainer entity with a semicolon (;).

Supported entity types settings:

Use this page to configure entity types that are supported by the member repositories.

To view this administrative console page, complete the following steps:

1. In the administrative console, click **Security > Secure administration, applications, and infrastructure**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Under Additional properties, click **Supported entity types**.
4. Click the name of a configured entity type to view or change its configuration.

You must configure the supported entity types before you can manage this account with Users and Groups in the administrative console. The Base entry for the default parent determines the repository location where entities of the specified type are placed on write operations by user and group management.

When you finish adding or updating your federated repository configuration, go to the **Security > Secure administration, applications, and infrastructure** panel and click **Apply** to validate the changes.

Entity type:

Specifies the name of the entity type.

Base entry for the default parent:

Specifies the distinguished name of a base entry in the repository.

This entry determines the default location in the repository where entities of this type are placed on write operations by user and group management.

Relative Distinguished Name properties:

Specifies the relative distinguished name (RDN) properties for the specified entity type.

Possible values are `cn` for Group, `uid` or `cn` for PersonAccount, and `o`, `ou`, `dc`, and `cn` for OrgContainer. Delimit multiple properties for the OrgContainer entity with a semicolon (;).

Managing repositories in a federated repository configuration

Follow this topic to manage repositories in a federated repository configuration.

1. In the administrative console, click **Security > Secure administration, applications, and infrastructure**.

2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Under Related items, click **Manage repositories**. Repositories that are configured in the system are listed in the collection panel. This list includes repositories that are configured using the federated repository functionality as well as repositories that are created using wsadmin commands described in the topic “Commands for the IdMgrRepositoryConfig group of the AdminTask object” on page 681.
4. **Optional:** Click **Add** to configure a new external repository. The Lightweight Directory Access Protocol (LDAP) repository configuration settings are described in detail in “Configuring Lightweight Directory Access Protocol in a federated repository configuration” on page 126.

Restriction: You cannot add a database repository using the administrative console. This repository configuration is supported by using wsadmin commands only.

5. **Optional:** Click **Delete** to delete a repository that you specified previously using the administrative console or wsadmin commands.

Restriction: You cannot delete the built-in, file-based repository from the collection panel.

6. **Optional:** Select one of the LDAP repository identifier entries to view or update an external repository that is configured in the system previously. The steps to configure LDAP settings are described in detail in “Configuring Lightweight Directory Access Protocol in a federated repository configuration” on page 126.

Restriction: While database repositories that are configured in the system are listed in the collection panel, you cannot update a database repository using the administrative console. Updates to a database repository are supported by using wsadmin commands only.

7. Click **OK**.

After completing these steps, the collection panel under Managing repositories reflects a current list of repositories that are configured in your system.

1. To add one or more external repositories that are listed on this collection panel into the realm, see “Managing the realm in a federated repository configuration” on page 115.
2. After configuring the federated repositories, click **Security > Secure administration, applications, and infrastructure** to return to the Secure administration, applications, and infrastructure panel. Verify that Federated repositories is identified in the Current realm definition field. If Federated repositories is not identified, select **Federated repositories** from the Available realm definitions field and click **Set as current**. To verify the federated repositories configuration, click **Apply** on the Secure administration, applications, and infrastructure panel. If Federated repositories is not identified in the Current realm definition field, your federated repositories configuration is not used by WebSphere Application Server.
3. If you are enabling security, complete the remaining steps as specified in “Enabling security for the realm” on page 72. As the final step, validate this setup by clicking **Apply** in the Secure administration, applications, and infrastructure panel.
4. Save, stop, and restart all the product servers (deployment managers, nodes, and Application Servers) for changes in this panel to take effect. If the server comes up without any problems, the setup is correct.

Manage repositories collection:

Use this page to list repositories that are configured in the system or to select a repository to view or change its configuration properties. You can add or delete external repositories.

To view this administrative console page, complete the following steps:

1. In the administrative console, click **Security > Secure administration, applications, and infrastructure**.

2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Under Related items, click **Manage repositories**.

When you finish adding or updating your federated repository configuration, go to the **Security > Secure administration, applications, and infrastructure** panel and click **Apply** to validate the changes.

Repository identifier:

Specifies a unique identifier for the repository. This identifier uniquely identifies the repository within the cell.

Repository type:

Specifies the repository type, such as File or LDAP.

Repository reference settings:

Use this page to configure a repository reference. A repository reference is a single repository that contains a set of identity entries that are referenced by a base entry into the directory information tree.

To view this administrative console page, complete the following steps:

1. In the administrative console, click **Security > Secure administration, applications, and infrastructure**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Click **Add base entry to realm**.

When you finish adding or updating your federated repository configuration, go to the **Security > Secure administration, applications, and infrastructure** panel and click **Apply** to validate the changes.

Repository:

Specifies a unique identifier for the repository. This identifier uniquely identifies the repository within the cell.

Expand the drop-down list to display a list of previously defined repository identifiers.

Distinguished name that uniquely identifies this set of entries in the realm:

Specifies the distinguished name (DN) that uniquely identifies this set of entries in the realm.

If multiple repositories are included in the realm, it is necessary to define an additional distinguished name that uniquely identifies this set of entries within the realm.

Distinguished name of a base entry in this repository:

Specifies the Lightweight Directory Access Protocol (LDAP) distinguished name (DN) of the base entry within the repository. The entry and its descendents are mapped to the subtree that is identified by the unique base name entry field.

If this field is left blank, then the subtree defaults to the root of the LDAP repository.

Increasing the performance of the federated repository configuration

Follow this page to manage the realm in a federated repository configuration.

The settings that are available on the Performance panel are independent options that pertain specifically to the federated repositories functionality. These options do not affect your entire WebSphere Application Server configuration.

1. In the administrative console, click **Security > Secure administration, applications, and infrastructure**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Under Related items, click **Manage repositories > repository_name**.
4. Under Additional properties, click **Performance**.
5. **Optional:** Select the **Limit search time** option and enter the maximum number of milliseconds that the Application Server can use to search through your Lightweight Directory Access Protocol (LDAP) entries.
6. **Optional:** Select the **Limit search returns** option and enter the maximum number of entries to return that match the search criteria.
7. **Optional:** Select the **Use connection pooling** option to specify whether the Application Server can store separate connections to the LDAP server for reuse.
8. **Optional:** Select the **Enable context pool** option to specify whether multiple applications can use the same connection to the LDAP server. If you select the option, specify the initial, preferred, and maximum number of entries that can use the same connection. The **Enable context pool** option can be enabled either in conjunction with the **Use connection pool** option or separately. If this option is disabled, a new connection is created for each context. You can also select the **Context pool times out** option and specify the number of seconds after which the entries in the context pool expire.
9. **Optional:** Select the **Cache the attributes** option and specify the maximum number of search attribute entries. This option enables WebSphere Application Server to save the LDAP entries so that it can search the entries locally rather than making multiple calls to the LDAP server. Click the **Cache times out** option that is associated with the **Cache the attributes** option to specify the maximum number of seconds that the Application Server can save these entries.
10. **Optional:** Select the **Cache the search results** option and specify the maximum number of search result entries. This option enables WebSphere Application Server to save the results of a search inquiry instead of making multiple calls to the LDAP server to search and retrieve the results of that search. Click the **Cache times out** option that is associated with the **Cache the search results** option to specify the maximum number of seconds that the Application Server can save the results.

These options are available to potentially increase the performance of your federated repositories configuration. However, the any increase in performance is dependant upon your specific configuration.

Lightweight Directory Access Protocol performance settings:

Use this page to minimize impacts to performance by adding opened connections and contexts to internally maintained pools and reusing them. Also minimize performance impacts by maintaining internal caches of retrieved data.

To view this administrative console page, complete the following steps:

1. In the administrative console, click **Security > Secure administration, applications, and infrastructure**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Under Related items, click **Manage repositories**.
4. Click **Add** to specify a new external repository or select an external repository that is preconfigured.
5. Under Additional properties, click **Performance**.

When you finish adding or updating your federated repository configuration, go to the **Security > Secure administration, applications, and infrastructure** panel and click **Apply** to validate the changes.

Limit search time:

Specifies the timeout value in milliseconds for a Lightweight Directory Access Protocol (LDAP) server to respond before stopping a request.

Data type:	Integer
Units:	Milliseconds
Default:	0
Range:	Equal to or greater than 0. A value of 0 specifies that no search time limit exists.

Limit search returns:

Specifies the maximum number of entries that are returned in a search result.

Data type:	Integer
Units:	Entries
Default:	0
Range:	Equal to or greater than 0. A value of 0 specifies that no search return limit exists.

Use connection pooling:

Specifies whether to utilize the connection pooling function, which is provided in the Software Development Kit (SDK).

Connection pooling is maintained by the Java run time. It is configured by system properties.

Default:	Disabled
Range:	Enabled or Disabled

Enable context pool:

Specifies whether context pooling is enabled to the LDAP server. To improve performance, use the context pool in combination with connection pooling.

Default:	Enabled
Range:	Enabled or Disabled

Initial size:

Specifies the number of context instances in the pool when the pool is initially created by the LDAP repository.

Data type:	Integer
Default:	1
Range:	1 to 50

Preferred size:

Specifies the preferred number of context instances that the context pool maintains. Both in-use and idle context instances contribute to this number.

Data type:	Integer
Default:	3
Range:	0 to 100

Maximum size:

Specifies the maximum number of context instances that can be maintained concurrently by the context pool. Both in-use and idle context instances contribute to this number.

When the pool size reaches the maximum size, no new context instances can be created for a new request. The new request is blocked until a context instance is released or removed. The request periodically checks for context instances that are available in the pool. A request for a pooled context instance uses an existing pooled and idle context instance or a newly created pooled context instance.

A maximum pool size of 0 indicates that the context pool can maintain an infinite number of context instances.

Data type:	Integer
Default:	0

Context pool times out:

Specifies the number of seconds for the context pool to time out and remove idle context instances.

A timeout value of 0 indicates that the context pool does not time out context instances.

Data type:	Integer
Default:	0

Cache the attributes:

Specifies whether to cache the attributes that are returned from the LDAP server.

Default:	Enabled
Range:	Enabled or Disabled

Cache size:

Specifies the maximum size of the cache.

Data type:	Integer
Default:	4000
Range:	Equal to or greater than 100

Cache times out:

Specifies the maximum number of seconds that the cached search results can stay in the cache.

A timeout value of 0 indicates that the cached search results stay in the cache until update operations are made.

Data type:	Integer
Units:	Seconds
Default:	1200
Range:	Equal to or greater than 0

Cache the search results:

Specifies whether to cache the search results that are returned from the LDAP server.

Default:	Enabled
Range:	Enabled or Disabled

Cache size:

Specifies the maximum size of the cache.

Data type:	Integer
Default:	2000
Range:	Equal to or greater than 100

Cache times out:

Specifies the maximum number of seconds that the cached search results can stay in the cache.

A timeout value of 0 indicates that the cached search results stay in the cache until update operations are made.

Data type:	Integer
Units:	Seconds
Default:	600
Range:	Equal to or greater than 0

Configuring Lightweight Directory Access Protocol entity types in a federated repository configuration

Follow this task to configure Lightweight Directory Access Protocol (LDAP) entity types in a federated repository configuration.

1. In the administrative console, click **Security > Secure administration, applications, and infrastructure**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Under Related items, click **Manage repositories**.
4. Click **Add** to specify a new external repository or select an external repository that is preconfigured.

Note: If you click **Add** to specify a new external repository, you must first complete the required fields and click **Apply** before you can proceed to the next step.

5. Under Additional properties, click **LDAP entity types**.
6. View the entity types that are supported by the member repositories, or select an entity type to view or change its configuration properties.
7. Supply the object classes that are mapped to this entity type in the Object classes field. LDAP entries that contain one or more of the object classes belong to this entity type.

8. Supply the search bases that are used to search this entity type. The search bases specified must be subtrees of the base entry in the repository. For example, you can specify the following search bases, where `o=ibm,c=us` is the base entry in the repository:

`o=ibm,c=us` or `cn=users,o=ibm,c=us` or `ou=austin,o=ibm,c=us`

In the preceding example, you cannot specify search bases `c=us` or `o=ibm,c=uk`.

Delimit multiple search bases with a semicolon (;). For example:

`ou=austin,o=ibm,c=us;ou=raleigh,o=ibm,c=us`

9. Supply the LDAP search filter that is used to search this entity type.
For example, use `(objectclass=ePerson)` to search for users or `(|(objectclass=groupOfNames)(objectclass=groupOfUniqueNames))` to search for groups in an external LDAP repository.

If a search filter is not specified, the object classes and the relative distinguished name (RDN) properties are used to generate the search filter. For information on RDN properties, see “Configuring supported entity types in a federated repository configuration” on page 147.

After completing these steps, LDAP entity types are configured for your LDAP repository.

1. After configuring the federated repositories, click **Security > Secure administration, applications, and infrastructure** to return to the Secure administration, applications, and infrastructure panel. Verify that Federated repositories is identified in the Current realm definition field. If Federated repositories is not identified, select **Federated repositories** from the Available realm definitions field and click **Set as current**. To verify the federated repositories configuration, click **Apply** on the Secure administration, applications, and infrastructure panel. If Federated repositories is not identified in the Current realm definition field, your federated repositories configuration is not used by WebSphere Application Server.
2. If you are enabling security, complete the remaining steps as specified in “Enabling security for the realm” on page 72. As the final step, validate this setup by clicking **Apply** in the Secure administration, applications, and infrastructure panel.
3. Save, stop, and restart all the product servers (deployment managers, nodes, and Application Servers) for changes in this panel to take effect. If the server comes up without any problems, the setup is correct.

Lightweight Directory Access Protocol entity types collection:

Use this page to list Lightweight Directory Access Protocol (LDAP) entity types that are supported by the member repositories or to select an LDAP entity type to view or change its configuration properties.

To view this administrative console page, complete the following steps:

1. In the administrative console, click **Security > Secure administration, applications, and infrastructure**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Under Related items, click **Manage repositories**.
4. Click **Add** to specify a new external repository or select an external repository that is preconfigured.
5. Under Additional properties, click **LDAP entity types**.

When you finish adding or updating your federated repository configuration, go to the **Security > Secure administration, applications, and infrastructure** panel and click **Apply** to validate the changes.

Entity type:

Specifies the entity type name.

Object classes:

Specifies the object classes that are mapped to this entity type. LDAP entries that contain one or more of the object classes belong to this entity type.

Lightweight Directory Access Protocol entity types settings:

Use this page to configure Lightweight Directory Access Protocol (LDAP) entity types that are supported by the member repositories.

To view this administrative console page, complete the following steps:

1. In the administrative console, click **Security > Secure administration, applications, and infrastructure**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Under Related items, click **Manage repositories**.
4. Click **Add** to specify a new external repository or select an external repository that is preconfigured.
5. Under Additional properties, click **LDAP entity types**.
6. Select an entity type to view or change its configuration properties.

When you finish adding or updating your federated repository configuration, go to the **Security > Secure administration, applications, and infrastructure** panel and click **Apply** to validate the changes.

Entity type:

Specifies the entity type.

Object classes:

Specifies the object classes that are mapped to this entity type. LDAP entries that contain one or more of the object classes belong to this entity type.

Search bases:

Specifies the search bases that are used to search this entity type.

The search bases specified must be subtrees of the base entry in the repository. For example, you can specify the following search bases, where `o=ibm,c=us` is the base entry in the repository:

```
o=ibm,c=us or cn=users,o=ibm,c=us or ou=austin,o=ibm,c=us
```

In the preceding example, you cannot specify search bases `c=us` or `o=ibm,c=uk`.

Delimit multiple search bases with a semicolon (;). For example:

```
ou=austin,o=ibm,c=us;ou=raleigh,o=ibm,c=us
```

Search filter:

Specifies the LDAP search filter that is used to search this entity type.

For example, use `(objectclass=ePerson)` to search for users or `(|(objectclass=groupOfNames)(objectclass=groupOfUniqueNames))` to search for groups in an external LDAP repository.

If a search filter is not specified, the object classes and the relative distinguished name (RDN) properties are used to generate the search filter.

Configuring group attribute definition settings in a federated repository configuration

Follow this task to configure group definition settings in a federated repository configuration.

Because group attribute definition settings apply only to a Lightweight Directory Access Protocol (LDAP) repository, you must first configure an LDAP repository. For more information, see “Managing repositories in a federated repository configuration” on page 149.

1. In the administrative console, click **Security > Secure administration, applications, and infrastructure**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Under Related items, click **Manage repositories**.
4. Click **Add** to specify a new external repository or select an external repository that is preconfigured.

Note: If you click **Add** to specify a new external repository, you must first complete the required fields and click **Apply** before you can proceed to the next step.

5. Under Additional properties, click **Group attribute definition**.
6. Supply the name of the group membership attribute in the Name of group membership attribute field. Only one membership attribute can be defined for each LDAP repository.

Every LDAP entry should have this attribute to indicate the groups to which this entry belongs. For example, `memberOf` is the name of the membership attribute that is used in Active Directory. The group membership attribute contains values that reference groups to which this entry belongs. If `UserA` belongs to `GroupA`, then the value of the `memberOf` attribute of `UserA` should contain the distinguished name of `GroupA`.

If your LDAP server does not support the group membership attribute, then do not specify this attribute. The LDAP repository can look up groups by searching the group member attributes, though the performance might be slower.

7. Select the scope of the group membership attribute. The default value is `Direct`.

Direct The membership attribute contains direct groups only. Direct groups are the groups that contain the member. For example, if `Group1` contains `Group2` and `Group2` contains `User1`, then `Group2` is a direct group of `User1`, but `Group1` is not a direct group of `User1`.

Nested

The membership attribute contains both direct groups and nested groups.

All The membership attribute contains direct groups, nested groups, and dynamic members.

After completing these steps, group attribute definition settings are configured for your LDAP repository.

1. After configuring the federated repositories, click **Security > Secure administration, applications, and infrastructure** to return to the Secure administration, applications, and infrastructure panel. Verify that `Federated repositories` is identified in the Current realm definition field. If `Federated repositories` is not identified, select **Federated repositories** from the Available realm definitions field and click **Set as current**. To verify the federated repositories configuration, click **Apply** on the Secure administration, applications, and infrastructure panel. If `Federated repositories` is not identified in the Current realm definition field, your federated repositories configuration is not used by WebSphere Application Server.
2. If you are enabling security, complete the remaining steps as specified in “Enabling security for the realm” on page 72. As the final step, validate this setup by clicking **Apply** in the Secure administration, applications, and infrastructure panel.
3. Save, stop, and restart all the product servers (deployment managers, nodes, and Application Servers) for changes in this panel to take effect. If the server comes up without any problems, the setup is correct.

Group attribute definition settings:

Use this page to specify the name of the group membership attribute. Every Lightweight Directory Access Protocol (LDAP) entry includes this attribute to indicate the group to which this entry belongs.

To view this administrative console page, complete the following steps:

1. In the administrative console, click **Security > Secure administration, applications, and infrastructure**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Under Related items, click **Manage repositories**.
4. Click **Add** to specify a new external repository or select an external repository that is preconfigured.
5. Under Additional properties, click **Group attribute definition**.

When you finish adding or updating your federated repository configuration, go to the **Security > Secure administration, applications, and infrastructure** panel and click **Apply** to validate the changes.

Name of group membership attribute:

Specifies the name of the group membership attribute. Only one membership attribute can be defined for each Lightweight Directory Access Protocol (LDAP) repository.

Every LDAP entry should have this attribute to indicate the groups to which this entry belongs. For example, `memberOf` is the name of the membership attribute that is used in Active Directory. The group membership attribute contains values that reference groups to which this entry belongs. If `UserA` belongs to `GroupA`, then the value of the `memberOf` attribute of `UserA` should contain the distinguished name of `GroupA`.

If your LDAP server does not support the group membership attribute, then do not specify this attribute. The LDAP repository can look up groups by searching the group member attributes, though the performance might be slower.

Scope of group membership attribute:

Specifies the scope of the group membership attribute.

Default:	Direct
Range:	Direct The membership attribute contains direct groups only. Direct groups are the groups that contain the member. For example, if <code>Group1</code> contains <code>Group2</code> and <code>Group2</code> contains <code>User1</code> , then <code>Group2</code> is a direct group of <code>User1</code> , but <code>Group1</code> is not a direct group of <code>User1</code> .
	Nested The membership attribute contains both direct groups and nested groups.
	All The membership attribute contains direct groups, nested groups, and dynamic members.

Configuring member attributes in a federated repository configuration

Follow this task to configure member attributes in a federated repository configuration.

Because member attributes apply only to a Lightweight Directory Access Protocol (LDAP) repository, you must first configure an LDAP repository. For more information, see “Managing repositories in a federated repository configuration” on page 149.

1. In the administrative console, click **Security > Secure administration, applications, and infrastructure**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Under Related items, click **Manage repositories**.
4. Click **Add** to specify a new external repository or select an external repository that is preconfigured.

Note: If you click **Add** to specify a new external repository, you must first complete the required fields and click **Apply** before you can proceed to the next step.

5. Under Additional properties, click **Group attribute definition**.
6. Under Additional properties, click **Member attributes**.
7. Click **New** to specify a new member attribute or **Delete** to remove a preconfigured member attribute.
8. Accept the default, or supply the name of the member attribute in the Name of member attribute field. For example, member and uniqueMember are two commonly used names of member attributes.
The member attribute is used to store the values that reference members that the group contains. For example, a group type with an object class groupOfNames has a member attribute named member; group type with object class groupOfUniqueNames has a member attribute named uniqueMember. An LDAP repository supports multiple group types if multiple member attributes and their associated group object classes are specified.
9. Supply the object class of the group that uses this member attribute in the Object class field. If this field is not defined, this member attribute applies to all group object classes.
10. Select the scope of the member attribute. The default value is Direct.

Direct The member attribute contains direct members only. Direct members are members that are directly contained by the group. For example, if Group1 contains Group2 and Group2 contains User1, then User1 is a direct member of Group2, but User1 is not a direct member of Group1.

Nested

The member attribute contains both direct members and nested members.

All

The member attribute contains direct members, nested members, and dynamic members.

After completing these steps, member attributes are configured for your LDAP repository.

1. After configuring the federated repositories, click **Security > Secure administration, applications, and infrastructure** to return to the Secure administration, applications, and infrastructure panel. Verify that Federated repositories is identified in the Current realm definition field. If Federated repositories is not identified, select **Federated repositories** from the Available realm definitions field and click **Set as current**. To verify the federated repositories configuration, click **Apply** on the Secure administration, applications, and infrastructure panel. If Federated repositories is not identified in the Current realm definition field, your federated repositories configuration is not used by WebSphere Application Server.
2. If you are enabling security, complete the remaining steps as specified in “Enabling security for the realm” on page 72. As the final step, validate this setup by clicking **Apply** in the Secure administration, applications, and infrastructure panel.
3. Save, stop, and restart all the product servers (deployment managers, nodes, and Application Servers) for changes in this panel to take effect. If the server comes up without any problems, the setup is correct.

Member attributes collection:

Use this page to list Lightweight Directory Access Protocol (LDAP) member attributes or to select a member attribute to view or change its configuration properties.

To view this administrative console page, complete the following steps:

1. In the administrative console, click **Security > Secure administration, applications, and infrastructure**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Under Related items, click **Manage repositories**.
4. Click **Add** to specify a new external repository or select an external repository that is preconfigured.
5. Under Additional properties, click **Group attribute definition**.
6. Under Additional properties, click **Member attributes**.

When you finish adding or updating your federated repository configuration, go to the **Security > Secure administration, applications, and infrastructure** panel and click **Apply** to validate the changes.

Name:

Specifies the name of the member attribute in LDAP. For example, member and uniqueMember are two commonly used names of member attributes.

The member attribute is used to store the values that reference members that the group contains. For example, a group type with an object class groupOfNames has a member attribute named member; group type with object class groupOfUniqueNames has a member attribute named uniqueMember. An LDAP repository supports multiple group types if multiple member attributes and their associated group object classes are specified.

Scope:

Specifies the scope of the member attribute.

Default:

Direct

Range:

- Direct** The member attribute contains direct members only. Direct members are members that are directly contained by the group. For example, if Group1 contains Group2 and Group2 contains User1, then User1 is a direct member of Group2, but User1 is not a direct member of Group1.
- Nested** The member attribute contains both direct members and nested members.
- All** The member attribute contains direct members, nested members, and dynamic members.

Object class:

Specifies the object class of the group that uses this member attribute. If this field is not defined, this member attribute applies to all group object classes.

Member attributes settings:

Use this page to configure Lightweight Directory Access Protocol (LDAP) member attributes.

To view this administrative console page, complete the following steps:

1. In the administrative console, click **Security > Secure administration, applications, and infrastructure**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.

3. Under Related items, click **Manage repositories**.
4. Click **Add** to specify a new external repository or select an external repository that is preconfigured.
5. Under Additional properties, click **Group attribute definition**.
6. Under Additional properties, click **Member attributes**.
7. Click **New** to specify a new member attribute.

When you finish adding or updating your federated repository configuration, go to the **Security > Secure administration, applications, and infrastructure** panel and click **Apply** to validate the changes.

Name of member attribute:

Specifies the name of the member attribute in LDAP. For example, member and uniqueMember are two commonly used names of member attributes.

The member attribute is used to store the values that reference members that the group contains. For example, a group type with an object class groupOfNames has a member attribute named member; group type with object class groupOfUniqueNames has a member attribute named uniqueMember. An LDAP repository supports multiple group types if multiple member attributes and their associated group object classes are specified.

Object class:

Specifies the object class of the group that uses this member attribute. If this field is not defined, this member attribute applies to all group object classes.

Scope:

Specifies the scope of the member attribute.

Default:	Direct
Range:	<p>Direct The member attribute contains direct members only. Direct members are members that are directly contained by the group. For example, if Group1 contains Group2 and Group2 contains User1, then User1 is a direct member of Group2, but User1 is not a direct member of Group1.</p> <p>Nested The member attribute contains both direct members and nested members.</p> <p>All The member attribute contains direct members, nested members, and dynamic members.</p>

Configuring dynamic member attributes in a federated repository configuration

Follow this task to configure dynamic member attributes in a federated repository configuration.

Because dynamic member attributes apply only to a Lightweight Directory Access Protocol (LDAP) repository, you must first configure an LDAP repository. For more information, see “Managing repositories in a federated repository configuration” on page 149.

1. In the administrative console, click **Security > Secure administration, applications, and infrastructure**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Under Related items, click **Manage repositories**.
4. Click **Add** to specify a new external repository or select an external repository that is preconfigured.

Note: If you click **Add** to specify a new external repository, you must first complete the required fields and click **Apply** before you can proceed to the next step.

5. Under Additional properties, click **Group attribute definition**.
6. Under Additional properties, click **Dynamic member attributes**.
7. Click **New** to specify a new dynamic member attribute or **Delete** to remove a preconfigured dynamic member attribute.
8. Accept the default, or supply the name of the dynamic member attribute in the Name of dynamic member attribute field. The name of the dynamic member attribute defines the filter for dynamic group members in LDAP, for example, memberURL is the name of a commonly used dynamic member attribute.

If both member and dynamic member attributes are specified for the same group type, this group type is a hybrid group with both static and dynamic members.

A dynamic group defines its members differently than a static group. Instead of listing the members individually, the dynamic group defines its members using an LDAP search. The filter for the search is defined in a dynamic member attribute. For example, the dynamic group uses the structural objectclass groupOfURLs, or auxiliary objectclass ibm-dynamicGroup, and the attribute memberURL, to define the search using a simplified LDAP URL syntax:

```
ldap:///<base DN of search> ? ? <scope of search> ? <searchfilter>
```

The following is an example of the LDAP URL that defines all entries that are under o=Acme with the objectclass=person:

```
ldap:///o=Acme,c=US??sub?objectclass=person
```

9. Supply the object class of the group that contains the dynamic member attribute in the Dynamic object class field, for example, groupOfURLs. If this property is not defined, the dynamic member attribute applies to all group object classes.

After completing these steps, dynamic member attributes are configured for your LDAP repository.

1. After configuring the federated repositories, click **Security > Secure administration, applications, and infrastructure** to return to the Secure administration, applications, and infrastructure panel. Verify that Federated repositories is identified in the Current realm definition field. If Federated repositories is not identified, select **Federated repositories** from the Available realm definitions field and click **Set as current**. To verify the federated repositories configuration, click **Apply** on the Secure administration, applications, and infrastructure panel. If Federated repositories is not identified in the Current realm definition field, your federated repositories configuration is not used by WebSphere Application Server.
2. If you are enabling security, complete the remaining steps as specified in “Enabling security for the realm” on page 72. As the final step, validate this setup by clicking **Apply** in the Secure administration, applications, and infrastructure panel.
3. Save, stop, and restart all the product servers (deployment managers, nodes, and Application Servers) for changes in this panel to take effect. If the server comes up without any problems, the setup is correct.

Dynamic member attributes collection:

Use this page to manage Lightweight Directory Access Protocol (LDAP) dynamic member attributes.

To view this administrative console page, complete the following steps:

1. In the administrative console, click **Security > Secure administration, applications, and infrastructure**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Under Related items, click **Manage repositories**.
4. Click **Add** to specify a new external repository or select an external repository that is preconfigured.
5. Under Additional properties, click **Group attribute definition**.

6. Under Additional properties, click **Dynamic member attributes**.

When you finish adding or updating your federated repository configuration, go to the **Security > Secure administration, applications, and infrastructure** panel and click **Apply** to validate the changes.

Name:

Specifies the name of the attribute that defines the filter for dynamic group members in LDAP. For example, memberURL is the name of a commonly used dynamic member attribute.

If both member and dynamic member attributes are specified for the same group type, this group type is a hybrid group with both static and dynamic members.

A dynamic group defines its members differently than a static group. Instead of listing the members individually, the dynamic group defines its members using an LDAP search. The filter for the search is defined in a dynamic member attribute. For example, the dynamic group uses the structural objectclass groupOfURLs, or auxiliary objectclass ibm-dynamicGroup, and the attribute memberURL, to define the search using a simplified LDAP URL syntax:

```
ldap:///<base DN of search>??<scope of search>?<searchfilter>
```

The following is an example of the LDAP URL that defines all entries that are under o=Acme with the objectclass=person:

```
ldap:///o=Acme,c=US??sub?objectclass=person
```

Object class:

Specifies the object class of the group that contains this dynamic member attribute, for example, groupOfURLs. If this property is not defined, the dynamic member attribute applies to all group object classes.

Dynamic member attributes settings:

Use this page to configure Lightweight Directory Access Protocol (LDAP) dynamic member attributes.

To view this administrative console page, complete the following steps:

1. In the administrative console, click **Security > Secure administration, applications, and infrastructure**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Under Related items, click **Manage repositories**.
4. Click **Add** to specify a new external repository or select an external repository that is preconfigured.
5. Under Additional properties, click **Group attribute definition**.
6. Under Additional properties, click **Dynamic member attributes**.
7. Click **New** to specify a new dynamic member attribute.

When you finish adding or updating your federated repository configuration, go to the **Security > Secure administration, applications, and infrastructure** panel and click **Apply** to validate the changes.

Name of dynamic member attribute:

Specifies the name of the attribute that defines the filter for dynamic group members in LDAP. For example, memberURL is the name of a commonly used dynamic member attribute.

If both member and dynamic member attributes are specified for the same group type, this group type is a hybrid group with both static and dynamic members.

A dynamic group defines its members differently than a static group. Instead of listing the members individually, the dynamic group defines its members using an LDAP search. The filter for the search is defined in a dynamic member attribute. For example, the dynamic group uses the structural objectclass `groupOfURLs`, or auxiliary objectclass `ibm-dynamicGroup`, and the attribute `memberURL`, to define the search using a simplified LDAP URL syntax:

```
ldap:///<base DN of search>??<scope of search>?<searchfilter>
```

The following is an example of the LDAP URL that defines all entries that are under `o=Acme` with the `objectclass=person`:

```
ldap:///o=Acme,c=US??sub?objectclass=person
```

Dynamic object class:

Specifies the object class of the group that contains this dynamic member attribute, for example, `groupOfURLs`. If this property is not defined, the dynamic member attribute applies to all group object classes.

Local operating system registries

With the registry implementation for the local operating system, the WebSphere Application Server authentication mechanism can use the user accounts database of the local operating system.

If you want to use the local operating system registry to represent the principals who access your WebSphere Application Server resources, you do not have to complete any special user registry setup steps. The local operating system registry is used for authentication and authorization of users who access WebSphere Application Server resources, but not for WebSphere Application Server users who access operating system resources. WebSphere Application Server does not run under the operating system user profile of Application Server users. Instead, WebSphere Application Server runs under the operating system profile that is configured by the Application Server administrator.

If you want to authorize a user for any WebSphere Application Server resource, a user profile for that user must exist in the operating system. Use the Create User Profile (CRTUSRPRF) command to create new user IDs that can be used by WebSphere Application Server

Do not use a local operating system registry in a WebSphere Application Server environment where application servers are dispersed across more than one machine because each machine has its own user registry.

As mentioned previously, the access IDs taken from the user registry are used during authorization checks. Because these IDs are typically unique identifiers, they vary from machine to machine, even if the exact users and passwords exist on each machine.

Web client certificate authentication is not currently supported when using the local operating system user registry. However, Java client certificate authentication does function with a local operating user registry. Java client certificate authentication maps the first attribute of the certificate domain name to the user ID in the user registry.

Even though Java client certificates function correctly, the following error displays in the `SystemOut.log` file:

```
CWSCJ0337E: The mapCertificate method is not supported
```

The error is intended for Web client certificates; however, it also displays for Java client certificates. Ignore this error for Java client certificates.

Using either the local or the domain user registry. If you want to access users and groups from either the local or the domain user registry, instead of both, set the `com.ibm.websphere.registry.UseRegistry` property. This property can be set to either `local` or `domain`. When this property is set to `local` (case insensitive) only the local user registry is used. When this property is set to `domain`, (case insensitive) only the domain user registry is used.

Set this property by completing the following steps to access the **Custom Properties** panel in the administrative console:

1. Click **Security > Secure administration, applications, and infrastructure**
2. Under User account repository, click the **Available realm definitions** drop-down list, select **Local operating system**, and click **Configure**.
3. Under Additional properties, click **Custom properties**.

You can also use `wsadmin` to configure this property. When the property is set, the privilege requirement for the user who is running the product process does not change. For example, if this property is set to `local`, the user that is running the process requires the same privilege, as if the property was not set.

Standalone Lightweight Directory Access Protocol registries

A Standalone Lightweight Directory Access Protocol (LDAP) registry performs authentication using an LDAP binding.

WebSphere Application Server security provides and supports the implementation of most major LDAP directory servers, which can act as the repository for user and group information. These LDAP servers are called by the product processes for authenticating a user and other security-related tasks. For example, the servers are used to retrieve user or group information. This support is provided by using different user and group filters to obtain the user and group information. These filters have default values that you can modify to fit your needs. The custom LDAP feature enables you to use any other LDAP server, which is not in the product-supported list of LDAP servers, for its user registry by using the appropriate filters.

To use LDAP as the user registry, you need to know a administrative user name that is defined in the registry, the server host and port, the base distinguished name (DN) and, if necessary, the bind DN and the bind password. You can choose any valid user in the registry that is searchable and have administrative privileges. In some LDAP servers, the administrative users are not searchable and cannot be used, for example, `cn=root` in SecureWay. This user is referred to as WebSphere Application Server security server ID, server ID, or server user ID in the documentation. Being a server ID means a user has special privileges when calling some protected internal methods. Normally, this ID and password are used to log into the administrative console after security is turned on. You can use other users to log in if those users are part of the administrative roles.

When security is enabled in the product, the primary administrative user name and password are authenticated with the registry during the product startup. If authentication fails, the server does not start. It is important to choose an ID and password that do not expire or change often. If the product server user ID or password need to change in the registry, make sure that the changes are performed when all the product servers are up and running.

When the changes are done in the registry, use the steps that are described in “Configuring Lightweight Directory Access Protocol user registries” on page 92. Change the ID, password, and other configuration information, save, stop, and restart all the servers so that the new ID or password is used by the product. If any problems occur starting the product when security is enabled, disable security before the server can start up. To avoid these problems, make sure that any changes in this panel are validated in the Secure administration, applications, and infrastructure panel. When the server is up, you can change the ID, password, and other configuration information and then enable security.

You can use the custom Lightweight Directory Access Protocol (LDAP) feature to support any LDAP server by setting up the correct configuration. However, support is not extended to these custom LDAP servers because many configuration possibilities exist.

The users and groups and security role mapping information is used by the configured authorization engine to perform access control decisions.

Dynamic groups and nested group support

Dynamic and nested groups simplify WebSphere Application Server security management and increase its effectiveness and flexibility.

Dynamic groups contain a group name and membership criteria:

- The group membership information is as current as the information on the user object.
- There is no need to manually maintain members on the group object.
- Dynamic groups are designed so an application does not need a large amount of information from the directory to find out if someone is a member of a group.

Nested groups enable the creation of hierarchical relationships that are used to define inherited group membership. A nested group is defined as a child group entry whose distinguished name (DN) is referenced by a parent group entry attribute.

You only need to assign a larger parent group if all nested groups share the same privilege. Assigning a role to a single parent group simplifies the run-time authorization table.

Dynamic groups and nested group support for the IBM Tivoli Directory Server:

Dynamic and nested groups simplify WebSphere Application Server security management and increase its effectiveness and flexibility.

WebSphere Application Server supports all Lightweight Directory Access Protocol (LDAP) dynamic and nested groups when using IBM Tivoli Directory Server. This function is enabled by default by taking advantage of a new feature in IBM Tivoli Directory Server. IBM Tivoli Directory Server uses the `ibm-allGroups` forward-reference group attribute that automatically calculates all the group memberships including dynamic and recursive memberships for a user. Security directly locates a user group membership from a user object rather than indirectly search all the groups to match group members.

For more information, see “Configuring dynamic and nested group support for the IBM Tivoli Directory Server” on page 111.

IBM Directory Services is the IBM Directory Server product that runs on the i5/OS platform. IBM Directory Server ships with either OS/400 Version 5 Release 2 or i5/OS Version 5 Release 3 and later. Fixes are required to provide full LDAP Version 5.1 support. For more information about IBM Directory Services and the necessary fixes, see *iSeries Directory Services (LDAP): New V5R2 Enhancements*.

When you create groups, ensure that nested and dynamic group memberships work correctly.

Attention: Configure IBM Directory Services Version 5 Release 1 and earlier in WebSphere Application Server as the SecureWay directory type. Dynamic and nested groups are not supported in these previous releases of IBM Directory Services.

Dynamic and nested group support for the SunONE or iPlanet Directory Server:

Dynamic and nested groups simplify WebSphere Application Server security management and increase its effectiveness and flexibility.

The SunONE or iPlanet Directory Server uses two grouping mechanisms:

Groups

Entries that name other entries as a list of members or as a filter for members.

Roles Entries that name other entries as a list of members or as a filter for members. Additional functionality is provided by generating the `nsrole` attribute on each role member.

Three types of roles are available:

Filtered roles

Depends upon the attributes that are contained in each entry. Entries are members, if they match a specified Lightweight Directory Access Protocol (LDAP) filter. This role is equivalent to a dynamic group.

Nested roles

Creates roles that contain other roles. This role is equivalent to a nested group.

Managed roles

Explicitly assigns a role to member entries. This role is equivalent to a static group.

Refer to “Configuring dynamic and nested group support for the SunONE or iPlanet Directory Server” on page 110 for more information.

Security failover among multiple LDAP servers

WebSphere Application Server security can be configured to attempt failovers between multiple Lightweight Directory Access Protocol (LDAP) hosts.

If the current active LDAP server is unavailable, WebSphere Application Server security attempts a failover to the first available LDAP host in the specified host list. The multiple LDAP servers can be replicas of the same master LDAP server, or they can be any LDAP host with the same schema, which contain data that is imported from the same LDAP Data Interchange Format (LDIF) file.

Whenever a failover occurs, WebSphere Application Server security always uses the first available LDAP server in the specified host list. For example, if there are four LDAP servers configured in the order of L1, L2, L3, and L4, L1 is treated as the primary LDAP server. The preference of connection is from L1 to L4. If, for example, WebSphere Application Server security is currently connected to L4, and failover or reconnection is necessary, WebSphere Application Server security first attempts to connect to L1, L2, and then L3 in that order until the connection is successful.

The current LDAP host name is logged in message `CWSCJ0419I` in the WebSphere Application Server log file, `SystemOut.log`. If you want to reconnect to the primary LDAP host, run the WebSphere Application Server MBean method, `resetLDAPBindInfo`, with `null,null` as the input.

To configure LDAP failover among multiple LDAP hosts, you must use `wsadmin` or `ConfigService` to include the backup LDAP host, which does not have a number limitation. The LDAP host that is displayed in the administrative console is the primary LDAP host, and is the first item listed in the LDAP host list in `security.xml`.

The WebSphere Application Server security realm name defaults to the primary LDAP host name that is displayed in the administrative console. It includes a trailing colon and a port number (if one exists). However, the custom property, `com.ibm.websphere.security ldap.logicRealm`, can be added to override the default security realm name. Use the `logicRealm` name to configure each cell to have its own LDAP host for interoperability and backward compatibility, and to provide flexibility for adding or removing the LDAP host dynamically. If migrating from a previous installation, the new `logicRealm` name does not take effect until administrative security is enabled again. To be compatible with a previous release that does not support logic realm, the `logicRealm` name has to be the same as that used by the previous installation (the LDAP host name, including a trailing colon and port number).

The following example shows how to use wsadmin to add a backup LDAP host for failover:

```
proc LDAPAdd {args} {
    global AdminConfig AdminControl ldapServer ldapPort
    set ldapServer [lindex $args 0]
    set ldapPort [lindex $args 1]
    global ldapUserRegistryId
    if {[catch {$AdminConfig list LDAPUserRegistry} result]} {
        puts stdout "\$AdminConfig list LDAPUserRegistry caught an exception $result\n"
        return
    } else {
        if {$result != {}} {
            set ldapUserRegistryId [lindex $result 0]
        } else {
            return;
        }
    }
    set secMbean [[$AdminControl queryNames type=SecurityAdmin,*]
    set Attrs2 [list [list hosts [list [list [list host $ldapServer]
        [list port $ldapPort]]]]]
    $AdminConfig modify $ldapUserRegistryId $Attrs2
    $AdminConfig save
}
```

Federated repositories

Federated repositories enable you to use multiple repositories with WebSphere Application Server. These repositories, which can be file-based repositories, LDAP repositories, or a sub-tree of an LDAP repository, are defined and theoretically combined under a single realm. All of the user repositories that are configured under the federated repository functionality are invisible to WebSphere Application Server.

When you use the federated repositories functionality, all of the configured repositories, which you specify as part of the federated repository configuration, become active. It is recommended that the user ID, and the distinguished name (DN) for an LDAP repository, be unique in multiple user repositories that are configured under the same federated repository configuration. For example, there might be three different repositories that are configured for the federated repositories configuration: Repository A, Repository B, and Repository C. When user1 logs in, the federated repository adapter searches each of the repositories for all of the occurrences of that user. If multiple instances of that user are found in the combined repositories, an error message displays.

In addition, the federated repositories functionality in WebSphere Application Server supports the logical joining of entries across multiple user repositories when the Application Server searches and retrieves entries from the repositories. For example, when an application calls for a sorted list of people whose age is greater than twenty, WebSphere Application searches all of the repositories in the federated repositories configuration. The results are combined and sorted before the Application Server returns the results to the application.

Unlike the local operating system, standalone LDAP registry, or custom registry options, federated repositories provide user and group management with read and write capabilities. When you configure federated repositories, you can use one of the following methods to add, create, and delete users and groups:

Important: If you configure multiple repositories under the federated repositories realm, you must also configure supported entity types and specify a base entry for the default parent. The base entry for the default parent determines the repository location where entities of the specified type are placed on write operations by user and group management. See “Configuring supported entity types in a federated repository configuration” on page 147 for details.

- Use the user management application programming interfaces (API). For more information, refer to articles under “Developing with virtual member manager” in this information center.

- Use the administrative console. To manage users and groups within the administrative console, click **Users and Groups > Manage Users** or **Users and Groups > Manage Groups**. For information on user and group management, click the Help link that displays in the upper right corner of the window. From the left navigation pane, click **Users and Groups**.
- Use the wsadmin commands. For more information, see “Commands for the WIMManagementCommands group of the AdminTask object” on page 778.

If you do not configure the federated repositories functionality or do not enable federated repositories as the active repository, you cannot use the user management capabilities that are associated with federated repositories. You can configure an LDAP server as the active user registry and configure the same LDAP server under federated repositories, but not select federated repositories as the active user repository. With this scenario, authentication takes place using the LDAP server, and you can use the user management functionality for the LDAP server that is available for federated repositories.

The following table compares the federated repository functionality that is available in WebSphere Application Server Version 6.1 with the registry functionality that remains unchanged from previous versions of the Application Server.

Table 3. Federated repositories versus user registry implementations

Federated repositories	User registry
Supports multiple types of repositories such as file-based, LDAP, database, and custom. In WebSphere Application Server Version 6.1, file-based and LDAP repositories are supported by the administrative console. However, the federated repositories functionality does not support local operating system implementations. For database and custom repositories, you can use the wsadmin command-line interface or the configuration application programming interfaces (API).	Supports multiple types of registries such as the local operating system, a standalone LDAP registry, and a standalone custom registry.
Supports multiple repositories in a realm within a cell.	Supports one registry only in a realm within a cell.
Provides read and write capabilities for the repositories that are defined in the federated repository configuration.	Provides read only capability for the registries.
Provides account and password policy support as defined by the registry type. However, this support is not provided by the federated repository functionality.	Provides account and password policy support as defined by the registry type.
Supports identity profiles.	Does not support identity profiles.
Uses the custom UserRegistry implementation.	Uses the custom UserRegistry implementation.

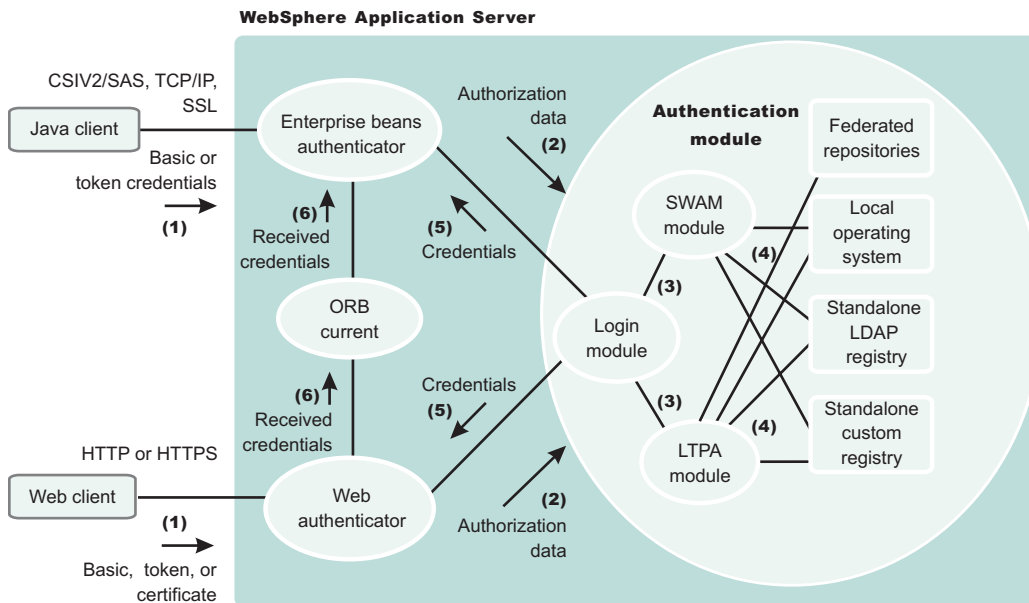

Authentication mechanisms

An *authentication mechanism* defines rules about security information, such as whether a credential is forwardable to another Java process, and the format of how security information is stored in both credentials and tokens.

Authentication is the process of establishing whether a client is who or what it claims to be in a particular context. A client can be either an end user, a machine, or an application. An authentication mechanism in WebSphere Application Server typically collaborates closely with a *user registry*. The user registry is the user and groups account repository that the authentication mechanism consults with when performing authentication. The authentication mechanism is responsible for creating a *credential*, which is an internal product representation of a successfully authenticated client user. Not all credentials are created equally. The abilities of the credential are determined by the configured authentication mechanism.

LTPA is the only authentication mechanism available in a Network Deployment environment.

Authentication

Authentication process

The figure demonstrates the authentication process. Authentication is required for enterprise bean clients and Web clients when they access protected resources. Enterprise bean clients, like a servlet or other enterprise beans or a pure client, send the authentication information to a Web application server using one of the following protocols: **V6.0.x**

- Common Secure Interoperability Version 2 (CSlv2)
- Secure Authentication Service (SAS)

Important: SAS is supported only between Version 6.0.x and previous version servers that have been federated in a Version 6.1 cell.

Web clients use the HTTP or HTTPS protocol to send the authentication information, as shown in the previous figure.

The authentication information can be basic authentication (user ID and password), a credential token (in the case of Lightweight Third Party Authentication (LTPA)), or a client certificate. The Web authentication is performed by the Web Authentication module.

You can configure Web authentication for a Web client by using the administrative console. Click **Security > Secure administration and applications**. Under Authentication, expand **Web security** and click **General settings**. The following options exist for Web authentication:

Authenticate only when the URI is protected

Specifies that the Web client can retrieve an authenticated identity only when it accesses a protected Uniform Resource Identifier (URI). WebSphere Application Server challenges the Web client to provide authentication data when the Web client accesses a URI that is protected by a J2EE role. This default option is also available in previous versions of WebSphere Application Server.

Use available authentication data when an unprotected URI is accessed

Specifies that the Web client is authorized to call the `getRemoteUser`, `isUserInRole`, and `getUserPrincipal` methods; retrieves an authenticated identity from either a protected or an

unprotected URI. Although the authentication data is not used when you access an unprotected URI, the authentication data is retained for future use. This option is available when you select the **Authentication only when the URI is protected** check box.

Authenticate when any URI is accessed

Specifies that the Web client must provide authentication data regardless of whether the URI is protected.

Default to basic authentication when certificate authentication for the HTTPS client fails.

Specifies that WebSphere Application Server challenges the Web client for a user ID and password when the required HTTPS client certificate authentication fails.

V6.0.x The enterprise bean authentication is performed by the Enterprise JavaBean (EJB) authentication module, which resides in the CSIv2 and SAS layer.

The authentication module is implemented using the Java Authentication and Authorization Service (JAAS) login module. The Web authenticator and the EJB authenticator pass the authentication data to the login module (2), which uses LTPA to authenticate the data.

The authentication module uses the registry that is configured on the system to perform the authentication (4). Four types of registries are supported:

- Federated repositories
- Local operating system
- Standalone Lightweight Directory Access Protocol (LDAP) registry
- Standalone custom registry

External registry implementation following the registry interface that is specified by IBM can replace either the local operating system or the LDAP registry.

The login module creates a JAAS subject after authentication and stores the credential that is derived from the authentication data in the public credentials list of the subject. The credential is returned to the Web authenticator or to the enterprise beans authenticator (5).

The Web authenticator and the enterprise beans authenticator store the received credentials in the Object Request Broker (ORB) current for the authorization service to use in performing further access control checks. If the credentials are forwardable, they are sent to other application servers.

Portlet URL security

WebSphere Application Server enables direct access to portlet Uniform Resource Locators (URLs), just like servlets. This section describes security considerations when accessing portlets using URLs.

For security purposes, portlets are treated similar to servlets. Most portlet security uses the underlying servlet security mechanism. However, portlet security information resides in the `portlet.xml` file, while the servlet and JavaServer Pages files reside in the `web.xml` file. Also, when you make access decisions for portlets, the security information, if any, in the `web.xml` file is combined with the security information in the `portlet.xml` file.

Portlet security must support both programmatic security, that is `isUserInRole`, and declarative security. The programmatic security is exactly the same as for servlets. However, for portlets, the `isUserInRole` method uses the information from the `security-role-ref` element in `portlet.xml`. The other two methods used by programmatic security, `getRemoteUser` and `getUserPrincipal`, behave the same way as they do when accessing a servlet. Both of these methods return the authenticated user information accessing the portlet.

The declarative security aspect of the portlets is defined by the security-constraint information in the `portlet.xml` file. This is similar to the security-constraint information used for the servlets in the `web.xml` file with the following differences:

- The `auth-constraint` element, which lists the names of the roles that can access the resources, does not exist in the `portlet.xml` file. The `portlet.xml` file contains only the `user-data-constraint` element, which indicates what type of transport layer security (HTTP or HTTPS) is required to access the portlet.
- The security-constraint information in the `portlet.xml` file contains the `portlet-collection` element, while the `web.xml` file contains the `web-resource-collection` element. The `portlet-collection` element contains only a list of simple portlet names, while the `web-resource-collection` contains the `url-patterns` as well as the HTTP methods that need protection.

The portlet container does not deal with the user authentication directly. For example, it does not prompt you to collect the credential information. The portlet container must, instead, use the underlying servlet container for the user authentication mechanism. As a result, there is no `auth-constraint` element in the security-constraint information in the `portlet.xml` file.

In WebSphere Application Server, when a portlet is accessed using a URL, the user authentication is processed based on the security-constraint information for that portlet in the `web.xml` file. This implies that to authenticate a user for a portlet, the `web.xml` file must contain the security-constraint information for that portlet with the relevant `auth-constraints` contained in it. If a corresponding `auth-constraint` for the portlet does not exist in the `web.xml` file, it indicates that the portlet is not required to have authentication. In this case, unauthenticated access is permitted just like a URL pattern for a servlet that does not contain any `auth-constraints` in the `web.xml` file. An `auth-constraint` for a portlet can be specified directly by using the portlet name in the `url-pattern` element, or indirectly by a `url-pattern` that implies the portlet.

Note: You cannot have a servlet or JSP with the same name as a portlet for WebSphere Application Server security to work with portlet.

The following examples demonstrate how the security-constraint information contained in the `portlet.xml` and `web.xml` files in a portlet application are used to make security decisions for portlets. The `security-role-ref` element, which is used for `isUserInRole` calls, is not discussed here because it is used the same way for servlets.

In the examples below (unless otherwise noted), there are four portlets (`MyPortlet1`, `MyPortlet2`, `MyPortlet3`, `MyPortlet4`) defined in `portlet.xml`. The portlets are secured by combining the information, if any, in the `web.xml` file when they are accessed directly through URLs.

All of the examples show the contents of the `web.xml` and `portlet.xml` files. Use the correct tools when creating these deployment descriptor files as you normally would when assembling a portlet application.

Example 1: The `web.xml` file does not contain any security-constraint data

In the following example, the security-constraint information is contained in `portlet.xml`:

```
<security-constraint id="SecurityConstraint_1">
  <web-resource-collection id="WebResourceCollection_1">
    <web-resource-name>Protected Area</web-resource-name>
    <url-pattern>/*</url-pattern>
  </web-resource-collection>
  <auth-constraint id="AuthConstraint_1">
    <role-name>Manager</role-name>
  </auth-constraint>
</security-constraint>
```

In this example, when you access anything under `MyPortlet1` and `MyPortlet3`, and these portlets are accessed using the unsecured HTTP protocol, you are redirected through the secure HTTPS protocol. The `transport-guarantee` is set to use secure connections. For `MyPortlet2` and `MyPortlet4`, unsecured (HTTP) access is permitted because the `transport-guarantee` is not set. There is no corresponding

security-constraint information for all four portlets in the `web.xml` file. Therefore, all of the portlets can be accessed without any user authentication and role authorization. The only security involved in this instance is the transport-layer security using Secure Sockets Layer (SSL) for MyPortlet1 and MyPortlet3.

The following table lists the security constraints that are applicable to the individual portlets.

URL	Transport Protection	User Authentication	Role Based Authorization
/MyPortlet1/*	HTTPS	None	None
/MyPortlet2/*	None	None	None
/MyPortlet3/*	HTTPS	None	None
/MyPortlet4/*	None	None	None

Example 2: The `web.xml` file contains portlet specific security-constraint data

In the following example, the security-constraint information that corresponds to the portlet is contained in `web.xml`. The `portlet.xml` file is the same as that shown in the previous example.

```
<security-constraint id="SecurityConstraint_1">
  <web-resource-collection id="WebResourceCollection_1">
    <web-resource-name>Protected Area</web-resource-name>
    <url-pattern>/MyPortlet1/*</url-pattern>
    <url-pattern>/MyPortlet2/*</url-pattern>
  </web-resource-collection>
  <auth-constraint id="AuthConstraint_1">
    <role-name>Employee</role-name>
  </auth-constraint>
</security-constraint>
```

The security-constraint information contained in the `web.xml` file in this example indicates that the user authentication must be performed when accessing anything under the MyPortlet1 and MyPortlet2 portlets. When you attempt to access these portlets directly using URLs, and there is no authentication information available, you are prompted to enter their credentials. After you are authenticated, the authorization check is performed to see if you are listed in the Employee role. The user/group to role mapping is assigned during the portlet application deployment. In the `web.xml` file listed above, note the following:

- Because the `web.xml` file uses `url-pattern`, the portlet names have been modified slightly. MyPortlet1 is now `/MyPortlet1/*`, which indicates that everything under the MyPortlet1 URL is protected. This matches the information in the `portlet.xml` file because the security runtime code converts the `portlet-name` element in the `portlet.xml` file to `url-pattern` (for example, MyPortlet1 to `/MyPortlet1/*`), even for the `transport-guarantee`.
- The `http-method` element in the `web.xml` file is not used in the example because all HTTP methods must be protected.

The following table lists the new security constraints that are applicable to the individual portlets.

URL	Transport Protection	User Authentication	Role Based Authorization
MyPortlet1/*	HTTPS	Yes	Yes (Employee)
MyPortlet2/*	None	Yes	Yes (Employee)
MyPortlet3/*	HTTPS	None	None
MyPortlet4/*	None	None	None

Example 3: The `web.xml` file contains generic security-constraint data implying all portlets.

In the following example, the security-constraint information is contained in the `web.xml` file that corresponds to the portlet. The `portlet.xml` file is the same as that shown in the first example.

```

<security-constraint id="SecurityConstraint_1">
  <web-resource-collection id="WebResourceCollection_1">
    <web-resource-name>Protected Area</web-resource-name>
    <url-pattern>*/</url-pattern>
  </web-resource-collection>
  <auth-constraint id="AuthConstraint_1">
    <role-name>Manager</role-name>
  </auth-constraint>
</security-constraint>

```

In this example, /* implies that all resources that do not contain their own explicit security-constraints should be protected by the Manager role as per the URL pattern matching rules. Because the portlet.xml file contains explicit security-constraint information for MyPortlet1 and MyPortlet3, these two portlets are not protected by the Manager role, only by the HTTPS transport. Because the portlet.xml file cannot contain the auth-constraint information, any portlets that contain security-constraints in it are rendered unprotected when an implying URL (/* for example) is listed in the web.xml file because of the URL matching rules.

In the case above, both MyPortlet1 and MyPortlet3 can be accessed without user authentication. However, because MyPortlet2 and MyPortlet4 do not have security-constraints in the portlet.xml file, the /* pattern is used to match these portlets and are protected by the Manager role, which requires user authentication.

The following table lists the new security constraints that are applicable to the individual portlets with this setup.

URL	Transport Protection	User Authentication	Role Based Authorization
MyPortlet1/*	HTTPS	None	None
MyPortlet2/*	None	Yes	Yes (Manager)
MyPortlet3/*	HTTPS	None	None
MyPortlet4/*	None	Yes	Yes (Manager)

If in the example above, if you must also protect a portlet contained in the portlet.xml file (for example, MyPortlet1), the web.xml file should contain an explicit security-constraint entry in addition to /* as shown in the following example:

```

<security-constraint id="SecurityConstraint_1">
  <web-resource-collection id="WebResourceCollection_1">
    <web-resource-name>Protected Area</web-resource-name>
    <url-pattern>*/</url-pattern>
  </web-resource-collection>
  <auth-constraint id="AuthConstraint_1">
    <role-name>Manager</role-name>
  </auth-constraint>
</security-constraint>
<security-constraint id="SecurityConstraint_2">
  <web-resource-collection id="WebResourceCollection_2">
    <web-resource-name>Protection for MyPortlet1</web-resource-name>
    <url-pattern>/MyPortlet1/*</url-pattern>
  </web-resource-collection>
  <auth-constraint id="AuthConstraint_1">
    <role-name>Manager</role-name>
  </auth-constraint>
</security-constraint>

```

In this case, MyPortlet1 is protected by the Manager role and requires authentication. The data-constraint of CONFIDENTIAL is also applied to it because the information in the web.xml file and the portlet.xml file are combined. Because MyPortlet3 is not explicitly listed in the web.xml file, it is still not protected by the Manager role and does not require user authentication.

The following table shows the effect of this change.

URL	Transport Protection	User Authentication	Role Based Authorization
MyPortlet1/*	HTTPS	Yes	Yes (Manager)
MyPortlet2/*	None	Yes	Yes (Manager)
MyPortlet3/*	HTTPS	None	None
MyPortlet4/*	None	Yes	Yes (Manager)

Lightweight Third Party Authentication

Lightweight Third Party Authentication (LTPA) is intended for distributed, multiple application server and machine environments. LTPA supports forwardable credentials and single sign-on (SSO). LTPA can support security in a distributed environment through cryptography. This support permits LTPA to encrypt, digitally sign, and securely transmit authentication-related data, and later decrypt and verify the signature.

Application servers distributed in multiple nodes and cells can securely communicate using the LTPA protocol. It also provides the single sign-on (SSO) feature wherein a user is required to authenticate only once in a domain name system (DNS) domain and can access resources in other WebSphere Application Server cells without getting prompted. The realm names on each system in the DNS domain are case sensitive and must match identically.

For local OS, the realm name is the same as the host name.

For the Lightweight Directory Access Protocol (LDAP), the realm name is the host:port value of the LDAP server.

The LTPA protocol uses cryptographic keys to encrypt and decrypt user data that passes between the servers. These keys must be shared between the different cells for the resources in one cell to access resources in other cells, assuming that all the cells involved use the same LDAP or custom registry.

When using LTPA, a token is created with the user information and an expiration time and is signed by the keys. The LTPA token is time sensitive. All product servers that participate in a protection domain must have their time, date, and time zone synchronized. If not, LTPA tokens appear prematurely expired and cause authentication or validation failures.

This token passes to other servers, in the same cell or in a different cell through cookies, for Web resources when SSO is enabled, or through the authentication protocol layer for enterprise beans.

If the receiving servers share the same keys as the originating server, the token can be decrypted to obtain the user information, which then is validated to make sure that it has not expired and that the user information in the token is valid in its registry. On successful validation, the resources in the receiving servers are accessible after the authorization check.

All of the WebSphere Application Server processes in a cell (deployment manager, nodes, application servers) share the same set of keys. If key sharing is required between different cells, export them from one cell and import them to the other. For security purposes, the exported keys are encrypted with a user-defined password. This same password is needed when importing the keys into another cell.

WebSphere Application Server supports the LTPA protocol.

Note: SWAM is deprecated in WebSphere Application Server Version 6.1 and will be removed in a future release.

When security is enabled during profile creation time, LTPA is configured by default.

LTPA requires that the configured user registry be a centrally shared repository such as LDAP or a Windows domain-type registry so that users and groups are the same, regardless of the machine.

The following table summarizes the authentication mechanism capabilities and user registries with which LTPA can work.

	Forwardable credentials	SSO	Local OS user registry	LDAP user registry	Custom user registry
LTPA	Yes	Yes	Yes	Yes	Yes

The use of LTPA with the local OS user registry is only applicable to configurations where all of the servers reside on the same system.

Lightweight Third Party Authentication key sets and key set groups

Key set groups contain lists of key sets and Lightweight Third Party Authentication (LTPA) key generation schedules. Each key set contains key references to keys in key stores. To generate keys automatically, each key set must be a member of a key set group.

The keys for some key configurations must be generated together. The LTPA key pair is referenced in one key set while the secret or private key is in a separate key set. When the key set group is created, the two key sets are added as members of the key set group. Key set group settings determine whether the keys for both key sets are generated together automatically or manually.

The key set group contains the following attributes:

- Member key sets
- Choice of either manual or automatic key generation in the member key sets
- Schedule for automatically generating keys

Trust associations

Trust association enables the integration of IBM WebSphere Application Server security and third-party security servers. More specifically, a reverse proxy server can act as a front-end authentication server while the product applies its own authorization policy onto the resulting credentials that are passed by the proxy server.

Demand for such an integrated configuration has become more compelling, especially when a single product cannot meet all of the customer needs or when migration is not a viable solution. This article provides a conceptual background behind the approach.

In this setup, WebSphere Application Server is used as a back-end server to further exploit its fine-grained access control. The reverse proxy server passes the HTTP request to WebSphere Application Server that includes the credentials of the authenticated user. WebSphere Application Server then uses these credentials to authorize the request.

Trust association model

The idea that WebSphere Application Server can support trust association implies that the product application security recognizes and processes HTTP requests that are received from a reverse proxy server. WebSphere Application Server and the proxy server engage in a contract in which the product gives its full trust to the proxy server and the proxy server applies its authentication policies on every Web request that is dispatched to WebSphere Application Server. This trust is validated by the interceptors that reside in the product environment for every request received. The method of validation is agreed upon by the proxy server and the interceptor.

Running in trust association mode does not prohibit WebSphere Application Server from accepting requests that did not pass through the proxy server. In this case, no interceptor is needed for validating trust. It is possible, however, to configure WebSphere Application Server to strictly require that all HTTP requests go through a reverse proxy server. In this case, all requests that do not come from a proxy server are immediately denied by WebSphere Application Server.

WebSphere Application Server supports the following trust association interceptor (TAI) interfaces:

com.ibm.ws.security.web.WebSealTrustAssociationInterceptor

This Tivoli TAI interceptor that implements the WebSphere Application Server TAI interface is provided to support WebSEAL Version 4.1. If you plan to use WebSEAL 5.1 or a later version of WebSEAL, it is recommended that you migrate to use the new com.ibm.ws.security.web.TAMTrustAssociationInterceptorPlus interceptor; which implements the new com.ibm.wsspi.security.tai.TrustAssociationInterceptor interface.

com.ibm.ws.security.web.TAMTrustAssociationInterceptorPlus

This TAI interceptor implementation that implements the new WebSphere Application Server interface supports WebSphere Application Server Version 5.1.1 and later. The interface supports WebSEAL Version 5.1 and later, but does not support WebSEAL Version 4.1. For an explanation of security attribute propagation, see “Security attribute propagation” on page 188

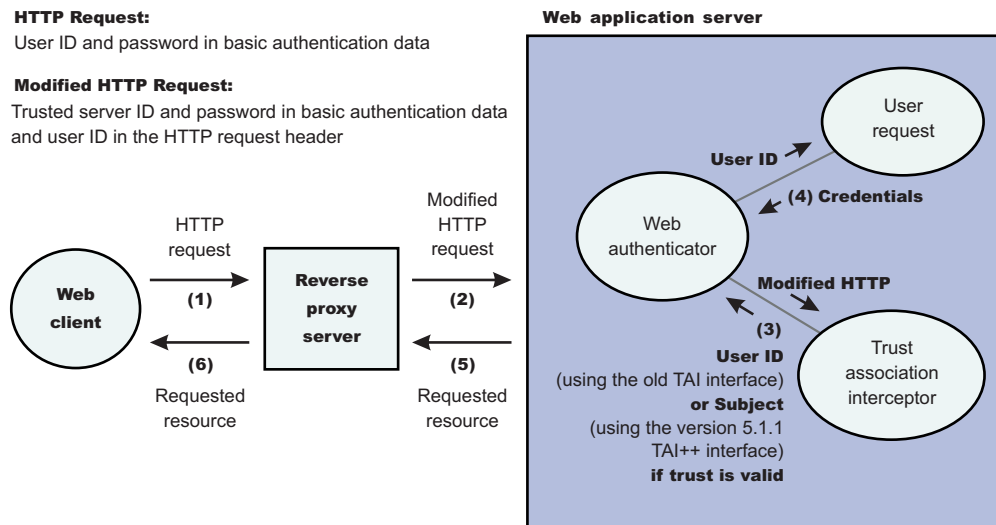

Trust association model

HTTP Request:

User ID and password in basic authentication data

Modified HTTP Request:

Trusted server ID and password in basic authentication data and user ID in the HTTP request header

IBM WebSphere Application Server: WebSEAL Integration

The integration of WebSEAL and WebSphere Application Server security is achieved by placing the WebSEAL server at the front-end as a reverse proxy server. From a WebSEAL management perspective, a junction is created with WebSEAL on one end, and the product Web server on the other end. A junction is a logical connection that is created to establish a path from the WebSEAL server to another server.

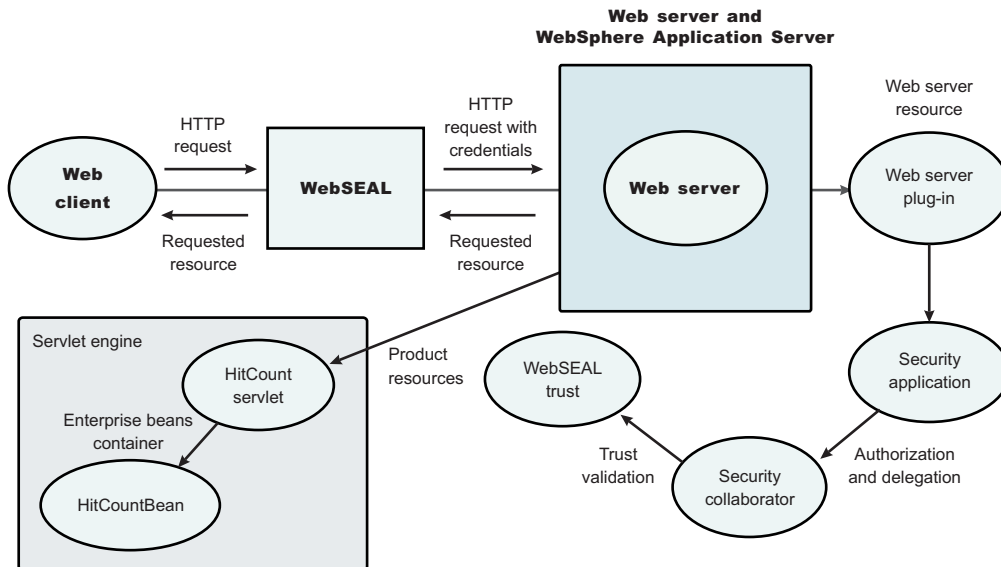

In this setup, a request for Web resources that are stored in a protected domain of the product is submitted to the WebSEAL server where it is authenticated against the WebSEAL security realm. If the requesting user has access to the junction, the request is transmitted to the WebSphere Application Server HTTP server through the junction, and then to the application server.

Meanwhile, WebSphere Application Server validates every request that comes through the junction to ensure that the source is a trusted party. This process is referenced as *validating the trust* and it is performed by a WebSEAL product-designated interceptor. If the validation is successful, WebSphere

Application Server authorizes the request by checking whether the client user has the required permissions to access the Web resource. If so, the Web resource is delivered to the WebSEAL server through the Web server, which then gives the resource to the client user.

WebSEAL server

The policy director delegates all of the Web requests to its Web component, the WebSEAL server. One of the major functions of the server is to perform authentication of the requesting user. The WebSEAL server consults a Lightweight Directory Access Protocol (LDAP) directory. It can also map the original user ID to another user ID, such as when global single sign-on (GSO) is used.

For successful authentication, the server plays the role of a client to WebSphere Application Server when channeling the request. The server needs its own user ID and password to identify itself to WebSphere Application Server. This identity must be valid in the security realm of WebSphere Application Server. The WebSEAL server replaces the basic authentication information in the HTTP request with its own user ID and password. In addition, WebSphere Application Server must determine the credentials of the requesting client so that the application server has an identity to use as a basis for its authorization decisions. This information is transmitted through the HTTP request by creating a header called `iv-creds`, with the Tivoli Access Manager user credentials as its value.

HTTP server

The junction that is created in the WebSEAL server must get to the HTTP server that serves as the product front end. However, the HTTP server is shielded from knowing that trust association is used. As far as it is concerned, the WebSEAL product is just another HTTP client, and as part of its normal routines, it sends the HTTP request to the product. The only requirement on the HTTP server is a Secure Sockets Layer (SSL) configuration using server authentication only. This requirement protects the requests that flow within the junction.

Web collaborator

When trust association is enabled, the Web collaborator manages the interceptors that are configured in the system. The Web collaborator loads and initializes these interceptors when you restart your servers. When a request is passed to WebSphere Application Server by the Web server, the Web collaborator eventually receives the request for a security check. Two actions must take place:

1. The request must be authenticated.
2. The request must be authorized.

The Web authenticator is called to authenticate the request by passing the HTTP request. If successful, a good credential record is returned by the authenticator, which the Web collaborator uses to base its authorization for the requested resource. If the authorization succeeds, the Web collaborator indicates to WebSphere Application Server that the security check has succeeded and that the requested resource can be served.

Web authenticator

The Web authenticator is asked by the Web collaborator to authenticate a given HTTP request. Knowing that trust association is enabled, the task of the Web authenticator is to find the appropriate trust association interceptor to direct the request for processing. The Web authenticator queries every available interceptor. If no target interceptor is found, the Web authenticator processes the request as though trust association is not enabled.

For an HTTP request sent by the WebSEAL server, the WebSEAL trust association interceptor replies with a positive response to the Web authenticator. Subsequently, the interceptor is asked to validate its trust association with the WebSEAL server and retrieve the Subject, using the new trust association interceptor (TAI) interface, or user ID, using the old TAI interface, of the original user client.

Note: The new Trust Association Interceptor (TAI) interface, `com.ibm.wsspi.security.tai.TrustAssociationInterceptor`, supports several new features and is different from the existing `com.ibm.websphere.security.TrustAssociationInterceptor` interface.

WebSphere Application Server Version 4 through WebSphere Application Server Version 5.x support the `com.ibm.websphere.security.TrustAssociationInterceptor.java` interface. WebSphere Application Server Version 6.0.x and later supports the `com.ibm.wsspi.security.tai.TrustAssociationInterceptor` interface.

Trust association interceptor interface

The intent of the trust association interceptor interface is to have reverse proxy security servers (RPSS) exist as the exposed entry points to perform authentication and coarse-grained authorization, while WebSphere Application Server enforces further fine-grained access control. Trust associations improve security by reducing the scope and risk of exposure.

In a typical e-business infrastructure, the distributed environment of a company consists of Web application servers, Web servers, existing systems, and one or more RPSS, such as the Tivoli WebSEAL product. Such reverse proxy servers, front-end security servers, or security plug-ins registered within Web servers, guard the HTTP access requests to the Web servers and the Web application servers. While protecting access to the Uniform Resource Identifiers (URIs), these RPSS perform authentication, coarse-grained authorization, and request routing to the target application server.

Using the trust association interceptor feature

The following points further describe the benefits of the trust association interceptor (TAI) feature:

- RPSS can authenticate WebSphere Application Server users up front and send credential information about the authenticated user to the product so that the product can trust the RPSS to perform authentication and not prompt the end user for authentication data later. The strength of the trust relationship between RPSS and the product is based on the criteria of trust association that is particular to RPSS and enforced through the TAI implementation. This level of trust might need relaxing based on the environment. Be aware of the vulnerabilities in cases where the RPSS is not trusted, based on a security technology.
- The end user credentials most likely are sent in a special format as part of the Hypertext Transfer Protocol (HTTP) headers as in the case of RPSS authentication. The credentials can be a special header or a cookie. The data that passes is implementation specific, and the TAI feature considers this fact and accommodates the idea. The TAI implementation works with the credential data and returns a Subject, using the new TAI interface, or a user ID, using the old TAI interface that represents the end user. WebSphere Application Server uses the information to enforce security policies.

Single sign-on

With single sign-on (SSO) support, Web users can authenticate once when accessing both WebSphere Application Server resources, such as HTML, JavaServer Pages (JSP) files, servlets, enterprise beans, and Lotus Domino resources, such as documents in a Domino database, or accessing resources in multiple WebSphere Application Server domains.

Application servers distributed in multiple nodes and cells can securely communicate using the Lightweight Third Party Authentication (LTPA) protocol. LTPA is intended for distributed, multiple application server and machine environments. LTPA can support security in a distributed environment through cryptography. This support permits LTPA to encrypt, digitally sign, and securely transmit authentication-related data, and later decrypt and verify the signature.

LTPA also provides the SSO feature wherein a user is required to authenticate only once in a domain name system (DNS) domain and can access resources in other WebSphere Application Server cells without getting prompted. Web users can authenticate once to a WebSphere Application Server or to a Domino server. This authentication is accomplished by configuring WebSphere Application Servers and the Domino servers to share authentication information.

Without logging in again, Web users can access other WebSphere Application Servers or Domino servers in the same DNS domain that are enabled for SSO. You can enable SSO among WebSphere Application Servers by configuring SSO for WebSphere Application Server. To enable SSO between WebSphere Application Servers and Domino servers, you must configure SSO for both WebSphere Application Server and for Domino.

Prerequisites and conditions

To take advantage of support for SSO between WebSphere Application Servers or between WebSphere Application Server and a Domino server, applications must meet the following prerequisites and conditions:

- Verify that all servers are configured as part of the same DNS domain. The realm names on each system in the DNS domain are case sensitive and must match identically. For example, if the DNS domain is specified as `mycompany.com`, then SSO is effective with any Domino server or WebSphere Application Server on a host that is part of the `mycompany.com` domain, for example, `a.mycompany.com` and `b.mycompany.com`.
- Verify that all servers share the same registry.

This registry can be either a supported Lightweight Directory Access Protocol (LDAP) directory server or, if SSO is configured between two WebSphere Application Servers, a standalone custom registry. Domino servers do not support standalone custom registries, but you can use a Domino-supported registry as a standalone custom registry within WebSphere Application Server.

You can use a Domino directory that is configured for LDAP access or other LDAP directories for the registry. The LDAP directory product must have WebSphere Application Server support. Supported products include both Domino and LDAP servers, such as IBM Tivoli Directory Server. Regardless of the choice to use an LDAP or a standalone custom registry, the SSO configuration is the same. The difference is in the configuration of the registry.
- Define all users in a single LDAP directory. Using LDAP referrals to connect more than one directory together is not supported. Using multiple Domino directory assistance documents to access multiple directories also is not supported.
- Enable HTTP cookies in browsers because the authentication information that is generated by the server is transported to the browser in a cookie. The cookie is used to propagate the authentication information for the user to other servers, exempting the user from entering the authentication information for every request to a different server.
- For a Domino server:
 - Domino Release 6.5.4 for iSeries and other platforms are supported.
 - A Lotus Notes client Release 5.0.5 or later is required for configuring the Domino server for SSO.
 - You can share authentication information across multiple Domino domains.
- For WebSphere Application Server:
 - WebSphere Application Server Version 3.5 or later for all platforms are supported.
 - You can use any HTTP Web server that is supported by WebSphere Application Server.
 - You can share authentication information across multiple product administrative domains.
 - Basic authentication (user ID and password) using the basic and form-login mechanisms is supported.
 - By default, WebSphere Application Server does a case-sensitive comparison for authorization. This comparison implies that a user who is authenticated by Domino matches the entry exactly (including the base distinguished name) in the WebSphere Application Server authorization table. If case sensitivity is not considered for the authorization, enable the **Ignore Case** property in the LDAP user registry settings.

Single sign-on for HTTP requests using SPNEGO

WebSphere Application Server provides a trust association interceptor (TAI) that uses the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) to securely negotiate and authenticate HTTP requests for secured resources in WebSphere Application Server.

SPNEGO is a standard specification defined in The Simple and Protected GSS-API Negotiation Mechanism (IETF RFC 2478).

When WebSphere Application Server administrative security is enabled, the SPNEGO TAI is initialized. While processing inbound HTTP requests, the Web authenticator component interacts with the SPNEGO TAI, which is defined and enabled in the security configuration repository. One interceptor is selected and is responsible for authenticating access to the secured resource that is identified in the HTTP request.

Important: The use of TAIs is an optional feature. If no TAI is selected, the authentication process continues normally.

HTTP users log in and authenticate only once at their desktop and are subsequently authenticated (internally) with WebSphere Application Server. The SPNEGO TAI is invisible to the end-user of WebSphere applications. The SPNEGO TAI is only visible to the Web administrator who is responsible for ensuring a proper configuration, capacity, and maintenance of the Web environment.

In addition to WebSphere Application Server security runtime services, some external components are required to completely enable operation of the SPNEGO TAI. The external components include:

- Microsoft's Windows 2000 or Windows 2003 Servers with Active Directory domain and associated Kerberos Key Distribution Center (KDC).
- A client application, for example, a browser or .NET client, that supports the SPNEGO authentication mechanism, as defined in IETF RFC 2478. Microsoft Internet Explorer Version 5.5 or later and Mozilla Firefox Version 1.0 are browser examples. Any browser needs to be configured to use the SPNEGO mechanism. For more information on performing this configuration, see "Configuring SPNEGO TAI in WebSphere Application Server" on page 233

The authentication of HTTP requests is triggered by the requestor (the client-side), which generates a SPNEGO token. WebSphere Application Server receives this token and validates trust between the requester and WebSphere Application Server. Specifically, the SPNEGO TAI decodes and retrieves the requester's identity from the SPNEGO token. The identity is used to establish a secure context between the requester and the application server.

Remember: The SPNEGO TAI is a server-side solution in WebSphere Application Server. Client-side applications are responsible for generating the SPNEGO token for use by the SPNEGO TAI. The requester's identity in WebSphere Application Server security registry must be identical to that identity the SPNEGO TAI retrieves. An identical match does occur when Microsoft Windows Active Directory server is the Lightweight Directory Access Protocol (LDAP) server that is used in WebSphere Application Server. A custom login module is available as a plug-in to support custom mapping of the identity from the Active Directory to the WebSphere Application Server security registry. See "Mapping user Ids from client to server for SPNEGO" on page 247 for details on using this custom login module.

WebSphere Application Server validates the identity against its security registry and, if the validation is successful, produces a Lightweight Third Party Authentication (LTPA) security token and places and returns a cookie to the requester in the HTTP response. Subsequent HTTP requests from this same requester to access additional secured resources in WebSphere Application Server use the LTPA security token previously created, to avoid repeated login challenges.

The challenge-response handshake process is illustrated in the following graphic:

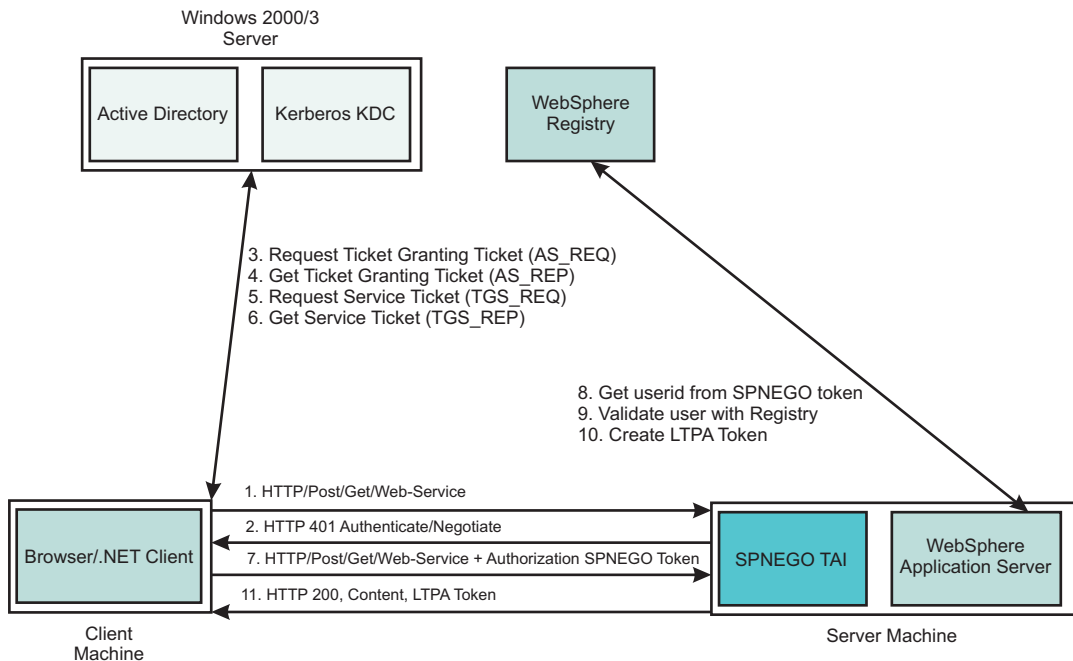

Figure 1. HTTP request processing, WebSphere Application Server - SPNEGO TAI

The SPNEGO TAI can be enabled for all or for selected WebSphere Application Servers in a WebSphere Application Server cell configuration. Also, the behavior of each SPNEGO TAI instance is controlled by custom configuration properties that are used to identify, for example, the criteria used to filter HTTP requests, such as the host name and security realm name used to construct the Kerberos Service Principal Name (SPN). For more information regarding establishing and setting the SPNEGO TAI custom configuration properties, see the following topics:

- Setting up the Kerberos configuration properties. See “Kerberos configuration requirements for SPNEGO TAI” on page 186.
- Setting or adjusting the SPNEGO TAI custom attributes. See SPNEGO TAI custom configuration attributes.
- Adjusting the SPNEGO TAI filter settings. See Filtering HTTP requests for SPNEGO TAI
- Using the custom login module to map the identity from the Active Directory to the WebSphere Application Server registry. See Mapping user Ids from client to server for SPNEGO.
- Setting the major and additional Java virtual machine (JVM) attributes. See SPNEGO TAI JVM configuration attributes

The Web administrator has access to the following SPNEGO TAI security components and associated configuration data, as illustrated in the following graphic.

Figure 2. SPNEGO TAI security and configuration elements

- The Web authentication module and the Lightweight Third Party Authentication (LTPA) mechanism provide the plug-in runtime framework for trust association interceptors. See “Configuring the Lightweight Third Party Authentication mechanism” on page 216 for more detail is configuring the LTPA mechanism for use with the SPNEGO TAI.
- The Java Generic Security Service (JGSS) provider is included in the Java SDK (`jre/lib/ibmjgssprovider.jar`) and used to obtain the Kerberos security context and credentials that are used for authentication. IBM JGSS 1.0 is a Java Generic Security Service Application Programming Interface (GSSAPI) framework with Kerberos V5 as the underlying default security mechanism. GSSAPI is a standardized abstract interface under which can be plugged different security mechanisms based on private-key, public-key and other security technologies. GSSAPI shields secure applications from the complexities and peculiarities of the different underlying security mechanisms. GSSAPI provides identity and message origin authentication, message integrity, and message confidentiality. For more information, see JGSS
- The Kerberos configuration properties (`krb5.conf` or `krb5.ini`) and Kerberos encryption keys (stored in a Kerberos keytab file) are used to establish secure mutual authentication.
The Kerberos key table manager (Ktab), which is part of JGSS, allows you to manage the principal names and service keys stored in a local Kerberos keytab file. Principal name and key pairs listed in the Kerberos keytab file allow services running on a host to authenticate themselves to the Kerberos Key Distribution Center (KDC). Before a server can use Kerberos, a Kerberos keytab file must be initialized on the host that runs the server.
“Kerberos configuration requirements for SPNEGO TAI” on page 186 highlights the Kerberos configuration requirements for the SPNEGO TAI as well as the use of Ktab.
- The SPNEGO provider supplies the implementation of the SPNEGO authentication mechanism, located at `/$WAS_HOME/java/jre/lib/ext/ibmspnego.jar`.
- The custom configuration properties control the runtime behavior of the SPNEGO TAI. Configuration operations are performed with the administrative console or scripting facilities. Refer to “SPNEGO TAI custom configuration attributes” on page 234 for more information about these custom configuration properties.
- Java virtual machine (JVM) system properties control diagnostic trace information for problem determination of the JGSS security provider and use of the property reload feature. “SPNEGO TAI JVM configuration attributes” on page 244 describes these JVM configuration attributes

The benefits of having WebSphere Application Server use the SPNEGO TAI include:

- An integrated single sign-on environment with Microsoft Windows 2000 or 2003 Servers using Active Directory domain is established.
- The cost of administering a large number of ids and passwords is reduced.
- A secure and mutually authenticated transmission of security credentials from the Web browser or .NET clients is established.
- Interoperability with Web services and .NET applications that use SPNEGO authentication at the transport level is achieved.

Using the SPNEGO TAI in your WebSphere Application Server environment requires planning then implementation. See “Configuring single sign-on capability with SPNEGO TAI” on page 229 for the steps to take in planning for SPNEGO TAI. Implementing the use of the SPNEGO TAI is divided into the following areas responsibility:

End user

The end user must configure the Web browser or .NET application to issue HTTP requests that are processed by the SPNEGO TAI.

Web administrator

The Web administrator is responsible for configuring the SPNEGO TAI of WebSphere Application Server to respond to HTTP requests of the client.

WebSphere Application Server administrator

The WebSphere Application Server administrator is responsible for configuring WebSphere Application Server and the SPNEGO TAI for optimum installation performance.

See “Configuring WebSphere Application Server environment to use SPNEGO” on page 230 for an explanation of the tasks required to use the SPNEGO TAI and the responsible party associated with each task.

Kerberos configuration requirements for SPNEGO TAI

Kerberos configuration settings, the Kerberos key distribution center (KDC) name, and realm settings for the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) trust association interceptor (TAI) are provided in the Kerberos configuration file or through `java.security.krb5.kdc` and `java.security.krb5.realm` system property files.

The Web administrator creates the Kerberos configuration file with the appropriate settings that allow HTTP requests to be processed by the SPNEGO TAI. See “Creating the Kerberos configuration file for use with the SPNEGO TAI” on page 232 for more information.

The Web administrator can provide the same Kerberos configuration system properties in separate files: `java.security.krb5.kdc` and `java.security.krb5.realm..` See Kerberos Requirements for information on how this is accomplished.

The Kerberos key table manager command (Ktab) allows the Web administrator to manage the principal names and service keys stored in a local Kerberos keytab file. Kerberos service principal (SPN) name and keys listed in the Kerberos keytab file allow services running on the host to authenticate themselves to the KDC. Before SPNEGO TAI can use Kerberos, the WebSphere Application Server administrator must setup a Kerberos keytab file on the host running WebSphere Application Server.

Important: It is very important to protect the keytab files, making them readable only by the authorized WebSphere users.

Important: Any updates to the Kerberos keytab file using Ktab do not affect the Kerberos database. If you change the keys in the Kerberos keytab file, you must also make the corresponding changes to the Kerberos database.

Below is an example of how Ktab is used on a LINUX platform to add new principal names to the Kerberos keytab file.

```
[root@wssecjibe bin]# ./java com.ibm.security.krb5.internal.tools.Ktab -a
HTTP/wssecjibe.austin.ibm.com@WSSEC.AUSTIN.IBM.COM ot56prod -k /etc/krb5.keytab
Done!
Service key for principal HTTP/wssecjibe.austin.ibm.com@WSSEC.AUSTIN.IBM.COM saved
[root@wssecjibe bin]# ./java com.ibm.security.krb5.internal.tools.Ktab
1 entries in keytab, name: /etc/krb5.keytab
    KVN0    Principal
    ----    -
    1       HTTP/wssecjibe.austin.ibm.com@WSSEC.AUSTIN.IBM.COM
```

```

[root@wssecjibe bin]# ls /etc/krb5.*
/etc/krb5.conf      /etc/krb5.ini.orig  /etc/krb5.keytab.good
/etc/krb5.conf.orig /etc/krb5.keytab
[root@wssecjibe bin]# ./java com.ibm.security.krb5.internal.tools.Ktab -a
HTTP/wssecredhat.austin.ibm.com@WSSEC.AUSTIN.IBM.COM ot56prod -k /etc/krb5.keytab
Done!
Service key for principal HTTP/wssecredhat.austin.ibm.com@WSSEC.AUSTIN.IBM.COM
saved
[root@wssecjibe bin]# ./java com.ibm.security.krb5.internal.tools.Ktab
2 entries in keytab, name: /etc/krb5.keytab
      KVNO      Principal
      ----      -
      1          HTTP/wssecjibe.austin.ibm.com@WSSEC.AUSTIN.IBM.COM
      1          HTTP/wssecredhat.austin.ibm.com@WSSEC.AUSTIN.IBM.COM

```

Tip: On WebSphere Application Server, Ktab is located at:

```
<install root>/java/jre/bin
```

Enterprise Identity Mapping

Enterprise Identity Mapping (EIM) for iSeries is the OS/400 implementation of an IBM infrastructure that allows administrators and application developers to solve the problem of managing multiple user registries across their enterprise.

Most network enterprises face the problem of multiple user registries, which require each person or entity within the enterprise to have a user identity in each registry. The need for multiple user registries quickly grows into a large administrative problem that affects users, administrators, and application developers. EIM enables inexpensive solutions for easier management of multiple user registries and user identities in your enterprise.

EIM is a mechanism for mapping and associating a person or entity to the appropriate user identities in various registries throughout the enterprise. EIM provides application programming interfaces (API) for creating and managing these identity mapping relationships and provides APIs that applications use to query this information. In addition, OS/400 uses EIM and Kerberos capabilities to provide a single sign-on environment.

iSeries Navigator, the iSeries graphical user interface, provides wizards to configure and manage EIM. In addition, administrators can manage EIM relationships for user profiles through iSeries Navigator.

For more information on Enterprise Identity Mapping, see Enterprise Identity Mapping concepts.

Global single sign-on principal mapping

You can use the Java Authorization Contract for Containers (JACC) provider for Tivoli Access Manager to manage authentication to enterprise information systems (EIS) such as databases, transaction processing systems, and message queue systems that are located within the WebSphere Application Server security domain. Such authentication is achieved using the global single sign-on (GSO) principal mapper Java Authentication and Authorization Service (JAAS) login module for Java 2 Platform, Enterprise Edition (J2EE) Connector Architecture resources.

With GSO principal mapping, a special-purpose JAAS login module inserts a credential into the subject header. This credential is used by the resource adapter to authenticate to the EIS. The JAAS login module used is configured on a per-connection factory basis. The default principal mapping module retrieves the user name and password information from XML configuration files. The JACC provider for Tivoli Access Manager bypasses the credential that is stored in the Extensible Markup Language (XML) configuration files and uses the Tivoli Access Manager global sign-on (GSO) database instead to provide the authentication information for the EIS security domain.

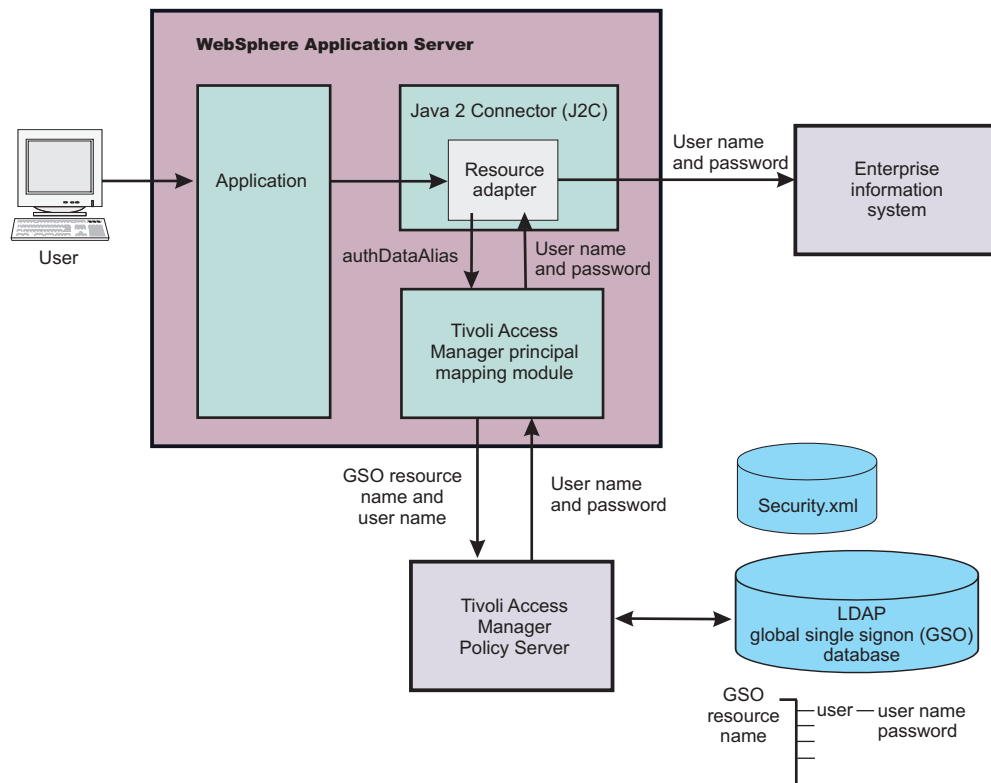

WebSphere Application Server provides a default principal mapping module that associates user credential information with EIS resources. The default mapping module is defined in the WebSphere Application Server administrative console on the Application login panel. To access the panel, click **Security > Secure administration, applications, and infrastructure**. Under Java Authentication and Authorization Service, click **Application logins**. The mapping module name is DefaultPrincipalMapping.

The EIS security domain user ID and password are defined under each connection factory by an authDataAlias attribute. The authDataAlias attribute does not contain the user name and password; this attribute contains an alias that refers to a user name and password pair that is defined elsewhere.

The Tivoli Access Manager principal mapping module uses the authDataAlias attribute to determine the GSO resource name and the user name that is required to perform the lookup on the Tivoli Access Manager GSO database. The Tivoli Access Manager Policy Server retrieves the GSO data from the user registry.

Tivoli Access Manager stores authentication information on the Tivoli Access Manager GSO database against a resource and user name pair.

GSO principal mapping architecture

Security attribute propagation

With *Security attribute propagation*, WebSphere Application Server can transport security attributes (authenticated Subject contents and security context information) from one server to another in your configuration. WebSphere Application Server might obtain these security attributes from either an enterprise user registry, which queries static attributes, or a custom login module, which can query static or dynamic attributes. Dynamic security attributes, which are custom in nature, might include the authentication strength that is used for the connection, the identity of the original caller, the location of the original caller, the IP address of the original caller, and so on.

Security attribute propagation provides propagation services using Java serialization for any objects that are contained in the Subject. However, Java code must be able to serialize and deserialize these objects. The Java programming language specifies the rules for how Java code can serialize an object. Because problems can occur when dealing with different platforms and versions of software, WebSphere Application Server also offers a token framework that enables custom serialization functionality. The token framework has other benefits that include the ability to identify the uniqueness of the token. This uniqueness determines how the Subject gets cached and the purpose of the token. The token framework defines four marker token interfaces that enable the WebSphere Application Server runtime to determine how to propagate the token.

Important: Any custom tokens that are used in this framework are not used by WebSphere Application Server for authorization or authentication. The framework serves as a way to notify WebSphere Application Server that you want these tokens propagated in a particular way. WebSphere Application Server handles the propagation details, but does not handle serialization or deserialization of custom tokens. Serialization and deserialization of these custom tokens are carried out by the implementation and handled by a custom login module.

With WebSphere Application Server Version 6.0 and later, a custom Java Authorization Contract for Container (JACC) provider can be configured to enforce access control for Java 2 Platform, Enterprise Edition (J2EE) applications. A custom JACC provider can explore the custom security attributes in the caller JAAS subject in making access control decisions.

When a request is being authenticated, a determination is made by the login modules whether this request is an *initial login* or a *propagation login*. An initial login is the process of authenticating the user information, typically a user ID and password, and then calling the application programming interfaces (APIs) for the remote user registry to look up secure attributes that represent the user access rights. A propagation login is the process of validating the user information, typically a Lightweight Third Party Authentication (LTPA) token, and then deserializing a series of tokens that constitute both custom objects and token framework objects known to WebSphere Application Server.

The following marker tokens are introduced in the framework:

Authorization token

The authorization token contains most of the authorization-related security attributes that are propagated. The default authorization token is used by the WebSphere Application Server authorization engine to make Java 2 Platform, Enterprise Edition (J2EE) authorization decisions. Service providers can use custom authorization token implementations to isolate their data in a different token, perform custom serialization and de-serialization, and make custom authorization decisions using the information in their token at the appropriate time. For information on how to use and implement this token type, see “Default propagation token” on page 192 and “Implementing a custom propagation token” on page 613.

Single sign-on (SSO) token

A custom SingleSignonToken token that is added to the Subject is automatically added to the response as an HTTP cookie and contains the attributes sent back to Web browsers. The token interface getName method with the getVersion method defines the cookie name. WebSphere Application Server defines a default SingleSignonToken token with the LtpaToken name and Version 2. The cookie name added is LtpaToken2. Do not add sensitive information, confidential information, or unencrypted data to the response cookie.

It is also recommended that any time that you use cookies, use the Secure Sockets Layer (SSL) protocol to protect the request. Using an SSO token, Web users can authenticate once when accessing Web resources across multiple WebSphere Application Servers. A custom SSO token extends this functionality by adding custom processing to the single sign-on scenario. For more information on SSO tokens, see “Implementing single sign-on to minimize Web user

authentications” on page 226. For information on how to use and implement this token type, see “Default single sign-on token” on page 200 and “Implementing a custom single sign-on token” on page 630.

Propagation token

The propagation token is not associated with the authenticated user so it is not stored in the Subject. Instead, the propagation token is stored on the thread and follows the invocation wherever it goes. When a request is sent outbound to another server, the propagation tokens on that thread are sent with the request and the tokens are run by the target server. The attributes that are stored on the thread are propagated regardless of the Java 2 Platform, Enterprise Edition (J2EE) RunAs user switches.

The default propagation token monitors and logs all user switches and host switches. You can add additional information to the default propagation token using the WSSecurityHelper application programming interfaces (APIs). To retrieve and set custom implementations of a propagation token, you can use the WSSecurityPropagationHelper class. For information on how to use and implement this token type, see “Default propagation token” on page 192 and “Implementing a custom propagation token” on page 613.

Authentication token

The authentication token flows to downstream servers and contains the identity of the user. This token type serves the same function as the Lightweight Third Party Authentication (LTPA) token in previous versions. Although this token type is typically reserved for internal WebSphere Application Server purposes, you can add this token to the Subject and the token is propagated using the `getBytes` method of the token interface.

A custom authentication token is used solely for the purpose of the service provider that adds it to the Subject. WebSphere Application Server does not use it for authentication purposes because a default authentication token exists that is used for WebSphere Application Server authentication. This token type is available for the service provider to identify how the custom data uses the token to perform custom authentication decisions. For information on how to use and implement this token type, see “Default authentication token” on page 201 and “Implementing a custom authentication token” on page 640.

Horizontal propagation versus downstream propagation

In WebSphere Application Server, both horizontal propagation, which uses single sign-on for Web requests, and downstream propagation, which uses Remote Method Invocation over the Internet Inter-ORB Protocol (RMI/IIOP) to access enterprise beans, are available.

Horizontal propagation

In horizontal propagation, security attributes are propagated among front-end servers. The serialized security attributes, which are the Subject contents and the propagation tokens, can contain both static and dynamic attributes. The single sign-on (SSO) token stores additional system-specific information that is needed for horizontal propagation. The information contained in the SSO token tells the receiving server where the originating server is located and how to communicate with that server. Additionally, the SSO token also contains the key to look up the serialized attributes. To enable horizontal propagation, you must configure the single sign-on token and the Web inbound security attribute propagation features. You can configure both of these features using the administrative console.

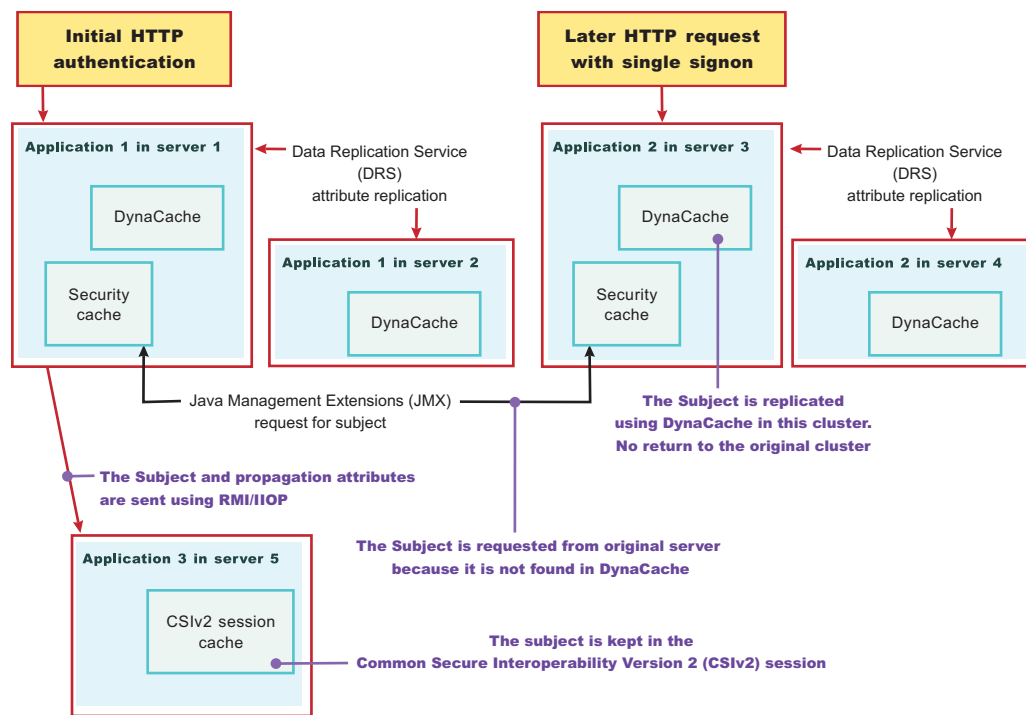

When front-end servers are configured and in the same distributed replication service (DRS) replication domain, the application server automatically propagates the serialized information to all of the servers within the same domain. In figure 1, application 1 is deployed on server 1 and server 2, and both servers are members of the same DRS replication domain. If a request originates from application 1 on server 1 and then gets redirected to application 1 on server 2, the original login attributes are found on server 2 without additional remote requests.

However, if the request originates from application 1 on either server 1 or server 2, but the request is redirected to application 2 on either server 1 or server 2, the serialized information is not found in the DRS cache because the servers are not configured in the same replication domain. As a result, a remote Java Management Extensions (JMX) request is sent back to the originating server that hosts application 1 to obtain the serialized information so that original login information is available to the application. By getting the serialized information using a single JMX remote call back to the originating server, the following benefits are realized:

- You gain the function of retrieving login information from the original server.
- You do not need to perform any remote user registry calls because the application server can regenerate the Subject from the serialized information. Without this ability, the application server might make five to six separate remote calls.

Figure 1

1. User authenticates to server 1.
2. Server 1 makes an RMI request to server 5.
3. User accesses another Web application on server 3.

Performance implications for horizontal propagation

The performance implications of either the DRS or JMX remote call depends upon your environment. THE DRS or JMX remote call is used for obtaining the original login attributes. Horizontal propagation reduces many of the remote user registry calls in cases where these calls cause the most performance problems for an application. However, the de-serialization of these objects also might cause performance degradation, but this degradation might be less than the remote user registry calls. It is recommended that you test your environment with horizontal propagation enabled and disabled. In cases where you must use horizontal propagation for preserving original login attributes, test whether DRS or JMX provides better performance in your environment. Typically, it is recommended that you configure DRS both for failover and performance reasons. However, because DRS propagates the information to all of the servers in the same replication domain (whether the servers are accessed or not), there might be a performance degradation if too many servers are in the same replication domain. In this case, either reduce the number of servers in the replication domain or do not configure the servers in a DRS replication domain. The later

suggestion causes a JMX remote call to retrieve the attributes, when needed, which might be quicker overall.

Downstream propagation

In *downstream propagation*, a Subject is generated at the Web front-end server, either by a propagation login or a user registry login. WebSphere Application Server propagates the security information downstream for enterprise bean invocations when both Remote Method Invocation (RMI) outbound and inbound propagation are enabled.

Benefits of propagating security attributes

The security attribute propagation feature of WebSphere Application Server has the following benefits:

- Enables WebSphere Application Server to use the security attribute information for authentication and authorization purposes. The propagation of security attributes can eliminate the need for user registry calls at each remote hop along an invocation. Previous versions of WebSphere Application Server propagated only the user name of the authenticated user, but ignored other security attribute information that needed to be regenerated downstream using remote user registry calls. To accentuate the benefits of this new functionality, consider the following example:

In previous releases, you might use a reverse proxy server (RPSS), such as WebSEAL, to authenticate the user, gather group information, and gather other security attributes. As stated previously, WebSphere Application Server accepted the identity of the authenticated user, but disregarded the additional security attribute information. To create a Java Authentication and Authorization Service (JAAS) Subject containing the needed WSCredential and WSPincipal objects, WebSphere Application Server made 5 to 6 calls to the user registry. The WSCredential object contains various security information that is required to authorize a J2EE resource. The WSPincipal object contains the realm name and the user that represents the principal for the Subject.

In the current release of the Application Server, information that is obtained from the reverse proxy server can be used by WebSphere Application Server and propagated downstream to other server resources without additional calls to the user registry. The retaining of the security attribute information enables you to protect server resources properly by making appropriate authorization and trust-based decisions. User switches that occur because of J2EE RunAs configurations do not cause the application server to lose the original caller information. This information is stored in the PropagationToken located on the running thread.

- Enables third-party providers to plug in custom tokens. The token interface contains a getBytes method that enables the token implementation to define custom serialization, encryption methods, or both.
- Provides the ability to have multiple tokens of the same type within a Subject created by different providers. WebSphere Application Server can handle multiple tokens for the same purpose. For example, you might have multiple authorization tokens in the Subject and each token might have distinct authorization attributes that are generated by different providers.
- Provides the ability to have a unique ID for each token type that is used to formulate a more unique subject identifier than just the user name in cases where dynamic attributes might change the context of a user login. The token type has a getUniqueld() method that is used for returning a unique string for caching purposes. For example, you might need to propagate a location ID, which indicates the location from which the user logs into the system. This location ID can be generated during the original login using either an reverse proxy server or the WEB_INBOUND login configuration and added to the Subject prior to serialization. Other attributes might be added to the Subject as well and use a unique ID. All of the unique IDs must be considered for the uniqueness of the entire Subject. WebSphere Application Server has the ability to specify what is unique about the information in the Subject, which might affect how the user accesses the Subject later.

Default propagation token

A default propagation token is located on the running thread for applications and the security infrastructure to use. WebSphere Application Server propagates this default propagation token downstream and the token stays on the thread where the invocation lands at each hop.

The data is available from within the container of any resource where the propagation token lands. Remember that you must enable the propagation feature at each server where a request is sent for propagation to work. Make sure that you enable security attribute propagation for all of the cells in your environment where you want propagation

There is a `WSSecurityHelper` class that has application programming interfaces (APIs) for accessing the `PropagationToken` attributes. This topic documents the usage scenarios and includes examples. A close relationship exists between the propagation token and the work area feature. The main difference between these features is that after you add attributes to the propagation token, you cannot change the attributes. You cannot change these attributes so that the security runtime can add auditable information and have that information remain there for the life of the invocation. Any time that you add an attribute to a specific key, an `ArrayList` object is stored to hold that attribute. Any new attribute that is added with the same key is added to the `ArrayList` object. When you call `getAttributes`, the `ArrayList` object is converted to a `String` array and the order is preserved. The first element in the `String` array is the first attribute added for that specific key.

In the default propagation token, a change flag is kept that logs any data changes to the token. These changes are tracked to enable WebSphere Application Server to know when to send the authentication information downstream again so that the downstream server has those changes. Normally, Common Secure Interoperability Version 2 (CSIv2) maintains a session between servers for an authenticated client. If the propagation token changes, a new session is generated and subsequently a new authentication occurs. Frequent changes to the propagation token during a method cause frequent downstream calls. If you change the token prior to making many downstream calls or you change the token between each downstream call, you might impact security performance.

Getting the server list from the default propagation token

Every time the propagation token is propagated and used to create the authenticated Subject, either horizontally or downstream, the name of the receiving application server is logged into the propagation token. The format of the host is "Cell:Node:Server", which provides you access to the cell name, node name, and server name of each application server that receives the invocation. The following code provides you with this list of names and can be called from a Java 2 Platform, Enterprise Edition (J2EE) application:

```
String[] server_list = null;

// If security is disabled on this application server, do not bother checking
// if (com.ibm.websphere.security.WSSecurityHelper.isServerSecurityEnabled())
{
    try
    {
        // Gets the server_list string array
        server_list = com.ibm.websphere.security.WSSecurityHelper.getServerList();
    }
    catch (Exception e)
    {
        // Performs normal exception handling for your application
    }

    if (server_list != null)
    {
        // print out each server in the list, server_list[0] is the first server
        for (int i=0; i<server_list.length; i++)
        {
            System.out.println("Server[" + i + "] = " + server_list[i]);
        }
    }
}
```

```

    }
  }
}

```

The format of each server in the list is: *cell:node_name:server_name*. The output, for example, is: myManager:node1:server1

Getting the caller list from the default propagation token

A default propagation token is generated any time an authenticated user is set on the running thread or anyone tries to add attributes to the propagation token. Whenever an authenticated user is set on the thread, the user is logged in the default propagation token. At times, the same user might be logged in multiple times if the RunAs user is different from the caller. The following list provides the rules that are used to determine if a user that is added to the thread gets logged into the propagation token:

- The current Subject must be authenticated. For example, an unauthenticated Subject is not logged.
- The current authenticated Subject is logged if a Subject is not previously logged.
- The current authenticated Subject is logged if the last authenticated Subject that is logged does not contain the same user.
- The current authenticated Subject is logged on each unique application server that is involved in the propagation process.

The following code sample shows how to use the `getCallerList` API:

```

String[] caller_list = null;

// If security is disabled on this application server, do not check the caller list
if (com.ibm.websphere.security.WSSecurityHelper.isServerSecurityEnabled())
{
    try
    {
        // Gets the caller_list string array
        caller_list = com.ibm.websphere.security.WSSecurityHelper.getCallerList();
    }
    catch (Exception e)
    {
        // Performs normal exception handling for your application
    }

    if (caller_list != null)
    {
        // Prints out each caller in the list, caller_list[0] is the first caller
        for (int i=0; i<caller_list.length;i++)
        {
            System.out.println("Caller[" + i + "] = " + caller_list[i]);
        }
    }
}

```

The format of each caller in the list is: *cell:node_name:server_name:realm:port_number/securityName*. The output, for example, is: myManager:node1:server1:ldap.austin.ibm.com:389/jsmith.

Getting the first caller from the default propagation token

Whenever you want to know which authenticated caller started the request, you can call the `getFirstCaller` method and the caller list is parsed. However, this method returns the security name of the caller only. If

you need to know more than the security name, call the `getCallerList` method and retrieve the first entry in the String array. This entry provides all the caller information. The following code sample retrieves the security name of the first authenticated caller using the `getFirstCaller` API:

```
String first_caller = null;

// If security is disabled on this application server, do not bother checking
if (com.ibm.websphere.security.WSSecurityHelper.isServerSecurityEnabled())
{
    try
    {
        // Gets the first caller
        first_caller = com.ibm.websphere.security.WSSecurityHelper.getFirstCaller();

        // Prints out the caller name
        System.out.println("First caller: " + first_caller);
    }
    catch (Exception e)
    {
        // Performs normal exception handling for your application
    }
}
```

The output, for example, is: `jsmith`.

Getting the first application server name from the default propagation token

Whenever you want to know what the first application server is for this request, call the `getFirstServer` method directly. The following code sample retrieves the name of the first application server using the `getFirstServer` API:

```
String first_server = null;

// If security is disabled on this application server, do not bother checking
if (com.ibm.websphere.security.WSSecurityHelper.isServerSecurityEnabled())
{
    try
    {
        // Gets the first server
        first_server = com.ibm.websphere.security.WSSecurityHelper.getFirstServer();

        // Prints out the server name
        System.out.println("First server: " + first_server);
    }
    catch (Exception e)
    {
        // Performs normal exception handling for your application
    }
}
```

The output, for example, is: `myManager:node1:server1`.

Adding custom attributes to the default propagation token

You can add custom attributes to the default propagation token for application usage. This token follows the request downstream so that the attributes are available when needed. When you use the default propagation token to add attributes, you must understand the following issues:

- Adding information to the propagation token affects CSV2 session caching. Add information sparingly between remote requests.
- After you add information with a specific key, the information cannot be removed.
- You can add as many values to a specific key as you need. However, all of the values must be available from a returned String array in the order that they were added.
- The propagation token is available only on servers where propagation and security are enabled.
- The Java 2 Security `javax.security.auth.AuthPermission wssecurity.addPropagationAttribute` attribute is needed to add attributes to the default propagation token.
- An application cannot use keys that begin with either `com.ibm.websphere.security` or `com.ibm.wsspi.security`. These prefixes are reserved for system usage.

The following code sample shows how to use the `addPropagationAttribute` API:

```
// If security is disabled on this application server,
// do not check the status of server security
if (com.ibm.websphere.security.WSSecurityHelper.isServerSecurityEnabled())
{
    try
    {
        // Specifies the key and values
        String key = "mykey";
        String value1 = "value1";
        String value2 = "value2";

        // Sets key, value1
        com.ibm.websphere.security.WSSecurityHelper.
            addPropagationAttribute (key, value1);

        // Sets key, value2
        String[] previous_values = com.ibm.websphere.security.WSSecurityHelper.
            addPropagationAttribute (key, value2);

        // Note: previous_values should contain value1
    }
    catch (Exception e)
    {
        // Performs normal exception handling for your application
    }
}
```

See “Getting custom attributes from the default propagation token” to retrieve attributes using the `getPropagationAttributes` application programming interface (API).

Getting custom attributes from the default propagation token

Custom attributes are added to the default propagation token using the `addPropagationAttribute` API. Retrieve these attributes using the `getPropagationAttributes` API. This token follows the request downstream so the attributes are available when needed. When you use the default propagation token to retrieve attributes, you must understand the following issues:

- The propagation token is available only on servers where propagation and security are enabled.
- The Java 2 Security `javax.security.auth.AuthPermission "wssecurity.getPropagationAttributes"` permission is needed to retrieve attributes from the default propagation token.

The following code sample shows how to use the `getPropagationAttributes` API:

```
// If security is disabled on this application server, do not bother checking
if (com.ibm.websphere.security.WSSecurityHelper.isServerSecurityEnabled())
{
    try
    {
        String key = "mykey";
        String[] values = null;

        // Sets key, value1
        values = com.ibm.websphere.security.WSSecurityHelper.
            getPropagationAttributes (key);

        // Prints the values
        for (int i=0; i<values.length; i++)
        {
            System.out.println("Value[" + i + "] = " + values[i]);
        }
    }
    catch (Exception e)
    {
        // Performs normal exception handling for your application
    }
}
```

The output, for example, is:

```
Value[0] = value1
Value[1] = value2
```

See [Adding custom attributes to the default PropagationToken](#) to add attributes using the `addPropagationAttributes` API.

Changing the token factory that is associated with the default propagation token

When WebSphere Application Server generates a default propagation token, the Application Server utilizes the `TokenFactory` class that is specified using the `com.ibm.wsspi.security.token.propagationTokenFactory` property. To modify this property using the administrative console, complete the following steps:

1. Click **Security > Secure administration, applications, and infrastructure**.
2. Under Additional properties, click **Custom properties**.

The default token factory that is specified for this property is called `com.ibm.ws.security.ltpa.AuthzPropTokenFactory`. This token factory encodes the data in the propagation token and does not encrypt the data. Because the propagation token typically flows over CSlv2 using Secure Sockets Layer (SSL), encrypting the token is not required. However, if you need additional security for the propagation token, you can associate a different token factory implementation with this property to get encryption. For example, if you choose to associate the `com.ibm.ws.security.ltpa.LTPAToken2Factory` token factory with this property, the token is AES encrypted. However, you need to weigh the performance impacts against your security needs. Adding sensitive information to the propagation token is a good reason to change the token factory implementation to something that encrypts rather than just encodes.

If you want to perform your own signing and encryption of the default propagation token, you must implement the following classes:

- `com.ibm.wsspi.security.ltpa.Token`
- `com.ibm.wsspi.security.ltpa.TokenFactory`

Your token factory implementation instantiates and validates your token implementation. You can choose to use the Lightweight Third Party Authentication (LTPA) keys and have them pass into the `initialize` method of the token factory, or you can use your own keys. If you use your own keys, they must be the same everywhere to validate the tokens that are generated using those keys. See the API documentation, available through a link on the front page of the information center, for more information on implementing your own custom token factory. To associate your token factory with the default propagation token, using the administrative console, complete the following steps:

1. Click **Security > Secure administration, applications, and infrastructure**.
2. Under Additional properties, click **Custom properties**.
3. Locate the `com.ibm.wsspi.security.token.propagationTokenFactory` property and verify that the value of this property matches your custom token factory implementation.
4. Verify that your implementation classes are put into the `app_server_root/classes` directory so that the WebSphere Application Server class loader can load the classes.
5. Verify that the QEJBSVR user profile has read, write, and execute (*RWX) authority to the classes directory. You can use the Work with Authority (WRKAUT) command to view the authority permissions for the directory.

Related tasks

“Propagating security attributes among application servers” on page 279

Use the security attribute propagation feature of WebSphere Application Server to send security attribute information regarding the original login to other servers using a token. This topic will help to configure WebSphere Application Server to propagate security attributes to other servers.

Default authorization token

This topic explains how WebSphere Application Server uses the default authorization token. Consider using the default authorization token when you are looking for a place to add string attributes that get propagated downstream.

However, make sure that the attributes you add to the authorization token are specific to the user that is associated with the authenticated Subject. If they are not specific to a user, the attributes probably belong in the propagation token, which is also propagated with the request. For more information on the propagation token, see “Default propagation token” on page 192. To add attributes into the authorization token, you must plug in a custom login module into the various system login modules that are configured. Any login module configuration that has the `com.ibm.ws.security.server.lm.wsMapDefaultInboundLoginModule` implementation configured can receive propagated information and can generate propagation information that can be sent outbound to another server.

If propagated attributes are not presented to the login configuration during an initial login, a default authorization token is created in the `wsMapDefaultInboundLoginModule` login module after the login occurs in the `ltpaLoginModule` login module. You can obtain a reference to the default authorization token from the login method using the `sharedState` hashmap. You must plug in the custom login module after the `wsMapDefaultInboundLoginModule` implementation for WebSphere Application Server to see the default authorization token.

For more information on the Java Authentication and Authorization Service (JAAS) programming model, see *Security: Resources for learning*.

Important: Add your login module to the `profile_root/classes` directory. For more information, see “Creating a classes subdirectory in your profile for custom classes” on page 516.

The following sample code shows you how to obtain a reference to the default authorization token from the login method, how to add attributes to the token, and how to read from the existing attributes that are used for authorization.

```
public customLoginModule()
{
    public void initialize(Subject subject, CallbackHandler callbackHandler,
        Map sharedState, Map options)
    {
        // (For more information on initialization, see
        //
```

```

“Custom login module development for a system login configuration” on page 593.) // Get a reference to
the sharedState map that is passed in during initialization. _sharedState = sharedState; } public boolean
login() throws LoginException { // (For more information on what to do during login, see // “Custom login
module development for a system login configuration” on page 593.) // Look for the default
AuthorizationToken in the shared state defaultAuthzToken =
(com.ibm.wsspi.security.token.AuthorizationToken) sharedState.get
(com.ibm.wsspi.security.auth.callback.Constants.WSAUTHZTOKEN_KEY); // Might not always have one of
these generated. It depends on the login // configuration setup. if (defaultAuthzToken != null) { try { // Add a
custom attribute defaultAuthzToken.addAttribute("key1", "value1"); // Determine all of the attributes and
values that exist in the token. java.util.Enumeration listOfAttributes = defaultAuthorizationToken.
getAttributeNames(); while (listOfAttributes.hasMoreElements()) { String key = (String)
listOfAttributes.nextElement(); String[] values = (String[]) defaultAuthorizationToken.getAttributes (key); for
(int i=0; i<values.length; i++) { System.out.println ("Key: " + key + ", Value[" + i + "]: " + values[i]); } } //
Read the existing uniqueID attribute. String[] uniqueID = defaultAuthzToken.getAttributes
(com.ibm.wsspi.security.token.AttributeNameConstants. WSCREDENTIAL_UNIQUEID); // Get the uniqueID
from the String[] String unique_id = (uniqueID != null && uniqueID[0] != null) ? uniqueID[0] : ""; // Read the
existing expiration attribute. String[] expiration = defaultAuthzToken.getAttributes
(com.ibm.wsspi.security.token.AttributeNameConstants. WSCREDENTIAL_EXPIRATION); // An example of
getting a long expiration value from the string array. long expire_time = 0; if (expiration != null &&
expiration[0] != null) expire_time = Long.parseLong(expiration[0]); // Read the existing display name
attribute. String[] securityName = defaultAuthzToken.getAttributes
(com.ibm.wsspi.security.token.AttributeNameConstants. WSCREDENTIAL_SECURITYNAME); // Get the
display name from the String[] String display_name = (securityName != null && securityName[0] != null) ?
securityName[0] : ""; // Read the existing long securityName attribute. String[] longSecurityName =
defaultAuthzToken.getAttributes (com.ibm.wsspi.security.token.AttributeNameConstants.
WSCREDENTIAL_LONGSECURITYNAME); // Get the long security name from the String[] String
long_security_name = (longSecurityName != null && longSecurityName[0] != null) ? longSecurityName[0] :
""; // Read the existing group attribute. String[] groupList = defaultAuthzToken.getAttributes
(com.ibm.wsspi.security.token.AttributeNameConstants. WSCREDENTIAL_GROUPS); // Get the groups
from the String[] ArrayList groups = new ArrayList(); if (groupList != null) { for (int i=0; i<groupList.length;
i++) { System.out.println ("group[" + i + "] = " + groupList[i]); groups.add(groupList[i]); } } catch (Exception
e) { throw new WSLoginFailedException (e.getMessage(), e); } } } public boolean commit() throws
LoginException { // (For more information on what to do during commit, see // “Custom login module
development for a system login configuration” on page 593.) } private java.util.Map _sharedState = null;
private com.ibm.wsspi.security.token.AuthorizationToken defaultAuthzToken = null; }

```

Changing the token factory that is associated with the default authorization token

When WebSphere Application Server generates a default authorization token, the application server utilizes the TokenFactory class that is specified using the com.ibm.wsspi.security.token.authorizationTokenFactory property. To modify this property using the administrative console, complete the following steps:

1. Click **Security > Secure administration, applications, and infrastructure**.
2. Under Additional properties, click **Custom properties**.

The `com.ibm.ws.security.ltpa.AuthzPropTokenFactory` token factory is the default. This token factory encodes the data, but does not encrypt the data in the authorization token. Because the authorization token typically flows over Common Secure Interoperability Version 2 (CSIv2) using Secure Sockets Layer (SSL), encrypting the token is not necessary. However, if you need additional security for the authorization token, you can associate a different token factory implementation with this property to get encryption. For example, if you associate the `com.ibm.ws.security.ltpa.LTPAToken2Factory` token factory with this property, the token uses Advanced Encryption Standard (AES) encryption. However, you need to weigh the performance impacts against your security needs. Adding sensitive information to the authorization token is one reason to change the token factory implementation to something that encrypts rather than just encodes.

If you want to perform your own signing and encryption of the default authorization token, you must implement the following classes:

- `com.ibm.wsspi.security.ltpa.Token`
- `com.ibm.wsspi.security.ltpa.TokenFactory`

Your token factory implementation instantiates and validates your token implementation. You can use the Lightweight Third Party Authentication (LTPA) keys that are passed into the initialize method of the token factory or you can use your own keys. If you use your own keys, they must be the same everywhere to validate the tokens that are generated using those keys. See the API documentation, that is available through a link on the front page of the information center, for more information on implementing your own custom token factory. To associate your token factory with the default authorization token, using the administrative console, complete the following steps:

1. Click **Security > Secure administration, applications, and infrastructure**.
2. Under Additional properties, click **Custom properties**.
3. Locate the `com.ibm.wsspi.security.token.authorizationTokenFactory` property and verify that the value of this property matches your custom token factory implementation.
4. Verify that your implementation classes are put into the `app_server_root/classes` directory so that the WebSphere Application Server class loader can load the classes.
5. Verify that the QEJBSVR user profile has read, write, and execute (*RWX) authority to the classes directory. You can use the Work with Authority (WRKAUT) command to view the authority permissions for the directory.

Default single sign-on token

Do not use the default single sign-on token in service provider code. This default token is used by the WebSphere Application Server run-time code only.

Size limitations exist for this token when it is added as an HTTP cookie. If you need to create an HTTP cookie using this token framework, you can implement a custom single sign-on token. To implement a custom single sign-on token see “Implementing a custom single sign-on token” on page 630 for more information.

Changing the token factory that is associated with the default single sign-on token

When the default single sign-on token is generated, the application server utilizes the `TokenFactory` class that is specified using the `com.ibm.wsspi.security.token.singleSignonTokenFactory` property. To modify this property using the administrative console, complete the following steps:

1. Click **Security > Secure administration, applications, and infrastructure**.
2. Under Additional properties, click **Custom properties**.

The `com.ibm.ws.security.ltpa.LTPAToken2Factory` token factory is the default that is specified for this property. This token factory creates a single sign-on (SSO) token called `LtpaToken2`, which WebSphere Application Server uses for propagation. This token factory uses the AES/CBC/PKCS5Padding cipher. If you change this token factory, you lose the interoperability with any servers running a version of WebSphere Application Server prior to version 5.1.1 that use the default token factory. Only servers

running WebSphere Application Server Version 5.1.1 or later with propagation enabled are aware of the LtpaToken2 cookie. If all of your application servers use WebSphere Application Server Version 5.1.1 or later and all of your servers use your new token factory this awareness is not a problem.

If you need to perform your own signing and encryption of the default single sign-on token, you must implement the following classes:

- `com.ibm.wsspi.security.ltpa.Token`
- `com.ibm.wsspi.security.ltpa.TokenFactory`

Your token factory implementation instantiates (`createToken`) and validates (`validateTokenBytes`) your token implementation. You can use the Lightweight Third-Party Authentication (LTPA) keys passed into the `initialize` method of the token factory or you can use your own keys. If you use your own keys, they must be the same everywhere to validate the tokens that are generated using those keys. See the API documentation, available through a link on the front page of the information center, for more information on implementing your own custom token factory. To associate your token factory with the default single sign-on token using the administrative console, complete the following steps:

1. Click **Security > Secure administration, applications, and infrastructure**.
2. Under Additional properties, click **Custom properties**.
3. Locate the `com.ibm.wsspi.security.token.singleSignonTokenFactory` property and verify that the value of this property matches your custom `TokenFactory` implementation.
4. Verify that your implementation classes are put into the `app_server_root/classes` directory so that the WebSphere Application Server class loader can load the classes.
5. Verify that the QEJBSVR user profile has read, write, and execute (*RWX) authority to the classes directory. You can use the Work with Authority (WRKAUT) command to view the authority permissions for the directory.

Related tasks

“Propagating security attributes among application servers” on page 279

Use the security attribute propagation feature of WebSphere Application Server to send security attribute information regarding the original login to other servers using a token. This topic will help to configure WebSphere Application Server to propagate security attributes to other servers.

“Implementing a custom single sign-on token” on page 630

You can create your own single sign-on token implementation. The single sign-on token implementation is set in the login Subject and added to the HTTP response as an HTTP cookie.

Default authentication token

Do not use the default authentication token in service provider code. This default token is used by the WebSphere Application Server run-time code only and is authentication mechanism specific.

Any modifications to this token by service provider code can potentially cause interoperability problems. If you need to create an authentication token for custom usage, see “Implementing a custom authentication token” on page 640 for more information.

Changing the token factory that is associated with the default authentication token

When WebSphere Application Server generates a default authentication token, the application server utilizes the `TokenFactory` class that is specified using the `com.ibm.wsspi.security.token.authenticationTokenFactory` property. To modify this property using the administrative console, complete the following steps:

1. Click **Security > Secure administration, applications, and infrastructure**.
2. Under Additional properties, click **Custom properties**.

The `com.ibm.ws.security.ltpa.LTPATokenFactory` token factory is the default for this property. The `LTPATokenFactory` token factory uses the DESede/ECB/PKCS5Padding cipher. This token factory creates an interoperable Lightweight Third Party Authentication (LTPA) token. If you change this token factory, you

lose the interoperability with any servers running a version of WebSphere Application Server prior to Version 5.1.1 and any other servers that do not support the new token factory implementation. However, if all of your application servers use WebSphere Application Server Version 5.1.1 or later and all of your servers use your new token factory, this interoperability is not a problem.

If you associate the `com.ibm.ws.security.ltpa.LTPAToken2Factory` token factory with the `com.ibm.wsspi.security.token.authenticationTokenFactory` property, the token is Advanced Encryption Standard (AES) encrypted. However, you need to weigh the performance against your security needs. You might add additional attributes to the authentication token in the Subject during a login that are available downstream.

If you need to perform your own signing and encryption of the default authentication token, you must implement the following classes:

- `com.ibm.wsspi.security.ltpa.Token`
- `com.ibm.wsspi.security.ltpa.TokenFactory`

Your token factory implementation instantiates (`createToken`) and validates (`validateTokenBytes`) your token implementation. You can use the LTPA keys that are passed into the `initialize` method of the token factory or you can use your own keys. If you use your own keys, they must be the same everywhere to validate the tokens that are generated using those keys. See the API documentation, available through a link on the front page of the information center, for more information on implementing your own custom token factory. To associate your token factory with the default authentication token using the administrative console, complete the following steps:

1. Click **Security > Secure administration, applications, and infrastructure**.
2. Under Additional properties, click **Custom properties**.
3. Locate the `com.ibm.wsspi.security.token.authenticationTokenFactory` property and verify that the value of this property matches your custom token factory implementation.
4. Verify that your implementation classes are put into the `install_dir/classes` directory so that the WebSphere Application Server class loader can load the classes.
5. Verify that the QEJBSVR user profile has read, write, and execute (*RWX) authority to the classes directory. You can use the Work with Authority (WRKAUT) command to view the authority permissions for that directory.

UserRegistry interface methods

Implementing this interface enables WebSphere Application Server security to use custom registries. This capability extends the `java.rmi` file. With a remote registry, you can complete this process remotely.

Implementation of this interface must provide implementations for:

- `initialize(java.util.Properties)`
- `checkPassword(String,String)`
- `mapCertificate(X509Certificate[])`
- `getRealm`
- `getUsers(String,int)`
- `getUserDisplayName(String)`
- `getUniqueUserId(String)`

- getUsersForGroup(String,int)
- createCredential(String)

```
public void initialize(java.util.Properties props)
    throws CustomRegistryException,
           RemoteException;
```

This method is called to initialize the UserRegistry method. All the properties that are defined in the Custom User Registry panel propagate to this method.

For the FileRegistrySample.java sample file, the initialize method retrieves the names of the registry files that contain the user and group information.

This method is called during server bringup to initialize the registry. This method is also called when validation is performed by the administrative console, when security is on. This method remains the same as in Version 4.x.

```
public String checkPassword(String userSecurityName, String password)
    throws PasswordCheckFailedException,
           CustomRegistryException,
           RemoteException;
```

The checkPassword method is called to authenticate users when they log in using a name or user ID and a password. This method returns a string which, in most cases, is the user security name. A credential is created for the user for authorization purposes. This user name is also returned for the getCallerPrincipal enterprise bean call and the servlet calls the getUserPrincipal and getRemoteUser methods. See the getUserDisplayName method for more information if you have display names in your registry. In some situations, if you return a user other than the one who is logged in, you must verify that the user is valid in the registry.

For the FileRegistrySample.java sample file, the mapCertificate method gets the distinguished name (DN) from the certificate chain and makes sure it is a valid user in the registry before returning the user. For the sample, the checkPassword method checks the name and password combination in the user registry and, if they match, the method returns the user being authenticated.

This method is called for various scenarios, for example, by the administrative console to validate the user information after the user registry is initialized. This method is also called when you access protected resources in the product for authenticating the user and before proceeding with the authorization. This method is the same as in Version 4.x.

```
public String mapCertificate(X509Certificate[] cert)
    throws CertificateMapNotSupportedException,
           CertificateMapFailedException,
           CustomRegistryException,
           RemoteException;
```

The mapCertificate method is called to obtain a user name from an X.509 certificate chain that is supplied by the browser. The complete certificate chain is passed to this method and the implementation can validate the chain if needed and get the user information. A credential is created for this user for authorization purposes. If browser certificates are not supported in your configuration, you can create the CertificateMapNotSupportedException exception. The consequence of not supporting certificates is authentication failure if the challenge type is certificates, even if valid certificates are in the browser.

This method is called when certificates are provided for authentication. For Web applications, when the authentication constraints are set to CLIENT-CERT in the web.xml file of the application, this method is called to map a certificate to a valid user in the registry. For Java clients, this method is called to map the

client certificates in the transport layer, when using transport layer authentication. When the identity assertion token, using the CSlv2 authentication protocol, is set to contain certificates, this method is called to map the certificates to a valid user.

In WebSphere Application Server Version 4.x, the input parameter is the X509Certificate certificate. In WebSphere Application Server Version 5.x and later, this parameter changes to accept an array of X509Certificate certificates such as a certificate chain. In Version 4.x, this parameter is called for Web applications only, but in version 5.x and later, you can call this method for both Web and Java clients.

```
public String getRealm()  
    throws CustomRegistryException,  
           RemoteException;
```

The `getRealm` method is called to get the name of the security realm. The name of the realm identifies the security domain for which the registry authenticates users. If this method returns a null value, a `customRealm` default name is used.

For the `FileRegistrySample.java` sample file, the `getRealm` method returns the `customRealm` string. One of the calls to this method occurs when the user registry information is validated. This method is the same method as in Version 4.x.

```
public Result getUsers(String pattern, int limit)  
    throws CustomRegistryException,  
           RemoteException;
```

The `getUsers` method returns the list of users from the registry. The names of users depend on the pattern parameter. The number of users are limited by the `limit` parameter. In a registry that has many users, getting all the users is not practical. So the `limit` parameter is introduced to limit the number of users retrieved from the registry. A limit of zero (0) indicates to return all the users that match the pattern and might cause problems for large registries. Use this limit with care.

The custom registry implementations are expected to support at least the wildcard search (*). For example, a pattern of asterisk (*) returns all the users and a pattern of (b*) returns the users starting with *b*.

The return parameter is an object with a `com.ibm.websphere.security.Result` type. This object contains two attributes, a `java.util.List` and a `java.lang.Boolean` attribute. The list contains the users that are returned and the Boolean flag indicates if more users are available in the user registry for the search pattern. This Boolean flag is used to indicate to the client whether more users are available in the registry.

In the `FileRegistrySample.java` sample file, the `getUsers` method retrieves the required number of users from the user registry and sets them as a list in the `Result` object. To find out if more users are presented than requested, the sample gets one more user than requested and if it finds the additional user, it sets the Boolean flag to `true`. For pattern matching, the `match` method in the `RegExpSample` class is used, which supports wildcard characters such as the asterisk (*) and the question mark (?).

This method is called by the administrative console to add users to roles in the various map-users-to-roles panels. The administrative console uses the Boolean `set` in the `Result` object to indicate that more entries matching the pattern are available in the user registry.

In WebSphere Application Server Version 4.x, this method specifies to take only the pattern parameter. The return is a list. In WebSphere Application Server Version 5.x or later, this method is changed to take one additional parameter, the `limit`. Ideally, your implementation changes to take the `limit` value and limits the users that are returned. The return is changed to return a `Result` object, which consists of the list and a flag that indicates if more entries exist. When the list returns, use the `Result.setList(List)` method to set

the list in the Result object. If more entries exist than requested in the limit parameter, set the Boolean attribute to true in the result object, using the Result.setHasMore method. The default for the Boolean attribute in the result object is false.

```
public String getUserDisplayName(String userSecurityName)
    throws EntryNotFoundException,
           CustomRegistryException,
           RemoteException;
```

The getUserDisplayName method returns a display name for a user, if one exists. The display name is an optional string that describes the user that you can set in some registries. This descriptive name is for the user and does not have to be unique in the registry.

For example, in i5/OS systems, you can display the text description for the user profile.

If you do not need display names in your registry, return null or an empty string for this method.

If display names existed for any user in WebSphere Application Server Version 4.x, these names were useful for the Enterprise JavaBean (EJB) method call getCallerPrincipal and the servlet calls getUserPrincipal and getRemoteUser. If the display names are not the same as the security name for any user, the display names are returned for the previously mentioned enterprise beans and servlet methods. Returning display names for these methods might become problematic in some situations because the display names might not be unique in the user registry. Avoid this problem by changing the default behavior to return the user security name instead of the user display name in this version of the product. For more information on how to set properties for the custom registry, see the section on *Setting Properties for Custom Registries*.

In the FileRegistrySample.java sample file, this method returns the display name of the user whose name matches the user name that is provided. If the display name does not exist, this method returns an empty string.

This method can be called by the product to present the display names in the administrative console, or by using the command line and the **wsadmin** tool. Use this method for display purposes only. This method is the same as in Version 4.x.

```
public String getUniqueUserId(String userSecurityName)
    throws EntryNotFoundException,
           CustomRegistryException,
           RemoteException;
```

This method returns the unique ID of the user, given the security name.

In the FileRegistrySample.java sample file, this method returns the uniqueUserId value of the user whose name matches the supplied name. This method is called when forming a credential for a user and also when creating the authorization table for the application.

```
public String getUserSecurityName(String uniqueUserId)
    throws EntryNotFoundException,
           CustomRegistryException,
           RemoteException;
```

This method returns the security name of a user given the unique ID. In the FileRegistrySample.java sample file, this method returns the security name of the user whose unique ID matches the supplied ID.

This method is called to make sure a valid user exists for a given uniqueUserId. This method is called to get the security name of the user when the uniqueUserId is obtained from a token.

```
public boolean isValidUser(String userSecurityName)
    throws CustomRegistryException,
           RemoteException;
```

This method indicates whether the given user is a valid user in the registry.

In the `FileRegistrySample.java` sample file, this method returns `true` if the user is found in the registry, otherwise this method returns `false`. This method is primarily called in situations where knowing if the user exists in the directory prevents problems later. For example, in the `mapCertificate` call, when the name is obtained from the certificate if the user is not found as a valid user in the user registry, you can avoid trying to create the credential for the user.

```
public Result getGroups(String pattern, int limit)
    throws CustomRegistryException,
           RemoteException;
```

The `getGroups` method returns the list of groups from the user registry. The names of groups depend on the pattern parameter. The number of groups is limited by the limit parameter. In a registry that has many groups, getting all the groups is not practical. So, the limit parameter is introduced to limit the number of groups retrieved from the user registry. A limit of zero (0) implies to return all the groups that match the pattern and can cause problems for large user registries. Use this limit with care. The custom registry implementations are expected to support at least the wildcard search (*). For example, a pattern of asterisk (*) returns all the users and a pattern of (b*) returns the users starting with *b*.

The return parameter is an object of the `com.ibm.websphere.security.Result` type. This object contains the `java.util.List` and `java.lang.Boolean` attributes. The list contains the groups that are returned and the Boolean flag indicates whether more groups are available in the user registry for the pattern searched. This Boolean flag is used to indicate to the client if more groups are available in the registry.

In the `FileRegistrySample.java` sample file, the `getUsers` method retrieves the required number of groups from the user registry and sets them as a list in the `Result` object. To find out if more groups are presented than requested, the sample gets one more user than requested and if it finds the additional user, it sets the Boolean flag to `true`. For pattern matching, the `match` method in the `RegExpSample` class is used, which supports the asterisk (*) and question mark (?) characters.

This method is called by the administrative console to add groups to roles in the various `map-groups-to-roles` panels. The administrative console uses the boolean `set` in the `Result` object to indicate that more entries matching the pattern are available in the user registry.

In `WebSphere Application Server Version 4`, this method is used to take the pattern parameter only and returns a list. In `WebSphere Application Server Version 5.x` or later, this method is changed to take the limit parameter. Change to take the limit value and limit the users that are returned. The return is changed to return a `Result` object, which consists of the list and a flag that indicates whether more entries exist. Use the `Result.setList(List)` method to set the list in the `Result` object. If more entries exist than requested in the limit parameter, set the Boolean attribute to `true` in the `Result` object using the `Result.setHasMore` method. The default for the Boolean attribute in the `Result` object is `false`.

```
public String getGroupDisplayName(String groupSecurityName)
    throws EntryNotFoundException,
           CustomRegistryException,
           RemoteException;
```

The `getGroupDisplayName` method returns a display name for a group if one exists. The display name is an optional string that describes the group that you can set in some user registries. This name is a descriptive name for the group and does not have to be unique in the registry. If you do not need to have display names for groups in your registry, return `null` or an empty string for this method.

In the `FileRegistrySample.java` sample file, this method returns the display name of the group whose name matches the group name that is provided. If the display name does not exist, this method returns an empty string.

The product can call this method to present the display names in the administrative console or through the command line using the **wsadmin** tool. This method is used for display purposes only.

```
public String getUniqueGroupId(String groupSecurityName)
    throws EntryNotFoundException,
           CustomRegistryException,
           RemoteException;
```

This method returns the unique ID of the group that is given the security name.

In the `FileRegistrySample.java` sample file, this method returns the unique ID of the group whose name matches the supplied name. This method is called when creating the authorization table for the application.

```
public List getUniqueGroupIds(String uniqueUserId)
    throws EntryNotFoundException,
           CustomRegistryException,
           RemoteException;
```

This method returns the unique IDs of all the groups to which a user belongs.

In the `FileRegistrySample.java` sample file, this method returns the unique ID of all the groups that contain this `uniqueUserId` ID. This method is called when creating the credential for the user. As part of creating the credential, all the `groupUniqueIds` IDs in which the user belongs are collected and put in the credential for authorization purposes when groups are given access to a resource.

```
public String getGroupSecurityName(String uniqueGroupId)
    throws EntryNotFoundException,
           CustomRegistryException,
           RemoteException;
```

This method returns the security name of a group given its unique ID.

In the `FileRegistrySample.java` sample file, this method returns the security name of the group whose unique ID matches the supplied ID. This method verifies that a valid group exists for a given `uniqueGroupId` ID.

```
public boolean isValidGroup(String groupSecurityName)
    throws CustomRegistryException,
           RemoteException;
```

This method indicates if the given group is a valid group in the registry.

In the `FileRegistrySample.java` sample file, this method returns `true` if the group is found in the registry, otherwise the method returns `false`. This method can be used in situations where knowing whether the group exists in the directory might prevent problems later.

```
public List getGroupsForUser(String userSecurityName)
    throws EntryNotFoundException,
           CustomRegistryException,
           RemoteException;
```

This method returns all the groups to which a user belongs whose name matches the supplied name. This method is similar to the `getUniqueGroupIds` method with the exception that the security names are used instead of the unique IDs.

In the `FileRegistrySample.java` sample file, this method returns all the group security names that contain the `userSecurityName` name.

This method is called by the administrative console or the scripting tool to verify that the users entered for the RunAs roles are already part of that role in the users and groups-to-role mapping. This check is required to ensure that a user cannot be added to a RunAs role unless that user is assigned to the role in the users and groups-to-role mapping either directly or indirectly through a group that contains this user. Because a group in which the user belongs can be part of the role in the users and groups-to-role mapping, this method is called to check if any of the groups that this user belongs to mapped to that role.

```
public Result getUsersForGroup(String groupSecurityName, int limit)
    throws NotImplementedException,
        EntryNotFoundException,
        CustomRegistryException,
        RemoteException;
```

This method retrieves users from the specified group. The number of users returned is limited by the `limit` parameter. A limit of zero (0) indicates to return all of the users in that group. This method is not directly called by the WebSphere Application Server security component. However, this method can be called by other components. In rare situations, if you are working with a user registry where getting all the users from any of your groups is not practical, you can create the `NotImplementedException` exception for the particular groups. In this case, verify that if the process choreographer is installed the staff assignments are not modeled using these particular groups. If no concern exists about returning the users from groups in the user registry, it is recommended that you do not create the `NotImplemented` exception when implementing this method.

The return parameter is an object with a `com.ibm.websphere.security.Result` type. This object contains the `java.util.List` and `java.lang.boolean` attributes. The list contains the users that are returned and the Boolean flag, which indicates whether more users are available in the user registry for the search pattern. This Boolean flag indicates to the client whether users are available in the user registry.

In the example, this method gets one user more than the requested number of users for a group, if the `limit` parameter is not set to zero (0). If the method succeeds in getting one more user, the Boolean flag is set to `true`.

In WebSphere Application Server Version 4, this `getUsers` method is mandatory for the product. For WebSphere Application Server Version 5.x or later, this method can create the `NotImplementedException` exception in situations where it is not practical to get the requested set of users. However, create this exception in rare situations when as other components can be affected. In Version 4, this method accepts only the pattern parameter and returns a list. In Version 5, this method accepts the `limit` parameter. Change your implementation to take the `limit` value and limit the users that are returned. The return changes to return a `Result` object, which consists of the list and a flag that indicates whether more entries exist. When the list is returned, use the `Result.setList(List)` method to set the list in the `Result` object. If more entries than requested are in the `limit` parameter, set the Boolean attribute to `true` in the `Result` object using `Result.setHasMore` method. The default for the Boolean attribute in the `Result` object is `false`.

Attention: The first two lines of the following code sample are split for illustrative purposes only.

```
public com.ibm.websphere.security.cred.WSCredential
    createCredential(String userSecurityName)
    throws NotImplementedException,
```

```
EntryNotFoundException,  
CustomRegistryException,  
RemoteException;
```

In this release the WebSphere Application Server, the `createCredential` method is not called. You can return `null`. In the example, a `null` value is returned.

Authentication protocol for EJB security

WebSphere Application Server Version 6.1 servers support the CSiv2 authentication protocol only. SAS is only supported between Version 6.0.x and earlier version servers that have been federated in a Version 6.1 cell. The option to select between SAS, CSiv2, or both is only available in the administration console when a Version 6.0.x or earlier release has been federated in a Version 6.1 cell.

V6.0.x SAS is the authentication protocol used by all previous releases of WebSphere Application Server and is maintained for backwards compatibility. The Object Management Group (OMG) has defined the authentication protocol called CSiv2 so that vendors can interoperate securely. CSiv2 is implemented in WebSphere Application Server with more features than SAS and is considered the strategic protocol.

Important: SAS is supported only between Version 6.0.x and previous version servers that have been federated in a Version 6.1 cell.

Invoking Enterprise Java Beans (EJB) methods in a secure WebSphere Application Server environment requires an authentication protocol to determine the level of security and the type of authentication that occur between any given client and server for each request. It is the job of the authentication protocol during a method invocation to merge the server authentication requirements that are determined by the object Interoperable Object Reference (IOR) with the client authentication requirements that are determined by the client configuration and come up with an authentication policy specific to that client and server pair.

The authentication policy makes the following decisions, among others, which are all based on the client and server configurations:

- What kind of connection can you make to this server--Secure Sockets Layer (SSL) or TCP/IP?
- If SSL is chosen, how strong is the encryption of the data?
- If SSL is chosen, do you authenticate the client using client certificates?
- Do you authenticate the client with a user ID and password? Does an existing credential exist?
- Do you assert the client identity to downstream servers?
- Given the configuration of the client and server, can a secure request proceed?

V6.0.x You can configure both protocols (SAS and CSiv2) to work simultaneously. If a server supports both protocols, it exports an IOR containing tagged components describing the configuration for SAS and CSiv2. If a client supports both protocols, it reads tagged components for both CSiv2 and SAS. If the client supports both and the server supports both, CSiv2 is used. However, if the server supports SAS (for example, it is a previous WebSphere Application Server release) and the client supports both, the client chooses SAS for this request because the SAS protocol is what both have in common.

V6.0.x Choose a protocol by specifying the `com.ibm.CSI.protocol` property on the client side and configuring through the administrative console on the server side. More details are included in the SAS and CSiv2 properties articles.

Common Secure Interoperability Specification, Version 2

V6.0.x The Common Secure Interoperability Specification, Version 2 (CSlv2) defines the Security Attribute Service (SAS) that enables interoperable authentication, delegation, and privileges. The CSlv2 SAS and SAS protocols are entirely different. The CSlv2 SAS is a subcomponent of CSlv2 that supports SSL and interoperability with the EJB Specification, Version 2.1.

Security Attribute Service

V6.0.x The Common Secure Interoperability Specification, Version 2 Security Attribute Service (CSlv2 SAS) protocol is designed to exchange its protocol elements in the service context of a General Inter-ORB Protocol (GIOP) request and reply messages that are communicated over a connection-based transport. The protocol is intended for use in environments where transport layer security, such as that available through Secure Sockets Layer (SSL) and Transport Layer Security (TLS), is used to provide message protection (that is, integrity and or confidentiality) and server-to-client authentication. The protocol provides client authentication, delegation, and privilege functionality that might be applied to overcome corresponding deficiencies in an underlying transport. The CSlv2 SAS protocol facilitates interoperability by serving as the higher-level protocol under which secure transports can be unified.

Connection and request interceptors

The authentication protocols that are used by WebSphere Application Server are add-on Interoperable Inter-ORB Protocol (IIOP) services. IIOP is a request-and-reply communications protocol that is used to send messages between two Object Request Brokers (ORBs). For each request made by a client ORB to a server ORB, an associated reply is made by the server ORB back to the client ORB. Prior to any request flowing, a connection between the client ORB and the server ORB must be established over the TCP/IP transport (SSL is a secure version of TCP/IP). The client ORB invokes the authentication protocol client connection interceptor, which is used to read the tagged components in the IOR of the object that is located on the server. As mentioned previously, the authentication policy is established here for the request. Given the authentication policy (a coalescing of the server configuration with the client configuration), the strength of the connection is returned to the ORB. The ORB makes the appropriate connection, usually over SSL.

After the connection is established, the client ORB invokes the authentication protocol client request interceptor, which is used to send security information other than what is established by the transport. The security information includes the user ID and password token that are authenticated by the server, an authentication mechanism-specific token that is validated by the server, or an identity assertion token. Identity assertion is a way for one server to trust another server without the need to re-authenticate or re-validate the originating client. However, some work is required for the server to trust the upstream server. This additional security information is sent with the message in a *service context*. A service context has a registered identifier so that the server ORB can identify which protocol is sending the information.

V6.0.x The fact that a service context contains a unique identity is another way for WebSphere Application Server to support both SAS and CSlv2 simultaneously because both protocols have different service context IDs. After the client request interceptor finishes adding the service context to the message, the message is sent to the server ORB.

V6.0.x When the message is received by the server ORB, the ORB invokes the authentication protocol server request interceptor. This interceptor looks for the service context ID known by the protocol. When both SAS and CSlv2 are supported by a server, two different server request interceptors are invoked and both interceptors look for different service context IDs.

However, only one finds a service context for any given request. When the server request interceptor finds a service context, it reads the information in the service context. A method is invoked to the security server to authenticate or validate client identity. The security server either rejects the information or returns a credential. A credential contains additional information about the client that is retrieved from the user registry so that authorization can make the appropriate decision. Authorization is the process of determining if the user can invoke the request based on the roles that are applied to the method and the roles given to the user.

If a service context is not found by the CSIv2 server request interceptor, the interceptor process looks at the transport connection to see if a client certificate chain is sent. This process is done when SSL client authentication is configured between the client and server.

If a client certificate chain is found, the distinguished name (DN) is extracted from the certificate and is used to map to an identity in the user registry. If the user registry is Lightweight Directory Access Protocol (LDAP), the search filters defined in the LDAP registry configuration determine how the certificate maps to an entry in the registry. If the user registry is local OS, the first attribute of the distinguished name (DN) maps to the user ID of the registry. This attribute is typically the common name.

If the certificate does not map, no credential is created and the request is rejected. When valid security information is not presented, the method request is rejected and a `NO_PERMISSION` exception is sent back with the reply. However, when no security information is presented, an unauthenticated credential is created for the request and the authorization engine determines if the method gets invoked. For an unauthenticated credential to invoke an Enterprise JavaBean (EJB) method, either no security roles are defined for the method or a special `Everyone` role is defined for the method.

When the method invocation is completed in the EJB container, the server request interceptor is invoked again to complete server authentication and a new reply service context is created to inform the client request interceptor of the outcome. This process is typically for making the request *stateful*. When a stateful request is made, only the first request between a client and server requires that security information is sent. All subsequent method requests need to send a unique context ID only so that the server can look up the credential that is stored in a session table. The context ID is unique within the connection between a client and server.

Finally, the method request cycle is completed by the client request interceptor receiving a reply from the server with a reply service context providing information so that the client-side stateful context ID can be confirmed and reused.

Specifying a stateful client is done through the property `com.ibm.CSI.performStateful` (true/false). Specifying a stateful server is done through the administrative console configuration.

Authentication protocol flow

Step 1:

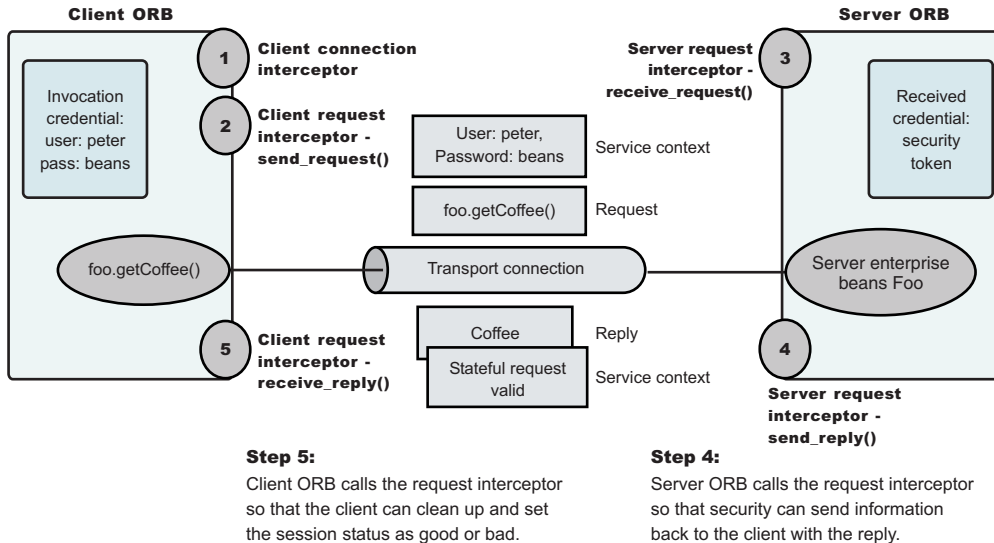

Client ORB calls the connection interceptor to create the connection.

Step 2:

Client ORB calls the request interceptor to get client security information.

Step 3:

Server ORB calls the request interceptor to receive the security information, authenticate, and set the received credential.

. Authentication protocol flow

Authentication policy for each request

The authentication policy of a given request determines the security protection between a client and a server. A client or server authentication protocol configuration can describe required features, supported features, and non-supported features. When a client requires a feature, it can talk only to servers that either require or support that feature. When a server requires a feature, it can talk only to clients that either require or support that feature. When a client supports a feature, it can talk to a server that supports or requires that feature, but can also talk to servers that do not support the feature. When a server supports a feature, it can talk to a client that supports or requires the feature, but can also talk to clients that do not support the feature or chose not to support the feature.

For example, for a client to support client certificate authentication, some setup is required to either generate a self-signed certificate or to get one from a certificate authority (CA). Some clients might not need to complete these actions, therefore, you can configure this feature as not supported. By making this decision, the client cannot communicate with a secure server that requires client certificate authentication. Instead, this client can choose to use the user ID and password as the method of authenticating itself to the server.

Typically, supporting a feature is the most common way of configuring features. It is also the most successful during runtime because it is more forgiving than requiring a feature. Knowing how secure servers are configured in your domain, you can choose the right combination for the client to ensure successful method invocations and still get the most security. If you know that all of your servers support both client certificate and user ID and password authentication for the client, you might want to require one and not support the other. If both the user ID and password and the client certificate are supported on the client and server, both are performed, but user ID and password take precedence at the server. This action is based on the CSiv2 specification requirements.

Supported authentication protocols

Use this page to reference information regarding supported authentication protocols.

V6.0.x Beginning with WebSphere Application Server Version 6.1, the WebSphere Application Server Version 6.1 servers only support the Common Secure Interoperability Version 2 (CSlv2) authentication protocol. Secure Authentication Service (SAS) is only supported between Version 6.0.x and previous version servers that have been federated in a Version 6.1 cell. The option to select between SAS, CSlv2, or both will only be made available in the administration console when a Version 6.0.x or previous release has been federated in a Version 6.1 cell.

V6.0.x In future releases, IBM will no longer ship or support the Secure Authentication Service (SAS) IIOP security protocol. It is recommended that you use the Common Secure Interoperability version 2 (CSlv2) protocol.

V6.0.x You can configure both protocols to work simultaneously between Version 6.0.x and previous version servers that have been federated in a Version 6.1 cell. If a server supports both protocols, it exports an interoperable object reference (IOR) that contains tagged components describing the configuration for SAS and CSlv2. If a client supports both protocols, it reads tagged components for both CSlv2 and SAS. If the client and server support both protocols, CSlv2 is used. However, if the server supports SAS (for example, the server is a previous WebSphere Application Server release) and the client supports both protocols, the client chooses SAS for this request.

Choose a protocol using the `com.ibm.CSI.protocol` property on the client side and configure this protocol through the administrative console on the server side.

Common Secure Interoperability Version 2 features

The following Common Secure Interoperability Version 2 (CSlv2) features are available in IBM WebSphere Application Server: Secure Sockets Layer (SSL) client certificate authentication, message layer authentication, identity assertion, and security attribute propagation.

- Identity Assertion.

Supports a downstream server in accepting the client identity that is established on an upstream server, without having to authenticate again. The downstream server trusts the upstream server.

- Message Layer Authentication.

Authenticates credential information and sends that information across the network so that a receiving server can interpret it.

- Security attribute propagation

Supports the use of the authorization token to propagate serialized Subject contents and PropagationToken contents with the request. You can propagate these objects using a pure client or a server login that adds custom objects to the Subject. Propagating security attributes prevents downstream logins from having to make user registry calls to look up these attributes.

Propagating security attributes is also useful when the security attributes contain information that is only available at the time of authentication. This information cannot be located using the user registry on downstream servers.

Identity assertion

Identity assertion is the invocation credential that is asserted to the downstream server.

When a client authenticates to a server, the received credential is set. When the authorization engine checks the credential to determine whether access is permitted, it also sets the *invocation* credential so that if the Enterprise JavaBeans (EJB) method calls another EJB method that is located on other servers, the invocation credential can be the identity used to invoke the downstream method. Depending on the RunAs mode for the enterprise beans, the invocation credential is set as the originating client identity, the server identity, or a specified different identity. Regardless of the identity that is set, when identity assertion is enabled, it is the invocation credential that is asserted to the downstream server.

The invocation credential identity is sent to the downstream server in an identity token. In addition, the sending server identity, including the password or token, is sent in the client authentication token when basic authentication is enabled. The sending server identity is sent through a Secure Sockets Layer (SSL) client certification authentication when client certificate authentication is enabled. Basic authentication takes precedence over client certificate authentication.

Both identity tokens are needed by the receiving server to accept the asserted identity. The receiving server completes the following actions to accept the asserted identity:

- The server determines whether the sending server identity, sent with a basic authentication token or with an SSL client certificate, is on the trusted principal list of the receiving server. The server determines whether the sending server can send an identity token to the receiving server.
- After it is determined that the sending server is on the trusted list, the server authenticates the sending server to verify its identity.
- The server is authenticated by comparing the user ID and password from the sending server to the receiving server. If the credentials of the sending server are authenticated and on the trusted principal list, then the server proceeds to evaluate the identity token.

Evaluation of the identity token consists of the following four identity formats that exist in an identity token:

- Principal name
- Distinguished name
- Certificate chain
- Anonymous identity

The product servers that receive authentication information typically support all four identity types. The sending server decides which one is chosen, based on how the original client authenticated. The existing type depends on how the client originally authenticates to the sending server. For example, if the client uses Secure Sockets Layer (SSL) client authentication to authenticate to the sending server, then the identity token sent to the downstream server contains the certificate chain. With this information, the receiving server can perform its own certificate chain mapping and interoperability is increased with other vendors and platforms.

After the identity format is understood and parsed, the identity maps to a credential. For an `ITTPPrincipal` identity token, this identity maps one-to-one with the user ID fields.

For an `ITTDistinguishedName` identity token, the mapping depends on the user registry. For Lightweight Directory Access Protocol (LDAP), the configured search filter determines how the mapping occurs. For LocalOS, the first attribute of the distinguished name (DN), which is typically the same as the common name, maps to the user ID of the registry.

Some user registry methods are called to gather additional credential information that is used by authorization. In a stateful server, this action completes once for the sending server and the receiving server pair where the identity tokens are the same. Subsequent requests are made through a session ID.

Identity assertion is only available using the Common Secure Interoperability Version 2 (CSIv2) protocol.

Identity assertions with trust validation

If you want an application or system provider to perform an identity assertion with trust validation, it can be accomplished by use of the Java Authentication and Authorization Service (JAAS) login framework, where trust validation is performed in one login module and credential creation in another. These two custom login modules are used to create a JAAS login configuration that performs a login to an identity assertion.

Two custom login module are required:

- A user-implemented trust association login module. This login module performs whatever trust verification the user requires. When trust is verified, the trust verification status and the login identity must be placed in a map in the share state of the login module to enable the credential creation login

module to use that information. The map must be stored in the `com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule.state` property. State maps contain the following information:

- `com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule.trusted` – set to `true`, if trusted, and `false`, if not trusted.
- `com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule.principal` – contains the principal of the identity.
- `com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule.certificates` – contains the certificate of the identity
- The `com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule` module performs the credential creation. It requires that the trust state information be in the login context's shared state. This login module is protected by the Java 2 security runtime permissions for the following:
 - `com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule.initialize`
 - `com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule.login`

`IdentityAssertionLoginModule` searches for the trust information in the shared state property, `com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule.state`. This is a map that contains the trust status and the identity used to login. The map includes the following:

- `com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule.trusted` – if set to `true` it is trusted, `false` if not trusted.
- `com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule.principal` – if a principal is used, it contains the principal of the identity necessary to login.
- `com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule.certificates` – if a certificate is used, it contains an array of a certificate chain that includes the identity necessary to login.

A `WSLoginFailedException` is returned if the state, trust, or identity information is missing. The login module then performs a login of the identity. The subject now contains the new identity.

Message layer authentication

Defines the credential information and sends that information across the network so that a receiving server can interpret it.

When you send authentication information across the network using a token the transmission is considered message layer authentication because the data is sent with the message inside a service context.

A pure Java client uses basic authentication, Generic Security Services Username Password (GSSUP), as the authentication mechanism to establish client identity.

However, a servlet can use either basic authentication (GSSUP) or the authentication mechanism of the server, Lightweight Third Party Authentication (LTPA), to send security information in the message layer. Use LTPA by authenticating or by mapping the basic authentication credentials to the security mechanism of the server.

The security token that is contained in a token-based credential is authentication mechanism-specific. The way that the token is interpreted is only known by the authentication mechanism. Therefore, each authentication mechanism has an object ID (OID) representing it. The OID and the client token are sent to the server, so that the server knows which mechanism to use when reading and validating the token. The following list contains the OIDs for each mechanism:

BasicAuth (GSSUP): `oid:2.23.130.1.1.1`
LTPA: `oid:1.3.18.0.2.30.2`
SWAM: No OID because it is not forwardable

Note: SWAM is deprecated in WebSphere Application Server Version 6.1 and will be removed in a future release.

On the server, the authentication mechanisms can interpret the token and create a credential, or they can authenticate basic authentication data from the client, and create a credential. Either way, the created credential is the *received* credential that the authorization check uses to determine if the user has access to invoke the method. You can specify the authentication mechanism by using the following property on the client side:

- `com.ibm.CORBA.authenticationTarget`

Basic authentication is currently the only valid value. You can configure the server through the administrative console.

Note: When **perform basic authentication** is enabled, if the client is not similarly configured (and does not pass a credential such as a user ID and password), the server object request broker (ORB) does not.

Configuring authentication retries

Situations occur where you want a prompt to display again if you entered your user ID and password incorrectly or you want a method to retry when a particular error occurs back at the client. If you can correct the error by information at the client side, the system automatically performs a retry without the client seeing the failure, if the system is configured appropriately.

Some of these errors include:

- Entering a user ID and password that are not valid
- Having an expired credential on the server
- Failing to find the stateful session on the server

By default, authentication retries are enabled and perform three retries before returning the error to the client. Use the `com.ibm.CORBA.authenticationRetryEnabled` property (`True` or `False`) to enable or disable authentication retries. Use the `com.ibm.CORBA.authenticationRetryCount` property to specify the number of retry attempts.

Immediate validating of a basic authentication login

In WebSphere Application Server Version 6.x, a behavior is defined during `request_login` for a `BasicAuth` login. In releases prior to Version 5, a `BasicAuth` login takes the user ID and password entered through the `loginSource` method and creates a `BasicAuth` credential. If either the user ID or the password is not valid, the client program does not find out until the first method request is attempted. When the user ID or password is specified during a prompt or programmatic login, the user ID and password are authenticated by default with the security server, with a `True` or `False` returned as the result. If `False`, an `org.omg.SecurityLevel2.LoginFailed` exception is returned to the client indicating that the user ID and password are not valid. If `True`, then the `BasicAuth` credential is returned to the caller of the `request_login`. To disable this feature on the pure client, specify `com.ibm.CORBA.validateBasicAuth=false`. By default, this feature is set to `True`. On the server side, specify this property in the security dynamic properties.

Configuring the Lightweight Third Party Authentication mechanism

You must configure Lightweight Third Party Authentication (LTPA) when you set up security for the first time. LTPA is the default authentication mechanism for WebSphere Application Server.

1. Open the administrative console.

Type `http://server_name:port_number/ibm/console` to access the administrative console in a Web browser.

Port 9060 is the default port number for accessing the administrative console. During installation, however, you might have specified a different port number. Use the appropriate port number.

2. Click **Security > Secure administration, applications, and infrastructure > Authentication mechanisms and expiration**.
3. Select the appropriate group from the **Key set group** field that contains your public, private, and shared LTPA keys. These keys are used to encrypt and decrypt data that is sent between servers. You can access these key set group configurations using the Key set group link. In the Key set group configuration, you can indicate whether to automatically generate new keys and when to generate them.
4. Enter a positive integer value in the **Authentication cache timeout** field. This timeout value refers to how long an LTPA token is valid in minutes. The token contains this expiration time so that any server that receives the token can verify that the token is valid before proceeding further. When the token expires, the user must log in again. An optimal value for this field depends on your configuration. However, the default value is 10 minutes.
5. Enter a positive integer in the **Timeout value for forwarded credentials between servers** field. This value refers to how long the server credentials from another server are valid before they expire. The default value is 120 minutes. The value in the **Timeout value for forwarded credentials between servers** field must be greater than the value in the **Authentication cache timeout** field.
6. Click **Apply** or **OK**. The LTPA configuration is now set. Do not generate the LTPA keys in this step because they are automatically generated later. Proceed with the rest of the steps that are required to enable security, and start with single sign-on (SSO), if it is required.
7. Complete the information in the Security > Secure administration, applications, and infrastructure panel and click **OK**. The LTPA keys are generated automatically the first time. Do not generate the keys manually.

The previous steps configured LTPA.

After configuring LTPA, you can also complete the following tasks:

1. Generate key files. For more information, see “Generating Lightweight Third Party Authentication keys” on page 220.
2. Export key files. For more information, see “Exporting Lightweight Third Party Authentication keys” on page 221.
3. Import key files. For more information, see “Importing Lightweight Third Party Authentication keys” on page 221.
4. Manage LPTA keys from multiple cells. For more information, see `tsec_sslmanagetakeys.dita`.
5. If you are enabling security, you can also enable single sign-on (SSO). See:
 - “Configuring single sign-on capability with Enterprise Identity Mapping” on page 250
 - “Configuring single sign-on capability with Lotus Domino” on page 262
 - “Configuring single sign-on capability with Tivoli Access Manager or WebSEAL” on page 265
6. If you generated a new set of keys or imported a new set of keys, verify that the keys are saved to the master configuration by clicking **Save** at the top of the panel. Because LTPA authentication uses time-sensitive tokens, verify that the time, date, and time zone are synchronized among all of the product servers that are participating in the protected domain. Changes to the time, date, and time zone are done independently from WebSphere Application Server. If the clock skew is too high between servers, the LTPA token seems prematurely expired and causes authentication or validation failures.

Authentication mechanisms and expiration

Use this page to specify the shared keys and configure the authentication mechanism that is used to exchange information between servers. You can also use this page to specify the amount of time that the authentication information remains valid and specify the single sign-on configuration.

To view this administrative console page, complete the following steps:

1. Click **Security > Secure administration, applications, and infrastructure**.
2. Under Authentication, click **Authentication mechanisms and expiration**.

After you configure the properties on this page, complete the following steps:

1. Click **Security > Secure administration, applications, and infrastructure**.
2. Verify that the appropriate registry is configured.
3. Click **Apply**. When security is enabled and any of these properties change, return to the Secure administration, applications, and infrastructure panel and click **Apply** to validate the changes.

Key set group

Specifies groups of public, private, and shared keys. These key groups enable the application server to manage multiple sets of Lightweight Third Party Authentication (LTPA) keys.

Generate Keys

Specifies whether to generate a new set of LTPA keys in the configured keystore, and to update the runtime with the new keys. By default, LTPA keys are regenerated on a schedule every 90 days, configurable to the day of the week.

Each new set of LTPA keys is stored in the keystore associated with the key set group. A maximum number of keys (or even one) can be configured. However, it is recommended to have at least two keys; the old keys can be used for validation while the new keys are being distributed.

This step is not necessary during security enablement. A default set of keys is created during the first server startup. If any nodes are down during a key generation event, the nodes should be synchronized with the Deployment Manager before restart.

Authentication cache timeout

Specifies the time period in minutes at which an LTPA token expires. Verify that this time period is less than the value for the Timeout value for forwarded credentials between servers field.

If the application server infrastructure security is enabled, the security cache timeout can influence performance. The timeout setting specifies how often to refresh the security-related caches. Security information pertaining to beans, permissions, and credentials is cached. When the cache timeout expires, all cached information not accessed within the timeout period is purged from the cache. Subsequent requests for the information result in a database lookup. Sometimes, acquiring the information requires invoking a Lightweight Directory Access Protocol (LDAP)-bind or native authentication. Both invocations are relatively costly operations for performance. Determine the best trade off for the application, by looking at usage patterns and security needs for the site.

The default security cache timeout value is 10 minutes. If you have a small number of users, it should be set higher than that, or if a large number of users, it should be set lower.

The LTPA timeout value should not be set lower than the security cache timeout. It is also recommended that the LTPA timeout value should be set higher than the orb request timeout value. However, there is no relation between the security cache timeout value and the orb request timeout value.

In a 20-minute performance test, setting the cache timeout so that a timeout does not occur yields a 40% performance improvement.

Data type	Integer
Units	Minutes and seconds
Default	10 minutes
Range:	Greater than 30 seconds

Timeout value for forwarded credentials between servers

Specifies the period of time after which forwarded credentials expire.

Specify a value for this field that is greater than the authentication cache timeout value.

Default 120 minutes

Password

Enter a password which will be used to encrypt and decrypt the LTPA keys from the SSO properties file. During import, this password should match the password used to export the keys at another LTPA server (for example, another application server Cell, Lotus Domino Server, and so on). During export, remember this password in order to provide it during the import operation.

After the keys are generated or imported, they are used to encrypt and decrypt the LTPA token. Whenever the password is changed, a new set of LTPA keys are automatically generated when you click **OK** or **Apply**. The new set of keys is used after the configuration changes are saved.

Data type String

Confirm password

Specifies the confirmed password that is used to encrypt and decrypt the LTPA keys.

Use this password when importing these keys into other application server administrative domain configurations and when configuring SSO for a Lotus Domino server.

Data type String

Fully qualified key file name

Specifies the name of the file that is used when importing or exporting keys.

Enter a fully qualified key file name, and click **Import Keys** or **Export Keys**.

Data type String

Internal server ID

Specifies the server ID that is used for interprocess communication between servers. The server ID is protected with an LTPA token when sent remotely. You can edit the internal server ID to make it identical to server IDs across multiple application server administrative domains (cells). By default this ID is the cell name.

This internal server ID should only be used in a Version 6.1 or higher environment. For mixed-version Cells, you should convert to using a server user ID and server password for interoperability.

To switch back to the server user ID and password for interoperability, complete the following steps:

1. Click **Security > Secure administration, applications, and infrastructure**.
2. Under User account repository, click the **Available realm definitions** drop-down list, select a user registry, and click **Configure**.
3. Select the **Server identity that is stored in the repository** option and type a valid registry ID and password.

Data type String

Import Keys

Specifies whether the server imports new LTPA keys.

To support single sign-on (SSO) in the application server product across multiple application server domains (cells), share the LTPA keys and the password among the domains. You can use the **Import Keys** option to import the LTPA keys from other domains. The LTPA keys are exported from one of the cells to a file. To import a new set of LTPA keys, complete the following steps:

1. Enter the appropriate password in the Password and Confirm password fields.
2. Click **OK** and click **Save**.
3. Enter the directory location where the LTPA keys are located in the Fully qualified key file name field prior to clicking **Import keys**.
4. Do not click **OK** or **Apply**, but save the settings.

Export Keys

Specifies whether the server exports LTPA keys.

To support single sign-on (SSO) in the WebSphere product across multiple application server domains (cells), share the LTPA keys and the password among the domains. Use the Export Keys option to export the LTPA keys to other domains.

To export the LTPA keys, make sure that the system is running with security enabled and is using LTPA. Enter the file name in the Fully qualified key file name field and click **Export Keys**. The encrypted keys are stored in the specified file.

Generating Lightweight Third Party Authentication keys

WebSphere Application Server generates Lightweight Third Party Authentication (LTPA) keys automatically during the first server startup. You can generate additional keys as you need them in the Authentication mechanisms and expiration panel.

At runtime, the default key sets are CellLTPASecret and CellLTPAKeyPair. The default key group is CellLTPAKeySetGroup. After generation, keys are stored in the default key store CellLTPAKeys.

Complete the following steps to generate new LTPA keys in the administrative console.

1. Access the administrative console.
Type `http://server_name:port_number/ibm/console` to access the administrative console in a Web browser.
2. Verify that all the WebSphere Application Server processes are running, including the cell, nodes, and application servers.

Important: If any of the servers are down at the time of key generation and then restarted later, these servers might contain old keys. Copy the new set of keys to these servers to restart them after you generate them.

3. Click **Security > Secure administration, applications, and infrastructure > Authentication mechanisms and expiration**.
4. Click **Generate keys** to generate a new set of LTPA keys in the local keystore and update the runtime with the new keys. By default, LTPA keys are regenerated on a schedule every 90 days, configurable to the day of the week. Each new set of LTPA keys is stored in the keystore that is associated with the key set group. The same password that is already stored in the configuration is used when you generate new keys.

Tip: This step is not necessary when you enable security because, by default, a set of keys is created during the first server startup. However, the keystore should have at least two keys: the old keys can be used for validation while the new keys are being distributed. If any nodes are down during a key generation event, the nodes should be synchronized with the Deployment Manager before restarting the server.

5. Restart the server for the changes to become active.

After WebSphere Application Server generates and saves a new set of keys, the generated keys are not used in the configuration until WebSphere Application Server is restarted. Token generation uses the keys that were last imported. To view the latest key version, see “Activating Lightweight Third Party Authentication key versions” on page 223.

You must recycle the node agents and application servers to accept the new keys. If any of the node agents are down, run a manual file synchronization utility from the node agent machine to synchronize the security configuration from the deployment manager.

Exporting Lightweight Third Party Authentication keys

To support single sign-on (SSO) in WebSphere Application Server across multiple WebSphere Application Server domains or cells, you must share the Lightweight Third Party Authentication (LTPA) keys and the password among the domains.

Make sure that the time in the domains is similar so that you do not mistakenly interpret the tokens as expired between the cells.

Complete the following steps in the administrative console to export key files for LTPA so that they can be shared across domains:

1. Type `http://server_name:port_number/ibm/console` in a Web browser to access the administrative console.
2. Click **Security > Secure administration, applications, and infrastructure > Authentication mechanisms and expiration**.
3. In the Password and Confirm password fields, enter the password that is used to encrypt the LTPA keys. Remember the password so that you can use it later when the keys are imported into the other cell.
4. In the Fully qualified key file name field, specify the fully qualified path to the location where you want the exported LTPA keys to reside. You must have write permission to this file.
5. Click **Export keys** to export the keys to the location that you specified in the **Fully qualified key file name** field.
6. Specify the **Internal server ID** that is used for interprocess communication between servers. The server ID is protected with an LTPA token when sent remotely. You can edit the internal server ID to make it identical to server IDs across multiple application server administrative domains (cells). By default this ID is the cell name.
7. Click **OK** and **Save**.

You can share LTPA keys and passwords among domains on WebSphere Application Server.

After exporting the keys from one cell, you must import those keys into the other cell. For more information, see “Importing Lightweight Third Party Authentication keys”

Importing Lightweight Third Party Authentication keys

To support single sign-on (SSO) in WebSphere Application Server across multiple WebSphere Application Server domains or cells, you must share the LTPA keys and the password among the domains. You can import LTPA keys from other domains and export keys to other domains.

After you export LTPA keys from one cell, you must import these keys into another cell. To import keys, you must know the password for the exported key file to access the LTPA keys. Verify that key files are exported from one of the cells into a file.

Complete the following steps in the administrative console to import key files for LTPA.

1. Access the administrative console for the cell that will receive the imported keys by typing `http://server_name:port_number/ibm/console` in a Web browser.

2. Click **Security > Secure administration, applications, and infrastructure > Authentication mechanisms and expiration**.
3. In the **Password** and **Confirm password** fields, enter the password that is used to decrypt the LTPA keys . This password must match the password that was used in the cell from which you are importing the keys.
4. In the **Fully qualified key file name** field, specify the fully qualified path to the location where the signer keys reside. You must have write permission to this file.
5. Click **Import keys** to import the keys to the location that you specified in the **Fully qualified key file name** field.
6. Click **OK** and **Save** to save the changes to the master configuration. It is important to save the new set of keys to match the new password so that no problems are encountered when starting the servers later.

After a new set of keys is generated and saved, the generated keys are not used in the configuration until WebSphere Application Server is restarted.

You must recycle the node agents and application servers to accept the new keys. If any of the node agents are down, run a manual file synchronization utility from the node agent machine to synchronize the security configuration from the deployment manager.

Important: After you enter the password in the Password and Confirm password fields and click **Save**, the password is not redisplayed on the administrative console panel.

Disabling automatic generation of Lightweight Third Party Authentication keys

You can disable the automatic generation of new Lightweight Third Party Authentication (LTPA) keys for key sets that are members of a key set group. Automatic generation creates new keys on a schedule that you specify when you configure a key set group, which manages one or more key sets. WebSphere Application Server uses key set groups to automatically generate cryptographic keys or multiple synchronized key sets.

You must know the name of the key set group and the management scope where the key set group is defined.

The default key set group is CellLTPAKeySetGroup.

LTPA keys are used to encrypt the LTPA token. You might want to disable the auto-generation of these keys so that you can generate them on a schedule. The following steps are needed to complete this task in the administrative console.

1. Click **Security > SSL certificate and key management > Manage endpoint security configurations**.
2. Expand the tree to the inbound or outbound management scope that contains the key set group, and then click the scope link.
3. Under Related Items, click **Key Set Groups**.
4. Click the key set group that you want to disable.
5. Clear the **Automatically generate keys** option.
6. Click **OK** and **Save** to save the changes to the master configuration.
7. Start the server again for the changes to become active.

You have disabled the automatic generation of LTPA keys for the key sets in the key set group.

Tip: You can generate keys manually at any time by completing the following steps:

1. Open the key set group collection.
2. Select the check box beside the key set group.
3. Click **Generate keys**.

Managing LTPA keys from multiple WebSphere Application Server cells

You can specify the shared keys and configure the authentication mechanism that is used to exchange information between servers to import and export LTPA keys across multiple WebSphere Application Server cells.

You must be sure that the exported key file for the multiple cells is accessible on the host where WebSphere Application Server is running. Also, you must know the password that was used when the keys were exported.

At runtime, the default key sets are CellLTPASecret and CellLTPAKeyPair. The default key group is CellLTPAKeySetGroup. After generation, keys are stored in the default key store CellLTPAKeys.

Complete the following steps to manage LTPA keys using the administrative console.

1. Access the administrative console.
Type `http://server_name:port_number/ibm/console` to access the administrative console in a Web browser.
2. Verify that all of the WebSphere Application Server processes are running, including cells, nodes, and all of the application servers. If any of the servers are down at the time of key generation and then brought back up later, these servers might contain old keys. Copy the new set of keys to these servers, then bring them back up.
3. Click **Security > Secure administration, applications, and infrastructure > Authentication mechanisms and expiration**.
4. Type the password for the LTPA keys in the **Password** field. Enter a password that is used to encrypt and decrypt the LTPA keys from the single sign-on (SSO) properties file. During import, this password should match the password that is used to export the keys at another LTPA server. During export, remember this password in order to provide it during the import operation.
5. Type the password again in the **Confirm password** field.
6. Select from among the following options:
 - To support SSO in the WebSphere product across multiple application server domains (cells), you can share the LTPA keys and the password among the domains. Before exporting, make sure that security is enabled and using LTPA on the system that is running. For more information, see “Exporting Lightweight Third Party Authentication keys” on page 221.
 - To support SSO in the application server product across multiple application server domains (cells), you can share the LTPA keys and the password among the domains. For more information, see “Importing Lightweight Third Party Authentication keys” on page 221.
 - To import LTPA keys for the current cell if they were previously exported, see “Importing Lightweight Third Party Authentication keys” on page 221.
7. Start the server again for any changes you make to become active.

The shared LTPA keys are now available for WebSphere Application Server to use for secure connections.

After the keys are generated or imported, they are used to encrypt and decrypt the LTPA token. To view the latest key version, see “Activating Lightweight Third Party Authentication key versions.”

Activating Lightweight Third Party Authentication key versions

Key sets manage Lightweight Third Party Authentication (LTPA) keys in a key store that is based on a key alias prefix. A key alias prefix is automatically generated when you generate a new key and store it in a

key store. Key stores can contain multiple versions of keys for any given key alias prefix. You can specify a maximum number of active keys in the key set configuration.

You must know the name of the key set group and the management scope where the key set group is defined.

The default key set group is CellLTPAKeySetGroup.

Complete the following steps in the administrative console.

LTPA keys are used to encrypt the LTPA token. You might want to set a specific number of active keys that WebSphere Application Server returns when the server queries for keys for a particular key set. The following steps are needed to complete this task in the administrative console.

1. Click **Security > SSL certificate and key management > Manage endpoint security configurations**.
2. Expand the tree to the inbound or outbound management scope that contains the key set group, and then click the scope link.
3. Under Related Items, click **Key Sets**.
4. Click the key set that you want to modify.
5. In the **Maximum number of keys referenced** field, type a numerical value for the maximum number of keys that you want to activate.
6. Click **OK** and **Save** to save the changes to the master configuration.
7. Start the server again for the changes to become active. WebSphere Application Server activates only the number of recent keys that you specified.

The **Maximum number of keys referenced** value determines how many active keys are returned when the server queries for keys for the selected key set.

You can click **Active key history** in the Key set panel to display the keys that are active for this key set.

Integrating third-party HTTP reverse proxy servers

These steps are required to use either a WebSEAL trust association interceptor or your own trust association interceptor with a reverse proxy security server.

WebSphere Application Server enables you to use multiple trust association interceptors. The Application Server uses the first interceptor that can handle the request.

1. Access the administrative console.
Type `http://server_name:port_number/ibm/console` in a Web browser.
Port 9060 is the default port number for accessing the administrative console. During installation, however, you might have specified a different port number. Use the appropriate port number.
2. Click **Security > Secure administration, applications, and infrastructure**.
3. Under Web security, click **Trust association**.
4. Select the **Enable trust association** option.
5. Under Additional properties, click **Interceptors**. The default value appears.
6. Verify that the appropriate trust association interceptors are listed. If you need to use a WebSEAL trust association interceptor, see “Configuring single sign-on using the trust association interceptor” on page 273 or “Configuring single sign-on using trust association interceptor ++” on page 274. If you are not using WebSEAL and need to use a different interceptor, complete the following steps:
 - a. Select both the **com.ibm.ws.security.web.WebSealTrustAssociationInterceptor** and the **com.ibm.ws.security.web.TAMTrustAssociationInterceptorPlus** class name and click **Delete**.
 - b. Click **New** and specify a trust association interceptor.

Enables trust association.

1. If you are enabling security, make sure that you complete the remaining steps for enabling security.
2. Save, stop and restart all of the product servers (deployment managers, nodes and Application Servers) for the changes to take effect.

Trust association settings

Use this page to enable trust association, which integrates application server security and third-party security servers. More specifically, a reverse proxy server can act as a front-end authentication server while the product applies its own authorization policy onto the resulting credentials passed by the proxy server.

To view this administrative console page, complete the following steps:

1. Click **Security > Secure administration, applications, and infrastructure**.
2. Under Authentication, expand Web security and click **Trust association**.

When security is enabled and any of these properties change, go to the Secure administration, applications, and infrastructure panel and click **Apply** to validate the changes.

Enable trust association

Specifies whether trust association is enabled.

Data type:	Boolean
Default:	Disable
Range:	Enable or Disable

Trust association interceptor collection

Use this page to specify trust information for reverse security proxy servers.

To view this administrative console page, complete the following steps:

1. Click **Security > Secure administration, applications, and infrastructure**.
2. Under Authentication, expand Web security and click **Trust association**.
3. Under Additional Properties, click **Interceptors**.

When security is enabled and any of these properties are changed, go to the Secure administration, applications, and infrastructure panel and click **Apply** to validate the changes.

Interceptor class name

Specifies the trust association interceptor class name.

Data type

String

Default

`com.ibm.ws.security.web.WebSealTrustAssociationInterceptor`

Trust association interceptor settings

Use this page to specify trust information for reverse security proxy servers.

To view this administrative console page, complete the following steps:

1. Click **Security > Secure administration, applications, and infrastructure**.
2. Under Authentication, expand Web security and click **Trust association**.
3. Under Additional Properties, click **Interceptors > New**.

When security is enabled and any of these properties are changed, go to the Secure administration, applications, and infrastructure panel and click **Apply** to validate the changes.

Interceptor class name

Specifies the trust association interceptor class name.

Data type

String

Default

`com.ibm.ws.security.web.WebSealTrustAssociationInterceptor`

Implementing single sign-on to minimize Web user authentications

With single sign-on (SSO) support, Web users can authenticate once when accessing Web resources across multiple WebSphere Application Servers. Form login mechanisms for Web applications require that SSO is enabled. Use this topic to configure single sign-on for the first time.

SSO is supported only when Lightweight Third Party Authentication (LTPA) is the authentication mechanism.

When SSO is enabled, a cookie is created containing the LTPA token and inserted into the HTTP response. When the user accesses other Web resources in any other WebSphere Application Server process in the same domain name service (DNS) domain, the cookie is sent in the request. The LTPA token is then extracted from the cookie and validated. If the request is between different cells of WebSphere Application Servers, you must share the LTPA keys and the user registry between the cells for SSO to work. The realm names on each system in the SSO domain are case sensitive and must match identically.

The realm name is the same as the host name.

For the Lightweight Directory Access Protocol (LDAP) the realm name is the host:port realm name of the LDAP server. The LTPA authentication mechanism requires that you enable SSO if any of the Web applications have form login as the authentication method.

Because single sign-on is a subset of LTPA, it is recommended that you read “Lightweight Third Party Authentication” on page 176 for more information.

When you enable security attribute propagation, the following cookies are added to the response:

LtpaToken

LtpaToken is used for inter-operating with previous releases of WebSphere Application Server. This token contains the authentication identity attribute only.

LtpaToken2

LtpaToken2 contains stronger encryption and enables you to add multiple attributes to the token. This token contains the authentication identity and additional information such as the attributes that are used for contacting the original login server and the unique cache key for looking up the Subject when considering more than just the identity in determining uniqueness.

For more information, see “Security attribute propagation” on page 188.

Note: LtpaToken is generated for releases prior to WebSphere Application Server Version 5.1.1. LtpaToken2 is generated for WebSphere Application Server Version 5.1.1 and beyond.

Token type	Purpose	How to specify
LtpaToken only	This token type is used for the same SSO behavior existing in WebSphere Application Server Version 5.1 and previous releases. Also, this token type is interoperable with those previous releases.	Disable the Web inbound security attribute propagation option, which is located in the SSO configuration panel in the administrative console. To access this panel, complete the following steps: <ol style="list-style-type: none"> 1. Click Security > Secure administration, applications, and infrastructure. 2. Under Web security, click Single sign-on (SSO).
LtpaToken2 only	This token type is used for Web inbound security attribute propagation and uses the AES, CBC, PKCS5 padding encryption strength (128-bit key size). However, this token type is not interoperable with releases prior to WebSphere Application Server Version 5.1.1. The token type supports multiple attributes that are specified in the token, mostly containing information to contact the original login server.	Enable the Web inbound security attribute propagation option in the SSO configuration panel within the administrative console. Disable the Interoperability mode option in the SSO configuration panel within the administrative console. To access this panel, complete the following steps: <ol style="list-style-type: none"> 1. Click Security > Secure administration, applications, and infrastructure. 2. Under Web security, click Single sign-on (SSO).
LtpaToken and LtpaToken2	These tokens together support both of the previous two options. The token types are interoperable with releases prior to WebSphere Application Server Version 5.1.1 because LtpaToken is present. The security attribute propagation function is enabled because the LtpaToken2 is present.	Enable the Web inbound security attribute propagation option in the SSO configuration panel within the administrative console. Enable the Interoperability mode option in the SSO configuration panel within the administrative console. To access this panel, complete the following steps: <ol style="list-style-type: none"> 1. Click Security > Secure administration, applications, and infrastructure. 2. Under Web security, click Single sign-on (SSO).

The following steps are required to configure SSO for the first time.

1. Open the administrative console.
Type `http://server_name:port_number/ibm/console` to access the administrative console in a Web browser.
Port 9060 is the default port number for accessing the administrative console. During installation, however, you might have specified a different port number. Use the appropriate port number.
2. Click **Security > Secure administration, applications, and infrastructure**.
3. Under Web security, click **Single sign-on (SSO)**.
4. Click the **Enabled** option if SSO is disabled. After you click the **Enabled** option, make sure that you complete the remaining steps to enable security.
5. Click **Requires SSL** if all of the requests are expected to use HTTPS.

6. Enter the fully qualified domain names in the **Domain name** field where SSO is effective. If you specify domain names, they must be fully qualified. If the domain name is not fully qualified, WebSphere Application Server does not set a domain name value for the LtpaToken cookie and SSO is valid only for the server that created the cookie.

When you specify multiple domains, you can use the following delimiters: a semicolon (;), a space (), a comma (,), or a pipe (|). WebSphere Application Server searches the specified domains in order from left to right. Each domain is compared with the host name of the HTTP request until the first match is located. For example, if you specify `ibm.com; austin.ibm.com` and a match is found in the `ibm.com` domain first, WebSphere Application server does not continue to search for a match in the `austin.ibm.com` domain. However, if a match is not found in either the `ibm.com` or `austin.ibm.com` domains, then WebSphere Application Server does not set a domain for the LtpaToken cookie.

You can configure the Domain name field using any of the following values:

Domain name value type	Example	Purpose
Blank		The domain is not set. This causes the browser to set the domain to the request host name. The sign-on is valid on that single host only.
Single domain name	<code>austin.ibm.com</code>	If the request is to a host within the configured domain, the sign-on is valid for all hosts within that domain. Otherwise, it is valid on the request host name only.
UseDomainFromURL	UseDomainFromURL	If the request is to a host within the configured domain, the sign-on is valid for all hosts within that domain. Otherwise, it is valid on the request host name only.
Multiple domain names	<code>austin.ibm.com;raleigh.ibm.com</code>	The sign-on is valid for all hosts within the domain of the request host name.
Multiple domain names and UseDomainFromURL	<ul style="list-style-type: none"> • <code>austin.ibm.com;raleigh.ibm.com; UseDomainFromURL</code> 	The sign-on is valid for all hosts within the domain of the request host name.

If you specify the `UseDomainFromURL`, WebSphere Application Server sets the SSO domain name value to the domain of the host that makes the request. For example, if an HTTP request comes from `server1.raleigh.ibm.com`, WebSphere Application Server sets the SSO domain name value to `raleigh.ibm.com`.

Tip: The value, `UseDomainFromURL`, is case insensitive. You can type `usedomainfromurl` to use this value.

For more information, see “Single sign-on settings” on page 266.

7. **Optional:** Enable the **Interoperability mode** option if you want to support SSO connections in WebSphere Application Server version 5.1.1 or later to interoperate with previous versions of the application server. This option sets the old-style LtpaToken token into the response so it can be sent to other servers that work only with this token type. However, this option applies only when the **Web inbound security attribute propagation** option is enabled. In this case, both the LtpaToken and LtpaToken2 tokens are added to the response. Otherwise, only the LtpaToken2 token is added to the response. If the **Web inbound security attribute propagation** option is disabled, then only the LtpaToken token is added to the response.
8. **Optional:** Enable the **Web inbound security attribute propagation** option if you want information added during the login at a specific front-end server to propagate to other front-end servers. The SSO token does not contain any sensitive attributes, but does understand where the original login server exists in cases where it needs to contact that server to retrieve serialized information. It also contains

the cache look-up value for finding the serialized information in DynaCache, if both front-end servers are configured in the same DRS replication domain. For more information, see “Security attribute propagation” on page 188.

Important: If the following statements are true, it is recommended that you disable the **Web inbound security attribute propagation** option for performance reasons:

- You do not have any specific information added to the Subject during a login that cannot be obtained at a different front-end server.
- You did not add custom attributes to the PropagationToken token using WSSecurityHelper application programming interfaces (APIs).

If you find that you are missing custom information in the Subject, re-enable the **Web inbound security attribute propagation** option to see if the information is propagated successfully to other front-end application servers. If you disable SSO, but use a trust association interceptor instead, you might still need to enable the **Web inbound security attribute propagation** option if you want to retrieve the same Subject generated at different front-end servers.

9. Click **OK**.

For the changes to take effect, save, stop, and restart all the product deployment managers, nodes, and servers.

Configuring single sign-on capability with SPNEGO TAI

WebSphere Application Server provides a trust association interceptor (TAI) that uses the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) to securely negotiate and authenticate HTTP requests for secured resources in WebSphere Application Server. To deploy and use the SPNEGO TAI you need to examine your installation and decide on how best to configure the SPNEGO TAI.

Lightweight Third Party Authentication (LTPA) is the default authentication mechanism for WebSphere Application Server. However, you may need to configure LTPA prior to configuring the SPNEGO TAI. LTPA is the required authentication mechanism for all trust association interceptors. You can configure LTPA by clicking **Security > Secure administration, applications, and infrastructure > Authentication mechanisms and expiration**.

Note: Enabling Web security single sign-on (SSO) is optional when you configure the SPNEGO TAI. For more information, see “Implementing single sign-on to minimize Web user authentications” on page 226.

Answer the following questions to establish how the SPNEGO TAI is deployed.

1. What is your criteria for intercepting HTTP requests?

- You must decide if the SPNEGO TAI deployment will use the HTTPHeaderFilter class as the default. If you do use this class, then you must specify the exact filter properties for this class. The default behavior of the SPNEGO TAI is to use the com.ibm.ws.spnego.HTTPHeaderFilter class to intercept all requests.
- If you do not use the sample com.ibm.ws.spnego.HTTPHeaderFilter class, then you must define a new class that implements the com.ibm.wsspi.security.spnego.SpnegoTAIFilter interface.
- You can decide to further control what HTTP requests are intercepted using the Service Provider Programming Interface (SPI), “Filtering HTTP requests for SPNEGO TAI” on page 248

See “SPNEGO TAI custom configuration attributes” on page 234 for descriptions of

- com.ibm.ws.security.spnego.SPN<id>.filterClass
- com.ibm.ws.security.spnego.SPN<id>.filter

2. Is user Id mapping to be used? If not, why not? WebSphere Application Server enables you to define or develop a custom login module to map user IDs. See “Mapping user Ids from client to server for SPNEGO” on page 247 for more detail about performing this mapping.

You must decide, before deploying the TAI, whether or not to use this custom login module to perform the SPNEGO TAI identity mapping

3. What type of encryption is to be used to process the SPNEGO tokens? Microsoft Windows Active Directory supports two different Kerberos encryption types: RC4-HMAC and DES-CBC-MD5. The IBM Java Generic Security Service (JGSS) library (and SPNEGO library) support both of these encryption types.

Restriction: RC4-HMAC encryption is only supported with a Windows 2003 Server key distribution center (KDC). RC4-HMAC encryption is not supported when using a Windows 2000 Server as a Kerberos KDC.

4. How will you handle credential delegation? Kerberos supports the delegation of credentials. A server that receives Kerberos credentials from a client can impersonate that client to other servers by using delegated credentials. Since SPNEGO TAI tokens are a wrapping of a Kerberos credential, a server that receives Kerberos credentials within an SPNEGO token can use those Kerberos credentials to impersonate the original user. That server can interact using SPNEGO over HTTP as a SPNEGO client to other SPNEGO servers by composing an appropriate HTTP Authorization header.

5. Will the SPNEGO TAI be deployed in a single or multiple domain name service (DNS) domain environment?

Web browsers running on Windows are sensitive to DNS domains. They only send a SPNEGO token when the target host name identifies a host name defined in the DNS domain of the client machine. You can use HTTP redirection to support this configuration with the creation of a pseudo Kerberos service principal name (SPN) in each DNS domain. All SPNs that WebSphere Application Server supports must have their secret keys available in Kerberos keytab files. To enable single sign-on across multiple DNS domains, a separate Kerberos keytab file is generated for each SPN per domain. These individual Kerberos keytab files must be merged before they can be used by WebSphere Application Server.

6. How frequently will application servers reload the SPNEGO TAI properties The SPNEGO TAI has an optional property reload feature that allows the reloading of the TAI properties without restarting the Java virtual machine (JVM). This reload feature is controlled by the system properties `com.ibm.ws.security.spnego.propertyReloadFile` and `com.ibm.ws.security.spnego.propertyReloadTimeout`. These properties taken together enable the SPNEGO TAI internal properties to be reloaded from a file on the file system after a certain time period. If the `com.ibm.ws.security.spnego.propertyReloadTimeout` attribute is set to a valid integer value, and the `com.ibm.ws.security.spnego.propertyReloadFile` attribute points to a file on the file system, then each JVM reloads the SPNEGO TAI properties from the file after the timeout period expires. Also, the SPNEGO TAI properties are reloaded only if the date on the file has changed. If these reload properties are not set, then the SPNEGO TAI properties are only loaded once, at JVM initialization, from the SPNEGO TAI custom properties that are defined in WebSphere Application Server configuration data. See “SPNEGO TAI JVM configuration attributes” on page 244 for more information about these reload properties.

The Windows Active Directory (Web) administrator, the WebSphere Application Server administrator, and the application team review and answer these questions to determine the best deployment and configuration settings for the SPNEGO TAI.

Configuring WebSphere Application Server environment to use SPNEGO

The objective of the Web administrator is to configure and administer the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) trust association interceptor (TAI) in WebSphere Application Server to provide users who successfully authenticated in a Microsoft Active Directory domain with a single sign-on capability. The administrator specifies additional criteria that selects what Web transactions to authenticate in the single sign-on environment.

Verify that the Web browser is configured to use the SPNEGO authentication mechanism. “Configuring the Web browser to use SPNEGO” on page 249 describes what the user needs to do to configure the Web browser.

The Web administrator configures and enables the SPNEGO TAI. The process to configure and enable the SPNEGO TAI operation in WebSphere Application Server requires some tasks that use tools not supplied by WebSphere Application Server. Refer to those appropriate documents that describe these tasks and tools. These documents are supplied by the appropriate supplier.

1. Create a user account in the Microsoft Active Directory.
2. Map the user account to the Kerberos service principal name (SPN). This user account represents the WebSphere Application Server as being a Kerberized service with the Kerberos key distribution center (KDC). Use the **setspn** tool to establish WebSphere Application Server as the user. This user account is not the account name of the user. More information about the **setspn** tool can be found here, Windows 2003 Technical Reference (setspn command)
3. Create the Kerberos keytab file and make it available to WebSphere Application Server. Use the **ktpass** tool to create the Kerberos keytab file (krb5.keytab). Windows 2003 Technical Reference (Kerberos keytab file and ktpass command) provides more information on creating the Kerberos keytab file.
4. Configure and enable the application server and the associated SPNEGO TAI using the administrative console or using the wsadmin command to perform command tasks. See “Configuring SPNEGO TAI in WebSphere Application Server” on page 233.
5. Select Lightweight Third-Party Authentication (LTPA) as the authentication mechanism. See “Configuring the Lightweight Third Party Authentication mechanism” on page 216.
6. Enable the SPNEGO TAI in each application server in which it is defined.
7. Install the Kerberos keytab file (krb5.keytab).
8. Update the associated Kerberos configuration (krb5.conf).
9. Configure JVM properties and enable SPNEGO TAI. See “Configuring JVM properties and enabling SPNEGO TAI in WebSphere Application Server” on page 243.

WebSphere Application Server is configured to use the SPNEGO TAI.

Configuring the Kerberos configuration properties:

The Kerberos configuration properties, or krb5.ini and krb5.conf files, must be configured on every WebSphere Application Server instance in a cell in order to use the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) trust association interceptor (TAI) for WebSphere Application Server.

You search for the default Kerberos configuration file in the order as follows:

1. The file referenced by the Java property java.security.krb5.conf
2. <java.home>/lib/security/krb5.conf
3. c:\winnt\krb5.ini on Microsoft Windows platforms
4. /etc/krb5/krb5.conf on UNIX platforms
5. /etc/krb5.conf on Linux™ platforms.

A configuration file for a Kerberos configuration on a UNIX platform follows:

```
[libdefaults]
  default_realm = WSSEC.AUSTIN.IBM.COM
  default_keytab_name = FILE:/etc/krb5.keytab
  default_tkt_enctypes = des-cbc-md5
  default_tgs_enctypes = des-cbc-md5
[realms]
  WSSEC.AUSTIN.IBM.COM = {
    kdc = axel.austin.ibm.com:88
    default_domain = austin.ibm.com
```

```

admin_server = axel.austin.ibm.com
    default domain = austin.ibm.com
}
[domain_realm]
.austin.ibm.com = WSSEC.AUSTIN.IBM.COM

```

In the above example, the Kerberos key distribution center (KDC) is axel.austin.ibm.com:88. The Kerberos keytab file is located at: FILE:/etc/krb5.keytab. The Kerberos realm name is WSSEC.AUSTIN.IBM.COM, which is also the Microsoft domain controller. After you update your Kerberos configuration properties for your particular system deployment, your Kerberos configuration is ready for use with the SPNEGO TAI.

The Kerberos configuration is configured for use with the SPNEGO TAI.

Creating the Kerberos configuration file for use with the SPNEGO TAI:

You use the wsadmin utility to create the Kerberos keytab configuration file for use with the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) trust association interceptor (TAI) for WebSphere Application Server.

Note: A Kerberos keytab configuration file contains a list of keys that are analogous to user passwords. It is important for hosts to protect their Kerberos keytab files by storing them on the local disk. The krb5.conf file permission must be 644, which means that you can read and write the file; however, members of the group that the file belongs to, and all others can only read the file.

Note: A Kerberos keytab configuration file contains a list of keys that are analogous to user passwords. It is important for hosts to protect their Kerberos keytab files by storing them on the local disk. The krb5.conf file permission must be 644, which means that you can read and write the file; however, members of the group that the file belongs to, and all others can only read the file. The user ID that runs adjunt, control, and servants must have read access to the krb5.conf and krb5.keytab files.

Verify that end-user desktop browsers are configured to support SPNEGO authentication, that the SPNEGO TAI is enabled, that the Java virtual machine (JVM) property is set and, that WebSphere Application Server is configured to enable the operation of the SPNEGO TAI.

Use the wsadmin utility to configure the SPNEGO TAI for WebSphere Application Server:

1. Start WebSphere Application Server.
2. Start the command-line utility by running the **wsadmin** command from the *app_server_root/bin* directory from the Qshell command line.
3. At the **wsadmin** prompt, enter the following command:

```
$AdminTask createKrbConfigFile
```

You can use the following parameters with this command:

Option	Description
<krbPath>	This parameter is required. It provides the fully qualified file system location of the Kerberos configuration (krb5.ini or krb5.conf) file.
<realm>	This parameter is required. It provides the Kerberos realm name. The value of this attribute is used by the SPNEGO TAI to form the Kerberos service principal name for each of the hosts specified with the property com.ibm.ws.security.spnego.SPN<id>.hostName.

Option	Description
<kdcHost>	This parameter is required. It provides the host name of the Kerberos Key Distribution Center (KDC).
<kdcPort>	This parameter is optional. It provides the port number of the KDC. The default value, if not specified, is 88.
<dns>	This parameter is required. It provides the default domain name service (DNS) that is used to produce a fully qualified host name.
<keytabPath>	This parameter is required. It provides the file system location of the Kerberos keytab file.
<encryption>	This parameter is optional. It identifies the list of supported encryption types, separated by a space. The specified value is used for the default_tkt_encetypes and default_tgs_encetypes. The default encryption types, if not specified, are des-cbc-md5 and rc4-hmac.

In the following example, the wsadmin command creates the krb5.ini file in the c:\winnt directory. The default Kerberos keytab file is also in c:\winnt. The actual Kerberos realm name is WSSEC.AUSTIN.IBM.COM and the KDC host name is host1.austin.ibm.com.

```
wsadmin>$AdminTask createKrbConfigFile {-krbPath
c:\winnt\krb5.ini -realm WSSEC.AUSTIN.IBM.COM -kdcHost host1.austin.ibm.com
-dns austin.ibm.com -keytabPath c:\winnt\krb5.keytab}
```

The Kerberos keytab configuration file is created for use with the SPNEGO TAI.

Note: The default Kerberos krb5.ini file on Windows is /winnt/krb5.ini and on a distributed environment is /etc/krb5. If you specify another location path, then you must also specify the java.security.krb5.conf JVM property.

For example, if your krb5.conf file is specified at /opt/IBM/WebSphere/profiles/AppServer/etc/krb5.conf, then you need to specify -Djava.security.krb5.conf=/opt/IBM/WebSphere/profiles/AppServer/etc/krb5.conf.

Configuring SPNEGO TAI in WebSphere Application Server:

Performing this task helps you, as Web administrator, to ensure that WebSphere Application Server is properly configured to enable the operation of the Simple and Protected GSS-API Negotiation (SPNEGO) trust association interceptor (TAI).

You need to know how to use the WebSphere Application Server administrative console to manage the security configuration and have the proper authority to modify the security configuration of the application server.

Note: It is recommended that you use wsadmin to manage the SPNEGO TAI properties.

Complete the following steps to enable the operation of the SPNEGO TAI.

1. Log on to the WebSphere Application Server administrative console.
2. Click **Security > Secure administration, applications, and infrastructure**.
3. Expand **Web security** and click **Trust association**.
4. Under the General Properties heading, select the **Enable trust association** check box, then click **Interceptors**.
5. Select the SPNEGO TAI in the list of interceptors, then click **Custom properties**.

6. Click **New** and then fill in the **Name** and **Value** fields. Click **OK**. Repeat this step for each custom property that you want to apply to the SPNEGO TAI.
7. After you finish defining your custom properties, click **Save** to store the updated SPNEGO TAI configuration.

Your SPNEGO TAI configuration is now configured for WebSphere Application Server. You must ensure that:

- A user account is created in the Microsoft Active Directory and mapped to a Kerberos principal name.
- A Kerberos keytab file (krb5.keytab) is created and made available to the WebSphere Application Server. The Kerberos keytab file contains keys WebSphere Application Server uses to authenticate the user in the Microsoft Active Directory and the Kerberos account.

SPNEGO TAI custom configuration attributes:

The Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) trust association interceptor (TAI) custom configuration attributes control different operational aspects of the SPNEGO TAI. You can specify different attribute values for each application server.

Each of the attributes defined in the following table is specified in the Custom Properties panel for the SPNEGO TAI using the administrative console facility. For convenience, you can optionally place these attributes in a properties file. In this case, the SPNEGO TAI loads the configuration attributes from the file instead of the Custom Properties panel definition. Refer to `com.ibm.ws.security.spnego.propertyReloadFile` property as defined in “SPNEGO TAI JVM configuration attributes” on page 244.

To assign unique attribute names that identify each possible SPN, an `SPN<id>` is embedded in the attribute name and used to group the attributes that are associated with each SPN. The `SPN<id>` s are numbered sequentially for each attribute group.

Table 4.

Attribute Name	Required	Default Value
<code>com.ibm.ws.security.spnego.SPN<id>.hostName</code>	Yes	None
<code>com.ibm.ws.security.spnego.SPN<id>.filterClass</code>	No	See the description that follows.
<code>com.ibm.ws.security.spnego.SPN<id>.filter</code>	No	See the description that follows.
<code>com.ibm.ws.security.spnego.SPN<id>.enableCredDelegate</code>	No	false
<code>com.ibm.ws.security.spnego.SPN<id>.spnegoNotSupportedPage</code>	No	See the description that follows.
<code>com.ibm.ws.security.spnego.SPN<id>.NTLMTokenReceivedPage</code>	No	See the description that follows.
<code>com.ibm.ws.security.spnego.SPN<id>.trimUserName</code>	No	true

`com.ibm.ws.security.spnego.SPN<id>.hostName`

This attribute is required. It specifies the hostname in the SPN used by the SPNEGO TAI to establish a Kerberos secure context.

Note: The hostname is the long form of hostname. For example, `myHostName.austin.ibm.com`. The Kerberos SPN is a string of the form `HTTP/hostname@realm`. The complete SPN is used with the Java Generic Security Service (JGSS) by the SPNEGO provider to obtain the security credential and security context that are used in the authentication process.

`com.ibm.ws.security.spnego.SPN<id>.filterClass`

This attribute is optional. It specifies the name of the Java class that is used by the SPNEGO TAI to

select which HTTP requests are subject to SPNEGO authentication. If no class is specified, the default `com.ibm.ws.security.spnego.HTTPHeaderFilter` implementation class is used. The Java class that is specified must implement the `com.ibm.wsspi.security.spnego.SpnegoFilter` interface. A default implementation of this interface is provided. Specify the `com.ibm.ws.security.spnego.HTTPHeaderFilter` class to use the default implementation. This class uses the selection rules specified with the `com.ibm.ws.security.spnego.SPN<id>.filter` property.

com.ibm.ws.security.spnego.SPN<id>.filter

This attribute is optional. It defines the filtering criteria that is used by the specified class with the previous attribute. It defines arbitrary criteria that is meaningful to the implementation class used. The `com.ibm.ws.security.spnego.HTTPHeaderFilter` default implementation class uses this attribute to define a list of selection rules that represent conditions that are matched against the HTTP request headers to determine whether or not the HTTP request is selected for SPNEGO authentication.

Each condition is specified with a key-value pair, separated from each other by a semicolon. The conditions are evaluated from left to right, as they display in the specified attribute. If all conditions are met, the HTTP request is selected for SPNEGO authentication.

The key and value in the key-value pair are separated by an operator that defines which condition is checked. The key identifies an HTTP request header to extract from the request and its value is compared with the value that is specified in the key-value pair according to the operator specification. If the header that is identified by the key is not present in the HTTP request, the condition is treated as not being met.

Any of the standard HTTP request headers can be used as the key in the key-value pairs. Refer to the HTTP specification for the list of valid headers. In addition, two keys are defined to extract information from the request, also useful as a selection criterion, which is not available through standard HTTP request headers. The `remote-address` key is used as a pseudo header to retrieve the remote TCP/IP address of the client application that sent the HTTP request. The `request-URL` key is used as a pseudo header to retrieve the URL that is used by the client application to make the request. The interceptor uses the result of the `getRequestURL` operation in the `javax.servlet.http.HttpServletRequest` interface to construct the Web address. If a query string is present, the result of the `getQueryString` operation in the same interface is also used. In this case, the complete URL is constructed as follows:

```
String url = request.getRequestURL() + '?' + request.getQueryString();
```

The following operators and conditions are defined:

Table 5. Filter conditions and operations

Condition	Operator	Example
Match exactly	= = Arguments are compared as equal.	host=host.my.company.com
Match partially (includes)	%= Arguments are compared with a partial match being valid.	user-agent%=IE 6
Match partially (includes one of many)	^= Arguments are compared with a partial match being valid for one of many arguments specified.	request-url^=webApp1 webApp2 webApp3
Does not match	!= Arguments are compared as not equal.	request-url!=noSPNEGO

Table 5. Filter conditions and operations (continued)

Condition	Operator	Example
Greater than	> Arguments are compared lexographically as greater than.	remote-address>192.168.255.130
Less than	< Arguments are compared lexographically as less than.	remote-address<192.168.255.135

com.ibm.ws.security.spnego.SPN<id>.enableCredDelegate

This attribute is optional. It indicates whether or not the Kerberos SPNEGO delegated credentials are stored by the SPNEGO TAI. This attribute enables the capability for an application to retrieve the stored credentials and propagate them to other applications downstream for additional SPNEGO authentication.

This attribute requires use of the advanced Kerberos credential delegation feature and requires development of custom logic by the application developer. The developer must interact directly with the Kerberos Ticket Granting Service (TGS) to obtain a Ticket Granting Ticket (TGT) using the delegated Kerberos credentials on behalf of the end-user who originated the request. The developer must also construct the appropriate Kerberos SPNEGO token and include it in the HTTP request to continue the downstream SPNEGO authentication process, including handling additional SPNEGO challenge-response exchange, if necessary.

com.ibm.ws.security.spnego.SPN<id>.spnegoNotSupportedPage

This attribute is optional. It specifies the Web address of a resource that contains the content that the SPNEGO TAI includes in the HTTP response that the (browser) client application displays if it does not support SPNEGO authentication. It can specify a Web (http://) or a file (file://) resource. If this attribute is not specified or the interceptor cannot find the specified resource, the following content is used:

```
<html><head><title>SPNEGO authentication is not supported</title></head>
<body>SPNEGO authentication is not supported on this client</body></html>;
```

com.ibm.ws.security.spnego.SPN<id>.NTLMTokenReceivedPage

This attribute is optional. It specifies the Web address of a resource that contains the content that the SPNEGO TAI includes in the HTTP response that the (browser) client application displays when the SPNEGO token is received by the interceptor when the challenge-response handshake contains a NT LAN Manager (NTLM) token instead of the expected SPNEGO token. It can specify a Web (http://) or a file (file://) resource. If this attribute is not specified or the interceptor cannot find the specified resource, the following content is used:

```
<html><head><title>An NTLM Token was received.</title></head>
<body>Your browser configuration is correct, but you have not logged into a supported
Microsoft(R) Windows(R) Domain.
<p>Please login to the application using the normal login page.</html>
```

com.ibm.ws.security.spnego.SPN<id>.trimUserName

This attribute is optional. It specifies whether (true) or not (false) the SPNEGO TAI is to remove the suffix of the principal user name, starting from the "@" that precedes the Kerberos realm name. If this attribute is set to true, the suffix of the principal user name is removed. If this attribute is set to false, the suffix of the principal name is retained. The default value used is true. For example,

When `com.ibm.ws.security.spnego.SPN<id>.trimUserName = true`
`bobsmith@myKerberosRealm` becomes `bobsmith`

When `com.ibm.ws.security.spnego.SPN<id>.trimUserName = false`
`bobsmith@myKerberosRealm` remains `bobsmith@myKerberosRealm`

Note: The following commands tasks can be used to operate on these SPNEGO TAI attributes:

- “Adding SPNEGO TAI properties using the wsadmin utility”
- “Deleting SPNEGO TAI properties using the wsadmin utility” on page 241
- “Modifying SPNEGO TAI properties using the wsadmin utility” on page 239
- “Displaying SPNEGO TAI properties using the wsadmin utility” on page 242

Related concepts

“Single sign-on for HTTP requests using SPNEGO” on page 182

WebSphere Application Server provides a trust association interceptor (TAI) that uses the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) to securely negotiate and authenticate HTTP requests for secured resources in WebSphere Application Server.

Related tasks

“Adding SPNEGO TAI properties using the wsadmin utility”

You use the wsadmin utility to add properties for the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) trust association interceptor (TAI) in the security configuration for WebSphere Application Server.

“Deleting SPNEGO TAI properties using the wsadmin utility” on page 241

You use the wsadmin utility to delete properties in the configuration of the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) trust association interceptor (TAI) for WebSphere Application Server.

“Modifying SPNEGO TAI properties using the wsadmin utility” on page 239

You use the wsadmin utility to modify the properties in the configuration of the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) trust association interceptor (TAI) for WebSphere Application Server.

“Displaying SPNEGO TAI properties using the wsadmin utility” on page 242

You use the wsadmin utility to display the properties in the configuration of the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) trust association interceptor (TAI) for WebSphere Application Server.

“Mapping user Ids from client to server for SPNEGO” on page 247

You can use a system programming interface to customize the behavior of the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) trust association interceptor (TAI) by implementing arbitrary mappings of the end-user’s identity, which is retrieved from Microsoft Active Directory to the identity that is used in the WebSphere Application Server security registry.

Adding SPNEGO TAI properties using the wsadmin utility:

You use the wsadmin utility to add properties for the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) trust association interceptor (TAI) in the security configuration for WebSphere Application Server.

Verify that end-user desktop browsers are configured to support SPNEGO authentication, that the SPNEGO TAI is enabled, that the Java virtual machine (JVM) property is set and, that WebSphere Application Server is configured to enable the operation of the SPNEGO TAI.

Use the wsadmin utility to configure the SPNEGO TAI for WebSphere Application Server:

1. Start WebSphere Application Server.
2. Start the command-line utility by running the **wsadmin** command from the *app_server_root/bin* directory from the Qshell command line.
3. At the **wsadmin** prompt, enter the following command:

```
$AdminTask addSpnegoTAIProperties
```

You can use the following parameters with this command:

Option	Description
<spnId>	This is the SPN identifier for the group of custom properties that are to be defined with this command. If you do not specify this parameter, an unused SPN identifier is assigned.
<host>	It specifies the host name portion in the SPN used by the SPNEGO TAI to establish a Kerberos secure context. This parameter is required.
<filter>	This attribute is optional. It defines the filtering criteria used by the class specified with the above attribute. If no filter is specified, all HTTP requests are subject to SPNEGO authentication.
<filterClass>	This attribute is optional. It specifies the name of the Java class used by the SPNEGO TAI to select which HTTP requests will be subject to SPNEGO authentication. If no filter class is specified, the default filter class, <code>com.ibm.ws.security.spnego.HTTPHeaderFilter</code> , is used.
<noSpnegoPage>	<p>This attribute is optional. It specifies the URL of a resource that contains the content the SPNEGO TAI will include in the HTTP response to be displayed by the (browser) client application if it does not support SPNEGO authentication.</p> <p>If you do not specify the <code>noSpnegoPage</code> attribute then the default is used:</p> <pre>"<html><head><title>SPNEGO authentication is not supported. </title></head>" + "<body>SPNEGO authentication is not supported on this client. </body></html>";</pre>
<ntlmTokenPage>	<p>This attribute is optional. It specifies the URL of a resource that contains the content the SPNEGO TAI will include in the HTTP response to be displayed by the (browser) client application when the SPNEGO token received by the interceptor after the challenge-response handshake contains a NT LAN manager (NTLM) token instead of the expected SPNEGO token.</p> <p>If you do not specify the <code>ntlmTokenPage</code> attribute then the default is used:</p> <pre>"<html><head><title>An NTLM Token was received.</title></head>" + "<body>Your browser configuration is correct, but you have not logged into a supported Windows Domain." + "<p>Please login to the application using the normal login page.</html>";</pre>
<trimUserName>	This parameter is optional. It specifies whether (true) or not (false) the SPNEGO TAI is to remove the suffix of the principal user name, starting from the "@" that precedes the Kerberos realm name. If this attribute is set to true, the suffix of the principal user name is removed. If this attribute is set to false, the suffix of the principal name is retained. The default value used is true.

SPNEGO TAI properties have been added for this WebSphere Application Server.

Example 1

The following example configures the SPNEGO TAI to intercept HTTP request that contain IE 6 in the user agent request header. The SPNEGO TAI uses the SPN of HTTP/myhost.ibm.com@<default_realm> to authenticate the request originator.

```
$AdminTask addSpnegoTAIProperties -host myhost.ibm.com -filter user-agent%=IE 6
```

Example 2

The following is an example of adding SPNEGOTAIProperties for SPN1 to use the default filterClass and to intercept all requests for the host, central01.austin.ibm.com.

```
wsadmin>$AdminTask addSpnegoTAIProperties -interactive
Add SPNEGO TAI properties
```

Add SPNEGO TAI configuration properties.

```
*Host name in Service Principal Name (host): central01.austin.ibm.com
Service Principal Name identifier (spnId): 1
HTTP header filter rule (filter):
Name of class used to filter HTTP requests (filterClass):
SPNEGO not supported browser response (noSpnegoPage):
NTLM Token received browser response (ntlmTokenPage):
Trim User Name browser response (trimUserName):
```

Add SPNEGO TAI properties

```
F (Finish)
C (Cancel)
```

```
Select [F, C]: [F] f
```

```
WASX7278I: Generated command line: $AdminTask addSpnegoTAIProperties {-host central01.austin.ibm.com}
com.ibm.ws.security.spnego.SPN1.hostName=central01.austin.ibm.com
wsadmin>
```

Modifying SPNEGO TAI properties using the wsadmin utility:

You use the wsadmin utility to modify the properties in the configuration of the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) trust association interceptor (TAI) for WebSphere Application Server.

Verify that end-user desktop browsers are configured to support SPNEGO authentication, that the SPNEGO TAI is enabled, that the Java virtual machine (JVM) property is set and, that WebSphere Application Server is configured to enable the operation of the SPNEGO TAI.

You use the wsadmin utility to configure the SPNEGO TAI for WebSphere Application Server:

1. Start WebSphere Application Server.
2. Start the command-line utility by running the **wsadmin** command from the *app_server_root/bin* directory from the Qshell command line.
3. At the **wsadmin** prompt, enter the following command:

```
$AdminTask modifySpnegoTAIProperties
```

You can use the following parameters with this command:

Option	Description
<spnId>	The SPN identifier for the group of custom properties that are to be defined with this command. You must specify this parameter.

Option	Description
<host>	This parameter is optional. It specifies the host name portion in the SPN used by the SPNEGO TAI to establish a Kerberos secure context.
<filter>	This parameter is optional. It defines the filtering criteria used by the class specified with the above attribute.
<filterClass>	This parameter is optional. It specifies the name of the Java class used by the SPNEGO TAI to select which HTTP requests will be subject to SPNEGO authentication. If no class is specified, all HTTP requests will be subject to SPNEGO authentication.
<noSpnegoPage>	<p>This parameter is optional. It specifies the URL of a resource that contains the content the SPNEGO TAI will include in the HTTP response to be displayed by the (browser) client application if it does not support SPNEGO authentication.</p> <p>If you do not specify the noSpnegoPage attribute then the default is used:</p> <pre data-bbox="800 789 1182 945"><html><head><title>SPNEGO authentication is not supported.</title></head>" + "<body>SPNEGO authentication is not supported on this client.</body></html>";</pre>
<ntlmTokenPage>	<p>This parameter is optional. It specifies the URL of a resource that contains the content the SPNEGO TAI will include in the HTTP response to be displayed by the (browser) client application when the SPNEGO token received by the interceptor after the challenge-response handshake contains a NT LAN manager (NTLM) token instead of the expected SPNEGO token.</p> <p>If you do not specify the ntlmTokenPage attribute then the default is used:</p> <pre data-bbox="800 1255 1243 1465"><html><head><title>An NTLM Token was received.</title></head>" + "<body>Your browser configuration is correct, but you have not logged into a supported Windows Domain." + "<p>Please login to the application using the normal login page.</html>";</pre>
<trimUserName>	This parameter is optional. It specifies whether (true) or not (false) the SPNEGO TAI is to remove the suffix of the principal user name, starting from the "@" that precedes the Kerberos realm name. If this attribute is set to true, the suffix of the principal user name is removed. If this attribute is set to false, the suffix of the principal name is retained. The default value used is true.

SPNEGO TAI properties are modified for this WebSphere Application Server.

Example 1

The following example configures the SPNEGO TAI to intercept HTTP request that contain IE 6 in the user agent request header. The SPNEGO TAI uses the SPN of HTTP/

myhost.ibm.com@<default_realm> to authenticate the request originator. Then the example modifies the value of the filter custom property that was defined and changes it from user-agent%=IE 6 to host==myhost.company.com.

```
$AdminTask addSpnegoTAIProperties -host myhost.ibm.com -filter user-agent%=IE 6
$AdminTask modifySpnegoTAIProperties -spnId 1 -filter host==myhost.company.com
```

Example 2

This is an example of modifying the SPNEGO TAI for SPN1 properties to add a filter for host central01.austin.ibm.com.

```
wsadmin>$AdminTask modifySpnegoTAIProperties -interactive
Modify SPNEGO TAI properties
```

Modify SPNEGO TAI configuration properties

```
*Service Principal Name identifier (spnId): 1
Host name in Service Principal Name (host): central01.austin.ibm.com
HTTP header filter rule (filter): request-url!=noSPNEGO;request-url%=snoop
Name of class used to filter HTTP requests (filterClass):
SPNEGO not supported browser response (noSpnegoPage):
NTLM Token received browser response (ntlmTokenPage):
Trim User Name browser response (trimUserName):
```

Modify SPNEGO TAI properties

```
F (Finish)
C (Cancel)
```

```
Select [F, C]: [F] f
```

```
WASX7278I: Generated command line: $AdminTask modifySpnegoTAIProperties {-spnId
1 -host w2003secdev.austin.ibm.com -filter request-url!=noSPNEGO;request-url%=sn
oop}
com.ibm.ws.security.spnego.SPN1.filter=request-url!=noSPNEGO;request-url%=snoop
com.ibm.ws.security.spnego.SPN1.hostName=central01.austin.ibm.com
wsadmin>
```

Deleting SPNEGO TAI properties using the wsadmin utility:

You use the wsadmin utility to delete properties in the configuration of the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) trust association interceptor (TAI) for WebSphere Application Server.

Verify that end-user desktop browsers are configured to support SPNEGO authentication, that the SPNEGO TAI is enabled, that the Java virtual machine (JVM) property is set and, that WebSphere Application Server is configured to enable the operation of the SPNEGO TAI.

You use the wsadmin utility to configure the SPNEGO TAI for WebSphere Application Server:

1. Start WebSphere Application Server.
2. Start the command-line utility by running the **wsadmin** command from the *app_server_root/bin* directory from the Qshell command line.
3. At the **wsadmin** prompt, enter the following command:

```
$AdminTask deleteSpnegoTAIProperties
```

You can use the following parameters with this command:

Option	Description
<spnId>	This is an optional parameter. The SPN identifier for the group of custom properties that are to be deleted with this command. If you do not specify this parameter, all SPNEGO TAI custom properties are deleted.

SPNEGO TAI properties are deleted for this WebSphere Application Server.

Example 1

The following example deletes all the SPNEGO TAI properties for SPN2

```
wsadmin>$AdminTask deleteSpnegoTAIProperties {-spnId 2}
```

Example 2

The following example deletes all SPNEGO TAI properties

```
wsadmin>$AdminTask deleteSpnegoTAIProperties
com.ibm.ws.security.spnego.SPN1.filter=request-url!=noSPNEGO;request-url%=snoop
com.ibm.ws.security.spnego.SPN1.hostName=central01.austin.ibm.com
com.ibm.ws.security.spnego.SPN2.hostName=wssecpd.austin.ibm.com
wsadmin>
```

Displaying SPNEGO TAI properties using the wsadmin utility:

You use the wsadmin utility to display the properties in the configuration of the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) trust association interceptor (TAI) for WebSphere Application Server.

Verify that end-user desktop browsers are configured to support SPNEGO authentication, that the SPNEGO TAI is enabled, that the Java virtual machine (JVM) property is set and, that WebSphere Application Server is configured to enable the operation of the SPNEGO TAI.

You use the wsadmin utility to configure the SPNEGO TAI for WebSphere Application Server:

1. Start WebSphere Application Server.
2. Start the command-line utility by running the **wsadmin** command from the *app_server_root/bin* directory from the Qshell command line.
3. At the **wsadmin** prompt, enter the following command:

```
$AdminTask showSpnegoTAIProperties
```

You can use the following parameters with this command:

Option	Description
<spnId>	This is an optional parameter. The service principal name (SPN) identifier for the group of custom properties that are to be displayed with this command. If you do not specify this parameter, all SPNEGO TAI custom properties are displayed.

SPNEGO TAI properties are displayed for this WebSphere Application Server.

Example 1

The following example displays all SPNEGO TAI properties.

```
wsadmin>$AdminTask showSpnegoTAIProperties
com.ibm.ws.security.spnego.SPN1.filter=request-url!=noSPNEGO;request-url%=snoop
com.ibm.ws.security.spnego.SPN1.hostName=central01.austin.ibm.com
com.ibm.ws.security.spnego.SPN2.hostName=wssecpd.austin.ibm.com
wsadmin>
```

Example 2

The following example displays SPNEGO TAI properties for SPN1 and host, central01.austin.ibm.com.

```
wsadmin>$AdminTask showSpnegoTAIProperties -interactive
Show SPNEGO TAI configuration properties.
```

Display SPNEGO TAI configuration properties.

Service Principal Name identifier (spnId): 1

Show SPNEGO TAI configuration properties.

F (Finish)

C (Cancel)

Select [F, C]: [F]

WASX7278I: Generated command line: \$AdminTask showSpnegoTAIProperties {-spnId 1}

```
com.ibm.ws.security.spnego.SPN1.filter=request-url!=noSPNEGO;request-url%=snoop
com.ibm.ws.security.spnego.SPN1.hostName=central01.austin.ibm.com
com.ibm.ws.security.spnego.SPN1.trimUserName=true
wsadmin>
```

Configuring JVM properties and enabling SPNEGO TAI in WebSphere Application Server:

Performing this task helps you, as Web administrator, to ensure that WebSphere Application Server is configured to enable the operation of the Simple and Protected GSS-API Negotiation mechanism (SPNEGO) trust association interceptor (TAI) with the required Java virtual machine (JVM) property.

You need to know how to use the WebSphere Application Server administrative console to manage the security configuration and have the proper authority to modify the security configuration of the application server.

Complete the following steps to enable the operation of the SPNEGO TAI by setting the JVM required property.

1. Log on to WebSphere Application Server administrative console.
2. Click **Servers > Application servers**.
3. Select the appropriate servers and click **Java and process management > Process Definition**.
4. Click **Java virtual machine**. In the **Generic JVM arguments** field, type
-Dcom.ibm.ws.security.spnego.isEnabled=true.
5. Click **Apply > OK** to save the configuration

The application server is configured and ready to provide a single sign-on environment for end users who have successfully authenticated in a Microsoft Active Directory domain. You must restart each application server that is configured for SPNEGO Web authentication.

Enabling the SPNEGO TAI using scripting:

You use the wsadmin utility to enable the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) trust association interceptor (TAI) for WebSphere Application Server.

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

Perform the following steps to enable the SPNEGO TAI:

1. Identify the server and assign it to the server1 variable:

- Using Jacl:

```
set server1 [$AdminConfig getid /Cell:mycell/Node:mynode/Server:server1/]
```
- Using Jython:

```
server1 = AdminConfig.getid("Cell:mycell/Node:mynode/Server:server1/")
print server1
```

Example output:

```
server1(cells/mycell/nodes/mynode|servers/seerver1|server.xml#Server_1)
```

2. Identify the Java virtual machine (JVM) belonging to this server and assign it to the jvm variable:

- Using Jacl:

```
set jvm [$AdminConfig list JavaVirtualMachine $server1]
```
- Using Jython:

```
jvm = AdminConfig.list('JavaVirtualMachine',server1')
```

Example output:

```
(cells/mycell/nodes/mynode/servers/server1:server.xml#JavaVirtualMachine_1)
(cells/mycell/nodes/mynode/servers/server1:server.xml#JavaVirtualMachine_2)
```

3. Identify the controller JVM of the server:

- Using Jacl:

```
set cjvm [lindex $jvm 0]
```
- Using Jython:

```
# get line separator
import java
lineSeparator = java.lang.System.getProperty('line.separator')
arrayJVMs = jvm.split(lineSeparator)
cjvm = arrayJVMs[0]
```

4. Modify the generic JVM arguments to enable SPNEGO TAI:

- Using Jacl:

```
$AdminConfig modify $cjvm { {genericJvmArguments "-Dcom.ibm.ws.security.spnego.isEnabled=true"} }
```
- Using Jython:

```
AdminConfig.modify(cjvm, [['genericJvmArguments', "-Dcom.ibm.ws.security.spnego.isEnabled=true"]])
```

5. Save the configuration changes. See the Saving configuration changes with the wsadmin tool article for more information.

6. In a network deployment environment only, synchronize the node. See the Synchronizing nodes with the wsadmin tool article for more information.

SPNEGO TAI JVM configuration attributes:

Java virtual machine (JVM) attributes control the operation of the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) trust association interceptor (TAI).

The following JVM attributes control operation of the SPNEGO TAI. Different attribute values can be specified for each application server.

Table 6. JVM configuration attributes

Attribute Name	Required	Value Type	Default Value	Recommended Value
com.ibm.ws.security.spnego.isEnabled	No	Boolean	False	True

Table 6. JVM configuration attributes (continued)

Attribute Name	Required	Value Type	Default Value	Recommended Value
com.ibm.ws.security.spnego.propertyReloadFile	No	String	None	For Windows C:\temp\TAI.props For UNIX /tmp/TestTAI.Properties
com.ibm.ws.security.spnego.propertyReloadTimeout	No	Integer	None	120

com.ibm.ws.security.spnego.isEnabled

Use this attribute to enable or disable operation of the SPNEGO TAI in a given application server. When set to `false`, the SPNEGO TAI is disabled and not used by the Web authentication module for authenticating any Web requests. When set to `true`, the SPNEGO TAI is enabled and used by the Web authentication module for authenticating any Web requests.

com.ibm.ws.security.spnego.propertyReloadFile

Use this attribute to identify the file that contains configuration properties for the SPNEGO TAI, when it is not convenient to stop and restart the application server. The properties contained in this file can be reloaded to configure the SPNEGO TAI.

Important: the properties that are defined in the specified file override any properties defined using the administrative console.

A sample of this reload file follows:

```
#####
# Template properties files for SPNEGO TAI
#
# Where possible defaults have been provided.
#
#####

#-----
# Hostname
#-----
com.ibm.ws.spnego.SPN1.HostName=wsecurity.austin.ibm.com

#-----
# (Optional) SpnegoNotSupportedPage
#-----
com.ibm.ws.spnego.SPN1.SpnegoNotSupportedPage=

#-----
# (Optional) NTLMTokenReceivedPage
#-----
com.ibm.ws.spnego.SPN1.NTLMTokenReceivedPage=

#-----
# (Optional) FilterClass
#-----
com.ibm.ws.spnego.SPN1.FilterClass=com.ibm.ws.spnego.HTTPHeaderFilter

#-----
# (Optional) Filter
#-----
com.ibm.ws.spnego.SPN1.Filter=
```

Important: If `com.ibm.ws.security.spnego.propertyReloadFile` attribute is set, but the `com.ibm.ws.security.spnego.propertyReloadTimeout` attribute is not, then the SPNEGO TAI is not initialized.

com.ibm.ws.security.spnego.propertyReloadTimeout

Use this attribute to specify a time interval in seconds that elapses after which the SPNEGO TAI reloads the configuration properties. Also, the SPNEGO TAI reloads the configuration properties if the file that is identified by the `com.ibm.ws.security.spnego.propertyReloadFile` attribute changed since the last time the configuration attributes were retrieved. This time interval in seconds must be specified as a positive integer.

Important:

- If the `com.ibm.ws.security.spnego.propertyReloadFile` attribute and the `com.ibm.ws.security.spnego.propertyReloadTimeout` attribute are not set, then the SPNEGO TAI properties are only loaded once from the SPNEGO TAI custom properties defined in the WebSphere Application Server configuration data. This one time loading occurs when the JVM is initialized.
- If `com.ibm.ws.security.spnego.propertyReloadTimeout` attribute is set, but the `com.ibm.ws.security.spnego.propertyReloadFile` attribute is not, then the SPNEGO TAI is not initialized.

The following examples show how to enable operation of the SPNEGO TAI by setting the `com.ibm.ws.security.spnego.isEnabled` JVM property to `true` using the scripting that is available in WebSphere Application Server for AdminConfig commands.

Using JACL:

```
set server [$AdminConfig getid /Cell:mycell/Node:mynode/Server:myserver]
set jvm [$AdminConfig list JavaVirtualMachine $server]
$AdminConfig modify $jvm {{genericJvmArguments "-Dcom.ibm.ws.security.spnego.isEnabled =true"}}
$AdminConfig save
```

Using Jython:

```
server = AdminConfig.getid('/Cell:mycell/Node:mynode/Server:myserver')
jvm = AdminConfig.list('JavaVirtualMachine', server)
AdminConfig.modify(jvm, [['genericJvmArguments', "Dcom.ibm.ws.security.spnego.isEnabled =true"]])
AdminConfig.save()
```

Remember: You can also use the `wsadmin` command for the AdminConfig scripting object to interactively set the `com.ibm.ws.security.spnego.isEnabled` attribute. See “Enabling the SPNEGO TAI using scripting” on page 243 for more information.

The following attributes are not used directly by the SPNEGO TAI; however, they affect the operation of the core security runtime and can also be used for problem determination.

Table 7. JVM configuration attributes

Attribute Name	Required	Value Type	Default Value	Recommended Value
<code>java.security.properties</code>	No	String	None	
<code>com.ibm.security.jgss.debug</code>	No	String	None	"off" or "all"
<code>com.ibm.security.krb5.Krb5Debug</code>	No	String	None	"off" or "all"
<code>javax.security.auth.useSubjectCredsOnly</code>	Yes	Boolean	True	False

java.security.properties

This property is optional. It can be used when different application servers in a cell have different security requirements and it is not convenient to modify the global `java.security` file for the entire cell. In such situations, the `java.security.properties` attribute is used to specify the location of the `java.security` file used by the JVM for each application server.

com.ibm.security.jgss.debug

This attribute is optional. It can be used to collect diagnostic trace information for problem determination in the Java Generic Security Service (JGSS) application programmer interface (API)

implementation. The value can be set to `all` or `off` to enable or disable tracing, respectively. See Java Generic Security Service User's Guide for specific JGSS API information.

com.ibm.security.krb5.Krb5Debug

This attribute is optional. It can be used to collect additional diagnostic trace information for problem determination in the JGSS implementation. The value can be set to `all` or `off` to enable or disable tracing, respectively.

javax.security.auth.useSubjectCredsOnly

JGSS includes an optional Java Authentication and Authorization Service (JAAS) login facility that saves Principal credentials and secret keys in the Subject of the application's JAAS login context. JGSS retrieves credentials and secret keys from the Subject by default. This feature can be disabled by setting the Java property `javax.security.auth.useSubjectCredsOnly` to `false`.

Attention: The SPNEGO TAI does not use the optional JAAS login module. The `javax.security.auth.useSubjectCredsOnly` property must be set to `false`.

Mapping user Ids from client to server for SPNEGO:

You can use a system programming interface to customize the behavior of the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) trust association interceptor (TAI) by implementing arbitrary mappings of the end-user's identity, which is retrieved from Microsoft Active Directory to the identity that is used in the WebSphere Application Server security registry.

You need to perform some administrative tasks in the WebSphere Application Server environment to use SPNEGO TAI and to ensure that the requester's identity matches the identity in the WebSphere Application Server user registry.

In the simplest deployment of the SPNEGO TAI, it is assumed that the requester's identity in the WebSphere Application Server user registry is identical to the identity retrieved. This is the case when Microsoft Windows Active Directory server is the lightweight directory access protocol (LDAP) server used in WebSphere Application Server. This is default behavior of the SPNEGO TAI.

You do not need to use this simple deployment of the SPNEGO TAI. WebSphere Application Server can use a different registry, such as a local OS, LDAP, or custom registry instead of the Microsoft Active Directory. If WebSphere Application Server uses a different registry than the Microsoft Active Directory, then a mapping from the Microsoft Windows user Id to a WebSphere Application Server user Id is necessary.

1. Configure the Web browser to use SPNEGO.
2. Configure Java virtual machine (JVM) properties and custom SPNEGO TAI properties.
3. Enable the SPNEGO TAI.
4. Use the custom login module to perform any custom mapping of user Ids from the user registry to the user registry of WebSphere Application Server. The custom login module is a plug-in mechanism that is defined for authenticating incoming and outgoing requests in WebSphere Application Server. The custom login module is inserted before the `ltpaLoginModule` and maps the name in the `com.ibm.wsspi.security.tai.TAIResult` (which was returned to the Web authenticator) to the corresponding name in the user registry. The `ltpaLoginModule` then uses the mapped identity to create a `WSCredential`.

The custom login module can also supply the full set of security attributes in the `javax.security.auth.Subject` in the `com.ibm.wsspi.security.tai.TAIResult` to fully assert the mapped identity. When the identity is fully asserted, the `wsMapDefaultInboundLoginModule` maps those security attributes to a `WSCredential`.

Using the custom login module, Microsoft Active Directory identities are mapped to the WebSphere Application Server's security registry.

Filtering HTTP requests for SPNEGO TAI:

You can use a system programming interface to customize the behavior of the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) trust association interceptor (TAI) by specifying whether or not a particular HTTP request should be intercepted.

Before you begin, you need to fully understand the deployment of the SPNEGO TAI in your installation.

Verify the configuration of your SPNEGO TAI. The deployment of the SPNEGO TAI can vary from a single WebSphere Application Server system on which a single application is running to a large multinode WebSphere Application Server Network Deployment (ND) cell, with dozens of application servers, hosting many applications. Every SPNEGO TAI is installed at the cell level. You must be aware of your particular SPNEGO TAI configuration.

The default behavior of the SPNEGO TAI is to not intercept HTTP requests. This default behavior ensures that the SPNEGO TAI can be installed into an existing cell, configured for a single application server and not change any other application servers in the cell. Other WebSphere Application Servers can run exactly as before within a given configuration.

Then decide whether or not to use the sample `SPN<id>.filter` class and determine the exact filter properties to use.

Note: The default behavior of the SPNEGO TAI is to use the `com.ibm.ws.security.spnego.SPN<id>.filter` class and intercept all requests.

If the default behavior is not appropriate, you can use a customer provided class, or extend or modify the sample class as required. The system programmer interface, `com.ibm.ws.security.spnego.SpnegoFilter` allows you to implement a custom filter to determine whether or not to intercept a particular HTTP request. With the default implementation, you can set filter rules for coarse as well as fine-grained criteria in selecting which HTTP requests to intercept.

1. Set the `com.ibm.ws.security.spnego.isEnabled` Java virtual machine (JVM) custom property to `true` to enable the SPNEGO TAI on any JVM.
2. Identify when the SPNEGO TAI intercepts a given request. A set of filter properties is provided, but you must determine what is appropriate and modify the `com.ibm.ws.security.spnego.SPN<id>.filter` class accordingly.

Your SPNEGO TAI is set to filter HTTP requests when it is operating.

Kerberos configuration requirements for SPNEGO TAI:

Kerberos configuration settings, the Kerberos key distribution center (KDC) name, and realm settings for the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) trust association interceptor (TAI) are provided in the Kerberos configuration file or through `java.security.krb5.kdc` and `java.security.krb5.realm` system property files.

The Web administrator creates the Kerberos configuration file with the appropriate settings that allow HTTP requests to be processed by the SPNEGO TAI. See “Creating the Kerberos configuration file for use with the SPNEGO TAI” on page 232 for more information.

The Web administrator can provide the same Kerberos configuration system properties in separate files: `java.security.krb5.kdc` and `java.security.krb5.realm`. See Kerberos Requirements for information on how this is accomplished.

The Kerberos key table manager command (`Ktab`) allows the Web administrator to manage the principal names and service keys stored in a local Kerberos keytab file. Kerberos service principal (SPN) name and keys listed in the Kerberos keytab file allow services running on the host to authenticate themselves to the

KDC. Before SPNEGO TAI can use Kerberos, the WebSphere Application Server administrator must setup a Kerberos keytab file on the host running WebSphere Application Server.

Important: It is very important to protect the keytab files, making them readable only by the authorized WebSphere users.

Important: Any updates to the Kerberos keytab file using Ktab do not affect the Kerberos database. If you change the keys in the Kerberos keytab file, you must also make the corresponding changes to the Kerberos database.

Below is an example of how Ktab is used on a LINUX platform to add new principal names to the Kerberos keytab file.

```
[root@wssecjibe bin]# ./java com.ibm.security.krb5.internal.tools.Ktab -a
HTTP/wssecjibe.austin.ibm.com@WSSEC.AUSTIN.IBM.COM ot56prod -k /etc/krb5.keytab
Done!
Service key for principal HTTP/wssecjibe.austin.ibm.com@WSSEC.AUSTIN.IBM.COM saved
[root@wssecjibe bin]# ./java com.ibm.security.krb5.internal.tools.Ktab
1 entries in keytab, name: /etc/krb5.keytab
    KVNO    Principal
    ----    -
1          HTTP/wssecjibe.austin.ibm.com@WSSEC.AUSTIN.IBM.COM
[root@wssecjibe bin]# ls /etc/krb5.*
/etc/krb5.conf      /etc/krb5.ini.orig /etc/krb5.keytab.good
/etc/krb5.conf.orig /etc/krb5.keytab
[root@wssecjibe bin]# ./java com.ibm.security.krb5.internal.tools.Ktab -a
HTTP/wssecredhat.austin.ibm.com@WSSEC.AUSTIN.IBM.COM ot56prod -k /etc/krb5.keytab
Done!
Service key for principal HTTP/wssecredhat.austin.ibm.com@WSSEC.AUSTIN.IBM.COM
saved
[root@wssecjibe bin]# ./java com.ibm.security.krb5.internal.tools.Ktab
2 entries in keytab, name: /etc/krb5.keytab
    KVNO    Principal
    ----    -
1          HTTP/wssecjibe.austin.ibm.com@WSSEC.AUSTIN.IBM.COM
1          HTTP/wssecredhat.austin.ibm.com@WSSEC.AUSTIN.IBM.COM
```

Tip: On WebSphere Application Server, Ktab is located at:

```
<install root>/java/jre/bin
```

Configuring the Web browser to use SPNEGO

You can configure your browser to utilize the Simple and Protected GSS-API Negotiation (SPNEGO) mechanism. Authentication of your browser requests are processed by the SPNEGO trust association interceptor (TAI) in the WebSphere Application Server.

You need to know how to display and set options in the Microsoft Internet Explorer browser or any other browser (such as Firefox). You must have a browser installed that supports SPNEGO authentication.

Complete the following steps to ensure that your Microsoft Internet Explorer browser is enabled to perform SPNEGO authentication.

1. At the desktop, log in to the windows active directory domain.
2. Activate Internet Explorer.
3. In the Internet Explorer window, click **Tools > Internet Options > Security** tab.
4. Select the **Local intranet** icon and click **Sites**.
5. In the Local intranet window, ensure that the "check box" to include all local (intranet) not listed in other zones is selected, then click **Advanced** .

6. In the **Local intranet** window, fill in the Add this Web site to the zone field with the Web address of the host name so that the single sign-on (SSO) can be enabled to the list Web sites shown in the Web sites field. Your site information technology staff provides this information. Click **OK** to complete this step and close the Local intranet window.
7. On the **Internet Options** window, click the **Advanced** tab and scroll to **Security settings**. Ensure that the **Enable Integrated Windows Authentication (requires restart)** box is selected.
8. Click **OK**. Restart your Microsoft Internet Explorer to activate this configuration.

Complete the following steps to ensure that your Firefox browser is enabled to perform SPNEGO authentication.

1. At the desktop, log in to the windows active directory domain.
2. Activate Firefox.
3. At the address field, type **about:config**.
4. In the Filter, type **network.n**
5. If the deployed SPNEGO solution is using the advanced Kerberos feature of Credential Delegation double click on **network.negotiate-auth.delegation-uris**. This preference lists the sites for which the browser may delegate user authorization to the server.
6. Enter a comma delimited list of trusted domains or URLs.
7. Click **OK**. The configuration appears as updated.
8. Restart your Firefox browser to activate this configuration.

Your Internet browser is properly configured for SPNEGO authentication. You can use applications that are deployed in WebSphere Application Server that use secured resources without being repeatedly requested for an ID and password.

Configuring single sign-on capability with Enterprise Identity Mapping

The Enterprise Identity Mapping (EIM) identity token connection factory is a type of Java 2 Connector (J2C) connection factory. Using EIM identity token connection factories along with EIM identity token-enabled products, such as IBM Toolbox for Java, provides a single sign-on capability for WebSphere Application Server applications that need to access server data and resources through your user ID.

The EIM identity token connection factory is supported on i5/OS V5R4, and OS/400 V5R2 and V5R3. It is supported on the following WebSphere Application Server products.

Attention: Either Lightweight Third Party Authentication (LTPA) or Simple WebSphere Authentication Mechanism (SWAM) may be used with the EIM identity token connection factory. Enabling Web security single sign-on (SSO) is optional when LTPA is used with the EIM identity token connection factory. For more information, see “Implementing single sign-on to minimize Web user authentications” on page 226.

Table 8. Supported editions per product

Edition name	Supported products
Version 6.1	WebSphere Application Server, Network Deployment for i5/OS (“Network Deployment Edition”)
Version 6.0.x	WebSphere Application Server, Network Deployment for OS/400 (“Network Deployment Edition”)
Version 5.1.x	WebSphere Application Server, Network Deployment for iSeries (“Network Deployment Edition”)
Version 5.0.x	WebSphere Application Server, Network Deployment for iSeries (“Network Deployment Edition”)

This topic describes how to configure EIM identity token connection factories for Version 6.1 only and provides information about a sample application that might be helpful to you when you develop your own applications.

Attention: Configuration tasks can vary slightly for other WebSphere Application Server products and editions.

The sample application uses an EIM identity token connection factory to provide EIM identity tokens for use with IBM Toolbox for Java `com.ibm.as400.access.AS400` objects. For example, if the sample application is deployed on SERVER A, you can log in once to WebSphere Application Server and use the sample application to perform i5/OS server commands under your i5/OS user profiles on SERVER B, SERVER C, or SERVER D.

When you make a request to the sample application, you must log in with your WebSphere Application Server user ID and password. Each request contains the server command and the target server name where the command runs. When the request is received, the application calls the connection factory to generate an identity token. The connection factory extracts your user ID from a Java Authentication and Authorization Service (JAAS) subject object provided by WebSphere Application Server security, and it collaborates with the EIM domain controller to create the identity token that is returned to the application. The application then creates a `com.ibm.as400.access.AS400` object for SERVER B and provides it with the identity token (instead of your i5/OS user profile) before it passes the server command to run.

Attention: A new identity token and `com.ibm.as400.access.AS400` object are created each time you send a request that contains a new target server. All `com.ibm.as400.access.AS400` objects are stored in an HTTP Session for use with subsequent requests.

1. Verify that you have all of the necessary prerequisites installed to use the EIM token connection factory. You must verify that you have installed the necessary program temporary fixes (PTF) to your server and applications. For more information, see “Verifying Enterprise Identity Mapping identity token connection factory prerequisite applications.”
2. Configure EIM work with the identity token connection factory. These instructions explain how to complete the following tasks:
 - a. Create a domain in EIM.
 - b. Add the domain to domain management.
 - c. Create a source user registry definition.
 - d. Create a user identifier.
 - e. Create a target association.
 - f. Create a source association.
 - g. Test the connection to the EIM domain controller

For more information, see “Configuring Enterprise Identity Mapping” on page 252.

3. Configure the EIM identity token connection factory. This step involves configuring two Java Archive (JAR) files and a shared library. For more information, see “Configuring the Enterprise Identity Mapping identity token connection factory” on page 255.
4. Configure the connection factory. For more information, see “Configuring the connection factory” on page 258.

After completing the previous steps, you have configured single sign-on for Enterprise Identity Mapping.

Verifying Enterprise Identity Mapping identity token connection factory prerequisite applications

Before you can use the Enterprise Identity Mapping (EIM) identity token connection factory, you must have the required cumulative program temporary fix (PTF) applied to your server. You might also need to apply PTFs to run the sample application.

Perform the following steps to verify that you have the necessary prerequisites installed to use the EIM identity token connection factory:

1. Verify that OS/400 - Extended Base Directory Support (5722-SS1 option 3) is installed on the i5/OS system that hosts WebSphere Application Server. This product is a requirement for the EIM Identity Token Connection Factory.
2. Verify that the latest operating system PTFs are applied to your i5/OS system for the EIM Identity Token Connection Factory. For information about the latest operating system PTFs, search the Technotes for "EIM Identity Token Connection Factory" on the WebSphere Application Server support page at: <http://www.ibm.com/software/webservers/appserv/support.html>.
3. Install the required PTFs for the sample application.
To run the sample application, verify that the latest IBM Toolbox for Java service packs and the required operating system PTFs are installed on all of your iSeries servers. For information on obtaining the latest service packs and required operating system PTFs, see Toolbox for Java and JOpen Service Packs.

After verifying that you have the necessary prerequisite applications installed, you can configure EIM for use with the identity token connection factory.

Configure EIM. See "Configuring Enterprise Identity Mapping."

Configuring Enterprise Identity Mapping

Use the iSeries Navigator to configure Enterprise Identity Mapping (EIM) for use with the identity token connection factory.

For these steps, assume that your EIM controller, which is your Lightweight Directory Access Protocol (LDAP) directory server, is your local directory server and that it resides on the iSeries server that is being configured for EIM. For detailed information about EIM, see "Enterprise Identity Mapping" on page 187.

You need the LDAP server administrator distinguished name (DN) and password to perform this task.

Tip: A server can participate only in one EIM domain at a time. If your server is already joined to an EIM domain and the domain is added to domain management, use that domain, and skip to Create a source user registry definition in EIM.

1. The identity token connection factory requires you to configure an EIM domain.

Create a domain in EIM:

Note: Depending on the setup of the machine, these steps might appear in a slightly different order. This assumes that LDAP is already configured and the network authentication service has not been configured.

- a. Make sure that the LDAP server started. You can verify the LDAP server administrator distinguished name (DN) and password. However, be aware that the LDAP server is stopped by the wizard later on.
- b. In iSeries Navigator, expand **server_name > Network > Enterprise Identity Mapping**, where *server_name* is the name of your iSeries server.
- c. Click **Enterprise Identity Mapping**.
- d. Right-click **Configuration** and select **Configure** to start the EIM Configuration wizard.

Note: This option is labeled **Reconfigure** if EIM has been previously configured on the system.

- e. On the Welcome page of the wizard, select **Create and join a new domain**.
- f. Click **Next**.
- g. On the Specify EIM Domain Location page, select **On the local Directory server** and then click **Next**.

- h. If the network authentication service has not been configured on the system to set up a single sign-on environment, the Configure Network Authentication Service page is displayed. Network Authentication Service is not required for the EIM identity token connection factory. Select **No** and then click **Next**.
- i. On the Specify User for Connection page, specify the distinguished name and password for the LDAP administrator to ensure that the wizard has enough authority to administer the EIM domain and the objects in it. Click **Next**.

Note: If you have not configured the local directory server before you use the EIM Configuration wizard, the Configure Directory Server page displays instead. Use this page to specify the distinguished name and password for the LDAP administrator and continue with the next step in this procedure. The LDAP distinguished name (DN) identifies the LDAP administrator for the directory server. The EIM Configuration wizard creates this LDAP administrator DN and uses it to configure the directory server as the domain controller for the new domain that you are creating.

- j. On the Specify Domain page, provide the name of the EIM domain, and click **Next**.
 - k. On the Specify Parent DN for Domain page, select **Yes** to specify a parent DN for the domain that you are creating, or specify **No** to have EIM data stored in a directory location with a suffix whose name is derived from the EIM domain name. Click **Next**.
 - l. A message is displayed that indicates that you must stop the LDAP server. Click **Yes** to continue.
 - m. On the Registry Information page, select **Local OS/400** and then click **Next**.
 - n. On the Specify EIM System User page, select **Distinguished name and password** as the user type, provide the DN and password for the directory server administrator, and optionally, verify the DN and password. Click **Next**.
 - o. In the Summary panel, review the configuration information that you have provided. If all information is correct, click **Finish**.
2. Add the domain to domain management:
- a. In the iSeries Navigator, expand **system_name > Network > Enterprise Identity Mapping > Domain Management**.
 - b. Right-click **Domain Management** and then select **Add Domain**.
 - c. In the Add Domain dialog, specify the domain you created earlier and click **OK**.

3. Create a source user registry definition in EIM.

The identity token connection factory requires a source user registry definition entry in EIM. The source user registry definition represents the registry that WebSphere Application Server uses for authentication. This registry can be a local OS registry or an LDAP registry.

- a. In iSeries Navigator, expand **system_name > Network > Enterprise Identity Mapping > Domain Management > domain_name > User Registries**.
- b. If you are prompted for the LDAP server password, provide the password and click **OK**.
- c. Right-click **User Registries** and select **Add Registry > System** to start the configuration wizard that adds the registry to your domain.

Provide the registry name and type. If your application server is hosted on an iSeries server and configured to use the local OS user registry, select **OS/400** as the EIM user registry type. If your application server is configured to use the LDAP user registry, enter 1.3.18.02.33.14-caseIgnore as the EIM registry type.

Note: The value 1.3.18.02.33.14-caseIgnore is the ObjectIdentifier-normalization form of the user registry type and principals are identified by the LDAP short name attribute. The wizard does not handle the descriptive name for this registry type.

- d. Click **OK**.
4. Create user identifier in EIM

The identity token connection factory requires a user identifier entry, which is equivalent to an EIM identifier; in EIM, the user identifier entry represents the user of the application.

- a. In iSeries Navigator, expand **system > Network > Enterprise Identity Mapping > Domain Management > domain > Identifiers**.
 - b. Right-click **Identifiers**, and select **New Identifier**.
 - c. Enter an identifier name, such as your full name, and click **OK**.
5. Create a target association in EIM for the user identifier.
- A target association represents the user profile on the target iSeries server for the identifier created earlier.
- a. In iSeries Navigator, expand **system > Network > Enterprise Identity Mapping > Domain Management > domain > Identifiers**.
 - b. Double-click the **Application Identifier** for the user created previously.
 - c. Click the **Associations** tab.
 - d. Click **Add**.
 - e. Provide the i5/OS user profile for the EIM identifier in the User field and click **OK**.
 - f. Click **OK** to save the association.

6. Create a source association in EIM for the user identifier.
- A source association is used to authenticate to WebSphere Application Server.
- a. In iSeries Navigator, expand **system > Network > Enterprise Identity Mapping > Domain Management > domain > Identifiers**.
 - b. Double-click the **Application Identifier** for the user created previously.
 - c. Click the **Associations** tab.
 - d. Click **Add**.
 - e. Click **Browse** and select the WebSphere Application Server user registry.
 - f. Specify your WebSphere Application Server user ID, such as `my_id`.
 - g. Select **Source**.
 - h. Click **OK** to add the new association.
 - i. Click **OK** to save the association.

7. **Optional:** Test the connection to the EIM domain controller.

Use the **idsldapsearch** command to test the connection to the EIM domain controller. For example, if the LDAP server is located on the `my_server` host, the EIM domain name is `My_EIM_Domain`, and the source user registry is WAS Registry, the steps to test the connection are as follows:

- a. Log on to the iSeries server that hosts your WebSphere Application Server profile.
- b. From a CL command line, specify QSH and press Enter.
- c. Specify the following command and press Enter:

```
idsldapsearch -h my_server -p 389 -D cn=administrator  
-w secret -b "ibm-eimDomainName=My_EIM_Domain"  
"ibm-eimRegistryName=WAS_Registry"
```

where:

- `my_server` is the name of the host server of the LDAP server.
- 389 is the port that is used by the LDAP server.
- `cn=administrator` is the LDAP DN of the LDAP administrator.
- `secret` is the LDAP administrator password.
- `ibm-eimDomainName=My_EIM_Domain` is the LDAP DN of the EIM domain name entry.

The previous lines display as multiple lines for illustrative purposes only. Specify the command as one continuous line.

In this example, no EIM domain parent name exists. If an EIM domain parent name did exist, such as `dc=myserver,dc=ibm,dc=com`, the LDAP DN is `ibm-eimDomainName=My_EIM_Domain,dc=myserver,dc=ibm,dc=com`.

The expected output looks similar to the following example:

```
ibm-eimRegistryName=WAS Registry,cn=Registries,ibm-eimdomainname=My_EIM_Domain
objectclass=top
objectclass=ibm-eimRegistry
objectclass=ibm-eimSystemRegistry
ibm-eimRegistryName=WAS_Registry
ibm-eimRegistryType=1.3.18.0.2.33.9-caseIgnore
description=Example Registry for WebSphere Application Server
```

Configure the EIM identity token connection factory. See “Configuring the Enterprise Identity Mapping identity token connection factory.”

Configuring the Enterprise Identity Mapping identity token connection factory

The Enterprise Identity Mapping (EIM) identity token connection factory requires the `eim.jar` file to be located in the class path for the connection factory. The `jt400.jar` file must be in the class path for the sample application.

Perform the following steps to configure the `eim.jar` and `jt400.jar` files:

1. “Configuring the `eim.jar` and `jt400.jar` files” on page 256
2. “Configuring a shared library for the `jt400.jar` file” on page 257

Enterprise Identity Mapping identity token connection factory parameters:

The following table is a summary of the parameters or custom properties that are referenced by the Enterprise Identity Mapping (EIM) identity token connection factory. These parameters are necessary when you configure the EIM identity token connection factory.

Parameter description	Parameter example	Required	Initially set by	Referenced by
LDAP administrator ID and password	<code>cn=administrator</code>	Yes	LDAP administrator using the iSeries Navigator when configuring LDAP	J2C Authentication Data entry
LDAP host name and port	<code>mysystem.com</code> and <code>389</code>	Yes	LDAP administrator using the iSeries Navigator	<code>LdapHostName</code> and <code>LdapHostPort</code> identity token resource adaptor properties
EIM domain name and parent domain	<code>EIM</code> and <code>dc=mysystem,dc=com</code>	Yes	EIM administrator using the iSeries Navigator when configuring EIM	<code>EimDomainName</code> and <code>ParentDomain</code> identity token resource adaptor properties
<code>sourceRegistryName</code>	LDAP	Yes	EIM administrator using the iSeries Navigator when configuring EIM user registries that are used by applications	<code>sourceRegistryName</code> identity token resource adaptor property
Key time out and size	<code>1200</code> and <code>512</code>	No	WebSphere Application Server administrator using the administrative console	<code>KeyTimeoutSeconds</code> and <code>KeySize</code> identity token resource adaptor properties

Parameter description	Parameter example	Required	Initially set by	Referenced by
UseSSL	false	No	WebSphere Application Server administrator using the administrative console	UseSSL identity token resource adaptor property
TrustStoreName	profile_root/etc/idtokTrustFile.jks	No	WebSphere Application Server administrator using the administrative console	TrustStoreName identity token resource adaptor property
TrustStorePassword	tspwd	No	WebSphere Application Server administrator using the administrative console	TrustStorePassword identity token resource adaptor property
KeyStoreName	profile_root/etc/idtokKeyFile.jks	No	WebSphere Application Server administrator using the administrative console	KeyStoreName identity token resource adaptor property
KeyStorePassword	kspwd	No	WebSphere Application Server administrator using the administrative console	KeyStorePassword identity token resource adaptor property

Identity token files

After applying the required PTFs, all of the files in the table below can be found on the server where you have WebSphere Application Server installed.

File Name	Directory
idTokenRA.rar	/QIBM/ProdData/OS400/security/eim
testIdentityToken.ear	/QIBM/ProdData/OS400/security/eim
cfgIdToken.jacl	/QIBM/ProdData/OS400/security/eim
eim.jar	/QIBM/ProdData/OS400/security/eim
jt400.jar	/QIBM/ProdData/HTTP/public/jt400/lib
idTokenRA.JCA15.rar	/QIBM/ProdData/OS400/security/eim

Related tasks

“Configuring Enterprise Identity Mapping” on page 252

Use the iSeries Navigator to configure Enterprise Identity Mapping (EIM) for use with the identity token connection factory.

Configuring the *eim.jar* and *jt400.jar* files:

Configure the *eim.jar* and *jt400.jar* files for the WebSphere Application Server node where the connection factory is to be configured.

Completing the steps in this topic is the first part of configuring the EIM identity token connection factory.

1. The *eim.jar* file is already configured on your iSeries server and no additional action is required.

2. For OS/400 V5R2, copy the jt400.jar file to the classes directory of the WebSphere Application Server profile where the sample application is deployed or to a different directory.

The file might be deployed to the *profile_root/classes* directory.

If you copy the file to a different directory, the following additional configuration tasks are required:

- Grant read and execute authority for the jt400.jar file to the user profile that the application server runs under.
- Configure a shared library for the jt400.jar file. See “Configuring a shared library for the jt400.jar file” for more information.

The eim.jar and the jt400.jar files are configured.

If you copy the jt400.jar file to a different directory, you must configure a shared library for the file. For OS/400 V5R3 or i5/OS V5R4, JTOpen Version 4.3 or later of the jt400.jar file is already on your server. However, you still must configure a shared library for the jt400.jar file. See the “Configuring a shared library for the jt400.jar file” topic for more information.

Configuring a shared library for the jt400.jar file:

Use the WebSphere Application Server administrative console to create a shared library for the jt400.jar file.

If you copied the jt400.jar file to a different directory, completing the steps in this topic is part of configuring the Enterprise Identity Mapping (EIM) token connection factory.

1. Create a shared library:

- a. In the WebSphere Application Server administrative console, expand **Environment**.
- b. Click **Shared Libraries**.
- c. Click to expand the **Scope** field.
- d. Select the node where you want to create the shared library.
- e. Click **Apply**.
- f. Click **New**.
- g. Specify the name of the shared library in the **Name** field.
- h. Specify the full path name of the jt400.jar file in the **Classpath** field. For OS/400 V5R3, this path name is /QIBM/ProdData/HTTP/public/jt400/lib/jt400.jar.
- i. Click **OK**.

2. Create an application class loader for the shared library. This step makes the jt400.jar file available to all applications that are deployed on the application server.

- a. In the WebSphere Application Server administrative console, click **Servers > Application servers > server_name**.
- b. Under the Server Infrastructure heading, click **Java and Process Management > Class loader > New**.
- c. Keep the Class loader order default as **Classes loaded with parent class loader first** and click **OK**.
- d. Click the Class loader ID for the class loader that was created.
- e. Under Additional properties, click **Shared library references**.
- f. Click **Add**.
- g. Select the name of the shared library you created earlier.
- h. Click **OK**.

3. Grant the java.security.AllPermission permission to the jt400.jar file in the server.policy file.

To grant the required permission to the `jt400.jar` file, edit the `server.policy` file for your WebSphere Application Server profile and add the following statement. The `server.policy` file is in the `profile_root/properties` directory.

```
grant codeBase "file:path_name/jt400.jar" {
    permission java.security.AllPermission;
};
```

where `path_name` is the fully qualified path name of the directory that contains the `jt400.jar` file. For OS/400 V5R3, this path is `/QIBM/ProdData/HTTP/public/jt400/lib/jt400.jar`.

4. Save your configuration changes.
 - a. Expand **System administration** and click **Save Changes to Master Repository**.
 - b. Click **Save**.

The shared library for the `jt400.jar` file is configured.

After completing these steps, continue with configuring the connection factory. See “Manually configuring the connection factory” to configure the connection factory manually, or see “Automatically configuring the connection factory” on page 259 to use a Jacl script to automatically configure the connection factory.

Configuring the connection factory

You can use the WebSphere Application Server administrative console to manually configure the connection factory, or you can use a Jacl script to automatically configure the connection factory.

Configure the `eim.jar` and `jt400.jar` files.

Select one of the following options:

- “Manually configuring the connection factory”
This topic describes how to use the WebSphere Application Server administrative console to manually configure the connection factory.
- “Automatically configuring the connection factory” on page 259
This topic describes how to use a Jacl script to automatically configure the connection factory.

Manually configuring the connection factory:

The following steps help you manually configure the connection factory.

Configure the `eim.jar` and `jt400.jar` files.

After you configure the `eim.jar` and `jt400.jar` files, you can choose to manually or automatically configure the connection factory. If you choose to automatically configure the connection factory, see “Automatically configuring the connection factory” on page 259 for more information. Perform the following steps to manually configure the Java 2 Connector (J2C) authentication data, the resource adapter, and the connection factory.

1. Configure the Java 2 Connector (J2C) authentication data.
 - a. In the WebSphere Application Server administrative console, click **Security >Secure administration, applications, and infrastructure**.
 - b. Under Java Authentication and Authorization Service, click **J2C Authentication data > New**
 - c. Specify the values for each of the required fields. The User ID (cn=adminstrator for example) and Password values are those that are used by the connection factory to bind to the Lightweight Directory Access Protocol (LDAP) server that contains your Enterprise Identity Mapping (EIM) data.
 - d. Click **OK**.
2. Configure the resource adapter.
 - a. In the WebSphere Application Server administrative console, click **Resources > Resource adapters > Resource adapters**.

- b. Select the node where you want to install the resource adapter.
 - c. Click **Apply**.
 - d. Click **Install RAR**.
 - e. Select **Local path** if you have a drive that is mapped to your iSeries server. Otherwise, select **Server path**.
 - f. Specify the path name or browse to the path name for the idTokenRA.JCA15.rar RAR file.
 - g. Click **Next**.
 - h. Specify the name of your adapter in the Name field. For example, specify identitytoken.
 - i. Click **OK**.
3. Configure the connection factory.
 - a. On the Resource Adapters panel, click the name of your newly created resource adapter.
 - b. Under Additional Properties, click **J2C connection factories > New**.
 - c. Specify the name of your connection factory in the Name field. For example, specify idtokenconnection.
 - d. Specify eis/IdentityToken in the Java Naming and Directory Interface (JNDI) name field. This name must match the JNDI name used during the deployment of the sample application. The name is used for reference binding.
 - e. In the Component-managed authentication alias and Container-managed authentication alias fields, select the authentication data alias that you created earlier.
 - f. In the Mapping-configuration alias field, select **DefaultPrincipalMapping**.
 - g. Click **Apply**.
 - h. Under Additional Properties, click **Custom properties**. The custom properties are used by the connection factory to communicate with the EIM controller. View the custom property descriptions, and determine whether the properties are required or optional. For more information, see “Enterprise Identity Mapping identity token connection factory parameters” on page 255.
 To set a property value, complete the following steps:
 - 1) Click the name of the custom property.
 - 2) Type the value of the property in the Value field.
 - 3) Click **OK**.
 4. Save your configuration changes.
 - a. Expand **System administration** and click **Save Changes to Master Repository**.
 - b. Click **Save**.

You have manually configured the connection factory.

After saving your configuration changes, you can deploy the EIM sample application into the WebSphere Application Server environment. The source code files that are used in the sample application can be used as a model for creating your own applications. See “Deploying the Enterprise Identity Mapping sample application” on page 261 for more information.

Automatically configuring the connection factory:

You can use the `cfgIdToken.jacl` script to automatically configure the Java 2 Connector (J2C) authentication data, the resource adapter, and the connection factory.

Configure the `eim.jar` and `jt400.jar` files.

After you configure the `eim.jar` and the `jt400.jar` files, you can choose to manually or automatically configure the connection factory. If you choose to manually configure the connection factory, see “Manually configuring the connection factory” on page 258 for more information.

Perform the following steps to create a connection factory named CF1 in the `my_profile` WebSphere Application Server profile:

1. Make sure that your deployment manager is started.
2. On the CL command line, enter QSH. This command starts the Qshell environment.
3. Change to the `app_server_root/bin` directory and specify the following command:

Note: The `/QIBM/ProdData/OS400/security/eim` directory contains two resource adapter archive files, `idTokenRA.rar` and `idTokenRA.JCA15.rar`. The resource adapter contained in `idTokenRA.rar` is implemented to the J2EE Connector Architecture (JCA) 1.0 specification, while the adapter in `idTokenRA.JCA15.rar` is implemented to the JCA 1.5 specification. The JCA 1.5 specification is included in the J2EE 1.4 specification. See Java 2 Platform, Enterprise Edition (J2EE) specification for more information.

```
wsadmin -profileName my_profile -f /QIBM/ProdData/OS400/security/eim/cfgIdToken.jacl
CF1 sys1.ibm.com 389 "Eim Domain 1" "Registry For my_profile"
-rarFile /QIBM/ProdData/OS400/security/eim/idTokenRA.JCA15.rar -authAlias myAlias1
-authUserName cn=administrator -authPassword pwd1 -nodeName SYS1_my_profile
```

where:

- `my_profile` is the name of the WebSphere Application Server profile.
- `/QIBM/ProdData/OS400/security/eim/cfgIdToken.jacl` is the path name to the `cfgIdToken.jacl` script.
- CF1 is the name of the connection factory.
- `sys1.ibm.com` is the Lightweight Directory Access Protocol (LDAP) server host name for the Enterprise Identity Mapping (EIM) domain controller.
- 389 is the LDAP server port.
- `Eim Domain 1` is the EIM domain name.
- `Registry For my_profile` is the EIM source user registry.
- `/QIBM/ProdData/OS400/security/eim/idTokenRA.JCA15.rar` is the path name to the `idTokenRA.JCA15.rar` file.
- `myAlias1` is the authentication alias name that is referenced by the connection factory when it authenticates to the EIM domain controller (LDAP server).
- `cn=administrator` is the distinguished name that is associated with the authentication alias.
- `pwd1` is the password that is associated with the authentication alias.
- `SYS1_my_profile` is the WebSphere Application Server node where the connection factory is created. Note that specifying `-nodeName` is required when the configuration contains more than one node.

Notes:

- The previous sample displays on multiple lines for illustrative purposes only. Type the command on one continuous line.
- Quote all argument values that contain embedded blanks.
- If an external Web server is configured, you must use the **-nodeName** parameter to specify the node within the cell where the connection factory is to be configured.
- If WebSphere Application Server administrative security is already enabled, use the `-username my_userid` and `-password my_password` **wsadmin** parameters in the command, where `my_userid` and `my_password` are the WebSphere Application Server administrative ID and password.

You have automatically configured the connection factory.

After performing the previous steps, you can deploy the EIM sample application into the WebSphere Application Server environment. The source code files that are used in the sample application can be used as a model for creating your own applications. See “Deploying the Enterprise Identity Mapping sample application” on page 261 for more information.

Deploying the Enterprise Identity Mapping sample application

You can deploy the sample application into the WebSphere Application Server environment.

Using Enterprise Identity Mapping (EIM) identity token connection factories requires that WebSphere Application Server administrative security be enabled. However, no restrictions or limitations exist on how you choose to configure administrative security.

Before you deploy the sample application, you must enable WebSphere Application Server administrative security. This step is not required if you already have administrative security enabled for your WebSphere Application Server profile. For more information on how to configure security, see “Enabling security” on page 43.

The source code files that are used to implement the sample application are contained in the `testIdentityToken.ear` file and can be used as a model for creating your own applications.

The `com.ibm.identitytoken.IdentityTokenTest` class is a servlet in the sample application. After the application is deployed, the source code file for the `IdentityTokenTest` servlet is in this directory:

```
profile_root/installedApps/testIdentityToken.ear/testIdentityTokenWeb.war  
/WEB-INF/source/com/ibm/identityToken/IdentityTokenTest.java
```

Note the `IdentityTokenTest` servlet design features when you implement your own application.

- A profile variable with a String type and the name, `sourceApplicationID`, is set in the `init` method of the `IdentityTokenTest` servlet. This variable is later used with the `setSourceApplicationID` method of a `ConnectionSpecImpl` object to uniquely identify the application to Enterprise Identity Mapping (EIM). When you implement your own applications, use a similar convention to assign a unique `SourceApplicationID` ID.
- After an identity token is generated, it is used to create a `com.ibm.as400.access.AS400` object, which is stored in an `HTTPSession` object immediately after the `AS400` object is used to run the OS/400 server command on the selected host server. Only the `AS400` object persists across requests to the server (not the `IdentityToken` object), which provides improved performance for subsequent requests, and the identity token does not expire.

The following steps help you deploy the sample application into the WebSphere Application Server environment.

1. Restart your application server.
See *Starting an application server* and *Stopping an application server* for more information on how to restart your application server.
2. Deploy the sample application.
 - a. In the WebSphere Application Server administrative console, click **Applications > Install applications**.
 - b. Select **Local path** if you have a drive mapped to your iSeries server. Otherwise, select **Server path**.
 - c. Specify the path name or browse to the path name for the `testidentitytoken.ear` enterprise archive (EAR) file. This file is found in the `/QIBM/ProdData/OS400/security/eim/` directory on your i5/OS V5R3 (or later) server.
 - d. Click **Next**.
 - e. **Optional:** Change the virtual host values.
 - f. Click **Next**.
 - g. Select your installation options, and click **Next**.
 - h. Decide whether to map modules to servers and click **Next**.
 - i. Select your module in the Map resource references to resources panel and click **Next**.

- j. **Optional:** Change the Java Naming and Directory Interface (JNDI) name for the `eis/IdentityToken_Shared_Reference` reference binding . Do this step if you configured your connection factory with a JNDI name other than `eis/IdentityToken`.
 - k. Accept the default values for the remainder of the panels and click **Next**.
 - l. On the Summary panel, click **Finish**.
 - m. Expand **System administration** and click **Save Changes to Master Repository**.
 - n. Click **Save**.
3. Run the sample application.
- a. In the WebSphere Application Server administrative console, click **Applications > Enterprise applications**.
 - b. Select the **testIdentityToken** application.
 - c. Click **Start**.
 - d. Open a new session of your Web browser.
 - e. If you mapped the sample application Web module to an external Web server, refresh your WebSphere Application Server Web server plug-in.
To refresh the Web server plug-in, perform the following steps:
 - 1) Click **Servers > Web servers > Web_server_name**.
 - 2) Click **Generate Plug-in**.
 - f. Specify the application welcome page from your Web browser. Use the following Web address:
`http://your.server.name:port/testIdentityTokenWeb/IDTknTest.jsp`
The *your.server.name* and *port* variables are the values for your external Web server or internal HTTP transport (WebSphere Application Server container).
 - g. Specify a value for OS/400 host system name and for OS/400 command. For example, if you have EIM configured for the `my_server` server, specify `my_server` in the **OS/400 host system name** field. Specify `crtlib my_library` in the **OS/400 command** field.
 - h. Click **Submit**.
 - i. Specify a user ID and password at the login prompt.
After you click **Submit**, the request is sent to the `IdentityTokenTest` servlet, which is protected by the `allUsers` role. The `allUsers` role is bound to the `AllAuthenticated` special subject so any user in the WebSphere Application Server user registry is authorized to access the `IdentityTokenTest` servlet.
 - j. Click **OK**. If you specified `my_library`, the response is similar to the following example:
`Library my_library created.`
 - k. Verify that the library is created under the user profile that is mapped by EIM:
 - 1) From a CL command line, enter `wrklnk '/QSYS.LIB/my_library.lib'`.
 - 2) On the Work with Object Links screen, enter 8 in the option field to the left of `my_library.lib`.
 - 3) Verify that the value of the Owner attribute for the `my_library` library is the user profile that is mapped by EIM.

Configuring single sign-on capability with Lotus Domino

These steps allow you to configure single sign-on for a single or multiple Lotus Domino servers.

Lightweight Third Party Authentication (LTPA) is the default authentication mechanism for WebSphere Application Server. However, if LTPA is not the currently configured authentication mechanism, you must configure LTPA prior to configuring single sign-on capability with Lotus Domino. You can configure LTPA by clicking **Security > Secure administration, applications, and infrastructure > Authentication mechanisms and expiration**. Additionally, enabling Web security single sign-on (SSO) is required. For more information, see “Implementing single sign-on to minimize Web user authentications” on page 226.

To configure single sign-on with Lotus Domino, you need the following information from your LTPA configuration: the path and name of the file that contains the Lightweight Third Party Authentication (LTPA) keys. Use the same password that you use to generate LTPA keys on the WebSphere Application Server. Also, from the Web security single sign-on (SSO) configuration, you need the domain name service (DNS) name where single sign-on with Lotus Domino will be effective.

You must select a new multi-server option in a server document for session-based authentication and create a new domain-wide configuration document in the Domino Directory. This configuration document is called the Web Single Sign-on (SSO) Configuration document. The Web SSO Configuration document, which must be replicated to all of the Domino servers that are participating in the single sign-on domain, is encrypted and contains a shared secret that is used to authenticate user credentials.

To configure single sign-on for Domino servers, complete the following steps:

1. Create the Web SSO Configuration document using Lotus Notes Client 5.0.5 or later.
 - a. In the Domino Directory, select the Servers view.
 - b. Click the Web menu item.
 - c. Select **Create Web SSO Configuration** to create the document.
 - d. On the Web SSO Configuration document, click the Keys menu.
 - e. Select **Import WebSphere LTPA Keys** to import the LTPA keys that WebSphere Application Server previously created and stored in a file.
 - f. Enter the fully-qualified path name of the file that contains the keys for WebSphere Application Server and click **OK**.
 - g. Enter the password that was used to generate the LTPA keys. The Web SSO Configuration document is automatically updated to reflect the information in the imported file.
 - h. Complete the Token expiration, DNS domain, Domino server names, and LDAP realm fields in this document. Groups and wildcards are not allowed in the fields. The following list describes the fields and the expected values:

Token expiration

Specifies the number of minutes a token can exist before expiring. A token does not expire based on inactivity; it is valid for only the number of minutes that is specified from the time of issue.

DNS domain

Specifies the DNS domain portion of your system's fully qualified Internet name. This is a required field.

All of the servers that participate in single sign-on must reside in the same DNS domain. This value must be the same as the Domain value that you specified in your WebSphere Application Server configuration. WebSphere Application Server treats the DNS domain as case sensitive so you must verify that the DNS domain value is specified exactly the same way.

Domino server names

Specifies the Domino servers that you want to participate in single sign-on. This Web SSO Configuration document is encrypted for the creator of the document, the members of the Owners and Administrators fields, and the servers that are specified in this field. These servers can be in different Domino domains; however they must be in the same DNS domain.

You must specify a fully qualified Domino server name. For example, you might specify MyDominoServer/MyOu. The Domino server name that you specify here must also match the name of the corresponding server Connection document in your client Domino Directory.

LDAP realm

Specifies the fully qualified DNS host name of the Lightweight Directory Access Protocol (LDAP) server. This field is initialized from the information that is provided in the imported

LTPA keys file. Change this value only if an port value for the LDAP server is specified for the WebSphere Application Server administrative domain. If a port is specified, you must insert an escape character (\) into the value before the colon character (:). For example, replace `myhost.mycompany.com:389` with `myhost.mycompany.com\ :389`.

- i. Save the Web SSO Configuration document. This configuration document displays in the Web Configurations view.
2. Configure the Server document. To update the Server document for single sign-on, complete the following steps:
 - a. In the Domino Directory, select the Servers view.
 - b. Edit the Server document.
 - c. Select the **Ports > Internet Ports > Web** tab.
 - d. To enable basic authentication for Web users in the HTTP Authentication options section, set Name and password to Yes.
 - e. Select **Internet Protocols > Domino Web Engine**.
 - f. Select **Multiple Servers (SSO)** in the Session Authentication field to enable single sign-on for Lotus Domino.
 - g. Click the Security tab.
 - h. In the Internet Access section select **More name variations with lower security** in the Internet authentication field so that short names can be used for authentication.
 - i. Save the Server document.
3. Finish the Lotus Domino configuration. Before continuing, finish configuring the Lotus Domino server for use by Web users. The remaining configuration steps are not specific to single sign-on and are not covered here in detail. For more information on the following remaining Lotus Domino configuration steps, see the Security topic in the Domino 5 Administration Help:
 - Configuring access to an LDAP directory when the Domino Directory is not being used.
 - Authorizing Web users to Domino resources.
4. Verify the single sign-on configuration for Lotus Domino. To verify the single sign-on configuration for Lotus Domino, ensure that the Lotus Domino server is configured correctly and that Web users are authorized to access Domino resources by performing the following steps:
 - a. To verify that the Lotus Domino server is configured correctly, stop and restart the Domino HTTP Web server.

If single sign-on is configured correctly, the following message is displayed on the Lotus Domino server console:

```
HTTP: Successfully loaded Web SSO Configuration
```

If a Domino server that is enabled for single sign-on cannot find a Web SSO Configuration document or the server is not included in the Domino Server Names field and therefore cannot decrypt the document, the following message is displayed on the Lotus Domino server console:

```
HTTP: Error Loading Web SSO configuration.  
Reverting to single-server session authentication
```
 - b. To verify that users are authorized, attempt to access a Domino resource, such as a Domino Directory.
 - To verify local authorization attempt to access a Lotus Domino resource as a user that is defined in the Domino Directory.
 - To verify the authorization for WebSphere Application Server users, attempt to access a Lotus Domino resources as a user that is defined in the LDAP directory service.
5. **Optional:** Configure additional Lotus Domino servers in a single domain. If you are using single sign-on with multiple Domino servers, perform the following steps for each additional server:
 - a. Replicate the initial Web SSO Configuration document to each additional Domino server.
 - b. Update the Server document for each additional Domino server.
 - c. Restart each of the Domino HTTP Web servers.

6. **Optional:** Configure Lotus Domino servers in multiple Domino domains. If you are using single sign-on with Domino servers in multiple Domino domains, you must also set up cross-domain authentication among the Domino servers. For example, assume there are Domino servers in two Domino domains, X and Y. Complete the following steps to enable the Domino servers to perform single sign-on between the domains:
 - a. As a Lotus Domino administrator, you must copy the Web SSO Configuration document from the Domino Directory for domain X and paste it into the Domino Directory for domain Y. The Domino administrator needs the rights associated with decrypting the Web SSO Configuration document in domain X and to creating documents in the Domino Directory for domain Y.
 - b. Ensure that your location home server for your Lotus Notes client is set to a Domino server in domain Y.
 - c. Edit the Web SSO Configuration document for domain Y.
 - d. In the Participating domino servers field, include only the Domino servers with server documents in domain Y that you want participate in single sign-on.
 - e. Save the Web SSO Configuration document. The configuration document is now to be encrypted for the participating Domino servers in domain Y. These servers have the same key information as the Domino servers in domain X. This shared information allows Domino servers in domain Y to perform single sign-on with Domino servers in domain X.

These steps enable you to configure single sign-on for a single or multiple Lotus Domino servers.

Configuring single sign-on capability with Tivoli Access Manager or WebSEAL

Either Tivoli Access Manager WebSEAL or Tivoli Access Manager plug-in for Web servers can be used as reverse proxy servers to provide access management and single sign-on (SSO) capability to WebSphere Application Server resources. With such an architecture, either WebSEAL or the plug-in authenticates users and forwards the collected credentials to WebSphere Application Server in the form of an IV Header. Two types of single sign-on are available, the TAI interface and the TAI++ interface, so named as both use WebSphere Application Server trust association interceptors (TAI). With the TAI, the end-user name is extracted from the HTTP header and forwarded to embedded Tivoli Access Manager where the end-user name is used to construct the client credential information and authorize the user. With the TAI++, all of the user credential information is available in the HTTP header and not just the user name. The TAI++ is the more efficient of the two solutions because a Lightweight Directory Access Protocol (LDAP) call is not required. TAI functionality is retained for backwards compatibility.

Complete the following tasks to enable single sign-on to WebSphere Application Server using either WebSEAL or the plug-in for Web servers. These tasks assume that embedded Tivoli Access Manager is configured for use.

1. Create a trusted user account for Tivoli Access Manager in the shared Lightweight Directory Access Protocol (LDAP) user registry. For more information, see “Creating a trusted user account in Tivoli Access Manager” on page 271.
2. Configure either WebSEAL or the Tivoli Access Manager plug-in for Web servers to work with WebSphere Application Server. For more information, see either of the following articles:
 - “Configuring WebSEAL for use with WebSphere Application Server” on page 271
 - “Configuring Tivoli Access Manager plug-in for Web servers for use with WebSphere Application Server” on page 272
3. Configure single sign-on using either the TAI or TAI++ interface. For more information, see either of the following articles:
 - “Configuring single sign-on using the trust association interceptor” on page 273
 - “Configuring single sign-on using trust association interceptor ++” on page 274

Single sign-on settings

Use this page to set the configuration values for single sign-on (SSO).

To view this administrative console page, complete the following steps:

1. Click **Security > Secure administration, applications, and infrastructure**.
2. Under Authentication, click **Web security > Single sign-on (SSO)**.

Enabled:

Specifies that the single sign-on function is enabled.

Web applications that use J2EE FormLogin style login pages, such as the administrative console, require single sign-on (SSO) enablement. Only disable SSO for certain advanced configurations where LTPA SSO-type cookies are not required.

Data type:	Boolean
Default:	Enabled
Range:	Enabled or Disabled

Requires SSL:

Specifies that the single sign-on function is enabled only when requests are made over HTTPS Secure Sockets Layer (SSL) connections.

Data type:	Boolean
Default:	Disable
Range:	Enable or Disable

Domain name:

Specifies the domain name (.ibm.com, for example) for all single sign-on hosts.

The application server uses all the information after the first period, from left to right, for the domain names. If this field is not defined, the Web browser defaults the domain name to the host name where the Web application is running. Also, single sign-on is then restricted to the application server host name and does not work with other application server host names in the domain.

You can specify multiple domains separated by a semicolon (;), a space (), a comma (,), or a pipe (|). Each domain is compared with the host name of the HTTP request until the first match is located. For example, if you specify `ibm.com;austin.ibm.com` and a match is found in the `ibm.com` domain first, the application server does not match the `austin.ibm.com` domain. However, if a match is not found in either `ibm.com` or `austin.ibm.com`, then the application server does not set a domain for the `LtpaToken` cookie.

If you specify the `UseDomainFromURL` value, the application server sets the SSO domain name value to the domain of the host that is used in the Web address. For example, if an HTTP request comes from `server1.raleigh.ibm.com`, the application server sets the SSO domain name value to `raleigh.ibm.com`.

Tip: The `UseDomainFromURL` value is case insensitive. You can type `usedomainfromurl` to use this value.

Data type:	String
-------------------	--------

Interoperability mode:

Specifies that an interoperable cookie is sent to the browser to support back-level servers.

In WebSphere Application Server, Version 6 and later, a new cookie format is needed by the security attribute propagation functionality. When the interoperability mode flag is enabled, the server can send a maximum of two single sign-on (SSO) cookies back to the browser. In some cases, the server just sends the interoperable SSO cookie.

Web inbound security attribute propagation:

When Web inbound security attribution propagation is enabled, security attributes are propagated to front-end application servers. When this option is disabled, the single sign-on (SSO) token is used to log in and recreate the Subject from the user registry.

If the application server is a member of a cluster and the cluster is configured with a distributed replication service (DRS) domain, then propagation occurs. If DRS is not configured, then the SSO token contains the originating server information. With this information, the receiving server can contact the originating server using an MBean call to get the original serialized security attributes.

com.tivoli.pd.jcfg.PDJrteCfg utility for Tivoli Access Manager single sign-on

The com.tivoli.pd.jcfg.PDJrteCfg utility configures the Java Runtime Environment component for Tivoli Access Manager. This component enables WebSphere Application Server to use Tivoli Access Manager security.

Purpose

Important: If you are using the WebSphere Application Server Network Deployment product, run the pdjrtecfg utility first on the deployment manager. Then, run the script on the other nodes in the cell.

Steps

To run the pdjrtecfg script, perform the following steps:

1. Log into your system with a user profile and the all object (*ALLOBJ) authority.
2. On the command line, enter the Start Qshell (STRQSH) command.
3. Change to the /bin subdirectory of WebSphere Application Server. For example:

```
cd app_server_rootND/bin
```

4. Run the script. For example:

```
pdjrtecfg -action config -profileName myprofile  
-host mypolicy.mycompany.com -config_type full
```

The previous example was split onto multiple lines for illustrative purposes only.

Syntax

The following syntax diagram shows the usage of the pdjrtecfg script:

```
pdjrtecfg  
-action config  
    -profileName profile_name  
    -host policy_server_name  
    -config_type { full | standalone }  
-action unconfig  
    -profileName profile_name
```

Parameters

-action {config|unconfig}

Specifies the action to be performed. Actions include:

config Use to configure the Access Manager Java Runtime Environment component.

unconfig

Use to reconfigure the Access Manager Java Runtime Environment component.

-config_type {fullstandalone}

Specifies the configuration type of Java Runtime Environment for Tivoli Access Manager. Specify full or standalone with this argument. This option is required.

-host *policy_server_host*

Specifies the policy server host name.

Valid values for *policy_server_host* include any valid IP host name.

Examples include:

```
host = libra  
host = libra.dallas.ibm.com
```

-profileName

Specifies the name of the WebSphere Application Server profile. If not specified, the default profile is used.

Comments

This command copies Tivoli Access Manager Java libraries to a library extensions directory that exists for a Java runtime that has already been installed on the system.

You can install more than one Java Runtime Environment (JRE) on a given machine. The `pdjrtecfg` command can be used to configure the Tivoli Access Manager Java Runtime Environment component independently for each of the JRE configurations.

com.tivoli.pd.jcfg.SvrSslCfg utility for Tivoli Access Manager single sign-on

The utility is used to configure and remove the configuration information associated with WebSphere Application Server and the Tivoli Access Manager server.

Purpose

The `svrsslcfg` script creates a user account and server entries that represent your WebSphere Application Server profile in the Tivoli Access Manager user registry. In addition, a configuration file and a Java keystore file, which securely stores a client certificate, are created in the application server profile. This client certificate permits callers to use Tivoli Access Manager authentication services. You can also choose to remove the user and server entries from the user registry and clean up the local configuration and keystore files.

The `svrsslcfg` script wraps the `SvrSslCfg` class and provides support for multiple WebSphere Application Server profiles. The use of multiple profiles allows you to create multiple WebSphere Application Server environments that are completely isolated from one another.

Run the `svrsslcfg` script first on the deployment manager and then on the other nodes in the cell.

Steps

To run the `svrsslcfg` script, perform the following steps:

1. Log on with a user profile and all object (*ALLOBJ) authority.
2. On the CL command line, enter the Start Qshell (STRQSH) command.
3. Change directories to the *app_server_root/bin* directory.
4. Enter the `svrsslcfg` command with the options that you want.

For example:

```
svrsslcfg -profileName myprofile -action config -admin_id sec_master
-admin_pwd pwd123 -appsvr_id ibm9 -appsvr_pwd ibm9pwd -mode remote
-port 8888 -policysvr ourserv.rochester.ibm.com:7135:1
-authzsvr ourserv.rochester.ibm.com:7136:1
-key_file profile_root/myprofile/etc/ibm9.kdb
-cfg_action create
```

The previous example displays on multiple lines for illustrative purposes only.

Syntax

The configuration syntax is:

```
svrsslcfg -action config
[ -profileName profile_name ]
-admin_id admin_user_id
-admin_pwd admin_password
-appsvr_id application_server_name
-port port_number
-mode { local | remote }
-policysvr policy_server_name
-authzsvr authorization_server_name
-key_file fully_qualified_name_of_key_file
-appsvr_pwd application_server_password
-cfg_action { create | replace }
[ -domain Tivoli_Access_Manager_domain ]
```

The unconfigure syntax is:

```
svrsslcfg -action unconfig
[ -profileName profile_name ]
-admin_id admin_user_id
-admin_pwd admin_password
-appsvr_id application_server_name
-policysvr policy_server_name
[ -domain Tivoli_Access_Manager_domain ]
```

You can enter the previous syntax as one continuous line.

Parameters

-action {config | unconfig}

Specifies the configuration action that is performed by the script. The following options apply:

-action config

Configuring a server creates user and server information in the user registry and creates local configuration and key store files on the application server. Use the `-action unconfig` option to reverse this operation.

If this action is specified, the following options are required: `-admin_id`, `-admin_pwd`, `-appsvr_id`, `-port`, `-mode`, `-policysvr`, `-authzsvr`, and `-key_file`.

-action unconfig

Reconfigures an application server to complete the following actions:

- Remove the user and server information from the user registry
- Delete the local key store file
- Remove information for this application from the configuration file without deleting the file

The reconfiguration operation fails only if the caller is unauthorized or the policy server cannot be contacted.

This action can succeed when a configuration file does not exist. When the configuration file does not exist, it is created and used as a temporary file to hold configuration information during the operation, and then the file is deleted completely.

If this action is specified, the following options are required: `-admin_id`, `-admin_pwd`, `-appsvr_id`, and `-policysvr`.

-admin_id *admin_user_ID*

Specifies the Tivoli Access Manager administrator name. If this option is not specified, `sec_master` is the default.

A valid administrative ID is an alphanumeric, case-sensitive string. String values are expected to be characters that are part of the local code set. You cannot use a space in the administrative ID.

For example, for U.S. English the valid characters are the letters a-Z, the numbers 0-9, a period (.), an underscore (_), a plus sign (+), a hyphen (-), an at sign (@), an ampersand (&), and an asterisk (*). The minimum and maximum lengths of the administrative ID, if there are limits, are imposed by the underlying registry.

-admin_password *admin_password*

Specifies the password of the Tivoli Access Manager administrator user that is associated with the `-admin_id` parameter. The password restrictions depend upon the password policy for your Tivoli Access Manager configuration.

-appsvr_id *application_server_name*

Specifies the name of the application server. The name is combined with the host name to create unique names for Tivoli Access Manager objects created for your application. The following names are reserved for Tivoli Access Manager applications: `ivaclid`, `secmgrd`, `ivnet`, and `ivweb`.

-appsvr_pwd *application_server_password*

Specifies the password of the application server. This option is required. A password is created by the system and the configuration file is updated with the password created by the system.

If this option is not specified, the server password will be read from standard input.

-authzsvr *authorization_server_name*

Specifies the name of the Tivoli Access Manager authorization server with which the application server communicates. The server is specified by fully qualified host name, the SSL port number, and the rank. The default SSL port number is 7136. For example: `myauth.mycompany.com:7136:1`. You can specify multiple servers if the entries are separated by a comma (,).

-cfg_action {**create** | **replace**}

Specifies the action to take when creating the configuration and key files. Valid values are **create** or **replace**. Use the **create** option to initially create the configuration and keystore files. Use the **replace** option if these files already exist. If you use the **create** option and the configuration or keystore files already exist, an exception is created.

Options are as follows:

create Specifies to create the configuration and key store files during server configuration. Configuration fails if either of these files already exists.

replace

Specifies to replace the configuration and key store files during server configuration. Configuration deletes any existing files and replaces them with new ones.

-domain *Tivoli_Access_Manager_domain*

Specifies the Tivoli Access Manager domain name to which the administrator is authenticated. This domain must exist and the administrator ID and password must be valid for this domain. The application server is specified in this domain.

If not specified, the local domain that was specified during Tivoli Access Manager runtime configuration will be used. The local domain value will be retrieved from the configuration file.

A valid domain name is an alphanumeric, case-sensitive string. String values are expected to be characters that are part of the local code set. You cannot use a space in the domain name.

For example, for U.S. English the valid characters for domain names are the letters a-Z, the numbers 0-9, a period (.), an underscore (_), a plus sign (+), a hyphen (-), an at sign (@), an ampersand (&), and an asterisk (*). The minimum and maximum lengths of the domain name, if there are limits, are imposed by the underlying registry.

-key_file *fully_qualified_name_of_keystore_file*

Specifies the directory that is to contain the key files for the server. A valid directory name is determined by the operating system. Use a fully qualified file name that contains the application server certificate and key file.

Make sure that server user (for example, ivmgr) or all users have permission to access the .kdb file and the folder that contains the .kdb file.

This option is required.

-mode *server_mode*

Specifies the mode in which the application server processes requests. Only the remote mode is supported.

-policysvr *policy_server_name*

Specifies the names of servers that run the Tivoli Access Manager policy server (ivmgrd) with which the application server communicates. A server is specified by a fully qualified host name, the SSL port number, and the rank. The default SSL port number is 7135. For example: mypolicy.mycompany.com:7135:1. You can specify multiple servers if the entries are separated by a comma (,).

-port *port_number*

Specifies the TCP/IP communications port on which the application server listens for communications from the policy servers.

-profileName *profile_name*

Specifies the name of your WebSphere Application Server profile. If this option is not specified, the default server1 profile is used.

Creating a trusted user account in Tivoli Access Manager

Tivoli Access Manager trust association interceptors require the creation of a trusted user account in the shared LDAP user registry.

This account includes the ID and password that WebSEAL uses to identify itself to WebSphere Application Server. To prevent potential vulnerabilities, do not use the sec_master ID as the trusted user account and ensure that the password you use is unique and generated randomly. Use the trusted user account should for the TAI or TAI++ only.

1. Use either the Tivoli Access Manager pdadmin command-line utility or Web Portal Manager to create the trusted user. For example, from the **pdadmin** command line.
2. Reference the code listed below as an example for creating a trusted user account.
3. Reference the following additional resources for more information:
 - a. “Configuring WebSEAL for use with WebSphere Application Server”
 - b. “Configuring Tivoli Access Manager plug-in for Web servers for use with WebSphere Application Server” on page 272

```
pdadmin> user create webseal_userid webseal_userid_DN firstname  
surname password
```

```
pdadmin> user modify webseal_userid account-valid yes
```

Configuring WebSEAL for use with WebSphere Application Server

Use this topic to set the SSO password in WebSEAL for single sign-on to WebSphere Application Server.

A junction must be created between WebSEAL and WebSphere Application Server. This junction carries the iv-credentials (for TAI++) or iv-user (for TAI) and the HTTP basic authentication headers with the

request. You can configure WebSEAL to pass the end user identity in other ways, the iv-credentials header is the only one supported by the TAI++ and the iv-user is the only one supported by TAI.

We recommend that communications over the junction use Secure Sockets Layer (SSL) for increased security. Setting up SSL across this junction requires that you configure the HTTP Server used by WebSphere Application Server, and WebSphere Application Server itself, to accept inbound SSL traffic and route it correctly to WebSphere Application Server. This activity requires importing the necessary signing certificates into the WebSEAL certificate keystore, and possibly also the HTTP Server certificate keystore.

Create the junction between WebSEAL and WebSphere Application Server using the **-c iv_creds** option for TAI++ and **-c iv_user** for TAI. Enter either of the following commands as one line using the variables that are appropriate for your environment:

TAI++

```
server task webseald-server create -t ssl -b supply -c iv_creds  
-h host_name -p websphere_app_port_number junction_name
```

TAI

```
server task webseald-server create -t ssl -b supply -c iv_user  
-h host_name -p websphere_app_port_number junction_name
```

Notes:

1. If warning messages are displayed about the incorrect setup of certificates and key databases, delete the junction, correct problems with the key databases, and recreate the junction.
2. The junction can be created as `-t tcp` or `-t ssl`, depending on your requirements.

For single sign-on (SSO) to WebSphere Application Server the SSO password must be set in WebSEAL. To set the password, complete the following steps:

1. Edit the WebSEAL configuration file `webseal_install_directory/etc/webseald-default.conf`. Set the following parameter: `basicauth-dummy-passwd=webseal_userid_passwd` where `webseal_userid_passwd` is the SSO password for the trusted user account set in “Creating a trusted user account in Tivoli Access Manager” on page 271.
2. Restart WebSEAL.

For more details and options about how to configure junctions between WebSEAL and WebSphere Application Server, including other options for specifying the WebSEAL server identity, refer to the *Tivoli Access Manager WebSEAL Administration Guide* as well as to the documentation for the HTTP Server you are using with your WebSphere Application Server. Tivoli Access Manager documentation is available at <http://publib.boulder.ibm.com/tividd/td/tprodlist.html>.

Configuring Tivoli Access Manager plug-in for Web servers for use with WebSphere Application Server

Tivoli Access Manager plug-in for Web servers can be used as a security gateway for your protected WebSphere Application Server resources.

With such an arrangement the plug-in authorizes all user requests before passing the credentials of the authorized user to WebSphere Application Server in the form of an iv-creds header. Trust between the plug-in and WebSphere Application Server is established through use of basic authentication headers containing the single sign-on (SSO) user password.

1. The Tivoli Access Manager plug-in for Web servers configuration shows IV headers configured for post-authorization processing, and basic authentication that is configured as the authentication mechanism and for post-authorization processing, as shown in the example below.
2. After a request is authorized, the basic authentication header is removed from the request (`strip-hdr=always`) and a new one is added (`add-hdr=supply`).

3. Included in this new header is the password that is set when the SSO user is created in “Creating a trusted user account in Tivoli Access Manager” on page 271.
4. Specify this password in the **supply-password** parameter and is passed in the newly created header. This basic authentication header enables trust between WebSphere Application Server and the plug-in.
5. An iv-creds header is also added (generate=iv-creds), which contains the credential information of the user passed onto WebSphere Application Server. Session cookies are used to maintain session state.

```
[common-modules]
authentication = BA
session = session-cookie
post-authzn = BA
post-authzn = iv-headers
```

```
[iv-headers]
accept = all
generate = iv-creds
```

```
[BA]
strip-hdr = always
add-hdr = supply
supply-password = sso_user_password
```

“Configuring single sign-on using the trust association interceptor” or “Configuring single sign-on using trust association interceptor ++” on page 274

Configuring single sign-on using the trust association interceptor

This task is performed to enable single sign-on using the trust association interceptor. These steps involve setting up trust association and creating the interceptor properties.

The following steps are required when setting up security for the first time. Ensure that Lightweight Third Party Authentication (LTPA) is the active authentication mechanism:

1. From the WebSphere Application Server console click **Security > Global security**.
2. Ensure that the Active authentication mechanism field is set to **Lightweight Third Party Authentication (LTPA)**. If not, set it and save your changes.

Lightweight Third Party Authentication (LTPA) is the default authentication mechanism for WebSphere Application Server. You can configure LTPA prior to configuring single sign-on (SSO) by clicking **Security > Secure administration, applications, and infrastructure > Authentication mechanisms and expiration**.

1. From the administrative console for WebSphere Application Server, click **Security > Secure administration, applications, and infrastructure**.
2. Under Web security, click **Trust association**.
3. Select the **Enable trust association** option.
4. Under Additional properties, click the **Interceptors** link.
5. Click **com.ibm.ws.security.web.WebSealTrustAssociationInterceptor** to use the WebSEAL interceptor. This interceptor is the default.
6. Under Additional properties, click **Custom Properties**.
7. Click **New** to enter the property name and value pairs. Ensure the following parameters are set:

Table 9. Trust association interceptor properties

Option	Description
com.ibm.websphere.security.trustassociation.types	Ensure that <i>webseal</i> is listed.

Table 9. Trust association interceptor properties (continued)

Option	Description
com.ibm.websphere.security.webseal.loginId	The WebSEAL trusted user as created in “Creating a trusted user account in Tivoli Access Manager” on page 271 The format of the username is the short name representation. This property is mandatory. If the property is not set in the WebSphere Application Server, TAI initialization fails.
com.ibm.websphere.security.webseal.id	The <i>iv-user</i> header, which is com.ibm.websphere.security.webseal.id=iv-user
com.ibm.websphere.security.webseal.hostnames	Do not set this property if using Tivoli Access Manager plug-in for Web servers. The host names (case sensitive) are trusted and expected in the request header. For example: com.ibm.websphere.security.webseal.hostnames=host1 This includes the proxy host names unless the com.ibm.websphere.security.webseal.ignoreProxy is set to <i>true</i> . Obtain a list of servers using the server list pdadmin command.
com.ibm.websphere.security.webseal.ports	Do not set this property if using Tivoli Access Manager Plug-in for Web Servers. The corresponding port number of the host names that are expected are in the request header. This includes the proxy ports unless the com.ibm.websphere.security.webseal.ignoreProxy is set to <i>true</i> . For example: com.ibm.websphere.security.webseal.ports=80,443
com.ibm.websphere.security.webseal.ignoreProxy	An optional property that if set to <i>true</i> or <i>yes</i> ignores the proxy host names and ports in the IV header. By default this property is set to <i>false</i> .

8. Click **OK**.
9. Save the configuration and log out.
10. Restart WebSphere Application Server.

Configuring single sign-on using trust association interceptor ++

Perform this task to enable single sign-on using trust association interceptor ++. The steps involve setting up trust association and creating the interceptor properties.

Although you can use Simple WebSphere Authentication Mechanism (SWAM) by selecting the **Use SWAM-no authenticated communication between servers** option on the Authentication mechanisms and expiration panel, single sign-on (SSO) requires LTPA as the configured authentication mechanism.

Lightweight Third Party Authentication (LTPA) is the default authentication mechanism for WebSphere Application Server. You can configure LTPA prior to configuring single sign-on (SSO) by clicking **Security > Secure administration, applications, and infrastructure > Authentication mechanisms and expiration**.

1. From the administrative console for WebSphere Application Server, click **Security > Secure administration, applications, and infrastructure**.
2. Under Web security, click **Trust association**.
3. Click **Enable Trust Association**.
4. Click **Interceptors**.
5. Click **com.ibm.ws.security.web.TAMTrustAssociationInterceptorPlus** to use the WebSEAL interceptor. This interceptor is the default.
6. Click **Custom Properties**.

7. Click **New** to enter the property name and value pairs. Verify that the following parameters are set:

Table 10. Custom properties

Option	Description
com.ibm.websphere.security.webseal.checkViaHeader	<p>You can configure TAI so that the via header can be ignored when validating trust for a request. Set this property to <i>false</i> if none of the hosts in the via header need to be trusted. When set to <i>false</i> you do not need to set the trusted host names and host ports properties. The only mandatory property to check when via header is <i>false</i> is com.ibm.websphere.security.webseal.loginId.</p> <p>The default value of the check via header property is <i>false</i>. When using Tivoli Access Manager plug-in for Web servers, set this property to <i>false</i>.</p> <p>Note: The via header is part of the standard HTTP header that records the server names the request that passed through.</p>
com.ibm.websphere.security.webseal.loginId	<p>The WebSEAL trusted user as created in “Creating a trusted user account in Tivoli Access Manager” on page 271 The format of the username is the short name representation. This property is mandatory. If it is not set in WebSphere Application Server, the TAI initialization fails.</p>
com.ibm.websphere.security.webseal.id	<p>A comma-separated list of headers that exists in the request. If all of the configured headers do not exist in the request, trust cannot be established. The default value for the ID property is <i>iv-creds</i>. Any other values set in WebSphere Application Server are added to the list along with <i>iv-creds</i>, separated by commas.</p>
com.ibm.websphere.security.webseal.hostnames	<p>Do not set this property if using Tivoli Access Manager Plug-in for Web Servers. The property specifies the host names (case sensitive) that are trusted and expected in the request header. Requests arriving from un-listed hosts might not be trusted. If the checkViaHeader property is not set or is set to false then the trusted host names property has no influence. If the checkViaHeader property is set to true, and the trusted host names property is not set, TAI initialization fails.</p>
com.ibm.websphere.security.webseal.ports	<p>Do not set this property if using Tivoli Access Manager plug-in for Web servers. This property is a comma-separated list of trusted host ports. Requests that arrive from unlisted ports might not be trusted. If the checkViaHeader property is not set, or is set to false this property has no influence. If the checkViaHeader property is set to true, and the trusted host ports property is not set in WebSphere Application Server, the TAI initialization fails.</p>
com.ibm.websphere.security.webseal.viaDepth	<p>A positive integer that specifies the number of source hosts in the via header to check for trust. By default, every host in the via header is checked, and if any host is not trusted, trust cannot be established. The via depth property is used when only some of the hosts in the via header have to be trusted. The setting indicates the number of hosts that are required to be trusted.</p> <p>As an example, consider the following header: Via: HTTP/1.1 webseal1:7002, 1.1 webseal2:7001</p> <p>If the viaDepth property is not set, is set to 2 or is set to 0, and a request with the previous via header is received then both webseal1:7002 and webseal2:7001 need to be trusted. The following configuration applies: com.ibm.websphere.security.webseal.hostnames = webseal1,webseal2 com.ibm.websphere.security.webseal.ports = 7002,7001</p> <p>If the via depth property is set to 1, and the previous request is received, then only the last host in the via header needs to be trusted. The following configuration applies: com.ibm.websphere.security.webseal.hostnames = webseal2 com.ibm.websphere.security.webseal.ports = 7001</p> <p>The viaDepth property is set to 0 by default, which means all of the hosts in the via header are checked for trust.</p>

Table 10. Custom properties (continued)

Option	Description
com.ibm.websphere.security.webseal.ssoPwdExpiry	After trust is established for a request, the single sign-on user password is cached, eliminating the need to have the TAI re-authenticate the single sign-on user with Tivoli Access Manager for every request. You can modify the cache timeout period by setting the single sign-on password expiry property to the required time in seconds. If the password expiry property is set to 0, the cached password never expires. The default value for the password expiry property is 600.
com.ibm.websphere.security.webseal.ignoreProxy	This property can be used to tell the TAI to ignore proxies as trusted hosts. If set to true the comments field of the hosts entry in the via header is checked to determine if a host is a proxy. Remember that not all proxies insert comments in the via header indicating that they are proxies. The default value of the ignoreProxy property is false. If the checkViaHeader property is set to false then the ignoreProxy property has no influence in establishing trust.
com.ibm.websphere.security.webseal.configURL	Set this property to <code>\${USER_INSTALL_ROOT}/etc/pd/PolicyDirector/PDPerm.properties</code> . For the TAI to establish trust for a request, it requires that a <code>PDPerm.properties</code> file exists in each node within the cell. Also, the correct URL of the properties file must be set in the config URL property. If this property is not set or the <code>PDPerm.properties</code> file is not in the specified location, the TAI initialization fails. The <code>PDPerm.properties</code> file is part of the Tivoli Access Manager configuration for a node. To create the Tivoli Access Manager configuration, run the <code>pdjrtcfg</code> script and then the <code>svrsslcfg</code> script for each node in the cell. The <code>PDPerm.properties</code> file is created in the <code>\${USER_INSTALL_ROOT}/etc/pd/PolicyDirector/</code> directory.

8. Click **OK**.
9. Save the configuration and log out.
10. Restart WebSphere Application Server.

Configuring global sign-on principal mapping

You can create a new application login that uses the Tivoli Access Manager GSO database to store the login credentials.

1. Click **Security > Secure administration, applications, and infrastructure**.
2. Under Authentication, click **Java Authentication and Authorization Service > Application logins**.
3. Click **New** to create a new Java Authentication and Authorization Service (JAAS) login configuration.
4. Enter the alias name of the new application login. Click **Apply**.
5. Under Additional properties, click **JAAS login modules** to define the JAAS Login Modules.
6. Click **New** and enter the following information:

Module class name: com.tivoli.pdwas.gso.AMPrincipalMapper
Use Login Module Proxy: enable
Authentication strategy: REQUIRED

7. Click **Apply**
8. Under Additional Properties section, click **Custom Properties** to define login module-specific values that are passed directly to the underlying login modules.
9. Click **New**.

The Tivoli Access Manager principal mapping module uses the `authDataAlias` configuration string to retrieve the correct user name and password from the security configuration.

The `authDataAlias` attribute that is passed to the module is configured for the J2C connection factory. Because the `authDataAlias` attribute is an arbitrary string that is entered at configuration time, the following scenarios are possible:

- The authDataAlias attribute contains both the global sign-on (GSO) resource name and the user name. The format of this string is "Resource/User".
- The authDataAlias attribute contains the GSO Resource name only. The user name is determined by using the Subject of the current session.

The scenario to use is determined by a JAAS configuration option, as shown here:

Name: com.tivoli.pd.as.gso.AliasContainsUserName

Value: True, if the alias contains the user name; false, if the user name must be retrieved from the security context

When entering authDataAlias attributes through the WebSphere Application Server administrative console, the node name is automatically pre-pended to the alias. The JAAS configuration entry determines whether this node name is removed or included as part of the resource name, as shown here:

Name: com.tivoli.pd.as.gso.AliasContainsNodeName

Value: True, if the alias contains the node name

Note: If the PdPerm.properties configuration file is not located in the JAVA_HOME/PdPerm.properties default location, then you also need to add the following property:

Name: com.tivoli.pd.as.gso.AMCfgURL

Value: file:///path to PdPerm.properties

Enter each new parameter using the following scenario information as a guide, then click **Apply**.

Scenario 1

Auth Data Alias - BackendEIS/eisUser

Resource - BackEndEIS

User - eisUser

Principal Mapping Parameters

Name	Value
delegate	com.tivoli.pdwas.gso.AMPrincipalMapper
com.tivoli.pd.as.gso.AliasContainsUserName	true
com.tivoli.pd.as.gso.AliasContainsNodeName	false
com.tivoli.pd.as.gso.AMLoggingURL	file:///jlog_props_path
debug	false

Scenario 2

Auth Data Alias - BackendEIS

Resource - BackEndEIS

User - Currently authenticated WebSphere Application Server user

Principal Mapping Parameters

Name	Value
delegate	com.tivoli.pdwas.gso.AMPrincipalMapper
com.tivoli.pd.as.gso.AliasContainsUserName	false
com.tivoli.pd.as.gso.AliasContainsNodeName	false
com.tivoli.pd.as.gso.AMLoggingURL	file:///jlog_props_path
debug	false

Scenario 3

Auth Data Alias - nodename/BackendEIS/eisUser

Resource - BackEndEIS

User - eisUser

Principal Mapping Parameters

Name	Value
delegate	com.tivoli.pdwas.gso.AMPrincipalMapper
com.tivoli.pd.as.gso.AliasContainsUserName	true
com.tivoli.pd.as.gso.AliasContainsNodeName	true
com.tivoli.pd.as.gso.AMLoggingURL	file:///jlog_props_path
debug	false

Scenario 4

Auth Data Alias - nodename/BackendEIS/eisUser

Resource - nodename/BackEndEIS (notice that node name is not removed)

User - eisUser

Principal Mapping Parameters

Name	Value
delegate	com.tivoli.pdwas.gso.AMPrincipalMapper
com.tivoli.pd.as.gso.AliasContainsUserName	true
com.tivoli.pd.as.gso.AliasContainsNodeName	false
com.tivoli.pd.as.gso.AMLoggingURL	file:///jlog_props_path
debug	false

Scenario 5

Auth Data Alias - BackendEIS/eisUser

Resource - BackEndEIS

User - eisUser

Principal Mapping Parameters

Name	Value
delegate	com.tivoli.pdwas.gso.AMPrincipalMapper
com.tivoli.pd.as.gso.AliasContainsUserName	false
com.tivoli.pd.as.gso.AliasContainsNodeName	true
com.tivoli.pd.as.gso.AMLoggingURL	file:///jlog_props_path
debug	false

Scenario 6

Auth Data Alias - nodename/BackendEIS/eisUser

Resource - nodename/BackendEIS/eisUser

(notice that the resource is the same as Auth Data Alias).

User - Currently authenticated WebSphere Application Server user

Principal Mapping Parameters

Name	Value
delegate	com.tivoli.pdwas.gso.AMPrincipalMapper
com.tivoli.pd.as.gso.AliasContainsUserName	false
com.tivoli.pd.as.gso.AliasContainsNodeName	false

com.tivoli.pd.as.gso.AMLoggingURL	file:///jlog_props_path
debug	false

10. Create the Java 2 Connector (J2C) authentication aliases. The user name and password that are assigned to these alias entries are irrelevant because Tivoli Access Manager is responsible for providing user names and passwords. However, the user name and password that are assigned to the J2C authentication aliases need to exist so that they can be selected for the J2C connection factory in the administrative console.

To create the J2C authentication aliases, from the WebSphere Application Server administrative console, click **Security > Secure administration, applications, and infrastructure**. Under Authentication, click **Java Authentication and Authorization Service > J2C authentication data**, and then click **New** for each new entry. Refer to the previous table for scenario inputs.

The connection factories for each resource adapter that need to use the GSO database must be configured to use the Tivoli Access Manager Principal mapping module:

- a. From the WebSphere Application Server administrative console, click **Applications > Enterprise Applications > application_name > Resourcer references**. Note that J2C connection factories must be already configured for the selected application. To configure a new J2C connection factory, see tdat_confconfac.dita.
- b. Under Additional properties, click **Resource Adapter**.
The resource adapter can be standalone and does not need to be packaged with the application. The resource adapter is configured from **Resources > Resource Adapters** for standalone scenarios.
- c. Under Additional properties, click **J2C Connection Factories**.
- d. Click **New** and enter the connection factory properties.
- e. When finished, click **Apply > Save**.

Attention:

Custom mapping configuration for the connection factory is deprecated in WebSphere Application Server Version 6. To configure the GSO credential mapping, use the Map Resource References to Resources panel on the administrative console. For more information, see J2EE connector security.

Propagating security attributes among application servers

Use the security attribute propagation feature of WebSphere Application Server to send security attribute information regarding the original login to other servers using a token. This topic will help to configure WebSphere Application Server to propagate security attributes to other servers.

To fully enable security attribute propagation, you must configure the single sign-on (SSO), Common Secure Interoperability Version 2 (CSIv2) inbound, and CSIv2 outbound panels in the WebSphere Application Server administrative console. You can enable just the portions of security attribute propagation relevant to your configuration. For example, you can enable Web propagation, which is propagation amongst front-end application servers, using either the push technique (DynaCache) or the pull technique (remote method to originating server).

You also can choose whether to enable Remote Method Invocation (RMI) outbound and inbound propagation, which is commonly called downstream propagation. Typically both types of propagation are enabled for any given cell. In some cases, you might want to choose a different option for a specific application server using the server security panel within the specific application server settings.

To access the server security panel in the administrative console, click **Servers > Application Servers > server_name**. Under Security, click **Server security**.

Complete the following steps to configure WebSphere Application Server for security attribute propagation:

1. Access the WebSphere Application Server administrative console by typing `http://server_name:port_number/ibm/console`. The administrative console address might differ if you have previously changed the port number.
2. Click **Security > Secure administration, applications, and infrastructure**.
3. Under Web security, click **Single sign-on (SSO)**.
4. **Optional:** Select the **Interoperability Mode** option if you need to interoperate with servers that do not support security attribute propagation. Servers that do not support security attribute propagation receive the Lightweight Third Party Authentication (LTPA) token and the Propagation token, but ignore the security attribute information that they do not understand.
5. Select the **Web inbound security attribute propagation** option. The Web inbound security attribute propagation option enables horizontal propagation, which allows the receiving SSO token to retrieve the login information from the original login server. If you do not enable this option, downstream propagation can occur if you enable the Security Attribute Propagation option on both the CSiv2 Inbound authentication and CSiv2 outbound authentication panels.

Typically, you enable the Web inbound security attribute propagation option if you need to gather dynamic security attributes set at the original login server that cannot be regenerated at the new front-end server. These attributes include any custom attributes that might be set in the PropagationToken token using the `com.ibm.websphere.security.WSSecurityHelper` application programming interfaces (APIs). You must determine whether enabling this option improves or degrades the performance of your system. While the option prevents some remote user registry calls, the deserialization and decryption of some tokens might impact performance. In some cases propagation is faster, especially if your user registry is the bottleneck of your topology. It is recommended that you measure the performance of your environment both using and not using this option. When you test the performance, it is recommended that you test in the operating environment of the typical production environment with the typical number of unique users accessing the system simultaneously.

6. Click **Security > Secure administration, applications, and infrastructure**. Under RMI/IOP security, click **CSiv2 inbound authentication**. The Login configuration field specifies `RMI_INBOUND` as the system login configuration that is used for inbound requests. To add custom Java Authentication and Authorization Service (JAAS) login modules, complete the following steps:
 - a. Click **Security > Secure administration, applications, and infrastructure**. Under Java Authentication and Authorization Service, click **System logins**. A list of the system login configurations is displayed. WebSphere Application Server provides the following pre-configured system login configurations: `DEFAULT`, `LTPA`, `LTPA_WEB`, `RMI_INBOUND`, `RMI_OUTBOUND`, `SWAM`, `WEB_INBOUND`, `wssecurity.IDAssertion`, and `wssecurity.Signature`. Do not delete these predefined configurations.

Note: SWAM is deprecated in WebSphere Application Server Version 6.1 and will be removed in a future release.

- b. Click the name of the login configuration that you want to modify.
 - c. Under Additional Properties, click **JAAS Login Modules**. The JAAS Login Modules panel is displayed, which lists all of the login modules that are processed in the login configuration. Do not delete the required JAAS login modules. Instead, you can add custom login modules before or after the required login modules. If you add custom login modules, do not begin their names with `com.ibm.ws.security.server`.
You can specify the order in which the login modules are processed by clicking **Set Order**.
7. Select the **Security attribute propagation** option on the CSiv2 inbound authentication panel. When you select **Security Attribute Propagation**, the server advertises to other application servers that it can receive propagated security attributes from another server in the same realm over the Common Secure Interoperability version 2 (CSiv2) protocol.
8. Click **Security > Secure administration, applications, and infrastructure**. Under RMI/IOP security, click **CSiv2 Outbound authentication**. The CSiv2 outbound authentication panel is displayed. The **Login configuration** field specifies `RMI_OUTBOUND` as the JAAS login configuration that is used for

outbound configuration. You cannot change this login configuration. Instead, you can customize this login configuration by completing the substeps that are listed previously for CSiv2 Inbound authentication.

9. **Optional:** Verify that the **Security Attribute Propagation** option is selected if you want to enable outbound Subject and security context token propagation for the Remote Method Invocation (RMI) protocol. When you select this option, WebSphere Application Server serializes the Subject contents and the PropagationToken contents. After the contents are serialized, the server uses the CSiv2 protocol to send the Subject and PropagationToken token to the target servers that support security attribute propagation. If the receiving server does not support security attribute tokens, WebSphere Application Server sends the Lightweight Third Party Authentication (LTPA) token only.

Important: WebSphere Application Server propagates only the objects within the Subject that it can serialize. The server propagates custom objects on a best-effort basis.

When **Security Attribute Propagation** is enabled, WebSphere Application Server adds marker tokens to the Subject to enable the target server to add additional attributes during the inbound login. During the commit phase of the login, the marker tokens and the Subject are marked as read-only and cannot be modified thereafter.

10. **Optional:** Select the **Custom Outbound Mapping** option if you clear the **Security Attribute Propagation** option and you want to use the RMI_OUTBOUND login configuration. If neither the **Custom Outbound Mapping** option nor the **Security Attribute Propagation** option is selected, WebSphere Application Server does not call the RMI_OUTBOUND login configuration. If you need to plug in a credential mapping login module, you must select the **Custom Outbound Mapping** option.
11. **Optional:** Specify trusted target realm names in the **Trusted Target Realms** field. By specifying these realm names, information can be sent to servers that reside outside the realm of the sending server to support inbound mapping that is at these downstream servers. To perform outbound mapping to a realm different from the current realm, you must specify the realm in this field so that you can get to this point without having the request rejected because of a realm mismatch. If you need WebSphere Application Server to propagate security attributes to another realm when a request is sent, you must specify the realm name in the **Trusted Target Realms** field. Otherwise, the security attributes are not propagated to the unspecified realm. You can add multiple target realms by adding a pipe (|) delimiter between each entry.
12. **Optional:** Enable propagation for a pure client. For a pure client to propagate attributes added to the invocation Subject, you must add the following property to the `com.ibm.CSI.rmiOutboundPropagationEnabled=true` file:

Note: The `com.ibm.CSI.rmiOutboundPropagationEnabled=true` file is located at `<WAS-HOME>/profiles/<ProfileName>/properties`.

After completing these steps, you have configured WebSphere Application Server to propagate security attributes to other servers.

If you need to disable security attribute propagation, determine whether you need to disable it for either the server level or the cell level.

Attention: Changes to the server-level settings override the cell settings.

To disable security attribute propagation on the server level, complete the following steps:

1. Click **Server > Application Servers > server_name**.
2. Under Security, click **Server security**.
3. Select the **RMI/IIOP security for this server overrides cell settings** option.
4. Disable security attribute propagation for inbound requests by clicking **CSI inbound authentication** under Additional Properties and clearing the **Security attribute propagation** option.
5. Disable security attribute propagation for outbound requests by clicking **CSI outbound authentication** under Additional Properties and clearing the **Security attribute propagation** option.

To disable security attribute propagation on the cell level, undo each of the steps that you completed to enable security attribute propagation in this task.

Configuring the authentication cache

The security authentication cache affects the frequency of rehashing and the distribution of the hash algorithms.

To configure the authentication cache properties, complete the following steps:

1. Click **Servers > Application Servers > *server_name***.
2. Under Server infrastructure, click **Java and Process Management > Process definition**.
3. Under Additional properties, click **Java Virtual Machine > Custom Properties**.
4. Click **New** to specify a new custom property.

For information on the supported authentication cache properties, see “Security cache properties.”

Security cache properties

The following Java virtual machine (JVM) security cache custom properties determine whether the authentication cache is enabled or disabled. If the authentication cache is enabled, as recommended, these custom properties specify the initial size of the primary and secondary hash table caches, which affect the frequency of rehashing and the distribution of the hash algorithms.

Important: The `com.ibm.websphere.security.util.tokenCacheSize` and `com.ibm.websphere.security.util.LTPAValidationCacheSize` properties were replaced with the `com.ibm.websphere.security.util.authCacheSize` property.

You can specify these system properties by completing the following steps:

1. Click **Servers > Application servers > *server_name***.
2. Click **Java and Process Management > Process Definition**.
3. Under Additional properties, click **Java Virtual Machine**.
4. Specify the property name and its value in the Generic JVM arguments field. You can specify multiple property name and value pairs delimited by a space.

WebSphere Application Server includes the following security cache custom properties:

`com.ibm.websphere.security.util.authCacheEnabled`

Specifies whether to disable the authentication cache. It is recommended that you leave the authentication cache enabled for performance reasons. However, you can disable the authentication cache for debug or measurement purposes.

Default:	True
----------	------

`com.ibm.websphere.security.util.authCacheSize`

Specifies the initial size of the primary and secondary hash table caches. A higher number of available hash values might decrease the occurrence of hash collisions. A hash collision results in a linear search for the hash bucket, which might decrease the retrieval time. If several entries compose a hash table cache, you create a table with a larger capacity that supports more efficient hash entries instead of allowing automatic rehashing determine the growth of the table. Rehashing causes every entry to move each time.

Default:	200
Type:	Integer

Configuring IOP authentication

WebSphere Application Server enables you to specify Internet Inter-ORB Protocol (IOP) authentication for both inbound and outbound authentication requests. For inbound requests, you can specify the type of accepted authentication, such as basic authentication. For outbound requests, you can specify properties such as type of authentication, identity assertion or login configurations that are used for requests to downstream servers.

The following topics are covered in this section:

- Configuring Common Secure Interoperability Version 2 inbound authentication
- Configuring Common Secure Interoperability Version 2 outbound authentication

Configuring Common Secure Interoperability Version 2 inbound authentication

Inbound authentication refers to the configuration that determines the type of accepted authentication for inbound requests. This authentication is advertised in the interoperable object reference (IOR) that the client retrieves from the name server.

1. Start the administrative console.
2. Click **Security > Secure administration, applications, and infrastructure**.
3. Under RMI/IOP security, click **CSIv2 inbound authentication**.
4. Consider the following layers of security:
 - Identity assertion (attribute layer).

When selected, this server accepts identity tokens from upstream servers. If the server receives an identity token, the identity is taken from an originating client. For example, the identity is in the same form that the originating client presented to the first server. An upstream server sends the identity of the originating client. The format of the identity can be either a principal name, a distinguished name, or a certificate chain. In some cases, the identity is anonymous. It is important to trust the upstream server that sends the identity token because the identity authenticates on this server. Trust of the upstream server is established either using Secure Sockets Layer (SSL) client certificate authentication or basic authentication. You must select one of the two layers of authentication in both inbound and outbound authentication when you choose identity assertion.

The server ID is sent in the client authentication token with the identity token. The server ID is checked against the trusted server ID list. If the server ID is on the trusted server list, the server ID is authenticated. If the server ID is valid, the identity token is put into a credential and used for authorization of the request.

For more information, refer to Identity assertion.

- User ID and password (message layer).

This type of authentication is the most typical. The user ID and password or authenticated token is sent from a pure client or from an upstream server. However, the upstream server cannot be a z/OS server because z/OS does not support a user ID or password from a server acting as a client. When a user ID and password are received at the server, they are authenticated with the user registry.

Usually, a token is sent from an upstream server and a user ID and password are sent from a client, including a servlet. When a token is received at the server level, the token is validated to determine whether tampering has occurred or whether it is expired.

For more information, refer to User ID and password.

- Secure Sockets Layer client certificate authentication (transport layer).

The SSL client certificate is used to authenticate instead of using user ID and Password. If a server delegates an identity to a downstream server, the identity comes from either the message layer (a client authentication token) or the attribute layer (an identity token), and not from the transport layer through the client certificate authentication.

A client has an SSL client certificate that is stored in the keystore file of the client configuration. When SSL client authentication is enabled on this server, the server requests that the client send

the SSL client certificate when the connection is established. The certificate chain is available on the socket whenever a request is sent to the server. The server request interceptor gets the certificate chain from the socket and maps this certificate chain to a user in the user registry. This type of authentication is optimal for communicating directly from a client to a server. However, when you have to go downstream, the identity typically flows over the message layer or through identity assertion.

5. Consider the following points when deciding what type of authentication to accept:
 - A server can receive multiple layers simultaneously, so an order of precedence rule decides which identity to use. The identity assertion layer has the highest priority, the message layer follows, and the transport layer has the lowest priority. The SSL client certificate authentication is used when it is the only layer provided. If the message layer and the transport layer are provided, the message layer is used to establish the identity for authorization. The identity assertion layer is used to establish precedence when provided.
 - Does this server usually receive requests from a client, from a server, or both? If the server always receives requests from a client, identity assertion is not needed. You can choose either the message layer, the transport layer, or both. You also can decide when authentication is required or just supported. To select a layer as required, the sending client must supply this layer, or the request is rejected. However, if the layer is only supported, the layer might not be supplied.
 - What kind of client identity is supplied? If the client identity is client certificates authentication and you want the certificate chain to flow downstream so that it maps to the downstream server user registries, identity assertion is the appropriate choice. Identity assertion preserves the format of the originating client. If the originating client authenticated with a user ID and password, a principal identity is sent. If authentication is done with a certificate, the certificate chain is sent.
In some cases, if the client authenticated with a token and a Lightweight Directory Access Protocol (LDAP) server is the user registry, then a distinguished name (DN) is sent.
6. Configure a trusted server list. When identity assertion is selected for inbound requests, insert a pipe-separated (|) list of server administrator IDs to which this server can support identity token submission. For backwards compatibility, you can still use a comma-delimited list. However, if the server ID is a distinguished name (DN), then you must use a pipe-delimited (|) list because a comma delimiter does not work. If you choose to support any server sending an identity token, you can enter an asterisk (*) in this field. This action is called *presumed trust*. In this case, use SSL client certificate authentication between servers to establish the trust.
7. Configure session management. You can choose either *stateful* or *stateless* security. Performance is optimum when choosing stateful sessions. The first method request between a client and server is authenticated. All subsequent requests (or until the credential token expires) reuse the session information, including the credential. A client sends a context ID for subsequent requests. The context ID is scoped to the connection for uniqueness.

When you finish configuring this panel, you have configured most of the information that a client gathers when determining what to send to this server. A client or server outbound configuration with this server inbound configuration, determines the security that is applied. When you know what clients send, the configuration is simple. However, if you have a diverse set of clients with differing security requirements, your server considers various layers of authentication.

For a J2EE application server, the authentication choice is usually either identity assertion or message layer because you want the identity of the originating client delegated downstream. You cannot easily delegate a client certificate using an SSL connection. It is acceptable to enable the transport layer because additional server security, as the additional client certificate portion of the SSL handshake, adds some overhead to the overall SSL connection establishment.

After you determine which type of authentication data this server might receive, you can determine what to select for outbound security. For more information, see *Configuring Common Secure Interoperability Version 2* outbound authentication.

Common Secure Interoperability inbound authentication settings

Use this page to specify the features that a server supports for a client accessing its resources.

To view this administrative console page, complete the following steps:

1. Click **Security > Secure administration, applications, and infrastructure**.
2. Under Authentication, click **RMI/IIOP security > CSiv2 inbound authentication**.

You can also view this administrative console page on the server page by completing the following steps:

1. Click **Servers > Application servers > server_name**.
2. Under Security, click **Server security**.
3. Under Additional properties, click **CSiv2 inbound authentication**.

Use common secure interoperability (CSI) inbound authentication settings for configuring the type of authentication information that is contained in an incoming request or transport.

Authentication features include three layers of authentication that you can use simultaneously:

- **Transport layer**. The transport layer, which is the lowest layer, might contain a Secure Sockets Layer (SSL) client certificate as the identity.
- **Message layer**. The message layer might contain a user ID and password or an authenticated token with an expiration.
- **Attribute layer**. The attribute layer might contain an identity token, which is an identity from an upstream server that already is authenticated. The identity layer has the highest priority, followed by the message layer, and then the transport layer. If a client sends all three, only the identity layer is used. The only way to use the SSL client certificate as the identity is if it is the only information that is presented during the request. The client picks up the interoperable object reference (IOR) from the namespace and reads the values from the tagged component to determine what the server needs for security.

Basic authentication:

Specifies that basic authentication occurs over the message layer.

Basic authentication occurs in the message layer. This type of authentication typically involves sending a user ID and a password from the client to the server for authentication.

This authentication also involves delegating a credential token from an already authenticated credential, provided the credential type is forwardable, for example, Lightweight Third Party Authentication (LTPA).

If you click **Basic Authentication** and LTPA is the configured authentication protocol, user name, password, and LTPA tokens are accepted.

The following options are available for Basic Authentication:

Never This option indicates that this server cannot accept user ID and password authentication.

Supported

This option indicates that a client communicating with this server can specify a user ID and password. However, a method might be invoked without this type of authentication. For example, an anonymous or client certificate might be used instead.

Required

This option indicates that clients communicating with this server must specify a user ID and password for any method request.

Basic authentication takes precedence over client certificate authentication, if both are performed.

Client certificate authentication:

Specifies that authentication occurs when the initial connection is made between the client and the server during a method request.

In the transport layer, Secure Sockets Layer (SSL) client certificate authentication occurs. In the message layer, basic authentication (user ID and password) is performed. Client certificate authentication typically performs better than message layer authentication, but requires some additional setup. These additional steps involve verifying that the server trusts the signer certificate of each client to which it is connected. If the client uses a certificate authority (CA) to create its personal certificate, you only need the CA root certificate in the server signer section of the SSL trust file.

When the certificate is authenticated to a Lightweight Directory Access Protocol (LDAP) user registry, the distinguished name (DN) is mapped based on the filter that is specified when configuring LDAP. When the certificate is authenticated to a local OS user registry, the first attribute of the distinguished name (DN) in the certificate, which is typically the common name, is mapped to the user ID in the registry.

The identity from client certificates is used only if no other layer of authentication is presented to the server.

Never This option indicates that clients cannot attempt Secure Sockets Layer (SSL) client certificate authentication with this server.

Supported

This option indicates that clients connecting to this server can authenticate using SSL client certificates. However, the server can invoke a method without this type of authentication. For example, anonymous or basic authentication can be used instead.

Required

This option indicates that clients connecting to this server must authenticate using SSL client certificates before invoking the method.

Trusted identities:

Use this list to decide whether a server is trusted. Even if the server is on the list, the sending server must still authenticate with the receiving server to accept the identity token of the sending server.

Data type String

Stateful sessions:

Select this option to enable stateful sessions, which are used mostly for performance improvements.

The first contact between a client and server must fully authenticate. However, all subsequent contacts with valid sessions reuse the security information. The client passes a context ID to the server, and the ID is used to look up the session. The context ID is scoped to the connection, which guarantees uniqueness. Whenever the security session is not valid and the authentication retry is enabled, which is the default, the client-side security interceptor invalidates the client-side session and submits the request again without user awareness. This situation might occur if the session does not exist on the server (the server failed and resumed operation). When this value is disabled, every method invocation must authenticate again.

Data type String

Login configuration:

Specifies the type of system login configuration to use for inbound authentication.

You can add custom login modules by clicking **Security > Secure administration, applications, and infrastructure**. Under Authentication, click **Java Authentication and Authorization Service > System logins**.

Security attribute propagation:

Select this option to support security attribute propagation during login requests. When you select this option, the application server retains additional information about the login request, such as the authentication strength used, and retains the identity and location of the request originator.

Verify that you are using Lightweight Third Party Authentication (LTPA) as your authentication mechanism. LTPA is the only authentication mechanism supported when you enable the security attribute propagation feature.

To configure LTPA, click **Security > Secure administration, applications, and infrastructure**. Under Authentication, click **Authentication mechanisms and expiration**.

If you do not select this option, the application server does not accept any additional login information to propagate to downstream servers.

Configuring Common Secure Interoperability Version 2 outbound authentication

The following choices are available when configuring the Common Secure Interoperability Version 2 (CSlv2) Outbound Authentication panel.

Outbound authentication refers to the configuration that determines the type of authentication that is performed for outbound requests to downstream servers. Several *layers* or *methods* of authentication can occur. The downstream server inbound authentication configuration must support at least one choice made in this server outbound authentication configuration. If nothing is supported, the request might go outbound as unauthenticated. This situation does not create a security problem because the authorization runtime is responsible for preventing access to protected resources. However, if you choose to prevent an unauthenticated credential from going outbound, you might want to designate one of the authentication layers as required, rather than supported. If a downstream server does not support authentication, then when authentication is required, the method request fails to go outbound.

The following choices are available in the Common Secure Interoperability Version 2 (CSlv2) Outbound Authentication panel. Remember that you are not required to complete these steps in the displayed order. Rather, these steps are provided to help you understand your choices for configuring outbound authentication.

- Select **Identity Assertion** (attribute layer). When selected, this server sends an identity token to a downstream server if the downstream server supports identity assertion. When an originating client authenticates to this server, the authentication information supplied is preserved in the outbound identity token. If the client authenticating to this server uses client certificate authentication, then the identity token format is a certificate chain, containing the exact client certificate chain from the inbound socket. The same scenario is true for other mechanisms of authentication. Read the Identity Assertion topic for more information.
- Select **User ID** and **Password** (message layer). This type of authentication is the most typical. The user ID and password (if BasicAuth credential) or authenticated token (if authenticated credential) are sent outbound to the downstream server if the downstream server supports message layer authentication in the inbound authentication panel. Refer to the Message Layer Authentication article for more information.
- Select **SSL Client certificate authentication** (transport layer). The main reason to enable outbound Secure Sockets Layer (SSL) client authentication from one server to a downstream server is to create a trusted environment between those servers. For delegating client credentials, use one of the two layers

mentioned previously. However, you might want to create SSL personal certificates for all the servers in your domain, and only trust those servers in your SSL truststore file. No other servers or clients can connect to the servers in your domain, except at the tiers where you want them. This process can protect your enterprise bean servers from access by anything other than your servlet servers.

Configuring session management

You can choose either *stateful* or *stateless* security. Performance is optimum when choosing stateful sessions. The first method request between this server and the downstream server is authenticated. All subsequent requests reuse the session information, including the credential. A *unique session entry* is defined as the combination of a unique client authentication token and an identity token, scoped to the connection.

Typically, the outbound authentication configuration is for an upstream server to communicate with a downstream server. Most likely, the upstream server is a servlet server and the downstream server is an Enterprise JavaBeans (EJB) server. On a servlet server, the client authentication that is performed to access the servlet can be one of many different types of authentication, including client certificate and basic authentication. When receiving basic authentication data, whether through a prompt login or a form-based login, the basic authentication information is typically authenticated to from a credential of the mechanism type that is supported by the server, such as the Lightweight Third Party Authentication (LTPA). When LTPA is the mechanism, a forwardable token exists in the credential. Choose the message layer (BasicAuth) authentication to propagate the client credentials. If the credential is created using a certificate login and you want to preserve sending the certificate downstream, you might decide to go outbound with identity assertion.

Save the configuration and restart the server for the changes to take effect.

Common Secure Interoperability Version 2 outbound authentication settings

Use this page to specify the features that a server supports when acting as a client to another downstream server.

To view this administrative console page, complete the following steps:

1. Click **Security > Secure administration, applications, and infrastructure**.
2. Under Authentication, click **RMI/IIOP security > CSiv2 outbound authentication**.

You also can view this administrative console page by completing the following steps:

1. Click **Servers > Application Servers > server_name**.
2. Under Security, click **Server security**.
3. Click **CSiv2 outbound authentication**.

Authentication features include the following layers of authentication that you can use simultaneously:

Transport layer

The transport layer, the lowest layer, might contain a Secure Sockets Layer (SSL) client certificate as the identity.

Message layer

The message layer might contain a user ID and password or authenticated token.

Attribute layer

The attribute layer might contain an identity token, which is an identity from an upstream server that is already authenticated. The attribute layer has the highest priority, followed by the message layer and then the transport layer. If this server sends all three - the attribute layer, the message layer, and the transport layer - only the attribute layer is used by the downstream server. The only way to use the SSL client certificate as the identity is if it is the only information presented during the outbound request.

Client certificate authentication:

Specifies whether a client certificate from the configured keystore is used to authenticate to the server when the SSL connection is made between this server and a downstream server, provided that the downstream server supports client certificate authentication.

Typically, client certificate authentication has a higher performance than message layer authentication, but requires some additional setup. These additional steps include verifying that this server has a personal certificate and that the downstream server has the signer certificate of this server.

If you select client certificate authentication, the following options are available:

Never This option indicates that this server does not attempt Secure Sockets Layer (SSL) client certificate authentication with downstream servers.

Supported

This option indicates that this server can use SSL client certificates to authenticate to downstream servers. However, a method can be invoked without this type of authentication. For example, the server can use anonymous or basic authentication instead.

Required

This option indicates that this server must use SSL client certificates to authenticate to downstream servers.

Identity assertion:

Specifies whether to assert identities from one server to another during a downstream enterprise bean invocation.

The identity asserted is the invocation credential that is determined by the RunAs mode for the enterprise bean. If the RunAs mode is Client, the identity is the client identity. If the RunAs mode is System, the identity is the server identity. If the RunAs mode is Specified, the identity is the identity specified. The receiving server receives the identity in an identity token and also receives the sending server identity in a client authentication token. The receiving server validates the identity of the sending server to ensure a trusted identity.

When specifying identity assertion on the CSiv2 authentication outbound panel, you must also select basic authentication as supported or required on the CSiv2 authentication inbound panel. The server identity can then be submitted with the identity token, so that the receiving server can *trust* the sending server. Without specifying basic authentication as supported or required, trust is not established and the identity assertion fails.

Use server trusted identity

Specifies the server identity that the application server uses to establish trust with the target server. The server identity can be sent using one of the following methods:

- A server ID and password when the server password is specified in the registry configuration.
- A server ID in a Lightweight Third Party Authentication (LTPA) token when the internal server ID is used.

For interoperability with application servers other than WebSphere Application Server, use of the following methods:

- Configure the server ID and password in the registry.
- Select the **Specify an alternative trusted identity** option and specify the trusted identity and password so that an interoperable Generic Security Services Username Password (GSSUP) token is sent instead of an LTPA token.

Specify an alternative trusted identity

Specifies an alternative user as the trusted identity that is sent to the target servers instead of sending the server identity. This option is recommended for identity assertion. The identity is automatically trusted when it is sent within the same cell and does not need to be in the trusted

identities list within the same cell. However, this identity must be in the registry of the target servers in an external cell and the user ID must be on the trusted identities list or the identity is rejected during trust evaluation.

Trusted identity

Specifies the trusted identity that is sent from the sending server to the receiving server.

If you specify an identity in this field, it can be selected on the panel for your configured user account repository. If you do not specify an identity, a Lightweight Third Party Authentication (LTPA) token is sent between the servers.

Password

Specifies the password that is associated with the trusted identity.

Confirm password

Confirms the password that is associated with the trusted identity.

Stateful sessions:

Specifies whether to reuse security information during authentication. This option is usually used to increase performance.

The first contact between a client and server must fully authenticate. However, all subsequent contacts with valid sessions reuse the security information. The client passes a context ID to the server, and that ID is used to look up the session. The context ID is scoped to the connection, which guarantees uniqueness. When the security session is not valid and if authentication retry is enabled, which is the default, the client-side security interceptor invalidates the client-side session and resubmits the request transparently. For example, if the session does not exist on the server; the server fails and resumes operation.

When this value is disabled, every method invocation must authenticate again.

Login configuration:

Specifies the type of system login configuration that is used for outbound authentication.

You can add custom login modules before or after this login module by completing the following steps:

1. Click **Security > Secure administration, applications, and infrastructure**.
2. Under Authentication, click **Java Authentication and Authorization Service > System logins > New**.

Custom outbound mapping:

Enables the use of custom Remote Method Invocation (RMI) outbound login modules.

The custom login module maps or performs other functions before the predefined RMI outbound call.

To declare a custom outbound mapping, complete the following steps:

1. Click **Security > Secure administration, applications, and infrastructure**.
2. Under Authentication, click **Java Authentication and Authorization Service > System logins > New**.

Security attribute propagation:

Enables the application server to propagate the Subject and the security content token to other application servers using the Remote Method Invocation (RMI) protocol.

Verify that you are using Lightweight Third Party Authentication (LTPA) as your authentication mechanism. LTPA is the only authentication mechanism that is supported when you enable the security attribute propagation feature. To configure LTPA, complete the following steps:

1. Click **Security > Secure administration, applications, and infrastructure**.
2. Under Authentication, click **Authentication mechanisms and expiration**.

By default, the Security attribute propagation option is enabled and outbound login configuration is invoked. If you clear this option, the application server does not propagate any additional login information to downstream servers. If you select the **Use SWAM-no authenticated communication between servers** option on the Authentication mechanisms and expiration panel, the security attribute propagation feature is not supported.

Note: SWAM is deprecated in the application server Version 6.1 and will be removed in a future release.

Trusted target realms:

Specifies a list of trusted target realms, separated by a pipe character (|), that differ from the current realm.

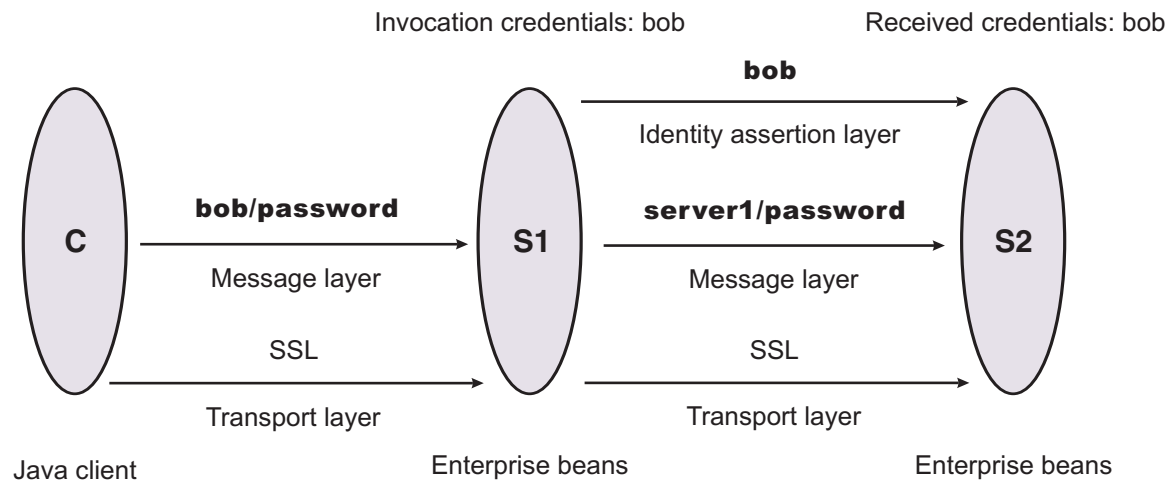

Prior to WebSphere Application Server, Version 5.1.1, if the current realm does not match the target realm, the authentication request is not sent outbound to other application servers.

Example: Common Secure Interoperability Version 2 scenarios

The articles included in this section provide specific scenarios demonstrating how to configure Common Secure Interoperability Version 2 (CSIv2).

Scenario 1: Basic authentication and identity assertion

This example presents a pure Java client, C, that accesses a secure enterprise bean on server, S1, through user bob. The following steps take you through the configuration of C, S1, and S2.

The enterprise bean code on S1 accesses another enterprise bean on server, S2. This configuration uses identity assertion to propagate the identity of bob to the downstream server, S2. S2 trusts that bob already is authenticated by S1 because it trusts S1. To gain this trust, the identity of S1 also flows to S2 simultaneously and S2 validates the identity by checking the trustedPrincipalList list to verify that it is a valid server principal. S2 also authenticates S1. The following steps take you through the configuration of C, S1, and S2.

Configuring client, C

Client C requires message layer authentication with a Secure Sockets Layer (SSL) transport. To accomplish this task:

1. Point the client to the `sas.client.props` file.
Use the `com.ibm.CORBA.ConfigURL=file:/profile_root /properties/sas.client.props` property. The `profile_root` variable is the specific profile that you are working with. All further configuration involves setting properties within this file.
2. Enable SSL.
In this case, SSL is supported but not required:
`com.ibm.CSI.performTransportAssocSSLTLSSupported=true,`
`com.ibm.CSI.performTransportAssocSSLTLSRequired=false`
3. Enable client authentication at the message layer.
In this case, client authentication is supported but not required:
`com.ibm.CSI.performClientAuthenticationRequired=false,`
`com.ibm.CSI.performClientAuthenticationSupported=true`
4. Use all of the remaining defaults in the `sas.client.props` file.

Configuring server, S1

In the administrative console, server S1 is configured for incoming requests to support message-layer client authentication and incoming connections to support SSL without client certificate authentication. Server S1 is configured for outgoing requests to support identity assertion.

1. Configure S1 for incoming connections.
 - a. Disable identity assertion.
 - b. Enable user ID and password authentication.
 - c. Enable SSL.
 - d. Disable SSL client certificate authentication.
2. Configure S1 for outgoing connections.
 - a. Enable identity assertion.
 - b. Disable user ID and password authentication.
 - c. Enable SSL.
 - d. Disable SSL client certificate authentication.

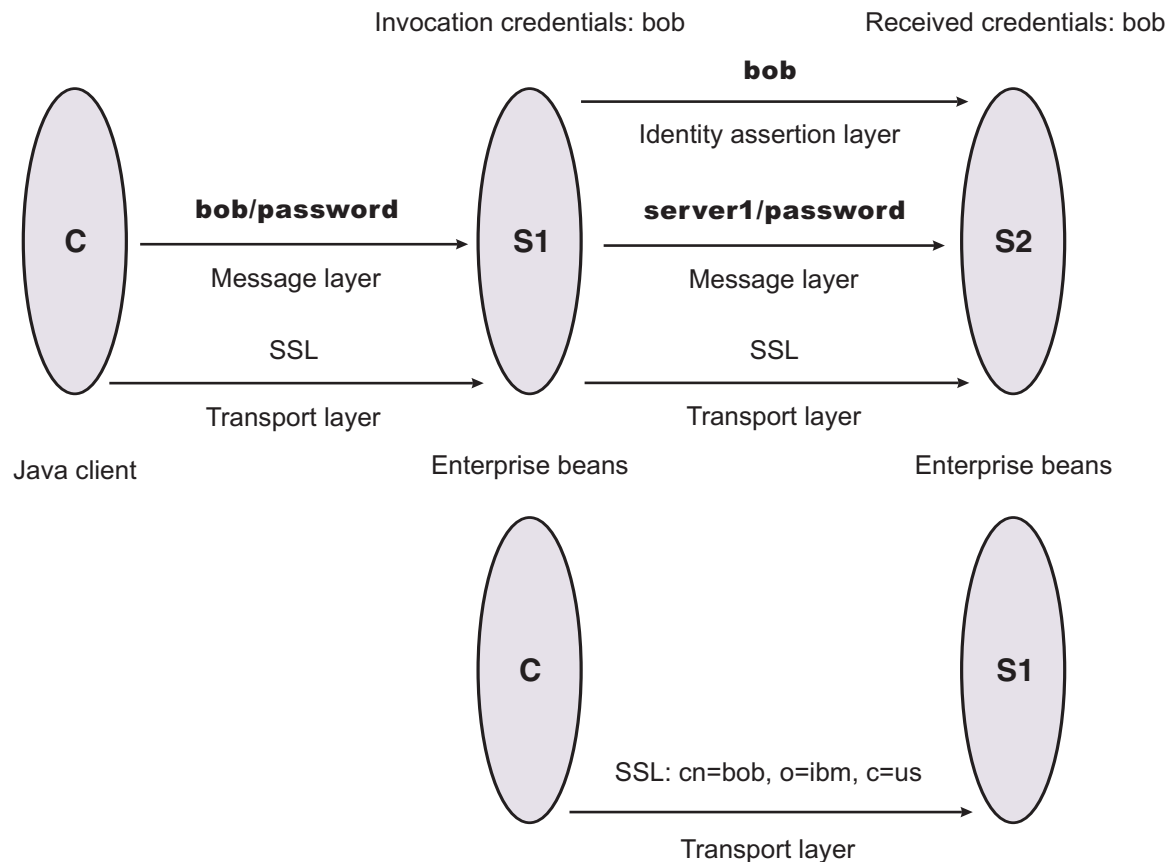

Configuring server, S2

In the administrative console, server S2 is configured for incoming requests to support identity assertion and to accept SSL connections. Complete the following steps to configure incoming connections. Configuration for outgoing requests and connections are not relevant for this scenario.

1. Enable identity assertion.
2. Disable user ID and password authentication.
3. Enable SSL.
4. Disable SSL client authentication.

Scenario 2: Basic authentication, identity assertion, and client certificates

This scenario is the same as Scenario 1, except for the interaction from client C2 to server S2. Therefore, the configuration of Scenario 1 still is valid, but you have to modify server S2 slightly and add a configuration for client C2. The configuration is not modified for C1 or S1.

Configuring client C2

Client C2 requires transport layer authentication (Secure Sockets Layer (SSL) client certificates). To configure transport layer authentication:

1. Point the client to the `sas.client.props` file.

Use the `com.ibm.CORBA.ConfigURL=file:/profile_root /properties/sas.client.props` property. The `profile_root` variable is the specific profile that you are working with. All further configuration involves setting properties within this file.

2. Enable SSL.

In this case, SSL is supported but not required:

```
com.ibm.CSI.performTransportAssocSSLTLSSupported=true,
com.ibm.CSI.performTransportAssocSSLTLSRequired=false
```

3. Disable client authentication at the message layer.

```
com.ibm.CSI.performClientAuthenticationRequired=false,
com.ibm.CSI.performClientAuthenticationSupported=false
```

4. Enable client authentication at the transport layer where it is supported, but not required:

```
com.ibm.CSI.performTLClientAuthenticationRequired=false,
com.ibm.CSI.performTLClientAuthenticationSupported=true
```

Configuring server, S2

In the administrative console, server S2 is configured for incoming requests to SSL client authentication and identity assertion. Configuration for outgoing requests is not relevant for this scenario.

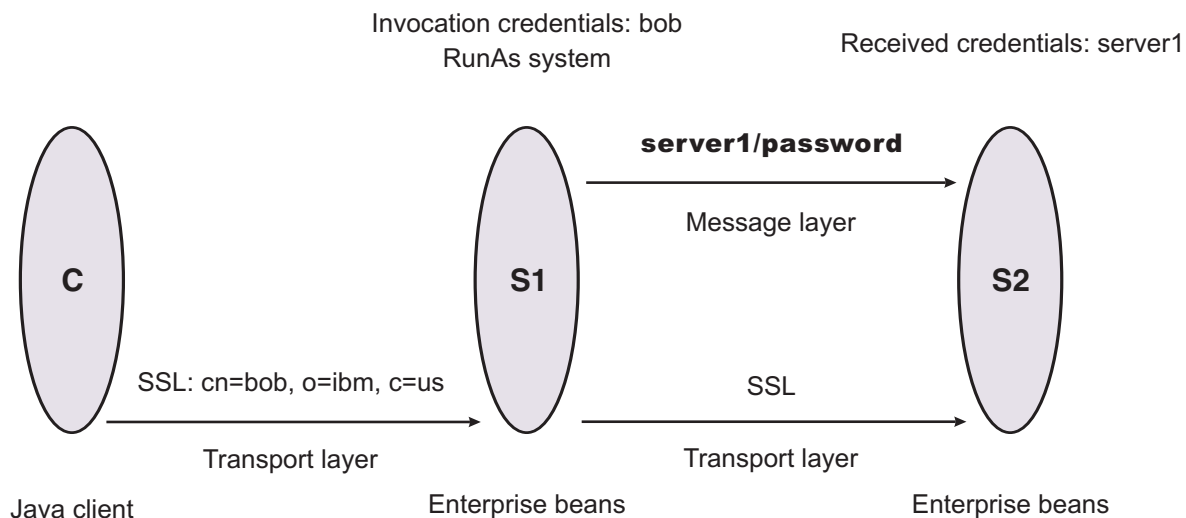

1. Enable identity assertion.
2. Disable user ID and password authentication.
3. Enable SSL.
4. Enable SSL client authentication.

You can mix and match these configuration options. However, a precedence exists as to which authentication features become the identity in the received credential:

1. Identity assertion
2. Message-layer client authentication (basic authentication or token)
3. Transport-layer client authentication (SSL certificates)

Scenario 3: Client certificate authentication and RunAs system

This example presents a pure Java client, C, accessing a secure enterprise bean on S1.

C authenticates to S1 using Secure Sockets Layer (SSL) client certificates. S1 maps the common name of the distinguished name (DN) in the certificate to a user in the local registry. The user in this case is bob. The enterprise bean code on S1 accesses another enterprise bean on S2. Because the RunAs mode is system, the invocation credential is set as server1 for any outbound requests.

Configuring C

C requires transport layer authentication (SSL client certificates):

1. Point the client to the sas.client.props file.

Use the `com.ibm.CORBA.ConfigURL=file:/profile_root /properties/sas.client.props` property. The `profile_root` variable is the specific profile that you are working with. All further configuration involves setting properties within this file.

2. Enable SSL.

In this case, SSL is supported but not required:

```
com.ibm.CSI.performTransportAssocSSLTLSSupported=true,
com.ibm.CSI.performTransportAssocSSLTLSRequired=false
```

3. Disable client authentication at the message layer:
`com.ibm.CSI.performClientAuthenticationRequired=false,`
`com.ibm.CSI.performClientAuthenticationSupported=false`

4. Enable client authentication at the transport layer. It is supported, but not required:
`com.ibm.CSI.performTLClientAuthenticationRequired=false,`
`com.ibm.CSI.performTLClientAuthenticationSupported=true`

Configuring S1

In the administrative console, S1 is configured for incoming connections to support SSL with client certificate authentication. The S1 server is configured for outgoing requests to support message layer client authentication.

1. Configure S1 for incoming connections:
 - a. Disable identity assertion.
 - b. Disable user ID and password authentication.
 - c. Enable SSL.
 - d. Enable SSL client certificate authentication.
2. Configure S1 for outgoing connections:
 - a. Disable identity assertion.
 - b. Disable user ID and password authentication.
 - c. Enable SSL.
 - d. Enable SSL client certificate authentication.

Configuring S2

In the administrative console, the S2 server is configured for incoming requests to support message layer authentication over SSL. Configuration for outgoing requests is not relevant for this scenario.

1. Disable identity assertion.
2. Enable user ID and password authentication.
3. Enable SSL.
4. Disable SSL client authentication.

Scenario 4: TCP/IP transport using a virtual private network

This scenario illustrates the ability to choose TCP/IP as the transport when it is appropriate. In some cases, when two servers are on the same virtual private network (VPN), it can be appropriate to select TCP/IP as the transport for performance reasons because the VPN already encrypts the message.

Virtual Private Network

Configuring C

C requires message layer authentication with an Secure Sockets Layer (SSL) transport:

1. Point the client to the `sas.client.props` file.
Use the `com.ibm.CORBA.ConfigURL=file:/profile_root/properties/sas.client.props` property. The `profile_root` variable is to the specific profile you are working with. All further configuration involves setting properties within this file.
2. Enable SSL. In this case, SSL is supported but not required:
`com.ibm.CSI.performTransportAssocSSLTLSSupported=true`,
`com.ibm.CSI.performTransportAssocSSLTLSRequired=false`
3. Enable client authentication at the message layer. In this case, client authentication is supported but not required: `com.ibm.CSI.performClientAuthenticationRequired=false`,
`com.ibm.CSI.performClientAuthenticationSupported=true`
4. Use the remaining defaults in the `sas.client.props` file.

Configuring the S1 server

In the administrative console, the S1 server is configured for incoming requests to support message-layer client authentication and incoming connections to support SSL without client certificate authentication. The S1 server is configured for outgoing requests to support identity assertion.

1. Configure S1 for incoming connections:
 - a. Disable identity assertion.
 - b. Enable user ID and password authentication.

- c. Enable SSL.
 - d. Disable SSL client certificate authentication.
2. Configure S1 for outgoing connections:
 - a. Disable identity assertion.
 - b. Enable user ID and password authentication.
 - c. Disable SSL.

It is possible to enable SSL for inbound connections and disable SSL for outbound connections. The same is true in reverse.

Configuring the S2 server

In the administrative console, the S2 server is configured for incoming requests to support identity assertion and to accept SSL connections. Configuration for outgoing requests and connections are not relevant for this scenario.

1. Disable identity assertion.
2. Enable user ID and password authentication.
3. Disable SSL.

Configuring RMI over IIOP

Complete the following steps to configure Common Secure Interoperability Version 2 (CSIV2) and Security Authentication Service (SAS).

Important: SAS is supported only between Version 6.0.x and previous version servers that have been federated in a Version 6.1 cell.

1. Determine how to configure security inbound and outbound at each point in your infrastructure.

For example, you might have a Java client communicating with an Enterprise JavaBeans (EJB) application server, which in turn communicates to a downstream EJB application server.

The Java client utilizes the `sas.client.props` file to configure outbound security. Pure clients must configure outbound security only.

The upstream EJB application server configures inbound security to handle the correct type of authentication from the Java client. The upstream EJB application server utilizes the outbound security configuration when going to the downstream EJB application server.

This type of authentication might be different than what you expect from the Java client into the upstream EJB application server. Security might be tighter between the pure client and the first EJB server, depending on your infrastructure. The downstream EJB server utilizes the inbound security configuration to accept requests from the upstream EJB server. These two servers require similar configuration options as well. If the downstream EJB application server communicates to other downstream servers, the outbound security might require a special configuration.

2. Specify the type of authentication.

By default, authentication by a user ID and password is performed.

Both Java client certificate authentication and identity assertion are disabled by default. If you want this type of authentication performed at every tier, use the CSIV2 authentication protocol configuration as is. However, if you have any special requirements where some servers authenticate differently from other servers, consider how to configure CSIV2 to its best advantage.

3. Configure clients and servers.

Configuring a pure Java client is done through the `sas.client.props` file, where properties are modified.

Configuring servers is always done from the administrative console or scripting, either from the security navigation for cell-level configurations or from the server security of the application server for

server-level configurations. If you want some servers to authenticate differently from others, modify some of the server-level configurations. When you modify the server-level configurations, you are overriding the cell-level configurations.

Configuring inbound transports

By using this configuration, you can configure a different transport for inbound security versus outbound security.

V6.0.x *Inbound transports* refer to the types of listener ports and their attributes that are opened to receive requests for this server. Both Common Secure Interoperability Specification, Version 2 (CSlv2) and Secure Authentication Service (SAS) have the ability to configure the transport.

Important: SAS is supported only between Version 6.0.x and previous version servers that have been federated in a Version 6.1 cell.

However, the following differences between the two protocols exist: **V6.0.x**

- CSlv2 is much more flexible than SAS, which requires Secure Sockets Layer (SSL); CSlv2 does not require SSL.
- SAS does not support SSL client certificate authentication, while CSlv2 does.
- CSlv2 can require SSL connections, while SAS only supports SSL connections.
- SAS always has two listener ports open: TCP/IP and SSL.
- CSlv2 can have as few as one listener port and as many as three listener ports. You can open one port for just TCP/IP or when SSL is required. You can open two ports when SSL is supported, and open three ports when SSL and SSL client certificate authentication is supported.

Complete the following steps to configure the Inbound transport panels in the administrative console:

1. Click **Security > Secure administration, applications, and infrastructure**.
2. Under RMI/IIOP security, click **CSlv2 inbound transport** to select the type of transport and the SSL settings. By selecting the type of transport, as noted previously, you choose which listener ports you want to open. In addition, you disable the SSL client certificate authentication feature if you choose TCP/IP as the transport.
3. Select the SSL settings that correspond to an SSL transport. You can define these settings by accessing the SSL configurations panel. For more information, see `tsec_sslconfiguration.dita`.
4. Click **Apply** in the CSlv2 inbound transport panel.
5. Consider fixing the listener ports that you configured.

You complete this action in a different panel, but think about this action now. Most endpoints are managed at a single location, which is why they do not display in the Inbound transport panels. Managing end points at a single location helps you decrease the number of conflicts in your configuration when you assign the endpoints. The location for SSL end points is at each server. The following port names are defined in the End points panel and are used for Object Request Broker (ORB) security:

- CSIV2_SSL_MUTUALAUTH_LISTENER_ADDRESS - CSlv2 Client Authentication SSL Port
- CSIV2_SSL_SERVERAUTH_LISTENER_ADDRESS - CSlv2 SSL Port
- **V6.0.x** SAS_SSL_SERVERAUTH_LISTENER_ADDRESS - SAS SSL Port
- ORB_LISTENER_PORT - TCP/IP Port

For an application server, click **Servers > Application servers > server_name**. Under Communications, click **Ports**. The Ports panel is displayed for the specified server.

The Object Request Broker (ORB) on WebSphere Application Server uses a listener port for Remote Method Invocation over the Internet Inter-ORB Protocol (RMI/IIOP) communications, and is statically specified using configuration dialogs or during migration. If you are working with a firewall, you must

specify a static port for the ORB listener and open that port on the firewall so that communication can pass through the specified port. The endPoint property for setting the ORB listener port is: ORB_LISTENER_ADDRESS.

In the WebSphere Application Server Network Deployment environment, the ORB_LISTENER_ADDRESS end point is specified on the node agent. The location service daemon resides on the node agent and piggybacks onto the ORB listener port, which results in needing the port fixed. Also, you must add the ORB_LISTENER_ADDRESS to the other application servers to set their ORB listener port. Each ORB has a distinct listener port. In WebSphere Application Server Network Deployment, you must specify a different listener port. For example, you might specify the following ports:

- Node agent: ORB_LISTENER_ADDRESS=9000
- Server1: ORB_LISTENER_ADDRESS=9811
- Server2: ORB_LISTENER_ADDRESS=9812

Federated servers can run without the node agent running. When ORB_LISTENER_ADDRESS is set to a value of zero (0) or greater, the server does not depend on the location service daemon to redirect connections to the server. When you set ORB_LISTENER_ADDRESS, all object references in the namespace specify the connection to the server, not the location service daemon. When the server is running without the node agent, all applications must be accessed through the name server that runs on the application server. The client must change the Java Naming Directory Interface (JNDI) reference to use the host and port of the application server.

Table 11.

ORB_LISTENER_ADDRESS

value = 0	The server starts on any available port and does not use the location service daemon.
value > 0	The server starts on the port that is specified by the value you enter. The location service daemon is not used.

Note: Work load management might not work without the node agent running.

Complete the following steps using the administrative console to specify the ORB_LISTENER_ADDRESS port or ports.

Complete the following steps for the node agent and the deployment manager.

- Click **Servers > Application Servers > server_name**. Under Communications, click **Ports > New**.
 - Select **ORB_LISTENER_ADDRESS** from the **Port name** field in the Configuration panel.
 - Enter the IP address, the fully qualified Domain Name System (DNS) host name, or the DNS host name by itself in the **Host** field. For example, if the host name is myhost, the fully qualified DNS name can be myhost.myco.com and the IP address can be 155.123.88.201.
 - Enter the port number in the **Port** field. The port number specifies the port for which the service is configured to accept client requests. The port value is used with the host name. Using the previous example, the port number might be 9000.
- Click **Security > Secure administration, applications, and infrastructure**. Under RMI/IIOP security, click **CSlv2 inbound transport** to select the SSL settings that are used for inbound requests from CSlv2 clients. Remember that the CSlv2 protocol is used to inter-operate with previous releases. When configuring the keystore and truststore files in the SSL configuration, these files need the right information for inter-operating with previous releases of WebSphere Application Server. For example, a previous release has a different truststore file than the Version 6 release. If you use the Version 6 keystore file, add the signer to the truststore file of the previous release for those clients connecting to this server.

The inbound transport configuration is complete. With this configuration, you can configure a different transport for inbound security versus outbound security. For example, if the application server is the first server that is used by users, the security configuration might be more secure. When requests go to

back-end enterprise bean servers, you might lessen the security for performance reasons when you go outbound. With this flexibility you can design the right transport infrastructure to meet your needs.

When you finish configuring security, perform the following steps to save, synchronize, and restart the servers:

1. Click **Save** in the administrative console to save any modifications to the configuration.
2. Stop and restart all servers, when synchronized.

Common Secure Interoperability Version 2 transport inbound settings

Use this page to specify which listener ports to open and which Secure Sockets Layer (SSL) settings to use. These specifications determine which transport a client or upstream server uses to communicate with this server for incoming requests.

To view this administrative console page, complete the following steps:

1. Click **Security > Secure administration, applications, and infrastructure**.
2. Under Authentication, click **RMI/IIOP security > CSIv2 inbound transport**.

Transport:

Specifies whether client processes connect to the server using one of its connected transports.

You can choose to use either Secure Sockets Layer (SSL), TCP/IP or both as the inbound transport that a server supports. If you specify TCP/IP, the server only supports TCP/IP and cannot accept SSL connections. If you specify SSL-supported, this server can support either TCP/IP or SSL connections. If you specify SSL-required, then any server communicating with this one must use SSL.

If you specify SSL-supported or SSL-required, decide which set of SSL configuration settings you want to use for the inbound configuration. This decision determines which key file and trust file are used for inbound connections to this server.

TCP/IP

If you select **TCP/IP**, then the server opens a TCP/IP listener port only and all inbound requests do not have SSL protection.

SSL-required

If you select **SSL-required**, then the server opens an SSL listener port only and all inbound requests are received using SSL.

Important: **V6.0.x** If you set the active authentication protocol to **CSI and SAS**, then the server opens a TCP/IP listener port for the Secure Authentication Service (SAS) protocol regardless of this setting.

V6.0.x Only an SSL listener port is opened, and all requests come through SSL connections. If you choose **SSL-required**, you must also choose **CSI** as the active authentication protocol. If you choose **CSI and SAS**, SAS requires an open TCP/IP socket for some special requests.

Important: SAS is supported only between Version 6.0.x and previous version servers that have been federated in a Version 6.1 cell.

SSL-supported

If you select **SSL-supported**, then the server opens both a TCP/IP and an SSL listener port and most inbound requests are received using SSL.

V6.0.x

By default, SSL ports for Common Secure Interoperability Version 2 (CSIV2) and Security Authentication Service (SAS) are dynamically generated. In cases where you need to fix the SSL ports on application servers, click **Servers > Application Servers > server_name**. Under Additional properties, click **Endpoint listeners**.

Provide a fixed port number for the following ports. A zero port number indicates that a dynamic assignment is made at runtime.

CSIV2_SSL_MUTUALAUTH_LISTENER_ADDRESS
 CSIV2_SSL_SERVERAUTH_LISTENER_ADDRESS
 SAS_SSL_SERVERAUTH_LISTENER_ADDRESS

Default: SSL-Supported
Range: TCP/IP, SSL Required, SSL-Supported

SSL settings:

Specifies a list of predefined SSL settings to choose from for inbound connections.

Note: **V6.0.x** This option is available for non-z/OS platform servers when there is a version 6.0.x server in your environment. However, if your environment contains only Version 6.1 servers, this option does not apply.

These settings are configured at the SSL Repertoire panel. To access the SSL Repertoire panel, complete the following steps:

1. Clicking **Security > SSL certificate and key management**.
2. Under configuration settings, click **Manage endpoint security configurations and trust zones**.
3. Expand Inbound and click *inbound_configuration*.
4. Under Related items, click **SSL configurations**.

Data type: String
Default: DefaultSSLSettings
DefaultIOPSSL
Range: Any SSL settings configured in the SSL Configuration Repertoire

Centrally managed:

Specifies that the selection of an SSL configuration is based upon the outbound topology view for the Java Naming and Directory Interface (JNDI) platform.

Centrally managed configurations support one location to maintain SSL configurations rather than spreading them across the configuration documents.

Default: Enabled

Use specific SSL alias:

Specifies the SSL configuration alias to use for LDAP outbound SSL communications.

This option overrides the centrally managed configuration for the JNDI platform.

z/OS SSL settings:

Specifies a list of predefined Secure Sockets Layer (SSL) settings for inbound connections. Configure these settings on the SSL panel by clicking Secure communications on the administrative console.

Secure Authentication Service inbound transport settings

Use this page to specify transport settings for connections that are accepted by this server using the Secure Authentication Service (SAS) authentication protocol. The SAS protocol is used to communicate securely to enterprise beans with previous releases of the application server.

To view this administrative console page, complete the following steps:

1. Click **Security > Secure administration, applications, and infrastructure**.
2. Under Authentication, expand RMI/IOP security and click **SAS inbound transport**.

Attention: V6.0.x The panel associated with this article displays only when you have a Version 6.0.x server in your environment. SAS is supported only between Version 6.0.x and previous version servers that have been federated in a Version 6.1 cell.

SSL Settings:

Specifies a list of predefined SSL settings to choose from for inbound connections.

These settings are configured on the Secure Sockets Layer (SSL) configuration panel. To access the SSL configuration panel, complete the following steps:

1. Click **Security > SSL certificate and key management > Manage endpoint security configurations and trust zones**.
2. Expand Inbound > *configuration_name*.
3. Under Related Items, click **SSL configurations**.

Data type: String
Default: DefaultSSLSettings

Configuring outbound transports

By using this configuration, you can configure a different transport for inbound security versus outbound security.

Outbound transports refers to the transport that is used to connect to a downstream server. When you configure the outbound transport, consider the transports that the downstream servers support. If you are considering Secure Sockets Layer (SSL), also consider including the signers of the downstream servers in this server truststore file for the handshake to succeed.

When you select an SSL configuration, that configuration points to keystore and truststore files that contain the necessary signers.

If you configured client certificate authentication for this server by completing the following steps, then the downstream servers contain the signer certificate belonging to the server personal certificate:

1. Click **Security > Secure administration, applications, and infrastructure**.
2. Under RMI/IOP security, click **CSlv2 outbound authentication**

Complete the following steps to configure the outbound transport panels.

1. Select the type of transport and the SSL settings by clicking **Security > Secure administration, applications, and infrastructure**. Under RMI/IOP security, click **CSlv2 outbound transport**. By

selecting the type of transport, you choose the transport to use when connecting to downstream servers. The downstream servers support the transport that you choose. If you choose **SSL-Supported**, the transport that is used is negotiated during the connection. If both the client and server support SSL, always select the **SSL-Supported** option unless the request is considered a special request that does not require SSL, such as if an object request broker (ORB) is a request.

2. Select the **SSL required** option if you want to use Secure Sockets Layer communications with the outbound transport.

If you select the **SSL required** option, you can select either the **Centrally managed** or **Use specific SSL alias** option.

Centrally managed

Enables you to specify an SSL configuration for particular scope such as the cell, node, server, or cluster in one location. To use the **Centrally managed** option, you must specify the SSL configuration for the particular set of endpoints. The Manage endpoint security configurations and trust zones panel displays all of the inbound and outbound endpoints that use the SSL protocol. If you expand the Inbound or Outbound section of the panel and click the name of a node, you can specify an SSL configuration that is used for every endpoint on that node. For an outbound transport, you can override the inherited SSL configuration by specifying an SSL configuration for a particular endpoint. To specify an SSL configuration for an outbound transport, click **Security > SSL certificate and key management > Manage endpoint security configurations and trust zones** and expand **Outbound**.

Use specific SSL alias

Select the **Use specific SSL alias** option if you intend to select one of the SSL configurations in the menu below the option.

This configuration is used only when SSL is enabled for LDAP. The default is *DefaultSSLSettings*. To modify or create a new SSL configuration, complete the steps described in “Creating a Secure Sockets Layer configuration” on page 429.

3. **V6.0.x** Select the SSL that are settings used for outbound requests to downstream Secure Authentication Service (SAS) servers. Click **Security > Secure administration, applications, and infrastructure**. Under RMI/IOP security, click **SAS outbound transport**. Remember that the SAS protocol allows interoperability with previous releases. When configuring the keystore and truststore files in the SSL configuration, these files have the correct information for inter-operating with previous releases of WebSphere Application Server. For example, a previous release has a different personal certificate than the Version 6.x release. If you use the keystore file from the Version 6.x release, you must add the signer to the truststore file of the previous release. Also, you must extract the signer for the Version 6.x release and import that signer into the truststore file of the previous release.

Important: SAS is supported only between Version 6.0.x and previous version servers that have been federated in a Version 6.1 cell.

The outbound transport configuration is complete. With this configuration, you can configure a different transport for inbound security versus outbound security. For example, if the application server is the first server used by end users, the security configuration might be more secure. When requests go to back-end enterprise beans servers, you might consider less security for performance reasons when you go outbound. With this flexibility you can design a transport infrastructure that meets your needs.

When you finish configuring security, perform the following steps to save, synchronize, and restart the servers.

- Click **Save** in the administrative console to save any modifications to the configuration.
- Stop and restart all servers, after synchronization.

Common Secure Interoperability Version 2 outbound transport settings

Use this page to specify which transports and Secure Sockets Layer (SSL) settings this server uses when communicating with downstream servers for outbound requests.

To view this administrative console page, complete the following steps:

1. Click **Security > Secure administration, applications, and infrastructure**.
2. Under Authentication, click **RMI/IOP security > CSiv2 outbound transport**.

You also can view this administrative console by completing the following steps:

1. Click **Servers > Application servers > server_name**.
2. Under Security, click **Server security**.
3. Under Additional properties, click **CSiv2 outbound transport**.

Transport:

Specifies whether the client processes connect to the server using one of the server-connected transports.

You can choose to use either SSL, TCP/IP, or Both as the outbound transport that a server supports. If you specify TCP/IP, the server supports only TCP/IP and cannot initiate SSL connections with downstream servers. If you specify SSL-supported, this server can initiate either TCP/IP or SSL connections. If you specify SSL-required, this server must use SSL to initiate connections to downstream servers. When you do specify SSL, decide which set of SSL configuration settings you want to use for the outbound configuration.

This decision determines which keyfile and trustfile to use for outbound connections to downstream servers.

Consider the following options:

TCP/IP

If you select this option, the server opens TCP/IP connections with downstream servers only.

SSL-required

If you select this option, the server opens SSL connections with downstream servers.

SSL-supported

If you select this option, the server opens SSL connections with any downstream server that supports them and opens TCP/IP connections with any downstream servers that do not support SSL.

Default:

SSL-supported

Range:

TCP/IP, SSL-required, SSL-supported

SSL settings:

Specifies a list of predefined SSL settings for outbound connections. These settings are configured at the SSL Configuration Repertoires panel.

To access the panel, complete the following steps:

1. Click **Security > SSL certificate and key management**.
2. Under Configuration settings, click **Manage endpoint security configurations and trust zones**.
3. Expand Outbound > *outbound_configuration_name*.
4. Under Related items, click **SSL configurations**.

Data type:

String

Range:

Any SSL settings that are configured in the SSL Configuration Repertoires panel

Note: V6.0.x This field is available only if a Version 6.0.x server exists in your environment.

SSL enabled:

Specifies whether secure socket communication is enabled to the server.

Centrally managed:

Specifies that the selection of an SSL configuration is based upon the outbound topology view for the Java Naming and Directory Interface (JNDI) platform.

Centrally managed configurations support one location to maintain SSL configurations rather than spreading them across the configuration documents.

Default: Enabled

Use specific SSL alias:

Specifies the SSL configuration alias that you want to use for outbound SSL communications.

This option overrides the centrally managed configuration for the JNDI (LDAP) protocol.

Secure Authentication Service outbound transport settings

Use this page to specify transport settings for connections that are accepted by this server using the Secure Authentication Service (SAS) authentication protocol.

To view this administrative console page, complete the following steps:

1. Click **Security > Secure administration, applications, and infrastructure**.
2. Under Authentication, expand RMI/IIOP security and click **SAS outbound transport**.

Attention: V6.0.x The panel associated with this article displays only when you have a Version 6.0.x server in your environment.

SSL settings:

Specifies a list of predefined Secure Sockets Layer (SSL) settings to choose from for outbound connections.

These settings are configured on the SSL configuration panel. To access the SSL configuration panel, complete the following steps:

1. Click **Security > SSL certificate and key management > Manage endpoint security configurations and trust zones**.
2. Expand Outbound > *configuration_name*.
3. Under Related Items, click **SSL configurations**.

Data type: String
Default: DefaultSSLSettings

Performing identity mapping for authorization across servers in different realms

Identity mapping is a one-to-one mapping of a user identity between two servers so that the proper authorization decisions are made by downstream servers. Identity mapping is necessary when the integration of servers is needed, but the user registries are different and not shared between the systems.

The following topics are covered in this section:

- Configuring inbound identity mapping
- Configuring outbound identity mapping to a different target realm

Configuring inbound identity mapping

For inbound identity mapping, write a custom login module and configure WebSphere Application Server to run the login module first within the system login configurations. Consider the following steps when you write your custom login module.

1. Get the inbound user identity from the callbacks and map the identity, if necessary. This step occurs in the login method of the login module. A valid authentication has either or both NameCallback and the WSCredTokenCallback callbacks present. The following code sample shows you how to determine the user identity:

```
javax.security.auth.callback.Callback callbacks[] =
    new javax.security.auth.callback.Callback[3];
callbacks[0] = new javax.security.auth.callback.NameCallback("");
callbacks[1] = new javax.security.auth.callback.PasswordCallback
    ("Password: ", false);
callbacks[2] = new com.ibm.websphere.security.auth.callback.
    WSCredTokenCallbackImpl("");
callbacks[3] = new com.ibm.wsspi.security.auth.callback.
    WSTokenHolderCallback("");

try
{
    callbackHandler.handle(callbacks);
}
catch (Exception e)
{
    // Handles exceptions
    throw new WLoginFailedException (e.getMessage(), e);
}

// Shows which callbacks contain information
boolean identitySwitched = false;
String uid = ((NameCallback) callbacks[0]).getName();
char password[] = ((PasswordCallback) callbacks[1]).getPassword();
byte[] credToken = ((WSCredTokenCallbackImpl) callbacks[2]).getCredToken();
java.util.List authzTokenList = ((WSTokenHolderCallback)
    callbacks[3]).getTokenHolderList();

if (credToken != null)
{
    try
    {
        String uniqueID = WSSecurityPropagationHelper.validateLTPAToken(credToken);
        String realm = WSSecurityPropagationHelper.getRealmFromUniqueID (uniqueID);
        // Now set the string to the UID so that you can use the result for either
        // mapping or logging in.
        uid = WSSecurityPropagationHelper.getUserFromUniqueID (uniqueID);
    }
    catch (Exception e)
    {
        // Handles the exception
    }
}
else if (uid == null)
{
    // Throws an exception if authentication data is not valid.
    // You must have either UID or CredToken
    throw new WLoginFailedException("invalid authentication data.");
}
else if (uid != null && password != null)
{
    // This is a typical authentication. You can choose to map this ID to
```

```

        // another ID or you can skip it and allow WebSphere Application Server
        // to log in for you. When passwords are presented, be very careful to not
        // validate the password because this is the initial authentication.

return true;
}

// If desired, map this uid to something else and set the identitySwitched
// boolean. If the identity was changed, clear the propagated attributes
// below so they are not used incorrectly.
uid = myCustomMappingRoutine (uid);

// Clear the propagated attributes because they are no longer applicable
// to the new identity
if (identitySwitched)
{
    ((WSTokenHolderCallback) callbacks[3]).setTokenHolderList(null);
}

```

2. Check to see if attribute propagation occurred and if the attributes for the user are already present when the identity remains the same. Check to see if the user attributes are already present from the sending server to avoid duplicate calls to the user registry lookup. To check for the user attributes, use a method on the WSTokenHolderCallback callback that analyzes the information present in the callback to determine if the information is sufficient for WebSphere Application Server to create a Subject. The following code sample checks for the user attributes:

```

boolean requiresLogin =
((com.ibm.wsspi.security.auth.callback.WSTokenHolderCallback)
callbacks[2]).requiresLogin();

```

If sufficient attributes are not present to form the WSCredential and the WSPincipal objects that are needed to perform authorization, the previous code sample returns a true result. When the result is false, you can choose to discontinue processing as the necessary information exists to create the Subject without performing additional remote user registry calls.

3. **Optional:** Look up the required attributes from the user registry, put the attributes in a hashtable, and add the hashtable to the shared state. If the identity is switched in this login module, you must complete the following steps:
 - a. Create the hashtable of attributes, as shown in the following example.
 - b. Add the hashtable to the shared state.

If the identity is not switched, but the value of the requiresLogin code sample shown previously is true, you can create the hashtable of attributes. However, you are not required to create a hashtable in this situation as WebSphere Application Server handles the login for you. However, you might consider creating a hashtable to gather attributes in special cases where you are using your own special user registry. Creating a UserRegistry implementation, using a hashtable, and letting WebSphere Application Server gather the user attributes for you might be the easiest solution. The following table shows how to create a hashtable of user attributes:

```

if (requiresLogin || identitySwitched)
{
    // Retrieves the default InitialContext for this server.
    javax.naming.InitialContext ctx = new javax.naming.InitialContext();

    // Retrieves the local UserRegistry implementation.
    com.ibm.websphere.security.UserRegistry reg = (com.ibm.websphere.
        security.UserRegistry)
    ctx.lookup("UserRegistry");

    // Retrieves the user registry uniqueID based on the uid specified
    // in the NameCallback.
    String uniqueid = reg.getUniqueUserId(uid);
    uid = WSSecurityPropagationHelper.getUserFromUniqueID (uniqueID);

    // Retrieves the display name from the user registry based on the uniqueID.

```

```

String securityName = reg.getUserSecurityName(uid);

    // Retrieves the groups associated with the uniqueID.
    java.util.List groupList = reg.getUniqueGroupIds(uid);

    // Creates the java.util.Hashtable with the information that you gathered
    // from the UserRegistry implementation.
    java.util.Hashtable hashtable = new java.util.Hashtable();
    hashtable.put(com.ibm.wsspi.security.token.AttributeNameConstants.
        WSCREDENTIAL_UNIQUEID, uniqueid);
    hashtable.put(com.ibm.wsspi.security.token.AttributeNameConstants.
        WSCREDENTIAL_SECURITYNAME, securityName);
    hashtable.put(com.ibm.wsspi.security.token.AttributeNameConstants.
        WSCREDENTIAL_GROUPS, groupList);

    // Adds a cache key that is used as part of the lookup mechanism for
    // the created Subject. The cache key can be an object, but should have
    // an implemented toString method. Make sure that the cacheKey contains
    // enough information to scope it to the user and any additional attributes
    // that you are using. If you do not specify this property the Subject is
    // scoped to the returned WSCREDENTIAL_UNIQUEID, by default.
    hashtable.put(com.ibm.wsspi.security.token.AttributeNameConstants.
        WSCREDENTIAL_CACHE_KEY, "myCustomAttribute" + uniqueid);
    // Adds the hashtable to the sharedState of the Subject.
    _sharedState.put(com.ibm.wsspi.security.token.AttributeNameConstants.
        WSCREDENTIAL_PROPERTIES_KEY, hashtable);
}

```

The following rules define in more detail how a hashtable login is performed. You must use a `java.util.Hashtable` object in either the Subject (public or private credential set) or the shared-state `HashMap`. The `com.ibm.wsspi.security.token.AttributeNameConstants` class defines the keys that contain the user information. If the `Hashtable` object is put into the shared state of the login context using a custom login module that is listed prior to the Lightweight Third Party Authentication (LTPA) login module, the value of the `java.util.Hashtable` object is searched using the following key within the shared-state `HashMap`:

Property

`com.ibm.wsspi.security.cred.propertiesObject`

Reference to the property

`AttributeNameConstants.WSCREDENTIAL_PROPERTIES_KEY`

Explanation

This key searches for the `Hashtable` object that contains the required properties in the shared state of the login context.

Expected result

A `java.util.Hashtable` object.

If a `java.util.Hashtable` object is found either inside the Subject or within the shared state area, verify that the following properties are present in the hashtable:

Property

`com.ibm.wsspi.security.cred.uniqueId`

Reference to the property

`AttributeNameConstants.WSCREDENTIAL_UNIQUEID`

Returns

`java.util.String`

Explanation

The value of the property must be a unique representation of the user. For the WebSphere Application Server default implementation, this property represents the information that is stored in the application authorization table. The information is located in the application deployment descriptor after it is deployed and user-to-role mapping is performed. See the

expected format examples if the user to role mapping is performed using a lookup to a WebSphere Application Server user registry implementation.

If a third-party authorization provider overrides the user-to-role mapping, then the third-party authorization provider defines the format. To ensure compatibility with the WebSphere Application Server default implementation for the unique ID value, call the WebSphere Application Server public String `getUniqueUserId(String userSecurityName)` `UserRegistry` method.

Expected format examples

Realm	Format (uniqueUserId)
Lightweight Directory Access Protocol (LDAP)	ldaphost.austin.ibm.com:389/cn=user,o=ibm,c=us
Windows	MYWINHOST/S-1-5-21-963918322-163748893-4247568029-500
UNIX	MYUNIXHOST/32

The `com.ibm.wsspi.security.cred.uniqueId` property is required.

Property

`com.ibm.wsspi.security.cred.securityName`

Reference to the property

`AttributeNameConstants.WSCREDENTIAL_SECURITYNAME`

Returns

`java.util.String`

Explanation

This property searches for the `securityName` of the authentication user. This name is commonly called the *display name* or *short name*. WebSphere Application Server uses the `securityName` attribute for the `getRemoteUser`, `getUserPrincipal` and `getCallerPrincipal` application programming interfaces (APIs). To ensure compatibility with the WebSphere Application Server default implementation for the `securityName` value, call the WebSphere Application Server public String `getUserSecurityName(String uniqueUserId)` `UserRegistry` method.

Expected format examples

Realm	Format (uniqueUserId)
LDAP	user (LDAP UID)
Windows	user (Windows username)
UNIX	user (UNIX username)

The `com.ibm.wsspi.security.cred.securityName` property is required.

Property

`com.ibm.wsspi.security.cred.groups`

Reference to the property

`AttributeNameConstants.WSCREDENTIAL_GROUPS`

Returns

`java.util.ArrayList`

Explanation

This key searches for the array list of groups to which the user belongs. The groups are specified in the *realm_name/user_name* format. The format of these groups is important as the groups are used by the WebSphere Application Server authorization engine for group-to-role mappings in the deployment descriptor. The format that is provided must match the format

expected by the WebSphere Application Server default implementation. When you use a third-party authorization provider, you must use the format that is expected by the third-party provider. To ensure compatibility with the WebSphere Application Server default implementation for the unique group IDs value, call the WebSphere Application Server public List `getUniqueGroupIds(String uniqueUserId) UserRegistry` method.

Expected format examples for each group in the array list

Realm	Format
LDAP	ldap1.austin.ibm.com:389/cn=group1,o=ibm,c=us
Windows	MYWINREALM/S-1-5-32-544
UNIX	MY/S-1-5-32-544

The `com.ibm.wsspi.security.cred.groups` property is not required. A user is not required to have associated groups.

Property

`com.ibm.wsspi.security.cred.cacheKey`

Reference to the property

`AttributeNameConstants.WSCREDENTIAL_CACHE_KEY`

Returns

`java.lang.Object`

Explanation

This key property can specify an object that represents the unique properties of the login, including the user-specific information and the user dynamic attributes that might affect uniqueness. For example, when the user logs in from location A, which might affect their access control, the cache key needs to include location A so that the Subject that is received is the correct Subject for the current location.

This `com.ibm.wsspi.security.cred.cacheKey` property is not required. When this property is not specified, the cache lookup is the value that is specified for `WSCREDENTIAL_UNIQUEID`. When this information is found in the `java.util.Hashtable` object, WebSphere Application Server creates a Subject similar to the Subject that goes through the normal login process at least for LTPA. The new Subject contains a `WSCredential` object and a `WSPrincipal` object that is fully populated with the information found in the `Hashtable` object.

4. Add your custom login module into the `RMI_INBOUND`, `WEB_INBOUND`, and `DEFAULT` Java Authentication and Authorization Service (JAAS) system login configurations. Configure the `RMI_INBOUND` login configuration so that WebSphere Application Server loads your new custom login module first.
 - a. Click **Security > Secure administration, applications, and infrastructure > Java Authentication and Authorization Service > System logins > RMI_INBOUND**
 - b. Under Additional Properties, click **JAAS login modules > New** to add your login module to the `RMI_INBOUND` configuration.
 - c. Return to the JAAS login modules panel for `RMI_INBOUND`.
 - d. Click **Set order** to change the order that the login modules are loaded so that WebSphere Application Server loads your custom login module first. Use the **Move Up** or **Move Down** buttons to arrange the order of the login modules.
 - e. Repeat the previous three steps for the `WEB_INBOUND` and `DEFAULT` login configurations.

This process configures identity mapping for an inbound request.

The “Example: Custom login module for inbound mapping” on page 312 topic shows a custom login module that creates a `java.util.Hashtable` hashtable that is based on the specified `NameCallback` callback.

The `java.util.Hashtable` hashtable is added to the `sharedState java.util.Map` map so that the WebSphere Application Server login modules can locate the information in the hashtable.

Identity mapping:

Identity mapping is a one-to-one mapping of a user identity between two servers so that the proper authorization decisions are made by downstream servers. Identity mapping is necessary when the integration of servers is needed, but the user registries are different and not shared between the systems.

In most cases, requests flow downstream between two servers that are part of the same security domain. In WebSphere Application Server, two servers that are members of the same cell are also members of the same security domain. In the same cell, the two servers have the same user registry and the same Lightweight Third Party Authentication (LTPA) keys for token encryption. These two commonalities ensure that the LTPA token, among other user attributes, which flows between the two servers, not only can be decrypted and validated, but also the user identity in the token can be mapped to attributes that are recognized by the authorization engine.

The most reliable and recommended configuration involves two servers within the same cell. However, sometimes you need to integrate multiple systems that cannot use the same user registry. When the user registries are different between two servers, the security domain or realm of the target server does not match the security domain of the sending server.

WebSphere Application Server enables mapping to occur either before sending the request outbound or before enabling the existing security credentials to flow to the target server. The credentials are mapped inbound with the specification that the target realm is trusted.

An alternative to mapping is to send the user identity without the token or the password to a target server without actually mapping the identity. The use of the user identity is based on trust between the two servers. Use Common Secure Interoperability Version 2 (CSIv2) identity assertion. When enabled, the server sends just the X.509 certificate, principal name, or distinguished name (DN) based upon what was used by the original client to perform the initial authentication. During CSIv2 identity assertion, trust is established between WebSphere Application Servers.

The user identity must exist in the target user registry for identity assertion to work. This process can also enable interoperability between other Java 2 Platform, Enterprise Edition (J2EE) Version 1.4 and higher compliant application servers. If both the sending server and target servers have identity assertion configured, WebSphere Application Server always uses this method of authentication, even when both servers are in the same security domain. For more information on CSIv2 identity assertion, see “Identity assertion” on page 213.

When the user identity is not present in the user registry of the target server, identity mapping must occur either before the request is sent outbound or when the request comes inbound. This decision depends upon your environment and requirements. However, it is typically easier to map the user identity before the request is sent outbound for the following reasons:

- You know the user identity of the existing credential as it comes from the user registry of the sending server.
- You do not have to worry about sharing Lightweight Third Party Authentication (LTPA) keys with the other target realm because you are not mapping the identity to LTPA credentials. Typically, you are mapping the identity to a user ID and password that are present in the user registry of the target realm.

When you do perform outbound mapping, in most cases, it is recommended that you use Secure Sockets Layer (SSL) to protect the integrity and confidentiality of the security information sent across the network. If LTPA keys are not shared between servers, an LTPA token cannot be validated at the inbound server. In this case, outbound mapping is necessary because the user identity cannot be determined at the inbound server to do inbound mapping. For more information, see “Configuring outbound mapping to a different target realm” on page 314.

When you need inbound mapping, potentially due to the mapping capabilities of the inbound server, you must ensure that both servers have the same LTPA keys so that you can get access to the user identity. Typically, in secure communications between servers, an LTPA token is passed into the WSCredTokenCallback callback of the inbound JAAS login configuration for the purposes of client authentication. A method is available that enables you to open the LTPA token, if valid, and get access to the user unique ID so that mapping can be performed. For more information, see “Configuring inbound identity mapping” on page 306. In other cases, such as identity assertion, you might receive a user name in the NameCallback callback of the inbound login configuration that enables you to map the identity.

Example: Custom login module for inbound mapping:

This sample shows a custom login module that creates a java.util.Hashtable hashtable that is based on the specified NameCallback callback. The java.util.Hashtable hashtable is added to the sharedState java.util.Map map so that the WebSphere Application Server login modules can locate the information in the Hashtable.

```
public customLoginModule()
{

public void initialize(Subject subject, CallbackHandler callbackHandler,
    Map sharedState, Map options)
{
    // (For more information on initialization, see
    // "Custom login module development for a system login configuration" on page 593.)
    _sharedState = sharedState;
}

public boolean login() throws LoginException
{
    // (For more information on what to do during login, see
    // "Custom login module development for a system login configuration" on page 593.)

    // Handles the WSTokenHolderCallback to see if this is an initial or
    // propagation login.
    javax.security.auth.callback.Callback callbacks[] =
        new javax.security.auth.callback.Callback[3];
    callbacks[0] = new javax.security.auth.callback.NameCallback("");
    callbacks[1] = new javax.security.auth.callback.PasswordCallback(
        "Password: ", false);
    callbacks[2] = new com.ibm.websphere.security.auth.callback.
        WSCredTokenCallbackImpl("");
    callbacks[3] = new com.ibm.wsspi.security.auth.callback.
        WSTokenHolderCallback("");

    try
    {
        callbackHandler.handle(callbacks);
    }
    catch (Exception e)
    {
        // Handles the exception
    }

    // Determines which callbacks contain information
    boolean identitySwitched = false;
    String uid = ((NameCallback) callbacks[0]).getName();
    char password[] = ((PasswordCallback) callbacks[1]).getPassword();
    byte[] credToken = ((WSCredTokenCallbackImpl) callbacks[2]).getCredToken();
    java.util.List authzTokenList = ((WSTokenHolderCallback) callbacks[3]).
        getTokenHolderList();

    if (credToken != null)
    {
        try
        {
```

```

String uniqueID = WSSecurityPropagationHelper.validateLTPAToken(credToken);
String realm = WSSecurityPropagationHelper.getRealmFromUniqueID (uniqueID);
    // Set the string to the UID so you can use the information to either
    // map or login.
uid = WSSecurityPropagationHelper.getUserFromUniqueID (uniqueID);
}
catch (Exception e)

Configuring outbound mapping to a different target realm

By default, when WebSphere Application Server makes an outbound request from one server to another server in a different security realm, the request is rejected. This topic details alternatives for enabling one server to send outbound requests to a target server in a different realm.

This outbound request is rejected to protect against a rogue server reading potentially sensitive information if successfully impersonating the home of the object. Select one of the following alternative procedures so that one server can send outbound requests to a target server in a different realm. When you are finished with a procedure on the administrative console, click **Apply**.

- Do not perform mapping. Instead, allow the existing security information to flow to a trusted target server, even if the target server resides in a different realm. Complete the following steps in the administrative console:
 1. Click **Security > Secure administration, applications, and infrastructure**.

2. Under RMI/IIOP security, click **CSlv2 outbound authentication**.
 3. Specify the target realms in the **Trusted target realms** field. You can specify each trusted target realm that is separated by a pipe (|) character. For example, specify *server_name.domain:port_number* for a Lightweight Directory Access Protocol (LDAP) server or the machine name for local operating system. If you want to propagate security attributes to a different target realm, you must specify that target realm in the **Trusted target realms** field.
- Use the Java Authentication and Authorization Service (JAAS) WSLogin application login configuration to create a basic authentication Subject that contains the credentials of the new target realm. This configuration enables you to log in with a realm, user ID, and password that are specific to the user registry of the target realm. You can provide the login information from within the Java 2 Platform, Enterprise Edition (J2EE) application that is making the outbound request or from within the RMI_OUTBOUND system login configuration. These two login options are described in the following information:
 1. Use the WSLogin application login configuration from within the J2EE application to log in and get a Subject that contains the user ID and the password of the target realm. The application can wrap the remote call with a WSSubject.doAs call. For an example, see “Example: Using the WSLogin configuration to create a basic authentication subject” on page 316.
 2. Use the code sample in “Example: Using the WSLogin configuration to create a basic authentication subject” on page 316 from this plug point within the RMI_OUTBOUND login configuration. Every outbound Remote Method Invocation (RMI) request passes through this login configuration when it is enabled. Complete the following steps to enable and plug in this login configuration:
 - a. Click **Security > Secure administration, applications, and infrastructure**.
 - b. Under RMI/IIOP security, click **CSlv2 outbound authentication**.
 - c. Select the **Custom outbound mapping** option. If the **Security Attribute Propagation** option is selected, then WebSphere Application Server is already using this login configuration and you do not need to enable custom outbound mapping.
 - d. Write a custom login module. For more information, see “Custom login module development for a system login configuration” on page 593.
The “Example: Sample login configuration for RMI_OUTBOUND” on page 317 shows a custom login module that determines whether the realm names match. In this example, the realm names do not match so the WSLoginmodule is used to create a basic authentication Subject based on custom mapping rules. The custom mapping rules are specific to the customer environment and must be implemented using a realm to user ID and password mapping utility.
 - e. Configure the RMI_OUTBOUND login configuration so that your new custom login module is first in the list.
 - 1) Click **Security > Secure administration, applications, and infrastructure**.
 - 2) Under Java Authentication and Authorization Service, click **System logins > RMI_OUTBOUND**
 - 3) Under Additional Properties, click **JAAS login modules > New** to add your login module to the RMI_OUTBOUND configuration.
 - 4) Return to the JAAS login modules panel for RMI_OUTBOUND.
 - 5) Click **Set order** to change the order that the login modules are loaded so that your custom login is loaded first.
 - Add the `use_realm_callback` and `use_appcontext_callback` options to the outbound mapping module for WSLogin. To add these options, complete the following steps:
 1. Click **Security > Secure administration, applications, and infrastructure**.
 2. Under Java Authentication and Authorization Service, click **Application logins > WSLogin**.
 3. Under Additional properties, click **JAAS login modules > com.ibm.ws.security.common.auth.module.WSLoginModuleImpl**.
 4. Under Additional properties, click **Custom Properties > New**.

5. On the Custom properties panel, enter use_realm_callback in the **Name** field and true in the **Value** field.
6. Click **OK**.
7. Click **New** to enter the second custom property.
8. On the Custom properties panel, enter use_appcontext_callback in the **Name** field and true in the **Value** field.

The following changes are made to the security.xml file:

```
<entries xmi:id="JAASConfigurationEntry_2" alias="WSLogin">
  <loginModules xmi:id="JAASLoginModule_2"
    moduleClassName="com.ibm.ws.security.common.auth.module.proxy.WSLoginModuleProxy"
    authenticationStrategy="REQUIRED">
    <options xmi:id="Property_2" name="delegate"
      value="com.ibm.ws.security.common.auth.module.WSLoginModuleImpl"/>
    <options xmi:id="Property_3" name="use_realm_callback" value="true"/>
    <options xmi:id="Property_4" name="use_appcontext_callback" value="true"/>
  </loginModules>
</entries>
```

Example: Using the WSLogin configuration to create a basic authentication subject:

This example shows how to use the WSLogin application login configuration from within a Java 2 Platform, Enterprise Edition (J2EE) application to log in and get a Subject that contains the user ID and the password of the target realm.

```
javax.security.auth.Subject subject = null;

try
{
  // Create a login context using the WSLogin login configuration and specify a
  // user ID, target realm, and password. Note: If the target_realm_name is the
  // same as the current realm, an authenticated Subject is created. However, if
  // the target_realm_name is different from the current realm, a basic
  // authentication Subject is created that is not validated. This unvalidated
  // Subject is created so that you can send a request to the different target
  // realm with valid security credentials for that realm.
  javax.security.auth.login.LoginContext ctx = new LoginContext("WSLogin",
    new WSCallbackHandlerImpl("userid", "target_realm_name", "password"));

  // Note: The following code is an alternative that validates the user ID and
  // password specified against the target realm. The code performs a remote call
  // to the target server and will return true if the user ID and password are
  // valid and false if the user ID and password are not valid. If false is
  // returned, a WSLoginFailedException exception is created. You can catch
  // that exception and perform a retry or stop the request from flowing by
  // allowing that exception to surface out of this login.

  // ALTERNATIVE LOGIN CONTEXT THAT VALIDATES THE USER ID AND PASSWORD TO THE
  // TARGET REALM

  /**** currently remarked out ****
  java.util.Map appContext = new java.util.HashMap();
    appContext.put(javax.naming.Context.INITIAL_CONTEXT_FACTORY,
      "com.ibm.websphere.naming.WsnInitialContextFactory");
    appContext.put(javax.naming.Context.PROVIDER_URL,
      "corbaloc:iiop:target_host:2809");

  javax.security.auth.login.LoginContext ctx = new LoginContext("WSLogin",
    new WSCallbackHandlerImpl("userid", "target_realm_name", "password", appContext));
  **** currently remarked out ****

  // Starts the login
  ctx.login();
```

```

// Gets the Subject from the context
subject = ctx.getSubject();
}
catch (javax.security.auth.login.LoginException e)
{
throw new com.ibm.websphere.security.auth.WSLoginFailedException (e.getMessage(), e);
}

if (subject != null)
{
// Defines a privileged action that encapsulates your remote request.
java.security.PrivilegedAction myAction = java.security.PrivilegedAction()
{
public Object run()
{
// Assumes a proxy is already defined. This example method returns a String
return proxy.remoteRequest();
}
});

// Starts this action using the basic authentication Subject needed for
// the target realm security requirements.
String myResult = (String) com.ibm.websphere.security.auth.WSSubject.doAs
(subject, myAction);
}

```

Example: Sample login configuration for RMI_OUTBOUND:

This example shows a sample login configuration for RMI_OUTBOUND that determines whether the realm names match between two servers.

```

public customLoginModule()
{
public void initialize(Subject subject, CallbackHandler callbackHandler,
Map sharedState, Map options)
{
// (For more information on what to do during initialization, see
// "Custom login module development for a system login configuration" on page 593.)
}

public boolean login() throws LoginException
{
// (For more information on what to do during login, see
// "Custom login module development for a system login configuration" on page 593.)

// Gets the WSPolicyCallback object
Callback callbacks[] = new Callback[1];
callbacks[0] = new com.ibm.wsspi.security.auth.callback.
WSPolicyCallback("Protocol Policy Callback: ");

try
{
callbackHandler.handle(callbacks);
}
catch (Exception e)
{
// Handles the exception
}

// Receives the RMI (CSIV2) policy object for checking the target realm
// based upon information from the IOR.
// Note: This object can be used to perform additional security checks.
// See the application programming interface (API) documentation for
// more information.
csiv2PerformPolicy = (CSIV2PerformPolicy) ((WSPolicyCallback)callbacks[0]).
getProtocolPolicy();
}
}

```

```

// Checks if the realms do not match. If they do not match, then log in to
// perform a mapping
if (!csiv2PerformPolicy.getTargetSecurityName().equalsIgnoreCase(csiv2PerformPolicy.
    getCurrentSecurityName()))
{
    try
    {
        // Do some custom realm -> user ID and password mapping
        MyBasicAuthDataObject myBasicAuthData = MyMappingLogin.lookup
            (csiv2PerformPolicy.getTargetSecurityName());

        // Creates the login context with basic authentication data gathered from
        // custom mapping
        javax.security.auth.login.LoginContext ctx = new LoginContext("WSLogin",
            new WSCallbackHandlerImpl(myBasicAuthData.userid,
                csiv2PerformPolicy.getTargetSecurityName(),
                    myBasicAuthData.password));

        // Starts the login
        ctx.login();

        // Gets the Subject from the context. This subject is used to replace
        // the passed-in Subject during the commit phase.
        basic_auth_subject = ctx.getSubject();
    }
    catch (javax.security.auth.login.LoginException e)
    {
        throw new com.ibm.websphere.security.auth.
            WSLoginFailedException (e.getMessage(), e);
    }
}

public boolean commit() throws LoginException
{
    // (For more information on what to do during commit, see
    // "Custom login module development for a system login configuration" on page 593.)

    if (basic_auth_subject != null)
    {
        // Removes everything from the current Subject and adds everything from the
        // basic_auth_subject
        try
        {
            public final Subject basic_auth_subject_priv = basic_auth_subject;
            // Do this in a doPrivileged code block so that application code
            // does not need to add additional permissions
            java.security.AccessController.doPrivileged(new java.security.
                PrivilegedExceptionAction()
            {
                public Object run() throws WSLoginFailedException
                {
                    // Removes everything user-specific from the current outbound
                    // Subject. This a temporary Subject for this specific invocation
                    // so you are not affecting the Subject set on the thread. You may
                    // keep any custom objects that you want to propagate in the Subject.
                    // This example removes everything and adds just the new information
                    // back in.

                    try
                    {
                        subject.getPublicCredentials().clear();
                        subject.getPrivateCredentials().clear();
                        subject.getPrincipals().clear();
                    }
                    catch (Exception e)
                    {
                        throw new WSLoginFailedException (e.getMessage(), e);
                    }
                }
            });
        }
    }
}

```

```

    }

    // Adds everything from basic_auth_subject into the login subject.
    // This completes the mapping to the new user.
    try
    {

javax.security.auth.Subject basic_auth_subject = null;
}

```

Common Secure Interoperability Version 2 and Security Authentication Service client configuration

A secure Java client requires configuration properties to determine how to perform security with a server.

These configuration properties are typically put into a properties file somewhere on the client system and referenced by specifying the following system property on the command line of the Java client. For example, this property accepts any valid Web address.

```
-Dcom.ibm.CORBA.ConfigURL=file:profile_root/properties/sas.client.props
```

When you use thin or thick clients, com.ibm.CORBA.ConfigURL is automatically set to the following file:

```
profile_root/properties/sas.client.props
```

When this file is processed by the Object Request Broker (ORB), security can be enabled between the Java client and the target server.

If any syntax problems exist with the ConfigURL property and the sas.client.props file is not found, the Java client proceeds to connect insecurely. Errors display indicating the failure to read the ConfigURL property. Typically the problem is related to having two slashes after file, which is not valid.

V6.0.x Use the following properties to configure the SAS and CSiv2 authentication protocols:

-
- “Security Authentication Service authentication protocol client settings” on page 323

Important: SAS is supported only between Version 6.0.x and previous version servers that have been federated in a Version 6.1 cell.

Common authentication protocol settings for a client configuration

You can use settings in the `sas.client.props` file to configure Security Authentication Service (SAS) and Common Secure Interoperability Version 2 (CSIv2) clients.

V6.0.x Use the following settings in the `sas.client.props` file to configure SAS and CSIv2 clients. By default, the `sas.client.props` file is located in the `profile_root/properties` directory of your WebSphere Application Server Network Deployment installation.

Important: SAS is supported only between Version 6.0.x and previous version servers that have been federated in a Version 6.1 cell.

com.ibm.CORBA.securityEnabled

Use to determine if security is enabled for the client process.

Setting	Value
Data Type	Boolean
Default	True
Valid values	True or false

com.ibm.CSI.protocol

Use to determine which authentication protocols are active.

The client can configure protocols of `ibm`, `csiv2` or both as active. The only possible values for an authentication protocol are `ibm`, `csiv2` and `both`. Do not use `sas` for the value of an authentication protocol. This restriction applies to both client and server configurations. The following list provides information about using each of these protocol options:

ibm Use this authentication protocol option when you are communicating with WebSphere Application Server Version 4.x or earlier servers.

V6.0.x csiv2

Use this authentication protocol option when you are communicating with WebSphere Application Server Version 5 or later servers because the SAS interceptors are not loaded and running for each method request.

both Use this authentication protocol option for interoperability between WebSphere Application Server Version 4.x or earlier servers and WebSphere Application Server Version 5 or later servers. Typically, specifying both provides greater interoperability with other servers.

Setting	Value
Data type	String
Default	Both
Valid values	<code>ibm</code> , <code>csiv2</code> , <code>both</code>

com.ibm.CORBA.authenticationTarget

Use to determine the type of authentication mechanism for sending security information from the client to the server.

If basic authentication is specified, the user ID and password are sent to the server. Using the Secure Sockets Layer (SSL) transport with this type of authentication is recommended; otherwise, the password is not encrypted. The target server must support the specified authentication target.

If you specify Lightweight Third Party Authentication (LTPA), then LTPA must be the mechanism configured at the server for a method request to proceed securely.

Setting	Value
Data type	String
Default	BasicAuth
Valid values	BasicAuth, LTPA

com.ibm.CORBA.validateBasicAuth

Use to determine if the user ID and password get validated immediately after the login data is entered when the authenticationTarget property is set to BasicAuth.

In previous releases, BasicAuth logins validated only with the initial method request. During the first request, the user ID and password are sent to the server. This request is the first time that the client can notice an error, if the user ID or password is incorrect. The validateBasicAuth method is specified and the validation of the user ID and password occurs immediately to the security server.

For performance reasons, you might want to disable this property if you do not want to verify the user ID and password immediately. If the client program can wait, it is better to have the initial method request flow to the user ID and password. However, program logic might not be this simple because of error handling considerations.

Setting	Value
Data type	Boolean
Default	True
Valid values	True, False

com.ibm.CORBA.authenticationRetryEnabled

Use to specify that a failed login attempt is retried. This property determines if a retry occurs for other errors, such as stateful sessions that are not found on a server or validation failures at the server because of an expiring credential.

The minor code in the exception that is returned to a client determines which errors are retried. The number of retry attempts is dependent upon the com.ibm.CORBA.authenticationRetryCount property.

Setting	Value
Data type	Boolean
Default	True
Valid values	True, False

com.ibm.CORBA.authenticationRetryCount

Use to specify the number of retries that occur until either a successful authentication occurs or the maximum retry value is reached.

When the maximum retry value is reached, the authentication exception is returned to the client.

Setting	Value
Data type	Integer
Default	3
Range	1-10

com.ibm.CORBA.loginSource

Use to specify how the request interceptor attempts to log in if it does not find an invocation credential already set.

This property is valid only if message layer authentication occurs. If only transport layer authentication occurs, this property is ignored. When specifying properties, the following two additional properties must be defined:

- com.ibm.CORBA.loginUserId
- com.ibm.CORBA.loginPassword

When performing a programmatic login, it is not necessary to specify none as the login source. The request fails if a credential is set as the invocation credential during a method request.

Setting	Value
Data type	String
Default	Prompt
Valid values	Prompt, key file, stdin, none, properties

com.ibm.CORBA.loginUserId

Use to specify the user ID when a properties login is configured and message layer authentication occurs.

This property is valid only when com.ibm.CORBA.loginSource=properties. Also set the com.ibm.CORBA.loginPassword property.

Setting	Value
Data type	String
Range	Any string that is appropriate for a user ID in the configured user registry of the server.

com.ibm.CORBA.loginPassword

Use to specify the password when a properties login is configured and message layer authentication occurs.

This property is valid only when com.ibm.CORBA.loginSource=properties. Also set the com.ibm.CORBA.loginUserId property.

Setting	Value
Data type	String
Range	Any string that is appropriate for a password in the configured user registry of the server.

com.ibm.CORBA.keyFileName

Use to specify the key file that is used to log in.

A key file is a file that contains a list of realm, user ID, and password combinations that a client uses to log into multiple realms. The realm that is used is the one found in the interoperable object reference (IOR) for the current method request. The value of this property is used when the com.ibm.CORBA.loginSource=key file is used.

Setting	Value
Data type	String
Default	C:/WebSphere/AppServer/properties/wssserver.key
Range	Any fully qualified path and file name of a WebSphere Application Server key file.

com.ibm.CORBA.loginTimeout

Use to specify the length of time that the login prompt stays available before it is considered a failed login.

Setting	Value
Data type	Integer
Units	Seconds
Default	300 (5 minute intervals)
Range	0 - 600 (10 minute intervals)

com.ibm.CORBA.securityEnabled

Use to determine if security is enabled for the client process.

Setting	Value
Data type	Boolean
Default	True
Range	True, False

Specifies the strength of the ciphers when making an Secure Sockets Layer (SSL) connection.

Data type:	String
Default:	High
Range	Low, Medium, High

Java Authentication and Authorization Service

The standard Java 2 security application programming interface (API) helps enforce access control based on the location of the code source or the author or packager of the code that signed the jar file. The current principal of the running thread is not considered in the Java 2 security authorization. Instances where authorization is based on the principal, as opposed to the code base, and the user exist. The Java Authentication and Authorization Service is a standard Java API that supports the Java 2 security authorization to extend the code base on the principal as well as the code base and users.

The Java Authentication and Authorization Service (JAAS) Version 1.0 extends the Java 2 security architecture of the Java 2 platform with additional support to authenticate and enforce access control with principals and users. JAAS implements a Java version of the standard Pluggable Authentication Module (PAM) framework, and extends the access control architecture of the Java 2 platform in a compatible fashion to support user-based authorization or principal-based authorization. WebSphere Application Server fully supports the JAAS architecture. JAAS extends the access control architecture to support role-based authorization for Java 2 Platform, Enterprise Edition (J2EE) resources including servlets, JavaServer Pages (JSP) files, and Enterprise JavaBeans (EJB) components.

Refer to “Java 2 security” on page 61 for more information.

The following sections cover the JAAS implementation and programming model:

- “Login configuration for Java Authentication and Authorization Service” on page 570
- “Programmatic login” on page 353
- “Java Authentication and Authorization Service authorization”

The JAAS documentation can be found at <http://www.ibm.com/developerworks/java/jdk/security>. Scroll down to find the JAAS documentation for your platform.

Java Authentication and Authorization Service authorization

Java 2 security architecture uses a security policy to specify which access rights are granted to running code. This architecture is *code-centric*. The permissions are granted based on code characteristics including where the code is coming from, whether it is digitally signed, and by whom. Authorization of the Java Authentication and Authorization Service (JAAS) augments the existing code-centric access controls with new user-centric access controls. Permissions are granted based on what code is running and who is running it.

When using JAAS authentication to authenticate a user, a *subject* is created to represent the authenticated user. A subject is comprised of a set of principals, where each principal represents an identity for that user. You can grant permissions in the policy to specific principals. After the user is authenticated, the application can associate the subject with the current access control context. For each subsequent security-checked operation, the Java runtime automatically determines whether the policy grants the required permission to a specific principal only. If so, the operation is supported if the subject that is associated with the access control context contains the designated principal only.

Associate a subject with the current access control context by calling the static `doAs` method from the subject class, passing it an authenticated subject and the `java.security.PrivilegedAction` or `java.security.PrivilegedExceptionAction` method. The `doAs` method associates the provided subject with the

current access control context and then invokes the run method from the action. The run method implementation contains all the code that ran as the specified subject. The action runs as the specified subject.

In the Java 2 Platform, Enterprise Edition (J2EE) programming model, when invoking the Enterprise JavaBeans (EJB) method from an enterprise bean or servlet, the method runs under the user identity that is determined by the run-as setting. The J2EE Version 1.4 Specification does not indicate which user identity to use when invoking an enterprise bean from a Subject.doAs action block within either the EJB code or the servlet code. A logical extension is to use the proper identity that is specified in the subject when invoking the EJB method within the Subject doAs action block.

Letting the Subject.doAs action overwrite the run-as identity setting is an ideal way to integrate the JAAS programming model with the J2EE run-time environment. However, JAAS introduced an issue into the Software Development Kit (SDK), Java Technology Edition Versions 1.3 or later when integrating the JAAS Version 1.0 or later implementation with the Java 2 security architecture. A subject, which is associated with the access control context is cut off by a doPrivileged call when a doPrivileged call occurs within the Subject.doAs action block. Until this problem is corrected, no reliable and run-time efficient way is available to guarantee the correct behavior of Subject.doAs action in a J2EE run-time environment.

The problem can be explained better with the following example:

```
Subject.doAs(subject, new java.security.PrivilegedAction() {
    Public Object run() {
        // Subject is associated with the current thread context
        java.security.AccessController.doPrivileged( new
            java.security.PrivilegedAction() {
                public Object run() {
                    // Subject was cut off from the current
                    // thread context

                }
            }
        );
        return null;
    }
});
// Subject is associated with the current thread context
return null;
}
```

In the previous code example, the Subject object is associated with the context of the current thread. Within the run method of a doPrivileged action block, the Subject object is removed from the thread context. After leaving the doPrivileged block, the Subject object is restored to the current thread context. Because doPrivileged blocks can be placed anywhere along the running path and instrumented quite often in a server environment, the run-time behavior of a doAs action block becomes difficult to manage.

To resolve this difficulty, WebSphere Application Server provides a WSSubject helper class to extend the JAAS authorization to a J2EE EJB method invocation, as described previously. The WSSubject class provides static doAs and doAsPrivileged methods that have identical signatures to the subject class. The WSSubject.doAs method associates the Subject to the currently running thread. The WSSubject.doAs and WSSubject.doAsPrivileged methods then invoke the corresponding Subject.doAs and Subject.doAsPrivileged methods. The original credential is restored and associated with the running thread upon leaving the WSSubject.doAs and WSSubject.doAsPrivileged methods.

The WSSubject class is not a replacement of the subject object, but rather a helper class to ensure consistent run-time behavior as long as an EJB method invocation is a concern.

The following example illustrates the run-time behavior of the WSSubject.doAs method:

```

WSSubject.doAs(subject, new java.security.PrivilegedAction() {
    Public Object run() {
        // Subject is associated with the current thread context
        java.security.AccessController.doPrivileged( new
            java.security.PrivilegedAction() {
                public Object run() {
                    // Subject was cut off from the current thread
                    // context.

                }
            }
        );
        return null;
    }
});
// Subject is associated with the current thread context
return null;
}
});

```

The Subject.doAs and Subject.doAsPrivileged methods are not integrated with the J2EE run-time environment. EJB methods that are invoked within the Subject.doAs and Subject.doAsPrivileged action blocks run under the identity that is specified by the run-as setting and not by the subject identity.

- The Subject object that is generated by the WSLoginModuleImpl instance and the WSClientLoginModuleImpl instance contains a principal that implements the WSPrincipal interface. Using the getCredential method for a WSPrincipal object returns an object that implements the WSCredential interface. You can also find the WSCredential object instance in the PublicCredentials list of the subject instance. Retrieve the WSCredential object from the PublicCredentials list instead of using the getCredential method.
- The getCallerPrincipal method for the WSSubject class returns a string that represents the caller security identity. The return type differs from the getCallerPrincipal method of the java.security.Principal EJBContext interface.
- The Subject object that is generated by the Java 2 Connector (J2C) DefaultPrincipalMapping module contains a resource principal and a PasswordCredentials list. The resource principal represents the RunAs identity.

For more information, see J2EE connector security.

Using the Java Authentication and Authorization Service programming model for Web authentication

WebSphere Application Server supports the Java 2 Platform, Enterprise Edition (J2EE) declarative security model. You can define the authentication and access control policy using the J2EE deployment descriptor. You can further stack custom login modules to customize the WebSphere Application Server authentication mechanism.

A custom login module can perform principal and credential mapping, custom security token and custom credential-processing, and error-handling among other possibilities. Typically, you do not need to use application code to perform authentication function. Use the programming techniques that are described in this section if you have to perform authentication function in application code. For example, if you have applications that programmed to the SSOAuthenticator helper function, you can use the following programming interface. The SSOAuthenticator helper function was deprecated starting with WebSphere Application Server Version 4.0. Use declarative security as a rule; use the techniques that are described in this section as a last resort.

When the Lightweight Third-Party Authentication (LTPA) mechanism single sign-on (SSO) option is enabled, the Web client login session is tracked by an LTPA SSO token cookie after successful login. At logout, this token is deleted to terminate the login session, but the server-side subject is not deleted. When you use the declarative security model, the WebSphere Application Server Web container performs client authentication and login session management automatically. You can perform authentication in application code by setting a login page without a J2EE security constraint and by directing client requests to your

login page first. Your login page can use the Java Authentication and Authorization Service (JAAS) programming model to perform authentication. To enable WebSphere Application Server Web login modules to generate SSO cookies, use the following steps.

1. Select the `wsMapDefaultInboundLoginModule` login module and click **Custom properties**. There are two login modules defined in your login configuration: `ltpaLoginModule` and `wsMapDefaultInboundLoginModule`.
2. Create a new system login JAAS configuration. To access the panel, click **Security > Secure administration, applications, and infrastructure**. Under Java Authentication and Authorization Service, click **System logins**.
3. Manually clone the `WEB_INBOUND` login configuration, and give it a new alias. To clone the login configuration, click **New**, enter a name for the configuration, click **Apply**, then click **JAAS login modules** under Additional properties. Click **New** and configure the JAAS login module. For more information, see “Login module settings for Java Authentication and Authorization Service” on page 580. WebSphere Application Server Web container uses the `WEB_INBOUND` login configuration to authenticate Web clients. Changing the `WEB_INBOUND` login configuration affects all Web applications in the cell. You should create your own login configuration by cloning the contents of the `WEB_INBOUND` login configuration.
4. Select the `wsMapDefaultInboundLoginModule` login module and click **Custom properties**. There are two login modules defined in your login configuration: `ltpaLoginModule` and `wsMapDefaultInboundLoginModule`.
5. Add a login property name `cookie` with a value of **true**. The two login modules are enabled to generate LTPA SSO cookies. Do not add the cookie login option to the original `WEB_INBOUND` login configuration.
6. Stack your custom `LoginModule(s)` in the new login configuration (optional).
7. Use your login page for programmatic login by perform a `JAAS LoginContext.login` using your newly defined login configuration. After a successful login, either the `ltpaLoginModule` or the `wsMapDefaultInboundLoginModule` generates an LTPA SSO cookie upon a successful authentication. Exactly which `LoginModule` generates the SSO cookie depends on many factors, including system authentication configuration and runtime condition (which is beyond the scope of this section).
8. Call the modified `WSSubject.setRunAsSubject` method to add the subject to the authentication cache. The subject must be a WebSphere Application Server JAAS subject created by `LoginModule`. Adding the subject to the authentication cache recreates a subject from SSO token.
9. Use your programmatic logout page to revoke SSO cookies by invoking the `revokeSSOCookies` method from the `WSSecurityHelper` class. The term `cookies` is used because WebSphere Application Server Release 5.1.1 (and later) release supports a new LTPA SSO token with a different encryption algorithm, but can be configured to generate the original LTPA SSO token for backward compatibility. Note that the subject is still in the authentication cache and only the SSO cookies are revoked.

Use the following code sample to perform authentication:

Suppose you wrote a `LoginServlet.java`:

```
import com.ibm.wsspi.security.auth.callback.WSCallbackHandlerFactory;
import com.ibm.websphere.security.auth.WSSubject;

public Object login(HttpServletRequest req, HttpServletResponse res)
throws ServletException {

    PrintWriter out = null;
    try {
        out = res.getWriter();
        res.setContentType("text/html");
    } catch (java.io.IOException e){
        // Error handling
    }

    Subject subject = null;
```

```

try {
    LoginContext lc = new LoginContext("system.Your_login_configuration",
WSCallbackHandlerFactory.getInstance().getCallbackHandler(
userid, null, password, req, res, null));
    lc.login();
    subject = lc.getSubject();
    WSSubject.setRunAsSubject(subject);
} catch(Exception e) {
    // catch all possible exceptions if you want or handle them separately
    out.println("Exception in LoginContext login + Exception = " +
e.getMessage());
    throw new ServletException(e.getMessage());
}

```

The following is sample code to revoke the SSO cookies upon a programming logout:

The LogoutServlet.java:

```

public void logout(HttpServletRequest req, HttpServletResponse res,
Object retCreds) throws ServletException {
    PrintWriter out =null;
    try {
        out = res.getWriter();
        res.setContentType("text/html");
    } catch (java.io.IOException e){
        // Error Handling
    }
    try {
        WSSecurityHelper.revokeSSOCookies(req, res);
    } catch(Exception e) {
        // catch all possible exceptions if you want or handle them separately
        out.println("JAASLogoutServlet: logout Exception = " + e.getMessage());
        throw new ServletException(e);
    }
}

```

For more information on JAAS authentication, refer to [Developing programmatic logins with the Java Authentication and Authorization Service](#). For more information on the `AuthenLoginModule` login module, refer to [Example: Customizing a server-side Java Authentication and Authorization Service authentication and login configuration](#).

Chapter 6. Authorizing access to resources

WebSphere Application Server provides many different methods for authorizing accessing resources. For example, you can assign roles to users and configure a built-in or external authorization provider.

You can create an application, an Enterprise JavaBeans (EJB) module, or a Web module and secure them using assembly tools.

To authorize user or group access to resources, read the following articles:

1. Secure you application during assembly and deployment. For more information on how to create a secure application using an assembly tool, such as the IBM Rational Application Developer, see “Securing applications during assembly and deployment” on page 927.
For general information about the tools that WebSphere Application Server supports, see Assembly tools and Assembling applications.
2. Authorize access to Java 2 Platform, Enterprise Edition (J2EE) resources. WebSphere Application Server supports authorization that is based on the Java Authorization Contract for Containers (JACC) specification in addition to the default authorization. When security is enabled in WebSphere Application Server, the default authorization is used unless a JACC provider is specified. For more information, see “Authorization providers” on page 339.
3. Authorize access to administrative resources. You can assign users and groups to predefined administrative roles such as the monitor, configurator, operator, administrator, and iscadmins roles. These roles determine which tasks a user can perform in the administrative console. For more information, see “Authorizing access to administrative roles” on page 382.

After authorizing access to resources, configure the Application Server for secure communication. For more information, see Chapter 7, “Securing communications,” on page 391.

Authorization technology

Authorization information determines whether a user or group has the necessary privileges to access resources.

WebSphere Application Server supports many authorization technologies including the following:

- Authorization involving the Web container and Java 2 Platform, Enterprise Edition (J2EE) technology
- Authorization involving an enterprise bean application and J2EE technology
- Authorization involving Web services and J2EE technology
- Java Message Service (JMS)
- Java Authorization Contract for Containers (JACC)

WebSphere Application Server supports both a default authorization provider, which was supported in previous releases, and an authorization provider that is based on the Java Authorization Contract for Containers (JACC) specification. The JACC-based authorization provider enables third-party security providers to handle the J2EE authorization. For more information, see “JACC support in WebSphere Application Server” on page 340.

- Java Authentication and Authorization Service (JAAS)
For more information, see “Java Authentication and Authorization Service” on page 324.
- Java 2 security
For more information, see “Java 2 security” on page 61.
- Naming and administrative authorization
- Pluggable authorization

WebSphere Application Server supports an authorization infrastructure that enables you to plug in an external authorization provider. For more information, see “Enabling an external JACC provider” on page 364.

Administrative roles and naming service authorization

WebSphere Application Server extends the Java 2 Platform, Enterprise Edition (J2EE) security role-based access control to protect the product administrative and naming subsystems.

Administrative roles

A number of administrative roles are defined to provide the degrees of authority that are needed to perform certain WebSphere Application Server administrative functions from either the administrative console or the system management scripting interface called wsadmin. The authorization policy is only enforced when administrative security is enabled. The following table describes the administrative roles:

Table 12. Administrative roles that are available through the administrative console and wsadmin

Role	Description
Monitor	<p>An individual or group that uses the monitor role has the least amount of privileges. A monitor can complete the following tasks:</p> <ul style="list-style-type: none"> • View the WebSphere Application Server configuration. • View the current state of the Application Server.
Configurator	<p>An individual or group that uses the configurator role has the monitor privilege plus the ability to change the WebSphere Application Server configuration. The configurator can perform all the day-to-day configuration tasks. For example, a configurator can complete the following tasks:</p> <ul style="list-style-type: none"> • Create a resource. • Map an application server. • Install and uninstall an application. • Deploy an application. • Assign users and groups-to-role mapping for applications. • Set up Java 2 security permissions for applications. • Customize the Common Secure Interoperability Version 2 (CSIv2), Security Authentication Service (SAS), and Secure Sockets Layer (SSL) configurations. <p>Important: SAS is supported only between Version 6.0.x and previous version servers that have been federated in a Version 6.1 cell.</p>
Operator	<p>An individual or group that uses the operator role has monitor privileges plus ability to change the runtime state. For example, an operator can complete the following tasks:</p> <ul style="list-style-type: none"> • Stop and start the server. • Monitor the server status in the administrative console.

Table 12. Administrative roles that are available through the administrative console and wsadmin (continued)

Role	Description
Administrator	<p>An individual or group that uses the administrator role has the operator and configurator privileges plus additional privileges that are granted solely to the administrator role. For example, an administrator can complete the following tasks:</p> <ul style="list-style-type: none"> • Modify the server user ID and password. • Configure authentication and authorization mechanisms. • Enable or disable administrative security. <p>Note: In previous releases of WebSphere Application Server, the Enable administrative security option is known as the Enable global security option.</p> • Enforce Java 2 security using the Use Java 2 security to restrict application access to local resources option. • Change the Lightweight Third Party Authentication (LTPA) password and generate keys. • Create, update, or delete users in the federated repositories configuration. • Create, update, or delete groups in the federated repositories configuration. <p>Note: An administrator cannot map users and groups to the administrator roles.</p>
AdminSecurityManager	<p>Only users who are granted this role can map users to administrative roles. Also, when fine-grained administrative security is used, only users who are granted this role can manage authorization groups. See “Administrative roles” on page 336 for more information.</p>

Table 13. Additional administrative role that is available through the administrative console

Role	Description
iscadmins	<p>This role is only available for administrative console users and not for wsadmin users. Users who are granted this role have administrator privileges for managing users and groups in the federated repositories. For example, a user of the iscadmins role can complete the following tasks:</p> <ul style="list-style-type: none"> • Create, update, or delete users in the federated repositories configuration. • Create, update, or delete groups in the federated repositories configuration.

Table 14. Additional administrative role that is available through wsadmin

Role	Description
Deployer	<p>This role is only available for wsadmin users and not for administrative console users. Users who are granted this role can perform both configuration actions and run-time operations on applications.</p>

When administrative security is enabled, the administrative subsystem role-based access control is enforced. The administrative subsystem includes the security server, the administrative console, the wsadmin scripting tool, and all the Java Management Extensions (JMX) MBeans. When administrative security is enabled, both the administrative console and the administrative scripting tool require users to provide the required authentication data. Moreover, the administrative console is designed so the control functions that display on the pages are adjusted, according to the security roles that a user has. For example, a user who has only the monitor role can see only the non-sensitive configuration data. A user with the operator role can change the system state.

When you are changing registries (for example, from a federated repository to LDAP), make sure you remove the information that pertains to the previously configured registry for console users and console groups.

When administrative security is enabled, WebSphere Application Servers run under the server identity that is defined under the active user registry configuration. Although it is not shown on the administrative console and in other tools, a special Server subject is mapped to the administrator role. The WebSphere Application Server runtime code, which runs under the server identity, requires authorization to runtime operations. If no other user is assigned administrative roles, you can log into the administrative console or to the wsadmin scripting tool using the server identity to perform administrative operations and to assign other users or groups to administrative roles. Because the server identity is assigned to the administrative role by default, the administrative security policy requires the administrative role to perform the following operations:

- Change server ID and server password
- Enable or disable WebSphere Application Server administrative security
- Enforce Java 2 security using the **Use Java 2 security to restrict application access to local resources** option.
- Change the LTPA password or generate keys
- Assign users and groups to administrative roles

Primary administrative user name

The Version 6.1 release of WebSphere Application Server requires an administrative user, distinguished from the server user identity, to improve auditability of administrative actions. The user name specifies a user with administrative privileges that is defined in the local operating system.

Server user identity

The Version 6.1 release of WebSphere Application Server distinguishes the server identity from the administrative user identity to improve auditability. The server user identity is used for authenticating server-to-server communications.

Internal server ID

The internal server ID enables the automatic generation of the user identity for server-to-server authentication. Automatic generation of the server identity supports improved auditability for cells only for Version 6.1 or later nodes. In the Version 6.1 release of WebSphere Application Server, you can save the internally-generated server ID because the Security WebSphere Common Configuration Model (WCCM) model contains a new tag, internalServerId. You do not need to specify a server user ID and a password during security configuration except in a mixed-cell environment. An internally-generated server ID adds a further level of protection to the server environment because the server password is not exposed as it is in releases prior to Version 6.1. However, to maintain backwards compatibility, you must specify the server user ID if you use earlier versions of WebSphere Application Server.

When enabling security, you can assign one or more users and groups to naming roles. For more information, see Assigning users to naming roles. However, before assigning users to naming roles, configure the active user registry. User and group validation depends on the active user registry. For more information, see Configuring user registries.

Special subject

In addition to mapping users or groups, you can map a *special-subject* to the administrative roles. A special-subject is a generalization of a particular class of users. The AllAuthenticated special subject means that the access check of the administrative role ensures that the user making the request is at least authenticated. The Everyone special subject means that anyone, authenticated or not, can perform the action as if security is not enabled.

Naming service authorization

CosNaming security offers increased granularity of security control over CosNaming functions. CosNaming functions are available on CosNaming servers such as the WebSphere Application Server. These functions affect the content of the WebSphere Application Server name space. Generally, you have two ways in which client programs result in CosNaming calls. The first is through the Java Naming and Directory Interface (JNDI) call. The second is with common object request broker architecture (CORBA) clients invoking CosNaming methods directly.

Four security roles are introduced :

- CosNamingRead
- CosNamingWrite
- CosNamingCreate
- CosNamingDelete

The roles have authority levels from low to high:

CosNamingRead

You can query the WebSphere Application Server name space, using, for example, the JNDI lookup method. The special-subject, Everyone, is the default policy for this role.

CosNamingWrite

You can perform write operations such as JNDI bind, rebind, or unbind, and CosNamingRead operations. As a default policy, Subjects are not assigned this role.

CosNamingCreate

You can create new objects in the name space through such operations as JNDI createSubcontext and CosNamingWrite operations. As a default policy, Subjects are not assigned this role.

CosNamingDelete

You can destroy objects in the name space, for example using the JNDI destroySubcontext method and CosNamingCreate operations. As a default policy, Subjects are not assigned this role.

Additionally, a Server special-subject is assigned to all of the four CosNaming roles by default. The Server special-subject provides a WebSphere Application Server process, which runs under the server identity, to access all the CosNaming operations. The Server special-subject does not display and cannot be modified through the administrative console or other administrative tools.

Special configuration is not required to enable the server identity as specified when enabling administrative security for administrative use because the server identity is automatically mapped to the administrator role.

Users, groups, or the special subjects AllAuthenticated and Everyone can be added or removed to or from the naming roles from the WebSphere Application Server administrative console at any time. However, a server restart is required for the changes to take effect. A best practice is to map groups or one of the special-subjects, rather than specific users, to naming roles because it is more flexible and easier to administer in the long run. By mapping a group to a naming role, adding or removing users to or from the group occurs outside of WebSphere Application Server and does not require a server restart for the change to take effect.

The CosNaming authorization policy is only enforced when administrative security is enabled. When administrative security is enabled, attempts to do CosNaming operations without the proper role assignment result in an org.omg.CORBA.NO_PERMISSION exception from the CosNaming server.

Each CosNaming function is assigned to only one role. Therefore, users who are assigned the CosNamingCreate role cannot query the name space unless they have also been assigned CosNamingRead. And in most cases a creator needs to be assigned three roles: CosNamingRead, CosNamingWrite, and CosNamingCreate. The CosNamingRead and CosNamingWrite roles assignment for

the creator example are included in the CosNamingCreate role. In most of the cases, WebSphere Application Server administrators do not have to change the roles assignment for every user or group when they move to this release from a previous one.

Although the ability exists to greatly restrict access to the name space by changing the default policy, unexpected org.omg.CORBA.NO_PERMISSION exceptions can occur at runtime. Typically, J2EE applications access the name space and the identity they use is that of the user that authenticated to WebSphere Application Server when accessing the J2EE application. Unless the J2EE application provider clearly communicates the expected naming roles, use caution when changing the default naming authorization policy.

Role-based authorization

Use authorization information to determine whether a caller has the necessary privileges to request a service.

The following figure illustrates the process that is used during authorization.

Authentication

Web resource access from a Web client is handled by a Web collaborator. The Enterprise JavaBeans (EJB) resource access from a Java client, whether an enterprise bean or a servlet, is handled by an EJB collaborator. The EJB collaborator and the Web collaborator extract the client credentials from the object request broker (ORB) current object. The client credentials are set during the authentication process as received credentials in the ORB current object. The resource and the received credentials are presented to the WSAccessManager access manager to check whether access is permitted to the client for accessing the requested resource.

The access manager module contains two main modules:

- The resource permission module helps determine the required roles for a given resource. This module uses a resource-to-roles mapping table that is built by the security runtime during application startup. To build the resource-to-role mapping table, the security runtime reads the deployment descriptor of the enterprise beans or the Web module (ejb-jar.xml file or web.xml file)

- The authorization table module consults a role-to-user or group table to determine whether a client is granted one of the required roles. The role-to-user or group mapping table, also known as the *authorization table*, is created by the security runtime during application startup.

To build the authorization table, the security runtime reads the `ibm-application-bnd.xml` application binding file.

Use authorization information to determine whether a caller has the necessary privilege to request a service. You can store authorization information many ways. For example, with each resource, you can store an access-control list, which contains a list of users and user privileges. Another way to store the information is to associate a list of resources and the corresponding privileges with each user. This list is called a *capability list*.

WebSphere Application Server uses the Java 2 Platform, Enterprise Edition (J2EE) authorization model. In this model, authorization information is organized as follows:

During the assembly of an application, permission to invoke methods is granted to one or more roles. A role is a set of permissions; for example, in a banking application, roles can include teller, supervisor, clerk, and other industry-related positions. The teller role is associated with permissions to run methods that are related to managing the money in an account, such as the withdraw and deposit methods. The teller role is not granted permission to close accounts; this permission is given to the supervisor role. The application assembler defines a list of method permissions for each role. This list is stored in the deployment descriptor for the application.

Two *special subjects* are not defined by the J2EE model: `AllAuthenticatedUsers` and `Everyone`. A special subject is a product-defined entity that is independent of the user registry. This entity is used to generically represent a class of users or groups in the registry.

- The `AllAuthenticatedUsers` subject permits all authenticated users to access protected methods. As long as the user can authenticate successfully, the user is permitted access to the protected resource. All of this is done independent of the user registry.
- `Everyone` is a special subject that permits unrestricted access to a protected resource. Users do not have to authenticate to get access; this special subject provides access to protected methods as if the resources are unprotected. All of this is done independent of the user registry.

During the deployment of an application, real users or groups of users are assigned to the roles. When a user is assigned to a role, the user gets all the method permissions that are granted to that role.

The application deployer does not need to understand the individual methods. By assigning roles to methods, the application assembler simplifies the job of the application deployer. Instead of working with a set of methods, the deployer works with the roles, which represent semantic groupings of the methods.

Users can be assigned to more than one role; the permissions that are granted to the user are the union of the permissions granted to each role. Additionally, if the authentication mechanism supports the grouping of users, these groups can be assigned to roles. Assigning a group to a role has the same effect as assigning each individual user to the role.

A best practice during deployment is to assign groups instead of individual users to roles for the following reasons:

- Improves performance during the authorization check. Typically far fewer groups exist than users.
- Provides greater flexibility, by using group membership to control resource access.
- Supports the addition and deletion of users from groups outside of the product environment. This action is preferred to adding and removing them to WebSphere Application Server roles. Stop and restart the enterprise application for these changes to take effect. This action can be very disruptive in a production environment.

At runtime, WebSphere Application Server authorizes incoming requests based on the user's identification information and the mapping of the user to roles. If the user belongs to any role that has permission to run a method, the request is authorized. If the user does not belong to any role that has permission, the request is denied.

The J2EE approach represents a declarative approach to authorization, but it also recognizes that you cannot deal with all situations declaratively. For these situations, methods are provided for determining user and role information programmatically. For enterprise beans, the following two methods are supported by WebSphere Application Server:

- **getCallerPrincipal**: This method retrieves the user identification information.
- **isCallerInRole**: This method checks the user identification information against a specific role.

For servlets, the following methods are supported by WebSphere Application Server:

- getRemoteUser
- isUserInRole
- getUserPrincipal

These methods correspond in purpose to the enterprise bean methods.

For more information on the J2EE security authorization model, see the following Web site:
<http://java.sun.com>

Administrative roles

The Java 2 Platform, Enterprise Edition (J2EE) role-based authorization concept is extended to protect the WebSphere Application Server administrative subsystem.

A number of administrative roles are defined to provide degrees of authority that are needed to perform certain administrative functions from either the Web-based administrative console or the system management scripting interface. The authorization policy is only enforced when administrative security is enabled. The following table describes the administrative roles:

Administrative roles

Role	Description
Monitor	An individual or group that uses the monitor role has the least amount of privileges. A monitor can complete the following tasks: <ul style="list-style-type: none"> • View the WebSphere Application Server configuration. • View the current state of the Application Server.
Configurator	An individual or group that uses the configurator role has the monitor privilege plus the ability to change the WebSphere Application Server configuration. The configurator can perform all the day-to-day configuration tasks. For example, a configurator can complete the following tasks: <ul style="list-style-type: none"> • Create a resource. • Map an application server. • Install and uninstall an application. • Deploy an application. • Assign users and groups-to-role mapping for applications. • Set up Java 2 security permissions for applications. • Customize the Common Secure Interoperability Version 2 (CSIv2), Security Authentication Service (SAS), and Secure Sockets Layer (SSL) configurations. <p>Important: SAS is supported only between Version 6.0.x and previous version servers that have been federated in a Version 6.1 cell.</p>

Administrative roles

Operator	An individual or group that uses the operator role has monitor privileges plus ability to change the runtime state. For example, an operator can complete the following tasks: <ul style="list-style-type: none">• Stop and start the server.• Monitor the server status in the administrative console.
Administrator	An individual or group that uses the administrator role has the operator and configurator privileges plus additional privileges that are granted solely to the administrator role. For example, an administrator can complete the following tasks: <ul style="list-style-type: none">• Modify the server user ID and password.• Configure authentication and authorization mechanisms.• Enable or disable administrative security.• Enable or disable Java 2 security.• Change the Lightweight Third Party Authentication (LTPA) password and generate keys.• Create, update, or delete users in the federated repositories configuration.• Create, update, or delete groups in the federated repositories configuration. Note: An administrator cannot map users and groups to the administrator roles.
iscadmins	This role is only available for administrative console users, not for wsadmin users. Users who are granted this role have administrator privileges for managing users and groups in the federated repositories. For example, a user of the iscadmins role can complete the following tasks: <ul style="list-style-type: none">• Create, update, or delete users in the federated repositories configuration.• Create, update, or delete groups in the federated repositories configuration.
Deployer	This role is only available for wsadmin users, not for administrative console users. Users granted this role can perform both configuration actions and runtime operations on applications. See the “Deployer role” section for more details.
AdminSecurityManager	This role is only available for wsadmin users, not for administrative console users. When using wsadmin, users granted this role can map users to administrative roles. Also, when fine grained admin security is used, users granted this role can manage authorization groups. See the “AdminSecurityManager role” on page 338 section for more details.

The server ID that is specified and the administrative ID, if specified, when enabling administrative security is automatically mapped to the administrator role.

Users and groups can be added or removed from the administrative roles from the WebSphere Application Server administrative console at any time. A best practice is to map a group or groups, rather than specific users, to administrative roles because it is more flexible and easier to administer.

In addition to mapping user or groups, a special-subject can also be mapped to the administrative roles. A special-subject subject is a generalization of a particular class of users. The AllAuthenticated special subject means that the access check of the administrative role ensures that the user making the request is at least authenticated. The Everyone special subject means that anyone, authenticated or not, can perform the action, as if security was not enabled.

Deployer role

A user that is granted a deployer role can perform all of the configuration and runtime operations on an application. A deployer role can be subsets of both configurator and operator roles. However, a user granted a deployer role cannot configure or operate any other resources (server, node).

When fine-grained administrative security is used, only a user granted a deployer role to an application can configure and operate that application.

Cell level configurators can configure applications (install, edit, deploy, and uninstall). Cell level operators can also operate (start and stop) applications. However, a user granted a deployer role at cell level can also perform configuration and operation on all applications.

The following table lists the capabilities of the deployer role when fine-grained administrative security is used:

Operation	Required Roles (Any one)
Install application	Cell-configurator, target-deployer
Uninstall application	Cell-configurator, application-deployer
List application	Cell-monitor, application-monitor
Edit, update and redeploy application	Cell-configurator, application-deployer
Export application	Cell-monitor, application-monitor
Start-stop application	Cell-operator, application-deployer

Where:

Cell-configurator

is the configurator role at cell level.

Application-deployer

is the deployer role for the application that is being managed.

Target-deployer

is the deployer role for all servers or clusters for which an application is targeted. If you have a target-deployer role, you can install a new application on the target. However, to edit or update the installed application, you must be included in the authorization group of the installed application-deployer.

The target-deployer can not explicitly start or stop a new application. However, when a target-deployer starts a server on a target, all of the applications that have their auto-start attribute set to yes are started when the server starts.

It is recommended that the application-deployer set this attribute to true if the application-deployer does not want the application to be started by the target-deployer.

AdminSecurityManager role

The AdminSecurityManager role separates administrative security administration from other application administration.

By default, serverId and adminID, if specified, are assigned to this role in the cell level authorization table. This role implies a monitor role. However, an administrator role does not imply the AdminSecurityManager role.

When fine-grained admin security is used, only a user granted this role at cell level can manage administrative authorization groups. However, a user granted this role for each administrative authorization group can map users to administrative roles for those groups. The following lists the capabilities of the AdminSecurityManager role at different levels (cell and administrative authorization group):

Action	Who can perform
Map users to administrative roles for cell level	Only the AdminSecurityManager of the cell

Action	Who can perform
Map users to administrative roles for an authorization group	Only the AdminSecurityManager of that authorization group or the AdminSecurityManager of the cell
Manage authorization groups (create, delete, add resource to an authorization group, or remove resource from an authorization group or list)	Only the AdminSecurityManager of the cell

Related tasks

“Assigning users to naming roles” on page 387

Use this task to assign users to naming roles by using the administrative console.

Enterprise bean component security

An Enterprise JavaBeans (EJB) module consists of one or more beans. You can use development tools such as Rational Application Developer to develop an EJB module. You can also enforce security at the EJB method level.

You can assign a set of EJB methods to a set of one or more roles. When an EJB method is secured by associating a set of roles, grant at least one role in that set so that you can access that method. To exclude a set of EJB methods from access mark the set **excluded**. You can give everyone access to a set of enterprise beans methods by clearing those methods. You can run enterprise beans as a different identity, using the runAs identity, before invoking other enterprise beans.

Authorization providers

WebSphere Application Server supports authorization that is based on the Java Authorization Contract for Containers (JACC) specification in addition to the default authorization.

JACC is a new specification in Java 2 Platform, Enterprise Edition (J2EE) 1.4. It enables third-party security providers to manage authorization in the application server.

When security is enabled in WebSphere Application Server, the default authorization is used unless a JACC provider is specified. The default authorization does not require special setup, and the default authorization engine makes all of the authorization decisions. However, if a JACC provider is configured and set up for WebSphere Application Server to use, all of the enterprise beans and Web authorization decisions are delegated to the JACC provider.

WebSphere Application Server supports security for J2EE applications and also for its administrative components. J2EE applications, such as Web and Enterprise JavaBeans (EJB) components are protected and authorized per the J2EE specification. The administrative components are internal to WebSphere Application Server and are protected by the role-based authorizer. The administrative components include the administrative console, MBeans, and other components such as naming and security. For more information on administrative security, see “Role-based authorization” on page 334.

When a JACC provider is used for authorization in WebSphere Application Server, all of the J2EE application-based authorization decisions are delegated to the provider per the JACC specification. However, all administrative security authorization decisions are made by the WebSphere Application Server default authorization engine. The JACC provider is not called to make the authorization decisions for administrative security.

When a protected J2EE resource is accessed, the authorization decision to give access to the principal is the same whether using the default authorization engine or a JACC provider. Both of the authorization models satisfy the J2EE specification, and function the same. Choose a JACC provider only when you want to work with an external security provider such as Tivoli Access Manager. In this instance, the security provider must support the JACC specification and be set up to work with WebSphere Application

Server. Setting up and configuring a JACC provider requires additional configuration steps, depending on the provider. Unless you have an external security provider that you can use with WebSphere Application Server, use the default authorization.

JACC support in WebSphere Application Server

WebSphere Application Server supports the Java Authorization Contract for Containers (JACC) specification, which enables third-party security providers to handle the Java 2 Platform, Enterprise Edition (J2EE) authorization.

The JACC specification requires that both the containers in the application server and the provider satisfy some requirements. Specifically, the containers are required to propagate the security policy information to the provider during the application deployment and to call the provider for all authorization decisions. The providers are required to store the policy information in their repository during application deployment. The providers then use this information to make authorization decisions when called by the container.

JACC access decisions

When security is enabled and an enterprise bean or Web resource is accessed, the Enterprise JavaBeans (EJB) container or Web container calls the security runtime to make an authorization decision on whether to permit access. When using an external provider, the access decision is delegated to that provider.

According to the Java Authorization Contract for Containers (JACC) specification, the appropriate permission object is created, the appropriate policy context handlers are registered, and the appropriate policy context identifier (contextID) is set. A call is made to the `java.security.Policy` object method that is implemented by the provider to make the access decision.

The following sections describe how the provider is called for both the enterprise bean and the Web resources.

Access decisions for enterprise beans

When security is enabled, and an EJB method is accessed, the EJB container delegates the authorization check to the security runtime. If JACC is enabled, the security runtime uses the following process to perform the authorization check:

1. Creates the `EJBMethodPermission` object using the bean name, method name, interface name, and the method signature.
2. Creates the context ID and sets it on the thread by using the `PolicyContext.setContextID(contextID)` method.
3. Registers the required policy context handlers, including the Subject policy context handler.
4. Creates the `ProtectionDomain` object with principal in the Subject. If no principal exists, null is passed for the principal name.
5. The access decision is delegated to the JACC provider by calling the `implies` method of the `Policy` object, which is implemented by the provider. The `EJBMethodPermission` and the `ProtectionDomain` objects are passed to this method.
6. The `isCallerInRole` access check also follows the same process, except that an `EJBRoleRefPermission` object is created instead of an `EJBMethodPermission` object.

Access decisions for Web resources

When security is enabled and configured to use a JACC provider, and when a Web resource such as a servlet or a JavaServer Pages (JSP) file is accessed, the security runtime delegates the authorization decision to the JACC provider by using the following process:

1. A `WebResourcePermission` object is created to see if the URI is cleared. If the provider honors the Everyone subject it is also selected here.

- a. The `WebResourcePermission` object is constructed with the `urlPattern` and the HTTP method accessed.
 - b. A `ProtectionDomain` object with a null principal name is created.
 - c. The JACC provider `Policy.implies` method is called with the permission and the protection domain. If the URI access is cleared or given access to the `Everyone` subject, the provider permits access (return `true`) in the `implies` method. Access is then granted without further checks.
2. If access is not granted in the previous step, a `WebUserDataPermission` object is created and used to see if the Uniform Resource Identifier (URI) is precluded, excluded or must be redirected using the HTTPS protocol.
 - a. The `WebUserDataPermission` object is constructed with the `urlPattern` accessed, the HTTP method invoked, and the transport type of the request. If the request is over HTTPS, the transport type is set to `CONFIDENTIAL`; otherwise, null is passed.
 - b. A `ProtectionDomain` object with a null principal name is created.
 - c. The JACC provider `Policy.implies` method is called with the permission and the protection domain. If the request is using the HTTPS protocol and the `implies` method returns `false`, the HTTP 403 error is returned to imply excluded and precluded permission. In this case no further checks are performed. If the request is not using the HTTPS protocol, and the `implies` returns `false`, the request is redirected over HTTPS.
 3. The security runtime attempts to authenticate the user. If the authentication information already exists (for example, LTPA token), it is used. Otherwise, the user's credentials must be entered.
 4. After the user credentials are validated, a final authorization check is performed to see if the user is granted access privileges to the URI.
 - a. As in Step 1, the `WebResourcePermission` object is created. The `ProtectionDomain` object now contains the Principal that is attempting to access the URI. The Subject policy context handler also contains the user's information, which can be used for the access check.
 - b. The provider `implies` method is called using the `Permission` object and the `ProtectionDomain` object created previously. If the user is granted permission to access the resource, the `implies` method returns `true`. If the user is not granted access, the `implies` method returns `false`.

Even if the order listed previously is changed later (for example, to improve performance) the end result is the same. For example, if the resource is precluded or excluded, the end result is that the resource cannot be accessed.

Using information from the Subject for access decision

If the provider relies on the WebSphere Application Server generated Subject for access decision, the provider can query the public credentials in the Subject to obtain the `WSCredential` credential. The `WSCredential` API is used to obtain information about the user, including the name and the groups that the user belongs to. This information is used to make the access decision.

If the provider adds the required information to the Subject, WebSphere Application Server can use the information to make the access decision. The provider might add the information by using the Trust Association Interface feature or by plugging login modules into the Application Server.

The security attribute propagation section contains additional documentation on how to add the WebSphere Application Server required information to the Subject. For more information, see "Propagating security attributes among application servers" on page 279.

Dynamic module updates in JACC

WebSphere Application Server supports dynamic updates to Web modules under certain conditions. If a Web module is updated, deleted or added to an application, only that module is stopped and started as appropriate. The other existing modules in the application are not impacted, and the application itself is not stopped and then restarted.

When using the default authorization engine, any security policies are modified in the Web modules and the application is stopped and then restarted. When using the Java Authorization Contract for Containers (JACC) based authorization, the behavior depends on the functionality that a provider supports. If a provider can handle dynamic changes to the Web modules, then only the Web modules are impacted. Otherwise, the entire application is stopped and restarted for the new changes in the Web modules to take effect.

A provider can indicate if it supports the dynamic updates by configuring the **Supports dynamic module updates** option in the JACC configuration model (see “Authorizing access to J2EE resources using Tivoli Access Manager” on page 360 for more information). This option can be enabled or disabled using the administrative console or by scripting. It is expected that most providers store the policy information in their external repository, which makes it possible for them to support these dynamic updates. This option should be enabled by default for most providers.

When the **Supports dynamic module updates** option is enabled, if a Web module that contains security roles is dynamically added, modified, or deleted, only the specific Web modules are impacted and restarted. If the option is disabled, the entire application is restarted. When dynamic updates are performed, the security policy information of the modules impacted are propagated to the provider. For more information about security policy propagation, see “JACC policy propagation” on page 344.

Initialization of the JACC provider

If a Java Authorization Contract for Containers (JACC) provider requires initialization during server startup, for example, to enable the client code to communicate to the server code, the provider can implement the `com.ibm.wsspi.security.authorization.InitializeJACCProvider` interface. See “Interfaces that support JACC” on page 377 for more information.

When this interface is implemented, it is called during server startup. Any custom properties in the JACC configuration model are propagated to the `initialize` method of this implementation. The custom properties can be entered using either the administrative console or by scripting.

During server shutdown, the `cleanup` method is called for any clean-up work that a provider requires. Implementation of this interface is strictly optional, and is used only if the provider requires initialization during server startup.

Mixed node environment and JACC

Authorization using Java Authorization Contract for Containers (JACC) is a new feature in WebSphere Application Server Version 6.0.x. Also, the JACC configuration is set up at the cell level and is applicable for all the nodes and servers in that cell.

If you are planning to use the JACC-based authorization, the cell must contain Version 6.0.x and later nodes only. This restriction implies that a mixed node environment containing a set of Version 5.x nodes in a Version 6.0.x or later cell is not supported.

JACC providers

The Java Authorization Contract for Containers (JACC) is a new specification that is introduced in Java 2 Platform, Enterprise Edition (J2EE) Version 1.4 through the Java Specifications Request (JSR) 115 process. This specification defines a contract between J2EE containers and authorization providers.

The contract enables third-party authorization providers to plug into J2EE 1.4 application servers, such as WebSphere Application Server, to make the authorization decisions when a J2EE resource is accessed. The access decisions are made through the standard `java.security.Policy` object.

In WebSphere Application Server, two authorization contracts are supported using both a native and a third-party JACC provider implementation.

To plug in to WebSphere Application Server, the third-party JACC provider must implement the policy class, policy configuration factory class, and policy configuration interface, which are all required by the JACC specification.

The JACC specification does not specify how to handle the authorization table information between the container and the provider. It is the responsibility of the provider to provide some management facilities to handle this information. The container is not required to provide the authorization table information in the binding file to the provider.

WebSphere Application Server provides the RoleConfigurationFactory and the RoleConfiguration role configuration interfaces to help the provider obtain information from the binding file, as well as an initialization interface (InitializeJACCProvider). The implementation of these interfaces is optional. See “Interfaces that support JACC” on page 377 for more information about these interfaces.

Tivoli Access Manager as the default JACC provider for WebSphere Application Server

The JACC provider in WebSphere Application Server is implemented by both the client and the server pieces of the Tivoli Access Manager. The client piece of Tivoli Access Manager is embedded in WebSphere Application Server. The server piece is located on a separate installable CD that is shipped as part of the WebSphere Application Server Network Deployment (ND) package.

The JACC provider is not the default authorization. You must configure WebSphere Application Server to use the JACC provider.

JACC policy context handlers

WebSphere Application Server supports all of the policy context handlers that are required by the Java Authorization Contract for Containers (JACC) specification. However, due to performance impacts, the Enterprise JavaBeans (EJB) arguments policy context handler is not activated unless it is specifically required by the provider. Performance impacts result if objects must be created for each arguments of each EJB method.

If the provider supports and requires this context handler, select the **Requires the EJB arguments policy context handler for access decisions** check box in the External JACC provider link under the Authorization providers panel or by using scripting. Any changes to this option are effective after the servers are restarted. By default this option is disabled. Disable this option when using Tivoli Access Manager as the JACC provider, because the argument values are not required for access decisions.

JACC policy context identifiers (ContextID) format

A policy context identifier is defined as a unique string that represents a policy context. A policy context contains all of the security policy statements as defined by the Java Contract for Containers (JACC) specification that affect access to the resources in a Web or Enterprise JavaBeans (EJB) module.

During policy propagation to the JACC provider, a PolicyConfiguration object is created for each policy context. The object is populated with the policy statements, represented by the JACC permission objects that correspond to the context. The object is propagated to the JACC provider using the JACC specification APIs.

WebSphere Application Server makes the contextID unique by using the href:cellName/appName/moduleName string as the contextID format for the modules. The href part of the string indicates that a hierarchical name is passed as the context ID.

The cellName represents the name of the deployment manager cell or the base cell where the application is installed. After an application is installed in one cell (for example, in a base application server where the cell name is base1) and is added to a deployment manager cell whose name is cell1 by using addNode, the context ID for the modules in the application contain base1 (not cell1) as the cell name because the application is initially installed in base1.

The `appName` part of the string in the context ID represents the application name containing the module. The `moduleName` refers to the name of the module.

As an example, the context ID for the module `Increment.jar` file in an application named `DefaultApplication` that is installed in `cell1` is the `href:cell1/DefaultApplication/Increment.jar` file.

JACC policy propagation

When an application is installed or deployed in WebSphere Application Server, the security policy information in the application is propagated to the provider when the configuration is saved. The context ID for the application is saved in its `application.xml` file, that is used for propagating the policy to the Java Authorization Contract for Containers (JACC) provider, and also for access decisions for Java 2 Platform, Enterprise Edition (J2EE) resources.

When an application is uninstalled, the security policy information in the application is removed from the provider when the configuration is saved.

If the provider implemented the `RoleConfiguration` interface, the security policy information that is propagated to the policy provider also contains the authorization table information. See “Interfaces that support JACC” on page 377 for more information about this interface.

If an application does not contain security policy information, the `PolicyConfiguration` (and the `RoleConfiguration`, if implemented) objects do not contain any information. The existence of empty `PolicyConfiguration` and `RoleConfiguration` objects indicates that security policy information for the module does not exist.

After an application is installed, it can be updated without being uninstalled and reinstalled. For example, a new module can be added to an existing application, or an existing module can be modified. In this instance, the information in the impacted modules is propagated to the provider by default. A module is impacted when the deployment descriptor of the module is changed as part of the update. If the provider supports the `RoleConfiguration` interfaces, the entire authorization table for that application is propagated to the provider.

If the security information is not propagated to the provider during application updates, you can set the `com.ibm.websphere.security.jacc.propagateonappupdate` Java virtual machine (JVM) property to `false` in the deployment manager, in a Network Deployment environment, or the unmanaged base application server. If this property is set to `false`, any updates to an existing application in the server are not propagated to the provider. You also can set this property on a per-application basis using the custom properties of an application. The `wsadmin` tool can be used to set the custom property of an application. If this property is set at the application level, any updates to that application are not propagated to the provider. If the update to an application is a full update, for example, a new application enterprise archive (EAR) file is used to replace the existing one, and the provider is refreshed with the entire application security policy information.

When an application is installed and saved, the security policy information in that application is updated in the provider from the deployment manager. The application is not propagated to its respective nodes until the synchronization command is issued and completed. Also, when an application is uninstalled and saved at the deployment manager, the policy for that application is removed from the JACC provider.

However, unless the synchronization command is issued and completed from the deployment manager to the nodes hosting the application, the applications are still running in the respective nodes. In this instance, deny any access to this application because the JACC provider does not contain the required information to make the access decision for that application. Any updates to the application already installed as described previously are also propagated to the provider from the deployment manager. The changes in the provider are not synchronized with the applications in the nodes until the synchronization is completed.

As mentioned earlier, the security policy information is propagated to the JACC provider during the save operation. The `SystemOut.log` file indicates the success or failure of the propagation to the provider. Check the log file after the installation to ensure that the propagation had no problems. If the propagation had any problems, access to the application fails when Tivoli Access Manager is used as the JACC provider.

If the security policy information for the application is successfully propagated to the provider, the audit statements with the message key `SECJ0415I` appear. However, if there was a problem propagating the security policy information to the provider (for example: network problems, JACC provider is not available), the `SystemOut.log` files contain the error message with the message keys `SECJ0396E` during install or `SECJ0398E` during modification. The installation of the application is not stopped due to a failure to propagate the security policy to the JACC provider. Also, in the case of failure, no exception or error messages appear during the save operation. When the problem causing this failure is fixed, run the **propagatePolicyToJaccProvider** tool to propagate the security policy information to the provider without reinstalling the application. For more information, see “Propagating security policy of installed applications to a JACC provider using wsadmin scripting” on page 666.

JACC registration of the provider implementation classes

The JACC specification states that providers can plug in their provider using the `javax.security.jacc.policy.provider` and the `javax.security.jacc.PolicyConfigurationFactory.provider` system properties.

The `javax.security.jacc.policy.provider` property is used to set the policy object of the provider, while the `javax.security.jacc.PolicyConfigurationFactory.provider` property is used to set the provider `PolicyConfigurationFactory` implementation.

Although both system properties are supported in WebSphere Application Server, it is highly recommended that you use the configuration model that is provided. You can set these values using either the JACC configuration panel (see “Authorizing access to J2EE resources using Tivoli Access Manager” on page 360 for more information) or by using wsadmin scripting. One of the advantages of using the configuration model instead of the system properties is that the information is entered in one place at the cell level, and is propagated to all nodes during synchronization. Also, as part of the configuration model, additional properties can be entered, as described in the JACC configuration panel.

Using the configuration model is especially recommended in the case of a Network Deployment (ND) environment where multiple application servers can exist in the configuration. If the system properties are used, you must ensure that each of the Java virtual machine (JVM) processes in the configuration set these properties. If the configuration model is used, the information is propagated to all processes through the synchronization process of the application server.

Role-based security with embedded Tivoli Access Manager

The Java 2 Platform, Enterprise Edition (J2EE) role-based authorization model uses the concepts of roles and resources. An example is provided here.

Roles	Methods		
	getBalance	deposit	closeAccount
Teller	granted	granted	
Cashier	granted		
Supervisor			granted

In the example of the banking application that is conceptualized in the previous table, three roles are defined: teller, cashier, and supervisor. Permission to perform the `getBalance`, `deposit`, and `closeAccount` application methods are mapped to these roles. From the example, you can see that users assigned the role, Supervisor, can run the `closeAccount` method, whereas the other two roles are unable to run this method.

The term, principal, within WebSphere Application Server security refers to a person or a process that performs activities. *Groups* are logical collections of principals that are configured in WebSphere Application Server to promote the ease of applying security. Roles can be mapped to principals, groups, or both. The entry that is invoked in the following table indicates that the principal or group can invoke any methods that are granted to that role.

Principal/Group	Roles		
	Teller	Cashier	Supervisor
TellerGroup	Invoke		
CashierGroup		Invoke	
SupervisorGroup			
Frank: A principal who is not a member of any of the previous groups		Invoke	Invoke

In the previous example, the principal Frank, can invoke the `getBalance` and the `closeAccount` methods, but cannot invoke the `deposit` method because this method is not granted either the Cashier or the Supervisor role.

At the time of application deployment, the Java Authorization Contract for Container (JACC) provider of Tivoli Access Manager populates the Tivoli Access Manager-protected object space with any security policy information that is contained in the application deployment descriptor. This security information is used to determine access whenever the WebSphere Application Server resource is requested.

By default, the Tivoli Access Manager access check is performed using the role name, the cell name, the application name, and the module name.

Tivoli Access Manager access control lists (ACLs) determine which application roles are assigned to a principal. ACLs are attached to the applications in the Tivoli Access Manager-protected object space at the time of application deployment.

Principal-to-role mappings are managed from the WebSphere Application Server administrative console and are never modified using Tivoli Access Manager. Direct updates to ACLs are performed for administrative security users only.

The following sequence of events occur:

1. During application deployment, policy information is sent to the JACC provider of Tivoli Access Manager. This policy information contains permission-to-role mappings and role-to-principal and role-to-group mapping information.
2. The JACC provider of Tivoli Access Manager converts the information into the required format, and passes this information to the Tivoli Access Manager policy server.
3. The policy server adds entries to the Tivoli Access Manager-protected object space to represent the roles that are defined for the application and the permission-to-role mappings. A permission is represented as a Tivoli Access Manager-protected object and the role that is granted to this object is attached as an extended attribute.

Tivoli Access Manager integration as the JACC provider

Tivoli Access Manager uses the Java Authorization Contract for Container (JACC) model in WebSphere Application Server to perform access checks.

Tivoli Access Manager consists of the following components:

- Run time
- Client configuration
- Authorization table support

- Access check
- Authentication using the PDLoginModule module

Tivoli Access Manager run-time changes that are used to support JACC

For the run-time changes, Tivoli Access Manager implements the PolicyConfigurationFactory and the PolicyConfiguration interfaces, as required by JACC. During the application installation, the security policy information in the deployment descriptor and the authorization table information in the binding files are propagated to the Tivoli provider using these interfaces. The Tivoli provider stores the policy and the authorization table information in the Tivoli Access Manager policy server by calling the respective Tivoli Access Manager application programming interfaces (API).

Tivoli Access Manager also implements the RoleConfigurationFactory and the RoleConfiguration interfaces. These interfaces are used to ensure that the authorization table information is passed to the provider with the policy information. See “Interfaces that support JACC” on page 377 for more information about these interfaces.

Tivoli Access Manager client configuration

To configure the Tivoli Access Manager client, you can use either the administrative console or wsadmin scripting. You can access the administrative console panels for the Tivoli Access Manager client configuration by clicking **Security > Secure administration, applications, and infrastructure > External authorization providers**. Under Related Items, click **External JACC provider**. The Tivoli client must be set up to use the Tivoli Access Manager JACC Provider.

For more information about how to configure the Tivoli Access Manager client, see “Tivoli Access Manager JACC provider configuration” on page 367.

Authorization table support

Tivoli Access Manager uses the RoleConfiguration interface to ensure that the authorization table information is passed to the Tivoli Access Manager provider when the application is installed or deployed. When an application is deployed or edited, the set of users and groups for the user or group-to-role mapping are obtained from the Tivoli Access Manager server, which shares the same Lightweight Directory Access Protocol (LDAP) server as WebSphere Application Server. This sharing is accomplished by plugging into the application management users or groups-to-role administrative console panels. The management APIs are called to obtain users and groups rather than relying on the WebSphere Application Server-configured LDAP registry.

The user or group-to-role mapping is on the application level, not on the node level.

Access check

When WebSphere Application Server is configured to use the JACC provider for Tivoli Access Manager, it passes the information to Tivoli Access Manager to make the access decision. The Tivoli Access Manager policy implementation queries the local replica of the access control list (ACL) database for the access decision.

Authentication using the PDLoginModule module

The custom login module in WebSphere Application Server can do the authentication. This login module is plugged in before the WebSphere Application Server-provided login modules. The custom login modules can provide information that can be stored in the Subject. If the required information is stored, no additional registry calls are made to obtain that information.

As part of the JACC integration, the Tivoli Access Manager-provided PDLoginModule module is also used to plug into WebSphere Application Server for both Lightweight Third Party Authentication (LTPA) and Simple WebSphere Authentication Mechanism (SWAM) authentication. The PDLoginModule module is modified to authenticate with the user ID or password. The module is also used to fill in the required attributes in the Subject so that no registry calls are made by the login modules in WebSphere Application Server. The information that is placed in the Subject is available for the Tivoli Access Manager policy object to use for access checking.

Note: **V6.0.x** SWAM is deprecated in WebSphere Application Server Version 6.1 and will be removed in a future release.

Tivoli Access Manager security for WebSphere Application Server

WebSphere Application Server provides embedded IBM Tivoli Access Manager client technology to secure your WebSphere Application Server-managed resources.

The benefits of using Tivoli Access Manager that are described here are only applicable when Tivoli Access Manager client code is used with the Tivoli Access Manager server:

- Robust container-based authorization
- Centralized policy management
- Management of common identities, user profiles, and authorization mechanisms
- Single-point security management for Java 2 Platform, Enterprise Edition (J2EE) compliant and non-compliant J2EE resources using the administrative console for Tivoli Access Manager Web Portal Manager
- No requirements for coding or deployment changes to applications
- Easy management of users, groups, and roles using the WebSphere Application Server administrative console

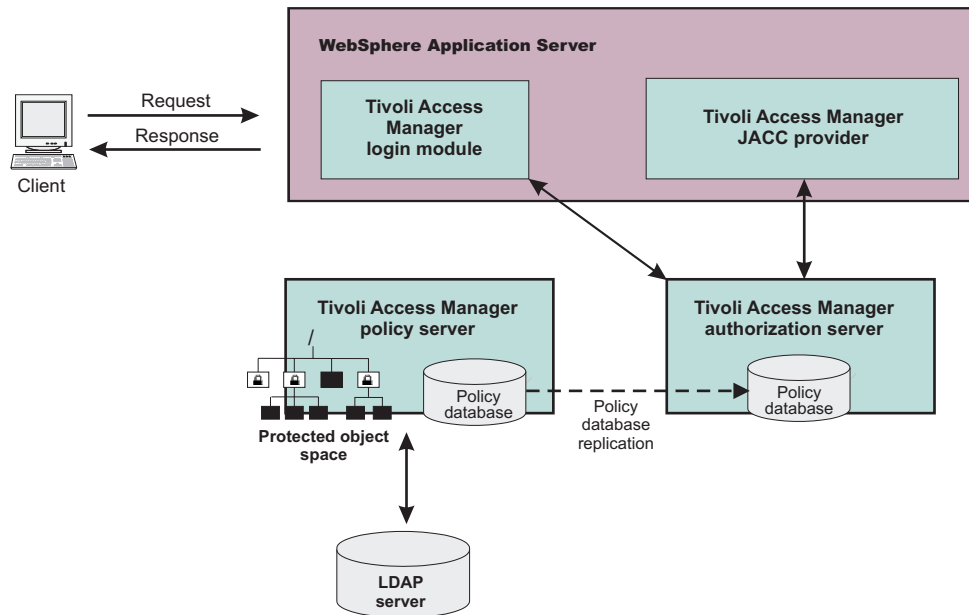

WebSphere Application Server supports the Java Authorization Contract for Containers (JACC) specification. JACC details the contract requirements for J2EE containers and authorization providers. With this contract, authorization providers can perform the access decisions for resources in J2EE Version 1.4 application servers such as WebSphere Application Server. The Tivoli Access Manager security utility that is embedded within WebSphere Application Server is JACC-compliant and is used to:

- Add security policy information when applications are deployed
- Authorize access to WebSphere Application Server-secured resources.

When applications are deployed, the embedded Tivoli Access Manager client takes any policy and or user and role information that is stored within the application deployment descriptor and stores it within the Tivoli Access Manager Policy Server.

The Tivoli Access Manager JACC provider is also called when a user requests access to a resource that is managed by WebSphere Application Server.

Embedded Tivoli Access Manager client architecture

The previous figure illustrates the following sequence of events:

1. Users that access protected resources are authenticated using the Tivoli Access Manager login module that is configured for use when the embedded Tivoli Access Manager client is enabled.
2. The WebSphere Application Server container uses information from the J2EE application deployment descriptor to determine the required role membership.
3. WebSphere Application Server uses the embedded Tivoli Access Manager client to request an authorization decision from the Tivoli Access Manager authorization server. Additional context information, when present, is also passed to the authorization server. This context information is comprised of the cell name, J2EE application name, and J2EE module name. If the Tivoli Access Manager policy database has policies that are specified for any of the context information, the authorization server uses this information to make the authorization decision.
4. The authorization server consults the permissions that are defined for the specified user within the Tivoli Access Manager-protected object space. The protected object space is part of the policy database.
5. The Tivoli Access Manager authorization server returns the access decision to the embedded Tivoli Access Manager client.
6. WebSphere Application Server either grants or denies access to the protected method or resource, based on the decision that is returned from the Tivoli Access Manager authorization server.

At its core, Tivoli Access Manager provides an authentication and authorization framework. You can learn more about Tivoli Access Manager, including the information that is necessary to make deployment decisions, by reviewing the product documentation. The following guides are available at the IBM Tivoli Access Manager for e-business information center:

- *IBM Tivoli Access Manager Base Installation Guide*

This guide describes how to plan, install, and configure a Tivoli Access Manager secure domain. Using a series of easy installation scripts, you can quickly deploy a fully functional secure domain. These scripts are very useful when prototyping the deployment of a secure domain.

To access this guide in the IBM Tivoli Access Manager for e-business information center, click **Access Manager for e-business > Base Information > Base Installation Guide**.

- *IBM Tivoli Access Manager Base Administration Guide*

This document presents an overview of the Tivoli Access Manager security model for managing protected resources. This guide describes how to configure the Tivoli Access Manager servers that

make access control decisions. In addition, detailed instructions describe how to perform important tasks, such as declaring security policies, defining protected object spaces, and administering user and group profiles.

To access this guide in the IBM Tivoli Access Manager for e-business information center, click **Access Manager for e-business > Base Information > Base Administration Guide**.

Tivoli Access Manager provides centralized administration of multiple servers.

WebSphere Application Server Cell

The previous figure is an example architecture showing WebSphere Application Servers secured by Tivoli Access Manager.

The participating WebSphere Application Servers use a local replica of the Tivoli Access Manager policy database to make authorization decisions for incoming requests. The local policy databases are replicas of the master policy database. The master policy database is installed as part of the Tivoli Access Manager installation. Having policy database replicas on each participating WebSphere Application Server node optimizes performance when making authorization decisions and provides failover capability.

Although the authorization server can also be installed on the same system as WebSphere Application Server, this configuration is not illustrated in the diagram.

All instances of Tivoli Access Manager and WebSphere Application Server in the example architecture share the Lightweight Directory Access Protocol (LDAP) user registry on Machine E.

The LDAP registries that are supported by WebSphere Application Server are also supported by Tivoli Access Manager.

It is possible to have separate WebSphere Application Server profiles on the same host that is configured for different Tivoli Access Manager servers. Such an architecture requires that the profiles are configured for separate Java Runtime Environments (JRE) and therefore you need multiple JREs installed on the same host.

Note: Even though all WebSphere Application Server profiles on the same host share a single Java Runtime Environment (JRE), you can configure separate WebSphere Application Server profiles on the same host for different Tivoli Access Manager servers.

Delegations

Delegation is a process security identity propagation from a caller to a called object. As per the Java 2 Platform, Enterprise Edition (J2EE) specification, a servlet and enterprise beans can propagate either the client or remote user identity when invoking enterprise beans, or they can use another specified identity as indicated in the corresponding deployment descriptor.

The extension supports enterprise bean propagation to the server ID when invoking other entity beans.

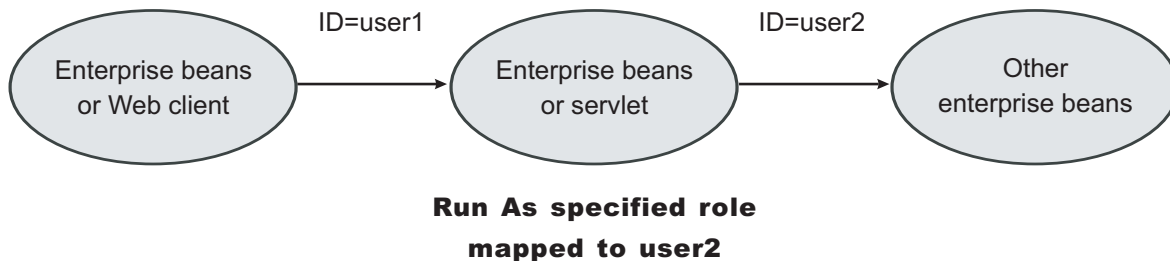

Three types of delegations are possible:

- Delegate (RunAs) client identity
- Delegate (RunAs) specified identity
- Delegate (RunAs) system identity

Delegate (RunAs) client identity

Delegate (RunAs) specified identity

Delegate (RunAs) system identity

Note: The RunAs system identity delegation only works when server ID and password are used. When the `internalServerId` feature is used, it does not work because runAs with system identity is not supported. You must specify RunAs roles. When `internalServerID` is used, use the `RunAsSpecified` with a user ID and password that is mapped to the administrator role. See “Administrative roles and naming service authorization” on page 330 for more information about `internalServerId`.

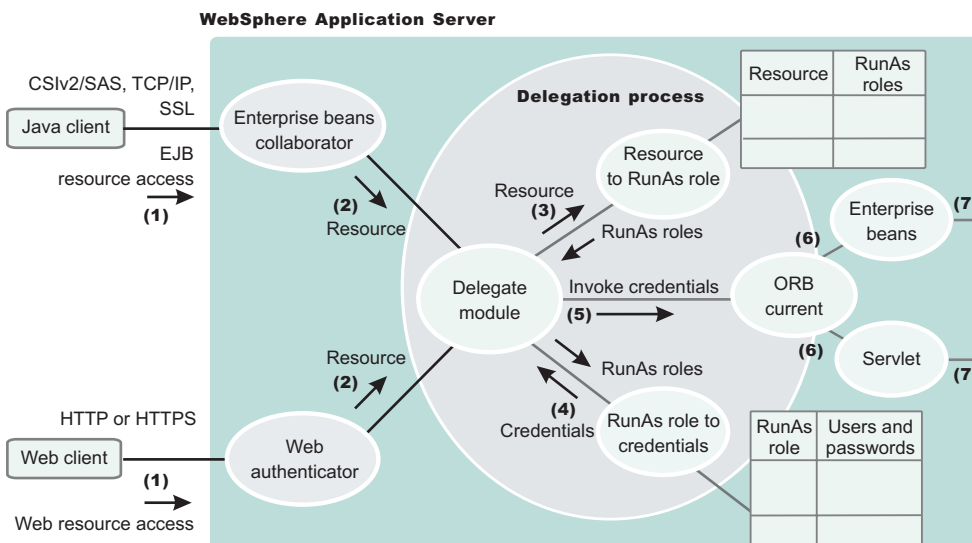

The EJB specification only supports delegation (RunAs) at the Enterprise JavaBeans (EJB) level. But an extension allows EJB method-level RunAs specification. With an EJB method level, the RunAs specification you can specify a different RunAs role for different methods within the same enterprise beans.

The RunAs specification is detailed in the deployment descriptor, which is the `ejb-jar.xml` file in the EJB module and the `web.xml` file in the Web module. The extension to the RunAs specification is included in the `ibm-ejb-jar-ext.xmi` file.

An IBM-specific binding file is available for each application that contains a mapping from the RunAs role to the user. This file is specified in the `ibm-application-bnd.xmi` file.

These specifications are read by the runtime during application startup. The following figure illustrates the delegation mechanism, as implemented in the WebSphere Application Server security model.

Delegation

Delegation Process

Two tables help in the delegation process:

- Resource to RunAs role mapping table
- RunAs role to user ID and password mapping table

Use the Resource to RunAs role mapping table to get the role that is used by a servlet or by enterprise beans to propagate to the next enterprise beans call.

Use the RunAsRole to user ID and password mapping table to get the user ID that belongs to the RunAs role and its password.

Delegation is performed after successful authentication and authorization. During this process, the delegation module consults the Resource to RunAs role mapping table to get the RunAs role (3). The delegation module consults the RunAs role to user ID and password mapping table to get the user that belongs to the RunAs role (4). The user ID and password is used to create a new credential using the authentication module, which is not shown in the figure.

The resulting credential is stored in the Object Request Broker (ORB) Current as an invocation credential (5). Servlet and enterprise beans when invoking other enterprise beans pick up the invocation credential from the ORB Current (6) and call the next enterprise beans (7).

Programmatic login

Programmatic login is a type of form login that supports application presentation site-specific login forms for the purpose of authentication.

When enterprise bean client applications require the user to provide identifying information, the writer of the application must collect that information and authenticate the user. The work of the programmer can be broadly classified in terms of where the actual user authentication is performed:

- In a client program
- In a server program

Users of Web applications can receive prompts for authentication data in many ways. The `<login-config>` element in the Web application deployment descriptor file defines the mechanism that is used to collect this information. Programmers who want to customize login procedures, rather than relying on general purpose devices like a 401 dialog window in a browser, can use a form-based login to provide an application-specific HTML form for collecting login information.

No authentication occurs unless administrative security is enabled. If you want to use form-based login for Web applications, you must specify `FORM` in the `auth-method` tag of the `<login-config>` element in the deployment descriptor of each Web application.

Applications can present site-specific login forms by using the WebSphere Application Server form-login type. The Java 2 Platform, Enterprise Edition (J2EE) specification defines form login as one of the authentication methods for Web applications. WebSphere Application Server provides a form-logout mechanism.

Java Authentication and Authorization Service programmatic login

Java Authentication and Authorization Service (JAAS) is a new feature in WebSphere Application Server. It is also mandated by the J2EE 1.4 Specification. JAAS is a collection of strategic authentication application programming interfaces (API) that replace the Common Object Request Broker Architecture (CORBA) programmatic login APIs. WebSphere Application Server provides some extensions to JAAS:

Before you begin developing with programmatic login APIs, consider the following points :

- For the pure Java client application or client container application, initialize the client Object Request Broker (ORB) security prior to performing a JAAS login. Do this by running the following code prior to the JAAS login:

```

...
import java.util.Hashtable;
import javax.naming.Context;
import javax.naming.InitialContext;
...
// Perform an InitialContext and default lookup prior to logging
// in to initialize ORB security and for the bootstrap host/port
// to be determined for SecurityServer lookup. If you do not want
// to validate the userid/password during the JAAS login, disable
// the com.ibm.CORBA.validateBasicAuth property in the
// sas.client.props file.

Hashtable env = new Hashtable();
env.put(Context.INITIAL_CONTEXT_FACTORY,
        "com.ibm.websphere.naming.WsnInitialContextFactory");
env.put(Context.PROVIDER_URL,
        "corbaloc:iiop:myhost.mycompany.com:2809");
Context initialContext = new InitialContext(env);
Object obj = initialContext.lookup("");

```

For more information, see “Example: Programmatic logins” on page 565.

- For the pure Java client application or the client container application, make sure that the host name and the port number of the target Java Naming and Directory Interface (JNDI) bootstrap properties are specified properly. See the Developing applications that use CosNaming (CORBA Naming interface) section for details.
- If the application uses custom JAAS login configuration, make sure that the custom JAAS login configuration is properly defined. See the “Configuring programmatic logins for Java Authentication and Authorization Service” on page 567 section for details.
- Some of the JAAS APIs are protected by Java 2 security permissions. If these APIs are used by application code, make sure that these permissions are added to the application was.policy file. See “Adding the was.policy file to applications” on page 540 to the application, “Using PolicyTool to edit policy files” on page 528 and “Configuring the was.policy file” on page 535 sections for details. For more details of which APIs are protected by Java 2 Security permissions, check the IBM Developer Kit, Java Technology Edition; JAAS and the WebSphere Application Server public APIs documentation for more details. The following list contains the APIs that are used in the samples code provided in this documentation.
 - javax.security.auth.login.LoginContext constructors are protected by javax.security.auth.AuthPermission “createLoginContext”.
 - javax.security.auth.Subject.doAs and com.ibm.websphere.security.auth.WSSubject.doAs are protected by javax.security.auth.AuthPermission “doAs”.
 - javax.security.auth.Subject.doAsPrivileged and com.ibm.websphere.security.auth.WSSubject.doAsPrivileged are protected by javax.security.auth.AuthPermission “doAsPrivileged”.
- com.ibm.websphere.security.auth.WSSubject: Due to a design oversight in JAAS Version 1.0, javax.security.auth.Subject.getSubject does not return the Subject associated with the running thread inside a java.security.AccessController.doPrivileged code block. This can present an inconsistent behavior that is problematic and causes an undesirable effort to work around. The com.ibm.websphere.security.auth.WSSubject API provides a workaround to associate the Subject to the running thread. The com.ibm.websphere.security.auth.WSSubject API extends the JAAS model to J2EE resources for authorization checks. The Subject that is associated with the running thread within com.ibm.websphere.security.auth.WSSubject.doAs or com.ibm.websphere.security.auth.WSSubject.doAsPrivileged code block is used for J2EE resources authorization checks.
- Administrative console support for defining new JAAS login configuration: You can configure JAAS login configuration in the administrative console and store it in the WebSphere Application Server configuration API. Applications can define new JAAS login configuration in the administrative console

and the data is persisted in the configuration repository that is stored with the WebSphere Application Server configuration API. However, WebSphere Application Server still supports the default JAAS login configuration format that is provided by the JAAS default implementation. If duplication login configurations are defined in both the WebSphere Application Server configuration API and the plain text file format, the login configuration in the WebSphere Application Server configuration API takes precedence. Advantages to define the login configuration in the WebSphere Application Server configuration API include:

- Defining the JAAS login configuration using the administrative console.
- Managing the JAAS login configuration centrally.
- Distributing the JAAS login configuration in a Network Deployment installation.
- JAAS login configurations for WebSphere Application Server: WebSphere Application Server provides JAAS login configurations for applications to perform programmatic authentication to the WebSphere Application Server security runtime. These JAAS login configurations for WebSphere Application Server perform authentication to the configured authentication mechanism, Simple WebSphere Authentication Mechanism (SWAM) or Lightweight Third-Party Authentication (LTPA), and user registry (Local OS, LDAP, or Custom) based on the authentication data supplied. The authenticated Subject from these JAAS login configurations contain the required principal and credentials that can be used by the WebSphere Application Server security runtime to perform authorization checks on J2EE role-based protected resources.

Note: SWAM is deprecated in WebSphere Application Server Version 6.1 and will be removed in a future release.

Here are the JAAS login configurations that are provided by WebSphere Application Server:

- *WSLogin JAAS login configuration:* A generic JAAS login configuration that a Java client, client container application, servlet, JSP file, enterprise bean, and so on, can use to perform authentication that is based on a user ID and password, or a token to the WebSphere Application Server security runtime. However, this configuration does not support the CallbackHandler handler that is specified in the client container deployment descriptor.
- *ClientContainer JAAS login configuration:* This JAAS login configuration recognizes the CallbackHandler handler that is specified in the client container deployment descriptor. The login module of this login configuration uses the CallbackHandler handler in the client container deployment descriptor if one is specified, even if the application code specified one CallbackHandler handler in the login context. This is for client container application.
- The Subjects that are authenticated with the previously mentioned JAAS login configurations contain a `com.ibm.websphere.security.auth.WSPPrincipal` principal and a `com.ibm.websphere.security.auth.WSCredential` credential. If the authenticated Subject is passed to the `com.ibm.websphere.security.auth.WSSubject.doAs` method or the other `doAs` methods, the WebSphere Application Server security runtime can perform authorization checks on J2EE resources, based on the Subject `com.ibm.websphere.security.auth.WSCredential` credential.
- **Customer-defined JAAS login configurations:** You can define other JAAS login configurations. See “Configuring programmatic logins for Java Authentication and Authorization Service” on page 567 for details. Use these login configurations to perform programmatic authentication to the custom authentication mechanism. However, the subjects from these customer-defined JAAS login configurations might not be used by the WebSphere Application Server security runtime to perform authorization checks if the subject does not contain the required principal and credentials.

Finding the root cause login exception from a JAAS login

If you get a `LoginException` exception after issuing the `LoginContext.login` API, you can find the root cause exception from the configured user registry. In the login modules, the registry exceptions are wrapped by a `com.ibm.websphere.security.auth.WSLoginFailedException` class. This exception has a `getCause` method with which you can pull out the exception that was wrapped after issuing the previous command.

You are not always guaranteed to get a `WSLoginFailedException` exception, but most of the exceptions that are generated from the user registry display here. The following example illustrates a

LoginContext.login API with the associated catch block. Cast the WSLoginFailedException exception to com.ibm.websphere.security.auth.WSLoginFailedException class if you want to issue the getCause API.

The following determineCause example can be used for processing CustomUserRegistry exception types.

```
try
{
    lc.login();
}
catch (LoginException le)
{
    // drill down through the exceptions as they might cascade through the runtime
    Throwable root_exception = determineCause(le);

    // now you can use "root_exception" to compare to a particular exception type
    // for example, if you have implemented a CustomUserRegistry type, you would
    // know what to look for here.
}

/* Method used to drill down into the WSLoginFailedException to find the
"root cause" exception */

public Throwable determineCause(Throwable e)
{
    Throwable root_exception = e, temp_exception = null;

    // keep looping until there are no more embedded WSLoginFailedException or
    // WSSecurityException exceptions
    while (true)
    {
        if (e instanceof com.ibm.websphere.security.auth.WSLoginFailedException)
        {
            temp_exception = ((com.ibm.websphere.security.auth.WSLoginFailedException)
                e).getCause();
        }
        else if (e instanceof com.ibm.websphere.security.WSSecurityException)
        {
            temp_exception = ((com.ibm.websphere.security.WSSecurityException)
                e).getCause();
        }
        else if (e instanceof javax.naming.NamingException)
            // check for Ldap embedded exception
            {
                temp_exception = ((javax.naming.NamingException)e).getRootCause();
            }
        else if (e instanceof your_custom_exception_here)
        {
            // your custom processing here, if necessary
        }
        else
        {
            // this exception is not one of the types we are looking for,
            // lets return now, this is the root from the WebSphere
            // Application Server perspective
            return root_exception;
        }
        if (temp_exception != null)
        {
            // we have an exception; go back and see if this has another
            // one embedded within it.
            root_exception = temp_exception;
            e = temp_exception;
        }
    }
}
```

```

        continue;
    }
    else
    {
        // we finally have the root exception from this call path, this
        // has to occur at some point
        return root_exception;
    }
}
}
}

```

Finding the root cause login exception from a Servlet filter

You can also receive the root cause exception from a servlet filter when addressing post-form login processing. This exception is useful because it shows the user what happened. You can issue the following API to obtain the root cause exception:

```

Throwable t = com.ibm.websphere.security.auth.WSSubject.getRootLoginException();
if (t != null)
    t = determineCause(t);

```

When you have the exception, you can run it through the previous `determineCause` example to get the native registry root cause.

Enabling root cause login exception propagation to pure Java clients

Currently, the root cause does not get propagated to a pure client for security reasons. However, you might want to propagate the root cause to a pure client in a trusted environment. If you want to enable root cause login exception propagation to a pure client, click **Security > Secure administration, applications, and infrastructure > Custom Properties** on the WebSphere Application Server Administrative Console and set the following property:

```
com.ibm.websphere.security.registry.propagateExceptionsToClient=true
```

Non-prompt programmatic login

WebSphere Application Server provides a non-prompt implementation of the `javax.security.auth.callback.CallbackHandler` interface, which is called `com.ibm.websphere.security.auth.callback.WSCallbackHandlerImpl`. Using this interface, an application can push authentication data to the WebSphere LoginModule instance to perform authentication. This capability is useful for server-side application code to authenticate an identity and to use that identity to invoke downstream J2EE resources.

```

javax.security.auth.login.LoginContext lc = null;

try {
    lc = new javax.security.auth.login.LoginContext("WSLogin",
        new com.ibm.websphere.security.auth.callback.WSCallbackHandlerImpl("user",
            "securityrealm", "securedpassword"));

    // create a LoginContext and specify a CallbackHandler implementation
    // CallbackHandler implementation determine how authentication data is collected
    // in this case, the authentication data is "push" to the authentication mechanism
    // implemented by the LoginModule.
} catch (javax.security.auth.login.LoginException e) {
    System.err.println("ERROR: failed to instantiate a LoginContext and the exception: "
        + e.getMessage());
    e.printStackTrace();

    // maybe javax.security.auth.AuthPermission "createLoginContext" is not granted
    // to the application, or the JAAS login configuration is not defined.

```

```

}

if (lc != null)
try {
lc.login(); // perform login
javax.security.auth.Subject s = lc.getSubject();
// get the authenticated subject

// Invoke a J2EE resource using the authenticated subject
com.ibm.websphere.security.auth.WSSubject.doAs(s,
new java.security.PrivilegedAction() {
public Object run() {
try {
bankAccount.deposit(100.00); // where bankAccount is a protected EJB
} catch (Exception e) {
System.out.println("ERROR: error while accessing EJB resource, exception: "
+ e.getMessage());
e.printStackTrace();
}
return null;
}
});
} catch (javax.security.auth.login.LoginException e) {
System.err.println("ERROR: login failed with exception: " + e.getMessage());
e.printStackTrace();

// login failed, might want to provide relogin logic
}

```

You can use the `com.ibm.websphere.security.auth.callback.WSCallbackHandlerImpl` callback handler with a pure Java client, a client application container, enterprise bean, JavaServer Pages (JSP) files, servlet, or other Java 2 Platform, Enterprise Edition (J2EE) resources. See “Example: Programmatic logins” on page 565 for more information about Object Request Broker (ORB) security initialization requirements in a pure Java client.

Note: The `WSCallbackHandlerImpl` callback handler is different depending on whether you use WebSphere Application Server security or Web services security. It is located in the `sas.jar` file for security, and in the `was-wssecurity.jar` file for Web services security.

User interface prompt programmatic login

WebSphere Application Server also provides a user interface implementation of the `javax.security.auth.callback.CallbackHandler` implementation to collect authentication data from a user through user interface login prompts. The `com.ibm.websphere.security.auth.callback.WSGUICallbackHandlerImpl` callback handler presents a user interface login panel to prompt users for authentication data.

```

javax.security.auth.login.LoginContext lc = null;

try {
lc = new javax.security.auth.login.LoginContext("WSLogin",
new com.ibm.websphere.security.auth.callback.WSGUICallbackHandlerImpl());

// create a LoginContext and specify a CallbackHandler implementation
// CallbackHandler implementation determine how authentication data is collected
// in this case, the authentication date is collected by GUI login prompt
// and pass to the authentication mechanism implemented by the LoginModule.
} catch (javax.security.auth.login.LoginException e) {
System.err.println("ERROR: failed to instantiate a LoginContext and the exception: "
+ e.getMessage());
}

```

```

e.printStackTrace();

// maybe javax.security.auth.AuthPermission "createLoginContext" is not granted
// to the application, or the JAAS login configuration is not defined.
}

if (lc != null)
try {
lc.login(); // perform login
javax.security.auth.Subject s = lc.getSubject();
// get the authenticated subject

// Invoke a J2EE resources using the authenticated subject
com.ibm.websphere.security.auth.WSSubject.doAs(s,
new java.security.PrivilegedAction() {
public Object run() {
try {
bankAccount.deposit(100.00); // where bankAccount is a protected enterprise bean
} catch (Exception e) {
System.out.println("ERROR: error while accessing EJB resource, exception: "
+ e.getMessage());
e.printStackTrace();
}
return null;
}
});
} catch (javax.security.auth.login.LoginException e) {
System.err.println("ERROR: login failed with exception: " + e.getMessage());
e.printStackTrace();

// login failed, might want to provide relogin logic
}

```

Attention: Do not use the `com.ibm.websphere.security.auth.callback.WSGUICallbackHandlerImpl` callback handler for server-side resources like enterprise bean, servlet, JSP files, and so on. The user interface login prompt blocks the server for user input. This behavior is not good for a server process.

Stdin prompt programmatic login

WebSphere Application Server also provides a stdin implementation of the `javax.security.auth.callback.CallbackHandler` interface. The callback handler, `com.ibm.websphere.security.auth.callback.WSStdinCallbackHandlerImpl`, prompts and collects authentication data from a user through the stdin prompt.

```

javax.security.auth.login.LoginContext lc = null;

try {
lc = new javax.security.auth.login.LoginContext("WSLogin",
new com.ibm.websphere.security.auth.callback.WSStdinCallbackHandlerImpl());

// create a LoginContext and specify a CallbackHandler implementation
// CallbackHandler implementation determines how authentication data is collected
// in this case, the authentication data is collected by stdin prompt
// and passed to the authentication mechanism implemented by the LoginModule.
} catch (javax.security.auth.login.LoginException e) {
System.err.println("ERROR: failed to instantiate a LoginContext and the exception:
" + e.getMessage());
e.printStackTrace();

// maybe javax.security.auth.AuthPermission "createLoginContext" is not granted

```

```

// to the application, or the JAAS login configuration is not defined.
}

if (lc != null)
try {
lc.login(); // perform login
javax.security.auth.Subject s = lc.getSubject();
// get the authenticated subject

// Invoke a J2EE resource using the authenticated subject
com.ibm.websphere.security.auth.WSSubject.doAs(s,
new java.security.PrivilegedAction() {
public Object run() {
try {
bankAccount.deposit(100.00);
// where bankAccount is a protected enterprise bean
} catch (Exception e) {
System.out.println("ERROR: error while accessing EJB resource, exception: "
+ e.getMessage());
e.printStackTrace();
}
return null;
}
});
} catch (javax.security.auth.login.LoginException e) {
System.err.println("ERROR: login failed with exception: " + e.getMessage());
e.printStackTrace();

// login failed, might want to provide relogin logic
}

```

Attention: Do not use the `com.ibm.websphere.security.auth.callback.WSStdinCallbackHandlerImpl` callback handler for server-side resources like enterprise beans, servlets, JSP files, and so on. The input from the stdin prompt is not sent to the server environment. Most servers run in the background and do not have a console. However, if the server does have a console, the stdin prompt blocks the server for user input. This behavior is not good for a server process.

Authorizing access to J2EE resources using Tivoli Access Manager

The Java Authorization Contract for Containers (JACC) defines a contract between Java 2 Platform, Enterprise Edition (J2EE) containers and authorization providers. You can use the default authorization or an external JACC authorization provider. When security is enabled in WebSphere Application Server, the default authorization is used unless a JACC provider is specified.

JACC enables any third-party authorization providers to plug into a J2EE application server (such as WebSphere Application Server) to make the authorization decisions when a J2EE resource is accessed. By default, WebSphere Application Server implements the JACC provider by using Tivoli Access Manager as the external authorization provider.

Read the following articles for more detailed information about JACC before you attempt to configure WebSphere Application Server to use a JACC provider:

- “JACC support in WebSphere Application Server” on page 340
- “JACC providers” on page 342
- “Tivoli Access Manager integration as the JACC provider” on page 346

Using the default authorization provider

You can extend the capabilities of WebSphere Application Server by plugging in your own authorization provider. You can use the default authorization or an external JACC authorization provider.

For an explanation of the administrative console panels that support these capabilities, see:

- Use the default authorization provider. It is recommended that you do not modify any settings on the authorization provider panels if you use the **Default authorization** option. For more information, see “External authorization provider settings.”
- Use an external authorization provider. If you use the **External authorization using a JACC provider** option, the external providers must be based on the Java™ Authorization Contract for Containers (JACC) specification to handle the Java 2 Platform, Enterprise Edition (J2EE) authorization. By default, WebSphere Application Server enables you to configure the Tivoli Access Manager Java Authorization Contract for Containers (JACC) provider as the default external JACC provider. For more information, see “External Java Authorization Contract for Containers provider settings” on page 362 and “Tivoli Access Manager JACC provider settings” on page 368.

External authorization provider settings

Use this page to enable a Java Authorization Contract for Containers (JACC) provider for authorization decisions.

To view this administrative console page, complete the following steps:

1. Click **Security > Secure administration, applications, and infrastructure**.
2. Click **External authorization providers**.

The application server provides a default authorization engine that performs all of the authorization decisions. In addition, the application server also supports an external authorization provider using the JACC specification to replace the default authorization engine for Java 2 Platform, Enterprise Edition (J2EE) applications.

JACC is part of the J2EE specification, which enables third-party security providers such as Tivoli Access Manager to plug into the application server and make authorization decisions.

Important: Unless you have an external JACC provider or want to use a JACC provider for Tivoli Access Manager that can handle J2EE authorizations based on JACC, and it is configured and set up to use with the application server, do not enable **External authorization using a JACC provider**.

Default authorization:

Use this option all the time unless you want an external security provider such as the Tivoli Access Manager to perform the authorization decision for J2EE applications that are based on the JACC specification.

Default: Enabled

External JACC provider: Use this link to configure the application server to use an external JACC provider. For example, to configure an external JACC provider, the policy class name and the policy configuration factory class name are required by the JACC specification.

The default settings that are contained in this link are used by Tivoli Access Manager for authorization decisions. If you intend to use another provider, modify the settings as appropriate.

External Java Authorization Contract for Containers provider settings

Use this page to configure the application server to use an external Java Authorization Contract for Containers (JACC) provider. For example, the policy class name and the policy configuration factory class name are required by the JACC specification.

Use these settings when you have set up an external security provider that supports the JACC specification to work with the application server. The configuration process involves installing and configuring the provider server and configuring the client of the provider in the application server to communicate with the server. If the JACC provider is not enabled, these settings will be ignored.

To view this administrative console page, complete the following steps:

1. Click **Security > Secure administration, applications, and infrastructure**.
2. Click **External authorization providers**.
3. Under Related items, click **External JACC provider**.

Use the default settings when you use Tivoli Access Manager as the JACC provider. Install and configure the Tivoli Access Manager server prior to using it with the application server. Use the Tivoli Access Manager properties link under Additional properties, and configure the Tivoli Access Manager client in the application server to use the Tivoli Access Manager server. If you intend to use another provider, modify the settings as appropriate.

Name:

Specifies the name that is used to identify the external JACC provider.

This field is required.

Data type: String

Description:

Provides an optional description for the provider.

Data type: String

Policy class name:

Specifies a fully qualified class name that represents the `javax.security.jacc.policy.provider` property as per the JACC specification. The class represents the provider-specific implementation of the `java.security.Policy` abstract methods.

The class file must reside in the class path of each application server process. This class is used during authorization decisions. The default class name is for Tivoli Access Manager implementation of the policy file.

This field is required. For information on enabling the JACC provider using this field, see the "Enabling the JACC provider for Tivoli Access Manager" article in the information center.

Data type: String

Default: `com.tivoli.pd.as.jacc.TAMPolicy`

Policy configuration factory class name:

Specifies a fully qualified class name that represents the `javax.security.jacc.PolicyConfigurationFactory.provider` property as per the JACC specification. The class represents the provider-specific implementation of the `javax.security.jacc.PolicyConfigurationFactory` abstract methods.

This class represents the provider-specific implementation of the `PolicyConfigurationFactory` abstract class. The class file must reside in the class path of each application server process. This class is used to propagate the security policy information to the JACC provider during the installation of the J2EE application. The default class name is for the Tivoli Access Manager implementation of the policy configuration factory class name.

This field is required.

Data type:	String
Default:	<code>com.tivoli.pd.as.jacc.TAMPolicyConfigurationFactory</code>

Role configuration factory class name:

Specifies a fully qualified class name that implements the `com.ibm.wsspi.security.authorization.RoleConfigurationFactory` interface.

The class file must reside in the class path of each application server process. When you implement this class, the authorization table information in the binding file is propagated to the provider during the installation of the J2EE application. The default class name is for the Tivoli Access Manager implementation of the role configuration factory class name.

This field is optional. For information on enabling the JACC provider using this field, see the "Enabling the JACC provider for Tivoli Access Manager" article in the information center.

Data type:	String
Default:	<code>com.tivoli.pd.as.jacc.TAMRoleConfigurationFactory</code>

Provider initialization class name:

Specifies a fully qualified class name that implements the `com.ibm.wsspi.security.authorization.InitializeJACCProvider` interface.

The class file must reside in the class path of each application server process. When implemented, this class is called at the start and the stop of all the application server processes. You can use this class for any required initialization that is needed by the provider client code to communicate with the provider server. The properties that are entered in the custom properties link are passed to the provider when the process starts up. The default class name is for the Tivoli Access Manager implementation of the provider initialization class name.

This field is optional. For information on enabling the JACC provider using this field, see the "Enabling the JACC provider for Tivoli Access Manager" article in the information center.

Data type:	String
Default:	<code>com.tivoli.pd.as.jacc.cfg.TAMConfigInitialize</code>

Requires the EJB arguments policy context handler for access decisions:

Specifies whether the JACC provider requires the `EJBArgumentsPolicyContextHandler` handler to make access decisions.

Because this option has an impact on performance, do not set it unless it is required by the provider. Normally, this handler is required only when the provider supports instance-based authorization. Tivoli Access Manager does not support this option for J2EE applications.

Default: Disabled

Supports dynamic module updates:

Specifies whether you can apply changes made to security policies of Web modules in a running application, dynamically without affecting the rest of the application.

If this option is enabled, the security policies of the added or modified Web modules are propagated to the JACC provider and only the affected Web modules are started.

If this option is disabled, then the security policies of the entire application are propagated to the JACC provider for any module-level changes. The entire application is restarted for the changes to take effect.

Typically, this option is enabled for an external JACC provider.

Default: Enabled

Custom properties:

Specifies the properties that are required by the provider.

These properties are propagated to the provider during the startup process when the provider initialization class name is initialized. If the provider does not implement the provider initialization class name as described previously, the properties are not used.

The Tivoli Access Manager implementation does not require that you enter any properties in this link.

Tivoli Access Manager properties:

Specifies properties that are required by the Tivoli Access Manager implementation.

These properties are used to set up the communication between the application server and the Tivoli Access Manager server. You must install and configure the Tivoli Access Manager server before entering these properties.

Enabling an external JACC provider

Use this topic to enable an external JACC provider using the administrative console.

The Java Authorization Contract for Containers (JACC) defines a contract between Java 2 Platform, Enterprise Edition (J2EE) containers and authorization providers. This contract enables any third-party authorization providers to plug into a J2EE 1.4 application server, such as WebSphere Application Server to make the authorization decisions when a J2EE resource is accessed.

1. From the WebSphere Application Server administrative console, click **Security > Secure administration, applications, and infrastructure > External authorization providers**.
2. Under Related items, click **External JACC provider**.
3. The fields are set for Tivoli Access Manager by default. If you do not plan to use Tivoli Access Manager as the JACC provider, replace these fields with the details for your own external JACC provider.
4. If any custom properties are required by the JACC provider, click **Custom properties** under Additional properties and enter the properties. When using the Tivoli Access Manager, use the **Tivoli Access**

Manager properties link instead of the Custom properties link. For more information, see “Configuring the JACC provider for Tivoli Access Manager using the administrative console.”

5. On the External authorization providers panel, select the **External authorization using a JACC provider** option and click **OK**.
6. Complete the remaining steps to enable security. If you are using Tivoli Access Manager, you must select LDAP as the user registry and use the same LDAP server. For more information on configuring LDAP registries, see “Configuring Lightweight Directory Access Protocol user registries” on page 92.
7. Verify that all of the changes are synchronized across all nodes. For more information, see Synchronizing nodes with the wsadmin tool
8. In a multinode environment, stop and start the deployment manager configuration.
Issue the following commands on the Qshell command line:

```
profile_root/bin/stopManager  
-username user_name  
-password password
```

```
profile_root/bin/startManager
```

9. Restart all servers to make these changes effective.

Configuring the JACC provider for Tivoli Access Manager using the administrative console

Use this task to configure Tivoli Access Manager as the Java Authorization Contract for Containers (JACC) provider using the administrative console.

Before configuring Tivoli Access Manager as the JACC provider, verify that all of the managed servers, including node agents, are started

Prior to completing the following steps, verify that you have previously created a security administrative user. For more information, see “Creating the security administrative user” on page 367.

The following configuration is performed on the management server. When you click either **Apply** or **OK**, configuration information is checked for consistency, saved, and applied if successful.

This configuration information is propagated to the nodes when synchronization is performed. Restart the nodes for the configuration changes to take effect.

To configure Tivoli Access Manager as the JACC provider using the administrative console, complete the following steps:

1. Start the WebSphere Application Server administrative console by clicking `http://yourhost.domain:port_number/ibm/console` after starting WebSphere Application Server. If security is currently disabled, log in with any user ID. If security is currently enabled, log in with a predefined administrative ID and password. This ID is typically the server user ID that is specified when you configure the user registry.
2. Click **Security > Secure administration, applications, and infrastructure > External authorization providers**.
3. Under General properties, select **External authorization using a JACC provider**.
4. Under Related items, click **External JACC provider**.
5. Under Additional properties, click **Tivoli Access Manager Properties**. The Tivoli Access Manager JACC provider configuration screen is displayed.
6. Enter the following information:

Enable embedded Tivoli Access Manager

Select this option to enable Tivoli Access Manager.

Ignore errors during embedded Tivoli Access Manager disablement

Select this option when you want to unconfigure the JACC provider. Do not select this option during configuration.

Client listening port set

WebSphere Application Server must listen using a TCP/IP port for authorization database updates from the policy server. More than one process can run on a particular node or machine. More than one authorization server can be specified by separating the entries with commas. Specifying more than one authorization server at a time is useful for reasons of failover and performance. Enter the listening ports used by Tivoli Access Manager clients, separated by a comma. If a range of ports is specified, separate the lower and higher values by a colon (:) (for example, 7999, 9990:999).

Policy server

Enter the name of the Tivoli Access Manager policy server and the connection port. Use the `policy_server:port` form. The policy communication port is set at the time of the Tivoli Access Manager configuration, and the default is 7135.

Authorization servers

Enter the name of the Tivoli Access Manager authorization server. Use the `auth_server:port:priority` form. The authorization server communication port is set at the time of the Tivoli Access Manager configuration, and the default is 7136. The priority value is determined by the order of the authorization server use (for example, `auth_server1:7136:1` and `auth_server2:7137:2`). A priority value of 1 is required when configuring against a single authorization server.

Administrator user name

Enter the Tivoli Access Manager administrator user name that was created when Tivoli Access Manager was configured; it is usually `sec_master`.

Administrator user password

Enter the Tivoli Access Manager administrator password.

User registry distinguished name suffix

Enter the distinguished name suffix for the user registry that is shared between Tivoli Access Manager and WebSphere Application Server, for example, `o=ibm, c=us`.

Security domain

You can create more than one security domain in Tivoli Access Manager, each with its own administrative user. Users, groups and other objects are created within a specific domain, and are not permitted to access resource in another domain. Enter the name of the Tivoli Access Manager security domain that is used to store WebSphere Application Server users and groups.

If a security domain is not established at the time of the Tivoli Access Manager configuration, leave the value as `Default`.

Administrator user distinguished name

Enter the full distinguished name of the WebSphere Application Server security administrator ID (for example, `cn=wasadmin, o=organization, c=country`). The ID name must match the Server user ID on the Lightweight Directory Access Protocol (LDAP) User Registry panel in the administrative console. To access the LDAP User Registry panel, click **Security > Secure administration, applications, and infrastructure**. Under **User account repository**, choose **Standalone LDAP registry** as the available realm definition. Then click **Configure**.

7. When all information is entered, click **OK** to save the configuration properties. The configuration parameters are checked for validity and the configuration is attempted at the host server or cell manager.

After you click **OK**, WebSphere Application Server completes the following actions:

- Validates the configuration parameters.

- Configures the host server or cell manager.

These processes might take some time depending on network traffic or the speed of your machine.

If the configuration is successful, the parameters are copied to all subordinate servers, including the node agents. To complete the embedded Tivoli Access Manager client configuration, you must restart all of the servers, including the host server, and enable WebSphere Application Server security.

Creating the security administrative user:

Enabling security requires the creation of a WebSphere Application Server administrative user. Use the Tivoli Access Manager command-line `pdadmin` utility to create the Tivoli Access Manager administrative user for WebSphere Application Server. This utility is available on the policy server host machine.

Follow these steps to use the `pdadmin` utility.

1. From a command line, start the `pdadmin` utility as the Tivoli Access Manager administrative user, `sec_master`:

```
pdadmin -a sec_master -p sec_master_password
```

2. Create a WebSphere Application Server security user. For example, the following instructions create a new user, `wasadmin`. The command is entered as one continuous line:

```
pdadmin> user create wasadmin cn=wasadmin,o=organization,  
c=country wasadmin wasadmin myPassword
```

Substitute values for organization and country that are valid for your Lightweight Directory Access Protocol (LDAP) user registry.

3. Enable the account for the WebSphere Application Server security administrative user by issuing the following command:

```
pdadmin> user modify wasadmin account-valid yes
```

Configure the Java Authorization Contract for Container (JACC) provider for Tivoli Access Manager. For more information, see “Tivoli Access Manager JACC provider configuration.”

Tivoli Access Manager JACC provider configuration:

You can configure the Java Authorization Contract for Containers (JACC) provider for Tivoli Access Manager to deliver authentication and authorization protection for your applications or for authentication only. Most deployments that use the JACC provider for Tivoli Access Manager to configure Tivoli Access Manager provide both authentication and authorization functionality.

If you want Tivoli Access Manager to provide authentication, but leave authorization as part of WebSphere Application Server’s native security, add the `com.tivoli.pd.as.amwas.DisableAddAuthorizationTableEntry=true` property to the `amwas.amjacc.template.properties` file. The file is located in the `profile_root/config/cells/cell_name` directory.

After this property is set, perform the tasks for setting Tivoli Access Manager Security, as documented.

You can configure the JACC provider for Tivoli Access Manager using either the WebSphere Application Server administrative console or the **wsadmin** command-line utility.

- For details on configuring the JACC provider for Tivoli Access Manager using the administrative console, refer to “Configuring the JACC provider for Tivoli Access Manager using the administrative console” on page 365.
- For details on configuring the Tivoli Access Manager JACC provider using the **wsadmin** command line utility, refer to “Configuring the JACC provider for Tivoli Access Manager using the `wsadmin` utility” on page 667.

The JACC configuration files for Tivoli Access Manager that are common across multiple WebSphere Application Server profiles are created by default under the `java/jre` directory. When you install WebSphere Application Server, you are given permissions to read and write to the files in this directory.

In addition, all users have read-only access to this directory.

This situation is not ideal because configuration of the JACC provider for Tivoli Access Manager fails in these situations. To avoid this situation, you can add the following property to the `profile_root/config/cells/cell_name/amwas.amjacc.template.properties` file: `com.tivoli.pd.as.jacc.CommonFileLocation=new location` where `new location` is a fully qualified directory name.

This property sets the location of the JACC provider for Tivoli Access Manager properties files that are common across profiles.

Because all WebSphere Application Server profiles are initially configured with the following setting, JACC configuration files for Tivoli Access Manager are not common across multiple WebSphere Application Server profiles:

```
com.tivoli.pd.as.jacc.CommonFileLocation=USER_INSTALL_ROOT/etc/pd
```

The **wsadmin** command is available to reconfigure the Java Authorization Contract for Containers (JACC) Tivoli Access Manager interface:

```
$AdminTask reconfigureTAM -interactive
```

This command effectively prompts you through the process of unconfiguring the interface and then reconfiguring it.

Tivoli Access Manager JACC provider settings:

Use this page to configure the Java Authorization Contract for Container (JACC) provider for Tivoli Access Manager.

Note: When a third-party authorization such as Tivoli Access Manager or SAF for z/OS is used, the information in the administrative console panel might not represent the data in the provider. Also, any changes to the panel might not be reflected in the provider automatically. Follow the provider's instructions to propagate any changes made to the provider.

To view the JACC provider settings for Tivoli Access Manager, complete the following steps:

1. Click **Security > Secure administration, applications, and infrastructure**.
2. Under Authentication, click **External authorization providers**.
3. Under Related items, click **External JACC provider**.
4. Under Additional properties, click **Tivoli Access Manager Properties**.

Enable embedded Tivoli Access Manager:

Enables or disables the embedded Tivoli Access Manager client configuration.

Default: Disabled
Range: Enabled or Disabled

Note: If you want to disable Tivoli Access Manager as the JACC provider, clear this option and also select **Default authorization**.

Ignore errors during embedded Tivoli Access Manager disablement:

When selected, errors are ignored during disablement of the embedded Tivoli Access Manager client.

This option is applicable only when re-configuring an embedded Tivoli Access Manager client or disabling an embedded Tivoli Access Manager.

Default: Disabled
Range: Enabled or Disabled

Client listening port set:

Enter the ports that are used as listening ports by Tivoli Access Manager clients.

The application server needs to listen on a TCP/IP port for authorization database updates from the policy server. More than one process can run on a particular node and machine, so a list of ports is required for use by the processes. If you specify a range of ports, separate the lower and higher values by a colon (:). Single ports and port ranges are specified on separate lines. An example list might look like the following example:

```
7999
9900:9999
```

Note: Each of the servants might need to open up a listener port.

Policy server:

Enter the name, fully-qualified domain name, or IP address of the Tivoli Access Manager policy server and the connection port.

Use the form *policy_server:port*. The policy server communication port was set at the time of the Tivoli Access Manager configuration. The default is 7135.

Authorization servers:

Enter the name, fully-qualified domain name, or IP address of the Tivoli Access Manager authorization server. Use the form, *auth_server:port:priority*.

The authorization server communication port is set at the time of Tivoli Access Manager configuration. The default is 7136. You can specify more than one authorization server by entering each server on a new line. Configuring more than one authorization server provides for failover. The priority value is the order of authorization server use. For example:

```
auth_server1.mycompany.com:7136:1
auth_server2.mycompany.com:7137:2
```

A priority of 1 is still required when configuring a single authorization server.

Administrator user name:

Enter the Tivoli Access Manager administration user ID, as created at the time of Tivoli Access Manager configuration. This ID is usually, *sec_master*.

Administrator user password:

Enter the Tivoli Access Manager administration password for the user ID that is entered in the **Administrator user name** field.

User registry distinguished name suffix:

Enter the distinguished name suffix for the user registry to share between Tivoli Access Manager and the application server. For example: *o=organization,c=country*

Security domain:

Enter the name of the Tivoli Access Manager security domain that is used to store application server users and groups.

Specification of the Tivoli Access Manager domain is required because more than one security domain can be created in Tivoli Access Manager with its own administrative user. Users, groups, and other objects are created within a specific domain and are not permitted to access resources in another domain. If a security domain is not established at the time of Tivoli Access Manager configuration, leave the value as *Default*.

Default: Default

Administrator user distinguished name:

Enter the fully distinguished name of the security administrator ID for the application server. For example, *cn=wasadmin,o=organization,c=country*

JACC provider configuration properties for Tivoli Access Manager:

The JACC provider configuration properties detailed below may require configuration.

The Java property files are created in the WebSphere Application Server *profile_root* directory.

Two properties files might require configuration:

- *amwas.node_name_server_name.amjacc.properties* contains properties that are used by the JACC provider of Tivoli Access Manager.
- *amwas.node_name_server_name.pdlog.properties* contains logging properties that are created from the *amwas.pdlog.template.properties* file for the specific node and server combination at the time of configuration.

Use *amwas.node_name_server_name.amjacc.properties* file to configure static role caching, dynamic role caching, object caching, and role-based policy framework properties.

Static role caching properties:

The static role cache holds role memberships that do not expire.

These properties are in the *profile_root/etc/tam/amwas.node_name_server_name.amjacc.properties* file.

The *profile_root* directory is the value of the *profilePath* parameter at profile creation time.

Enabling static role caching

```
com.tivoli.pd.as.cache.EnableStaticRoleCaching=true
```

Enables or disables static role caching. Static role caching is enabled by default.

Setting the static role cache

```
com.tivoli.pd.as.cache.StaticRoleCache=com.tivoli.pd.as.cache.StaticRoleCacheImpl
```

This property holds the implementation class of the static role cache. You do not need to change this property, although the opportunity exists to implement your own cache, if necessary.

Define static roles

```
com.tivoli.pd.as.cache.StaticRoleCache.Roles=Administrator,Operator,Monitor,Deployer
```

Defines the administration roles for WebSphere Application Server.

Tip: Enhance Application performance by adding the static roles: **CosNamingRead**, **CosNamingWrite**, **CosNamingCreate**, **CosNamingDelete**. These roles support for improved lookup performance within the application naming service.

Dynamic role caching properties:

The dynamic role cache holds role memberships that expire.

These properties are in the *profile_root/etc/tam/amwas.node_name_server_name.amjacc.properties* file.

The *profile_root* directory is the value of the *profilePath* parameter at profile creation time.

Enabling dynamic role caching

```
com.tivoli.pd.as.cache.EnableDynamicRoleCaching=true
```

Enables or disables dynamic role caching. Dynamic role caching is enabled by default.

Setting the dynamic role cache

```
com.tivoli.pd.as.cache.DynamicRoleCache=com.tivoli.pd.as.cache.DynamicRoleCacheImpl
```

This property holds the implementation class of the dynamic role cache. You do not need to change this property, although the opportunity exists to implement your own cache, if necessary.

Specifying the maximum number of users

```
com.tivoli.pd.as.cache.DynamicRoleCache.MaxUsers=100000
```

The maximum number of users that the cache supports before a cache cleanup is performed. The default number of users is 100000.

Specifying the number of cache tables

```
com.tivoli.pd.as.cache.DynamicRoleCache.NumBuckets=20
```

The number of tables that is used internally by the dynamic role cache. The default is 20. When a large number of threads use the cache, increase the value to tune and optimize cache performance.

Specifying the principal lifetime

```
com.tivoli.pd.as.cache.DynamicRoleCache.PrincipalLifeTime=10
```

The period of time in minutes that a principal entry is stored in the cache. The default time is 10 minutes. The term, *principal*, here refers to the Tivoli Access Manager credential that is returned from a unique Lightweight Directory Access Protocol user.

Specifying the role lifetime

```
com.tivoli.pd.as.cache.DynamicRoleCache.RoleLifetime=20
```

The period of time in seconds that a role is stored in the role list for a user before it is discarded. The default is 20 seconds.

Object caching properties:

The object cache is used to cache all Tivoli Access Manager objects, including their extended attributes. This bypasses the need to query the Tivoli Access Manager authorization server for each resource request.

These properties are in the *profile_root/etc/tam/amwas.node_name_server_name.amjacc.properties* file.

The *profile_root* directory is the value of the *profilePath* parameter when the profile is created.

Enabling object caching

```
com.tivoli.pd.as.cache.EnableObjectCaching=true
```

This property enables or disables object caching. The default value is true.

Setting the object cache

```
com.tivoli.pd.as.cache.ObjectCache=com.tivoli.pd.as.cache.ObjectCacheImpl
```

This property is the class used to perform object caching. You can implement your own object cache if required. This can be done by implementing the *com.tivoli.pd.as.cache.IObjectCache* interface. The default is *com.tivoli.pd.as.cache.ObjectCacheImpl*.

Setting the number of cache buckets

```
com.tivoli.pd.as.cache.ObjectCache.NumBuckets=20
```

This property specifies the number of buckets used to store object cache entries in the underlying hash table. The default is 20.

Setting the number of cache bucket entries

```
com.tivoli.pd.as.cache.ObjectCache.MaxResources=10000
```

This property specifies the total number of entries for all buckets in the cache. This figure, divided by *NumBuckets* determines the maximum size of each bucket. The default is 10000.

Setting the resource lifetime

```
com.tivoli.pd.as.cache.ObjectCache.ResourceLifeTime=20
```

This property specifies the length of time in minutes that objects are kept in the object cache. The default is 20.

These object cache properties cannot be changed after configuration. If any require changing, it should be done before configuration of the nodes in the cell. Changes need to be made in the template properties file before any configuration actions are performed. Properties changed after configuration might cause access decisions to fail.

Role-based policy framework properties:

Although it is very unlikely that you will need to change these properties, use this file to reference supported properties within the role-based policy framework.

The role-based policy framework parameters are located in the Java Authorization Contract for Containers (JACC) configuration file and in the authorization configuration file. They are set at the time of JACC provider configuration and authorization server configuration. The role-based policy framework settings for the authorization table and the JACC provider can be modified separately for each WebSphere Application Server instance. The `amwas.node_server.authztable.properties` configuration file is generated from the authorization table. The `amwas.node_name_server_name.amjacc.properties` configuration file is generated from the JACC provider. Both files are stored in the `profile_root/etc/tam` directory. It is very unlikely that you might need to change these properties. The properties are described here for reference:

Supported properties include:

com.tivoli.pd.as.rbpf.AMAction=i

This property is used to signify that a user is granted access to a role. This value is added to a Tivoli Access Manager access control list (ACL) and places invoke access on roles for users and groups.

com.tivoli.pd.as.rbpf.AMActionGroup=WebAppServer

This property sets the Tivoli Access Manager action group that serves as a container for the action that is specified by the `com.tivoli.pd.as.rbpf.AMAction` property. The permission set in the `com.tivoli.pd.as.rbpf.AMAction` property goes into this action group.

com.tivoli.pd.as.rbpf.PosRoot=WebAppServer

This property is used to determine where roles are stored in the protected object space.

com.tivoli.pd.as.rbpf.ProductId=deployedResources

This property specifies the location under the root location that is specified in the `posroot` property to separate other products in the protected object space. Embedded Tivoli Access Manager objects are found in the `/WebAppServer/deployedResources` directory. The default value is `deployedResources`.

com.tivoli.pd.as.rbpf.ResourceContainerName=Resources

This property specifies the Tivoli Access Manager object space container name for the protected resources. The default location is the `/WebAppServer/deployedResources/Resources` directory.

com.tivoli.pd.as.rbpf.RoleContainerName=Roles

This property specifies the Tivoli Access Manager protected object space container name for the security roles. The default location is the `/WebAppServer/deployedResources/Roles` directory.

The previous settings cannot be changed after configuration. Make changes in the template properties file before any configuration actions are performed. Properties that are changed after configuration will cause access decisions to fail.

System-dependent configuration properties:

Do not change these system-dependent configuration properties. These properties are included in this article for reference only.

These properties are in the `profile_root/etc/tam/amwas.node_name_server_name.amjacc.properties` file.

The `profile_root` variable is the value of the `profilePath` parameter when the profile is created.

The supported arguments include:

com.tivoli.pd.as.rbpf.AmasSession.CfgURL=file:/user_root/etc/tam/ amwas.node_server.pdperm.properties

This entry is generated by the Java Authorization Contract for Containers (JACC) provider

configuration. It specifies the location of the file that contains information about the Tivoli Access Manager JACC provider. Do not change this entry or the properties in the `amwas.node_server.pdperm.properties` file.

**com.tivoli.pd.as.rbpf.AmasSession.LoggingURL=file:/user_root/etc/tam/
amwas.node_server.pdlog.properties**

This entry contains the location of the logging configuration file for the Tivoli Access Manager JACC provider. The file referenced is generated by the Tivoli Access Manager JACC provider configuration. Do not change this entry.

Administering security users and roles with Tivoli Access Manager

Use these steps to manage user-to-role mappings and user-to-group mappings for applications.

User-to-role mapping and user-to-group mapping for the JACC provider of Tivoli Access Manager are performed using the WebSphere Application Server administrative console.

1. Click **Applications > Enterprise applications > *application_name***.
2. Under Additional properties, click **Security role to user/group mapping**. The user and groups management screen is displayed.
3. Select the role that requires user or group management and use **Lookup users** or **Lookup groups** to manage the users or groups for the selected role. The native role mapping uses the `MapRolesToUsers` administrative task. If you are using Tivoli Access Manager, use the `TAMMapRolesToUsers` administrative task instead. The syntax and options for the Tivoli version are the same as those used in the native version. For more information, see `csec_role_based_sec.dita` and `tsec_use_TAM_groups.dita`.

Configuring Tivoli Access Manager groups

Use these steps to configure the WebSphere Application Server administrative console to add objects of the `accessGroup` class to the list of object classes that represent user registry groups.

You can use the WebSphere Application Server administrative console to specify security policies for applications that run in the WebSphere Application Server environment. You can also use the WebSphere Application Server administrative console specify security policies for other Web resources, based on the entities that are stored in the user registry.

Tivoli Access Manager adds the `accessGroup` object class to the registry. Tivoli Access Manager administrators can use the `pdadmin` utility, which is available only on the policy server host in the `PD.RTE` fileset, to create new groups. These new groups are added to the registry as the `accessGroup` object class.

The WebSphere Application Server administrative console is not configured by default to recognize objects of the `accessGroup` class as user registry groups. You can configure the WebSphere Application Server administrative console to add this object class to the list of object classes that represent user registry groups. To do this configuration, complete the following instructions:

1. From the WebSphere Application Server administrative console, access the advanced settings for configuring security by clicking **Security > Secure administration, applications, and infrastructure**.
2. Under User account repository, click the **Available realm definitions** drop-down list, select **Standalone LDAP registry**, and click **Configure**.
3. Under Additional properties, click **Advanced Lightweight Directory Access Protocol (LDAP) user registry settings**.
4. Modify the **Group Filter** field. Add the following entry: `(objectclass=accessGroup)`

The Group Filter field looks like the following example:

```
(&(cn=%w)(|(objectclass=groupOfNames)
(objectclass=groupOfUniqueNames)(objectclass=accessGroup)))
```

5. Modify the **Group Member ID Map** field. Add the following entry: `accessGroup:member` The Group Member ID Map field looks like the following example:

```
groupOfNames:member;groupOfUniqueNames:uniqueMember;
accessGroup:member
```

6. Stop and restart WebSphere Application Server.

Configuring additional authorization servers

Tivoli Access Manager secure domains can contain more than one authorization server. Having multiple authorization servers is useful for providing a failover capability as well as improving performance when the volume of access requests is large.

1. Refer to the *Tivoli Access Manager Base Administration Guide* for details on installing and configuring authorization servers. This document is available in the IBM Tivoli Access Manager for e-business information center.
2. Re-configure the Java Authorization Contract for Containers (JACC) provider using the `$AdminTask reconfigureTAM interactive wsadmin` command. Enter all new and existing options.

Logging Tivoli Access Manager security

Use this topic to enable the trace specification to indicate tracing at the required level.

The Java Authorization Contract for Containers (JACC) for Tivoli Access Manager provider messages are logged to the configured trace output location, and messages are written to standard out `SystemOut.log` file. When trace is enabled, all logging, both trace and messaging, is sent to the `trace.log` file.

1. The `amwas.node_server.pdjlog.properties` file must be updated and the **isLogging** attribute set to `true` for the required component. For example, to enable tracing for the JACC provider for Tivoli Access Manager, set the following line to `true`:
`amwas.node_server.pdjlog.properties:baseGroup.AMWASWebTraceLogger.isLogging=true`
2. Enable tracing for the JACC provider of Tivoli Access Manager components in the WebSphere Application Server administrative console by completing the following steps:
 - a. Click **Troubleshooting > Logs and Trace > server_name**.
 - b. Under Logs and Trace tasks, click **Diagnostic trace**.
 - c. Select the **Enable Log** option.
 - d. Click **Apply**.
 - e. Click **Troubleshooting > Logs and Trace > server_name**.
 - f. Click **Change Log Detail Levels**.
 - g. Click **Components**. Tracing for all components can be enabled using the `com.tivoli.pd.as.*` command. Tracing for separate components can be enabled using the following commands:
 - `com.tivoli.pd.as.rbpf.*` for role-based policy framework tracing
 - `com.tivoli.pd.as.jacc.*` for JACC provider tracing
 - `com.tivoli.pd.as.pdwas.*` for the authorization table
 - `com.tivoli.pd.as.cfg.*` for configuration
 - `com.tivoli.pd.as.cache.*` for cachingFor more information, see `utrb_loglevel.dita`.
 - h. Click **Apply**.

The trace specification now indicates that tracing is enabled at the required level. Save the configuration and restart the server for the changes to take effect.

Tivoli Access Manager loggers:

The Java Authorization Contract for Containers (JACC) for Tivoli Access Manager provider messages are logged to the configured trace output location, and messages are written to standard out SystemOut.log file. When trace is enabled, all logging, both trace and messaging, is sent to the trace.log file.

The JACC provider for Tivoli Access Manager uses the JLog logging framework as does the Java runtime environment for Tivoli Access Manager. You can enable tracing and messaging selectively for specific JACC provider for Tivoli Access Manager components.

Tracing and message logging for the JACC provider for Tivoli Access Manager are configured in the `amwas.node_server.pdjlog.properties` properties file, which is located in the `profile_root/etc/tam` directory. This file contains logging properties from the `amwas.pdjlog.template.properties` template file for the specific node and server combination at the time of JACC provider for Tivoli Access Manager configuration.

The contents of this file let the user control:

- Whether tracing is enabled or disabled for the JACC provider of Tivoli Access Manager components.
- Whether message logging is enabled or disabled for the JACC provider of Tivoli Access Manager components.

The `amwas.node_server.pdjlog.properties` file defines several loggers, each of which is associated with one JACC provider of Tivoli Access Manager component. These loggers include:

Logger Name	Description
AmasRBPFTraceLogger AmasRBPFMessageLogger	Logs messages and trace for the role-based policy framework. This underlying framework is used by embedded Tivoli Access Manager to make access decisions.
AmasCacheTraceLogger AmasCacheMessageLogger	Logs messages and trace for the policy caches that are used by the role-based policy framework.
AMWASWebTraceLogger AMWASWebMessageLogger	Logs messages and trace for the WebSphere Application Server authorization plug-in.
AMWASConfigTraceLogger AMWASConfigMessageLogger	Logs messages and trace for the configuration actions of the JACC provider for Tivoli Access Manager .
JACCTraceLogger JACCMessageLogger	Logs messages and trace for the JACC provider activity of Tivoli Access Manager .

Note: Tracing can have a significant impact on system performance. Enable tracing only when diagnosing the cause of a problem.

The implementation of these loggers routes messages to the WebSphere Application Server logging sub-system. All messages are written to the WebSphere Application Server `trace.log` file.

For each logger, the `amwas.node_server.pdjlog.properties` file defines an `isLogging` attribute which, when set to `true`, enables logging for the specific component. A value of `false` disables logging for that component.

The `amwas.node_server.pdjlog.properties` file defines the parent loggers `MessageLogger` and `TraceLogger` that also have an `isLogging` attribute. If the child loggers do not specify this `isLogging` attribute, they inherit the value of their respective parent. When the JACC provider for Tivoli Access Manager is enabled, the `isLogging` attribute is set to `true` for the `MessageLogger` and set to `false` for the `TraceLogger` logger. Message logging is enabled for all components and tracing is disabled for all components, by default.

To turn on tracing for a JACC provider component, see [Logging Tivoli Access Manager security](#) .

Interfaces that support JACC

WebSphere Application Server provides the RoleConfigurationFactory and the RoleConfiguration interfaces, which are similar to PolicyConfigurationFactory and PolicyConfiguration interfaces so the information that is stored in the bindings file can be propagated to the provider during installation. The implementation of these interfaces is optional.

RoleConfiguration interface

Use the RoleConfiguration interface to propagate the authorization information to the provider. This interface is similar to the PolicyConfiguration interface that is found in Java Authorization Contract for Containers (JACC).

```
RoleConfiguration
    - com.ibm.wsspi.security.authorization.RoleConfiguration

/**
 * This interface is used to propagate the authorization table information
 * in the binding file during application installation. Implementation of this interface is
 * optional. When a JACC provider implements this interface during an application, both
 * the policy and the authorization table information are propagated to the provider.
 * If this is not implemented, only the policy information is propagated as per
 * the JACC specification.
 * @ibm-spi
 * @ibm-support-class-A1
 */

public interface RoleConfiguration

/**
 * Add the users to the role in RoleConfiguration.
 * The role is created, if it does not exist in RoleConfiguration.
 * @param role the role name.
 * @param users the list of the user names.
 * @exception RoleConfigurationException if the users cannot be added.
 */
public void addUsersToRole(String role, List users)
    throws RoleConfigurationException

/**
 * Remove the users to the role in RoleConfiguration.
 * @param role the role name.
 * @param users the list of the user names.
 * @exception RoleConfigurationException if the users cannot be removed.
 */
public void removeUsersFromRole(String role, List users)
    throws RoleConfigurationException

/**
 * Add the groups to the role in RoleConfiguration.
 * The role is created if it does not exist in RoleConfiguration.
 * @param role the role name.
 * @param groups the list of the group names.
 * @exception RoleConfigurationException if the groups cannot be added.
 */
public void addGroupsToRole(String role, List groups)
    throws RoleConfigurationException

/**
 * Remove the groups to the role in RoleConfiguration.
 * @param role the role name.
 * @param groups the list of the group names.
 * @exception RoleConfigurationException if the groups cannot be removed.
 */
public void removeGroupsFromRole( String role, List groups)
    throws RoleConfigurationException
```

```

/**
 * Add the everyone to the role in RoleConfiguration.
 * The role is created if it does not exist in RoleConfiguration.
 * @param role the role name.
 * @exception RoleConfigurationException if the everyone cannot be added.
 */
public void addEveryoneToRole(String role)
throws RoleConfigurationException

/**
 * Remove the everyone to the role in RoleConfiguration.
 * @param role the role name.
 * @exception RoleConfigurationException if the everyone cannot be removed.
 */
public void removeEveryoneFromRole( String role)
throws RoleConfigurationException

/**
 * Add the all authenticated users to the role in RoleConfiguration.
 * The role is created if it does not exist in RoleConfiguration.
 * @param role the role name.
 * @exception RoleConfigurationException if the authentication users cannot
 * be added.
 */

```

RoleConfigurationFactory interface

The RoleConfigurationFactory interface is similar to the PolicyConfigurationFactory interface that is introduced by JACC, and is used to obtain RoleConfiguration objects based on the contextID IDs.

RoleConfigurationFactory
 - com.ibm.wsspi.security.authorization.RoleConfigurationFactory

```

/**
 * This interface is used to instantiate the com.ibm.wsspi.security.authorization.RoleConfiguration

```

```

* objects based on the context identifier similar to the policy context identifier.
* Implementation of this interface is required only if the RoleConfiguration interface is implemented.
*
* @ibm-spi
* @ibm-support-class-A1
*/

public interface RoleConfigurationFactory
/**
* This gets a RoleConfiguration with contextID from the
* RoleConfigurationFactory. If the RoleConfiguration does not exist
* for the contextID in the RoleConfigurationFactory, a new
* RoleConfiguration with contextID is created in the
* RoleConfigurationFactory. The contextID is similar to
* PolicyContextID, but it does not contain the module name.
* If remove is true, the old RoleConfiguration is removed and a new
* RoleConfiguration is created, and returns with the contextID.
* @return the RoleConfiguration object for this contextID
* @param contextID the context ID of RoleConfiguration
* @param remove true or false
* @exception RoleConfigurationException if RoleConfiguration
* cannot be obtained.
**/
public abstract com.ibm.ws.security.policy.RoleConfiguration
    getRoleConfiguration(String contextID, boolean remove)
        throws RoleConfigurationException

```

InitializeJACCProvider provider

When implemented by the provider, this interface is called by every process where the JACC provider can be used for authorization. All additional properties that are entered during the authorization check are passed to the provider. For example, the provider can use this information to initialize client code to communicate with their server or repository. The cleanup method is called during server shutdown to clean up the configuration.

Declaration

```
public interface InitializeJACCProvider
```

Description

This interface has two methods. The JACC provider can implement the interface, and WebSphere Application Server calls it to initialize the JACC provider. The name of the implementation class is obtained from the value of the initializeJACCProviderClassName system property.

This class must reside in a Java archive (JAR) file on the class path of each server that uses this provider.

```

InitializeJACCProvider
- com.ibm.wsspi.security.authorization.InitializeJACCProvider

/**
* Initializes the JACC provider
* @return 0 for success.
* @param props the custom properties that are included for this provider will
* pass to the implementation class.
* @exception Exception for any problems encountered.
**/
public int initialize(java.util.Properties props)
throws Exception

/**
* This method is for the JACC provider cleanup and will be called during a process stop.
**/
public void cleanup()

```

Enabling the JACC provider for Tivoli Access Manager

The Java Authorization Contract for Container (JACC) provider for Tivoli Access Manager is configured by default. Use this topic to enable the JACC provider for Tivoli Access Manager.

Restriction: Do not perform this task if you are configuring the JACC provider for Tivoli Access Manager to supply authentication services only. Only perform this task for installations that require both Tivoli Access Manager authentication and authorization protection.

The JACC provider for Tivoli Access Manager is configured by default. The following list shows the JACC provider configuration settings for Tivoli Access Manager:

Field	Value
Name	Tivoli Access Manager
Description	This field is optional and used as a reference.
J2EE policy class name	com.tivoli.pd.as.jacc.TAMPolicy
Policy configuration factory class name	com.tivoli.pd.as.jacc.TAMPolicyConfigurationFactory
Role configuration factory class name	com.tivoli.pd.as.jacc.TAMRoleConfigurationFactory
JACC provider initialization class name	com.tivoli.pd.as.jacc.cfg.TAMConfigInitialize
Requires the EJB arguments policy context handler for access decisions	false
Supports dynamic module updates	true

To enable the JACC provider for Tivoli Access Manager, use the previous settings and complete the following steps:

1. Click **Security > Secure administration, applications, and infrastructure > External authorization providers**.
2. Select the **External authorization using a JACC provider** option, then click **Apply**.
3. Under Related Items, click **External JACC provider**. The JACC provider settings for Tivoli Access Manager are displayed.
4. Verify that the correct settings are present to work with your Tivoli Access Manager configuration. For more information, see “External Java Authorization Contract for Containers provider settings” on page 362.
5. Under Additional properties, click **Tivoli Access Manager properties**.
6. Click the **Enable embedded Tivoli Access Manager** option and verify that the correct Tivoli Access Manager server and WebSphere Application Server settings exist. For more information, see “Tivoli Access Manager JACC provider settings” on page 368.
7. Click **OK**.
8. Save the settings by clicking **Save** at the top of the page.
9. Log out of the WebSphere Application Server administrative console.
10. Restart WebSphere Application Server. The security configuration is now replicated to managed servers and node agents. These other servers within a cell also require restarting before the security changes take effect.

Enabling embedded Tivoli Access Manager

Embedded Tivoli Access Manager is not enabled by default, and you need to configure it for use.

Enabling Tivoli Access Manager security within WebSphere Application Server requires:

- A supported Lightweight Directory Access Protocol (LDAP) installed somewhere on your network. This user registry contains the user and group information for both Tivoli Access Manager and WebSphere Application Server.

- Tivoli Access Manager server exists and is configured to use the user registry. For details on the installation and configuration of Tivoli Access Manager, refer to the IBM Tivoli Access Manager for e-business information center.

Note: WebSphere Application Server contains an embedded client for Tivoli Access Manager. To use Tivoli Access Manager, you must also configure the Tivoli Access Manager server.

However, the server version must be the same version or later as the client version. For information on the supported version of Tivoli Access Manager, see WebSphere Application Server - Supported Prerequisites.

Tivoli Access Manager server is bundled with WebSphere Application Server.

- WebSphere Application Server is installed either in a single server model or as WebSphere Application Server Network Deployment.
- When administrative security is configured with a Federal Information Processing Standard (FIPS) provider, the Tivoli Access Manager server must be configured for FIPS as well

Complete the following steps to enable embedded Tivoli Access Manager security:

1. Create the security administrative user.
For more information, see the *Securing applications and their environment* PDF.
2. Configure the Java Authorization Contract for Containers (JACC) provider for Tivoli Access Manager .
For more information, see the *Securing applications and their environment* PDF.
3. Enable WebSphere Application Server security. When you are using Tivoli Access Manager you must configure LDAP as the user registry.
For more information, see the *Securing applications and their environment* PDF.
4. Enable the JACC provider for Tivoli Access Manager.
For more information, see the *Securing applications and their environment* PDF.

Disabling embedded Tivoli Access Manager client

To unconfigure Tivoli Access Manager Security in WebSphere Application Server, you can use either the wsadmin command-line utility or the WebSphere Application Server administrative console.

- For details on unconfiguring the embedded Tivoli Access Manager client using the WebSphere Application Server administrative console, refer to “Disabling embedded Tivoli Access Manager client using the administrative console.”
- For details on unconfiguring the embedded Tivoli Access Manager client using the wsadmin command line utility, refer to “Disabling embedded Tivoli Access Manager client using wsadmin” on page 669.

Disabling embedded Tivoli Access Manager client using the administrative console

To unconfigure the JACC provider for Tivoli Access Manager, you can use the WebSphere Application Server administrative console.

Ensure that all the managed servers, including node agents, are started. Perform the following process once on the deployment management server. Information from the unconfigure operation is forwarded to managed servers, including node agents, when the server is restarted. The managed servers require their own restart for changes to take effect.

1. Restart the deployment manager process.
2. Click **Security > Secure administration, applications, and infrastructure > External authorization providers**.
3. Under Related items, click **External JACC provider**.
4. Under Additional properties, click **Tivoli Access Manager Properties**. The configuration screen for the JACC provider for Tivoli Access Manager is displayed.

5. Clear the **Enable embedded Tivoli Access Manager** option. If you want to ignore errors when unconfiguring, select the **Ignore errors during embedded Tivoli Access Manager disablement** option. Select this option only when the Tivoli Access Manager domain is in an irreparable state.
6. Click **OK**.
7. **Optional:** If you want security enabled without Tivoli Access Manager re-enable administrative security.
8. **Optional:** Synchronize all nodes.
9. Restart all WebSphere Application Server instances for the changes to take effect.

Forcing the unconfiguration of the Tivoli Access Manager JACC provider

If you find you cannot restart WebSphere Application Server after configuring the JACC provider for Tivoli Access Manager a utility is available to clear the security configuration and return WebSphere Application Server to an operable state.

The utility removes all of the PDLoginModuleWrapper entries as well as the Tivoli Access Manager authorization table from `security.xml` and `wsjaas.conf` files. This utility effectively removes the JACC provider for Tivoli Access Manager.

1. Back up the `security.xml` and `wsjaas.conf` files.
2. Enter the following command as one continuous line.

```
java -Djava.version=1.5 -classpath
"app_server_root/$WAS_HOME/plugin/com.ibm.ws.runtime_1.0.0.jar"
com.tivoli.pd.as.jacc.cfg.CleanSecXML fully_qualified_path/security.xml
fully_qualified_path/wsjaas.conf
```

Authorizing access to administrative roles

You can assign users and groups to administrative roles to identify users who can perform WebSphere Application Server administrative functions.

Administrative roles enable you to control access to WebSphere Application Server administrative functions. Refer to the descriptions of these roles in `rsec_adminroles.dita`.

Before you assign users to administrative roles, you must set up your user registry. For information on the supported registry types, see "Selecting a registry or repository" on page 87.

The following steps are needed to assign users to administrative roles.

In the administrative console, click **Users and Groups**. Click either **Administrative User Roles** or **Administrative Group Roles**.

1. To add a user or a group, click **Add** on the Console users or Console groups panel.
2. To add a new administrator user, enter a user identity in the User field, highlight **Administrator**, and click **OK**. If there is no validation error, the specified user is displayed with the assigned security role.
3. To add a new administrative group, either enter a group name in the **Specify group** field or select EVERYONE or ALL AUTHENTICATED from the **Special subject** menu, highlight **Administrator**, and click **OK**. If no validation error occurs, the specified group or special subject is displayed with the assigned security role.
4. To remove a user or group assignment, click **Remove** on the Console Users or the Console Groups panel. On the Console Users or the Console Groups panel, select the check box of the user or group to remove and click **OK**.
5. To manage the set of users or groups to display, click **Show filter function** on the User Roles or Group Roles panel. In the **Search term(s)** box, type a value, then click **Go**. For example, `user*` displays only users with the user prefix.
6. After the modifications are complete, click **Save** to save the mappings.

7. Restart the application server for changes to take effect.
8. Shut down the nodes, node agents, and the deployment manager.
9. Verify that Java processes are not running. If they are running, discontinue these processes.
10. Restart the deployment manager.
11. Resynchronize the nodes. To resynchronize the nodes, run the `install_root/bin/syncNode` script from the Qshell command line for each node. For more information, see the `syncNode` command in the documentation.
12. Restart the nodes. To restart the nodes, run the `install_root/bin/startNode` script from the Qshell command line for each node. For more information, see the `startNode` command in the documentation.
13. Start any clusters, if applicable.

Administrative user roles settings and CORBA naming service user settings

Use the Administrative User Roles page to give users specific authority to administer application servers through tools such as the administrative console or `wsadmin` scripting. The authority requirements are only effective when global security is enabled. Use the Common Object Request Broker Architecture (CORBA) naming service users settings page to manage CORBA naming service users settings.

To view the Console Users administrative console page, complete either of the following steps:

- Click **Security > Secure administration, applications, and infrastructure > Administrative User Roles**.
- Click **Users and Groups > Administrative User Roles**.

To view the CORBA naming service groups administrative console page, click **Environment > Naming > CORBA Naming Service Groups**.

Note: When a third-party authorization such as Tivoli Access Manager or Service Access Facility (SAF) for z/OS is used, the information in this panel might not represent the data in the provider. Also, any changes to this panel might not be reflected in the provider automatically. Follow the provider's instructions to propagate any changes made here to the provider.

User (Administrative user roles)

Specifies users.

The users that are entered must exist in the configured active user registry.

Data type: String

User (CORBA naming service users)

Specifies CORBA naming service users.

The users that are entered must exist in the configured active user registry.

Data type: String

Role (Administrative user roles)

Specifies user roles.

The following administrative roles provide different degrees of authority that are needed to perform certain application server administrative functions:

Administrator

The administrator role has operator permissions, configurator permissions, and the permission that is required to access sensitive data including server password, Lightweight Third Party Authentication (LTPA) password and keys, and so on.

Operator

The operator role has monitor permissions and can change the run-time state. For example, the operator can start or stop services.

Configurator

The configurator role has monitor permissions and can change the WebSphere Application Server configuration.

Monitor

The monitor role has the least permissions. This role primarily confines the user to viewing the application server configuration and current state.

adminsecuritymanager

The adminsecuritymanager role has privileges for managing users and groups from within the administrative console and determines who has access to modify users and groups using administrative role mapping. Only the adminsecuritymanager role can map users and groups to administrative roles, and by default, AdminId is granted to the adminsecuritymanager.

iscadmins

The iscadmins role has administrator privileges for managing users and groups from within the administrative console only.

Note: To manage users and groups, click **Users and Groups** in the console navigation tree. Click either **Manage Users** or **Manage Groups**.

Data type:

String

Range:

Administrator, Operator, Configurator, Monitor, and
iscadmins

Note: Other arbitrary administrative roles might also be visible in the administrative console collection table. Other contributors to the console might create these additional roles, which can be used for applications that are deployed to the console.

Role (CORBA naming service users)

Specifies naming service user roles.

A number of naming roles are defined to provide degrees of authority that are needed to perform certain application server naming service functions. The authorization policy is only enforced when global security is enabled. The following roles are valid: CosNamingRead, CosNamingWrite, CosNamingCreate, and CosNamingDelete.

The roles now have authority levels from low to high:

CosNamingRead

You can query the application server name space by using, for example, the Java Naming and Directory Interface (JNDI) lookup method. The EVERYONE special-subject is the default policy for this role.

CosNamingWrite

You can perform write operations such as JNDI bind, rebind, or unbind, plus CosNamingRead operations.

CosNamingCreate

You can create new objects in the name space through operations such as JNDI createSubcontext and CosNamingWrite operations.

CosNamingDelete

You can destroy objects in the name space, for example using the JNDI `destroySubcontext` method and `CosNamingCreate` operations.

Data type:

String

Range:

`CosNamingRead`, `CosNamingWrite`, `CosNamingCreate` and `CosNamingDelete`

Login status (Administrative user roles)

Species whether the user is active or inactive.

Administrative group roles and CORBA naming service groups

Use the Administrative Group Roles page to give groups specific authority to administer application servers through tools such as the administrative console or `wsadmin` scripting. The authority requirements are only effective when administrative security is enabled. Use the Common Object Request Broker Architecture (CORBA) naming service groups page to manage CORBA Naming Service groups settings.

To view the Console Groups administrative console page, complete either of the following steps:

- Click **Security > Secure administration, applications, and infrastructure > Administrative Group Roles**.
- Click **Users and Groups > Administrative Group Roles**.

To view the CORBA naming service groups administrative console page, click **Environment > Naming > CORBA Naming Service Groups**.

Group (CORBA naming service groups)

Identifies CORBA naming service groups.

In previous releases of WebSphere Application Server, there were two default groups: `ALL AUTHENTICATED` and `EVERYONE`. However, `EVERYONE` is now the only default group, and it provides `CosNamingRead` privileges only.

Data type:

String

Range:

`EVERYONE`

Role (CORBA naming service groups)

Identifies naming service group roles.

A number of naming roles are defined to provide the degrees of authority that are needed to perform certain application server naming service functions. The authorization policy is only enforced when global security is enabled.

Four name space security roles are available: `CosNamingRead`, `CosNamingWrite`, `CosNamingCreate`, and `CosNamingDelete`. The roles have authority levels from low to high:

Cos Naming Read

You can query the application server name space using, for example, the Java Naming and Directory Interface (JNDI) lookup method. The `EVERYONE` special-subject is the default policy for this role.

Cos Naming Write

You can perform write operations such as JNDI bind, rebind, or unbind, and `CosNamingRead` operations. The `ALL_AUTHENTICATED` special-subject is the default policy for this role.

Cos Naming Create

You can create new objects in the name space through operations such as JNDI createSubcontext and CosNamingWrite operations. The ALL_AUTHENTICATED special-subject is the default policy for this role.

Cos Naming Delete

You can destroy objects in the name space, for example using the JNDI destroySubcontext method and CosNamingCreate operations. The ALL_AUTHENTICATED special-subject is the default policy for this role.

Data type:

String

Range:

CosNamingRead, CosNamingWrite, CosNamingCreate, and CosNamingDelete

Group (Administrative group roles)

Specifies groups.

The ALL_AUTHENTICATED and the EVERYONE groups can have the following role privileges: Administrator, Configurator, Operator, and Monitor.

Data type:

String

Range:

ALL_AUTHENTICATED, EVERYONE

Role (Administrative group roles)

Specifies user roles.

The following administrative roles provide different degrees of authority needed to perform certain application server administrative functions:

Administrator

The administrator role has operator permissions, configurator permissions, and the permission that is required to access sensitive data, including server password, Lightweight Third Party Authentication (LTPA) password and keys, and so on.

Operator

The operator role has monitor permissions and can change the run-time state. For example, the operator can start or stop services.

Configurator

The configurator role has monitor permissions and can change the application server configuration.

Monitor

The monitor role has the least permissions. This role primarily confines the user to viewing the application server configuration and current state.

iscadmins

The iscadmins role has administrator privileges for managing users and groups from within the administrative console only.

Note: To manage users and groups, click **Users and Groups** in the console navigation tree. Click either **Manage Users** or **Manage Groups**.

Data type:

String

Range:

Administrator, Operator, Configurator, Monitor, and iscadmins

Note: Other arbitrary administrative roles might also be visible in the administrative console collection table. Other contributors to the console might create these additional roles, which can be used for applications that are deployed to the console.

Assigning users to naming roles

Use this task to assign users to naming roles by using the administrative console.

The following steps are needed to assign users to naming roles. In the administrative console, click **Environment > Naming**, and click **CORBA Naming Service Users** or **CORBA Naming Service Groups**.

1. Click **Add** on the CORBA Naming Service Users or the CORBA Naming Service Groups panel.
2. To add a new naming service user, enter a user identity in the **User** field, highlight one or more naming roles, and click **OK**. If no validation errors occur, the specified user is displayed with the assigned security role.
3. To add a new naming service group, either select **Specify group** and enter a group name or select **Select from special subject** and then select **EVERYONE**. Click **OK**. If no validation errors occur, the specified group or special subject is displayed with the assigned security role.
4. To remove a user or group assignment, go to the **CORBA Naming Service Users** or **CORBA Naming Service Groups** panel. Select the check box next to the user or group that you want to remove and click **Remove**.
5. To manage the set of users or groups to display, expand the **Filter** folder on the right panel, and modify the filter text box. For example, setting the filter to `user*` displays only users with the user prefix.
6. After modifications are complete, click **Save** to save the mappings. Restart the server for the changes to take effect.

The default naming security policy is to grant all users read access to the CosNaming space and to grant any valid user the privilege to modify the contents of the CosNaming space. You can perform the previously mentioned steps to restrict user access to the CosNaming space. However, use caution when changing the naming security policy. Unless a Java 2 Platform, Enterprise Edition (J2EE) application has clearly specified its naming space access requirements, changing the default policy can result in unexpected `org.omg.CORBA.NO_PERMISSION` exceptions at runtime.

Propagating administrative role changes to Tivoli Access Manager

These steps provide an example of how to migrate the `admin-authz.xml` file.

Additions and changes to console users and groups are not automatically added to the Tivoli Access Manager object space after the Java Authorization Contract for Containers (JACC) provider for Tivoli Access Manager is configured. Changes to console users and groups are saved in the `admin-authz.xml` file and this file must be migrated before any changes take effect. The JACC provider for Tivoli Access Manager includes the **migrateEAR** migration utility for incorporating console user and group changes into the Tivoli Access Manager object space.

Note: The **migrateEAR** utility is used to migrate the changes made to console users and groups after the JACC provider for Tivoli Access Manager is configured. The utility does not need to run for changes and additions to console user and groups made prior to the configuration of the JACC provider for Tivoli Access Manager because the changes made to the `admin-authz.xml` and `naming-authz.xml` files are automatically migrated at configuration time. Furthermore, the migration tool does not need to run before deploying standard Java 2 Platform, Enterprise Edition (J2EE) applications; J2EE application policy deployment is also performed automatically.

For example, if you wanted to migrate the `admin-authz.xml` file, perform the following steps:

1. Change to the `app_server_root/bin` directory where the `migrateEAR` utility is located.
2. Run the **migrateEAR** utility to migrate the data contained in the `admin-authz.xml` file. Use the parameter descriptions that are listed in “The `migrateEAR` utility for Tivoli Access Manager” on page 388.

For example:

```
migrateEAR -profileName default
-j profile_root/config/cells/cell_name/xml_filename
-a sec_master
-p password
-w wsadmin
-d o=ibm,c=us
-c file:profile_root/etc/pd/PdPerm.properties
```

where *xml_filename* might be *admin-authz.xml* or *naming-authz.xml*.

- The `-j` parameter defaults to the file: *profile_root/config/cells/cell_name/admin-authz.html*
- The `-c` parameter defaults to the file: *profile_root/etc/pd/PdPerm.properties*. The output of the utility is logged in the *pdwas_migrate.log* file. The *pdwas_migrate.log* file is created in the *profile_root/logs* directory.
- The `-profile_name` parameter is optional and defaults to the default profile name.

A status message is displayed when the migration completes. Output of the utility is logged to the *pdwas_migrate.log* file, which is created in the directory where the utility is run. Check the log file after each migration. If the log file displays errors, check the last recorded transaction, correct the source of the error, and rerun the migration utility. If the migration is unsuccessful, verify that you supplied the correct values for the `-c` and `-j` options.

3. WebSphere Application Server does not require a restart for the changes to take effect.

The migrateEAR utility for Tivoli Access Manager

The **migrateEAR** utility migrates changes made to console users and groups in the *admin-authz.xml* and *naming-authz.xml* files into the Tivoli Access Manager object space.

Syntax

```
migrateEAR -profile_name default
-j fully_qualified_filename
-a Tivoli_Access_Manager_administrator_ID
-p Tivoli_Access_Manager_administrator_password
-w WebSphere_Application_Server_administrator_user_name
-d user_registry_domain_suffix
-c PdPerm.properties_file_location
```

Attention:

- The `-j` parameter defaults to the file: *profile_root/config/cells/cell_name/admin-authz.html*
- The `-c` parameter defaults to: *file:profile_root/etc/pd/PdPerm.properties*. The output of the utility is logged in the *pdwas_migrate.log* file. The *pdwas_migrate.log* file is created in the *profile_root/logs* directory.
- The `-profile_name` parameter is optional and defaults to the default profile name.

Parameters

-a *Tivoli_Access_Manager_administrator_ID*

The administrative user identifier. The administrative user must have the privileges required to create users, objects, and access control lists (ACLs). For example, `-a sec_master`.

This parameter is optional. When the parameter is not specified, you are prompted to supply it at run time.

-c *PdPerm.properties_file_location*

The Uniform Resource Indicator (URI) location of the *PdPerm.properties* file that is configured by the *pdwascfg* utility. When WebSphere Application Server is installed in the default location, the URI is:

```
file:profile_root/etc/pd/PdPerm.properties
```

-d *user_registry_domain_suffix*

The domain suffix for the user registry to use. For example, for Lightweight Directory Access Protocol (LDAP) user registries, this value is the domain suffix, such as: "o=ibm,c=us"

You can use the **pdadmin user show** command to display the distinguished name (DN) for a user.

-j *fully_qualified_pathname*

The fully qualified path and file name of the Java 2 Platform, Enterprise Edition application archive file ,admin-authz.xml or the roles definitions file naming-authz.xml that is used for a naming operation authorization. Optionally, this path can also be a directory of an expanded enterprise application. For example, when WebSphere Application Server is installed in the default location, the path to the data files to migrate includes:

profile_root/config/cells/cell_name

-p *Tivoli_Access_Manager_administrator_password*

The password for the Tivoli Access Manager administrative user. The administrative user must have the privileges that are required to create users, objects, and access control lists (ACLs). For example, you can specify the password for the -a sec_master administrative user as -p myPassword.

When this parameter is not specified, the user is prompted to supply the password for the administrative user name.

-w *WebSphere_Application_Server_administrator_user_name*

The user name that is configured in the WebSphere Application Server security user registry field as the administrator. This value matches the account that you created or imported in "Creating the security administrative user" on page 367. Access permission for this user is needed to create or update the Tivoli Access Manager protected object space.

When the WebSphere Application Server administrative user does not already exist in the protected object space, it is created or imported. In this case, a random password is generated for the user and the account is set to not valid. Change this password to a known value and set the account to valid.

A protected object and access control list (ACL) are created. The administrative user is added to the pdwas-admin group with the following ACL attributes:

T Traverse permission

i Invoke permission

WebAppServer

You can overwrite the action group name. The default name is WebAppServer. This action group name and the matching root object space can be overwritten when the migration utility is run with the **-r** option.

Comments

This utility migrates security policy information from deployment descriptors or enterprise archive files to Tivoli Access Manager for WebSphere Application Server. The script calls com.tivoli.pdwas.migrate.Migrate the Java class.

Before you invoke the script, you must run the **setupCmdLine** script from the Qshell command line. You can find this file in the *profile_root/bin* directory, where *profile_root* is your installation path. In a default installation, *profile_root* is *app_server_rootND*.

The script is dependent on finding the correct environment variables for the location of prerequisite software.

To enable a new user access to the administrative group in WebSphere Application Server, it is recommended that the user be added to the pdwas-admin group after JACC has been enabled. You can enter the administrative primary ID (adminID) in the group. This is required when the serverID is not the same as the adminID.

The following is an example of this command:

```
pdadmin> group modify pdwas-admin add adminID
```

Return codes

The utility can return the following exit status codes:

- 0** The command completed successfully.
- 1** The command failed.

Chapter 7. Securing communications

WebSphere Application Server provides several methods to secure communication between a server and a client.

The following topics are covered in this section:

- Secure communications using Secure Sockets Layer
- Creating an SSL configuration
- Creating a keystore configuration
- Creating a self-signed certificate
- Creating a certificate authority request
- Extracting a signer certificate from a personal certificate
- Retrieving signers from a remote SSL port
- Adding a signer certificate to a keystore
- Exchanging signer certificates in a keystore
- Configuring certificate expiration monitoring
- Key management for cryptographic uses
- Creating a key set configuration
- Creating a key set group configuration

Secure communications using Secure Sockets Layer

The Secure Sockets Layer (SSL) protocol provides transport layer security including authenticity, data signing, and data encryption to ensure a secure connection between a client and server that uses WebSphere Application Server. The foundation technology for SSL is *public key cryptography*, which guarantees that when an entity encrypts data using its private key, only entities with the corresponding public key can decrypt that data.

WebSphere Application Server uses Java Secure Sockets Extension (JSSE) as the SSL implementation for secure connections. JSSE is part of the Java 2 Standard Edition (J2SE) specification and is included in the IBM implementation of the Java Runtime Extension (JRE). JSSE handles the handshake negotiation and protection capabilities that are provided by SSL to ensure secure connectivity exists across most protocols. JSSE relies on X.509 certificate-based asymmetric key pairs for secure connection protection and some data encryption. Key pairs effectively encrypt session-based secret keys that encrypt larger blocks of data. The SSL implementation manages the X.509 certificates.

Managing X.509 certificates

Secure communications for WebSphere Application Server require digitally-signed X.509 certificates. The contents of an X.509 certificate, such as its distinguished name and expiration, are either signed by a certificate authority (CA) or are self-signed. When a trusted CA signs an X.509 certificate, WebSphere Application Server identifies the certificate and freely distributes it. A certificate must be signed by a CA because the certificate represents the identity of an entity to the general public. Server-side ports that accept connections from the general public must use CA-signed certificates. Most clients or browsers already have the signer certificate that can validate the X.509 certificate so signer exchange is not necessary for a successful connection.

You can trust the identity of a self-signed X.509 certificate only when a peer in a controlled environment, such as internal network communications, accepts the signer certificate. To complete a trusted handshake,

you must first send a copy of the entity certificate to every peer that connects to the entity. Self-signed certificates are less expensive than CA-signed certificates because they do not require signer exchange for a secure connection.

CA and self-signed X.509 certificates reside in Java *keystores*. JSSE provides a reference to the keystore in which a certificate resides. You can select from many types of keystores, including Java Cryptographic Extension (JCE)-based and hardware-based keystores. Typically, each JSSE configuration has two Java keystore references: a keystore and a *truststore*. The keystore reference represents a Java keystore object that holds personal certificates. The truststore reference represents a Java keystore object that holds signer certificates.

A personal certificate without a private key is an X.509 certificate that represents the entity that owns it during a handshake. Personal certificates contain both public and private keys. A signer certificate is an X.509 certificate that represents a peer entity or itself. Signer certificates contain just the public key and verify the signature of the identity that is received during a peer-to-peer handshake.

For more information, see “Extracting a signer certificate from a personal certificate” on page 484

For more information about keystores, see `csec_sslkeystoreconfs.dita`.

Signer exchange

When you configure an SSL connection, you can exchange signers to establish trust in a *personal certificate* for a specific entity. Signer exchange enables you to extract the X.509 certificate from the peer keystore and add it into the truststore of another entity so that the two peer entities can connect. The signer certificate also can originate from a CA as a root signer certificate or an intermediate signer certificate. You can also extract a *signer certificate* directly from a *self-signed certificate*, which is the X.509 certificate with the public key.

Figure 1 illustrates a hypothetical keystore and truststore configuration. An SSL configuration determines which entities can connect to other entities, and the peer connections that are trusted by an SSL handshake. If you do not have the necessary signer certificate, the handshake fails because the peer cannot be trusted.

Figure 3. Signer exchange

In this example, the truststore for Entity A contains three signers. Entity A can connect to any peer as long as one of the three signers validates its personal certificate. For example, Entity A can connect to Entity B or Entity C because the signers can trust both signed personal certificates. The truststore for Entity-B contains one signer. Entity B is able to connect to Entity C only, and only when the peer endpoint is using certificate Entity-C Cert 1 as its identity. The ports that use the other personal certificate for Entity C are not trusted by Entity B. Entity C can connect to Entity A only.

In the example, the self-signed configuration seems to represent a one-to-one relationship between the signer and the certificate. However, when a CA signs a certificate, it typically signs many at a time. The advantage of using a single CA signer is that it can validate personal certificates that are generated by the CA for use by peers. However, if the signer is a public CA, you must be aware that the signed certificates might have been generated for another company other than your target entity. For your internal communications, private CAs and self-signed certificates are preferable to public CAs because they enable you to isolate the connections that you want to occur and prevent those that you do not want to occur.

SSL configurations

An SSL configuration comprises a set of configuration attributes that you can associate with an *endpoint* or set of endpoints in the WebSphere Application Server topology. The SSL configuration enables you to create an SSLContext object, which is the fundamental JSSE object that the server uses to obtain SSL socket factories. You can manage the following configuration attributes:

- An alias for the SSLContext object
- A handshake protocol version
- A keystore reference
- A truststore reference
- A key manager
- One or more trust managers
- A security level selection of a cipher suite grouping or a specific cipher suite list
- A certificate alias choice for client and server connections

To understand the specifics of each SSL configuration attribute, see “Secure Sockets Layer configurations” on page 397.

Selecting SSL configurations

In previous releases of WebSphere Application Server, you can reference an SSL configuration only by selecting the SSL configuration alias directly. Each secure endpoint was denoted by an alias attribute that references a valid SSL configuration within a repertoire of SSL configurations. When you made a single configuration change, you had to re-configure many alias references across the various processes. Although the current release still supports direct selection, this approach is no longer recommended.

The current release provides improved capabilities for managing SSL configurations and more flexibility when you select SSL configurations. In this release, you can select from the following approaches:

Programmatic selection

You can set an SSL configuration on the running thread prior to an outbound connection. WebSphere Application Server ensures that most system protocols, including Internet Inter-ORB Protocol (IIOP), Java Message Service (JMS), Hyper Text Transfer Protocol (HTTP), and Lightweight Directory Access Protocol (LDAP), accept the configuration. See “Example: Programmatically specifying an outbound SSL configuration using JSSEHelper API” on page 449

Dynamic selection

You can associate an SSL configuration dynamically with a specific target host, port, or outbound protocol by using a predefined selection criteria. When it establishes the connection, WebSphere Application Server checks to see if the target host and port match a predefined criteria that includes the domain portion of the host. Additionally, you can predefine the protocol for a specific outbound SSL configuration and certificate alias selection. See “Dynamic outbound selection of Secure Sockets Layer configurations” on page 405 for more information.

Direct selection

You can select an SSL configuration by using a specific alias, as in past releases. This method of selection is maintained for backwards compatibility because many applications and processes rely on alias references.

Scope selection

You can associate an SSL configuration and its certificate alias, which is located in the keystore associated with that SSL configuration, with a WebSphere Application Server management scope. This approach is recommended to manage SSL configurations centrally. You can manage endpoints more efficiently because they are located in one topology view of the cell. The inheritance relationship between scopes reduces the number of SSL configuration assignments that you must set.

Each time you associate an SSL configuration with a cell scope, the node scope within the cell automatically inherits the configuration properties. However, when you assign an SSL configuration to a node, the node configuration overrides the configuration that the node inherits from the cell. Similarly, all of the application servers for a node automatically inherit the SSL configuration for that node unless you override these assignments. Unless you override a specific configuration, the topology relies on the rules of inheritance from the cell level down to the endpoint level for each application server.

The topology view displays an inbound tree and outbound tree. You can make different SSL configuration selections for each side of the SSL connection based on what that server connects to as an outbound connection and what the server connects to as an inbound connection. See “Central management of Secure Sockets Layer configurations” on page 407 for more information.

The runtime uses an order of precedence for determining which SSL configuration to choose because you have many ways to select SSL configurations. Consider the following order of precedence when you select a configuration approach:

1. Programmatic selection. If an application sets an SSL configuration on the running thread using the `com.ibm.websphere.ssl.JSSEHelper` application programming interface (API), the SSL configuration is guaranteed the highest precedence.

2. Dynamic selection criteria for outbound host and port or protocol.
3. Direct selection.
4. Scope selection. Scope inheritance guarantees that the endpoint that you select is associated with an SSL configuration and is inherited by every scope beneath it that does not override this selection.

Default self-signed certificate configuration

By default, WebSphere Application Server creates a unique self-signed certificate for each node. WebSphere Application Server no longer relies on the default or dummy certificate that is shipped with the product. The `key.p12` default keystore and the `trust.p12` truststore are stored in the configuration repository within the node directory.

All of the nodes put their signer certificates in this common truststore (`trust.p12`). Additionally, after you federate a node, the default SSL configuration is automatically modified to point to the common truststore, which is located in the cell directory. The node can now communicate with all other servers in the cell.

All default SSL configurations contain a keystore with the name suffix `DefaultKeyStore` and a truststore with the name suffix `DefaultTrustStore`. These default suffixes instruct the WebSphere Application Server runtime to add the signer of the personal certificate to the common truststore. If a keystore name does not end with `DefaultKeyStore`, the keystore signer certificates are not added to the common truststore when you federate the server. You can change the default SSL configuration, but you must ensure that the correct trust is established for administrative connections, among others.

For more information, see “Default self-signed certificate configuration” on page 413 and “Web server plug-in default configuration” on page 423.

Certificate expiration monitoring

Certificate monitoring ensures that the self-signed certificate for each node is not allowed to expire. The certificate expiration monitoring function issues a warning before certificates and signers are set to expire. Those certificates and signers that are located in keystores managed by the WebSphere Application Server configuration can be monitored. You can configure the expiration monitor to automatically replace a self-signed certificate with a new self-signed certificate that is based upon the same data that is used for the initial creation. The monitor also can automatically replace old signers with the signers from the new self-signed certificates in keystores that are managed by WebSphere Application Server. The existing signer exchanges that occurred by the runtime during federation and by administration are preserved. For more information, see “Certificate expiration monitoring” on page 422.

WebSphere Application Server clients: signer-exchange requirements

A new self-signed certificate is generated for each node during its initial startup. To ensure trust, clients must be given these generated signers to establish a connection. Several enhancements in the current release make this process simpler. You can gain access to the signer certificates of various nodes to which the client must connect with any one of the following options (for more information, see “Secure installation for client signer retrieval” on page 417):

- A signer exchange prompt enables you to import signer certificates that are not yet present in the truststores during a connection to a server. By default, this prompt is enabled for administrative connections and can be enabled for any client SSL configuration. When this prompt is enabled, any connection that is made to a server where the signer is not already present offers the signer of the server along with the certificate information and a Secure Hash Algorithm (SHA) digest of the certificate for verification. The user is given a choice whether to accept these credentials. If the credentials are accepted, the signer is added to the truststore of the client until the signer is explicitly removed. The signer exchange prompt does not occur again when connecting to the same server unless the personal certificate changes.

Attention: It is unsafe to trust a signer exchange prompt without verifying the SHA digest. An unverified prompt can originate from a browser when a certificate is not trusted.

- You can run a `retrieveSigners` administrative script from a client prior to making connections to servers. To download signers, no administrative authority is required. To upload signers, you must have Administrator role authority. The script downloads all of the signers from a specified server truststore into the specified client truststore and can be called to download only a specific alias from a truststore. You can also call the script to upload signers to server truststores. When you select the `CellDefaultTrustStore` truststore as the specified server truststore and common truststore for a cell, all of the signers for that cell are downloaded to the specified client truststore, which is typically `ClientDefaultTrustStore`. For more information, see `rxml_retrievesigners.dita`.
- You can physically distribute to clients the `trust.p12` common truststore that is located in the cell directory of the configuration repository. When doing this distribution, however, you must ensure that the correct password has been specified in the `ssl.client.props` client SSL configuration file. The default password for this truststore is `WebAS`. Change the default password prior to distribution. Physical distribution is not as effective as the previous options. When changes are made to the personal certificates on the server, automated exchange can fail.

Dynamic SSL configuration changes

The SSL runtime for WebSphere Application Server maintains listeners for most SSL connections. A change to the SSL configuration causes the inbound connection listeners to create a new `SSLContext` object. Existing connections continue to use the current `SSLContext` object. Outbound connections automatically use the new configuration properties when they are attempted.

Make dynamic changes to the SSL configuration during off-peak hours to reduce the possibility of timing-related problems and to prevent the possibility of the server starting again. If you enable the runtime to accept dynamic changes, then change the SSL configuration and save the `security.xml` file. Your changes take effect when the new `security.xml` file reaches each node.

Note: If configuration changes cause SSL handshake failures, administrative connectivity failures also can occur, which can lead to outages. In this case, you must re-configure the SSL connections then perform manual node synchronization to correct the problem. You must carefully complete any dynamic changes. It is highly recommended that you perform changes to SSL configurations on a test environment prior to making the same changes to a production system. For more information, see “Dynamic configuration updates” on page 423.

Built-in certificate management

Certificate management that is comparable to `iKeyMan` functionality is now integrated into the keystore management panels of the administrative console. Use built-in certificate management to manage personal certificates, certificate requests, and signer certificates that are located in keystores. Additionally, you can remotely manage keystores. For example, you can manage a file-based keystore that is located outside the configuration repository on any node from the deployment manager. You also can remotely manage hardware cryptographic keystores from the deployment manager.

With built-in certificate management, you can replace a self-signed certificate along with all of the signer certificates scattered across many truststores and retrieve a signer from a remote port by connecting to the remote SSL host and port and intercepting the signer during the handshake. The certificate is first validated according to the certificate SHA digest, then the administrator must accept the validated certificate before it can be placed into a truststore.

When you make a certificate request, you can send it to a certificate authority (CA). When the certificate is returned, you can accept it within the administrative console. For more information, see “Certificate management” on page 426.

Tip: Although iKeyMan functionality still ships with WebSphere Application Server, configure keystores from the administrative console using the built-in certificate management functionality. iKeyMan is still an option when it is not convenient to use the administrative console. For more information, see `csec_sslikeymancertman.dita`.

AdminTask configuration management

The SSL configuration management panels in the administrative console rely primarily on administrative tasks, which are maintained and enhanced to support the administrative console function. You can use `wsadmin` commands from a Java console prompt to automate the management of keystores, SSL configurations, certificates, and so on.

Secure Sockets Layer configurations

Secure Sockets Layer (SSL) configurations contain attributes that enable you to control the behavior of both client and server SSL endpoints. You can identify SSL configurations by their user-assigned names or aliases, and assign them to specific management scopes. The scope that an SSL configuration inherits depends upon whether you create it using a cell, node, server, or endpoint link in the configuration topology.

When you create an SSL configuration, you can set the following SSL connection attributes:

- Keystore
- Default client certificate for outbound connections
- Default server certificate for inbound connections
- Truststore
- Key manager for selecting a certificate
- Trust manager or managers for establishing trust during the handshake
- Handshaking protocol
- Ciphers for negotiating the handshake
- Client authentication support and requirements

You can manage an SSL configuration using any of the following methods:

- Central management selection
- Direct reference selection
- Dynamic outbound connection selection
- Programmatic selection

You can view an SSL configuration in the topology at the point where it was created and at all of the scopes below that point. If you want the entire cell to view an SSL configuration, you must create the configuration at the cell level in the topology. Using the administrative console, you can manage all of the SSL configurations for WebSphere Application Server. From the administrative console, click **Security > SSL certificates and key management > Manage endpoint security configurations > Inbound | Outbound > SSL_configuration**. Using the `ssl.client.props` properties file, you can manage client SSL configurations. The `ssl.client.props` file is located in the `${USER_INSTALL_ROOT}/properties` directory for each profile. For more information about configuring this file, see the “`ssl.client.props` client configuration file” on page 458.

SSL configuration in the security.xml file

In the `security.xml` file, you can define specific attributes to configure an SSL configuration repertoire entry at a specific management scope. The scope determines the point at which other levels in the cell topology can see the configuration, as shown in the following example:

```

<repertoire xmi:id="SSLConfig_1" alias="NodeDefaultSSLSettings"
managementScope="ManagementScope_1" type="JSSE">
<setting xmi:id="SecureSocketLayer_1" clientAuthentication="false"
clientAuthenticationSupported="false" securityLevel="HIGH" enabledCiphers=""
jsseProvider="IBMJSSE2" sslProtocol="SSL_TLS" keyStore="KeyStore_1"
trustStore="KeyStore_2" trustManager="TrustManager_1" keyManager="KeyManager_1"
clientKeyAlias="default" serverKeyAlias="default"/>
</repertoire>

```

The SSL configuration attributes that display in the previous code are described in Table 1.

Table 15. security.xml Attributes

security.xml attribute	Description	Default	Associated SSL property
xmi:id	The xmi:id attribute represents the unique identifier for this XML entry and determines how the SSL configuration is linked to other XML objects, such as SSLConfigGroup. This system-defined value must be unique.	The administrative configuration service defines the default value.	None. This value is used only for XML associations.
alias	The alias attribute defines the name of the SSL configuration. Direct selection uses the alias attribute and the node is not prefixed to the alias. Rather, the management scope takes care of ensuring that the name is unique within the scope.	The default is CellDefaultSSLSettings.	com.ibm.ssl.alias
managementScope	The managementScope attribute defines the management scope for the SSL configuration and determines the visibility of the SSL configuration at runtime.	The default scope is the cell.	The managementScope attribute is not mapped to an SSL property. However, it confirms whether or not the SSL configuration is associated with a process.
type	The type attribute defines the Java Secure Socket Extension (JSSE) or System Secure Sockets Layer (SSSL) configuration option. JSSE is the SSL configuration type for most secure communications within WebSphere Application Server.	The default is JSSE.	com.ibm.ssl.sslType
clientAuthentication	The clientAuthentication attribute determines whether SSL client authentication is required.	The default is false.	com.ibm.ssl.clientAuthentication
clientAuthenticationSupported	The clientAuthenticationSupported attribute determines whether SSL client authentication is supported. The client does not have to supply a client certificate if it does not have a client certificate. Attention: When you set the clientAuthentication attribute to true, you override the value that is set for the clientAuthenticationSupported attribute.	The default is false.	com.ibm.ssl.client.AuthenticationSupported

Table 15. security.xml Attributes (continued)

security.xml attribute	Description	Default	Associated SSL property
securityLevel	The securityLevel attribute determines the cipher suite group. Valid values include HIGH (128-bit ciphers), MEDIUM (40-bit ciphers), LOW (for all ciphers without encryption), and CUSTOM (if the cipher suite group is customized. When you set the enabledCiphers attribute with a specific list of ciphers, the system ignores this attribute.	The default is HIGH.	com.ibm.ssl.securityLevel
enabledCiphers	You can set the enabledCiphers attribute to specify a unique list of cipher suites. Separate each cipher suite in the list with a space.	The default is the securityLevel attribute for cipher suite selection.	com.ibm.ssl.enabledCipherSuites
jsseProvider	The jsseProvider attribute defines a specific JSSE provider.	The default is IBMJSSE2.	com.ibm.ssl.contextProvider
sslProtocol	The sslProtocol attribute defines the SSL handshake protocol. Valid options include: SSLv2 (client-side only), SSLv3, SSL, SSL_TLS, TLSv1, and TLS values. The SSL option includes SSLv2 and SSLv3 values. The TLS option includes the TLSv1 value. SSL_TLS, which is the most interoperable protocol, includes all these values and defaults to a Transport Layer Security (TLS) handshake.	The default is SSL_TLS.	com.ibm.ssl.protocol
keyStore	The keyStore attribute defines the keystore and attributes of the keyStore instance that the SSL configuration uses for key selection.	The default is CellDefaultKeyStore.	For more information, see Keystore configurations.
trustStore	The trustStore attribute defines the key store that the SSL configuration uses for certificate signing verification.	The default is CellDefaultTrustStore.	A trustStore is a logical JSSE term. It signifies a key store that contains signer certificates. Signer certificates validate certificates that are sent to WebSphere Application Server during an SSL handshake.
keyManager	The keyManager attribute defines the key manager that WebSphere Application Server uses to select keys from a key store. A JSSE key manager controls the javax.net.ssl.X509KeyManager interface. A custom key manager controls the javax.net.ssl.X509KeyManager and the com.ibm.wsspi.ssl.KeyManagerExtendedInfo interfaces. The com.ibm.wsspi.ssl.KeyManagerExtendedInfo interface provides more information from WebSphere Application Server.	The default is IbmX509.	com.ibm.ssl.keyManager defines a well-known key manager and accepts the algorithm and algorithm provider formats, for example IbmX509 and IbmX509 IBMJSSE2. com.ibm.ssl.customKeyManager defines a custom key manager and takes precedence over the other keyManager properties. This class must implement javax.net.ssl.X509KeyManager and can implement com.ibm.wsspi.ssl.KeyManagerExtendedInfo. For more information, see csec_sslx509certIDkeyman.dita

Table 15. *security.xml* Attributes (continued)

security.xml attribute	Description	Default	Associated SSL property
trustManager	The trustManager determines which trust manager or list of trust managers to use for determining whether to trust the peer side of the connection. A JSSE trust manager implements the javax.net.ssl.X509TrustManager interface. A custom trust manager might also implement com.ibm.wsspi.ssl.TrustManagerExtendedInfo interface to get more information from the WebSphere Application Server environment.	The default is IbmX509. You can specify the IbmPKIX trust manager for certificate revocation list (CRL) verification when the certificate contains a CRL distribution point.	com.ibm.ssl.trustManager defines a well-known trust manager, which is required for most handshake situations. com.ibm.ssl.trustManager performs certificate expiration checking and signature validation. You can define com.ibm.ssl.customTrustManagers with additional custom trust managers that are called during an SSL handshake. Separate additional trust managers with the vertical bar () character. For more information, see csec_sslx509certtrustdecisions.dita

Trust manager control of X.509 certificate trust decisions

The role of the trust manager is to validate the Secure Sockets Layer (SSL) certificate that is sent by the peer, which includes verifying the signature and checking the expiration date of the certificate. A Java Secure Socket Extension (JSSE) trust manager determines if the remote peer can be trusted during an SSL handshake.

WebSphere Application Server has the ability to call multiple trust managers during an SSL connection. The default trust manager does the standard certificate validation; custom trust manager plug-ins run customized validation such as host name verification. For more information, see “Example: Developing a custom trust manager for custom SSL trust decisions” on page 439

When a trust manager is configured in a server-side SSL configuration, the server calls the isClientTrusted method. When a trust manager is configured in a client-side SSL configuration, the client calls the isServerTrusted method. The peer certificate chain is passed to these methods. If the trust manager chooses not to trust the peer information, it might produce an exception to force a handshake failure.

Optionally, WebSphere Application Server provides the com.ibm.wsspi.ssl.TrustManagerExtendedInfo interface so that additional information can be passed to the trust manager. For more information, see the com.ibm.wsspi.ssl.TrustManagerExtendedInfo interface.

Default IbmX509 trust manager

The default IbmX509 trust manager, which is used in the following code sample, establishes trust by performing standard certificate validation.

```
<trustManagers xmi:id="TrustManager_1132357815717" name="IbmX509" provider="IBMJSSE2"
algorithm="IbmX509" managementScope="ManagementScope_1132357815717"/>
```

The trust manager provides a signer certificate to verify the peer certificate that is sent during the handshake. The signers who are added to the truststore for the SSL configuration must be trustworthy. If you do not trust the signers or do not want to allow others to connect to your servers, consider removing default root certificates from certificate authorities (CA). You might also remove any self-signed certificates if you cannot verify their origination.

Default IbmPKIX trust manager

You can use the default IbmPKIX trust manager to replace the IbmX509 trust manager, which is shown in the following code sample:

```
<trustManagers xmi:id="TrustManager_1132357815719" name="IbmPKIX" provider="IBMJSSE2"
algorithm="IbmPKIX" trustManagerClass="" managementScope="ManagementScope_1132357815717">
<additionalTrustManagerAttrs xmi:id="DescriptiveProperty_1132357815717"
```

```

name="com.ibm.security.enableCRLDP" value="true" type="boolean"/>
<additionalTrustManagerAttrs xmi:id="DescriptiveProperty_1132357815718"
name="com.ibm.jsse2.checkRevocation" value="true" type="boolean"/>
</trustManagers>

```

In addition to its role of standard certificate verification, the IbmPKIX trust manager checks for certificates that contain certificate revocation list (CRL) distribution points. This process is known as *extended CRL checking*. When you select a trust manager, its associated properties are automatically set as Java System properties so that the IBM CertPath and IBMJSSE2 providers are aware that CRL checking is enabled.

Custom trust manager

You can define a custom trust manager to perform additional trust checking, which is based upon the needs of the environment. For example, in one environment, you might enable connections from the same Transmission Control Protocol (TCP) subnet only. The `com.ibm.wsspi.ssl.TrustManagerExtendedInfo` interface provides extended information about the connection that is not provided by the standard Java Secure Sockets Extension (JSSE) `javax.net.ssl.X509TrustManager` interface. The configured `trustManagerClass` attribute determines which class is instantiated by the runtime, as shown in the following code sample:

```

<trustManagers xmi:id="TrustManager_1132357815718" name="CustomTrustManager"
trustManagerClass="com.ibm.ws.ssl.core.CustomTrustManager"
managementScope="ManagementScope_1132357815717"/>

```

The `trustManagerClass` attribute must implement the `javax.net.ssl.X509TrustManager` interface and, optionally, can implement the `com.ibm.wsspi.ssl.TrustManagerExtendedInfo` interface.

Disabling the default trust manager

In some cases, you might not want to perform the standard certificate verification that is provided by the IbmX509 and IbmPKIX default trust managers. For example, you might be working with an internal automated test infrastructure that is not concerned with SSL client or server authentication, integrity, or confidentiality. The following sample code shows a basic custom trust manager such as `com.ibm.ws.ssl.core.CustomTrustManager` whose property is set to `true`.

```
com.ibm.ssl.skipDefaultTrustManagerWhenCustomDefined=true
```

You can set this property in the global properties at the top of the `ssl.client.props` file for clients or in the `security.xml` custom properties file for servers. You must configure a custom trust manager when you disable the default trust manager to prevent the server from calling the default trust manager even though it is configured. Disabling the default trust manager is not a common practice. Be sure to test the system with the disabled default trust manager in a test environment first. For more information on setting up a custom trust manager, see “Creating a custom trust manager configuration” on page 436

Key manager control of X.509 certificate identities

The role of a Java Secure Socket Extension (JSSE) key manager is to retrieve the certificate that is used to identify the client or server during a Secure Sockets Layer (SSL) handshake.

WebSphere Application Server provides a default key manager that can select a certificate from a keystore when you define the following SSL configuration properties:

com.ibm.ssl.keyStoreClientAlias

Defines the alias that is chosen from the keystore for the client side of a connection. This alias must be present in the keystore.

com.ibm.ssl.keyStoreServerAlias

Defines the alias that is chosen from the keystore for the server side of a connection. This alias must be present in the keystore.

These two properties are set automatically when you use the administrative console because the default key manager is already configured.

With WebSphere Application Server, you can configure only one key manager at a time for a given SSL configuration. If you want custom certificate selection logic on the client side, you must write a new custom key manager. The custom key manager could provide function that prompts the user to choose a certificate dynamically. Also, you can implement an extended interface so that a key manager can provide information during connection time. For more information on the extended interface, see the `com.ibm.wsspi.ssl.KeyManagerExtendedInfo` interface. For more information on custom key manager development, see `rsec_ssldevcustomkeymgr.dita`.

Default IbmX509 key manager

The default IbmX509 key manager chooses a certificate to serve as the identity for an SSL handshake. The key manager is called to enable client authentication on either side of the SSL handshake; frequently on the server-side, and less frequently on the client side according to client and server requirements. If a keystore is not configured on the client-side and SSL client authentication is enabled, the key manager cannot select a certificate to send to the server. Therefore, the handshake fails.

The following sample code shows the key manager configuration in the `security.xml` file for an IbmX509 key manager.

```
<keyManagers xmi:id="KeyManager_1" name="IbmX509"
provider="IBMJSSE2" algorithm="IbmX509" keyManagerClass=""
managementScope="ManagementScope_1"/>
```

You do not specify the `keyManagerClass` class because the key manager is provided by the IBMJSSE2 provider. However, you can specify whether the key manager is a custom class implementation, in which case you must specify the `keyManager` class, or an algorithm name that WebSphere Application Server can start from the Java security provider framework.

Custom key manager

The following sample code shows the key manager configuration in the `security.xml` file for a custom class.

```
<keyManagers xmi:id="KeyManager_2" name="CustomKeyManager"
keyManagerClass="com.ibm.ws.ssl.core.CustomKeyManager"
managementScope="ManagementScope_1"/>
```

The custom class must implement the `javax.net.ssl.X509KeyManager` interface and, optionally, implement the `com.ibm.wsspi.ssl.KeyManagerExtendedInfo` interface to retrieve additional WebSphere Application Server information. This interface replaces the function of the default key manager because you can configure only one key manager at a time. Therefore, the custom key manager has sole responsibility for selecting the alias to use from the configured keystore. The benefit of a custom key manager is its ability, on the client side, to prompt for an alias. This process enables the user to decide which certificate to use in situations where the user knows the client certificate identity. For more information, see `tsec_sslcreatecuskeymgr.dita`.

Keystore configurations

Use keystore configurations to define how the runtime for WebSphere Application Server loads and manages keystore types for Secure Sockets Layer (SSL) configurations.

By default, the `java.security.Security.getAlgorithms("KeyStore")` attribute does not display a predefined list of keystore types in the administrative console. Instead, WebSphere Application Server retrieves all of the `KeyStore` types that can be referenced by the `java.security.KeyStore` object, including hardware cryptographic, z/OS platform, i5/OS platform, IBM Java Cryptography Extension (IBMJCE), and Java-based content management system (CMS)-provider keystores. If you specify a keystore provider in

the java.security file or add it to the provider list programmatically, WebSphere Application Server also retrieves custom keystores. The retrieval list depends upon the java.security configuration for that platform and process.

IBMJCE file-based keystores (JCEKS, JKS, and PKCS12)

A typical IBMJCE file-based keystore configuration is shown in the following sample code:

```
<keyStores xmi:id="KeyStore_1" name="NodeDefaultKeyStore"
password="{xor}349dkckdd=" provider="IBMJCE"
location="{USER_INSTALL_ROOT}/config/cells/myhostNode01Cell
/nodes/myhostNode01/key.p12" type="PKCS12" fileBased="true"
hostList="" initializeAtStartup="true" readOnly="false"
managementScope="ManagementScope_1"/>
```

For more information about default keystore configurations, see csec_ssldefselfsigncertconf.dita.

Table 1 describes the attributes that are used in the sample code.

Table 16. keystore configurations

Attribute name	Default	Description
xmi:id	Varies	A value that issued to reference the keystore from another area in the configuration, for example, from an SSL configuration. Make this value unique within the security.xml file.
name	For JSSE keystore: CellDefaultKeyStore. For JSSE truststore: CellDefaultTrustStore.	A name that is used to identify the keystore by sight. The name can determine if the keystore is a default keystore based upon whether the name ends with DefaultKeyStore or DefaultTrustStore.
password	The default keystore password is WebAS. It is recommended that this be changed as soon as possible. See "Updating default key store passwords using scripting" on page 676 for more information.	The password that is used to access the keystore name is also the default that is used to store keys within the keystore.
provider	The default provider is IBMJCE.	The Java provider that implements the type attribute (for example, PKCS12 type). The provider can be left unspecified and the first provider that implements the keystore type specified is used.
location	The default varies, but typically references a key.p12 file or a trust.p12 file in the node or cell directories of the configuration repository. These files are PKCS12 type keystores.	The keystore location reference. If the keystore is file-based, the location can reference any path in the file system of the node where the keystore is located. However, if the location is outside of the configuration repository, and you want to manage the keystore remotely from the administrative console or from the wsadmin utility, then specify the hostList attribute that contains the host name of the node where it resides.

Table 16. keystore configurations (continued)

Attribute name	Default	Description
type	The default Java crypto device keystore type is PKCS12.	This type specifies the keystore. Valid types can be those returned by the <code>java.security.Security.getAlgorithms("KeyStore")</code> attribute. These types include the following keystore types, and availability depends on the process and platform <code>java.security</code> configuration: <ul style="list-style-type: none"> • JKS • JCEKS • PKCS12 • PKCS11 (Java crypto device) • CMSKS • IBMi5OSKeyStore • JCERACFKS • JCE4758KS (z/OS crypto device)
fileBased	The default is true.	This option is required for default keystores. It indicates a file-system keystore so you can use a <code>FileInputStream</code> or <code>FileOutputStream</code> for loading and storing the keystore.
hostList	The <code>hostList</code> attribute is used to specify a remote hostname so that the keystore can be remotely managed. There are no remotely managed keystores by default. All default keystores are managed locally in the configuration repository and synchronized out to each of the nodes.	The option manages a keystore remotely. You can set the host name of a valid node for a keystore. When you use either the administrative console or the <code>wsadmin</code> utility to manage certificates for this keystore, an MBean call is made to the node where the keystore exists for the approved operation. You can specify multiple hosts, although synchronization of the keystore operations are not guaranteed. For example, one of the hosts that is listed might be down when a specific operation is performed. Therefore, use multiple hosts in this list.
initializeAtStartup	The default is true.	This option informs the runtime to initialize the keystore during startup. This option can be important for hardware cryptographic device acceleration.
readOnly	The default is false.	This option informs the configuration that you cannot write to this keystore. That is, certain update operations on the keystore cannot be attempted and are not allowed. An example of a read-only keystore type is JCERACFKS on the z/OS platform. This type is read-only from the WebSphere certificate management standpoint, but you can also update it using the keystore management facility for RACF.
managementScope	The default scope is the node scope for a base Application Server environment and the cell scope for a Network Deployment environment.	This option references a particular management scope in which you can see this keystore. For example, if a hardware cryptographic device is physically located on a specific node, then create the keystore from a link to that node in the topology view under Security > Security Communications > SSL configurations . You can also use management scope to isolate a keystore reference. In some cases, you might need to allow only a specific application server to reference the keystore; the management scope is for that specific server.

CMS keystores

You can set some provider-specific attributes in CMS keystores.

When you create a CMS keystore, the CMS provider is `IBMi50SJSSEProvider`, and the CMS type is `IBMi50SKeyStore`, as shown in the following sample code:

```
<keyStores xmi:id="KeyStore_1132071489571" name="CMSKeyStore"
password="{xor}HRYNFAtRbxEw0zpvbhw6MzM=" provider="IBMi50SJSSEProvider"
location="{USER_INSTALL_ROOT}\profiles\AppSrv01/config/cells/myhostCell01
/nodes/myhostNode01/servers/webserver1/plugin-key.kdb" type="IBMi50SKeyStore"
fileBased="true" createStashFileForCMS="true"
managementScope="ManagementScope_1132071489569"/>
```

Note: The i5/OS keystore type `IBMi50SKeyStore` does not recognize or generate `.sth` password stash files. Instead it keeps an internal record of the password for the `.kdb` keystore file where it is created. If the `.kdb` file is moved, the password is no longer associated with the keystore. In that case, the Digital Certificate Manager (DCM) must be used to recreate the internal record of the password for the `.kdb` key store file. For more information, see “Recreating the `.kdb` keystore internal password record” on page 466.

Hardware cryptographic keystores

For cryptographic device configuration, see “Key management for cryptographic uses” on page 500 and “Configuring a hardware cryptographic keystore” on page 467

You can add a slot either as the custom property, `com.ibm.ssl.keyStoreSlot`, or as the configuration attribute, `slot="0"`. The custom property is read before the attribute for backwards compatibility.

In certain environments, you can use the hardware cryptographic card for hardware acceleration. Either set the `useForAcceleration` attribute to `true` or set the `com.ibm.ssl.keyStoreUseForAcceleration` custom property. When you set the attribute to `true`, you are not required to configure a password. However, you cannot use the device to store keys. For more information on configuring a hardware cryptographic keystore, see [Configuring hardware cryptographic keystore configurations](#).

Default key store passwords

When WebSphere Application Server starts for the first time as a standalone application server or as a network deployment, each server creates a key store and trust store for the default SSL configuration. When WebSphere Application Server creates these files, they use a default password (WebAS). Because the default password is well known, it is important that you change the password to protect the security of the key store files and the SSL configuration.

You can change the keystore passwords of:

- A single keystore or multiple key stores using a command task
- Multiple keystores using a command task
- A single keystore, using the administrative console

Dynamic outbound selection of Secure Sockets Layer configurations

WebSphere Application Server provides dynamic outbound selection that enables you to choose a specific Secure Sockets Layer (SSL) configuration and certificate alias for each outbound protocol, target host, target port, or any combination of these attributes. You can specify the dynamic selection information for outbound connections from a pure client or from a server that is acting as a client.

Before the SSL runtime for WebSphere Application Server starts an outbound connection, the runtime attempts to match the outbound protocol, target host, and target port attributes with the dynamic outbound selection information that is associated with an SSL configuration and certificate alias in the configuration.

The runtime caches both selection misses and selection hits, so the impact on performance can be minimal. However, a relationship exists between the amount of dynamic outbound selection information and its impact on the initial connection performance.

Dynamic selection information for outbound administrative SOAP connections

The default dynamic outbound selection configuration specifies that all outbound administrative SOAP connections use the same SSL configuration and certificate alias within the entire cell.

The management scope of the SSL configuration is at the cell level so every process in the cell sees this configuration. When an administrative SOAP client makes an outbound connection, the client provides protocol, target host, and target port information to the SSL runtime, as shown in the following sample code:

```
<dynamicSSLConfigSelections xmi:id="DynamicSSLConfigSelection_1"
name="AdminSSLOutbound" description="Uses the AdminSSL configuration
for all outbound SOAP calls." dynamicSelectionInfo="ADMIN_SOAP,*,*"
certificateAlias="default" sslConfig="SSLConfig_2"
managementScope="ManagementScope_1"/>
```

The SSL runtime checks the configuration and confirms that `certificateAlias="default"` and `sslConfig="SSLConfig_2"` for the `ADMIN_SOAP` protocol when you enable client certificate authentication.

Note: The configured target host and port are represented by the `*` character because both the host and the port attributes can be any value.

Target information during outbound connections

The dynamic outbound selection configurations are only effective when the outbound protocol uses the JSSEHelper application programming interface (API) when you select an SSL configuration with a specified `connectionInfo` hash map. This hash map must contain the following properties:

com.ibm.ssl.direction

The value for outbound connections is `OUTBOUND`.

com.ibm.ssl.remoteHost

The format should match what the protocol provides. Typically this is the canonical Domain Name Space (DNS), but it also could be the IP address.

com.ibm.ssl.remotePort

The port is target port.

com.ibm.ssl.endPointName

The value for an outbound connection must be one of the following protocol strings:

- IIOP
- HTTP
- SIP
- LDAP
- ADMIN_SOAP
- BUS_TO_BUS
- BUS_CLIENT
- BUS_TO_WEBSPPHERE_MQ

Central management of Secure Sockets Layer configurations

By default, Secure Sockets Layer (SSL) configurations for servers are managed from a central location in the topology view in the administrative console. You can associate an SSL configuration and certificate alias with a management scope. This method is the most efficient method to manipulate and modify configurations when the server topology changes.

In prior releases, SSL configurations are managed in the `server.xml` file for each process. You have to edit individual `server.xml` documents to modify individual SSL configuration aliases in the configuration topology. In this release of WebSphere Application Server, management control of SSL configurations offers more flexibility and options. You can make coarse-grained changes using the cell-scope and fine-grained changes using a particular endpoint name, as defined in the `serverindex.xml` file for a specific application server process.

Because SSL configuration associations manifest inheritance behaviors, you can simplify the number of associations by referencing only the highest level management scope that needs a unique configuration. Obviously, the security environment influences issues such as SSL configuration uniqueness, and SSL configuration and certificate alias placement in the topology.

To configure the inbound and outbound topologies, which must be done separately in the administrative console, click **Security > SSL certificates and key management > Manage endpoint security configurations > Inbound | Outbound**.

The topology view provides the scoping mechanism. The SSL configuration inherits its visibility, which is its display in the topology, at the scope where you created the configuration and at all the scopes beneath this parent scope. When you create an SSL configuration at a specific node, the configuration can be seen by that node agent and by every application server that is part of that node. Any application server or node that is not part of this particular node cannot see this SSL configuration. You can configure different certificate aliases and SSL configurations for inbound versus outbound connections.

Default centrally managed SSL configuration

While it is easier to manage SSL configurations centrally in the topology view of the administrative console, you can also use `wsadmin` scripting within `AdminTasks`. You can manage SSL configuration associations in the configuration element of the `security.xml` file.

The `sslConfigGroup` configuration object is the mechanism that is used to associate a connection direction and management scope with a specific SSL configuration and certificate alias. The default `sslConfigGroups` cell attribute has a predefined inbound and outbound cell-scoped configuration that each endpoint in the cell inherits. Because rules of precedence must guide you when you select SSL configurations, see `csec_sslsecurecom.dita` before you modify your configurations.

```
<sslConfigGroups xmi:id="SSLConfigGroup_1"
name="myhostCell01" direction="inbound" certificateAlias="default"
sslConfig="SSLConfig_1" managementScope="ManagementScope_1"/>
<sslConfigGroups xmi:id="SSLConfigGroup_2" name="myhostCell01"
direction="outbound" certificateAlias="default" sslConfig="SSLConfig_1"
managementScope="ManagementScope_1"/>
```

```
<managementScopes xmi:id="ManagementScope_1"
scopeName="(cell):myhostCell01" scopeType="cell"/>
```

In the previous sample code, the `sslConfigGroups` attribute references the cell management scope. For this example, the following list shows the precedence order for selecting management scopes, from the highest order of precedence to the lowest. Each time an endpoint scope is defined, it uses the specified SSL configuration and certificate alias. However, you can use a more dynamic or direct technique for selecting an SSL configuration such as dynamic outbound, programmatic selection, or direct selection.

For more information, see `csec_sslodynoutboundconfigs.dita`.

Endpoint scope

```
<managementScopes xmi:id="ManagementScope_1" scopeName="(cell):myhostCell01:  
(node):myhostNode01:(server):server1:(endpoint):ENDPOINT_NAME_IN_SERVERINDEX"  
scopeType="endpoint"/>
```

Cluster scope

```
<managementScopes xmi:id="ManagementScope_1" scopeName="(cell):myhostCell01:  
(node):myhostNode01:(server):server1:(endpoint):ENDPOINT_NAME_IN_SERVERINDEX"  
scopeType="endpoint"/>
```

Server scope

```
<managementScopes xmi:id="ManagementScope_1" scopeName="(cell):myhostCell01:  
(node):myhostNode01:(server):server1" scopeType="server"/>
```

Node scope

```
<managementScopes xmi:id="ManagementScope_1" scopeName="(cell):myhostCell01:  
(node):myhostNode01" scopeType="node"/>
```

Nodegroup scope

```
<managementScopes xmi:id="ManagementScope_1" scopeName="(cell):myhostCell01:  
(nodegroup):DefaultNodeGroup" scopeType="nodegroup"/>
```

Cell scope

```
<managementScopes xmi:id="ManagementScope_1" scopeName="(cell):myhostCell01"  
scopeType="cell"/>
```

Secure Sockets Layer node, application server, and cluster isolation

Secure Sockets Layer (SSL) enables you to ensure that any client that attempts to connect to a server during the handshake first performs server authentication. You can isolate communications between servers that must not communicate with each other over secure ports using SSL configurations at the node, application server, and cluster scopes.

Before you attempt to isolate communications controlled by WebSphere Application Server, you must have a good understanding of the deployment topology and application environment. To isolate a node, application server, or cluster, you must be able to control the signers that are contained in the trust stores that are associated with the SSL configuration. When the client does not contain the server signer, it cannot establish a connection to the server. If you use self-signed certificates, the server that created the personal certificate controls the signer, although you do have to manage the self-signed certificates. If you obtain certificates from a certificate authority (CA), you must obtain multiple CA signers because all of the servers can connect to each other if they share the same signer.

Authenticating only the server-side of a connection is not adequate protection when you need to isolate a server. Any client can obtain a signer certificate for the server and add it to its trust store. SSL client authentication must also be enabled between servers so that the server can control its connections by deciding which client certificates it can trust. For more information, see `tsec_sslclientauthinbound.dita`, which applies as well to enabling SSL client authentication at the cell level.

Isolation also requires that you use centrally managed SSL configurations for all or most endpoints in the cell. Centrally managed configurations can be scoped, unlike direct or end point configuration selection, and they enable you to create SSL configurations, key stores, and trust stores at a particular scope. Because of the inheritance hierarchy of WebSphere Application Server cells, if you select only the properties that you need for an SSL configuration, only these properties are defined at your selected scope or lower. For example, if you configure at the node scope, your configuration applies to the application server and individual end point scopes below the node scope. For more information, see `tsec_sslassocconfigscope.dita`, `tsec_sslselconfigdirect.dita`, and `tsec_sslassocconfigout.dita`

When you configure the key stores, which contain cryptographic keys, you must work at the same scope at which you define the SSL configuration and not at a higher scope. For example, if you create a key store that contains a certificate whose host name is part of the distinguished name (DN), then store that

keystore in the node directory of the configuration repository. If you decide to create a certificate for the application server, then store that keystore on the application server in the application server directory.

When you configure the trust stores, which control trust decisions on the server, you must consider how much you want to isolate the application servers. You cannot isolate the application servers from the node agents or the deployment manager. However, you can configure the SOAP connector end points with the same personal certificate or to share trust. Naming persistence requires IIOp connections when they pass through the deployment manager. Because application servers always connect to the node agents when the server starts, the IIOp protocol requires that WebSphere Application Server establish trust between the application servers and the node agents.

Establishing node SSL isolation

By default, WebSphere Application Server uses a single self-signed certificate for each node so you can isolate nodes easily. A common trust store, which is located in the cell directory of the configuration repository, contains all of the signers for each node that is federated into the cell. After federation, each cell process trusts all of the other cell processes because every SSL configuration references the common trust store.

You can modify the default configuration so that each node has its own trust store, and every application server on the node trusts only the node agent that uses the same personal certificate. You must also add the signer to the node trust store so that WebSphere Application Server can establish trust with the deployment manager. To isolate the node, ensure that the following conditions are met:

- The deployment manager must initiate connections to any process
- The node agent must initiate connections to the deployment manager and its own application servers
- The application servers must initiate connections to the applications servers on the same node, to its own node agent, and the deployment manager

Figure 1 shows Node Agent A contains a key.p12 keystore and a trust.p12 trust store at the node level of the configuration repository for node A.

Figure 4.

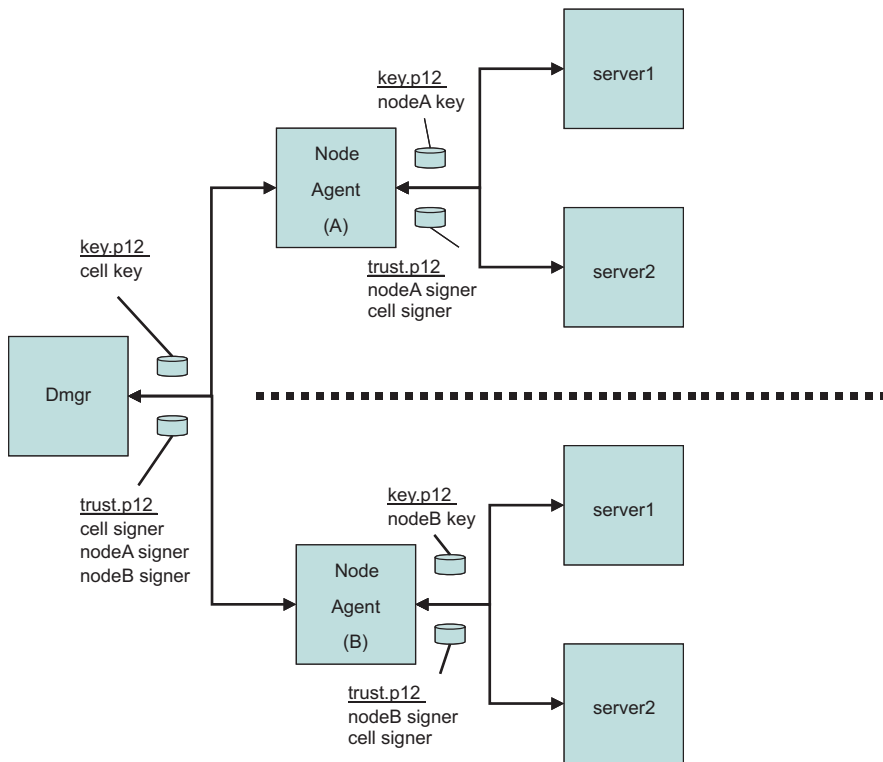

Figure 1: SSL Node Isolation

When you associate an SSL configuration with this keystore and truststore, you break the link with the cell-scoped trust store. To isolate the node completely, repeat this process for each node in the cell. WebSphere Application Server SSL configurations override the cell scope and use the node scope instead so that each process at this scope uses the SSL configuration and certificate alias that you selected at this scope. You establish proper administrative trust by ensuring that nodeA signer is in the common trust store and the cell signer is in the nodeA trust store. The same logic applies to node B as well. For more information, see `tsec_sslassocconfigscope.dita`.

Establishing application server SSL isolation

Isolating application server processes from one another is more challenging than isolating nodes. You must consider the following application design and topology conditions:

- An application server process might need to communicate with the node agent and deployment manager
- Isolating application server processes from each other might disable single sign-on capabilities for horizontal propagation

If you configure outbound SSL configurations dynamically, you can accommodate these conditions. When you define a specific outbound protocol, target host, and port for each different SSL configuration, you can override the scoped configuration.

Figure 2 shows how you might isolate an application server completely, although in practice this approach would be more complicated.

Figure 5.

Figure 2: SSL Application Server Isolation

The dynamic configuration enables server1 on Node A to communicate with server 1 on Node B only over IIOp. The dynamic outbound rule is IIOp,nodeBhostname,* . For more information, see tsec_sslssoconfigout.dita

Establishing cluster SSL isolation

You can configure application servers into clusters instead of scoping them centrally at the node or dynamically at the server to establish cluster SSL isolation. While clustered servers can communicate with each other, application servers outside of the cluster cannot communicate with the cluster, thus isolating the clustered servers. For example, you might need to separate applications from different departments while maintaining a basic level of trust among the clustered servers. Using the dynamic outbound SSL configuration method described for servers above, you can easily extend the isolated cluster as needed.

Figure 3 shows a sample cluster configuration where cluster 1 contains a key.p12 with its own self-signed certificate, and a trust.p12 that is located in the config/cells/<cellname>/clusters/<clustername> directory.

Figure 6.

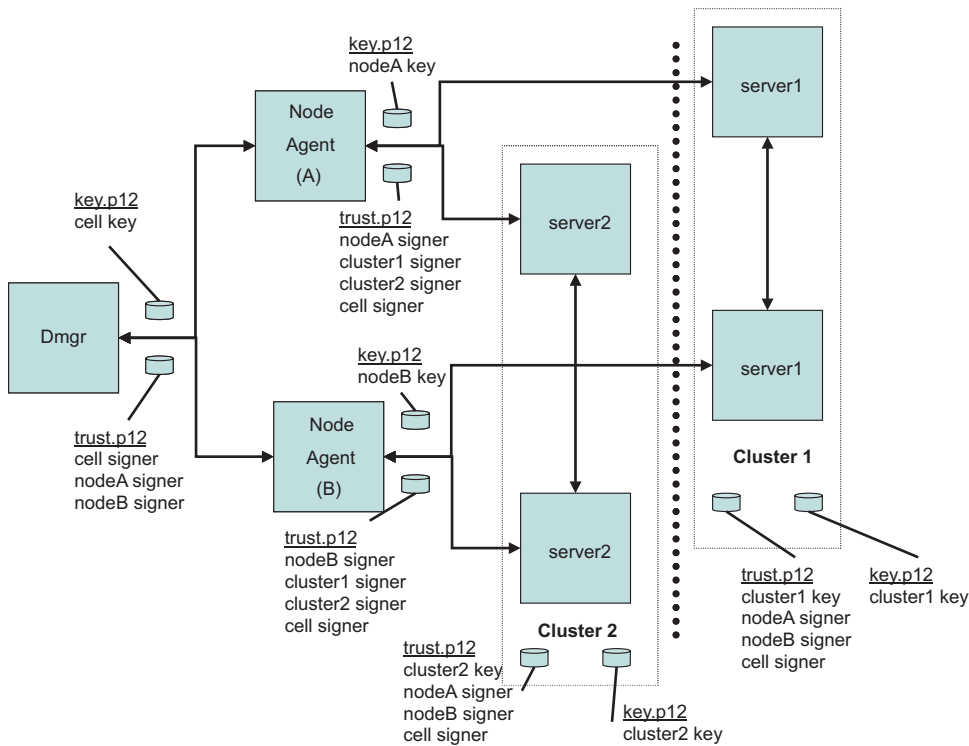

Figure 3: SSL Cluster Isolation

In the example, cluster1 might contain web applications, and cluster2 might contain EJB applications. Considering the various protocols, you decide to enable IIOF traffic between the two clusters. Your task is to define a dynamic outbound SSL configuration at the cluster1 scope with the following properties:

```
IIOP,nodeAhostname,9403|IIOP,nodeAhostname,9404|IIOP,nodeBhostname,9403|IIOP,nodeBhostname,9404
```

You must create another SSL configuration at the cluster1 scope that contains a new trust.p12 file with the cluster2 signer. Consequently, outbound IIOF requests go either to nodeAhostname ports 9403 and 9404 or to nodeBhostname ports 9403 and 9404. The IIOF SSL port numbers on these two application server processes in cluster2 identify the ports.

As you review Figure 3, notice the following features of the cluster isolation configuration:

- The trust.p12 for cluster1 contains signers that allow communications with itself (cluster1 signer), between both node agents (nodeAsigner and nodeBsigner), and with the deployment manager (cell signer).
- The trust.p12 for cluster2 contains signers that allow communications with itself (cluster2 signer), between both node agents (nodeAsigner and nodeBsigner), and with the deployment manager (cell signer).
- Node agent A and Node agent B can communicate with themselves, the deployment manager, and both clusters.

For more information, see tsec_sslasocconfigout.dita.

Although this article presents an overview of isolation methods from an SSL perspective, you must also ensure that non-SSL ports are closed or applications require the confidentiality constraint in the deployment descriptor. For example, you can set the CSiv2 inbound transport panel to require SSL and disable the channel ports that are not secure from the server ports configuration.

Also, you must enable SSL client authentication for SSL to enforce the isolation requirements on both sides of a connection. Without mutual SSL client authentication, a client can easily obtain a signer for the server programmatically and thus bypass the goal of isolation. With SSL client authentication, the server would require the client's signer for the connection to succeed. For HTTP/S protocol, the client is typically a browser, a Web Service, or a URL connection. For the IIOP/S protocol, the client is typically another application server or a Java client. WebSphere Application Server must know the clients to determine if SSL client authentication enablement is possible. Any applications that are available through a public protocol must not enable SSL client authentication because the client may fail to obtain a certificate to authenticate to the server.

Note: It is beyond the scope of this article to describe all of the factors you must consider to achieve complete isolation.

Default self-signed certificate configuration

When a WebSphere Application Server process starts for the first time, the Secure Sockets Layer (SSL) runtime initializes the default keystores and truststores that are specified in the SSL configuration.

Default keystore and truststore properties

WebSphere Application Server creates the key.p12 default keystore file and the trust.p12 default truststore file during profile creation. A default, self-signed certificate is also created in the key.p12 file at this time. The signer or public key is extracted from the key.p12 file and added to the trust.p12 file. If the files do not exist during process startup, they are recreated during startup.

You can easily identify keystore and truststore defaults because of their suffixes: DefaultKeyStore and DefaultTrustStore. Also, in the SSL configuration, you must set the fileBased attribute to true so that the runtime uses the default keystores and truststores only.

On a base application server, default key and truststores are stored in the node directory of the configuration repository. For example, the default key.p12 and trust.p12 stores are created with the AppSrv01 profile name, the myhostNode01Cell name, and the myhostNode01 node name. The key and truststores are located in the following directories:

```
/QIBM/UserData/WebSphere/AppServer/V61/ND/profiles/default/config  
/cells/myhostNode01Cell/nodes/myhostNode01/key.p12  
/QIBM/UserData/WebSphere/AppServer/V61/ND/profiles/default/config  
/cells/myhostNode01Cell/nodes/myhostNode01/trust.p12
```

The default password is WebAS for all default keystores generated by WebSphere Application Server. Change the default password after the initial configuration for a more secure environment.

Default self-signed certificate

The default self-signed certificate is created during profile creation for both the server and client for that profile.

Use caution since the new self-signed certificates created must have the signers added to the common truststore. This should be done through the administrative console.

If you want to set up SSL client authentication between the client and server, you must perform a signer exchange. The certificate properties below that exist in the ssl.client.props file do not exist in the server configuration. However, you can use these values in the server configuration by adding them as custom security properties in the administrative console. The certificate properties appear in the ssl.client.props file, but do not appear in the server configuration. However, you can modify these values in the server configuration by adding them as custom properties in the administrative console.

Click **Security > Secure administration, applications, and infrastructure > Custom properties** to change the following properties:

```
com.ibm.ssl.defaultCertReqAlias=default_alias
com.ibm.ssl.defaultCertReqSubjectDN=cn=${hostname},o=IBM,c=US
com.ibm.ssl.defaultCertReqDays=365
com.ibm.ssl.defaultCertReqKeySize=1024
```

If a default_alias value already exists, the runtime appends `_#`, where the number sign (#) is a number that increments until it is unique in the keystore. `${hostname}` is a variable that is resolved to the host name where it was originally created. The default expiration date of self-signed certificates is one year from their creation date.

The runtime monitors the expiration dates of self-signed certificates using the Certificate Expiration Monitor. These self-signed certificates are automatically replaced along with the signer certificates when they are within the expiration threshold, which is typically 30 days before expiration. You can increase the default key size beyond 1024 bits only when the Java Runtime Environment policy files are unrestricted, that is, not exported. For more information, see `csec_sslcertmonitoring.dita`.

Default keystore and truststore configurations for new deployment manager processes

Default SSL configurations

The following sample code shows the default SSL configurations for a deployment manager:

```
<repertoire xmi:id="SSLConfig_1" alias="CellDefaultSSLSettings"
managementScope="ManagementScope_1">
<setting xmi:id="SecureSocketLayer_1" clientAuthentication="false"
securityLevel="HIGH" enabledCiphers="" jsseProvider="IBMJSSE2" sslProtocol="SSL_TLS"
keyStore="KeyStore_1" trustStore="KeyStore_2" trustManager="TrustManager_1"
keyManager="KeyManager_1"/>
</repertoire>

<repertoire xmi:id="SSLConfig_2" alias="AdminSoapSSLSettings"
managementScope="ManagementScope_1">
<setting xmi:id="SecureSocketLayer_2" clientAuthentication="false" securityLevel="HIGH"
enabledCiphers="" jsseProvider="IBMJSSE2" sslProtocol="SSL_TLS" keyStore="KeyStore_1"
trustStore="KeyStore_2" trustManager="TrustManager_1" keyManager="KeyManager_1"/>
</repertoire>
```

Note: The keystore and truststore reference `KeyStore_1` and `KeyStore_2`, respectively. By default, all of the SOAP connector secure communications use `AdminSoapSSLSettings` and all other secure communications use `CellDefaultSSLSettings`. For more information on how you can create and manage new configurations centrally, see `csec_sslcentralmanconfigs.dita`.

Default keystores and truststores

In the following sample code, the keystores and truststores for a deployment manager are referenced by the previous SSL configurations:

```
<keyStores xmi:id="KeyStore_1" name="CellDefaultKeyStore"
password="{xor}123skfkdki=" provider="IBMJCE" location="{USER_INSTALL_ROOT}
/config/cells/myhostCell01/key.p12" type="PKCS12" fileBased="true" hostList=""
initializeAtStartup="true" managementScope="ManagementScope_2"/>

<keyStores xmi:id="KeyStore_2" name="CellDefaultTrustStore"
password="{xor}123skfkdki=" provider="IBMJCE" location="{USER_INSTALL_ROOT}
/config/cells/myhostCell01/trust.p12" type="PKCS12" fileBased="true" hostList=""
initializeAtStartup="true" managementScope="ManagementScope_2"/>

<managementScopes xmi:id="ManagementScope_2" scopeName="(cell):myhostCell01"
scopeType="cell"/>
```

Note: In the sample code, the default key and truststores are located in the cell directory of the configuration repository. Because the scopeType management scope is set to the cell level, every process in the cell can see the key and truststores. If the physical location of the keystore is lower in the node directories hierarchy, the keystore is not visible to other nodes.

The trust.p12 truststore for the deployment manager is referred to as common because it can be seen by all of the processes. In fact, when a base application server is federated into a network deployment environment, the SSL configurations for nodes whose truststores end in DefaultTrustStore automatically change and point to the CellDefaultTrustStore common truststore. For every keystore that ends in DefaultKeyStore, the signer from the self-signed certificate is added to the common truststore. After federation, all of the default SSL configurations reference the common truststore and trusted secure communications are established for all of the server processes.

Clients that need to communicate with servers in the cell can run the retrieveSigners script that references the CellDefaultTrustStore. The script obtains all of the signers for the cell, including the self-signed certificate for the deployment manager. For more information, see csec_sslsecinstallclientsignret.dita.

Default key and truststore configurations for a Network Deployment cell with one federated node

When the key.p12 file is defined in the configuration repository, the deployment manager can locally manage the keystore and synchronize to the node that owns it. The key.p12 file physically exists in the myhostNode01 directory of the repository, which makes it available to that node and the deployment manager only.

After federation, the NodeDefaultTrustStore is not referenced by default SSL configurations. However, the truststore remains in the configuration code if you decide that a node must not trust other servers in the same cell; thus, it must not use the common CellDefaultTrustStore truststore. If you switch back to the node-specific truststore, you can add the signers from only the nodes you want to trust to obtain a higher level of isolation, even within the same cell. See “Secure Sockets Layer node, application server, and cluster isolation” on page 408 for information about how to obtain a higher level of SSL isolation among processes within the same cell.

Default SSL configurations

The following sample code shows the CellDefaultSSLSettings and AdminSoapSSLSettings SSL configurations for the deployment manager, and the NodeDefaultSSLSettings SSL configuration for the federated node:

```
<repertoire xmi:id="SSLConfig_1" alias="CellDefaultSSLSettings"
managementScope="ManagementScope_1">
<setting xmi:id="SecureSocketLayer_1" clientAuthentication="false" securityLevel="HIGH"
enabledCiphers="" jsseProvider="IBMJSSE2" sslProtocol="SSL_TLS" keyStore="KeyStore_1"
trustStore="KeyStore_2" trustManager="TrustManager_1" keyManager="KeyManager_1"/>
</repertoire>
```

```
<repertoire xmi:id="SSLConfig_2" alias="AdminSoapSSLSettings"
managementScope="ManagementScope_1">
<setting xmi:id="SecureSocketLayer_2" clientAuthentication="false" securityLevel="HIGH"
enabledCiphers="" jsseProvider="IBMJSSE2" sslProtocol="SSL_TLS" keyStore="KeyStore_1"
trustStore="KeyStore_2" trustManager="TrustManager_1" keyManager="KeyManager_1"/>
</repertoire>
```

```
<repertoire xmi:id="SSLConfig_1128545825854" alias="NodeDefaultSSLSettings"
managementScope="ManagementScope_1128545825854">
<setting xmi:id="SecureSocketLayer_1128545825854" clientAuthentication="false"
securityLevel="HIGH" enabledCiphers="" jsseProvider="IBMJSSE2" sslProtocol="SSL_TLS"
keyStore="KeyStore_1128545825854" trustStore="KeyStore_2"
trustManager="TrustManager_1128545825854" keyManager="KeyManager_1128545825854"/>
</repertoire>
```

Note: In the sample code, the cell is configured for dynamic selection. When the node is federated, all of the Simple Object Access Protocol (SOAP) connector communications use the AdminSoapSSLSettings property. For more information about protocol, host, and port specific associations with SSL configurations, see csec_ssldynoutboundconfigs.dita.

Default key and truststores

The following sample code shows the default key and truststores configurations:

```
<keyStores xmi:id="KeyStore_1" name="CellDefaultKeyStore"
password="{xor}123skfkdkid=" provider="IBMJCE" location="{USER_INSTALL_ROOT}
/config/cells/myhostCell01/key.p12" type="PKCS12" fileBased="true" hostList=""
initializeAtStartup="true" managementScope="ManagementScope_1"/>

<keyStores xmi:id="KeyStore_2" name="CellDefaultTrustStore"
password="{xor}123skfkdkid=" provider="IBMJCE" location="{USER_INSTALL_ROOT}
/config/cells/myhostCell01/trust.p12" type="PKCS12" fileBased="true" hostList=""
initializeAtStartup="true" managementScope="ManagementScope_1"/>

<keyStores xmi:id="KeyStore_1128545825854" name="NodeDefaultKeyStore"
password="{xor}349dkckdd=" provider="IBMJCE" location="{USER_INSTALL_ROOT}/config
/cells/myhostCell01/nodes/myhostNode01/key.p12" type="PKCS12" fileBased="true"
hostList="" initializeAtStartup="true" managementScope="ManagementScope_1128545825854"/>

<keyStores xmi:id="KeyStore_1128545825874" name="NodeDefaultTrustStore"
password="{xor}349dkckdd=" provider="IBMJCE" location="{USER_INSTALL_ROOT}/config
/cells/myhostCell01/nodes/myhostNode01/trust.p12" type="PKCS12" fileBased="true"
hostList="" initializeAtStartup="true" managementScope="ManagementScope_1128545825854"/>
```

Default management scopes

The management scope for a federated node is node-specific. In general, configuration objects that are scoped for a particular node can reference only that scope. WebSphere Application Server only uses the default key and truststores in the nodes to which they are scoped.

Configuration objects can maintain their uniqueness even when multiple node configurations are located in the same security.xml file. The following sample code shows how the management scope also can define the NodeDefaultKeyStore and NodeDefaultTrustStore keystores that are added from multiple nodes.

```
<managementScopes xmi:id="ManagementScope_1" scopeName="(cell):myhostCell01"
scopeType="cell"/>
<managementScopes xmi:id="ManagementScope_1128545825854" scopeName="(cell):myhostCell01:
(node):myhostNode01" scopeType="node"/>
```

Contents of the default truststore

After federation, the CellDefaultTrustStore () common truststore contains two signers: the deployment manager signer and the federated node signer. In the following sample code, the deployment manager and node host are the same:

```
keytool -list -keystore /QIBM/UserData/WebSphere/AppServer/V61/ND/profile/dmgr/config/cells
/myhostCell01/trust.p12 -storepass myhostCell01 -storetype PKCS12 -v
```

```
Alias name: default_signer
Entry type: trustedCertEntry
```

```
Owner: CN=myhost.austin.ibm.com, O=IBM, C=US
Issuer: CN=myhost.austin.ibm.com, O=IBM, C=US
Valid from: 10/5/05 3:34 PM until: 10/5/06 3:34 PM
Certificate fingerprints:
```

```
SHA1: 91:A1:A9:2D:F2:7D:70:0F:04:06:73:A3:B4:A4:9C:56:9D:A8:A3:BA
```

```
*****
*****
```

```
Alias name: default
Entry type: trustedCertEntry
```

Owner: CN=myhost.austin.ibm.com, O=IBM, C=US
Issuer: CN=myhost.austin.ibm.com, O=IBM, C=US
Valid from: 10/18/05 4:06 PM until: 10/18/06 4:06 PM
Certificate fingerprint:
SHA1: 33:6E:9E:10:65:04:CE:7A:6C:C3:B1:79:8B:9A:05:49:AC:E5:67:F3

In cases where nodes are federated from remote hosts, the CN contains the host name of the remote hosts. This node configuration enables a custom trust manager to perform host name verification using the remote certificates that it receives during the connection. The custom trust manager must implement the `com.ibm.wsspi.ssl.TrustManagerExtendedInfo` interface to gain access to the remote host name from the runtime. For more information, see `rsec_ssldevcustomtrustmgr.dita`.

Secure installation for client signer retrieval

Each profile in the WebSphere Application Server environment contains a unique self-signed certificate that was created when the profile was created. This certificate replaces the default dummy certificate that ships with WebSphere Application Server in releases prior to version 6.1. When a profile is federated to a deployment manager, the signer for that self-signed certificate is added to the common truststore for the cell.

transition: Beginning with version 6.1, clients and servers that are not within the same cell require more complex Secure Sockets Layer (SSL) configurations than do servers that are within the same cell and that use the default self-signed certificate configuration.

By default, clients do not trust servers from different profiles in the WebSphere Application Server environment. That is, they do not contain the signer for these servers. There are some things that you can do to assist in establishing this trust:

1. Enable the signer exchange prompt to except the signer during the connection attempt.
2. Run the **retrieveSigners** utility to download the signers from that system prior to making the connection.
3. Copy the `trust.p12` file from the `/config/cells/<cell_name>/nodes/<node_name>` directory of the server profile to the `/etc` directory of the client. Update the SSL configuration to reflect the new file name and password, if they are different. Copying the file provides the client with a `trust.p12` that contains all signers from servers in that cell. Also, you might need to perform this step for back-level clients that are still using the `DummyClientTrustFile.jks` file. In this case, you might need to change the `sas.client.props` or `soap.client.props` file to reflect the new truststore, truststore password, and truststore type (PKCS12).

For clients to perform an in-band signer exchange, you must specify the `ssl.client.props` file as a `com.ibm.SSL.ConfigURL` property in the SSL configuration. For managed clients, this is done automatically. Signers are designated either as in-band during the connection or out-of-band during runtime. You must also set the `com.ibm.ssl.enableSignerExchangePrompt` attribute to `true`.

Tip: You can configure a certificate expiration monitor to replace server certificates that are about to expire. For more information about how clients can retrieve the new signer from the configuration, see `csec_sslcertmonitoring.dita`.

Using the signer exchange prompt to retrieve signers from a client

When the client does not already have a signer to connect to a process, you must enable the signer exchange prompt. The prompt displays once for each unique certificate and for each node. After the signer for the node is added, the signer remains in the client truststore. The following sample code shows the signer exchange prompt retrieving a signer from a client:

```
/QIBM/UserData/WebSphere/AppServer/V61/ND/profiles/dmgr/bin/serverStatus -all
ADMU0116I: Tool information is being logged in file
/QIBM/UserData/WebSphere/AppServer/V61/ND/profiles/dmgr/logs/serverStatus.log
ADMU0128I: Starting tool with the dmgr profile
```

```
ADMU0503I: Retrieving server status for all servers
ADMU0505I: Servers found in configuration:
ADMU0506I: Server name: dmgr
```

```
*** SSL SIGNER EXCHANGE PROMPT ***
```

```
SSL signer from target host 192.168.1.5 is not found in truststore
/QIBM/UserData/WebSphere/AppServer/V61/ND/profiles/dmgr/etc/trust.p12.
```

Here is the signer information (verify the digest value matches what is displayed at the server):

```
Subject DN:   CN=myhost.austin.ibm.com, O=IBM, C=US
Issuer DN:   CN=myhost.austin.ibm.com, O=IBM, C=US
Serial number: 1128544457
Expires:     Thu Oct 05 15:34:17 CDT 2006
SHA-1 Digest: 91:A1:A9:2D:F2:7D:70:0F:04:06:73:A3:B4:A4:9C:56:9D:A8:A3:BA
MD5 Digest:  88:72:C5:88:00:1C:A7:FA:D6:EB:04:88:AC:A1:C9:13
```

Add signer to the truststore now? (y/n) y

A retry of the request may need to occur.

```
ADMU0508I: The Deployment Manager "dmgr" is STARTED
```

To automate this process, see `rxml_retrievesigners.dita`.

When a prompt occurs to accept the signer, a socket timeout can occur and the connection might be broken. For this reason, the message `A retry of the request may need to occur.` displays after answering the prompt. The message informs the user to resubmit the request. This problem should not happen frequently, and it might be more prevalent for some protocols than others.

Verify the displayed SHA-1 digest, which is the signature of the certificate that is sent by the server. If you look at the certificate on the server, verify that the same SHA-1 digest displays.

You can disable the prompt when you do not want it to display by running the **retrieveSigners** utility to retrieve all of the signers for a particular cell. You can download or upload the signers from any remote keystore to any local keystore by referencing a common truststore with this client script. For more information, see `csec_ssldefsselfsigncertconf.dita`.

Using the **retrieveSigners** utility to download signers for a client

You can run the **retrieveSigners** utility to retrieve all of the signers from the remote keystore for a specified client keystore.

The typical remote keystore to reference is `CellDefaultTrustStore`.

The truststore contains the signers that enable the client to connect to its processes. The **retrieveSigners** utility can point to any keystore in the target configuration, within the scope of the target process, and can download the signers (certificate entries only) to any client keystore in the `ssl.client.props` file.

The following sample code shows the **retrieveSigners** utility in a deployment manager environment.

```
/QIBM/UserData/WebSphere/AppServer/V61/ND/profiles/dmgr/bin
```

```
retrieveSigners CellDefaultTrustStore  
ClientDefaultTrustStore -autoAcceptBootstrapSigner
```

```
CWPKI0308I: Adding signer alias "CN=myhost.austin.ibm.com, O=IBM, C=US" to  
local keystore "ClientDefaultTrustStore" with the following SHA  
digest: 91:A1:A9:2D:F2:7D:70:0F:04:06:73:A3:B4:A4:9C:56:9D:A8:A3:BA
```

```
CWPKI0308I: Adding signer alias "default" to local keystore  
"ClientDefaultTrustStore" with the following SHA digest:  
40:20:CF:BE:B4:B2:9C:F0:96:4D:EE:E5:14:92:9E:37:8D:51:A5:47
```

Use the **-autoAcceptBootstrapSigner** option to enable WebSphere Application Server automatically to retrieve and accept the signer for administrative connections. The SHA-1 digest is printed while the signer is added so you can verify the digest after the operation is complete.

Obtaining signers for clients and servers from a previous release

When a client from a release prior to version 6.1 connects to the current release, the client must obtain signers for a successful handshake. Clients using previous releases of WebSphere Application Server cannot obtain signers as easily as in the current release. You can copy the deployment manager *common* truststore to your back-level client or server, and then re-configure the SSL configuration to directly reference that truststore. This common truststore of type PKCS12 is located in the `/config/cells/<cell_name>/nodes/<node_name>` directory in the configuration repository and has a default password of WebAS.

To collect all of the signers for the cell in a single `trust.p12` keystore file, complete following steps:

1. Copy the `trust.p12` keystore file on the server and replicate it on the client. The client references the file directly from the `sas.client.props` and `soap.client.props` files that specify the SSL properties for previous releases.
2. Change the client-side keystore password so that it matches the default cell name that is associated with the copied keystore.
3. Change the default keystore type for the `trust.p12` file to PKCS12 in the client configuration.

The following two code samples show you a before and an after view of the changes to make.

Default SSL configuration of `sas.client.props` for a previous release

```
com.ibm.ssl.protocol=SSL
com.ibm.ssl.keyStore=/QIBM/UserData/WebSphere/AppServer/V6/ND/profiles/dmgr/etc/DummyClientKeyFile.jks
com.ibm.ssl.keyStorePassword={xor}CDo9Hgw\=
com.ibm.ssl.keyStoreType=JKS
com.ibm.ssl.trustStore=/QIBM/UserData/WebSphere/AppServer/V6/ND/profiles/dmgr/etc/DummyClientTrustFile.jks
com.ibm.ssl.trustStorePassword={xor}CDo9Hgw\=
com.ibm.ssl.trustStoreType=JKS
```

SSL configuration changes that are required to common truststore file in the `/etc` directory of the client

```
com.ibm.ssl.protocol=SSL
com.ibm.ssl.keyStore=/QIBM/UserData/WebSphere/AppServer/V6/ND/profiles/dmgr/etc/DummyClientKeyFile.jks
com.ibm.ssl.keyStorePassword={xor}CDo9Hgw\=
com.ibm.ssl.keyStoreType=JKS
com.ibm.ssl.trustStore=/QIBM/UserData/WebSphere/AppServer/V6/ND/profiles/dmgr/etc/trust.p12
com.ibm.ssl.trustStorePassword=myhostNode01Cell
com.ibm.ssl.trustStoreType=PKCS12
```

Tip: You can run the **PropsFilePasswordEncoder** script, which is located in the `/bin` directory to reset the password.

You can also make these changes in the `soap.client.props` file and specify the `key.p12` file in place of the `DummyClientKeyFile.jks` file. However, you must also change the `keyStorePassword` and `keyStoreType` values to match those in the default `key.p12` file.

In releases of WebSphere Application Server prior to version 6.1, you must edit the SSL configuration on the server to replace the common truststore. The `trust.p12` file, which is used by the server, also must contain the default dummy certificate signer for connections among servers at previous release levels. You might need to manually extract the default certificate from the `DummyServerKeyFile.jks` file and then import the certificate into the `trust.p12` file that you added to the configuration.

retrieveSigners command: The **retrieveSigners** command creates a new client self-signed certificate, keystore, and SSL configuration in the `ssl.client.props` file. Using this command you can optionally extract the signer to a file.

For more information about where to run this command, see the [Using command tools](#) article.

Syntax

The command syntax is as follows:

```
retrieveSigners <remoteKeyStoreName> <localKeyStoreName> [options]
```

where the `<remoteKeyStoreName>` and `<localKeyStoreName>` parameters are required. The optional parameters include the following:

```
[-remoteAlias aliasFromRemoteStore]  
[-localAlias storeAsAlias]  
[-listRemoteKeyStoreNames] [-listLocalKeyStoreNames]  
[-autoAcceptBootstrapSigner] [-uploadSigners] [-host host]  
[-port port] [-conntype RMI|SOAP] [-user user]  
[-password password]  
[-trace] [-logfile filename]  
[-replaceLog] [-quiet] [-help]
```

Parameters

The following parameters are available for the **retrieveSigners** command:

-remoteKeyStoreName

The name of a truststore that is located in the server configuration from which to retrieve the signers. This will typically be the `CellDefaultTrustStore` file for an managed environment or the `NodeDefaultTrustStore` file for an unmanaged environment.

-localKeyStoreName

The name of the truststore that is located in the `ssl.client.props` file for the profile to which the retrieved signers is added. This will typically be the `ClientDefaultTrustStore` file for either a managed or unmanaged environment.

-remoteAlias <aliasFromRemoteStore>

Specifies one alias from the remote truststore that you want to retrieve. Otherwise, all signers from the remote truststore will be retrieved.

-localAlias <storeAsAlias>

Determines the name of the alias stored in the local truststore. This option is only valid if you specify the `-remoteAlias` option. If you do not specify the `-localAlias` option, the alias name from the remote truststore will be used, if possible. If an alias clash occurs, the alias name will be used and it will have an incremented number appended to the end of it until it finds a unique alias.

-listRemoteKeyStoreNames

Sends a remote request to the server to list all keystores that you can specify for the `remoteKeyStoreName` parameter. Use this command when you are unsure of the name of the remote truststore that you want to download the signers from.

-listLocalKeyStoreNames

Lists the keystores located in the `ssl.client.props` file that you can specify for the `localKeyStoreName` parameter. This truststore will receive the signers from the server. Use this parameter when you are unsure of the name of the local truststore that you want to retrieve the signers into. The default name of the truststore is `ClientDefaultTrustStore` and is located in the `ssl.client.props` file.

-autoAcceptBootstrapSigner

Automatically adds a signer in order to make a secure connection to the server. The purpose of the

option is to allow automation of the command so that you do not need to accept the signer. After the signer is added to the local truststore, a SHA hash will print so that you can verify the certificate.

-uploadSigners

Converts the signer download into a signer upload. The signers from the `localKeyStoreName` parameter will be sent to the `remoteKeyStoreName` parameter instead.

-host <host>

Specifies the target host from which the signers will be retrieved.

-port <port>

Specifies the target administrative port to which to connect. You must specify the port based on the `-conntype` parameter. If the `conntype` is SOAP, the default port is 8879. This can vary for different servers. If the `conntype` is RMI, the default port is 2809. This can vary for different servers.

-conntype <RMISoap>

Determines the administrative connector type that is used for the MBean call to retrieve the signers.

-user <user>

When global security is enabled, you can specify this option to supply the user name that will be authenticated for the MBean operation. This must be an identity with administrator authority. If you do not specify this parameter when global security is enabled, you will be prompted for credentials by default.

-password <password>

When global security is enabled, you can specify this option to supply the password that will be authenticated for the MBean operation. The password goes along with the `-user` parameter.

-trace

When specified, this enables tracing of the trace specification necessary to debug this component. By default, the trace will appear in the `profiles/profile_name/log/retrieveSigners.log` file.

-logfile <filename>

Overrides the default trace file. By default, the trace will appear in the `profiles/profile_name/log/retrieveSigners.log` file.

-replacelog

Causes the existing trace file to be replaced when the command is executed.

-quite

Suppresses most messages from printing out on the console.

-help

Prints a usage statement.

-? Prints a usage statement.

Usage scenario

The following examples demonstrate correct syntax:

- The following example lists remote and local keystores:

```
retrieveSigners -listRemoteKeyStoreNames -listLocalKeyStoreNames -conntype RMI -port 2809
```

Example output

```
CWPKI0306I: The following remote keystores exist on the specified server:
           CMSKeyStore, NodeLTPAKeys, NodeDefaultTrustStore, NodeDefaultKeyStore
CWPKI0307I: The following local keystores exist on the client:
           ClientDefaultKeyStore, ClientDefaultTrustStore
```

- The following example retrieves all signers from `NodeDefaultTrustStore`:

```
retrieveSigners NodeDefault TrustStore ClientDefaultTrustStore -autoAcceptBootstrapSigner
-conntype RMI -port 2809
```

Example output

```
CWPKI0308I: Adding signer alias "CN=BIRKT40.austin.ibm.com, O=IBM, C=US" to
             local keystore "ClientDefaultTrustStore" with the following SHA
             digest: 40:20:CF:BE:B4:B2:9C:F0:96:4D:EE:E5:14:92:9E:37:8D:51:A5:47
```

Certificate expiration monitoring

The certificate expiration monitor administrative task cycles through all the keystores that are configured in the `security.xml` file and reports on any certificates that expire within a specified threshold, which is typically within 30 days.

The default self-signed certificate on each node expires 365 days after creation. You can modify the certificate validity period by changing the default value for the `com.ibm.ssl.defaultCertReqDays=365` property in the `ssl.client.props` global property area for clients. You can also specify this property as a security custom property on the administrative console. Click **Security > Secure administration, applications, and infrastructure > Custom properties**.

The certificate expiration monitor task runs under the deployment manager process.

You can configure this monitor task to run according to a particular schedule. The schedule produces the next start date that persists in the configuration and, when the date is reached, WebSphere Application Server starts the monitor to check all of the keystores for certificates that meet the expiration threshold. You can start the task manually to run at any time.

The following `security.xml` configuration object specifies when the monitor task starts, determines the certificate expiration threshold, and indicates whether you are notified in an e-mail using Simple Mail Transfer Protocol (SMTP) or in a message log.

```
<wsCertificateExpirationMonitor xmi:id="WSCertificateExpirationMonitor_1"
name="Certificate Expiration Monitor" daysBeforeNotification="30"
isEnabled="true" autoReplace="true" deleteOld="true"
wsNotification="WSNotification_1" wsSchedule="WSSchedule_2"
nextStartDate="1134358204849"/>
```

The expiration monitor automatically replaces only self-signed certificates that meet the expiration threshold criteria. To replace all of the signers from the old certificate with the signer that belongs to the new certificate in all the keystores in the configuration for that cell, set the `autoReplace` attribute to `true`. When the `deleteOld` attribute is `true`, the old personal certificate and old signers also are deleted from the keystores. The `isEnabled` attribute determines whether the expiration monitor task runs based upon the `nextStartDate` attribute that is derived from the schedule. The `nextStartDate` attribute is derived from the schedule in milliseconds since 1970, and is identical to the `System.currentTimeMillis()`. If the `nextStartDate` has already passed when an expiration monitor process begins, and the expiration monitor is enabled, the task is started, but a new `nextStartDate` value is established based on the schedule.

The following sample code shows the frequency attribute as the number of days between each run.

```
<wsSchedules xmi:id="WSSchedule_2" name="ExpirationMonitorSchedule"
frequency="30" dayOfWeek="1" hour="21" minute="30"/>
```

The `dayOfWeek` attribute adjusts the schedule to run on a specified day of the week, which is always the same day regardless of whether the frequency is set to 30 or 31 days. Based on 24-hour clock, the hour and minute attributes determine when the expiration monitor is started on the specified day.

The following sample code shows the notification configuration, which notifies you after the expiration monitor runs.

```
<wsNotifications xmi:id="WSNotification_1" name="MessageLog" logToSystemOut="true" emailList=""/>
```

For expiration monitor notifications, you can select message log, e-mail using SMTP server, or both methods of notification. When you configure the e-mail option, use the format `user@domain@smtpserver`. If you do not specify an SMTP server, WebSphere Application Server defaults to the same domain as the e-mail address. For example, if you configure `joeuser@ibm.com`, WebSphere Application Server attempts

to call smtp-server.ibm.com. To specify multiple e-mail addresses using scripting, you must add a pipe (|) character between entries. When you specify the logToSystemOut attribute, the expiration monitor results are sent to the message log for the environment, which is typically the SystemOut.log file.

Web server plug-in default configuration

When you create a new Web server definition, WebSphere Application Server associates the Web server plug-in with a Certificate Management Services (CMS) keystore for a specific node. The keystore contains all of the signers for the current cell with the self-signed certificate, which belongs to the node. The plug-in can communicate securely to WebSphere Application Server, even when the plug-in is configured with Secure Sockets Layer (SSL) client authentication enabled.

When you set the Web server definition to webserver1 on node myhostNode01, WebSphere Application Server creates the keystore configuration. The keystore is scoped to the webserver1 server, which makes it visible to this server only. Other processes cannot use this keystore definition.

The default password for the keystore is WebAS. You can change the default keystore password by using either the administrative console or the appropriate **AdminTask** command. Also, you can create only one CMSKeyStore entry for each management scope. If a CMS keystore already exists for scope (cell):myhostCell01:(node):myhostNode01:(server):webserver1, then you cannot create another CMSKeyStore entry. WebSphere Application Server uses the plug-in name to create a self-signed certificate, if a self-signed certificate does not already exist for that particular node. If a self-signed certificate already exists for the node, then the certificate is put into the CMS keystore and all the signers from the cell are added, by default.

When additional nodes are federated, the signers for these nodes are not automatically added to each Web server for the CMS keystore. For the Web server plug-in to be able to communicate with a newly federated node, you must manually exchange signers with the CMSKeyStore keystore. Use the administrative console keystore certificate management function to exchange signers. For more information, see “Extracting a signer certificate from a personal certificate” on page 484.

Dynamic configuration updates

During the Secure Sockets Layer (SSL) runtime, dynamic configuration updates affect both inbound and outbound SSL endpoints. For inbound SSL endpoints, the changes that are implemented by the SSL channel are only affected by dynamic changes. For outbound SSL endpoints, all outbound connections inherit the new configuration changes.

In this release, dynamic update functionality provides you with greater flexibility and efficiency. You can change SSL configurations without restarting WebSphere Application Server for the changes to take effect.

To make dynamic changes, in the administrative console click **Security > SSL certificates and key management**, then select the **Dynamically update the runtime when SSL configuration changes occur** check box. You must save your changes and then synchronize the security.xml file with remote systems. A remote system must be able to confirm that dynamicallyUpdateSSLConfig=true is in the security.xml file.

The SSL runtime reloads the modified SSL configuration and creates a new SSLEngine for the modified connections that are associated with inbound endpoints. New outbound connections use the new configuration while existing connections continue to use the old SSLEngine object and are not affected.

Tip: Make dynamic changes to the SSL configuration during off-peak hours. Synchronization delays can negatively affect connections when you update SSL configurations during peak hours.

You can turn on and off the dynamicallyUpdateSSLConfig attribute in the security.xml file to ensure successful updates by doing the following actions:

1. Set dynamicallyUpdateSSLConfig=On.

2. Save the updated configuration.
3. Synchronize the `security.xml` file with remote systems.
4. Set the `dynamicallyUpdateSSLConfig` attribute to `0ff`.

You must verify that all of the nodes receive the changes before turning off the `dynamicallyUpdateSSLConfig` attribute. Test the changes in a test environment before updating the production environment.

Tip: Some SSL changes, especially administrative SSL changes, can cause server outages if you fail to test them first. When a change prevents trust between two endpoints, the endpoints cannot communicate with each other. Additionally, if administrative SSL connection updates cause system outages, you might need to disable the nodes after you make corrective changes using the deployment manager. From the command line, you can manually synchronize the server to retrieve the new SSL changes, then restart the nodes.

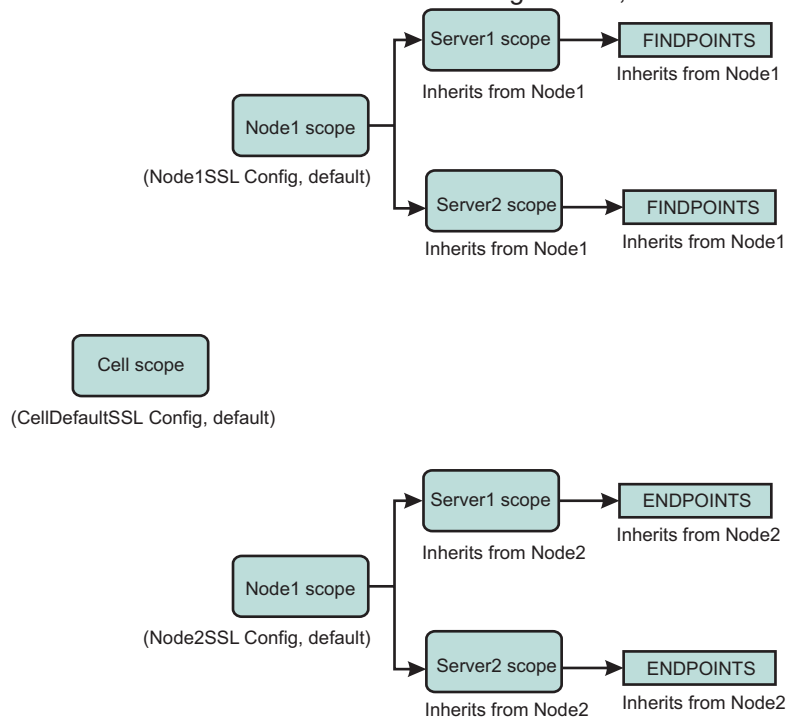

Restriction: In this release, the Object Request Broker (ORB) inbound SSL socket factory and the Admin SOAP inbound SSL socket factory are not affected by dynamic configuration changes. SSL socket factories cannot be bound to a port again without affecting the existing connections, with the exception of the SSL channel. You must restart the server to make a change to the SSL configuration for these two inbound protocols. Outbound configurations can still be changed dynamically. These changes are affected because the sockets are created during each new outbound connection.

Management scope configurations

Inbound and outbound management scopes represent opposing directions during the connection handshake process. To view inbound and outbound management scopes, use the topology tree view in the administrative console. You can define Secure Sockets Layer (SSL) configurations to distinguish the connection requirements for each direction inbound or outbound).

When expanded, the topology tree represents inbound and outbound connections for each management scope, cell, node group, node, server, cluster, and endpoint. Inbound endpoints require a server certificate. The SSL configuration specifies the server certificate for server authentication. Outbound endpoints require validated signers. Outbound endpoints connect to one or more target servers; inbound endpoints receive requests from one or more clients. The set of peer endpoints for outbound connections is typically a subset of the set of peer endpoints for inbound connections, which means you must define different requirements for inbound and outbound connections.

The following figure shows an example of two nodes: Node1 and Node2. These two nodes are isolated from one another because their SSL configurations, truststore files, and keystore files are different.

DynamicOutbound. AdminSoapSSLConfig,default ->ADMIN_SOAP
(to allow admin communications to use the same SSL configuration)

In the example of two nodes, note that Node1 cannot communicate with Node2, but each of the two nodes must be able to communicate with the deployment manager and its administrative functions. With dynamic outbound selection, you can choose an SSL configuration and a certificate alias that reference a common truststore. When a process requires the ADMIN_SOAP protocol for an outbound connection, the server uses this single SSL configuration. Because all of the scopes under the cell level inherit this configuration, all outbound connections can communicate with the deployment manager. For more information, see “Dynamic outbound selection of Secure Sockets Layer configurations” on page 405.

Another way to accomplish this same result is to associate the SSL configuration with the ADMIN_SOAP endpoint for each individual process, deployment manager, Node1, Node2, Node1Server1, Node1Server2, Node2Server1, and Node2Server2. However, it is recommended that you use dynamic outbound selection because it is more efficient when defining a basic SSL configuration, its keystores, and its truststores at the cell scope. The example shows how to apply the node scope association, but the same principles apply for node groups, clusters, servers, and endpoints.

Note: If your topology includes clusters that span nodes or if your applications need to communicate between nodes, the configuration that is shown in the example does not work.

Certificate management using iKeyman

Starting in WebSphere Application Server Version 6.1, you can manage your certificates from the administrative console. When using versions of WebSphere Application Server prior to Version 6.1, use iKeyman for certificate management. iKeyman is a key management utility.

WebSphere Application Server certificate management requires that you define the keystores in your WebSphere Application Server configuration. With iKeyman, you need access to the keystore file only. You can read a keystore file with personal certificates and signers that is created in iKeyman can be read into the WebSphere Application Server configuration by using the **createKeyStore** command.

The majority of certificate management functions are the same between WebSphere Application Server and iKeyman, especially for personal certificates and signer certificates. However, certificate requests are special. The underlying behavior is different in the two certificate management schemes. Because of the different behavior, when a certificate request is generated from iKeyman, the process must be completed in iKeyman. For example, a certificate that is generated by a certificate request that originated in iKeyman must be received in iKeyman as well.

The same is true for WebSphere Application Server. For example, when a certificate is generated from a certificate request that originated in WebSphere Application Server, the certificate must be received in WebSphere Application Server.

You can perform the following certificate operations using iKeyman:

Types of certificates	Functions	Description
Personal certificates	Create a self-signed certificate	Creates a self-signed certificate and stores it in a keystore.
	List personal certificates	Lists all the personal certificates in a keystore.
	Get information about a personal certificate	Gets information about a personal certificate.
	Delete a personal certificate	Deletes a personal certificate from a keystore.
	Import a certificate	Imports a certificate from a keystore to a keystore.
	Export a certificate	Exports a certificate from a keystore to another keystore.
	Extract a certificate	Extracts the signer part of a personal certificate to a file.
Signer certificates	Receive a certificate	Reads a certificate that comes from a certificate authority (CA) into a keystore.
	Add a signer certificate	Adds a signer certificate from a file to a keystore.
	List signer certificates	Lists all the signer certificates in a keystore.
	Get information about a signer certificate	Gets information about a signer certificate.
	Delete a signer certificate	Deletes a signer certificate from a keystore.
Certificate requests	Extract a signer certificate	Extracts a signer certificate from a keystore, and stores the certificate in a file.
	Create a certificate request	Creates a certificate request that can be sent to a CA.
	List certificate requests	Lists the certificate requests in a keystore.
	Get information about a certificate request	Gets information about a certificate request.
	Delete a certificate request	Deletes a certificate request from a keystore.
	Extract a certificate request	Extracts a certificate request to a file.

Certificate management

You can manage certificate operations that involve personal certificates, signer certificates, and personal certificate requests on the administrative console.

Types of certificates

WebSphere Application Server uses the certificates that reside in keystores to establish trust for a Secure Sockets Layer (SSL) connection. Click **Security > SSL certificate and key management > Manage**

endpoint security configurations > Inbound | Outbound > *SSL_configuration_name* > Key stores and certificates, then select an existing or create a new keystore. After selecting a keystore, and depending on the type of certificate you need, choose one of the following types of certificates under Related Items:

- Personal certificate
- Signer certificate
- Personal certificate request

The following table describes the certificate operations that you can perform on the administrative console:

Types of certificates	Functions	Description
Personal certificates	Create a self-signed certificate	Creates a self-signed certificate and stores it in a keystore.
	List personal certificates	Lists all the personal certificates in a keystore.
	Get information about a personal certificate	Gets information about a personal certificate.
	Delete a personal certificate	Deletes a personal certificate from a keystore.
	Import a certificate	Imports a certificate from a keystore to a keystore.
	Export a certificate	Exports a certificate from a keystore to another keystore.
	Extract a certificate	Extracts the signer part of a personal certificate to a file.
	Exchange signer certificates	Exchange signer part of a personal certificate between key store.
	Receive a certificate	Reads a certificate that comes from a certificate authority (CA) into a keystore.
Signer certificates	Replace a certificate	Replaces all occurrences of a personal certificate alias in the WebSphere Application Server configuration with another certificate. Also, replaces all occurrences of the personal certificates signer with the new personal certificate signer.
	Add a signer certificate	Adds a signer certificate from a file to a keystore.
	List signer certificates	Lists all the signer certificates in a keystore.
	Get information about a signer certificate	Gets information about a signer certificate.
	Delete a signer certificate	Deletes a signer certificate from a keystore.
	Extract a signer certificate	Extracts a signer certificate from a keystore, and stores the certificate in a file.
Certificate requests	Retrieve a signer from a port	Retrieves a signer certificate from a port, and stores it in a key store.
	Create a certificate request	Creates a certificate request that can be sent to a CA.
	List certificate requests	Lists the certificate requests in a keystore.
	Get information about a certificate request	Gets information about a certificate request.
	Delete a certificate request	Deletes a certificate request from a keystore.
	Extract a certificate request	Extracts a certificate request to a file.

Personal certificates

The following table lists the operations that you can perform on personal certificates, the AdminTask object that you can use to perform that operation, and how to navigate to the certificate on the console:

Function	AdminTask object	Administrative console
Create a self-signed certificate	createSelfSignCertificate	Security > Secure Communications > Key store and certificates > key store > Create a Self-Signed Certificate
List personal certificates	listPersonalCertificates	Security > Secure Communications > Key store and certificates > key store > personal certificates
Get information about a personal certificate	getPersonalCertificate	Security > Secure Communications > Key store and certificates > key store > personal certificates > alias
Delete a personal certificate	deletePersonalCertificate	Security > Secure Communications > Key store and certificates > key store > personal certificates > delete
Import a certificate	importCertificate	Security > Secure Communications > Key store and certificates > key store > personal certificates > import
Export a certificate	exportCertificate	Security > Secure Communications > Key store and certificates > key store > personal certificates > export
Extract a certificate	extractCertificate	Security > Secure Communications > Key store and certificates > key store > personal certificates > extract
Exchange signer certificates	exchangeSignerCertificates	Security > Secure Communications > Key store and certificates > Exchange signers

Signer certificates

The following table lists the operations that you can perform with signer certificates, the AdminTask object that you can use to perform the operation, and how to navigate to the certificate on the console:

Function	AdminTask object	Administrative console
Add a signer certificate	addSignerCertificate	Security > Secure communications > Key store and certificates > key store > signer certificates > Add
List signer certificates	listSignerCertificates	Security > Secure communications > Key store and certificates > key store > signer certificates
Get information about a signer certificate	getSignerCertificate	Security > Secure communications > Key store and certificates > key store > signer certificates > alias
Delete a signer certificate	deleteSignerCertificate	Security > Secure communications > Key store and certificates > key store > signer certificate > delete
Extract a signer certificate to a file	extractSignerCertificate	Security > Secure communications > Key store and certificates > key store > signer certificates > extract
Retrieve a signer certificate from a port	retrieveSignerFromPort	Security > Secure communications > Key store and certificates > key store > signer certificates > retrieve from port

Personal certificate requests

The following table lists the operations that you can perform on personal certificate requests, the AdminTask object that you can use to perform that operation, and how to navigate to the certificate request on the console:

Function	AdminTask object	Administrative console
Create a personal certificate request	createCertificateRequest	Security > Secure communications > Key store and certificates > key store > Personal certificate Requests > Add
List personal certificate requests	listCertificateRequests	Security > Secure communications > Key store and certificates > key store > Personal certificate requests
Get information about a personal certificate request	getCertificateRequest	Security > Secure communications > Key store and certificates > key store > Personal certificate requests > alias
Delete a personal certificate request	deleteCertificateRequest	Security > Secure communications > Key store and certificates > key store > Personal certificate requests > delete
Extract a personal certificate request to a file	extractCertificateRequest	Security > Secure communications > Key store and certificates > key store > Personal certificate requests > Extract

Creating a Secure Sockets Layer configuration

Secure Sockets Layer (SSL) configurations contain the attributes that you need to control the behavior of client and server SSL endpoints. You create SSL configurations with unique names within specific management scopes on the inbound and outbound tree in the configuration topology. This task shows you how to define SSL configurations, including quality of protection and trust and key manager settings.

You must decide at which scope you need to define an SSL configuration, for instance, the cell, node group, node, server, cluster, or endpoint scope, from the least specific to the most specific scope. When you define an SSL configuration at the node scope, for example, only those processes within that node can load the SSL configuration; however, any processes at the endpoint in the cell can use an SSL configuration at the cell scope, which is higher in the topology.

You must also decide which scope to associate with the new SSL configuration, according to the processes that the configuration affects. For example, an SSL configuration for a hardware cryptographic device might require a keystore that is available only on a specific node, or you might need an SSL configuration for a connection to a particular SSL host and port. For more information, see “Dynamic outbound selection of Secure Sockets Layer configurations” on page 405.

Complete the following steps in the administrative console:

1. Click **Security > SSL certificate and key management > Manage endpoint security configurations**.
2. Select an SSL configuration link on either the Inbound or Outbound tree, depending on the process you are configuring.
 - If the scope is already associated with a configuration and alias, the SSL configuration alias and certificate alias are noted in parentheses.
 - If the parenthetical information is not included, then the scope is not associated. Instead, the scope inherits the configuration properties of the first scope above it that is associated with an SSL configuration and certificate alias.

The cell scope must be associated with an SSL configuration because it is at the top of the topology and represents the default SSL configuration for the inbound or outbound connection.

3. Click **SSL configurations** under Related Items. You can view and select any of the SSL configurations that are configured at this scope. You can also view and select these configuration at every scope that is lower on the topology.
4. Click **New** to display the SSL configuration panel. You cannot select links under Additional Properties until you type a configuration name and click **Apply**.
5. Type an SSL configuration name. This field is required. The configuration name is the SSL configuration alias. Make the alias name unique within the list of SSL configuration aliases that are already created at the selected scope. The new SSL configuration uses this alias for other configuration tasks.
6. Select a truststore name from the drop-down list. A truststore name refers to a specific truststore that holds signer certificates that validate the trust of certificates sent by remote connections during an SSL handshake. If there is no truststore in the list, see “Creating a keystore configuration” on page 465 to create a new truststore, which is a keystore whose role is to establish trust during the connection.
7. Select a keystore name from the drop-down list. A keystore contains the personal certificates that represent a signer identity and the private key that WebSphere Application Server uses to encrypt and sign data.
 - If you change the keystore name, click **Get certificate aliases** to refresh the list of certificates from which you can choose a default alias. WebSphere Application Server uses a server alias for inbound connections and a client alias for outbound connections.
 - If there is no keystore in the list, see “Creating a keystore configuration” on page 465 to create a new keystore.
8. Choose a default server certificate alias for inbound connections. Select the default only when you have not specified an SSL configuration alias elsewhere and have not selected a certificate alias. A centrally managed SSL configuration tree can override the default alias. For more information, see “Central management of Secure Sockets Layer configurations” on page 407.
9. Choose a default client certificate alias for outbound connections. Select the default only when the server SSL configuration specifies an SSL client authentication.
10. Review the identified management scope for the SSL configuration. Make the management scope in this field identical to the link you selected in Step 2. If you want to change the scope, you must click a different link in the topology tree and continue at Step 3.
11. Click **Apply** if you intend to configure Additional Properties. If not, go to Step 24.
12. Click **Quality of protection (QoP) settings** under Additional Properties. QoP settings define the strength of the SSL encryption, the integrity of the signer, and the authenticity of the certificate.
13. Select a client authentication setting to establish an SSL configuration for inbound connections and for clients to send their certificates, if appropriate.
 - If you select **None**, the server does not request that a client send a certificate during the handshake.
 - If you select **Supported**, the server requests that a client send a certificate. However, if the client does not have a certificate, the handshake might still succeed.
 - If you select **Required**, the server requests that a client send a certificate. However, if the client does not have a certificate, the handshake fails.

Important: The signer certificate that represents the client must be in the truststore that you select for the SSL configuration. By default, servers within the same cell trust each other because they use the common truststore, trust.p12, that is located in the cell directory of the configuration repository. However, if you use keystores and truststores that you create, perform a signer exchange before you select either **Supported** or **Required**.

14. Select a protocol for the SSL handshake.

- The default protocol, SSL_TLS, supports client protocols TLSv1, SSLv3, and SSLv2.
- The TLSv1 protocol supports TLS and TLSv1. The SSL server connection must support this protocol for the handshake to proceed.
- The SSLv3 protocol supports SSL and SSLv3. The SSL server connection must support this protocol for the handshake to proceed.

Important: Do not use the SSLv2 protocol for the SSL server connection. Use it only when necessary on the client side.

15. Select one of the following options:
 - A predefined Java Secure Socket Extension (JSSE) provider. The IBMJSSE2 provider is recommended for use on all platforms which support it. It is required for use by the channel framework SSL channel. When Federal Information Processing Standard (FIPS) is enabled, IBMJSSE2 is used in combination with the IBMJCEFIPS crypto provider.
 - A custom JSSE provider. Type a provider name in the **Custom provider** field.
16. Select from among the following cipher suite groups:
 - **Strong:** WebSphere Application Server can perform 128-bit confidentiality algorithms for encryption and support integrity signing algorithms. However, a strong cipher suite can affect the performance of the connection.
 - **Medium:** WebSphere Application Server can perform 40-bit encryption algorithms for encryption and support integrity signing algorithms.
 - **Weak:** WebSphere Application Server can support integrity signing algorithms but not to perform encryption. Select this option with care because passwords and other sensitive information that cross the network are visible to an Internet Protocol (IP) sniffer.
 - **Custom:** you can select specific ciphers. Any time you change the ciphers that are listed from a specific cipher suite group, the group name changes to Custom.
17. Click **Update selected ciphers** to view a list of the available ciphers for each cipher strength.
18. Click **OK** to return to the new SSL configuration panel.
19. Click **Trust and key managers** under Additional Properties.
20. Select a default trust manager for the primary SSL handshake trust decision.
 - Choose **IbmPKIX** when you require certificate revocation list (CRL) checking using CRL distribution points in the certificates.
 - Choose **IbmX509** when you do not require CRL checking but do need increased performance. You can configure a custom trust manager to perform CRL checking, if necessary.
21. Define a custom trust manager, if appropriate. You can define a custom trust manager that runs with the default trust manager you select. The custom trust manager must implement the JSSE `javax.net.ssl.X509TrustManager` interface and, optionally, the `com.ibm.wsspi.ssl.TrustManagerExtendedInfo` interface to obtain product-specific information.
 - a. Click **Security > SSL certificate and key management > Manage endpoint security configurations > SSL_configuration > Trust and key managers > Trust managers > New**.
 - b. Type a unique trust manager name.
 - c. Select the **Custom** option.
 - d. Type a class name.
 - e. Click **OK**. When you return to the Trust and key managers panel, the new custom trust manager displays in the **Additional ordered trust managers** field. Use the left and right list boxes to add and remove custom trust managers.
22. Select a key manager for the SSL configuration. By default, IbmX509 is the only key manager unless you create a custom key manager.

Important: If you choose to implement your own key manager, you can affect the alias selection behavior because the key manager is responsible for selecting the certificate alias from

the keystore. The custom key manager might not interpret the SSL configuration as the WebSphere Application Server key manager IbmX509 does. To define a custom key manager, click **Security > Secure communications > SSL configurations > SSL_configuration > Trust and key managers > Key managers > New**.

23. Click **OK** to save the trust and key manager settings and return to the new SSL configuration panel.
24. Click **Save** to save the new SSL configuration.

Important: You can override the default trust manager when you configure at least one custom trust manager and set the `com.ibm.ssl.skipDefaultTrustManagerWhenCustomDefined` property to `true`. Click **Custom Property** on the SSL configuration panel. However, if you change the default, you leave all the trust decisions to the custom trust manager, which is not recommended for production environments. In test environments, use a dummy trust manager to avoid certificate validation. Remember that these environment are not secure.

In this release of WebSphere Application Server, you can associate SSL configurations with protocols using one of the following methods:

- Set the SSL configuration on the thread programmatically
- Associate the SSL configuration with an outbound protocol, and target host and port. For more information, see “Associating a Secure Sockets Layer configuration dynamically with an outbound protocol and remote secure endpoint” on page 448
- Associate the SSL configuration directly using the alias. For more information, see `tsec_sslselconfigdirect.dita`
- Manage the SSL configurations centrally by associating them with SSL configuration groups or zones that are scoped for endpoints. For more information, see “Associating Secure Sockets Layer configurations centrally with inbound and outbound scopes” on page 451

SSL certificate and key management

Use this page to configure security for Secure Socket Layer (SSL) and key management, certificates, and notifications. The SSL protocol provides secure communications between remote server processes or endpoints. SSL security can be used for establishing communications inbound to and outbound from an endpoint. To establish secure communications, a certificate and an SSL configuration must be specified for the endpoint.

To view this administrative console page, click **Security > SSL certificate and key management**.

Configuration settings

Specifies the following administrative console tasks:

- Manage endpoint security configurations
- Manage certificate expiration

Use Federal Information Processing Standard (FIPS) algorithms

Specifies the Federal Information Processing Standard (FIPS)-compliant Java cryptography engine is enabled.

- Does not affect the SSL cryptography that is performed by the application server for z/OS System Secure Sockets Layer (SSSL).
- Does not change the JSSE provider if this cell includes any Application Server versions before the application server for z/OS Version 6.0.x.

When you select the **Use the Federal Information Processing Standard (FIPS)** option, the Lightweight Third Party Authentication (LTPA) implementation uses IBMJCEFIPS. IBMJCEFIPS supports the Federal Information Processing Standard (FIPS)-approved cryptographic algorithms for Data Encryption Standard (DES), Triple DES, and Advanced Encryption Standard (AES). Although the LTPA keys are backwards

compatible with prior releases of the application server, the LTPA token is not compatible with prior releases. In prior releases, the application server did not generate the LTPA token using a FIPS-approved algorithm.

The IBMJSSE2 JSSE provider does not perform cryptographic functions directly, and therefore does not need to be FIPS-approved. Instead, the IBMJSSE2 JSSE provider uses the JCE framework for cryptographic functions and uses IBMJCEFIPS when FIPS mode is enabled.

Default: Disabled

Dynamically update the runtime when SSL configuration changes occur

Specifies that all of the SSL-related attributes that change must be read from the configuration dynamically after they have been saved, then reused for new connections. To avoid customer impact, it is recommended that changes to production servers be made during off-peak periods.

Default: Disabled

When this option is selected, the configuration is updated each time you configure an SSL communication.

SSL configurations for selected scopes

Use this page to display Secure Socket Layer (SSL) configurations for selected scopes, such as a cell, node, server, or cluster. From this page you can navigate to configuration panels for the following: SSL configurations, dynamic inbound and outbound endpoint SSL configurations, key stores, key sets, key set groups, key managers, and trust managers.

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > *ssl_configuration***.

Name

Specifies the SSL configuration scope, which is derived from the selected object in the hierarchy.

Data type: Text

Direction

Specifies the direction for which the SSLConfig applies. Inbound refers to any listener port. Outbound refers to outbound end point connections.

Data type: Text

Inherited SSL configuration name

Specifies the name of the SSL configuration that is inherited from a higher level scope

This field displays for server and nodegroups within the object hierarchy.

This field does not display for the top-level cell.

Data type: Text

Inherited certificate alias

Specifies the certificate alias that is inherited from a higher-level scope.

This field displays for server and node groups within the object hierarchy.

This field does not display for the top-level cell.

Data type: Text

Override inherited values

Specifies the SSL configuration to be used for this scope and any lower scopes that have not already designated an SSL configuration.

This field displays for server and node groups within the object hierarchy.

This field does not display for the top-level cell.

Default: Disabled

SSL configuration

Specifies the SSL configuration that is used by requests at this scope.

Data type: Text

Update certificate alias list

Specifies the certificate aliases contained in the key store for this SSL configuration can be selected from the **Certificate alias in key store** list. You must update the certificate list after choosing a different SSL configuration alias. If you do not update the list, you will save a certificate alias that is not contained in the SSL configuration.

Manage certificates

Specifies to open the keystore panel for the key store in this SSL configuration, which enables you to manage personal certificates, signers, and certificate requests.

Certificate alias in key store

Specifies the certificate to use in the key store.

If you select **None**, the Java Secure Sockets Extension (JSSE) key manager determines which certificate is used. If multiple certificates exist in the key store, the key manager might not consistently select the same certificate.

Data type: Text

SSL configurations collection

Use this page to define a list of Secure Sockets Layer (SSL) configurations.

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > ssl_configuration** . Under Related items, click **SSL configurations**.

Button	Resulting action
New	The Java Secure Socket Extension (JSSE) repertoire is for Java-based SSL communications. You can define a new JSSE configuration that can be used to create an SSLContext, URLStreamHandler, SSLSocketFactory, SSLServerSocketFactory, and so on, using the com.ibm.websphere.ssl.JSSEHelper API.

Button	Resulting action
Delete	Deletes an existing JSSE configuration (administrator only). Be careful that any references to the SSL configuration have been removed prior to deleting this SSL configuration.

Name

Specifies the unique name of the SSL configuration in the management scope.

SSL configuration settings

Use this page to define Secure Sockets Layer (SSL) configuration properties.

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > SSL_configuration_name**. Under **Related items** click **SSL configurations > New**.

Name

Specifies the unique name of the SSL configuration within the management scope in which it resides. For ways to programmatically access the properties that are configured for this SSL configuration, see the `com.ibm.websphere.ssl.JSSEHelper` application programming interface (API).

Data type: Text

Trust store name

Specifies a reference to a specific trust store used by Java Secure Sockets Extension (JSSE). The trust store holds signer certificates that validate the trust of certificates sent by remote connections during an SSL handshake.

Data type: Text
Default: *selected trust store*

Key store name

Specifies a reference to a specific key store. The key store holds personal certificates that represent the identity of one side of a connection. The public key of this personal certificate is sent to the other side of the connection to establish trust during the handshake. The remote side of the connection needs the root certificate authority (CA) certificate or self-signed public key (signer) to be in the trust store to validate this personal certificate.

Data type: Text
Default: *selected key store*

Get certificate aliases

Queries the keystore for the aliases of all the personal certificates in the keystore from which to choose.

Default server certificate alias

Specifies the certificate alias used as the identity for this SSL configuration if one has not been specified elsewhere.

If you select **None**, the Java Secure Sockets Extension (JSSE) key manager determines which certificate is used. If multiple certificates exist in the key store, the key manager might not consistently select the same certificate.

Data type: Text

Default client certificate alias

Specifies the description for a client certificate alias.

If you select **None**, the Java Secure Sockets Extension (JSSE) key manager determines which certificate is used. If multiple certificates exist in the key store, the key manager might not consistently select the same certificate.

Data type: Text

Management scope

Specifies the scope where this SSL configuration is visible. For example, if you choose a specific node, then the configuration is visible only on that node and on any servers that are part of that node.

Data type: Text

Creating a custom trust manager configuration

You can create a custom trust manager configuration at any management scope and associate the new trust manager with a Secure Sockets Layer (SSL) configuration.

You must develop, package, and locate a Java Archive JAR file for a custom key manager in the `was.install.root/lib/ext` directory on WebSphere Application Server. For more information, see “Example: Developing a custom trust manager for custom SSL trust decisions” on page 439.

Complete the following steps in the administrative console:

1. Decide whether you want to create the custom trust manager at the cell scope or below the cell scope at the node, server, or cluster, for example.

Important: When you create a custom trust manager at a level below the cell scope, you can associate it only with a Secure Sockets Layer (SSL) configuration at the same scope or higher. An SSL configuration at a scope lower than the trust manager does not see the trust manager configuration.

- To create a custom trust manager at the cell scope, click **Security > SSL certificate and key management > Trust managers**. Every SSL configuration in the cell can select the trust manager at the cell scope.
 - To create a custom trust manager at a scope below the cell level, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > ssl_configuration > Trust managers**.
2. Click **New** to create a new custom trust manager.
 3. Type a unique trust manager name.
 4. Select the **Custom** implementation setting. The custom setting enables you to define a Java class with an implementation of the `javax.net.ssl.X509TrustManager` Java interface and, optionally, the `com.ibm.wsspi.ssl.TrustManagerExtendedInfo` WebSphere Application Server interface.

Note: The standard implementation setting applies only when the trust manager is already defined in the Java security provider list as a provider and an algorithm, which is not the case for a custom trust manager.

5. Type a class name, for example, `com.ibm.test.CustomTrustManager`.
6. Select one of the following actions:
 - Click **Apply**, then click **Custom properties** under Additional Properties to add custom properties to the new custom trust manager. When you are finished adding custom properties, click **OK** and **Save**, then go to the next step.
 - Click **OK** and **Save**, then go to the next step.

7. Click **SSL certificate and key management** in the page navigation at the top of the panel.
8. Select one of the following actions:
 - Click **SSL configurations** under Related Items for a cell-scoped SSL configuration.
 - Click **Manage endpoint security configurations** to select an SSL configuration at a lower scope.
9. Click the link for the existing SSL configuration that you want to associate with the new custom trust manager. You can create a new SSL configuration instead of associating the custom trust manager with an existing configuration. For more information, see “Creating a Secure Sockets Layer configuration” on page 429.
10. Click **Trust and Key managers** under Additional Properties. If the new custom trust manager is not listed in the **Additional ordered trust managers** list, verify that you selected an SSL configuration scope that is at the same level or below the scope that you selected in Step 8.
11. Click **Add**. This action adds the new trust manager to the list of custom trust managers.
12. Click **OK** and **Save**.

You have created a custom trust manager configuration that references a JAR file in the install directory of WebSphere Application Server and associates it with an SSL configuration during the connection handshake.

You can create a custom trust manager for a pure client. For more information, see “Commands for the TrustManagerCommands group of the AdminTask object” on page 823.

Trust and key managers settings

Use this page to specify trust and key managers for the selected SSL configuration.

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > Inbound | Outbound > SSL_configuration_name**. Under **Related items** click **SSL configurations > SSL_configuration_name | New**. Under **Additional Properties** click **Trust and key managers**.

Attention: The application server checks the default trust managers first before checking the additional ordered trust managers in descending order.

Default trust manager:

Specifies the default trust manager, which is typically the IbmX509 trust manager by the IBMJSSE2 provider. The other default trust manager is IbmPKIX, which can be selected when certificate revocation checks must be made using the X509Certificate CRL distribution list. The IbmPKIX trust manager does not perform as well as the IbmX509 trust manager.

Data type:	Text
Default:	ibmX509TrustManager

Additional ordered trust managers:

Specifies additional trust managers that are used in the order shown for this SSL configuration.

Add:

Specifies to add the selection to the **Additional ordered trust managers** right-hand list.

Remove:

Specifies to remove the selection from the **Additional ordered trust managers** right-hand list.

Key manager:

Specifies the key manager that runs for this SSL configuration.

Data type: Text
Default: IbmX509KeyManager

Trust managers collection

Use this page to define the implementation settings for the trust manager. A trust manager is a class that is invoked during an Secure Sockets Layer (SSL) handshake to make trust decisions about the remote end point. A default trust manager is used to validate the signature and expiration of the certificate. Custom trust managers can be plugged in to perform an extended certificate and host name check.

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > ssl_configuration** . Under Related items, click **Trust managers**.

Button	Resulting action
New	Adds a new trust manager that can be selected by an SSL configuration. A trust manager is invoked during an SSL handshake and can decide whether the handshake should be accepted based on the information it knows about the remote certificate and host.
Delete	Deletes an existing trust manager. Make sure the trust manager is not referenced by any SSL configuration before you delete it.

Name:

Specifies the name of the trust manager. This name is used as a selection in the SSL configuration panel.

Class name:

Specifies a class that implements the javax.net.ssl.X509TrustManager interface. Optionally, the class can implement the com.ibm.wsspi.ssl.TrustMangerExtendedInfo interface to get extended information about the connection. The class can use the information to verify the host name and so on.

Algorithm:

Specifies the algorithm name of the trust manager that is implemented by the selected provider.

Trust managers settings

This page enables you to view and set definitions for trust manager implementation settings. A trust manager is a class that gets invoked during a Secure Sockets Layer (SSL) handshake to make trust decisions about the remote end point. A default trust manager is used to validate the signature and expiration of the certificate. Custom trust managers can be plugged in to perform an extended certificate and hostname check.

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > ssl_configuration** . Under Related items click **Trust managers > New** .

Name:

Specifies the name of the trust manager.

Data type: Text

Default: `ibmX509TrustManager`

Standard:

Specifies that the trust manager selection is available from a Java provider that is installed in the `java.security` file. This provider might be shipped by the Java Secure Sockets Extension (JSSE) or might be a custom provider that implements the `javax.net.ssl.X509TrustManager` interface.

Default: `Enabled`

Provider:

Specifies the provider name that has an implementation of the `javax.net.ssl.X509TrustManager` interface. This provider is typically set to `IBMJSSE2`.

Enabled when **Standard** is selected.

Default `IBMJCE`

Algorithm:

Specifies the algorithm name of the trust manager implemented by the selected provider.

Enabled when **Standard** is selected.

Default `ibmX509` or `IbmPKIX`
Range `ibmX509, IbmPKIX`

Custom:

Specifies that the trust manager selection is based on a custom implementation class that implements the `javax.net.ssl.X509TrustManager` interface and optionally the `com.ibm.wsspi.ssl.TrustManagerExtendedInfo` interface to obtain additional connection information that is not otherwise available.

Default: `Disabled`

Class name:

Specifies a class that implements the `javax.net.ssl.X509TrustManager` interface. Optionally, the class can implement the `com.ibm.wsspi.ssl.TrustMangerExtendedInfo` interface to get extended information about the connection. The class can use the information to verify the host name and so on.

Enabled when **Custom** is selected.

Data type: `Text`

Example: Developing a custom trust manager for custom SSL trust decisions

The following example is of a sample custom trust manager. The custom trust manager makes no trust decisions but instead uses the information in the X.509 certificate that it references to make decisions.

After you build and package the custom trust manager, configure it either from the `ssl.client.props` file for a pure client or the `SSLConfiguration TrustManager` link in the administrative console. See “Trust manager control of X.509 certificate trust decisions” on page 400 for more information about trust managers.

Note: This example should only be used as a sample, and is not supported.

Related concepts

“Trust manager control of X.509 certificate trust decisions” on page 400

The role of the trust manager is to validate the Secure Sockets Layer (SSL) certificate that is sent by the peer, which includes verifying the signature and checking the expiration date of the certificate. A Java Secure Socket Extension (JSSE) trust manager determines if the remote peer can be trusted during an SSL handshake.

Creating a custom key manager

You can create a custom key manager configuration at any management scope and associate the new key manager with a Secure Sockets Layer (SSL) configuration.

You must develop, package, and locate a Java Archive (.JAR) file for a custom key manager in the `was.install.root/lib/ext` directory on WebSphere Application Server. For more information, see `rsec_ssldevcustomkeymgr.dita`.

Complete the following steps in the administrative console:

1. Decide whether you want to create the custom key manager at the cell scope or below the cell scope at the node, server, or cluster, for example.

Important: When you create a custom key manager at a level below the cell scope, you can associate it only with a Secure Sockets Layer (SSL) configuration at the same scope or higher. An SSL configuration at a scope lower than the key manager does not see the key manager configuration.

- To create a custom key manager at the cell scope, click **Security > SSL certificate and key management > Key managers**. Every SSL configuration in the cell can select the key manager at the cell scope.
 - To create a custom key manager at a scope below the cell level, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > SSL_configuration > Key managers**.
2. Click **New** to create a new key manager.
 3. Type a unique key manager name.
 4. Select the **Custom** implementation setting. With the custom setting, you can define a Java class that has an implementation on the Java interface `javax.net.ssl.X509KeyManager` and, optionally, the `com.ibm.wsspi.ssl.KeyManagerExtendedInfo` WebSphere Application Server interface. The standard implementation setting applies only when the key manager is already defined in the Java security provider list as a provider and an algorithm, which is not the case for a custom key manager. The typical standard key manager is `algorithm = IbmX509`, `provider = IBMJSSE2`.
 5. Type a class name. For example, `com.ibm.test.CustomKeyManager`.
 6. Select one of the following actions:
 - Click **Apply**, then click **Custom properties** under Additional Properties to add custom properties to the new custom key manager. When you are finished adding custom properties, click **OK** and **Save**, then go to the next step.
 - Click **OK** and **Save**, then go to the next step.
 7. Click **SSL certificate and key management** in the page navigation at the top of the panel.
 8. Select one of the following actions:
 - Click **SSL configurations** under Related Items for a cell-scoped SSL configuration.
 - Click **Manage endpoint security configurations** to select an SSL configuration at a lower scope.

9. Click the link for the existing SSL configuration that you want to associate with the new custom key manager. You can create a new SSL configuration instead of associating the custom key manager with an existing configuration. For more information, see “Creating a Secure Sockets Layer configuration” on page 429.
10. Click **Trust and Key managers** under Additional Properties.
11. Select the new custom key manager in the **Key manager** drop-down list. If the new custom key manager is not listed, verify that you selected an SSL configuration scope that is at the same level or below the scope that you selected in Step 8.
12. Click **OK** and **Save**.

You have created a custom key manager configuration that references a JAR file in the installation directory of WebSphere Application Server and associates the custom configuration with an SSL configuration during the connection handshake.

You can create a custom key manager for a pure client. For more information, see “Commands for the keyManagerCommands group of the AdminTask object” on page 827.

Example: Developing a custom key manager for custom Secure Sockets Layer key selection

The following example is of a sample custom key manager. This simple key manager provides the alias if it is set, and defers to the custom key manager if it is not set. Additional code can be added, for example, to prompt for a key that is given to the issuers that are provided.

After you build and package a custom key manager, you can configure it from either the `ssl.client.props` file for a pure client or by using the SSLConfiguration KeyManager link in the administrative console. See “Key manager control of X.509 certificate identities” on page 401 for more information about key managers.

Because only one key manager can be configured at a time for any given Secure Sockets Layer (SSL) configuration, the certificate selections on the server side might not work as they would when the default `ibmX509` key manager is specified. When a custom key manager is configured, it is up to the owner of that key manager to ensure that the selection of the alias from the SSL configuration supplied is set properly when `chooseClientAlias` or `chooseServerAlias` are called. Look for the `com.ibm.ssl.keyStoreClientAlias` and `com.ibm.ssl.keyStoreServerAlias` SSL properties.

Note: This example should only be used as a sample, and is not supported.

Associating a Secure Sockets Layer configuration dynamically with an outbound protocol and remote secure endpoint

After you create a Secure Sockets Layer (SSL) configuration, you must associate a secure outbound management scope with the new configuration. In this release, you can associate one SSL configuration with one remote secure endpoint and a different SSL configuration to another remote secure endpoint. Both endpoints can use the same outbound protocol, if appropriate. This task describes how to create the association dynamically.

Dynamic outbound selection requires that you provide only the outbound protocol name, the target host, and the target port so that WebSphere Application Server can make a connection between the SSL configuration and the outbound protocol or remote secure endpoint. The dynamic outbound selection method takes precedence over other selection methods, such as central management and direct selection, but is second to the programmatic method, that is, setting an SSL configuration on the running thread. For more information about the selection types and precedence rules, see “Secure communications using Secure Sockets Layer” on page 391.

Complete the following steps in the administrative console:

1. Click **Security > SSL certificate and key management > Manage endpoint security configurations > Outbound**.
2. Select the management scope that you want to associate with an SSL configuration on the topology tree.
3. Under Related Items, click **Dynamic outbound endpoint SSL configurations**. The default dynamic outbound configuration name, the target protocol, host, and port connection information, and the SSL configuration name display.
4. Click **New** to create a new dynamic outbound configuration.
5. Type a dynamic outbound configuration name. Use a name that is descriptive of the purpose of the dynamic selection configuration.
6. Optionally, type a dynamic selection configuration description.
7. Type the connection information that you want to associate with the configuration that is displayed in the SSL configuration drop-down list. The connection information must be in the format *protocol name, target host, target port*. You can substitute an asterisk (*) for any value, as in the following examples:
 - *,*,443
 - *,www.ibm.com,443
 - HTTP,.austin.ibm.com,*where 443 is a port, www.ibm.com is a host, HTTP is a protocol, and .austin.ibm.com is a target host. You can add multiple connections, but each additional connection can affect outbound performance.
8. Click **Add** to add the new connection to the set of SSL configuration connections. To remove a connection, select it and click **Remove**.
9. Select an SSL configuration from the list.
10. Click **Get certificate aliases** to refresh the certificate aliases that are contained in the associated key store.
11. Choose a certificate alias from the list.
12. Click **OK** and **Save**.

WebSphere Application Server is ready to connect one or more SSL configurations to one or more remote secure endpoints.

You can return to the outbound tree and select another management scope to associate with the same or a new outbound configuration.

Example: Programmatically specifying an outbound SSL configuration using JSSEHelper API

WebSphere Application Server provides a way to specify programmatically which Secure Sockets Layer (SSL) configurations to use prior to making an outbound connection. The `com.ibm.websphere.ssl.JSSEHelper` interface provides a complete set of application programming interfaces (APIs) for handling SSL configurations.

You must perform the following steps for your application when using the JSSEHelper API to establish an SSL properties object on the thread for use by the runtime. Some of these APIs have Java 2 Security permission requirements. See the JSSEHelper API documentation for more information about the permissions required by your application.

1. Obtain an instance of the JSSEHelper API by typing the following command:

```
com.ibm.websphere.ssl.JSSEHelper jsseHelper
= com.ibm.websphere.ssl.JSSEHelper.getInstance();
```

2. Obtain SSL properties from the WebSphere Application Server configuration or use those provided by your application. You can obtain these properties in several ways:

- By direction selection of an alias name, within the same management scope or higher as in the following example:

```
try
{
    String alias = "NodeAServer1SSLSettings";
    // As specified in the WebSphere SSL configuration
    Properties sslProps = jsseHelper.getProperties(alias);
}
catch (com.ibm.websphere.ssl.SSLException e)
{
    e.printStackTrace(); // handle exception
}
```

- By using the `getProperties` API for programmatic, direction, dynamic outbound, or management scope selection (based on precedence rules and inheritance). The SSL runtime uses the `getProperties` API to determine which SSL configuration to use for a particular protocol. This decision is based on both the input (`sslAlias` and `connectionInfo`) and the management scope from which the property is called. The `getProperties` API makes decisions in the following order:
 - a. The API checks the thread to see if properties already exist.
 - b. The API checks for a dynamic outbound configuration that matches the `ENDPOINT_NAME`, `REMOTE_HOST`, and or `REMOTE_PORT`.
 - c. The API checks to see if the optional `sslAlias` property is specified. You can configure any protocol as direct or centrally managed. When a protocol is configured as direct, the `sslAlias` parameter is `null`. When a protocol is configured as centrally managed, the `sslAlias` parameter is also `null`.
 - d. If no selection has been made, the API chooses the dynamic outbound configuration based on the management scope it was called from. If the dynamic outbound configuration is not defined in the same scope, it then searches the hierarchy to locate one.

The last choice is the cell-scoped SSL configuration (in Network Deployment) or the node-scoped SSL configuration (in Base Application Server). The

`com.ibm.websphere.ssl.SSLConfigChangeListener` parameter is notified when the SSL configuration that is chosen by a call to the `getProperties` API changes. The protocol can then call the API again to obtain the new properties as in the following example:

```
try
{
    String sslAlias = null; // The sslAlias is not specified directly at this time.
    String host = "myhost.austin.ibm.com"; // the target host
    String port = "443"; // the target port

    HashMap connectionInfo = new HashMap();
    connectionInfo.put(JSSEHelper.CONNECTION_INFO_DIRECTION,
```

```

        JSSEHelper.DIRECTION_OUTBOUND);
    connectionInfo.put(JSSEHelper.CONNECTION_INFO_REMOTE_HOST, host);
    connectionInfo.put(JSSEHelper.CONNECTION_INFO_REMOTE_PORT,
        Integer.toString(port));
    connectionInfo.put(JSSEHelper.CONNECTION_INFO_ENDPOINT_NAME,
        JSSEHelper.ENDPOINT_IIOPI);

    java.util.Properties props = jsseHelper.getProperties(sslAlias,
        connectionInfo, null);
}
catch (com.ibm.websphere.ssl.SSLException e)
{
    e.printStackTrace(); // handle exception
}

```

- By creating your own SSL properties and then passing them to the runtime, as in the following example:

```

try
{
    // This is the recommended "minimum" set of SSL properties. The trustStore can
    // be the same as the keyStore.
    Properties sslProps = new Properties();
    sslProps.setProperty("com.ibm.ssl.trustStore", "some value");
    sslProps.setProperty("com.ibm.ssl.trustStorePassword", "some value");
    sslProps.setProperty("com.ibm.ssl.trustStoreType", "some value");
    sslProps.setProperty("com.ibm.ssl.keyStore", "some value");
    sslProps.setProperty("com.ibm.ssl.keyStorePassword", "some value");
    sslProps.setProperty("com.ibm.ssl.keyStoreType", "some value");

    jsseHelper.setSSLPropertiesOnThread(sslProps);
}
catch (com.ibm.websphere.ssl.SSLException e)
{
    e.printStackTrace(); // handle exception
}

```

3. Use the `JSSEHelper.setSSLPropertiesOnThread(props)` API to set the `Properties` object on the thread so that the runtime picks it up and uses the same `JSSEHelper.getProperties` API. You can also obtain properties from the thread after they are set with the `jsseHelper.getSSLPropertiesOnThread()` API, as in the following example:

```

try
{
    Properties sslProps = jsseHelper.getProperties(null,
        connectionInfo, null); jsseHelper.setSSLPropertiesOnThread(sslProps);
}
catch (com.ibm.websphere.ssl.SSLException e)
{
    e.printStackTrace(); // handle exception
}

```

4. When the connection is completed, you must clear the SSL properties from the thread by passing the `null` value to the `setPropertiesOnThread` API, as in the following example:

```

try
{
    jsseHelper.setSSLPropertiesOnThread(null);
}
catch (com.ibm.websphere.ssl.SSLException e)
{
    e.printStackTrace(); // handle exception
}

```

Select the approach that best fits your connection situation when you specify programmatically which Secure Sockets Layer (SSL) configurations to use prior to making an outbound connection.

Associating Secure Sockets Layer configurations centrally with inbound and outbound scopes

After you create a Secure Sockets Layer (SSL) configuration, you must associate a secure inbound or outbound management scope with the new configuration. You can manage the association centrally so that you can easily make changes that affect all the scopes that are lower on the topology and that are associated with the configuration. Beginning with WebSphere Application Server version 6.1, the recommended and the default configuration method is centrally managed SSL configurations.

You can simplify the number of associations that you need to make for an SSL configuration by associating the configuration with the highest level management scope requiring a unique configuration. SSL configuration associations manifest inheritance behaviors. Because of the inheritance behaviors, all of the scopes that are lower on the topology inherit this SSL configuration. For example, an association you make at the cell level affects nodes, servers, clusters, and endpoints. For more information, see “Central management of Secure Sockets Layer configurations” on page 407.

A precedence rule determines which SSL configuration association is used at a particular scope. The highest precedence is given to endpoints on the topology. If you establish an association at the endpoint, this association overrides any prior association that you made higher up on the management scope topology.

Complete the following steps in the administrative console:

1. Click **Security > SSL certificate and key management**.
2. Select the **Dynamically update the runtime when SSL configuration changes** check box if you want changes that you make to an existing SSL configuration to occur dynamically. All outbound SSL communications honor the dynamic SSL changes. Protocols that do not use the channel frameworks SSL channel for inbound communications, including Object Request Broker (ORB) and administrative SOAP protocols, do not honor dynamic updates. For more information, see “Dynamic configuration updates” on page 423.
3. Click **Manage endpoint security configurations**.
4. Select either the inbound or the outbound tree. After finishing the selected tree, you can return to this step to repeat the following steps for the other tree.
5. Click the link for the selected cell, node, node group, server, cluster, or endpoint on the topology tree. If the scope already has an associated SSL configuration and alias, these objects display in parentheses immediately following the scope name, for example: Node01(NodeDefaultSSLSettings,default). If the deployment manager has federated a node, the node scope SSL configuration overrides the cell scope configuration above it in the topology.
6. Decide whether to override the inherited values that display in the read-only fields. Read-only fields include the management scope name, the direction, and the inherited SSL configuration name and certificate alias.
 - If you are satisfied with these values, do not override them.
 - If you want to override the inherited values, select the **Override inherited values** check box.
7. Select an SSL configuration from the list.
8. Click **Update certificate alias list**. The certificate alias list comes from the key store that is referenced by the new SSL configuration.
9. Click **Manage certificates** if you want to manage the personal certificates that are contained in the key store that is referenced in the SSL configuration.
10. Click **Update certificate alias list** to refresh the list of aliases.
11. Select a certificate alias in the key store to represent the identity of the endpoint.
12. Click **OK** to save your changes.
13. Click **Manage endpoint security configurations and trust zones** to return to the topology tree.
14. Configure the opposite direction on the topology tree using the steps in this task. You can also select additional scopes to associate with the SSL configuration, as needed.

Each SSL configuration at the selected scope and at scopes beneath it on the topology tree have the same SSL configuration properties. The following SSL configuration methods override the centrally managed configurations that you associate in the tree view:

- Direct selection at the endpoint
- Dynamic outbound SSL configuration associations
- Programmatic specifications

At any management scope, you can configure the following objects: dynamic outbound endpoint SSL configurations, key stores, key sets, key set groups, key managers, and trust managers. Like SSL configurations, these objects are scoped automatically so that they are not visible higher up in the tree nor are they loaded during runtime by processes that are higher up in the tree.

Selecting an SSL configuration alias directly from an endpoint configuration

You can associate a secure outbound endpoint with a new Secure Sockets Layer (SSL) configuration directly. If you are migrating from a release prior to version 6.1, WebSphere Application Server still supports configurations that were selected directly at an endpoint. Direct selection always overrides centrally managed configurations and preserves migrated configurations.

Select an SSL configuration alias directly at the following endpoints:

- **Security > Secure administration, applications, and infrastructure > RMI/IIOP security > CSiv2 outbound transport**
- **Security > Secure administration, applications, and infrastructure > RMI/IIOP security > CSiv2 inbound transport**
- **System administration > Deployment manager > Transport Chain > WCInboundAdminSecure > SSL inbound channel (SSL_1)**
- **System administration > Deployment manager > Administration Services > JMX connectors > SOAPConnector > Custom Properties > sslConfig**
- **System administration > Node agents > nodeagent > Administration Services > JMX connectors > SOAPConnector > Custom Properties > sslConfig**
- **Servers > Application servers > server1 > Messaging engine inbound transports > InboundSecureMessaging > SSL inbound channel (SIB_SSL_JFAP)**
- **Servers > Application servers > server1 > WebSphere MQ link inbound transports > InboundSecureMQLink > SSL inbound channel (SIB_SSL_MQFAP)**
- **Servers > Application servers > server1 > SIP Container Settings > SIP container transport chains > SIPInboundDefaultSecure > SSL inbound channel (SSL_5)**
- **Servers > Application servers > server1 > Web Container Settings > Web container transport chains > WCInboundAdminSecure > SSL inbound channel (SSL_1)**
- **Servers > Application servers > server1 > Web Container Settings > Web container transport chains > WCInboundDefaultSecure > SSL inbound channel (SSL_2)**

Attention: Keep in mind that central management of SSL configurations can be a more efficient strategy because multiple configurations can be contained within a single SSLConfigGroup. If you need to convert configuration references that are already directly managed to centrally managed configurations, modify each endpoint individually. For more information on specific wsadmin commands, see “Commands for the SSLConfigGroupCommands group of the AdminTask object” on page 831.

Complete the following steps in the administrative console:

Note: These steps provide an example to follow when you directly select any of the endpoints listed above.

1. Click **Security > Secure administration, applications, and infrastructure > RMI/IIOP security > CSiv2 outbound transport**.

2. Click **Use specific SSL alias**. When you identify a specific SSL alias, you override the centrally managed scope associations.
3. Select an SSL configuration alias from the drop-down list.
4. Click **OK**.
5. Repeat these steps for additional protocols or endpoints, if desired.

By associating the endpoint directly, you have overridden a centrally managed SSL configuration.

If you decide to use management scopes instead of endpoints to associate an SSL configuration, follow the steps above, but click **Centrally managed** instead of **Use specific SSL alias**, then click **Manage endpoint security configurations**. The console is redirected to **Security > SSL certificate and key management > Manage endpoint security configurations**.

Enabling Secure Sockets Layer client authentication for a specific inbound endpoint

When you establish a Secure Sockets Layer (SSL) configuration, you can enable client authentication for a specific inbound endpoint.

The endpoint configuration must already exist in the SSL topology.

Complete the following steps in the administrative console:

1. Click **Security > SSL certificate and key management > Manage endpoint security configurations > Inbound > SSL_configuration**. If you want to enable SSL client authentication for all processes, define an SSL configuration for the new endpoint at the node or cell level so that it is visible to all processes on the same node or on the entire cell. For more information, see “Creating a Secure Sockets Layer configuration” on page 429.
2. Select **Override inherited values**. The SSL configuration is used for the current scope and any lower scopes that have not already designated an SSL configuration. This field displays for server and node groups within the object hierarchy and does not display for the top-level node or cell.
3. Select an SSL configuration from the drop-down list.
4. Click **Update certificate alias list**.
5. Select a **Certificate alias** from the drop-down list.
6. Click **OK** to save the configuration.

You can repeat the previous steps for each endpoint that uses the same SSL configuration to enable client authentication for the inbound endpoints.

CSlv2 Protocol Exception:

The Common Secure Interoperability Version 2 (CSlv2) secure endpoints, used for Remote Method Invocation over the Internet Inter-ORB Protocol (RMI/IIOP) security, cannot override inherited values. While the rest of the SSL properties are effective for CSlv2 when they are selected at the centrally-managed Secure Communications panel, the client authentication selection is controlled by the CSlv2 protocol configuration.

To enable SSL client certificate authentication for the CSlv2 protocol, you must use the CSlv2 inbound and outbound authentication panels. For SSL client authentication to occur between two servers, you must enable (support or require) SSL client certificate authentication for both the inbound and the outbound policies.

WebSphere Application Server can either request (support) clients to provide signer certificates for the SSL handshake, or the server can require clients to provide a valid signer certificates for the SSL

handshake, which is a more secure method. However, when the server requires certificates, the server must obtain a signer for each client that connects to the server, which involves more server-side management.

The client certificate should not be used for the identity when it is used from server-to-server. However, when a pure client sends the client certificate it is used for the identity unless a message level identity is specified, such as a user ID or a password.

Do the following to enable client certificate authentication for the CSiv2 protocol for server-to-server:

1. **Click Security > Secure administration, applications, and infrastructure.**
2. Expand the **RMI/IIOP** security section.
3. Click **CSiv2 inbound authentication**.
4. Under Client authentication, select either **supported** or **required**. When you select required, only one SSL port is opened (CSV2_SSL_MUTUALAUTH_LISTENER_ADDRESS). When you select supported, two SSL ports are opened (both CSIV2_SSL_MUTUALAUTH_LISTENER_ADDRESS and CSIV2_SSL_SERVERAUTH_LISTENER_ADDRESS).
If there are two ports, the client can select either based on the security configuration policy of the port.
5. Click **OK** to save.
6. If you want server-to-server SSL client authentication, then complete the remaining steps. If you don't complete the remaining steps, only pure clients are enabled to send client certificates.
7. Expand the **RMI/IIOP** security section.
8. Click **CSiv2 outbound authentication**.
9. Under Client authentication, select either **supported** or **required**.

The SSL configuration for the inbound secure endpoints for which you enable SSL client certificate authentication must have the signer certificate from any client that attempts to open a connection to that inbound secure endpoint. You must collect those signers and then add them to the trust store associated with the inbound secure endpoints SSL configuration.

Manage endpoint security configurations

Use this page to select a Secure Socket Layer (SSL) configuration from the Local Topology hierarchy, which includes cells, nodes, node groups, servers, and clusters.

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations**.

Local topology:

The Local topology represents the hierarchy of nodes, node groups, clusters, servers, and end points within the cell that comprise a centralized SSL configuration.

The topology acts as a hierarchical tree in terms of inheritance. For example, if an SSL configuration has been associated with a specific node, then all servers within that node will inherit that SSL configuration selection, provided the servers are not associated with an SSL configuration at the server scope. Centralized management of SSL is the default configuration; however, it can be overridden at various locations to directly select a specific SSL alias as in previous releases for backwards compatibility.

Scope	Description
Inbound/Outbound	Specifies the topology tree in terms of connection direction. For example, the inbound tree represents all server endpoints that receive connections at the various servers within the cell. The outbound tree represents the client side of connections from the various servers within the cell.

Scope	Description
Nodes	Specifies the nodes that are part of the cell. The list of nodes is updated anytime a node gets federated into the cell.
Servers	Specifies the servers that are part of a specific node. You can enable a specific server to have an SSL configuration associated with it so that resources within the same server can use the associated SSL configuration.
Clusters	Specifies the clusters that are part of the cell. When an SSL configuration is associated with a cluster, all servers within the cluster will use the same SSL configuration unless specified at a lower level in the topology.
Nodegroups	Specifies the node groups that are part of the cell. When an SSL configuration is associated with a node group, all nodes within that node group may use the same SSL configuration unless one is specified at a lower scope in the topology or the specific end point has chosen a direct alias reference.
Secure port and transport	Specifies an endpoint name to associate with an SSL configuration when more specific SSL settings are needed at this level. You could select an alias directly at the endpoint panel; however, when you use Secure port and transport , you can maintain more centralized control of the SSL configuration and make changes more easily.

Dynamic inbound and outbound endpoint SSL configurations collection

Use this page to manage dynamic endpoint Secure Sockets Layer (SSL) configurations, which represent associations between Secure Socket Layer (SSL) configurations and their target protocol, host, and port.

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > ssl_configuration**. Under Related items, click **Dynamic [inbound | outbound] endpoint SSL configurations**.

When an outbound connection is attempted, this association is checked ahead of the SSL configuration scope association. Based on the target protocol, host, port, the outbound SSL configuration used can be different from the default specified in the SSL scope configuration.

Button	Resulting action
New	Adds a new dynamic outbound selection criteria. The outbound connection selects an SSL configuration based upon connection information, including DNS host name and domain, port, and protocol type. When an outbound connection is being made, the dynamic outbound selection criteria are queried for a match, and if found the SSL configuration associated is used.
Delete	Deletes an existing dynamic outbound endpoint SSL configuration.

Name:

Specifies the unique name of the dynamic endpoint configuration.

Connection information:

Specifies the set of target protocol, host, port for the outbound request in the form *protocol,host,port*.

SSL Configuration:

Specifies the SSL configuration that is used by requests at this scope when a match occurs for the given selection criteria.

Dynamic outbound endpoint SSL configuration settings

Use this page to set properties for dynamic outbound endpoint SSL configurations, which represent associations between SSL configurations and their target protocol, host, and port.

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > ssl_configuration** . Under Related items, click **Dynamic [inbound | outbound] endpoint SSL configurations > New**.

When an outbound connection is attempted, this association is checked ahead of the Secure Sockets Layer (SSL) configuration scope association. This means based on the target protocol, host, port, the outbound SSL configuration used can be different than the default specified in the SSL scope configuration.

Name:

Specifies the unique name of the dynamic endpoint configuration.

Data type: Text

Description:

Specifies text that describes the purpose of this dynamic selection criteria.

Data type: Text

Add connection information:

Specifies select information in the form protocol, host, port for the outbound connection. Multiple selection criteria can be entered. An asterisk (*) can be used to mean all protocols, hosts, or ports. You can use an * for any field.

Data type: Text

An example of selection criteria is `*,www.ibm.com,*`, which means that any time the target host is `www.ibm.com`, you must use the SSL configuration specified here. Another example selection criteria is `IIOP,*,*`, which means that any outbound IIOP request uses the SSL configuration that is specified in the SSL configuration field. When there is a conflict between two selection criteria, the application server uses the first match. The list of valid protocols you can use include: IIOP, HTTP, JMS, LDAP, SIP, ADMIN_SOAP, or ADMIN_IIOP.

Add:

Specifies to add the selected information from the **Add select information** menu to the right-hand list.

Remove:

Specifies to remove the selection from the right-hand list.

SSL Configuration:

Specifies the SSL configuration to be used by requests at this scope when a match occurs for the given selection criteria.

Data type: Text

Get certificate alias:

When selected, the keystore within the selected SSL configuration is queried for a list of personal certificates from which to choose.

Certificate alias:

Specifies the certificate alias that is used as the identity for the connection.

If you select **None**, the Java Secure Sockets Extension (JSSE) key manager determines which certificate is used. If multiple certificates exist in the keystore, the key manager might not consistently select the same certificate.

Data type: Text
Default: (none)

Quality of protection (QoP) settings

Use this page to specify security level, ciphers, and mutual authentication settings for the Secure Socket Layer (SSL) configuration.

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound *SSL_configuration_name*}**. Under **Related Items**, click **SSL configurations > {*SSL_configuration_name* | New}**. Under **Additional Properties**, click **Quality of protection (QoP) settings**.

Client authentication

Specifies the whether SSL client authentication should be requested if the SSL connection is used for the server side of the connection.

If None is selected, the server does not request that a client certificate be sent during the handshake. If Supported is selected, the server requests that a client certificate be sent. If the client does not have a certificate, the handshake might still succeed. If Required is selected, the server requests that a client certificate be sent. If the client does not have a certificate, the handshake fails.

Data type: Text
Default: None

Protocol

Specifies the Secure Sockets Layer (SSL) handshake protocol. This protocol is typically SSL_TLS, which supports all handshake protocols except for SSLv2 on the server side. When United States Federal Information Processing standard (FIPS) option is enabled, Transport Layer Security (TLS) is automatically used regardless of this setting.

Data type: text
Default: SSL_TLS

Predefined JSSE provider

Specifies one of the predefined Java Secure Sockets Extension (JSSE) providers. The IBMJSSE2 provider is recommended for use on all platforms which support it. It is required for use by the channel framework SSL channel. When Federal Information Processing Standard (FIPS) is enabled, IBMJSSE2 is used in combination with the IBMJCEFIPS crypto provider.

Default: Enabled

Select provider

Specifies a package that implements a subset of the cryptography aspects for the Java security application programming interface (API). This value is a JSSE provider name that is listed in the `java.security` file. Note that cipher suites and protocol values depend upon the provider.

Data type: Text
Default: IBMJSSE2

Custom JSSE provider

Specifies that a custom JSSE provider should be used.

Default: Disabled

Custom provider

Specifies a package that implements a subset of the cryptography aspects for the Java security application programming interface (API). This value is a Java Secure Sockets Extension (JSSE) provider name that is listed in the `java.security` file. Note that cipher suites and protocol values depend upon the provider.

Data type: Text

Cipher suite groups

Specifies the various cipher suite groups that can be chosen depending upon your security needs. The stronger the cipher suite strength, the better the security; however, this can result in performance consequences.

Data type: Text
Default: Strong

Update selected ciphers

When selected, the cipher suites that are contained within the selected Cipher suite group are added to the list of **Selected ciphers**. Any change to this list changes the Cipher suite group to custom.

Selected ciphers

Specifies the ciphers that are effective when the configuration is saved. These ciphers are used to negotiate with the remote side of the connection during the handshake. A common cipher needs to be selected or the handshake fails.

Data type: Text

Add

Specifies to add the selected cipher to the **Selected ciphers** list.

Remove

Specifies to remove the selected cipher from the **Selected ciphers** list.

ssl.client.props client configuration file

Use the `ssl.client.props` file to configure Secure Sockets Layer (SSL) for clients. In previous releases of WebSphere Application Server, SSL properties were specified in the `sas.client.props` or `soap.client.props` files or as system properties. By consolidating the configurations, WebSphere

Application Server enables you to manage security in a manner that is comparable to server-side configuration management. You can configure the `ssl.client.props` file with multiple SSL configurations.

Setting up the SSL configuration for clients

Client runtimes are dependent on the WebSphere Application Server `ssl.client.props` configurations.

Use the `setupCmdLine` script on the command line to specify the `com.ibm.SSL.ConfigURL` system property. The `setupclient` script also sets the `CLIENTSSL` variable.

```
-Dcom.ibm.SSL.ConfigURL=file:/QIBM/UserData/WebSphere/AppServer/V61/ND  
/profiles/dmgr/properties/ssl.client.props
```

The `com.ibm.SSL.ConfigURL` property references a file URL that points to the `ssl.client.props` file. You can reference the `CLIENTSSL` variable on the command line of any script that uses the `setupCmdLine` file.

When you specify the `com.ibm.SSL.ConfigURL` system property, the SSL configuration is available to all protocols that use SSL. SSL configurations, which are referenced in the `ssl.client.props` file, also have aliases that you can reference. In the following sample code from the `sas.client.props` file, all of the SSL properties are replaced with a property that points to an SSL configuration in the `ssl.client.props` file:

```
com.ibm.ssl.alias=default
```

The following sample code shows a property in the `soap.client.props` file that is similar to the `com.ibm.SSL.ConfigURL` property. This property references a different SSL configuration on the client side:

```
com.ibm.ssl.alias=ADMIN_SOAP
```

In the `ssl.client.props` file, you can change the administrative SSL configuration to avoid modifying the `soap.client.props` file.

Tip: In WebSphere Application Server Version 6.1, support for SSL properties is still specified in the `sas.client.props` and `soap.client.props` files. However, consider moving the SSL configurations to the `ssl.client.props` file, because this file is the new configuration model for client SSL.

Properties of the `ssl.client.props` file

This section describes the default `ssl.client.props` file properties in detail, by sections within the file.

Global properties

Global SSL properties are process-specific properties that include Federal Information Processing Standard (FIPS) enablement, the default SSL alias, the `profile_root` of the profile for specifying the root location of the key and truststore paths, and so on.

Property	Default	Description
<code>com.ibm.ssl.defaultAlias</code>	<code>DefaultSSLSettings</code>	Specifies the default alias that is used whenever an alias is not specified by the protocol that calls the JSSEHelper API to retrieve an SSL configuration. This property is the final arbiter on the client side for determining which SSL configuration to use.
<code>com.ibm.ssl.validationEnabled</code>	<code>false</code>	When set to <code>true</code> , this property validates each SSL configuration as it is loaded. Use this property for debug purposes only, to avoid unnecessary performance overhead during production.

Property	Default	Description
com.ibm.ssl.performURLHostNameVerification	false	When set to true, this property enforces URL host name verification. When HTTP URL connections are made to target servers, the common name (CN) from the server certificate must match the target host name. Without a match, the host name verifier rejects the connection. The default value of false omits this check. As a global property, it sets the default host name verifier. Any javax.net.ssl.HttpURLConnection object can choose to enable host name verification for that specific instance by calling the setHostnameVerifier method with its own HostnameVerifier instance.
com.ibm.security.useFIPS	false	When set to true, FIPS-compliant algorithms are used for SSL and other Java Cryptography Extension (JCE)-specific applications. This property is typically not enabled unless the property is required by the operating environment.
user.root	/QIBM/UserData /WebSphere/ AppServe r/v61/ND/profiles/ dmgr	This property can be used by key and truststore location properties as a single property for specifying the root path to the key and truststores. Typically, this property is the profile root. However, you can modify this property to any root directory on the local machine that has the proper read and potentially write authority to that directory.

Certificate creation properties

Use certificate creation properties to specify the default self-signed certificate values for the major attributes of a certificate. You can define the distinguished name (DN), expiration date, key size, and alias that are stored in the keystore.

Property	Default	Description
com.ibm.ssl.defaultCertReqAlias	default_alias	This property specifies the default alias to use to reference the self-signed certificate that is created in the keystore. If the alias already exists with that name, the default alias is appended with <code>_#</code> , where the number sign (#) is an integer that starts with 1 and increments until it finds a unique alias.
com.ibm.ssl.defaultCertReqSubjectDN	cn=\${hostname}, o=IBM,c=US	This property uses the property distinguished name (DN) that you set for the certificate when it is created. The <code>\${hostname}</code> variable is expanded to the host name on which it resides. You can use correctly formed DNs as specified by the X.509 certificate.
com.ibm.ssl.defaultCertReqDays	365	This property specifies the validity period for the certificate and can be as small as 1 day and as large as the maximum number of days that a certificate can be set, which is approximately 20 years.
com.ibm.ssl.defaultCertReqKeySize	1024	This property is the default key size. The valid values depend upon the Java Virtual Machine (JVM) security policy files that are installed. By default, the product JVMs ship with the export policy file that limits the key size to 1024. To get a large key size such as 2048, you can download the restricted policy files from the Web site.

SSL configuration properties

Use the SSL configuration properties section to set multiple SSL configurations. For a new SSL configuration specification, set the `com.ibm.ssl.alias` property because the parser starts a new SSL configuration with this alias name. The SSL configuration is referenced by using the alias property from another file, such as `sas.client.props` or `soap.client.props`, through the default alias property. The properties that are specified in the following table enable you to create a `javax.net.ssl.SSLContext`, among other SSL objects.

Property	Default	Description
<code>com.ibm.ssl.alias</code>	<code>DefaultSSLSettings</code>	This property is the name of this SSL configuration and must be the first property for an SSL configuration because it references the SSL configuration. If you change the name of this property after it is referenced elsewhere in the configuration, the runtime defaults to the <code>com.ibm.ssl.defaultAlias</code> property whenever the reference is not found. The error <code>trust file is null</code> or <code>key file is null</code> might display when you start an application using an SSL reference that is no longer valid.
<code>com.ibm.ssl.protocol</code>	<code>SSL_TLS</code>	This property is the SSL handshake protocol that is used for this SSL configuration. This property attempts Transport Layer Security (TLS) first, but accepts any remote handshake protocol, including SSLv3 and TLS. Valid values for this property include SSLv2 (client side only), SSLv3, SSL, TLS, TLSv1, and SSL_TLS.
<code>com.ibm.ssl.securityLevel</code>	<code>HIGH</code>	This property specifies the cipher group that is used for the SSL handshake. The typical selection is <code>HIGH</code> , which specifies 128-bit or higher ciphers. The <code>MEDIUM</code> selection provides 40-bit ciphers. The <code>LOW</code> selection provides ciphers that do not perform encryption, but do perform signing for data integrity. If you specify your own cipher list selection, uncomment the property <code>com.ibm.ssl.enabledCipherSuites</code> .
<code>com.ibm.ssl.trustManager</code>	<code>IbmX509</code>	This property specifies the default trust manager that you must use to validate the certificate sent by the target server. This trust manager does not perform certificate revocation list (CRL) checking. You can choose to change this to <code>IbmPKIX</code> for CRL checking using CRL distribution lists in the certificate, which is a standard way to perform CRL checking. When you want to perform custom CRL checking, you must implement a custom trust manager and specify the trust manager in the <code>com.ibm.ssl.customTrustManagers</code> property. The <code>IbmPKIX</code> option might affect performance because this option requires <code>IBMCertPath</code> for trust validation. Use <code>IbmX509</code> unless CRL checking is necessary.
<code>com.ibm.ssl.keyManager</code>	<code>IbmX509</code>	This property specifies the default key manager to use for choosing the client alias from the specified keystore. This key manager uses the <code>com.ibm.ssl.keyStoreClientAlias</code> property to specify the keystore alias. If this property is not specified, the choice is delegated to Java Secure Socket Extension (JSSE). JSSE typically chooses the first alias that it finds.

Property	Default	Description
com.ibm.ssl.contextProvider	IBMJSSE2	This property is used to choose the JSSE provider for the SSL context creation. It is recommended that you default to IBMJSSE2 when you use a Java virtual machine (JVM). The client plug-in can use the SunJSSE provider when using a Sun JVM.
com.ibm.ssl.enableSignerExchangePrompt		This property determines whether to display the signer exchange prompt when a signer is not present in the client truststore. The prompt displays information about the remote certificate so that WebSphere Application Server can decide whether or not to trust the signer. It is very important to validate the certificate signature. This signature is the only reliable information that can guarantee that the certificate has not been modified from the original server certificate. For automated scenarios, disable this property to avoid SSL handshake exceptions. Run the <code>retrieveSigners</code> script, which sets up the SSL signer exchange, to download the signers from the server prior to running the client.
com.ibm.ssl.keyStoreClientAlias	default	This property is used to reference an alias from the specified keystore when the target does not request client authentication. When WebSphere Application Server creates a self-signed certificate for the SSL configuration, this property determines the alias and overrides the global <code>com.ibm.ssl.defaultCertReqAlias</code> property.
com.ibm.ssl.customTrustManagers	Commented out by default	This property enables you to specify one or more custom trust managers, which are separated by commas. These trust managers can be in the form of <code>algorithm provider</code> or <code>classname</code> . For example, <code>IbmX509 IBMJSSE2</code> is in the <code>algorithm provider</code> format, and the <code>com.acme.myCustomTrustManager</code> interface is in the <code>classname</code> format. The class must implement the <code>javax.net.ssl.X509TrustManager</code> interface. Optionally, the class can implement the <code>com.ibm.wsspi.ssl.TrustManagerExtendedInfo</code> interface. These trust managers run in addition to the default trust manager that is specified by the <code>com.ibm.ssl.trustManager</code> interface. These trust managers do not replace the default trust manager.
com.ibm.ssl.customKeyManager	Commented out by default	This property enables you to have one, and only one, custom key manager. The key manager replaces the default key manager that is specified in the <code>com.ibm.ssl.keyManager</code> property. The form of the key manager is <code>algorithm provider</code> or <code>classname</code> . See the format examples for the <code>com.ibm.ssl.customTrustManagers</code> property. The class must implement the <code>javax.net.ssl.X509KeyManager</code> interface. Optionally, the class can implement the <code>com.ibm.wsspi.ssl.KeyManagerExtendedInfo</code> interface. This key manager is responsible for alias selection.

Property	Default	Description
com.ibm.ssl.dynamicSelectionInfo	Commented out by default	<p>This property enables dynamic association with the SSL configuration. The syntax for a dynamic association is <i>outbound_protocol</i>, <i>target_host</i>, or <i>target_port</i>. For multiple specifications, use the vertical bar () as the delimiter. You can replace any of these values with an asterisk (*) to indicate a wildcard value. Valid <i>outbound_protocol</i> values include: IIOP, HTTP, LDAP, SIP, BUS_CLIENT, BUS_TO_WEBSPHERE_MQ, BUS_TO_BUS, and ADMIN_SOAP. When you want the dynamic selection criteria to choose the SSL configuration, uncomment the default property, and add the connection information. For example, add the following on one line</p> <pre>com.ibm.ssl.dynamicSelectionInfo=HTTP, .ibm.com,443 HTTP,.ibm.com,9443</pre> <p>. ADMIN_IIOP, and ADMIN_SOAP represent administrative uses of these protocols for the Remote Method Invocation (RMI) and SOAP connectors, respectively. In the SSL configuration alias AdminSOAPSSLSettings, you can set the value to ADMIN_SOAP,*,*, which indicates that any outbound administrative SOAP connection can use this SSL configuration. Dynamic selection takes precedence over direct alias selection in the soap.client.props file.</p>
com.ibm.ssl.enabledCipherSuites	Commented out by default	<p>This property enables you to specify a custom cipher suite list and override the group selection in the com.ibm.ssl.securityLevel property. The valid list of ciphers varies according to the provider and JVM policy files that are applied. For cipher suites, use a space as the delimiter.</p>
com.ibm.ssl.keyStoreName	ClientDefaultKeyStore	<p>This property references a keystore configuration name. If you have not already defined the keystore, the rest of the keystore properties must follow this property. After you define the keystore, you can specify this property to reference the previously specified keystore configuration. New keystore configurations in the ssl.client.props file have a unique name.</p>
com.ibm.ssl.trustStoreName	ClientDefaultTrustStore	<p>This property references a truststore configuration name. If you have not already defined the truststore, the rest of the truststore properties must follow this property. After you define the truststore, you can specify this property to reference the previously specified truststore configuration. New truststore configurations in the ssl.client.props file should have a unique name.</p>

Keystore configurations

SSL configurations reference keystore configurations whose purpose is to identify the location of certificates. Certificates represent the identity of clients that use the SSL configuration. You can specify keystore configurations with other SSL configuration properties. However, it is recommended that you specify the keystore configurations in this section of the ssl.client.props file after the com.ibm.ssl.keyStoreName property identifies the start of a new keystore configuration. After you fully define the keystore configuration, the com.ibm.ssl.keyStoreName property can reference the keystore configuration at any other point in the file.

Property	Default	Description
com.ibm.ssl.keyStoreName	ClientDefaultKeyStore	This property specifies the name of the keystore as it is referenced by the runtime. Other SSL configurations can reference this name further down in the <code>ssl.client.props</code> file to avoid duplication.
com.ibm.ssl.keyStore	<code>\${user.root}/etc/key.p12</code>	This property specifies the location of the keystore in the required format of the <code>com.ibm.ssl.keyStoreType</code> property. Typically, this property references a keystore file name. However, for cryptographic token types, this property references a Dynamic Link Library (DLL) file.
com.ibm.ssl.keyStorePassword	WebAS	This property is the default password, which is the cell name for the profile when it is created. The password is typically encoded using an {xor} algorithm. You can use <code>iKeyman</code> to change the password in the keystore, then change this reference. If you do not know the password and if the certificate is created for you, change the password in this property, then delete the keystore from the location where it resides. Restart the client to recreate the keystore by using the new password, but only if the keystore name ends with <code>DefaultKeyStore</code> and if the <code>fileBased</code> property is <code>true</code> . Delete both the keystore and truststore at the same time so that a proper signer exchange can occur when both are recreated together.
com.ibm.ssl.keyStoreType	PKCS12	This property is the keystore type. Use the default, PKCS12, because of its interoperability with other applications. You can specify this property as any valid keystore type that is supported by the JVM on the provider list.
com.ibm.ssl.keyStoreProvider	IBMJCE	The IBM Java Cryptography Extension property is the keystore provider for the keystore type. The provider is typically IBMJCE or IBMPKCS11Impl for cryptographic devices.
com.ibm.ssl.keyStoreFileBased	true	This property indicates to the runtime that the keystore is file-based, meaning it is located on the file system.
com.ibm.ssl.keyStoreReadOnly	false	This property indicates to the runtime whether the keystore can be modified during the runtime.

Truststore Configurations

SSL configurations reference truststore configurations, whose purpose is to contain the signer certificates for servers that are trusted by this client. You can specify these properties with other SSL configuration properties. However, it is recommended that you specify truststore configurations in this section of the `ssl.client.props` file after the `com.ibm.ssl.trustStoreName` property has identified the start of a new truststore configuration. After you fully define the truststore configuration, the `com.ibm.ssl.trustStoreName` property can reference the configuration at any other point in the file.

A truststore is a keystore that JSSE uses for trust evaluation. A truststore contains the signers that WebSphere Application Server requires before it can trust the remote connection during the handshake. If you configure the `com.ibm.ssl.trustStoreName=ClientDefaultKeyStore` property, you can reference the keystore as the truststore. Further configuration is not required for the truststore because all of the signers that are generated through signer exchanges are imported into the keystore where they are called by the runtime.

Property	Default	Description
com.ibm.ssl.trustStoreName	ClientDefaultTrustStore	This property specifies the name of the truststore as it is referenced by the runtime. Other SSL configurations can reference further down in the <code>ssl.client.props</code> file to avoid duplication.
com.ibm.ssl.trustStore	<code>\${user.root}/etc/trust.p12</code>	This property specifies the location of the truststore in the format that is required by the truststore type that is referenced by the <code>com.ibm.ssl.trustStoreType</code> property. Typically, this property references a truststore file name. However, for cryptographic token types, this property references a DLL file.
com.ibm.ssl.trustStorePassword	WebAS	This property specifies the default password, which is the cell name for the profile when it is created. The password is typically encoded using an <code>{xor}</code> algorithm. You can use <code>iKeyman</code> to change the password in the keystore, then change the reference in this property. If you do not know the password and if the certificate was created for you, change the password in this property, then delete the truststore from the location where it resides. Restart the client to recreate the truststore by using the new password, but only if the keystore name ends with <code>DefaultTrustStore</code> and the <code>fileBased</code> property is <code>true</code> . It is recommended that you delete the keystore and the truststore at the same time so that a proper signer exchange can occur when both are recreated together.
com.ibm.ssl.trustStoreType	PKCS12	This property is the truststore type. Use the default PKCS12 type because of its interoperability with other applications. You can specify this property as any valid truststore type that is supported by the JVM functionality on the provider list.
com.ibm.ssl.trustStoreProvider	IBMJCE	This property is the truststore provider for the truststore type. The provider is typically <code>IBMJCE</code> or <code>IBMPKCS11Impl</code> for cryptographic devices.
com.ibm.ssl.trustStoreFileBased	true	This property indicates to the runtime that the truststore is file-based, meaning it is located on the file system.
com.ibm.ssl.trustStoreReadOnly	false	This property indicates to the runtime whether the truststore can be modified during the runtime.

Creating a keystore configuration

A Secure Sockets Layer (SSL) configuration references keystore configurations during WebSphere Application Server runtime. Whether a keystore file was created by another keystore tool or saved from a previous configuration, the file must be part of a keystore configuration object. You can create a keystore configuration for the existing keystore object.

A keystore must already exist.

Complete the following steps in the administrative console:

1. Click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > SSL_configuration > Key stores and certificates > New**.
2. Type a name in the **Name** field. This name uniquely identifies the keystore in the configuration.
3. Type the location of the keystore file in the **Path** field. The location can be a file name or a file URL to an existing keystore file.

4. Type the keystore password in the **Password** field. This password is for the keystore file that you specified in the **Path** field.
5. Type the keystore password again in the **Confirm Password** field to confirm the password.
6. Select a keystore type from the list. The type that you select is for the keystore file that you specified in the **Path** field.
7. Select any of the following optional selections:
 - The **Read only selection** creates a keystore configuration object but does not create a keystore file. If this option is selected, the keystore file that you specified in the **Path** field must already exist.
 - The **Initialize at startup selection** initializes the keystore during runtime.
8. Click **Apply** and **Save**.

You have created a keystore configuration object for the keystore file that you specified. This keystore can now be used in an SSL configuration.

You can create additional keystore configurations, as needed.

Changing a keystore password

You can change the WebSphere Application Server password from the default password value, WebAS, in the administrative console or at a Java command prompt. Because the default password is well known, it is important that you change the password after you install WebSphere Application Server to protect the security of the keystore files and the Secure Sockets Layer (SSL) configuration.

When WebSphere Application Server starts for the first time as a standalone application server or as a Network Deployment Server, each server creates a keystore and truststore for the default SSL configuration. WebSphere Application Server creates these files and assigns the default password, WebAS.

Complete the following steps in the administrative console:

1. Click **Security > SSL certificate and key management > Key Stores and Certificates**.
2. Select a keystore.
3. Type the new keystore password in the **Change Password** field.
4. Type the keystore password again in the **Confirm Password** field to confirm the password.
5. Select **Apply**.

WebSphere Application Server and its keystores are protected by a unique password.

Use the new password the next time you start the WebSphere Application Server.

Recreating the .kdb keystore internal password record

The i5/OS keystore type IBMi50SKeyStore does not recognize or generate .sth password stash files. Instead it keeps an internal record of the password for the .kdb keystore file where it is created. If the .kdb file is moved, the password is no longer associated with the keystore. In that case, you must use the Digital Certificate Manager (DCM) to recreate the internal record of the password for the .kdb keystore file.

Refer to the topic `csec_sslkeystoreconfs.dita` before attempting this task.

To recreate the internal record of the password for the .kdb keystore file, start the DCM. For more information, see Digital Certificate Manager.

1. Click **Select a Certificate Store**.
2. Select **Other System Certificate Store**.
3. Enter the certificate store path and filename.
4. Enter the certificate store password.

5. Click **Continue**.
6. In the left hand panel, select **Manage Certificate Store**.
7. Click **Change password**.
8. Enter the new password and confirm it. Note that DCM requires a different password than the one you specified in step 4.
9. Select **Automatic login**.
10. Click **Continue**.
11. Click **OK** when a message displays that confirms that the password is changed.
12. Repeat steps 1 through 5 to create the internal record of the new password for the .kdb keystore file.
13. Repeat steps 1 through 12 to change the password back to the original password and to create the internal record of the original password for the .kdb keystore file.

You have recreated the internal record of the password for the .kdb keystore file.

Configuring a hardware cryptographic keystore

You can create a hardware cryptographic keystore that WebSphere Application Server can use to provide cryptographic token support in the server configuration.

Complete the following steps in the administrative console:

1. Click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > SSL_configuration > Key stores and certificates**.
2. Click **New**.
3. Type a name to identify the keystore. This name is used to enable hardware cryptography in the Web services security configuration.
4. Type the path for the hardware device-specific configuration file. The configuration file is a text file that contains entries in the following format: *attribute = value*. The valid values for attribute and value are described in detail in the Software Developer Kit, Java Technology Edition documentation. The two mandatory attributes are name and library, as shown in the following sample code:

```
name = FooAccelerator
library = /opt/foo/lib/libpkcs11.so
slotListIndex = 0
```
5. Type a password if the token login is required. Operations that use keys on the token require a secure login. This field is optional if the keystore is used as a cryptographic accelerator. In this case, you need to select **Enable pure acceleration for hardware cryptographic operations**.
6. Select the **PKCS11** type.
7. Select **Read only**.
8. Click **OK** and **Save**.

WebSphere Application Server can now provide cryptographic token support in the server configuration.

You can refer to this keystore in any server Secure Sockets Layer (SSL) configuration to achieve the following results:

- Cryptographic acceleration because the cryptographic hardware device has no persistent key storage
- Secure cryptographic hardware because a cryptographic token generates and securely stores the private key that WebSphere Application Server uses for SSL key exchange.

You can also refer to this keystore in the Web services security default bindings configuration to achieve similar results.

Managing keystore configurations remotely

You can manage keystores remotely in a Network Deployment environment on separate machines. A node server can hold the configuration for a keystore, while the actual keystore resides on another system. After you set up a remotely managed configuration, you can perform all of the certificate and keystore operations for the keystore on the remote machine from the server that contains the keystore remote configuration.

Key stores can be remotely managed only in network deployed environments.

Complete the following steps in the administrative console:

1. Click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > *ssl_configuration* > Key stores and certificates**.
2. Click **New**.
3. Type a name in the **Name** field. This name uniquely identifies the keystore in the configuration.
4. Type the location of the keystore file in the **Path** field. The location can be a file name or a file Uniform Resource Locator (URL) to an existing keystore file.
5. Type the keystore password in the **Password** field. This password is for the keystore file that you specified in the **Path** field.
6. Type the keystore password again in the **Confirm Password** field to confirm the password.
7. Select a keystore type from the list. The type you select is for the keystore file that you specified in the **Path** field.
8. Select the **Remotely managed** check box, and then fill in one or more hosts names of the systems where the keystore file is to be located. If you provide multiple host names, separate the host names with a pipe (|).
9. Select any of the following optional selections:
 - The **Read only selection** creates a keystore configuration object but does not create a keystore file. If this option is selected, the keystore file that you specified in the **Path** field must already exist.
 - The **Initialize at startup selection** initializes the keystore during run time.
10. Select **Apply** and **Save**.

A keystore configuration object is created on the server from where the command was run. The keystore file for the configuration will be created on each system that you specified in the host list.

Now, you can perform all certificate management operations on the keystore from the system where the keystore configuration resides. For example, you can perform certificate management operations, such as: creating a self-signed certificate, extracting a certificate, or extracting a signer certificate.

To manage a self-signed certificates by using the wsadmin tool, use the PersonalCertificateCommands group commands of the AdminTask object. For more information, see “Commands for the PersonalCertificateCommands group of the AdminTask object” on page 882.

Key stores and certificates collection

Use this page to manage key store types, including cryptography, Resource Access Control Facility (RACF) , Certificate Management Services (CMS), Java, and all trust store types.

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > Inbound | Outbound > *SSL_configuration_name***. Under Related items, click **Key stores and certificates**.

Button	Resulting action
New	Adds a new key store object that can be referenced by Secure Sockets Layer (SSL) configurations or KeySets. The KeyStore management scope is based on the part of the topology tree from which it was created.
Delete	Deletes an existing key store. The key store should not be referenced by any other parts of the configuration before you delete it.
Exchange signers	Refers to exchanging signers in a key store. You can select two key stores, along with personal certificates from a selected key store, then add them as a signer to another selected key store.

Name

Specifies the unique name that is used to identify the key store. This name is typically scoped by the ManagementScope scopeName and based upon the location of the key store. The name must be unique within the existing key store collection.

This is a user-defined name.

Path

Specifies the location of the key store file in the format needed by the key store type. This file can be a card-specific configuration file for cryptographic devices or a filename or file URL for file-based key stores. It can be a safkeyring URL for RACF keyrings.

Key store settings

Use this page to create all keystore types, including cryptographic, Resource Access Control Facility (RACF), Certificate Management Services (CMS), Java, and all truststore types.

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound SSL_configuration_name}**. Under Related Items, click **Key stores and certificates**. Click either **New** or an existing keystore.

Links to Personal certificates, Signer certificates, and Personal certificate requests enable you to manage certificates in a manner similar to iKeyman capabilities. A keystore can be file-based, such as CMS or Java keystore types, or it can be remotely managed.

Note: Any changes made to this panel are permanent.

Name

Specifies the unique name to identify the keystore. The keystore is typically scoped by the ManagementScope scopeName based on the location of the keystore. The name must be unique within the existing keystore collection.

Data type: Text

Path

Specifies the location of the keystore file in the format needed by the keystore type. This file can be a dynamic link library (DLL) for cryptographic devices or a filename or file URL for file-based keystores. It can be a safkeyring URL for RACF keyrings.

Data type: Text

Enable cryptographic operations on hardware device

Specifies whether a hardware cryptographic device is used for cryptographic operations only. Operations that require a login are not supported when using this option.

Default: Disabled

Password [new keystore] | Change password [existing keystore]

Specifies the password used to protect the keystore. For the default keystore (names ending in DefaultKeyStore or DefaultTrustStore), the password is the Cell name. This default password must be changed.

This field can be edited.

Data type: Text

Confirm password

Specifies confirmation of the password to open the keystore file or device.

Data type: Text

Type

Specifies the implementation for keystore management. This value defines the tool that operates on this keystore type.

The list of options is returned by `java.security.Security.getAlgorithms("KeyStore")`. Some options might be filtered and some might be added based on the `java.security` configuration.

Data type: Text
Default: PKCS12

Read only

Specifies whether the keystore can be written to or not. If the keystore cannot be written to, certain operations cannot be performed, such as creating or importing certificates.

Default: Disabled

Initialize at startup

Specifies whether the keystore needs to be initialized before it can be used for cryptographic operations. If enabled, the keystore is initialized at server startup.

Default: Disabled

Key managers collection

Use this page to define the implementation settings for key managers. A key manager is invoked during a Secure Sockets Layer (SSL) handshake to determine which certificate alias is used. The default key manager (WSX509KeyManager) performs alias selection. If more advanced function is desired, define a custom key manager and select it on the **Manage endpoint security configurations** panel.

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > Inbound | Outbound > *SSL_configuration_name***. Under Related items, click **Key managers**.

Button	Resulting action
New	Adds a new key manager that can be selected by an SSL configuration. A key manager is invoked during an SSL handshake to select a specific certificate alias to use from a key store.

Button	Resulting action
Delete	Deletes an existing key manager. The key manager should not be referenced by any SSL configuration before you can delete it.

Name

Specifies the name of the key manager, which you can select on the SSL configuration panel.

Class name

Specifies the name of the key manager implementation class. This class implements javax.net.ssl.X509KeyManager interface and, optionally, the com.ibm.wsspi.ssl.KeyManagerExtendedInfo interface.

Algorithm

Specifies the algorithm name of the key manager that is implemented by the selected provider.

Key managers settings

Use this page to define key managers implementation settings. A key manager gets invoked during an Secure Sockets Layer (SSL) handshake to determine the certificate alias to be used. The default key manager (WSX509KeyManager) performs alias selection. If more advanced function is desired, a custom key manager can be specified here and selected in the SSL configuration.

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > Inbound | Outbound > *SSL_configuration_name***. Under Related items, click **Key managers > New**.

Name

Specifies the name of the key manager, which you can select on the SSL configuration panel.

Data type: Text

Standard

Specifies the key manager selection that is available from a Java provider that is installed in the java.security file. This provider might be shipped by Java Secure Sockets Extension (JSSE) or be a custom provider that implements an X509KeyManager interface.

Default: Enabled

Provider

Specifies the provider name that has an implementation of an X509KeyManager interface. This provider is typically set to IBMJSSE2.

Data type: Text

Default: IBMJCE

Algorithm

Specifies the algorithm name of the trust manager implemented by the selected provider.

Data type: Text

Default: IbmX509

Custom

Specifies that the key manager selection is based on a custom implementation class that implements the `javax.net.ssl.X509KeyManager` interface and optionally the `com.ibm.wsspi.ssl.KeyManagerExtendedInfo` interface to obtain additional connection information not otherwise available.

Default: Disabled

Class name

Specifies the name of the key manager implementation class.

Data type: Text

Creating a self-signed certificate

You can create a self-signed certificate. WebSphere Application Server uses the certificate at runtime during the handshake protocol. Self-signed certificates are located in the default keystore.

You must create a keystore before you can create a self-signed certificate.

Complete the following steps in the administrative console:

1. Click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > *ssl_configuration* > Key stores and certificates > [*keystore*]**.
2. From Additional Properties, click **Personal certificates**.
3. Click **Create a self-signed certificate**.
4. Type a certificate alias name. The alias identifies the certificate request in the keystore.
5. Type a common name (CN) value. This value is the CN value in the certificate distinguished name (DN).
6. Type an organization value. This value is the O value in the certificate DN.
7. You can configure one or more of the following optional values:
 - a. **Optional:** Select a key size value. The default key size value is 1024 bits.
 - b. **Optional:** Type an organizational unit value. This organizational unit value is the OU value in the certificate DN.
 - c. **Optional:** Type a locality value. This locality value is the L value in the certificate DN.
 - d. **Optional:** Type a state or providence value. This value is the ST value in the certificate DN.
 - e. **Optional:** Type a zip code value. This zip code value is the POSTALCODE value in the certificate DN.
 - f. **Optional:** Select a country value from the list. This country value is the C= value in the certificate request DN.
8. Click **Apply**.

You have created a self-signed certificate that resides in the keystore. The SSL configuration for the WebSphere Application Server runtime uses this certificate for SSL communication. Extract the signer of the self-signed certificate to add the signer to another keystore.

To create a self-signed certificate by using the `wsadmin` tool, use the `createSelfSignedCertificate` command of the `AdminTask` object. For more information, see “Commands for the `PersonalCertificateCommands` group of the `AdminTask` object” on page 882.

Replacing an existing self-signed certificate

Occasionally, you need to replace an existing or expired self-signed certificate with a new certificate. Certificates are referenced in the runtime configuration by the Secure Sockets Layer (SSL) Configuration

object and the Dynamic SSL Configuration Selection object. You can replace a certificate with a new certificate alias reference or with a new signer certificate.

The current certificate and the certificate replacement must exist in the same keystore before you can replace a certificate.

Complete the following steps in the administrative console:

1. Click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > ssl_configuration > Key stores and certificates > [keystore]**.
2. Under Additional Properties, click **Personal certificates**.
3. Select a personal certificate. The alias list must include at least two certificates that reside in the keystore.
4. Click **Replace**.
5. Select a replacement certificate alias from the list.
6. You can delete one of the following types of certificates:
 - Select **Delete old certificate** to delete the existing certificate.
 - Select **Delete old signers** to delete the existing signer certificates.
7. Click **Apply**.

Your results depend on what you selected:

- If you selected **Delete old certificate**, the new certificate alias replaces all of the references to the certificate alias in the configuration.
- If you selected **Delete old signers**, the new signer certificate replaces all of the occurrences of the old signer certificates.
- If the new certificate alias replaces the existing alias, the WebSphere Application Server runtime checks to make sure that:
 - All of the SSL Configurations objects reference the certificate
 - The Dynamic SSL Configuration Selections objects and the SSL Configuration group objects reference the certificate.
- If you selected **Delete old signers**, the existing signer certificates are replaced.
- If you selected **Delete old certificate**, the existing certificate are deleted.

To replace a self-signed certificate by using the wsadmin tool, use the **replaceCertificate** command of the AdminTask object. For more information, see `rxml_atpersonalcert.dita`.

Creating a certificate authority request

To ensure Secure Sockets Layer (SSL) communication, servers require a personal certificate that is either self-signed or signed by a certificate authority (CA). You must first create a personal certificate request to obtain a certificate that is signed by a CA.

The keystore that contains a personal certificate request must already exist.

Complete the following steps in the administrative console:

1. Click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > ssl_configuration > Key stores and certificates > keystore**.
2. Click **Personal certificate requests > New**.
3. Type the full path of the certificate request file. The certificate request is created in this location.
4. Type an alias name in the **Key label** field. The alias identifies the certificate request in the keystore.
5. Type a common name (CN) value. This value is the CN value in the certificate distinguished name (DN).

6. Type an organization value. This value is the O value in the certificate DN.
7. You can configure one or more of the following optional values:
 - a. **Optional:** Select a key size value. The default key size value is 1024 bits.
 - b. **Optional:** Type an organizational unit value. This organizational unit value is the OU value in the certificate DN.
 - c. **Optional:** Type a locality value. This locality value is the L value in the certificate DN.
 - d. **Optional:** Type a state or province value. This value is the ST value in the certificate DN.
 - e. **Optional:** Type a zip code value. The zip code value is the POSTALCODE value in the certificate DN.
 - f. **Optional:** Select a country value from the list. This country value is the C= value in the certificate request DN.
8. Click **Apply**.

The certificate request is created in the specified file location in the keystore. The request functions as a temporary placeholder for the signed certificate until you manually receive the certificate in the keystore.

To create a certificate request using the wsadmin tool, use the **createCertificateRequest** command of the AdminTask object. For more information, see “Commands for the PersonalCertificateCommands group of the AdminTask object” on page 882.

Note: Key store tools (such as iKeyman and keyTool) cannot receive signed certificates that are generated by certificate requests from WebSphere Application Server. Similarly, WebSphere Application Server cannot accept certificates that are generated by certificate requests from other keystore utilities.

Now you can receive the CA-signed certificate into the keystore to complete the process of generating a signed certificate for your server.

Certificate request settings

Use this page to verify the properties of a personal certificate request.

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > Inbound | Outbound > *ssl_configuration***. Under Related items, click **Key stores and certificates > *key store***. Under Additional Properties, click **Personal certificate requests > *certificate request***.

Key label

Specifies the certificate alias name for the signer in the key store, which is specified in the SSL configuration.

Key size

Specifies the size of the keys that are generated.

Requested by

Specifies the Subject distinguished name (DN) that represents the identity of the certificate request.

Fingerprint (SHA Digest)

Specifies the SHA hash of the personal certificate, which can be used to verify that the certificate has not been altered when it is used in a remote connection.

Signature algorithm

Specifies the algorithm used to sign the certificate.

Personal certificates collection

Use this page to manage personal certificates.

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > ssl_configuration**. Under Related items, click **Key stores and certificates > key store**. Under Additional Properties, click **Personal certificates**.

The **Personal certificates** page lists all Personal certificates in the selected key store. You can do most certificate management operations in this panel, including creating a new self-signed certificate, deleting a certificate, receiving one generated from a CA, replacing a certificate (simultaneous delete and create, replacing references across all key stores), extracting the signer, and importing or exporting a personal certificate.

Personal certificate requests are temporary place holders for certificates that will be signed by a certificate authority (CA).

The Key store collection must contain at least two key store files. You must select one file in order to replace, extract, or export a key store,

Button	Resulting action
Create a self-signed certificate	Enables the application server to create a new self-signed certificate.
Delete	Specifies to delete a certificate from the key store. Be careful that the certificate alias is not referenced elsewhere in the Secure Sockets Layer configuration.
Receive a certificate from a certificate authority	Enables the application server to receive a certificate authority (CA)-generated certificate from a file to complete a certificate request.
Replace	Replaces a self-signed certificate with another self-signed certificate that contains the same information, but with a new expiration period. The signer from the old certificate that is contained in any managed key store in the cell is replaced by the signer from the new certificate.
Extract	Extracts a certificate from the key store that will be added to another key store as a trusted certificate (signer).
Import	Imports a certificate, including the private key, from a key store file.
Export	Exports a certificate, including the private key, to a specified key store file.

Alias

Specifies the alias by which the personal certificate is referenced in the key store.

When you select an alias, the View Certificate panel opens.

Issued by

Specifies the distinguished name of the entity by which the certificate was issued. This name is the same as the issued-to distinguished name when the personal certificate is self-signed.

Issued to

Specifies the distinguished name of the entity to which the certificate was issued.

Serial number

Specifies the certificate serial number that is generated by the issuer of the certificate.

Expiration

Specifies the expiration date of the signer certificate for validation purposes.

Personal certificates settings

Use this page to create new personal certificates.

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > Inbound | Outbound > *SSL_configuration_name***. Under Related items, click **Key stores and certificates > *key store***. Under Additional Properties, click **Personal certificates > Create a self-signed certificate**.

This same help file is available when you create a new certificate or modify an existing certificate. The fields in this file are marked according to when they show on the administrative console.

Alias

Specifies the alias for the personal certificate in the key store.

This field displays when you create a new certificate. This field is read-only when you view an existing certificate.

Data type: Text

Version

Specifies the version of the personal certificate. Valid versions include X509 V3, X509 V2, or X509 V1. It is recommended to use X509 V3 certificates.

This field is read-only when you create or view a certificate.

Data type: Text
Default: X509 V3
Range:

Key size

Specifies the key size of the private key that is used by the personal certificate.

This field displays when you create or view a certificate.

Data type: Integer
Default: 1024

Common name

Specifies the common name portion of the distinguished name (DN). It is recommended that this name be the host name of the machine on which the certificate resides. In some cases, the common name is used to login during Secure Socket Layer (SSL) certificate authentication; therefore, in some cases, this name might be used as a user ID for a local operating system registry.

This field displays when you create a new certificate, but does not display when you view an existing certificate.

Data type: Text

Serial number

Specifies the certificate serial number that is generated by the issuer of the certificate.

This field displays only when you view an existing certificate.

Validity period

Specifies the length in days during which the certificate is valid. The default is 365 days.

This field displays when you create or view a certificate.

Data type: Text

Organization

Specifies the organization portion of the distinguished name.

This field displays only when you create a new certificate.

Data type: Text

Organization unit

Specifies the organization unit portion of the distinguished name. This field is optional.

This field displays only when you create a new certificate.

Data type: Text

Locality

Specifies the locality portion of the distinguished name. This field is optional.

This field displays only when you create a new certificate.

Data type: Text

State/Province

Specifies the state portion of the distinguished name. This field is optional.

This field displays only when you create a new certificate.

Data type: Text

Zip code

Specifies the zip code portion of the distinguished name. This field is optional.

This field displays only when you create a new certificate.

Data type: Integer

Country or region

Specifies the country portion of the distinguished name.

This field displays only when you create a new certificate.

Data type: Text
Default: (none)

Refer to <http://www.iso.org/iso/en/prods-services/iso3166ma/02iso-3166-code-lists/list-en1.html> for a list of ISO 3166 country codes.

Validity period

Specifies the length, in days, when the certificate is valid. The default is 365 days.

This read-only field displays only when you view an existing certificate.

Issued to

Specifies the distinguished name of the entity to which the certificate was issued.

This read-only field displays only when you view an existing certificate.

Issued by

Specifies the distinguished name of the entity that issued the certificate. When the personal certificate is self-signed, this name is identical to the **Issued to** distinguished name.

This read-only field displays only when you view an existing certificate.

Fingerprint (SHA Digest)

Specifies the Secure Hash Algorithm (SHA hash) of the certificate, which can be used to verify the certificate's hash at another location, such as the client side of a connection.

This read-only field displays only when you view an existing certificate.

Signature algorithm

Specifies the algorithm used to sign the certificate.

This read-only field displays only when you view an existing certificate.

Personal certificate requests collection

Use this page to manage personal certificate requests. Personal certificate requests are temporary place holders for certificates that will be signed by a certificate authority (CA).

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > ssl_configuration** . Under Related items, click **Key stores and certificates > key store** . Under Additional Properties, click **Personal certificate requests**.

A private key is generated during the certificate request generation, but only the certificate is sent to the CA. The CA generates a new certificate, signed by the CA. This can be added in the Personal Certificates panel.

Button	Resulting action
New	Creates a personal certificate request that can be given to a certificate authority to complete.
Delete	Deletes a personal certificate request.
Extract	Extracts a personal certificate request. Only one certificate request can be selected at a time.

Note: Any changes made to this panel are permanent.

Key label

Specifies the alias that represents the personal certificate request in the key store.

Requested by

Specifies the Subject distinguished name (DN) that represents the identity of the certificate request.

Personal certificate requests settings

Use this page to create a new certificate request that can be extracted and sent to a certificate authority (CA).

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > ssl_configuration** . Under Related items, click **Key stores and certificates > key store** . Under Additional Properties, click **Personal certificate requests > New**.

Personal certificate requests are temporary place holders for certificates that will be signed by a certificate authority (CA). The private key is generated during the certificate request generation, but only the certificate is sent to the CA. The CA generates a new certificate, signed by the CA.

Note: Any changes made to this panel are permanent.

File for certificate request

Specifies the fully qualified file name from which the certificate request is exported. This portion of the certificate request can be given to the certificate authority to generate the real certificate. After the real certificate is generated, you can perform an "Receive a certificate from a certificate authority" from the personal certificate collection view.

Data type: Text

Key label

Specifies the alias that represents the personal certificate request in the key store.

Data type: Text

Key size

Specifies the size of the keys that are generated.

Data type: Integer
Default: 1024

Common name

Specifies the name of the entity that the certificate represents. This common name can represent a person, company, or machine. For Web sites, the common name is frequently the DNS host name where the server resides.

Data type: Text

Organization

Specifies the organization portion of the distinguished name.

Data type: Text

Organizational unit

Specifies the organization unit portion of the distinguished name. This field is optional.

Data type: Text

Locality

Specifies the locality portion of the distinguished name. This field is optional.

Data type: Text

State/Province

Specifies the state portion of the distinguished name. This field is optional.

Data type: Text

Zip code

Specifies the zip code portion of the distinguished name. This field is optional.

Data type: Integer

Country or region

Specifies the country portion of the distinguished name.

Data type: Text

Default: US

Refer to <http://www.iso.org/iso/en/prods-services/iso3166ma/02iso-3166-code-lists/list-en1.html> for a list of ISO 3166 country codes.

Extract certificate request

Use this page to extract a certificate request and send it to a certificate authority (CA).

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > ssl_configuration** . Under Related items, click **Key stores and certificates > key store** . Under Additional Properties, click **Personal certificate requests > Extract**.

Key label

Specifies the alias that represents the personal certificate request in the key store.

File for certificate request

Specifies the filename where the extracted certificate request is placed.

Data type: Text

Receiving a certificate issued by a certificate authority

When a certificate authority (CA) receives a certificate request, it issues a new certificate that functions as a temporary placeholder for a CA-issued certificate. A keystore receives the certificate from the CA and generates a CA-signed personal certificate that WebSphere Application Server can use for Secure Sockets Layer (SSL) security.

The keystore must contain the certificate request that was created and sent to the CA. Also, the keystore must be able to access the certificate that is returned by the CA.

WebSphere Application Server can receive only those certificates that are generated by a WebSphere Application Server certificate request. It cannot receive certificates that are created with certificate requests from other keystore tools, such as **iKeyman** and **keyTool**.

Complete the following steps in the administrative console:

1. Click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > ssl_configuration > Key stores and certificates > [keystore]**.
2. Under Additional Properties, click **Personal certificates**.
3. Select a personal certificate.
4. Click **Receive a certificate from a certificate authority**.
5. Type the full path and name of the certificate file.
6. Select a data type from the list.
7. Click **Apply** and **Save**.

The keystore contains a new personal certificate that is issued by a CA. The original certificate request is changed to a personal certificate.

The SSL configuration is ready to use the new CA-signed personal certificate.

To receive a certificate by using the wsadmin tool, use the **receiveCertificate** command of the AdminTask object. For more information, see “Commands for the PersonalCertificateCommands group of the AdminTask object” on page 882.

Export certificate to a key file

Use this page to specify a personal certificate to export to a key file.

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > ssl_configuration** . Under Related items, click **Key stores and certificates > key store** . Under Additional Properties, click **Personal certificates > Export**.

Certificate alias to export:

Displays the name of the certificate that you selected to export on the previous panel.

Data type: Text

Alias:

Specifies the alias that the personal certificate is referenced by in the key store.

Data type: Text

Key file name:

Specifies the key store file name into which the exported certificate is added. If the key store file name already exists, the exported certificate will be added. If the key store file name does not already exist, one will be created, and the exported certificate will be added.

Data type: Text

Type:

Specifies the type of key store file. The valid types are listed in the menu.

Data type: Text

Default: JKS

Key file password:

Specifies the password that is used to access the key store file.

Data type: Text

Confirm password:

Confirms the password entered in the previous field.

The key file password and the new alias must be specified in case a certificate already exists with the same name.

Data type: Text

Import certificate from a key file

Use this page to specify a personal certificate to import from a key file.

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > Inbound | Outbound > *SSL_configuration_name***. Under Related items, click **Key stores and certificates > *key store***. Under Additional Properties, click **Personal certificates > Import certificates from a key file**.

Key file name:

Specifies the fully qualified path to keystore file that contains the certificate to import.

Data type: Text

Type:

Specifies the type of keystore file. The valid types are listed in the menu.

Data type: Text

Key file password:

Specifies the password that is used to access the keystore file.

Data type: Text

Certificate alias to import:

Specifies the certificate alias identified as the **Key file name** that you want to import into the current key store.

Data type: Text
Default: (none)

Imported certificate alias:

Specifies the new alias that you want the certificate to be named in the current key store.

Data type: Text

Receive certificate from CA

Use this page to import your personal certificate from the certificate authority (CA). The imported certificate replaces the temporary certificate associated with the public/private keys in the certificate request that is stored in the key store.

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > ssl_configuration** . Under Related items click **Key stores and certificates > key store** . Under Additional Properties, click **Personal certificates > Receive certificate from CA**.

Certificate file name:

Specifies the filename that contains the certificate generated by the certificate authority (CA).

Data type: Text

Data type:

Specifies the format of the file that is either Base64 encoded ASCII data or Binary DER data.

Data type: Text

Default: Base64-encoded ASCII data

Replace a certificate

Use this page to specify two certificates: the first selected certificate is replaced by the second selected certificate. The replace function replaces all the old signer certificates in key stores that are managed throughout the cell with the new signer from the new certificate. The same level of trust that was established with the old certificate is maintained.

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > Inbound | Outbound > ssl_configuration** . Under Related items, click **Key stores and certificates > key store** . Under Additional Properties click **Personal certificates > Replace certificate**.

Old certificate

Specifies the certificate that you want to replace.

Data type: Text

Replace with

Specifies the certificate that you want to replace the old certificate.

Data type: Text

Default: (none)

Delete old certificate after replacement

Specifies that you want to delete the old certificate and all associated signer certificates after the new certificate replaces it. If you do not replace the old personal certificate, it might be assigned a new alias name.

Default: Disabled

Delete old signers

Specifies that you want to delete the old signer certificates that are associated with the old certificate after the new signer certificates replace them. If you do not delete the old signer certificates, they might be assigned new alias names.

Default: Disabled

Extracting a signer certificate from a personal certificate

Personal certificates contain a private key and a public key. You can extract the public key, called the *signer certificate*, to a file, then import the certificate into another keystore. The client requires the signer portion of a personal certificate for Security Socket Layer (SSL) communication.

The keystore that contains a personal certificate must already exist.

Complete the following steps in the administrative console:

1. Click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > ssl_configuration > Key stores and certificates > keystore** .
2. Under Additional Properties, click **Personal certificates**.
3. Select a personal certificate.
4. Click **Extract**.
5. Type the full path for the certificate file name. The signer certificate is written to this certificate file.
6. Select a data type from the list.
7. Click **Apply**.

The signer portion of the personal certificate is stored in the file that is provided.

This signer can now be imported into other keystores.

To extract a signer certificate from a personal certificate using the wsadmin tool, use the **extractCertificate** command of the AdminTask object. For more information, see “Commands for the PersonalCertificateCommands group of the AdminTask object” on page 882.

Extract certificate

Use this page to extract the signer from the personal certificate. The certificate can be imported into a trust store for trust verification.

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > ssl_configuration** . Under Related items, click **Key stores and certificates > key store** . Under Additional Properties, click **Personal certificates > Extract**.

Certificate alias to extract

Specifies the filename that contains the extracted certificate.

Data type: Text

Certificate file name

Specifies the fully qualified path where the certificate file will reside.

Data type: Text

Data type

Specifies the format of the file, which is either Base64-encoded ASCII data or Binary DER data.

Data type: Text
Default: Base64-encoded ASCII data

Extract signer certificate

Use this page to extract a signer certificate that can be added elsewhere.

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > Key stores and certificates > key store > Signer Certificates > Extract signer certificate.**

File name

Specifies the fully qualified file name where the extracted signer certificate is placed.

Data type: Text

Data type

Specifies the format of the file, which is either Base64 encoded ASCII data or Binary DER data.

Data type: Text

Retrieving signers using the retrieveSigners utility at the client

The client requires the signer certificates from the server to be able to communicate with WebSphere Application Server. Use the **retrieveSigners** command to get the signer certificate from a server.

The retrieveSigners utility is located in one of the following directories, depending on your operating system:

- On Windows operating system: *profile_root\bin* . For example: C:\WebSphere\AppServer\profiles\AppSrv01\bin
- On UNIX operating systems: *../profile_root/bin*

In this release, a Java client that does not have access to a stdin console prompt should use the retrieveSigners utility to download the signers from the remote server key store when signers are needed for a Secure Sockets Layer (SSL) handshake. For example, you might interpret the client as failing to respond if an applet client or Java Web Start Client application cannot access the stdin signer exchange prompt. Thus, you must add the WebSphere Java method call **com.ibm.wsspi.ssl.RetrieveSignersHelper.callRetrieveSigners** to your client application to retrieve the signers and to avoid running the retrieveSigners utility manually.

Use the retrieveSigners utility for situations where you cannot verify whether or not the `com.ibm.ssl.enableSignerExchangePrompt=` property is enabled or disabled when the application makes a request. Set the `com.ibm.ssl.enableSignerExchangePrompt=` property to `false` in the `ssl.client.props` file if you cannot see the console.

Alternatively, you can manually create the server key in the client truststore.

Complete the following steps, as required:

1. Use the **retrieveSigners** command to get the signer certificate from a server. You can find details about the **retrieveSigners**. parameters in “Secure installation for client signer retrieval” on page 417.
2. If the client and server are on the same machine, you will need only the *remoteKeyStoreName* and *localKeyStoreName* parameters. The most typical key store to reference on a remote system is *CellDefaultTrustStore* on a network deployed environment and *NodeDefaultTrustStore* on an application server.
3. When retrieving signers from a remote server, add these required connection-related parameters: **-host** *host*, **-port** *port*, **-conntype** {*RMI* | *SOAP*}.
4. If the remote server has security enabled, also supply the **-user** *user* **-password** *password* parameters.
5. Use the **-autoAcceptBootstrapSigner** parameter if you want to enable automation of the signer retrieval. This parameter automatically adds to the server all the signers that are needed to make the connection.

After running, the command displays the SHI-1 digest of the signers added. The output looks similar to the following output:

```
/QIBM/UserData/WebSphere/AppServer/V61/ND/profiles/AppSrv01/bin/retrieveSigners
CellDefaultTrustStore ClientDefaultTrustStore
CWPKI0308I: Adding signer alias "default_signer" to local keystore
           "ClientDefaultTrustStore" with the following SHA digest:
```

See the following examples of how to call the `retrieveSigners` file on the Windows operating system:

To retrieve signers on the same system, enter:

```
'profile_home'/bin/retrieveSigners CellDefaultTrustStore ClientDefaultTrustStore
```

To retrieve signers on a remote system with a SOAP connection, enter:

```
'profile_home'/bin/retrieveSigners CellDefaultTrustStore ClientDefaultTrustStore
-host myRemoteHost -port 8879 -conntype SOAP -autoAcceptBootstrapSigner
```

To retrieve signers on a remote system that has security enabled, enter:

```
'profile_home'/bin/retrieveSigners CellDefaultTrustStore ClientDefaultTrustStore
-host myRemoteHost -port 8879 -conntype SOAP -user testuser -password testuserpwd
-autoAcceptBootstrapSigner
```

To retrieve signers on a remote system that has security enabled, enter:

```
'profile_home'/bin/retrieveSigners CellDefaultTrustStore ClientDefaultTrustStore
-host myRemoteHost -port 8879 -conntype SOAP -user testuser -password testuserpwd
-autoAcceptBootstrapSigner
```

Changing the signer auto-exchange prompt at the client

For clients to communicate with WebSphere Application Server, clients must obtain a signer certificate from the server. Clients can use the **retrieveSigners** command to connect to a server to obtain the appropriate signer. A prompt displays that asks whether or not you want to add a signer to the truststore. If the Secure Sockets Layer (SSL) configuration uses an automated script that might hang, use the prompt to obtain the certificate.

The `com.ibm.ssl.enableSignerExchangePrompt` property in the `profile_home/properties/ssl.client.props` file controls the signer certificate prompt. By default, this property is set to `true`, meaning the prompt is enabled.

Complete the following steps to disable or enable the signer-exchange prompt at the client:

1. Open the `profile_home/properties/ssl.client.props` file using an editor.

2. Locate the section containing the SSL configuration information for the client that you are working with.
3. Change the value of the `com.ibm.ssl.enableSignerExchangePrompt` property to `false` if you do not want the signer-exchange prompt, or set it to `true` if you want to be prompted.
4. Save and close the file.

When the `com.ibm.ssl.enableSignerExchangePrompt` property is set to `false`, no prompt displays, so you can exchange signers while some administrative clients are running. When the `com.ibm.ssl.enableSignerExchangePrompt` property is set to `true`, a signer-exchange prompt displays, and you are asked to accept or reject the certificate. The prompt looks like the following example:

```
/QIBM/UserData/WebSphere/AppServer/V61/ND/profiles/default/bin/serverStatus -all
ADMU0116I: Tool information is being logged in file
/QIBM/UserData/WebSphere/AppServer/V61/ND/profiles/default/logs/serverStatus.log
ADMU0128I: Starting tool with the default profile
ADMU0503I: Retrieving server status for all servers
ADMU0505I: Servers found in configuration:
ADMU0506I: Server name: server1
```

```
*** SSL SIGNER EXCHANGE PROMPT ***
SSL signer from target host 192.174.1.5 is not found in truststore
/QIBM/UserData/WebSphere/AppServer/V61/ND/profiles/default/etc/trust.p12.
```

Verify that the digest value matches what is displayed at the server in the following signer information:

```
Subject DN: CN=hostname.austin.ibm.com, O=IBM, C=US
Issuer DN: CN=hostname.austin.ibm.com, O=IBM, C=US
Serial number: 1128544457
Expires: Thu Oct 20 15:34:17 CDT 2006
SHA-1 Digest: 91:A1:A9:2D:F2:7D:70:0F:04:06:73:A3:B4:A4:9C:56:9D:A8:A3:BA
MD5 Digest: 88:72:C5:88:00:1C:A7:FA:D6:EB:04:88:AC:A1:C9:13
```

```
Add signer to the truststore now? (y/n) y
A retry of the request might need to occur.
ADMU0508I: The Application Server "server1" is STARTED.
```

Clients can instigate communications for various processes using signer certificates obtained from WebSphere Application Server.

Importing a signer certificate from a truststore to a z/OS keyring

You can import a signer certificate, which is also called a certificate authority (CA) certificate, from a truststore on a non-z/OS platform server to a z/OS keyring.

To import a certificate to a z/OS keyring, complete the following steps:

1. On the non-z/OS platform server, change to the `install_root/bin` directory and start the `iKeyman` utility, which is called `keyman.bat` (Windows) or `keyman.sh` (UNIX). The `install_root` variable refers to the installation path for WebSphere Application Server.
2. Within the `iKeyman` utility, open the server truststore. The default server truststore is called the `DummyServerTrustFile.jks` file. The file is located in the `[/etc/]` directory. The default password is `WebAS`.
3. Extract the signer certificate from the truststore using the **`ikeyman`** utility. Complete the following steps to extract the signer certificate:
 - a. Select **Signer certificates** from the menu.
 - b. Select **new websphere dummy server alias**.
 - c. Select **Extract**.
 - d. Select the correct data type. The `signer_certificate` can have either a Base64-encoded ASCII data type or a Binary DER data type.
 - e. Specify the fully qualified path and the file name of the certificate.
4. From an FTP prompt on the non-z/OS platform server, type `cd bin` to change to binary mode.

5. From an FTP prompt on the non-z/OS platform server, type `put 'signer_certificate' mvs.dataset`. The *signer_certificate* variable refers to the name of the signer certificate on the non-z/OS platform server. The *mvs.dataset* variable is the data set name to which the certificate was exported.

The RACDCERT CERTAUTH ADD command in the next step works with a Multiple Virtual Storage (MVS) data set only. You can either turn the certificate file into a binary MVS data set or use the `put` command with an Hierarchical File System (HFS) file, and then use the following command to copy the file into a MVS data set:

```
0GET file_name mvs.dataset
```
6. On the z/OS platform server, go to option 6 in the Interactive System Productivity Facility (ISPF) dialog panels and issue the following commands as a super user to add the signer certificate to the z/OS keyring:
 - a. Type `RACDCERT CERTAUTH ADD ('signer_certificate') WITHLABEL('Dummy Server CA') TRUST` The Dummy Server CA variable refers to the label name for the certificate authority (CA) certificate that you are importing from a non-z/OS platform server. The *keyring_name* variable refers to the name of the z/OS keyring that is used by the servers in the cell.
 - b. Type `RACDCERT ID(ASCR1) CONNECT(CERTAUTH LABEL('Dummy Server CA') RING(keyring_name))`
 - c. Type `RACDCERT ID(DMCR1) CONNECT(CERTAUTH LABEL('Dummy Server CA') RING(keyring_name))`
 - d. Type `RACDCERT ID(DMSR1) CONNECT(CERTAUTH LABEL('Dummy Server CA') RING(keyring_name))` In the previous commands, ASCR1, DMCR1, and DMSR1 are the RACF IDs under which the started tasks for the cell run in WebSphere Application Server for z/OS. The ASCR1 value is the RACF ID for the application server control region. The DMCR1 value is the RACF ID for the deployment manager control region. The DMSR1 value is the RACF ID for the deployment manager server region.

After completing these steps, the z/OS keyring contains the signer certificates that originated on the non-z/OS platform server.

To verify that the certificates were added, use option 6 on the ISPF dialog panel and type the following command:

```
RACDCERT ID(CBSYMSR1) LISTRING(keyring_name)
```

The CBSYMSR1 value is the RACF ID for the application server region.

Note: Although iKeyman is supported for WebSphere Application Server Version 6.1, customers are encouraged to use the administrative console to export signer certificates.

Exporting a signer certificate from WebSphere Application Server for z/OS to a truststore

You can export a signer certificate, which is also called a certificate authority (CA) certificate, from WebSphere Application Server for z/OS to a truststore.

WebSphere Application Server, WebSphere Application Server Network Deployment, or WebSphere Application Server - Express can use the certificate in the truststore.

To export the certificate to a truststore, complete the following steps:

1. Export the z/OS[®] signer certificate to a data set by issuing the following Resource Access Control Facility (RACF) command as a super user using Time Sharing Option (TSO) option 6:

```
RACDCERT CERTAUTH EXPORT(LABEL('signer_certificate')) DSN('mvs.dataset') FORMAT(CERTDER)
```

The *signer_certificate* variable is the RACF label name of the certificate that is used by the cell. The *signer_certificate* can have either a Base64-encoded ASCII data type or a Binary DER data type. The *mvs.dataset* variable is the data set name to which the certificate is exported. You do not need to pre-allocate this data set because it is created by RACF.

2. From a command line on the non-z/OS platform server, type `cd` and change to the following directory:

`install_root/profiles/default/etc`

3. From an FTP prompt on the non-z/OS platform server, type `cd bin` to change to binary mode.
4. From an FTP prompt on the non-z/OS platform server, type the following command:
`get 'mvs.dataset' signer_certificate`
5. On the non-z/OS platform server, change to the `install_root/bin` directory and start the **iKeyman** utility, which is called `ikeyman.bat` for Windows or `ikeyman.sh` for UNIX.
6. Within the iKeyman utility, open the server truststore. The default server truststore is called the `DummyServerTrustFile.jks` file. The file is located in the `${USER_INSTALL_ROOT}/etc/` directory. The default password is `WebAS`. It is recommended that you create a new key file and trust file if you plan to use the certificate in a production environment.
7. Add your exported signer certificate to the server truststore using the iKeyman utility. Complete the following steps to add your exported signer certificate:
 - a. Select **Signer certificates** from the menu.
 - b. Select the correct data type. The signer certificate can have either a Base64-encoded ASCII data type or a Binary DER data type.
 - c. Specify the fully qualified path and file name of the signer certificate.
8. Within the iKeyman utility, open the client truststore. The default client truststore is called the `DummyClientTrustFile.jks` file. The file is located in the `${USER_INSTALL_ROOT}/etc/` directory. The default password is `WebAS`. It is recommended that you create a new key file and trust file if you plan to use the certificate in a production environment.
9. Add your exported signer certificate to the client truststore using the iKeyman utility. Complete the following steps to add your exported signer certificate:
 - a. Select **Signer certificates** from the menu.
 - b. Select the correct data type. The signer certificate can have either a Base64-encoded ASCII data type or a Binary DER data type.
 - c. Specify the fully qualified path and file name of the signer certificate.
10. Restart the server process to use the new signer certificates.

After completing these steps, you can use the exported signer certificates with the WebSphere Application Server, WebSphere Application Server Network Deployment, or WebSphere Application Server - Express products.

Importing a signer certificate from a truststore to a z/OS keyring

You can import a signer certificate, which is also called a certificate authority (CA) certificate, from a truststore on a non-z/OS platform server to a z/OS keyring.

To import a certificate to a z/OS keyring, complete the following steps:

1. On the non-z/OS platform server, change to the `install_root/bin` directory and start the iKeyman utility, which is called `ikeyman.bat` (Windows) or `ikeyman.sh` (UNIX). The `install_root` variable refers to the installation path for WebSphere Application Server.
2. Within the iKeyman utility, open the server truststore. The default server truststore is called the `DummyServerTrustFile.jks` file. The file is located in the `[$USER_INSTALL_ROOT]/etc/` directory. The default password is `WebAS`.
3. Extract the signer certificate from the truststore using the **ikeyman** utility. Complete the following steps to extract the signer certificate:
 - a. Select **Signer certificates** from the menu.
 - b. Select **new websphere dummy server alias**.
 - c. Select **Extract**.
 - d. Select the correct data type. The `signer_certificate` can have either a Base64-encoded ASCII data type or a Binary DER data type.

- e. Specify the fully qualified path and the file name of the certificate.
4. From an FTP prompt on the non-z/OS platform server, type `cd bin` to change to binary mode.
 5. From an FTP prompt on the non-z/OS platform server, type `put 'signer_certificate' mvs.dataset`. The *signer_certificate* variable refers to the name of the signer certificate on the non-z/OS platform server. The *mvs.dataset* variable is the data set name to which the certificate was exported.
The RACDCERT CERTAUTH ADD command in the next step works with a Multiple Virtual Storage (MVS) data set only. You can either turn the certificate file into a binary MVS data set or use the `put` command with an Hierarchical File System (HFS) file, and then use the following command to copy the file into a MVS data set:

```
0GET file_name mvs.dataset
```
 6. On the z/OS platform server, go to option 6 in the Interactive System Productivity Facility (ISPF) dialog panels and issue the following commands as a super user to add the signer certificate to the z/OS keyring:
 - a. Type `RACDCERT CERTAUTH ADD ('signer_certificate') WITHLABEL('Dummy Server CA') TRUST` The Dummy Server CA variable refers to the label name for the certificate authority (CA) certificate that you are importing from a non-z/OS platform server. The *keyring_name* variable refers to the name of the z/OS keyring that is used by the servers in the cell.
 - b. Type `RACDCERT ID(ASCR1) CONNECT(CERTAUTH LABEL('Dummy Server CA') RING(keyring_name)`
 - c. Type `RACDCERT ID(DMCR1) CONNECT(CERTAUTH LABEL('Dummy Server CA') RING(keyring_name)`
 - d. Type `RACDCERT ID(DMSR1) CONNECT(CERTAUTH LABEL('Dummy Server CA') RING(keyring_name)` In the previous commands, ASCR1, DMCR1, and DMSR1 are the RACF IDs under which the started tasks for the cell run in WebSphere Application Server for z/OS. The ASCR1 value is the RACF ID for the application server control region. The DMCR1 value is the RACF ID for the deployment manager control region. The DMSR1 value is the RACF ID for the deployment manager server region.

After completing these steps, the z/OS keyring contains the signer certificates that originated on the non-z/OS platform server.

To verify that the certificates were added, use option 6 on the ISPF dialog panel and type the following command:

```
RACDCERT ID(CBSYMSR1) LISTRING(keyring_name)
```

The CBSYMSR1 value is the RACF ID for the application server region.

Note: Although iKeyman is supported for WebSphere Application Server Version 6.1, customers are encouraged to use the administrative console to export signer certificates.

Exporting a signer certificate from WebSphere Application Server for z/OS to a truststore

You can export a signer certificate, which is also called a certificate authority (CA) certificate, from WebSphere Application Server for z/OS to a truststore.

WebSphere Application Server, WebSphere Application Server Network Deployment, or WebSphere Application Server - Express can use the certificate in the truststore.

To export the certificate to a truststore, complete the following steps:

1. Export the z/OS[®] signer certificate to a data set by issuing the following Resource Access Control Facility (RACF) command as a super user using Time Sharing Option (TSO) option 6:

```
RACDCERT CERTAUTH EXPORT(LABEL('signer_certificate')) DSN('mvs.dataset') FORMAT(CERTDER)
```

The *signer_certificate* variable is the RACF label name of the certificate that is used by the cell. The *signer_certificate* can have either a Base64-encoded ASCII data type or a Binary DER data type. The

mvs.dataset variable is the data set name to which the certificate is exported. You do not need to pre-allocate this data set because it is created by RACF.

2. From a command line on the non-z/OS platform server, type `cd` and change to the following directory:
`install_root/profiles/default/etc`
3. From an FTP prompt on the non-z/OS platform server, type `cd bin` to change to binary mode.
4. From an FTP prompt on the non-z/OS platform server, type the following command:
`get 'mvs.dataset' signer_certificate`
5. On the non-z/OS platform server, change to the `install_root/bin` directory and start the **iKeyman** utility, which is called `ikeyman.bat` for Windows or `ikeyman.sh` for UNIX.
6. Within the iKeyman utility, open the server truststore. The default server truststore is called the `DummyServerTrustFile.jks` file. The file is located in the `${USER_INSTALL_ROOT}/etc/` directory. The default password is `WebAS`. It is recommended that you create a new key file and trust file if you plan to use the certificate in a production environment.
7. Add your exported signer certificate to the server truststore using the iKeyman utility. Complete the following steps to add your exported signer certificate:
 - a. Select **Signer certificates** from the menu.
 - b. Select the correct data type. The signer certificate can have either a Base64-encoded ASCII data type or a Binary DER data type.
 - c. Specify the fully qualified path and file name of the signer certificate.
8. Within the iKeyman utility, open the client truststore. The default client truststore is called the `DummyClientTrustFile.jks` file. The file is located in the `${USER_INSTALL_ROOT}/etc/` directory. The default password is `WebAS`. It is recommended that you create a new key file and trust file if you plan to use the certificate in a production environment.
9. Add your exported signer certificate to the client truststore using the iKeyman utility. Complete the following steps to add your exported signer certificate:
 - a. Select **Signer certificates** from the menu.
 - b. Select the correct data type. The signer certificate can have either a Base64-encoded ASCII data type or a Binary DER data type.
 - c. Specify the fully qualified path and file name of the signer certificate.
10. Restart the server process to use the new signer certificates.

After completing these steps, you can use the exported signer certificates with the WebSphere Application Server, WebSphere Application Server Network Deployment, or WebSphere Application Server - Express products.

Retrieving signers from a remote SSL port

To perform Secure Sockets Layer (SSL) communication with a server, WebSphere Application Server must retrieve a signer certificate from a secure remote SSL port during the handshake. After the signer certificate is retrieved, you can add the signer certificate to a keystore.

The keystore that is to contain the signer certificate must already exist.

Complete the following steps in the administrative console:

1. Click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > Key stores and certificates > keystore > Signer certificates > Retrieve from port**.
2. Click **Retrieve from port**.
3. Type the host name of the machine on which the signer resides.

4. Type the port location on the host machine on which the signer resides. The port location is not limited to ports on WebSphere Application Server. The ports can include Lightweight Directory Access Protocol (LDAP) ports or ports on any server on which an SSL port is already configured, such as `SIB_ENDPOINT_SECURE_ADDRESS`.
5. Select an SSL configuration for the outbound connection from the list.
6. Type an alias name for the certificate.
7. Click **Retrieve signer information**. A message window displays information about the retrieved signer certificate, such as: the serial number, issued-to and issued-by identities, SHA hash, and expiration date.
8. Click **Apply**. This action indicates that you accept the credentials of the signer.

The signer certificate that is retrieved from the remote port is stored in the keystore.

An SSL configuration or client process that requires an SSL connection to the server can use the retrieved and approved signer certificate.

To retrieve a signer certificate from a port using the wsadmin tool, use the **retrieveSignerFromPort** command of the AdminTask object. For more information, see “Commands for the PersonalCertificateCommands group of the AdminTask object” on page 882.

Retrieve from port

Use this page to retrieve a signer certificate from a remote SSL port. The system connects to the specified remote SSL host and port and receives the signer during the handshake using a trust manager. The signer SHA hash displays for validation and, if approved by an administrator, is added to the currently selected trust store.

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > ssl_configuration**. Under Related items, click **Key stores and certificates > key store > Signer certificates > Retrieve from port**.

Host

Specifies the host name to which you connect when attempting to retrieve the signer certificate from the Secure Sockets Layer (SSL) port.

Data type: Text

Port

Specifies the SSL port to which you connect when attempting to retrieve the signer certificate.

Data type: Text

SSL configuration for outbound connection

Specifies the SSL configuration that is used to connect to the previously specified SSL port. This configuration is also the SSL configuration that contains the signer after retrieval. This SSL configuration does not need to have the trusted certificate for the SSL port as it is retrieved during validation and presented here.

Data type: Text
Default: DefaultSSLConfig

Alias

Specifies the certificate alias name that you want to reference the signer in the key store, which is specified in the SSL configuration.

Data type: Text

Retrieved signer information

Specifies the signer certificate information if it is retrieved from the remote host and port.

Serial number

Specifies the certificate serial number that is generated by the issuer of the certificate.

Issued to

Specifies the distinguished name of the entity to which the certificate was issued.

Issued by

Specifies the distinguished name of the entity that issued the certificate. This name is the same as the issued-to distinguished name when the signer certificate is self-signed.

Fingerprint (SHA Digest)

Specifies the Secure Hash Algorithm (SHA hash) of the certificate, which can be used to verify the certificate's hash at another location, such as the client side of a connection.

Expiration

Specifies the expiration date of the retrieved signer certificate for validation purposes.

Adding a signer certificate to a keystore

Signer certificates establish the trust relationship in SSL communication. You can extract the signer part of a personal certificate from a keystore, and then you can add the signer certificate to other keystores.

The keystore that you want to add the signer certificate to must already exist.

Complete the following steps in the administrative console:

1. Click **Security > SSL certificate and key management > Manage endpoint security configurations > Inbound | Outbound > SSL_configuration_name > Key stores and certificates.**
2. Select a keystore from the list of keystores.
3. Click **Add signers.**
4. Enter an alias for the signer certificate in the **Alias** field
5. Enter the full path to the signer certificate file in the **File name** field.
6. Select a data type from the list in the **Data type** field.
7. Click **Apply.**

When these steps are completed, the signer from the certificate file is stored in the keystore. You can see the signer in the keystore files list of signer certificates. Use the keystore to establish trust relationships for the SSL configurations.

To add a signer certificate to a keystore by using the wsadmin tool, use the **addSignerCertificate** command of the AdminTask object. For more information, see `rxml_atpersonalcert.dita`.

Add signer certificate

Use this page to add a signer certificate to the key store.

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > ssl_configuration**. Under Related items click **Key stores and certificates > key store > Signer certificates > Add.**

Alias

Specifies the alias that the signer certificate is referenced by in the key store.

Data type: Text

File name

Specifies the filename where the encoded signer certificate is located.

Data type: Text

Data type

Specifies the format of the file, which is either Base64 encoded ASCII data or Binary DER data.

Data type: Text

Signer certificates collection

Use this page to manage signer certificates in key stores. Signer certificates are used by Java Secure Socket Extensions (JSSE) to validate certificates sent by the remote side of the connection during a Secure Sockets Layer (SSL) handshake. If a signer does not exist in the trust store that can validate the certificate sent, the handshake fails and generates an "unknown certificate" error.

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > ssl_configuration** . Under Related items click **Key stores and certificates > key store > Signer certificates**.

Button	Resulting action
Add	Adds a new trusted (signer) certificate.
Delete	Deletes an existing signer certificate.
Extract	Extracts a signer certificate from a personal certificate to a file.
Retrieve from port	Makes a test connection to an SSL port and retrieves the signer from the server during the handshake. The information from the certificate will be displayed so you can decide whether to trust it based upon the MD5 and/or SHA hash.

Alias

Specifies the alias for this signer certificate in the key store.

Issued to

Specifies the distinguished name of the entity that requested the certificate.

Fingerprint (SHA digest)

Specifies the Secure Hash Algorithm (SHA hash) of the certificate. This can be used to verify the hash for the certificate at another location, such as the client side of a connection.

Expiration

Specifies the expiration date of the signer certificate for validation purposes.

Signer certificate settings

Use this page to verify the general properties of the selected signer certificate.

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > ssl_configuration** . Under Related items, click **Key stores and certificates > key store > Signer certificates > signer certificate** .

Alias

Specifies the alias for this signer certificate in the key store.

Version

Specifies the version of the personal certificate. Valid versions include X509 V3, X509 V2, or X509 V1.

Key size

Specifies the key size of the public key used by the signer certificate.

Serial number

Specifies the certificate serial number that is generated by the issuer of the certificate.

Validity period

Specifies the begin and end dates of the certificate.

Issued to

Specifies the distinguished name of the entity that requested the certificate.

Issued by

Specifies the distinguished name of the entity that issued the certificate. This name is the same as the issued-to distinguished name when the signer certificate is self-signed.

Fingerprint (SHA Digest)

Specifies the Secure Hash Algorithm (SHA) hash of the certificate, which can be used to verify the hash for the certificate at another location such as the client side of a connection.

Signature algorithm

Specifies the algorithm that is used to sign the certificate.

Exchanging signer certificates

To establish trust relationships, you can exchange signer certificates between keystores. When you exchange signer certificates, you are extracting a personal certificate from one keystore and adding it to another keystore as a *signer certificate*.

To exchange signer certificates, there must be two keystores.

Complete the following steps in the administrative console:

1. Click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > ssl_configuration > Key stores and certificates**.
2. Select two keystores from the list of keystores.
3. Click **Exchange signers**.
4. Select any of the certificates in the first personal certificates list, and click **Add**. After adding, the signer part of the selected personal certificate appears in the other (second) keystore signers list.
5. Select any of the certificates in the second personal certificates list, and click **Add**. After adding, the signer part of the selected personal certificate appears in the other (first) keystore signers list.
6. **Optional:** If you need to remove any of the certificates from either of the signers lists, highlight one or more of the certificates, and click **Remove**.
7. Click **Apply** and **Save**.

The signer certificate appears in the list for each keystore.

The extracted signer certificate is available to both keystores during the connection handshake.

Key stores and certificates exchange signers

Use this page to extract a personal certificate from one keystore and add it to another keystore as a signer certificate.

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > ssl_configuration**. Under Related items, click **Key stores and certificates > Exchange signers**.

Note: Any changes made to this panel are permanent.

[key store] personal certificates

Specifies the personal certificates that are currently stored in the specified key store.

Press and hold the **Ctrl** key to select more than one item from the list.

Data type: Text

[key store] signers

Specifies the trusted signer certificates that are currently stored in the specified key store and selected for the exchange.

Press and hold the **Ctrl** key to select more than one item from the list.

Data type: Text

Add

Specifies to extract the signer from the selected personal certificate in the key store list on the left and add it to the signers list of the key store on the right.

After the certificate is added, it no longer displays in the left-hand list. The personal certificate is still in the key store, but it is no longer selectable

Remove

Specifies to remove a selected signer from the signers list of the key store on the right. The removed certificate displays in the key store list on the left.

Configuring certificate expiration monitoring

When certificates expire, they can no longer be used by the system. WebSphere Application Server provides a utility to monitor certificates that are close to expiration or have already expired. You can schedule certificate monitoring, or you can request certificate monitoring on demand. You can also configure options for deleting expired certificates and for recreating certificates.

WebSphere Application Server notifies you when a certificate is about to expire. Complete the information required for notification messaging in “Notifications” on page 499.

Complete the following configuration steps in the administrative console:

1. Click **Security > SSL certificate and key management > Manage certificate expiration**.
2. Type a number for the number of days threshold in the **Expiration notification threshold** field. WebSphere Application Server issues an expiration warning *n* number of days before expiration.
3. Select or check one or more of the following options:

- **Expiration check notification.** Select the method from the list that you want to use to receive your notification.
 - **Automatically replace expiring self-signed certificates.** If you do not want to recreate the self-signed certificate, clear the check box.
 - **Delete expiring certificates and signers after replacement.** If you do not want to delete the expired certificates and signers, clear the check box.
 - **Enable checking.** If you do not want to have certificate monitoring enabled, clear the check box.
4. Enter the time of day when you want certificate monitoring to take place to schedule the running of the certificate expiration monitor.
 5. Select one of the following options:
 - **Check by calendar.** For **Weekday**, enter the day of week that you want to run the certificate expiration monitor. For **Repeat Interval**, specify the frequency to run the certificate monitor.
 - **Check by number of days.** Enter a number for how frequently the monitor runs, in number of days.
 6. Click **Apply**.

After completing the settings, a certificate expiration monitor object and a schedule are set up in the configuration. The certificate expiration monitor runs according to the configurations options that you configured.

You can generate reports that state which certificates have expired. The reports identify the notifications of certificate replacements and deletions. The report is sent according to the notification option that you specified.

Manage certificate expiration settings

Use this page to configure the certificate expiration monitor.

To view this administrative console page, click **Security > SSL certificate and key management > Manage certificate expiration**.

Attention: To see the changes to the Expiration checking fields, you must click **Apply**.

Expiration notification threshold

Specifies a threshold number of days during which the application warns specified individuals that a certificate is about to expire. For example, when the expiration monitor is run and the threshold is 30 days, if the current date is 30 days or less from the certificate expiration date, the certificate is flagged for notification. The application server can be configured to provide certification expiration notification through either e-mail or the message log file.

Data type:	Integer
Default:	30 days

Expiration check notification

Specifies the notification type (such as e-mail or System Out) when an expiration monitor runs.

Default:

Automatically replace expiring self-signed certificates

Specifies a new self-signed certificate be generated using the same certificate information if the expiration notification threshold is reached. The old certificate is replaced and uses the same alias. All old signers are managed by the key store configuration are also replaced. The system only replaces self-signed certificates.

Default: Enabled

Delete expiring certificates and signers after replacement

Specifies whether to completely remove old, self-signed certificates from the key store during a replace operation or leave them there under a renamed alias. If an old certificate is not deleted, the system renames the alias so that the new certificate can use the old alias, which might be referenced elsewhere in the configuration.

Default: Enabled

Enable checking

Specifies the certificate monitor is active and will run as scheduled.

Scheduled time of day to check for expired certificates

Specifies the scheduled time that the system checks for expired certificates.

You can type the scheduled time in hours and minutes, specify either A.M. or P.M., or 24-hour.

Data type Integer
Default: 0, 0
Range: 1–12, 0–59

Check by calendar

Indicates that you want to schedule a specific day of the week on which the expiration monitor runs. For example, it might run on Sunday.

Default: Disabled

Weekday

Specifies the day of the week on which the expiration monitor runs if **Check on a specific day** is selected.

Default: Sunday
Range: Sunday, Monday, Tuesday, Wednesday, Thursday, Friday, Saturday

Repeat interval

Specifies the period of time between each schedule time to check for expired certificates or the interval between schedule checks.

Default: Daily
Range: Daily, Weekly

Check by number of days

Specifies that you want to schedule a specific number of days between each run of the expiration monitor. The day of the week on which this occurs is not counted. For example, if you set the interval to check for expired certificates every seven days, the expiration monitor runs on day eight.

Default: Disabled

Next start date

Specifies the date for the next scheduled check. This allows the deployment manager to be stopped and restarted without resetting the date.

Notifications

Use this page to specify the generic notification definitions that are used in certificate expiration monitors.

To view this administrative console page, complete the following steps:

1. Click **Security > SSL certificate and key management**.
2. Under Configuration settings, click **Manage certificate expiration**.
3. Under Related items, click **Notifications**.

Button	Resulting action
New	Adds a notification. The notification configures how the expiration monitor notifies the administrator of certificates that will expire within the specified threshold.
Delete	Deletes an existing notification.

Notification name

Specifies the notification name.

Message log

Specifies that this configuration intends to log certificate expiration information to the message log file.

List of e-mail addresses

Specifies the e-mail addresses that are sent notifications when certificates fall within the expiration threshold. You must specify the SMTP server for each e-mail address. If an e-mail address is not specified, by default the application server assumes that the SMTP server is "smtp-server." For example, if you type *name@domain*, the SMTP server will be smtp-server.domain.

Notifications settings

Use this page to set properties for new notifications used in certificate expiration monitors.

To view this administrative console page, complete the following steps:

1. Click **Security > SSL certificate and key management**.
2. Under Configuration settings, click **Manage certificate expiration**.
3. Under Related items, click **Notifications > New**.

Notification name

Specifies the name of the notification configuration.

Data type: Text

Message log

Specifies that this configuration will log certificate expiration information to a message log file.

Default: Disabled

Email sent to notification list

Specifies that this configuration intends to send certificate expiration information in an e-mail to the e-mail list.

Default: Disabled

Email address to add

Specifies the e-mail addresses that are sent notifications when certificates fall within the expiration threshold. You must specify the SMTP server for each e-mail address. If an e-mail address is not specified, by default the application server assumes that the SMTP server is "smtp-server." For example, if you type *name@domain*, the SMTP server will be smtp-server.domain.

Data type: Text (format as valid Internet mail address)

Add

Adds the e-mail address to the right-hand list.

Remove

Removes the e-mail address from the right-hand list.

Outgoing mail (SMTP) server

Specifies the SMTP server to be used with the e-mail address. If none is specified, the e-mail realm will be used.

Key management for cryptographic uses

WebSphere Application Server provides a framework for managing keys (secret keys or key pairs) that applications use to perform cryptographic operations on data. The key management framework provides an application programming interface (API) for retrieving these keys. Keys are managed in keystores so the keystore type can be supported by WebSphere Application Server, provided that the keystores can store the referenced key type. You can configure keys and scope keystores so that they are visible only to particular processes, nodes, clusters, and so on.

The key management infrastructure is based on two key configuration object types: key sets and key set groups. WebSphere Application Server uses a key set to manage instances of keys of the same type. You can configure a key set to generate a single key or a key pair, depending on the key or key pair generator class. A key set group manages one or more key sets and enables you to configure and generate different key types at the same time. For example, if your application needs both a secret key and key pair for cryptographic operations, you can configure two key sets, one for the key pair and one for the secret key that the key set group manages. The key set group controls the auto-generation characteristics of the keys, including the schedule. The framework can automatically generate keys on a scheduled basis, such as on a particular day of the week and time of day, so that key generation is done during off-peak hours.

Figure 1 shows an example of a key set group that is configured to manage two key sets: key set 1 and key set 2.

Figure 1: Key Management Infrastructure

Figure 7.

Key set 1 generates key pairs. Key set 2 generates secret keys. The application needs both types of keys for its cryptographic operations, signing and encryption, on data. The keys for each key set need to be generated in tandem. The application stores the key set group name with the encrypted data. The key set group generates a new set of keys every Sunday night at 11 P.M.. The application maintains key generation data for two weeks.

Creating a key set configuration

You can use key sets to manage multiple instances of cryptographic keys. WebSphere Application Server uses keys to encrypt or sign outbound data, and decrypt or verify inbound data during cryptographic operations.

You must have write-access to the keystore that will contain the keys after you generate them from a key set. However, if you want to generate keys outside of WebSphere Application Server, you can reference the keys from a read-only keystore that contains a secret key that you can access when you generate the keys. If you are creating a key pair using an X509Certificate and a PrivateKey object, see “Example: Developing a key or key pair generation class for automated key generation” on page 508.

Complete the following steps in the administrative console:

1. Decide whether you want to create the key set at the cell scope or below the cell scope at the node, server, or cluster, for example:
 - To create a key set at the cell scope, click **Security > SSL certificate and key management > Key sets**.

- To create a key set at a scope below the cell level, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > ssl_configuration > Key sets.**
2. Click **New** to create a new key set.
 3. Type a key set name. For example, CellmyKey.
 4. Type a key alias prefix name. For example, myKey. This field specifies the prefix for the key alias when the new key is generated and stored in the keystore. Following the prefix is the key reference version number, for example, 2, so that the full key alias name would be myKey_2. If the key reference already has a specified alias for a key that exists in the keystore, then WebSphere Application Server ignores this field.
 5. Type a key password. The key password protects the key in the keystore. This password is ignored by WebSphere Application Server if you already specified a password for the key alias reference. To check for a key reference password, click **Active key history** under Additional Properties. The key reference password protects keys that are generated by a key generator class.
 6. Type the password again to confirm it.
 7. **Optional:** Type the key generator class name. For example, com.ibm.ws.security.ltpa.LTPAKeyGenerator. The class name generates keys. If the class implements com.ibm.websphere.crypto.KeyGenerator, then a getKey method returns a java.security.Key object that is set in the keystore using the setKey method without a certificate chain. If the class implements com.ibm.websphere.crypto.KeyPairGenerator, then a getKeyPair method returns a com.ibm.websphere.crypto.KeyPair object that contains either a java.security.PublicKey and java.security.PrivateKey or a java.security.cert.Certificate and a java.security.PrivateKey object. The key generator class and the KeySetHelper API specify the details of the keys that are generated.
 8. **Optional:** Select **Delete key references that are beyond the maximum number of keys** if you do not want old keys saved in the keystore after WebSphere Application Server removes their references from the Active key history listing. The Active key history lists the keys that the KeySetHelper API is currently tracking. The number of keys in the list is equal to the number of keys that you specify in **Maximum number of keys referenced.**
 9. Type a numeric value for the maximum number of keys referenced. For example, if you type 3 and select **Delete key references that are beyond the maximum number of keys**, the fourth key version generation automatically triggers WebSphere Application Server to delete the first key version from the keystore. If you choose not to delete the old keys, they do not display in the Active key history list but instead remain in the keystore where you can remove them manually.
 10. Select a keystore from the drop-down list.
 - Select a JCEKS keystore if you are storing a secret key.
 - Select any keystore if you are storing a key pair with an X509Certificate and PrivateKey object.
 11. **Optional:** Select **Generates key pair** if your key generator class name implements the com.ibm.websphere.crypto.KeyPairGenerator interface instead of the com.ibm.websphere.crypto.KeyGenerator interface. This option designates that the key references a key pair instead of a single key. A key pair contains both a public key and a private key. The WebSphere Application Server run time determines whether or not key pairs are stored and loaded differently than single keys.
 12. **Optional:** Click **Apply** if you want to select **Active key history** under Additional Properties to add alias references or generate more keys.
 - a. Click **Active key history.**
 - b. Click **Add key alias reference** if you are not using the key generator class name to add key alias references to the keys that already exist in the keystore. Use this option to retrieve the keys from a read-only keystore without the key set generating them.
 - c. Type an alias reference.
 - d. Click **Generate key** if you want to generate a key using the class name that you defined in the key sets panel. Each new key increments numerically, for example, myAlias_2.

- e. Click **Apply**.
- 13. Click the key set name in the navigation path at the top of the panel.
- 14. Click **OK** and **Save**.

You have created a key set that you can manage using the **Active key history** link. You can generate keys manually to associate them with specified key sets.

After you generate new keys from a key set, you can access them programmatically using the `com.ibm.websphere.crypto.KeySetHelper` API. You must have Java 2 Security permissions, if enabled, to access keys in key sets. Specify the key set name within the fine-grained permissions, as in the following code sample: `WebSphereRuntimePermission "getKeySets.keySetName".` For more information, see “Example: Retrieving the generated keys from a key set group” on page 507. To generate multiple key types at the same time or to schedule the key generation on a specific schedule, see “Creating a key set group configuration” on page 506.

Active key history collection

Use this page to manage key alias references.

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > SSL_configuration_name**. Under Related items, click **Key Sets > key set > Active key history**.

Button	Resulting action
Add key alias reference	Adds a reference to a key that already exists in a key store. If a key generation class is configured, the references are added automatically during generation and do not need to be added manually.
Delete	Deletes an existing key reference. This action does not delete the key in the keystore.
Generate key	Generates a key. The button is displayed only if a generator class name is specified for the key set, and the selected key store is editable.

Key alias reference

Specifies the name of the alias as it appears in the keystore.

Add key alias reference settings

Use this page to access key alias reference information.

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > SSL_configuration_name**. Under Related items, click **Key Sets > key set > Active key history > Add key alias reference**.

Alias reference

Specifies the name of the alias as it appears in the key store.

Data type: Text

Password

Specifies the key password to get access to the key. This password is enforced by the keystore for that specific key. If the key does not have a password, this field can be left blank.

Data type: Text

Confirm password

Confirms the password entered in the previous field.

Data type: Text

Key sets collection

Use this page to manage key sets, which control a set of key instances of the same type for use in cryptographic operations. The keys can either be generated using a custom class or reference keys that already exist in a keystore.

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > ssl_configuration** . Under Related items, click **Key sets**.

Button	Resulting action
New	Adds a new key set.
Delete	Deletes an existing key set. Make sure the key set is not referenced by a key set group before deleting it.

Key set name

Specifies the key set name that is used to select the key set from a key set group and from runtime application programming interfaces (API).

Key store

Specifies the key store that contains the keys for storage, retrieval, or both.

Key alias prefix name

Specifies the prefix for the key alias when a new key is generated and stored in a key store. The rest of the key alias comes from the key reference version number.

For example, if the alias prefix is mykey and the key reference version is 2, the keystore references the key using alias mykey_2. If the key reference already has a specified alias for a key already existing in the keystore, this field is ignored.

Key sets settings

Use this page to set the properties for a new key set.

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > ssl_configuration** . Under Related items, click **Key sets > New**.

Key set name

Specifies the key set name that is used to select the key set from a key set group and from runtime application programming interfaces (API).

Data type: Text

Key alias prefix name

Specifies the prefix for the key alias when a new key is generated and stored in a keystore. The rest of the key alias comes from the key reference version number. For example, if the alias prefix is mykey and the key reference version is 2, the keystore references the key using alias mykey_2. If the key reference already has a specified alias for a key already existing in the keystore, this field is ignored.

Data type: Text

Key password

Specifies the password used to protect the key in the keystore. If a password is specified in the key reference as well, this password is ignored. This password is used for keys that get generated by a key generator class.

Data type: Text

Confirm password

Specifies the same password again to confirm it was entered correctly the first time.

Data type: Text

Key generator class name

Specifies the class name that generates keys. If the class implements `com.ibm.websphere.crypto.KeyGenerator`, then a `getKey()` method should return a `java.security.Key` object that is set in the key store using the `setKey` method without a certificate chain. The key store type associated with the key set must support storing keys without certificates, such as JCEKS.

Data type: Text

If the class implements `com.ibm.websphere.crypto.KeyPairGenerator`, then a `getKeyPair()` method should return a `com.ibm.websphere.crypto.KeyPair` object containing either a `java.security.PublicKey` and `java.security.PrivateKey`, or a `java.security.cert.Certificate[]` and a `java.security.PrivateKey`. The key generator class and the caller of the `KeySetHelper` API should know the details of the keys that are generated. This framework does not need to understand the key algorithms and lengths.

Delete key references that are beyond the maximum number of keys:

Specifies that the keys are deleted from the keystore at the same time that the key reference is deleted. The server deletes the older key references as the `Maximum number of keys referenced` value is exceeded.

Maximum number of keys referenced

Specifies the maximum number of key instances that are returned when keys from this key set are requested. The oldest key reference gets removed whenever a new key reference gets generated after the maximum has been reached.

Data type: Integer

Default: 3

Key store

Specifies the key store that contains the keys for storage, retrieval, or both.

Data type: Text

Generates key pair

Specifies that a key references a key pair instead of a key. The key pair contains both a public key and a private key.

Creating a key set group configuration

A key set group manages one or more key sets. WebSphere Application Server uses key set groups to automatically generate cryptographic keys or multiple synchronized key sets.

Complete the following steps in the administrative console:

1. Decide whether you want to create the key set group at the cell scope or below the cell scope at the node, server, or cluster, for example.
 - To create a key set group at the cell scope, click **Security > SSL certificate and key management > Key set groups**.
 - To create a key set group at a scope below the cell level, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > SSL_configuration > Key set groups**.
2. You can choose to generate a key for an existing key set group, delete an existing key set group, or create a new key set group.
 - To generate a key for an existing key set group, select a key set group from the list of existing key set groups, and click **Generate keys**. You have generated a new key for each key set in the selected group.
 - To delete an existing key set group, select a key set group from the list of existing key set groups, and click **Delete**. You have deleted the key set group.
 - To create a new key set group, go to step 3.

CAUTION:

Do not delete the cell or node LTPAKeySetGroup, which is used by the Lightweight Third Party Authentication (LPTA) mechanism.

3. Click **New** to create a new key set group.
4. Type a key set group name. You can reference this name by using the `com.ibm.websphere.crypto.KeySetHelper` API to retrieve the managed keys from an application.
5. Select one or more key sets from the Key sets list.

Note: If the key set(s) you want is not listed, make sure that it was created at the same scope or a higher scope than where you are creating the new key set group.

6. Click **Add** to add the selected key set(s) to the new key set group.
7. Select **Automatically generate keys** to generate the new keys on a schedule. If you decide to generate keys automatically, then you must specify a scheduled time of day.
8. Specify the scheduled time to generate keys automatically in hours and minutes, A.M. or P.M., or every 24 hours.
9. You can choose to generate new keys on a specific day or at an interval.
 - Select **Generate on a specific day**. Select a day of the week from the drop-down list, and type a repeat interval number for the number of days between each key generation. This choice enables you to schedule key generation when your systems are least busy.
 - Select **Generate at an interval**. Type a repeat interval number for the number of days between each key generation. This choice enables you to schedule key generation more frequently than once a week.

Note: The **Next start date** is a read-only field that specifies the date for the next scheduled generation. You can stop and restart the deployment manager or base application server without resetting this date. If you do not see the next start date appear after changing the configuration, click **OK** to save it, then check that the next start date displays.

10. Click **Save**.

You have created a new key set group to manage key sets and key generation on a schedule.

After you generate new keys from a key set, you can access them programmatically using the `com.ibm.websphere.crypto.KeySetHelper` API. You must have Java 2 Security permissions, if enabled, to access keys in key sets. Specify the key set name within the fine-grained permissions, as in the following code sample: `WebSphereRuntimePermission "getKeySets.keySetName".` For more information, see “Example: Retrieving the generated keys from a key set group.”

Example: Retrieving the generated keys from a key set group

This example shows how applications can use the `com.ibm.websphere.crypto.KeySetHelper` API to retrieve managed keys from the `KeySet` or `KeySetGroup` configurations. Use the `com.ibm.websphere.crypto.KeySetHelper` API to get either the latest set of keys or the all keys in the `KeySet` or `KeySetGroup` object.

Use the latest keys when performing any new cryptographic operations. All of the other keys that are defined in the `KeySet` or `KeySetGroup` object are for the validation of previously performed cryptographic operations.

The following example uses a method that an application might use to initialize the keys in the associated `KeySetGroup` object. The application might want to store the keys in two separate maps, one for generation and one for validation. Refer to the API documentation for `KeySetHelper` API to determine which Java 2 Security requirements are required.

```
/**
 * Initializes the primary and secondary Maps used for initializing the keys.
 */

public void initializeKeySetGroupKeys() throws com.ibm.websphere.crypto.KeyException
{
    java.util.Map generationKeys = null;
    java.util.Map validationKeys = null;

    PublicKey tempPublicKey = null;
    PrivateKey tempPrivateKey = null;
    byte[] tempSharedKey = null;

    keySetGroupName = "ApplicationKeySetGroup";
    com.ibm.websphere.crypto.KeySetHelper ksh = com.ibm.websphere.crypto.KeySetHelper.getInstance();
    generationKeys = ksh.getLatestKeysForKeySetGroup(keySetGroupName);

    /**
     * Latest keys: {
     *   KeyPair_3=com.ibm.websphere.crypto.KeyPair@64ec64ec,
     *   Secret_3=javax.crypto.spec.SecretKeySpec@fffe8aa7
     * }
     */

    if (generationKeys != null)
    {
        Iterator iKeySet = generationKeys.keySet().iterator();

        while (iKeySet.hasNext())
        {
            String keyAlias = (String)iKeySet.next();

            Object key = generationKeys.get(keyAlias);

            if (key instanceof java.security.Key)
            {
                tempSharedKey = ((java.security.Key)key).getEncoded();
            }
            else if (key instanceof com.ibm.websphere.crypto.KeyPair)
            {
                java.security.Key publicKeyAsSecret =
                ((com.ibm.websphere.crypto.KeyPair)key).getPublicKey();
            }
        }
    }
}
```

```

        tempPublicKey = new PublicKey(publicKeyAsSecret.getEncoded());
        java.security.Key privateKeyAsSecret =
((com.ibm.websphere.crypto.KeyPair)key).getPrivateKey();
        tempPrivateKey = new PrivateKey(privateKeyAsSecret.getEncoded());
    }
}

// save these for use later, if necessary
validationKeys = ksh.getAllKeysForKeySetGroup(keySetGroupName);

/**
 * All keys: {
 * version_1=
 * {Secret_1=javax.crypto.spec.SecretKeySpec@178cf,
 * KeyPair_1=com.ibm.websphere.crypto.KeyPair@1c121c12},
 * version_2=
 * {Secret_2=javax.crypto.spec.SecretKeySpec@17a77,
 * KeyPair_2=com.ibm.websphere.crypto.KeyPair@182e182e},
 * version_3=
 * {Secret_3=javax.crypto.spec.SecretKeySpec@fffe8aa7,
 * KeyPair_3=com.ibm.websphere.crypto.KeyPair@4da04da0}
 * }
 ***/
}
else
{
    throw new com.ibm.websphere.crypto.KeyException("Could not generateKeys.");
}
}
}

```

Example: Developing a key or key pair generation class for automated key generation

A class that generates keys for cryptographic operations can be created automatically. With this capability, the key management infrastructure can maintain a list of keys for a predefined key set, and applications can access these keys.

You can schedule new key generation at predefined frequencies. Remember that key generation frequency affects the security of your data. For example, for persistent data, you might schedule key generation less frequently than for real time communications, which require that the keys be generated more often as old keys expire.

When you develop a key generation class, decide if you are creating a shared key or a key pair because this decision determines the interface you must use.

If you are developing shared keys, refer to the following example, which uses the KeyGenerator class to implement the com.ibm.websphere.crypto.KeyGenerator interface. The interface returns a java.security.Key key, which is stored as a SecretKey in a JCEKS keystore type. You can use any other keystore type that supports storing secret keys.

```

package com.ibm.test;

import java.util.*;
import com.ibm.ws.ssl.core.*;
import com.ibm.ws.ssl.config.*;
import com.ibm.websphere.crypto.KeyException;

public class KeyGenerator implements com.ibm.websphere.crypto.KeyGenerator
{
    private java.util.Properties customProperties = null;
    private java.security.Key secretKey = null;

    public KeyGenerator()
    {
    }
}

```

```

/**
 * <p>
 * This method is called to pass any custom properties configured with
 * the KeySet to the implementation of this interface.
 * </p>
 *
 * @param java.util.Properties
 */
public void init (java.util.Properties customProps)
{
    customProperties = customProps;
}

/**
 * <p>
 * This method is called whenever a key needs to be generated either
 * from the schedule or manually requested. The key is stored in the
 * KeyStore referenced by the configured KeySet that contains the
 * keyGenerationClass implementing this interface. The implementation of
 * this interface manages the key type. The user of the KeySet
 * must know the type that is returned by this keyGenerationClass.
 * </p>
 *
 * @return java.security.Key
 * @throws com.ibm.websphere.crypto.KeyException
 */
public java.security.Key generateKey () throws KeyException
{
    try
    {
        // Assume generate3DESKey is there to create the key.
        byte[] tripleDESKey = generate3DESKey();
        secretKey = new javax.crypto.spec.SecretKeySpec(tripleDESKey, 0, 24, "3DES");

        if (secretKey != null)
        {
            return secretKey;
        }
        else
        {
            throw new com.ibm.websphere.crypto.KeyException ("Key could not be generated.");
        }
    }
    catch (Exception e)
    {
        e.printStackTrace(); // handle exception
    }
}
}

```

If you are developing a key pair, refer to the following example, which uses the KeyPairGenerator class to implement the com.ibm.websphere.crypto.KeyPairGenerator interface.

```

package com.ibm.test;

import java.util.*;
import javax.crypto.spec.SecretKeySpec;
import com.ibm.websphere.crypto.KeyException;

/**
 * <p>
 * This implementation defines the method to generate a java.security.KeyPair.
 * When a keyGeneration class implements this method, the generateKeyPair method
 * is called and a KeyPair is stored in the keystore. The isKeyPair
 * attribute is ignored since the KeyGenerationClass is an
 * implementation of KeyPairGenerator. The isKeyPair attributes is for when
 * the keys already exist in a KeyStore, and are just read (not
 * generating them).
 * </p>
 * @author IBM Corporation

```

```

* @version WebSphere Application Server 6.1
* @since WebSphere Application Server 6.1
**/
public class KeyPairGenerator implements com.ibm.websphere.crypto.KeyPairGenerator
{
    private java.util.Properties customProperties = null;

    public KeyPairGenerator()
    {
    }

    /**
     * <p>
     * This method is called to pass any custom properties configured with
     * the KeySet to the implementation of this interface.
     * </p>
     *
     * @param java.util.Properties
     **/
    public void init (java.util.Properties customProps)
    {
        customProperties = customProps;
    }

    /**
     * <p>
     * This method is called whenever a key needs to be generated either
     * from the schedule or manually requested and isKeyPair=true in the KeySet
     * configuration. The key is stored in the KeyStore referenced by
     * the configured KeySet which contains the keyGenerationClass implementing
     * this interface. The implementation of this interface manages the
     * type of the key. The user of the KeySet must know the type that
     * is returned by this keyGenerationClass.
     * </p>
     *
     * @return com.ibm.websphere.crypto.KeyPair
     * @throws com.ibm.websphere.crypto.KeyException
     **/
    public com.ibm.websphere.crypto.KeyPair generateKeyPair () throws KeyException
    {
        try
        {
            java.security.KeyPair keyPair = generateKeyPair();

            // Store as SecretKeySpec
            if (keyPair != null)
            {
                java.security.PrivateKey privKey = keyPair.getPrivate();
                java.security.PublicKey pubKey = keyPair.getPublic();

                SecretKeySpec publicKeyAsSecretKey = new SecretKeySpec
                    (pubKey.getEncoded(), "RSA_PUBLIC");
                SecretKeySpec privateKeyAsSecretKey = new SecretKeySpec
                    (privKey.getEncoded(), "RSA_PRIVATE");

                com.ibm.websphere.crypto.KeyPair pair = new
com.ibm.websphere.crypto.KeyPair(publicKeyAsSecretKey, privateKeyAsSecretKey);
                return pair;
            }
            else
            {
                throw new com.ibm.websphere.crypto.KeyException ("Key pair could
not be generated.");
            }
        }
        catch (Exception e)
        {
            e.printStackTrace(); // handle exception
        }
    }
}

```

This interface returns a `com.ibm.websphere.crypto.KeyPair` key pair, which can contain either a `X509Certificate` and `PrivateKey` object or `PublicKey` and `PrivateKey` objects. If the `com.ibm.websphere.crypto.KeyPair` interface contains a `X509Certificate` and `PrivateKey` object, the certificate and private key are stored in the keystore. Consequently, they can use any `KeyStore` type.

If the `com.ibm.websphere.crypto.KeyPair` interface contains `PublicKey` and `PrivateKey` objects, you must convert the encoded values to the `SecretKeySpec` object in order to store them. The WebSphere Application Server runtime stores and retrieves the key pair as secret keys. The runtime converts the key pair back to `PublicKey` and `PrivateKey` objects when the server retrieves the pair during the handshake.

Use the following constructors to develop the `com.ibm.websphere.crypto.KeyPair` interface:

- Public and private constructor

```
public KeyPair(java.security.Key publicKey, java.security.Key privateKey)
```
- Certificate and private constructor.

```
public KeyPair(java.security.cert.Certificate[] certChain,
java.security.Key privateKey)
```

The previous example code shows the `KeyPairGenerator` class using the public and private constructor. Each call to this class generates a new and unique key pair, and this class is invoked by a `KeySet` to create a new key pair when `isKeyPair=true`. The version number in the key set increments each time it is called.

Key set groups collection

Use this page to manage groups of public, private, and shared keys. These key groups enable the application server to control multiple sets of Lightweight Third Party Authentication (LTPA) keys.

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > ssl_configuration** . Under Related items, click **Key set groups**.

Button	Resulting action
New	Adds a key set group. A key set group combines one or more key sets together as a single key set group. It allows the generation of multiple different types of keys to occur at the same time. A single key set represents one type of key, so a key set group allows you to group the different types.
Delete	Deletes an existing key set group. You must be sure that there are no other references to this key set group before you delete it.
Generate keys	Generates keys for key set group. The system generates keys for each key set within the key set group so that the keys remain synchronized with each other in terms of version. You must configure a valid key generation class and a key store that is writable. See the <code>com.ibm.websphere.crypto.KeySetHelper</code> application programming interfaces (APIs) to enable the use of keys that are managed by a <code>KeySetGroup</code> or <code>KeySet</code> .

Key set group name

Specifies the name of the key set group used to reference it.

Automatically generate keys

Specifies that the keys are to be generated automatically on a schedule.

Key set groups settings

Use this page to create new key set groups.

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > ssl_configuration** . Under Related items, click **Key set groups > New**.

Key set group name

Specifies the name of key set group used. This name can be referenced using the `com.ibm.websphere.crypto.KeySetHelper` API to retrieve the managed keys from an application.

Data type: Text

Key sets

Specifies a set of key instances of the same type for use in cryptographic operations.

Add

Specifies to add the selected key set part of this key set group.

Remove

Specifies to remove the selection from the **Key sets** list.

Automatically generate keys

Specifies that the keys are generated automatically on a schedule. When a new key is generated, the `security.xml` is updated and saved by the runtime to track the key reference version. This can cause save conflicts when updating the same file from admin applications.

Default: Disabled

Scheduled time for generation

Specifies the scheduled time when the system generates selected key set group or groups. You can specify the scheduled time in hours and minutes; specify either A.M. or P.M., or specify 24-hour. You can also specify the day of the week you want the scheduled event to occur. It is recommended that you set this event to occur during a low peak time, especially for keys that are used by runtime for token validation.

Data type: Integer
Default: 0, 0
Range: 1–12, 0–59

Generate on a specific day

Specifies whether to have the generation occur on a specific day of the week. It is best to auto-generate keys during a low peak day.

Default: Enabled

Weekday

Specifies the day of the week on which the expiration monitor will run if the Check on a specific day option is selected.

Default: Sunday
Range: Sunday, Monday, Tuesday, Wednesday, Thursday, Friday, Saturday

Repeat interval

Specifies the period of time between each schedule time to check for expired certificates or the interval between schedule checks.

Default: Daily
Range: Daily, Weekly

Generate at an interval

Specifies to generate keys at the specified frequency regardless of the day of the week on which generation occurs.

Default: Disabled

Next start date

Specifies the date for the next scheduled check. This allows the deployment manager to be stopped and restarted without resetting the date.

Chapter 8. Developing extensions to the WebSphere security infrastructure

WebSphere Application Server provides various plug points so that you can extend the security infrastructure.

The following topics are covered in this section:

- Developing custom user registries
- Developing applications that use programmatic security
- Customizing Web application login forms
- Customizing application login forms with Java Authentication and Authorization Service (JAAS)
- Securing transports with Java Secure Sockets Extension (JSSE) and Java Cryptography Extension (JCE) programming interfaces
- Implementing tokens for security attribute propagation

Developing standalone custom registries

This development provides considerable flexibility in adapting WebSphere Application Server security to various environments where some notion of a user registry, other than LDAP or Local OS, already exists in the operational environment.

WebSphere Application Server security supports the use of standalone custom registries in addition to the local operating system registry, standalone Lightweight Directory Access Protocol (LDAP) registries, and federated repositories for authentication and authorization purposes. A standalone custom-implemented registry uses the `UserRegistry` Java interface as provided by WebSphere Application Server. A standalone custom-implemented registry can support virtually any type or notion of an accounts repository from a relational database, flat file, and so on.

Implementing a standalone custom registry is a software development effort. Use the methods that are defined in the `UserRegistry` interface to make calls to the appropriate registry to obtain user and group information. The interface defines a general set of methods for encapsulating a wide variety of registries. You can configure a standalone custom registry as the selected repository when configuring WebSphere Application Server security on the Secure administration, applications, and infrastructure panel.

In WebSphere Application Server Version 6.1, make sure that your implementation of the standalone custom registry does not depend on any WebSphere Application Server components such as data sources, Enterprise JavaBeans (EJB) and Java Naming and Directory Interface (JNDI). You can not have this dependency because security is initialized and enabled prior to most of the other WebSphere Application Server components during startup. If your previous implementation used these components, make a change that eliminates the dependency. For example, if your previous implementation used data sources to connect to a database, use `DriverManager` to connect to the database.

Refer to the “Migrating custom user registries” on page 31 for more information on migrating. If your previous implementation uses data sources to connect to a database, change the implementation to use Java database connectivity (JDBC) connections. However, it is recommended that you use the new interface to implement your custom registry.

1. Implement all the methods in the interface except for the `CreateCredential` method, which is implemented by WebSphere Application Server. `FileRegistrySample.java` file is provided for reference.

Attention: The sample provided is intended to familiarize you with this feature. Do not use this sample in an actual production environment.

2. Build your implementation.

To compile your code, you need the `com.ibm.ws.runtime_6.1.0.jar` and the `com.ibm.ws.security.crypto_6.1.0` files in your class path. For example:

```
javac -extdirs app_server_rootBase/java/ext:/QIBM/UserData/Java400/ext:  
/QIBM/ProdData/Java400/jdk15/lib/ext:app_server_rootBase/lib  
-classpath app_server_rootBase/plugins/com.ibm.ws.runtime_6.1.0.jar:  
app_server_rootBase/plugins/com.ibm.ws.security.crypto_6.1.0  
/cryptosf.jar com/ibm/websphere/security/FileRegistrySample.java
```

3. Create a classes subdirectory in your instance for custom classes. For more information, see “Creating a classes subdirectory in your profile for custom classes.”

Create the classes subdirectory for each node in the cell.

4. Copy the class files that are generated in the previous step to the product class path.
The preferred location is the `app_server_root/classes` directory. For more information, see “Creating a classes subdirectory in your profile for custom classes.” Copy the class files to all the product process class paths including the cell, all of the node agents.
5. Follow the steps in “Configuring standalone custom registries” on page 111 to configure your implementation using the administrative console. This step is required to implement custom user registries.

If you enable security, make sure that you complete the remaining steps:

1. Save and synchronize the configuration and restart all of the servers.
2. Try accessing some J2EE resources to verify that the custom registry implementation is correct.

Creating a classes subdirectory in your profile for custom classes

You can create a classes subdirectory in the profile in which you can place your custom security components.

WebSphere Application Server resides in two main default directories:

app_server_root

Contains product Java archive (JAR) files, scripts, and the master copies of the administrative application, samples, and properties files. This directory is referred to by the `#{WAS_INSTALL_ROOT}` WebSphere Application Server variable. Do not modify files in these directories.

profile_root

Contains user profile data, that is a combination of unique files and symmetric links to files in the `app_server_root` directories. This directory is referred to by the `#{USER_INSTALL_ROOT}` WebSphere Application Server variable.

The product files are separated for the following reasons:

- To separate the files that run the product from files that you can modify, either by editing or through the administrative interfaces. When you apply product fixes, the separate directory structure keeps these fixes from overwriting user-defined data, such as modifying properties files.
- To isolate configuration differences between profiles. For example, each profile subdirectory can have its own copy of the Java 2 Security files, by which the profile can have a unique Java 2 Security configuration, rather than all profiles conforming to one product-wide configuration only.

WebSphere Application Server provides application programming interfaces (APIs) that you can use to develop your own security components for WebSphere Application Server. For example, you can create custom user registries, custom trust association interceptors, and custom login modules. For other WebSphere Application Server platforms, place the files for your custom security component in the `app_server_root/classes` directory.

For the i5/OS platform, this action is not recommended because the files are accessible from all server profiles, which might not be a desirable or secure behavior. Additionally, the classes directory is granted Java 2 Security AllPermissions authority, which might not be appropriate for your secured environment.

Therefore, create a `/classes` subdirectory in the profile in which you can place your custom security components. Additionally, the QEJBSVR user profile must have authority to the directory. To create the classes subdirectory and grant the necessary authorities, complete the following steps:

1. Use the **CRTDIR DIR** command to create the classes subdirectory. For example, run the following command from the CL command line:

```
CRTDIR DIR('profile_root/classes')
```

Alternatively, you can map or mount a workstation network drive to the iSeries server and create the `/classes` subdirectory from the workstation command prompt or a graphical file explorer utility such as Windows Explorer.

2. If you are using Java 2 Security, update your `profile_root/properties/server.policy` file to grant the appropriate Java 2 Security permissions to the classes in the directory. For more information about the permissions, see “server.policy file permissions” on page 544.
3. If you create the directory from the Qshell command line, explicitly grant the QEJBSVR user profile read, write, and run (*RWX) authority to the directory because the proper authorities are not inherited from the parent directory. For example, run the following command:

```
CHGAUT OBJ('profile_root/classes') USER(QEJBSVR) DTAAUT(*RWX)
```

The directory variable is the fully qualified path of your `profile_root/classes` subdirectory.

You have a classes subdirectory that you can use for custom classes.

Example: Standalone custom registries

Use these links to view registry examples.

A *standalone custom registry* is a customer-implemented registry that implements the UserRegistry Java interface, as provided by WebSphere Application Server. A custom-implemented registry can support virtually any type or form of an accounts repository from a relational database, flat file, and so on. The custom registry provides considerable flexibility in adapting WebSphere Application Server security to various environments where some form of a registry, other than a federated repository, Lightweight Directory Access Protocol (LDAP) registry, or local operating system registry, already exist in the operational environment.

To view a sample standalone custom registry, refer to the following files:

- FileRegistrySample.java file
- users.props file
- groups.props file

Result.java file

This module is used by user registries in WebSphere Application Server when calling the `getUsers` and `getGroups` methods. The user registries use this method to set the list of users and groups and to indicate if more users and groups in the user registry exist than requested.

        CustomRegistryException,
        RemoteException;
}

```

Implementing custom password encryption

WebSphere Application Server supports the use of custom password encryption.

An installation can implement any password encryption algorithm it chooses.

Complete the following steps to implement custom password encryption:

1. Build your custom password encryption class. An example of a custom password encryption class follows.

```

// CustomPasswordEncryption
// Encryption and decryption functions
public interface CustomPasswordEncryption {
    public EncryptedInfo encrypt(byte[] clearText) throws PasswordEncryptException;
    public byte[] decrypt(EncryptedInfo cipherTextInfo) throws PasswordEncryptException;
    public void initialize(HashMap initParameters);
};
// Encapsulation of cipher text and label
public class EncryptedInfo {
    public EncryptedInfo(byte[] bytes, String keyAlias);
    public byte[] getEncryptedBytes();
    public String getKeyAlias();
};

```

2. Enable custom password encryption.
 - a. Set the custom property **com.ibm.wsspi.security.crypto.customPasswordEncryptionClass** to the name of the class that is to be given control.
 - b. Enable the function. Set the custom property, **com.ibm.wsspi.security.crypto.customPasswordEncryptionEnabled** to true.

Custom password encryption at the installation is complete.

Developing applications that use programmatic security

For some applications, declarative security is not sufficient to express the security model of the application. Use this topic to develop applications that use programmatic security.

IBM WebSphere Application Server provides security components that provide or collaborate with other services to provide authentication, authorization, delegation, and data protection. WebSphere Application Server also supports the security features that are described in the Java 2 Platform, Enterprise Edition (J2EE) specification. An application goes through three stages before it is ready to run:

- Development
- Assembly
- Deployment

Most of the security for an application is configured during the assembly stage. The security that is configured during the assembly stage is called *declarative security* because the security is *declared* or

defined in the deployment descriptors. The declarative security is enforced by the security runtime. For some applications, declarative security is not sufficient to express the security model of the application. For these applications, you can use *programmatic security*.

1. Develop secure Web applications. For more information, see “Developing with programmatic security APIs for Web applications” on page 547.
2. Develop servlet filters for form login processing. For more information, see “Developing servlet filters for form login processing” on page 559.
3. Develop form login pages. For more information, see “Customizing Web application login” on page 555.
4. Develop enterprise bean component applications. For more information, see “Developing with programmatic APIs for EJB applications” on page 551.
5. Develop with Java Authentication and Authorization Service to log in programmatically. For more information, see “Developing programmatic logins with the Java Authentication and Authorization Service” on page 563.
6. Develop your own Java 2 security mapping module. For more information, see “Configuring programmatic logins for Java Authentication and Authorization Service” on page 567.
7. Develop custom user registries. For more information, see “Developing standalone custom registries” on page 515.
8. Develop a custom interceptor for trust associations.

Protecting system resources and APIs (Java 2 security)

Java 2 security is a programming model that is very pervasive and has a huge impact on application development.

Java 2 security is orthogonal to Java 2 Platform, Enterprise Edition (J2EE) role-based security; you can disable or enable it independently of administrative security.

However, it does provide an extra level of access control protection on top of the J2EE role-based authorization. It particularly addresses the protection of system resources and application programming interfaces (API). Administrators need to consider the benefits against the risks of disabling Java 2 security.

The following recommendations are provided to help enable Java 2 security in a test or production environment:

1. Make sure the application is developed with the Java 2 security programming model. Developers have to know whether or not the APIs that are used in the applications are protected by Java 2 security. It is very important that the required permissions for the APIs used are declared in the policy file (`was.policy`), or the application fails to run when Java 2 security is enabled. Developers can reference the Web site for Development Kit APIs that are protected by Java 2 security. See the Programming model and decisions section of the Security: Resources for learning topic to visit this Web site.
2. Make sure that migrated applications from previous releases are given the required permissions. Because Java 2 security is not supported or partially supported in previous WebSphere Application Server releases, applications developed prior to Version 5 most likely are not using the Java 2 security programming model. No easy way to find out all the required permissions for the application is available. The following are activities you can perform to determine the extra permissions that are required by an application:
 - Code review and code inspection
 - Application documentation review
 - Sandbox testing of migrated enterprise applications with Java 2 security enabled in a preproduction environment. Enable tracing in WebSphere Java 2 security manager to help determine the missing permissions in the application policy file. The trace specification is:
`com.ibm.ws.security.core.SecurityManager=all=enabled.`
 - Use the `com.ibm.websphere.java2secman.norethrow` system property to aid debugging. Do not use this property in a production environment..

Refer to “Java 2 security” on page 61

The default permission set for applications is the recommended permission set defined in the J2EE 1.3 Specification. The default is declared in the *profile_root/config/cells/cell_name/nodes/node_name/app.policy* policy file with permissions defined in the Development Kit policy file that grants permissions to everyone. The *java.policy* file is located in the */QIBM/ProdData/Java400/jdk15/lib/security/* directory, which is used system-wide. Do not edit the *java.policy* file on the server. Applications are denied permissions that are declared in the *profile_root/config/cells/cell_name/filter.policy* file. Permissions declared in the *filter.policy* file are filtered for applications during the permission check.

Define the required permissions for an application in a *was.policy* file and embed the *was.policy* file in the application enterprise archive (EAR) file as *YOURAPP.ear/META-INF/was.policy*, see “Configuring Java 2 security policy files” on page 529 for details.

The following steps describe how to enforce Java 2 security on the cell level for WebSphere Application Server Network Deployment and the server level for WebSphere Application Server and WebSphere Application Server Express:

1. Click **Security > Secure administration, applications, and infrastructure**. The Secure administration, applications, and infrastructure panel is displayed.
2. Select the **Use Java 2 security to restrict application access to local resources** option.
3. Click **OK** or **Apply**.
4. Click **Save** to save the changes.
5. Restart the server for the changes to take effect.

Java 2 security is enabled and enforced for the servers. Java 2 security permission is selected when a Java 2 security protected API is called.

When to use Java 2 security

1. Enable protection on system resources, for example when opening or listening to a socket connection, reading or writing to operating system file systems, reading or writing Java virtual machine system properties, and so on.
2. Prevent application code from calling destructive APIs, for example, calling the `System.exit` method brings down the application server.
3. Prevent application code from obtaining privileged information (passwords) or gaining extra privileges (obtaining server credentials).

You can enforce Java 2 security on the server level for WebSphere Application Server Network Deployment by completing the following steps.

Note: Changes to Java 2 security settings on the server level override the settings on the cell level.

1. Click **Servers > Application servers > server_name**.
2. Under Security, click **Server security**.
3. Select the **Security settings for this server override cell settings** option.
4. Select the **Use Java 2 security to restrict application access to local resources** option.
5. Click **OK** or **Apply**.
6. Click **Save** to save the changes.
7. Restart the server for the changes to take effect.

The Java 2 security manager is enhanced to dump the Java 2 security permissions that are granted to all classes on the call stack when an application is denied access to a resource. The `java.security.AccessControlException` exception is created. However, this tracing capability is disabled by default. You can enable this capability by specifying the server trace service with the `com.ibm.ws.security.core.SecurityManager=all=enabled` trace specification. When the exception is

created, the trace dump provides hints to determine whether the application is missing permissions or the product runtime code or the third-party libraries that are used are not properly marked as privileged when accessing Java 2 security-protected resources. See the Security Problem Determination Guide for details.

Using PolicyTool to edit policy files

Use the **PolicyTool** utility to update policy files.

Java 2 security uses several policy files to determine the granted permission for each Java program. The Java Development Kit provides the **PolicyTool** tool to edit these policy files. This tool is recommended for editing any policy file to verify the syntax of its contents. Syntax errors in the policy file cause an `AccessControlException` exception when the application runs, including the server start. Identifying the cause of this exception is not easy because the user might not be familiar with the resource that has an access violation. Be careful when you edit these policy files.

See “Java 2 security policy files” on page 66 for the list of available policy files.

You must install either the client or plug-ins component of WebSphere Application Server on a workstation in order to access the **PolicyTool**. It is not currently supported on the iSeries server.

1. Map a drive to the operating system to navigate the directory tree to the policy file.
2. Start the **PolicyTool**.
Click **OK**.
3. Click **File > Open**.
4. Navigate the directory tree in the **Open** window to pick up the policy file that you need to update. After selecting the policy file, click **Open**. The code base entries are listed in the window.
5. Create or modify the code base entry.
 - a. Modify the existing code base entry by double-clicking the code base, or click the code base and click **Edit Policy Entry**. The Policy Entry window opens with the permission list defined for the selected code base.
 - b. Create a new code base entry by clicking **Add Policy Entry**.
The Policy Entry window opens. At the code base column, enter the code base information as a URL format.
For example, you can enter:
`profile_root/InstalledApps/testcase.ear`
6. Modify or add the permission specification.
 - a. Modify the permission specification by double-clicking the entry that you want to modify, or by selecting the permission and clicking **Edit Permission**. The Permissions window opens with the selected permission information.
 - b. Add a new permission by clicking **Add Permission**. The Permissions window opens. In the Permissions window are four rows for Permission, Target Name, Actions, and Signed By.
7. Select the permission from the Permission list. The selected permission displays. After a permission is selected, the Target Name, Actions, and Signed By fields automatically show the valid choices or they enable text input in the right text input area.
 - a. Select **Target Name** from the list, or enter the target name in the right text input area.
 - b. Select **Actions** from the list.
 - c. Input **Signed By** if it is needed.

Important: The Signed By keyword is not supported in the following policy files: `app.policy`, `spi.policy`, `library.policy`, `was.policy`, and `filter.policy` files. However, the Signed By keyword is supported in the following policy files: `#java.policy`, `server.policy`, and `client.policy` files. The Java Authentication and Authorization Service (JAAS) is not supported in the `app.policy`, `spi.policy`, `library.policy`, `was.policy`, and `filter.policy` files. However, the JAAS principal keyword is

supported in a JAAS policy file when it is specified by the `java.security.auth.policy` Java virtual machine (JVM) system property.

- Click **OK** to close the Permissions window. Modified permission entries of the specified code base display.
- Click **Done** to close the window. Modified code base entries are listed. Repeat the previous steps until you complete editing.
- Click **File > Save** after you finish editing the file.

A policy file is updated. If any policy files need editing, use the **PolicyTool** utility. Do not edit the policy file manually. Syntax errors in the policy files can potentially cause application servers or enterprise applications to not start or function incorrectly. For the changes in the updated policy file to take effect, restart the Java processes.

Configuring Java 2 security policy files

Use can configure Java 2 security policy files so that the required permission is granted for the specified WebSphere Application Server enterprise application.

Java 2 security uses several policy files to determine the permissions for each Java programs.

See the “Java 2 security policy files” on page 66 topic for the list of available policy files that are supported by WebSphere Application Server.

Two types of policy files are supported by WebSphere Application Server: dynamic policy files and static policy files. Static policy files provide the default permissions. Dynamic policy files provide application permissions. Six dynamic policy files are provided:

Policy file name	Description
<code>app.policy</code>	Contains default permissions for all of the enterprise applications in the cell.
<code>was.policy</code>	Contains application-specific permissions for an WebSphere Application Server enterprise application. This file is packaged in an enterprise archive (EAR) file.
<code>ra.xml</code>	Contains connector application specific permissions for a WebSphere Application Server enterprise application. This file is packaged in a resource adapter archive (RAR) file.
<code>spi.policy</code>	Contains permissions for Service Provider Interface (SPI) or third-party resources that are embedded in WebSphere Application Server. The default contents grant everything. Update this file carefully when the cell requires more protection against SPI in the cell. This file is applied to all of the SPIs that are defined in the <code>resources.xml</code> file.
<code>library.policy</code>	Contains permissions for the shared library of enterprise applications.
<code>filter.policy</code>	Contains the list of permissions that require filtering from the <code>was.policy</code> file and the <code>app.policy</code> file in the cell. This filtering mechanism only applies to the <code>was.policy</code> and <code>app.policy</code> files.

In WebSphere Application Server, applications must have the appropriate thread permissions specified in the `was.policy` or `app.policy` file. Without the thread permissions specified, the application cannot manipulate threads and WebSphere Application Server creates a `java.security.AccessControlException` exception. The `app.policy` file applies to a specified node. If you change the permissions in one `app.policy` file, you must incorporate the new thread policy in the same file on the remaining nodes. Also, if you add the thread permissions to the `app.policy` file, you must restart WebSphere Application Server to enforce the new permissions. However, if you add the permissions to the `was.policy` file for a specific application, you do not need to restart WebSphere Application Server. An administrator must add the following code to a `was.policy` or `app.policy` file for an application to manipulate threads:

```
grant codeBase "file:${application}" {
permission java.lang.RuntimePermission "stopThread";
permission java.lang.RuntimePermission "modifyThread";
permission java.lang.RuntimePermission "modifyThreadGroup";
};
```

Important: The Signed By keyword is not supported in the following policy files: `app.policy`, `spi.policy`, `library.policy`, `was.policy`, and `filter.policy` files. However, the Signed By keyword is supported in the following policy files: `java.policy`, `server.policy`, and `client.policy` files. The Java Authentication and Authorization Service (JAAS) is not supported in the `app.policy`, `spi.policy`, `library.policy`, `was.policy`, and `filter.policy` files. However, the JAAS principal keyword is supported in a JAAS policy file when it is specified by the `java.security.auth.policy` Java virtual machine (JVM) system property. You can statically set the authorization policy files in `java.security.auth.policy` with `auth.policy.url.n=URL`, where `URL` is the location of the authorization policy.

1. Identify the policy file to update.
 - If the permission is required by an application, update the static policy file. Refer to “Configuring static policy files” on page 542.
 - If the permission is required by all of the WebSphere Application Server enterprise applications in the node, refer to “spi.policy file permissions” on page 538.
 - If the permission is required only by specific WebSphere Application Server enterprise applications and the permission is required only by connector, update the `ra.xml` file. Refer to Assembling resource adapter (connector) modules. Otherwise, update the `was.policy` file. Refer to “Configuring the was.policy file” on page 535 and “Adding the was.policy file to applications” on page 540.
 - If the permission is required by shared libraries, refer to “library.policy file permissions” on page 539.
 - If the permission is required by SPI libraries, refer to “spi.policy file permissions” on page 538.

Tip: Pick up the policy file with the smallest scope. You can avoid giving an extra permission to the Java programs and protect the resources. You can update the `ra.xml` file or the `was.policy` file rather than the `app.policy` file. Use specific component symbols (`$(ejbcomponent)`, `$(webComponent)`, `$(connectorComponent)` and `$(jars)`) than `$(application)` symbols. Update dynamic policy files, rather than static policy files.

Add any permission that you never want granted to the WebSphere Application Server enterprise application in the cell to the `filter.policy` file. Refer to “filter.policy file permissions” on page 533.

2. Restart the WebSphere Application Server enterprise application.

The required permission is granted for the specified WebSphere Application Server enterprise application.

If an WebSphere Application Server enterprise application in a cell requires permissions, some of the dynamic policy files need updating. The symptom of the missing permission is the `java.security.AccessControlException` exception. The missing permission is listed in the exception data.

```
java.security.AccessControlException: access denied (java.io.FilePermission
app_server_root/java/ext/mail.jar read)
```

The previous two lines were split onto two lines because of the width of the page. Enter the permission on one line.

When a Java program receives this exception and adding this permission is justified, add a permission to an adequate dynamic policy file.

```
grant codeBase "file:user_client_installed_location" {
permission java.io.FilePermission
"app_server_root/java/ext/mail.jar", "read";
};
```

The previous permission information lines were split onto more than one line because of their length. Enter the permission on one line.

To decide whether to add a permission, refer to the “Access control exception” on page 70 topic.

app.policy file permissions:

Java 2 security uses several policy files to determine the granted permissions for each Java program.

For the list of available policy files that are supported by WebSphere Application Server, see the “Java 2 security policy files” on page 66 article The `app.policy` file is a default policy file that is shared by all of the WebSphere Application Server enterprise applications. The union of the permissions that are contained in the following files is applied to the WebSphere Application Server enterprise application:

- Any policy file that is specified in the `policy.url.*` properties in the `java.security` file.
- The `app.policy` files, which are managed by configuration and file replication services.
- The `server.policy` file.
- The `java.policy` file.
- The application `was.policy` file.
- The permission specification of the `ra.xml` file.
- The shared library, which is the `library.policy` file.

Changes made in these files are replicated to other nodes in the Network Deployment cell.

In WebSphere Application Server, applications that manipulate threads must have the appropriate thread permissions specified in the `was.policy` or `app.policy` file. Without the thread permissions specified, the application cannot manipulate threads and WebSphere Application Server creates a `java.security.AccessControlException` exception. If an administrator adds thread permissions to the `app.policy` file, the permission change requires a restart of the WebSphere Application Server. An administrator must add the following code to a `was.policy` or `app.policy` file for an application to manipulate threads:

```
grant codeBase "file:${application}" {
permission java.lang.RuntimePermission "stopThread";
permission java.lang.RuntimePermission "modifyThread";
permission java.lang.RuntimePermission "modifyThreadGroup";
};
```

Important: The Signed By and the Java Authentication and Authorization Service (JAAS) principal keywords are not supported in the `app.policy` file. However, the Signed By keyword is supported in the following files: `java.policy`, `server.policy`, and the `client.policy` files. The JAAS principal keyword is supported in a JAAS policy file when it is specified by the `java.security.auth.policy` Java virtual machine (JVM) system property. You can statically set the authorization policy files in the `java.security.auth.policy` property with `auth.policy.url.n=URL` where `URL` is the location of the authorization policy.

If the default permissions for enterprise applications (the union of the permissions that is defined in the `java.policy` file, the `server.policy` file and the `app.policy` file) are enough; no action is required. The default `app.policy` file is used automatically. If a specific change is required to all of the enterprise applications in the cell, update the `app.policy` file. Syntax errors in the policy files cause start failures in the application servers. Edit these policy files carefully.

To extract the policy file, use a command prompt to enter the following command on one line using the appropriate variable values for your environment:

```
wsadmin> set obj [$AdminConfig extract profiles/profile_name/cells/cell_name/node/
node_name/app.policy /temp/test/library.policy]
```

Edit the extracted `app.policy` file with the Policy Tool. For more information, see “Using PolicyTool to edit policy files” on page 528. Changes to the `app.policy` file are local for the node.

To check in the policy file, use a command prompt to enter the following command on one line using the appropriate variable values for your environment:

```
wsadmin> $AdminConfig checkin profiles/profile_name/cells/cell_name/nodes/node_name/app.policy temp/test/library.policy $obj
```

Several product-reserved symbols are defined to associate the permission lists to a specific type of resource.

Symbol	Meaning
<code>file:\${application}</code>	Permissions apply to all resources within the application
<code>file:\${jars}</code>	Permissions apply to all utility Java archive (JAR) files within the application
<code>file:\${ejbComponent}</code>	Permissions apply to enterprise bean resources within the application
<code>file:\${webComponent}</code>	Permissions apply to Web resources within the application
<code>file:\${connectorComponent}</code>	Permissions apply to connector resources both within the application and within standalone connector resources.

Five embedded symbols are provided to specify the path and name for the `java.io.FilePermission` permission. These symbols enable flexible permission specifications. The absolute file path is fixed after the installation of the application.

Symbol	Meaning
<code>\${app.installed.path}</code>	Path where the application is installed
<code>\${was.module.path}</code>	Path where the module is installed
<code>\${current.cell.name}</code>	Current cell name
<code>\${current.node.name}</code>	Current node name
<code>\${current.server.name}</code>	Current server name

Tip: You cannot use the `${was.module.path}` in the `${application}` entry.

The `app.policy` file supplied by WebSphere Application Server is located in the `profile_root/config/cells/cell_name/nodes/node_name/app.policy`, which contains the following default permissions:

Attention: In the following code sample, the first two lines that are related to `java.io.FilePermission` permission are split into two lines for illustrative purposes only.

```
grant codeBase "file:${application}" {
    // The following are required by Java mail
    permission java.io.FilePermission "${was.install.root}${/}lib${/}mail-impl.jar", "read";
    permission java.io.FilePermission "${was.install.root}${/}lib${/}activation-impl.jar", "read";
};

grant codeBase "file:${jars}" {
    permission java.net.SocketPermission "*", "connect";
    permission java.util.PropertyPermission "*", "read";
};

grant codeBase "file:${connectorComponent}" {
    permission java.net.SocketPermission "*", "connect";
    permission java.util.PropertyPermission "*", "read";
};

grant codeBase "file:${webComponent}" {
```

```

permission java.io.FilePermission "${was.module.path}${/}-", "read, write";
permission java.lang.RuntimePermission "loadLibrary.*";
permission java.lang.RuntimePermission "queuePrintJob";
permission java.net.SocketPermission "*", "connect";
permission java.util.PropertyPermission "*", "read";
};

grant codeBase "file:${ejbComponent}" {
    permission java.lang.RuntimePermission "queuePrintJob";
    permission java.net.SocketPermission "*", "connect";
    permission java.util.PropertyPermission "*", "read";
};

```

If all of the WebSphere Application Server enterprise applications in a cell require permissions that are not defined as defaults in the `java.policy` file, the `server.policy` file and the `app.policy` file, then update the `app.policy` file. The symptom of a missing permission is the exception, `java.security.AccessControlException`. The missing permission is listed in the exception data, for example, `java.security.AccessControlException: access denied (java.io.FilePermission app_server_rootBase/lib/mailimpl.jar read)`.

When a Java program receives this exception and adding this permission is justified, add a permission to the `server.policy` file, for example:

```

grant codeBase "file:user_client_installed_location" {
    permission java.io.FilePermission
    "app_server_rootBase/lib/mail-impl.jar", "read"; };

```

To decide whether to add a permission, refer to the `AccessControlException` topic.

Restart all WebSphere Application Server enterprise applications to ensure that the updated `app.policy` file takes effect.

filter.policy file permissions:

Java 2 security uses several policy files to determine the granted permission for each Java program. Java 2 security policy filtering is only in effect when Java 2 security is enabled.

Before modifying the `filter.policy` file, you must start the `wsadmin` tool. See the `Starting the wsadmin scripting client` article for more information.

Refer to “Protecting system resources and APIs (Java 2 security)” on page 526. The filtering policy defined in the `filter.policy` file is cell wide. The `filter.policy` file is the only policy file that is used when restricting the permission instead of granting permission. The permissions that are listed in the filter policy file are filtered out from the `app.policy` file and the `was.policy` file. Permissions that are defined in the other policy files are not affected by the `filter.policy` file.

When a permission is filtered out, an audit message is logged. However, if the permissions that are defined in the `app.policy` file and the `was.policy` file are compound permissions like the `java.security.AllPermission` permission, for example, the permission is not removed. A warning message is logged. If the `Issue Permission Warning` flag is enabled (default) and if the `app.policy` file and the `was.policy` file contain custom permissions (non-Java API permission, the permission package name begins with characters other than `java` or `javax`), a warning message is logged and the permission is not removed. You can change the value of the **Warn if applications are granted custom permissions** option on the `Secure administration, applications, and infrastructure` panel. It is not recommended that you use the `AllPermission` permission for the enterprise application.

Some default permissions that are defined in the `filter.policy` file. These permissions are the minimal ones that are recommended by the product. If more permissions are added to the `filter.policy` file, certain operations can fail for enterprise applications. Add permissions to the `filter.policy` file carefully.

You cannot use the Policy Tool to edit the `filter.policy` file. Editing must be completed in a text editor. Be careful and verify that no syntax errors exist in the `filter.policy` file. If any syntax errors exist in the `filter.policy` file, the file is not loaded by the product security runtime, which implies that filtering is disabled.

To extract the `filter.policy` file, enter the following command using information from your environment:

```
set obj [$AdminConfig extract cells/cell_name/filter.policy /temp/test/filter.policy]
```

To check in the policy file, enter the following command using information from your environment:

```
$AdminConfig checkin cells/cell_name/filter.policy /temp/test/filter.policy $obj
```

An updated `filter.policy` file is applied to all of the WebSphere Application Server enterprise applications after the servers are restarted. The `filter.policy` file is managed by configuration and file replication services.

Changes made in the file are replicated to other nodes in the cell.

The `filter.policy` file supplied by WebSphere Application Server resides at: `profile_root/config/cells/cell_name/filter.policy`.

This fill contains these permissions as defaults:

```
filterMask {
permission java.lang.RuntimePermission "exitVM";
permission java.lang.RuntimePermission "setSecurityManager";
permission java.security.SecurityPermission "setPolicy";
permission javax.security.auth.AuthPermission "setLoginConfiguration"; };
runtimeFilterMask {
permission java.lang.RuntimePermission "exitVM";
permission java.lang.RuntimePermission "setSecurityManager";
permission java.security.SecurityPermission "setPolicy";
permission javax.security.auth.AuthPermission "setLoginConfiguration"; };
```

The permissions that are defined in `filterMask` filter are for static policy filtering. The security runtime tries to remove the permissions from applications during application startup. Compound permissions are not removed, but are issued with a warning, and application deployment is stopped if applications contain permissions that are defined in the `filterMask` filter, and if scripting is used. The `runtimeFilterMask` filter defines permissions that are used by the security runtime to deny access to those permissions to application thread. Do not add more permissions to the `runtimeFilterMask` filter. Application start failure or incorrect functioning might result. Be careful when adding more permissions to the `runtimeFilterMask` filter. Usually, you only need to add permissions to the `filterMask` stanza.

WebSphere Application Server relies on the filter policy file to restrict or disallow certain permissions that can compromise the integrity of the system. For instance, WebSphere Application Server considers the `exitVM` and `setSecurityManager` permissions as those permissions that most applications never have. If these permissions are granted, the following scenarios are possible:

exitVM

A servlet, JavaServer Pages (JSP) file, enterprise bean, or other library that is used by the aforementioned might call the `System.exit` API and cause the entire WebSphere Application Server process to terminate.

setSecurityManager

An application might install its own security manager and either grant more permissions or bypass the default policy that the WebSphere Application Server security manager enforces.

Important: In application code, do not use the `setSecurityManager` permission to set a security manager. When an application uses the `setSecurityManager` permission, a conflict exists with the internal security manager within WebSphere Application Server. If you must set a security manager in an application for Remote Method Invocation (RMI) purposes, you also must enable the **Enforce Java 2 Security** option on the Global security settings page within the WebSphere Application Server administrative console. WebSphere Application Server then registers a security manager, which the application code can verify is registered by using the `System.getSecurityManager` application programming interface (API).

Important: In application code, do not use the `setSecurityManager` permission to set a security manager. When an application uses the `setSecurityManager` permission, a conflict exists with the internal security manager within WebSphere Application Server. If you must set a security manager in an application for Remote Method Invocation (RMI) purposes, you also must enable the **Use Java 2 security to restrict application access to local resources** option on the Secure administration, applications, and infrastructure panel within the WebSphere Application Server administrative console. WebSphere Application Server then registers a security manager, which the application code can verify is registered by using the `System.getSecurityManager` application programming interface (API).

For the updated `filter.policy` file to take effect, restart related Java processes.

Configuring the `was.policy` file:

You should update the `was.policy` file if the application has specific resources to access.

Java 2 security uses several policy files to determine the granted permission for each Java program. The `was.policy` file is an application-specific policy file for WebSphere Application Server enterprise applications. This file is embedded in the `META-INF/was.policy` enterprise archive (.EAR) file. The `was.policy` file is located in:

```
profile_root/config/cells/cell_name/applications/  
ear_file_name/deployments/application_name/META-INF/was.policy
```

See “Java 2 security policy files” on page 66 for the list of available policy files that are supported by WebSphere Application Server Version 6.1.

The union of the permissions that are contained in the following files is applied to the WebSphere Application Server enterprise application:

- Any policy file that is specified in the `policy.url.*` properties in the `java.security` file.
- The `app.policy` files, which are managed by configuration and file replication services.
- The `server.policy` file.
- The `java.policy` file.
- The application `was.policy` file.
- The permission specification of the `ra.xml` file.
- The shared library, which is the `library.policy` file.

Changes made in these files are replicated to other nodes in the cell.

Several product-reserved symbols are defined to associate the permission lists to a specific type of resources.

Symbol	Definition
<code>file:\${application}</code>	<code>file:\${application}</code>
<code>file:\${jars}</code>	Permissions apply to all utility Java archive (JAR) files within the application

Symbol	Definition
file:\${ejbComponent}	Permissions apply to enterprise bean resources within the application
file:\${webComponent}	Permissions apply to Web resources within the application
file:\${connectorComponent}	Permissions apply to connector resources within the application

In WebSphere Application Server, applications that manipulate threads must have the appropriate thread permissions specified in the `was.policy` or `app.policy` file. Without the thread permissions specified, the application cannot manipulate threads and WebSphere Application Server creates a `java.security.AccessControlException` exception. If you add the permissions to the `was.policy` file for a specific application, you do not need to restart WebSphere Application Server. An administrator must add the following code to a `was.policy` or `app.policy` file for an application to manipulate threads:

```
grant codeBase "file:${application}" {
  permission java.lang.RuntimePermission "stopThread";
  permission java.lang.RuntimePermission "modifyThread";
  permission java.lang.RuntimePermission "modifyThreadGroup";
};
```

An administrator can add the thread permissions to the `app.policy` file, but the permission change requires a restart of WebSphere Application Server.

Important: The Signed By and the Java Authentication and Authorization Service (JAAS) principal keywords are not supported in the `was.policy` file. The Signed By keyword is supported in the `java.policy`, `server.policy`, and `client.policy` policy file. The JAAS principal keyword is supported in a JAAS policy file when it is specified by the `java.security.auth.policy` Java virtual machine (JVM) system property. You can statically set the authorization policy files in the `java.security.auth.policy` file with the `auth.policy.url.n=URL`, where `URL` is the location of the authorization policy.

Other than these blocks, you can specify the module name for granular settings. For example,

```
"file:DefaultWebApplication.war" {
  permission java.security.SecurityPermission "printIdentity";
};

grant codeBase "file:IncCMP11.jar" {
  permission java.io.FilePermission
    "${user.install.root}${/}bin${/}DefaultDB${/}-",
    "read,write,delete";
};
```

Five embedded symbols are provided to specify the path and name for the `java.io.FilePermission` permission. These symbols enable flexible permission specification. The absolute file path is fixed after the application is installed.

Symbol	Definition
<code>\${app.installed.path}</code>	Path where the application is installed
<code>\${was.module.path}</code>	Path where the module is installed
<code>\${current.cell.name}</code>	Current cell name
<code>\${current.node.name}</code>	Current node name
<code>\${current.server.name}</code>	Current server name

If the default permissions for the enterprise application are enough, an action is not required. The default permissions are a union of the permissions that are defined in the `java.policy` file, the `server.policy` file, and the `app.policy` file. If an application has specific resources to access, update the `was.policy` file. The first two steps assume that you are creating a new policy file.

Tip: Syntax errors in the policy files cause the application server to fail. Use care when editing these policy files.

1. Create or edit a new `was.policy` file by using the PolicyTool. For more information, see “Using PolicyTool to edit policy files” on page 528.
2. Package the `was.policy` file into the enterprise archive (EAR) file.
For more information, see “Adding the `was.policy` file to applications” on page 540. The following instructions describe how to import a `was.policy` file.
 - a. Import the EAR file into an assembly tool.
 - b. Open the Project Navigator view.
 - c. Expand the EAR file and click **META-INF**. You might find a `was.policy` file in the META-INF directory. If you want to delete the file, right-click the file name and select **Delete**.
 - d. At the bottom of the Project Navigator view, click **J2EE Hierarchy**.
 - e. Import the `was.policy` file by right-clicking the **Modules** directory within the deployment descriptor and by clicking **Import > Import > File system**.
 - f. Click **Next**.
 - g. Enter the path name to the `was.policy` file in the **From directory** field or click **Browse** to locate the file.
 - h. Verify that the path directory that is listed in the **Into directory** field lists the correct META-INF directory.
 - i. Click **Finish**.
 - j. To validate the EAR file, right-click the EAR file, which contains the Modules directory, and click **Run Validation**.
 - k. To save the new EAR file, right-click the EAR file, and click **Export > Export EAR file**. If you do not save the revised EAR file, the EAR file will contain the new `was.policy` file. However, if the workspace becomes corrupted, you might lose the revised EAR file.
 - l. To generate deployment code, right-click the EAR file and click **Generate Deployment Code**.
3. Update an existing installed application, if one already exists.
 - a. Modify the `was.policy` file with the Policy Tool. For more information, see “Using PolicyTool to edit policy files” on page 528.

The updated `was.policy` file is applied to the application after the application restarts.

```
java.policyserver.policyapp.policywas.policyjava.security.  
AccessControlExceptionjava.security.AccessControlException:  
access denied (java.io.FilePermission  
app_server_root/Base/java/jre/lib/ext/mail-impl.jar read)
```

The previous example was split onto several lines for illustrative purposes only.

When a Java program receives this exception and adding this permission is justified, add the following permission to the `was.policy` file:

```
grant codeBase "file:user_client_installed_location" {  
permission java.io.FilePermission  
"app_server_root/java/jre/lib/ext/mail-impl.jar", "read"; };
```

The previous example was split onto several lines for illustrative purposes only.

To determine whether to add a permission, see “Access control exception” on page 70.

Restart all applications for the updated `app.policy` file to take effect.

spi.policy file permissions:

Java 2 security uses several policy files to determine the granted permission for each Java program.

For the list of available policy files that are supported by WebSphere Application Server Version 6.0.x, see “Java 2 security policy files” on page 66.

Because the default permission for the Service Provider Interface (SPI) is the `AllPermission` permission, the only reason to update the `spi.policy` file is a restricted SPI permission. When a change in the `spi.policy` is required, complete the following steps.

Syntax errors in the policy files cause the application server to fail. Edit these policy files carefully.

Important: Do not place the `codebase` keyword or any other keyword after the `filterMask` and `runtimeFilterMask` keywords. The `Signed By` and the Java Authentication and Authorization Service (JAAS) `Principal` keywords are not supported in the `spi.policy` file. The `Signed By` keyword is supported in the `java.policy`, `server.policy`, and `client.policy` policy files. The JAAS `Principal` keyword is supported in a JAAS policy file that is specified by the `java.security.auth.policy` Java virtual machine (JVM) system property. You can statically set the authorization policy files in `java.security.auth.policy` with `auth.policy.url.n=URL`, where `URL` is the location of the authorization policy.

To extract the `filter.policy` file, enter the following command using information from your environment:

```
set obj [$AdminConfig extract profiles/profile_name/cells/cell_name/nodes/node_name/spi.policy  
/tmp/test/spi.policy]
```

Edit the file using the Policy Tool. For more information, see “Using PolicyTool to edit policy files” on page 528.

To check in the policy file, enter the following command using information from your environment:

```
$AdminConfig checkin profiles/profile_name/cells/cell_name/nodes/node_name/spi.policy  
/tmp/test/spi.policy $obj
```

The updated `spi.policy` is applied to the Service Provider Interface (SPI) libraries after the Java process is restarted.

Examples

The `spi.policy` file is the template for SPIs or third-party resources embedded in the product. Examples of SPIs are Java Message Services (JMS) (MQSeries) and Java database connectivity (JDBC) drivers. They are specified in the `resources.xml` file. The dynamic policy grants the permissions that are defined in the `spi.policy` file to the class paths defined in the `resources.xml` file. The union of the permission that is contained in the `java.policy` file and the `spi.policy` file are applied to the SPI libraries. The `spi.policy` files are managed by configuration and file replication services.

Changes made in these files are replicated to other nodes in the cell.

You can find the `spi.policy` file that is supplied by WebSphere Application Server in the following location: `profile_root/config/cells/cell_name/nodes/node_name/spi.policy`. It contains the following default permission:

```
grant {  
    permission java.security.AllPermission;  
};
```

Restart the related Java processes for the changes in the `spi.policy` file to become effective.

library.policy file permissions:

Java 2 security uses several policy files to determine the granted permission for each Java program.

For the list of available policy files that are supported by WebSphere Application Server, see “Java 2 security policy files” on page 66.

The `library.policy` file is the template for shared libraries (Java library classes). Multiple enterprise applications can define and use shared libraries. Refer to *Managing shared libraries* for information on how to define and manage the shared libraries.

If the default permissions for a shared library (union of the permissions defined in the `java.policy` file, the `app.policy` file and the `library.policy` file) are enough, no action is required. The default library policy is picked up automatically. If a specific change is required to share a library in the cell, update the `library.policy` file.

Syntax errors in the policy files cause the application server to fail. Edit these policy files carefully.

Important: Do not place the `codebase` keyword or any other keyword after the `grant` keyword. The `Signed By` keyword and the Java Authentication and Authorization Service (JAAS) `Principal` keyword are not supported in the `library.policy` file. The `Signed By` keyword is supported in the `java.policy`, the `server.policy`, and the `client.policy` policy files. The JAAS `Principal` keyword is supported in a JAAS policy file when it is specified by the Java virtual machine (JVM) system property, `java.security.auth.policy`. You can statically set the authorization policy files in the `java.security.auth.policy` file with `auth.policy.url.n=URL` where `URL` is the location of the authorization policy.

To extract the policy file, use a command prompt to enter the following command using the appropriate variable values for your environment:

```
wsadmin> set obj [$AdminConfig extract cells/cell_name/nodes/  
node_name/library.policy /temp/test/library.policy]
```

The previous two lines were split onto two lines for illustrative purposes only.

Edit the extracted `library.policy` file with the Policy Tool. For more information, see “Using PolicyTool to edit policy files” on page 528.

To check in the policy file, use a command prompt to enter the following command using the appropriate variable values for your environment:

```
wsadmin> $AdminConfig checkin cells/cell_name/nodes/node_name/library.policy  
temp/test/library.policy $obj
```

An updated `library.policy` is applied to shared libraries after the servers restart.

Example

The union of the permission that is contained in the `java.policy` file, the `app.policy` file, and the `library.policy` file are applied to the shared libraries. The `library.policy` file is managed by configuration and file replication services.

Changes made in the file are replicated to other nodes in the cell.

The `library.policy` file supplied by WebSphere Application Server resides in the `profile_root/config/cells/cell_name/nodes/node_name/` directory. The file contains an empty permission entry as a default. For example:

```
grant {  
};
```

If the shared library in a cell requires permissions that are not defined as defaults in the `java.policy` file, the `app.policy` file and the `library.policy` file, update the `library.policy` file. The missing permission causes the `java.security.AccessControlException` exception. The missing permission is listed in the exception data.

For example:

```
java.security.AccessControlException: access denied (java.io.FilePermission  
app_server_rootBase/lib/mail-impl.jar read)
```

The previous lines are split into two lines for illustrative purposes only.

When a Java program receives this exception and adding this permission is justified, add a permission to the `library.policy` file.

For example:

```
grant codeBase "file:user_client_installed_location" { permission  
java.io.FilePermission "app_server_rootBase/lib/mail-impl.jar", "read"; };
```

The previous lines are split into two lines for illustrative purposes only.

To decide whether to add a permission, refer to “Access control exception” on page 70.

Restart the related Java processes for the changes in the `library.policy` file to become effective.

Adding the was.policy file to applications:

An application might need a `was.policy` file if it accesses resources that require more permissions than those granted in the default `app.policy` file.

When Java 2 security is enabled for a WebSphere Application Server, all the applications that run on WebSphere Application Server undergo a security check before accessing system resources. An application might need a `was.policy` file if it accesses resources that require more permissions than those granted in the default `app.policy` file. By default, the product security reads an `app.policy` file that is located in each node and grants the permissions in the `app.policy` file to all the applications. Include any additional required permissions in the `was.policy` file. The `was.policy` file is only required if an application requires additional permissions.

The default policy file for all applications is specified in the `app.policy` file. This file is provided by the product security, is common to all applications, and you do not change this file. Add any new permissions that are required for an application in the `was.policy` file.

The app.policy file is located in the *profile_root/config/cells/cell_name/nodes/node_name* directory. The contents of the app.policy file are presented in the following example:

Attention: In the following code sample, the two permissions that are required by JavaMail are split onto two lines for illustrative purposes only.

```
// The following permissions apply to all the components under the application.
grant codeBase "file:${application}" {
    // The following are required by JavaMail
    permission java.io.FilePermission "
        ${was.install.root}${/}lib${/}mail-impl.jar","read";
    permission java.io.FilePermission "
        ${was.install.root}${/}lib${/}activation-impl.jar","read"; };
    // The following permissions apply to all utility .jar files (other
    // than enterprise beans JAR files) in the application.
grant codeBase "file:${jars}" {
    permission java.net.SocketPermission "*", "connect";
    permission java.util.PropertyPermission "*", "read";
};

// The following permissions apply to connector resources within the application
grant codeBase "file:${connectorComponent}" {
    permission java.net.SocketPermission "*", "connect";
    permission java.util.PropertyPermission "*", "read";
};

// The following permissions apply to all the Web modules (.war files)
// within the application.
grant codeBase "file:${webComponent}" {
    permission java.io.FilePermission "${was.module.path}${/}-", "read, write";
    // where "was.module.path" is the path where the Web module is
    // installed. Refer to Dynamic policy concepts for other symbols.
    permission java.lang.RuntimePermission "loadLibrary.*";
    permission java.lang.RuntimePermission "queuePrintJob";
    permission java.net.SocketPermission "*", "connect";
    permission java.util.PropertyPermission "*", "read";
};

// The following permissions apply to all the EJB modules within the application.
grant codeBase "file:${ejbComponent}" {
    permission java.lang.RuntimePermission "queuePrintJob";
    permission java.net.SocketPermission "*", "connect";
    permission java.util.PropertyPermission "*", "read";
};
```

If additional permissions are required for an application or for one or more modules of an application, use the was.policy file for that application. For example, use codeBase of `${application}` and add required permissions to grant additional permissions to the entire application. Similarly, use codeBase of `${webComponent}` and `{ejbComponent}` to grant additional permissions to all the Web modules and all the enterprise bean modules in the application. You can assign additional permissions to each module (.war file or .jar file), as shown in the following example.

The following example illustrates adding extra permissions for an application in the was.policy file:

Attention: In the following code sample, the permission for the EJB module was split onto two lines for illustrative purposes only.

```
// grant additional permissions to a Web module
grant codeBase " file:aWebModule.war" {
    permission java.security.SecurityPermission "printIdentity";
};

// grant additional permission to an EJB module
grant codeBase "file:aEJBModule.jar" {
    permission java.io.FilePermission "
```

```

    ${user.install.root}${/}bin${/}DefaultDB${/}-" .read.write.delete";
// where, ${user.install.root} is the system property whose value is
// located in the app_server_root directory.
};

```

To use a `was.policy` file for your application, perform the following steps:

1. Create a `was.policy` file using the policy tool. For more information on using the policy tool, see “Using PolicyTool to edit policy files” on page 528.
2. Add the required permissions in the `was.policy` file using the policy tool.
3. Place the `was.policy` file in the application enterprise archive (EAR) file under the META-INF directory. Update the application EAR file with the newly created `was.policy` file by using the `jar` command.
4. Verify that the `was.policy` file is inserted and start an assembly tool.

Note: An assembly tool is not available. Use an assembly tool on another platform such as Linux Intel or Windows.

5. Verify that the `was.policy` file in the application is syntactically correct. In an assembly tool, right-click the enterprise application module and click **Run Validation**.

An application EAR file is now ready to run when Java 2 security is enabled.

This step is required for applications to run properly when Java 2 security is enabled. If the `was.policy` file is not created and it does not contain required permissions, the application might not access system resources.

The symptom of the missing permissions is the `java.security.AccessControlException` exception. The missing permission is listed in the exception data, for example:

```

java.security.AccessControlException: access denied (java.io.FilePermission
app_server_root/lib/mail-impl.jar read)

```

The previous two lines are one continuous line for illustration purposes only.

When an application program receives this exception and adding this permission is justified, include the permission in the `was.policy` file, for example,

```

grant codeBase "file:${application}" {
    permission java.io.FilePermission
    "app_server_root/lib/mail-impl.jar", "read";
};

```

Lines are split in this example for illustration purposes only.

Install the application.

Configuring static policy files

By configuring the static policy files, the required permission will be granted for all of the Java programs.

Java 2 security uses several policy files to determine the granted permission for each Java program.

See the “Java 2 security policy files” on page 66 topic for the list of available policy files that are supported by WebSphere Application Server.

Two types of policy files are supported by WebSphere Application Server: dynamic policy files and static policy files. Static policy files provide the default permissions. Dynamic policy files provide application permissions.

Policy file name	Description
java.policy	Contains default permissions for all of the Java programs on the node. This file seldom changes.
server.policy	Contains default permissions for all of the WebSphere Application Server programs on the node. This file is rarely updated.
client.policy	Contains default permissions for all of the applets and client containers on the node.

The static policy file is not a configuration file that is managed by the repository and the file replication service. Changes to this file are local and do not get replicated to the other machine.

1. Identify the policy file to update.

- If the permission is required only by an application, update the dynamic policy file. Refer to “Configuring Java 2 security policy files” on page 529.
- If the permission is required only by applets and client containers, update the `client.policy` file. Refer to “client.policy file permissions” on page 545.
- If the permission is required only by WebSphere Application Server (servers, agents, managers and application servers), update the `server.policy` file. Refer to “server.policy file permissions” on page 544.
- If the permission is required by all of the Java programs running on the Java virtual machine (JVM), update the `java.policy` file. Refer to “java.policy file permissions.”

2. Stop and restart WebSphere Application Server.

The required permission is granted for all of the Java programs that run with the restarted JVM.

If Java programs on a node require permissions, the policy file needs updating. If the Java program that required the permission is not part of an enterprise application, update the static policy file. The missing permission results in the creation of the `java.security.AccessControlException` exception. The missing permission is listed in the exception data.

For example:

```
java.security.AccessControlException: access denied (java.io.FilePermission
app_server_root/Base/lib/mail-impl.jar read)
```

When a Java program receives this exception and adding this permission is justified, add a permission to an adequate policy file.

For example:

```
grant codeBase "file:user_client_installed_location" {
    permission java.io.FilePermission
        "app_server_root/Base/lib/mail-impl.jar",
        "read";
};
```

To decide whether to add a permission, refer to “Access control exception” on page 70.

java.policy file permissions:

Java 2 security uses several policy files to determine the granted permission for each Java program.

See “Java 2 security policy files” on page 66 for the list of available policy files that are supported by WebSphere Application Server.

The `java.policy` file is located in the `/QIBM/ProdData/Java400/jdk15/lib/security/` directory. Do not edit the file as it is used throughout the operating system.

server.policy file permissions:

Java 2 security uses several policy files to determine the granted permission for each Java program.

See “Java 2 security policy files” on page 66 for the list of available policy files that are supported by WebSphere Application Server.

The `server.policy` file is a default policy file that is shared by all of the WebSphere Application Servers on a node. The `server.policy` file is not a configuration file that is managed by the repository and the file replication service. Changes to this file are local and do not replicate to the other machine.

If the default permissions for a server (the union of the permissions that is defined in the `java.policy` file and the `server.policy` file) are enough, no action is required. The default server policy is picked up automatically. If a specific change is required to some of the server programs on a node, update the `server.policy` file with the Policy Tool. Refer to the “Using PolicyTool to edit policy files” on page 528 topic to edit policy files. Changes to the `server.policy` file are local for the node. Syntax errors in the policy files cause the application server to fail. Edit these policy files carefully. An updated `server.policy` file is applied to all the server programs on the local node. Restart the servers for the updates to take effect.

If you want to add permissions to an application, use the `app.policy` file and the `was.policy` file.

When you do need to modify the `server.policy` file, locate this file at: `install_root/properties/server.policy`. This file contains these default permissions:

```
// Allow to use ibm jdk extensions
grant codeBase "file:${was.install.root}/java/ext/-" {
    permission java.security.AllPermission;
};

// Allow to use ibm tools
grant codeBase "file:${was.install.root}/java/tools/ibmtools.jar" {
    permission java.security.AllPermission;
};

// Allow to use sun tools
grant codeBase "file:/QIBM/ProdData/Java400/jdk14/lib/tools.jar" {
    permission java.security.AllPermission;
};

// Allow to use sun tools (V5R2M0 codebase)
grant codeBase "file:/QIBM/ProdData/OS400/Java400/jdk/lib/tools.jar" {
    permission java.security.AllPermission;
};

// WebSphere system classes
grant codeBase "file:${was.install.root}/plugins/-" {
    permission java.security.AllPermission;
};
grant codeBase "file:${was.install.root}/lib/-" {
    permission java.security.AllPermission;
};
grant codeBase "file:${was.install.root}/classes/-" {
    permission java.security.AllPermission;
};

// Allow the WebSphere deploy tool all permissions
grant codeBase "file:${was.install.root}/deploytool/-" {
    permission java.security.AllPermission;
};

// Allow the WebSphere deploy tool all permissions
grant codeBase "file:${was.install.root}/optionalLibraries/-" {
    permission java.security.AllPermission;
};
```

```

};

// Allow Channel Framework classes all permission
grant codeBase "file:${was.install.root}/installedChannels/-" {
    permission java.security.AllPermission;
};

grant codeBase "file:${user.install.root}/lib/-" {
    permission java.security.AllPermission;
};

grant codeBase "file:${user.install.root}/classes/-" {
    permission java.security.AllPermission;
};

```

If some server programs on a node require permissions that are not defined as defaults in the `server.policy` file and the `server.policy` file, update the `server.policy` file. The missing permission creates the `java.security.AccessControlException` exception. The missing permission is listed in the exception data.

For example:

```

java.security.AccessControlException: access denied (java.io.FilePermission
app_server_rootBase/lib/mail-impl.jar read)

```

The previous two lines are split into two lines for illustrative purposes only.

When a Java program receives this exception and adding this permission is justified, add a permission to the `server.policy` file.

For example:

```

grant codeBase "file:user_client_installed_location" {
    permission java.io.FilePermission
"app_server_root/Base/lib/mail-impl.jar", "read"; };

```

To decide whether to add a permission, refer to “Access control exception” on page 70.

Restart all of the Java processes for the updated `server.policy` file to take effect.

client.policy file permissions:

Java 2 security uses several policy files to determine the granted permission for each Java program.

For the list of available policy files that are supported by WebSphere Application Server, see “Java 2 security policy files” on page 66.

- The `client.policy` file is a default policy file that is shared by all of the WebSphere Application Server client containers and applets on a node.
- The union of the permissions that is contained in the `java.policy` file and the `client.policy` file are given to all of the client containers for WebSphere Application Server and applets running on the node.
- The `client.policy` file is not a configuration file that is managed by the repository and the file replication service. Changes to this file are local and do not replicate to the other machine.
- The `client.policy` file supplied by WebSphere Application Server is located in the `profile_root/properties/client.policy`.
- If the default permissions for a client (union of the permissions defined in the `java.policy` file and the `client.policy` file) are enough, no action is required. The default client policy is picked up automatically.

- If a specific change is required to some of the client containers and applets on a node, modify the `client.policy` file with the Policy Tool. Refer to “Using PolicyTool to edit policy files” on page 528, to edit policy files. Changes to the `client.policy` file are local for the node.

This file contains these default permissions:

```
grant codeBase "file:${was.install.root}/java/ext/*" {
    permission java.security.AllPermission;
};

// JDK classes
grant codeBase "file:${was.install.root}/java/ext/-" {
    permission java.security.AllPermission;
};

// Allow to use sun and ibm tools
grant codeBase "file:${was.install.root}/java/tools/-" {
    permission java.security.AllPermission;
};

// WebSphere system classes
grant codeBase "file:${was.install.root}/lib/-" {
    permission java.security.AllPermission;
};
grant codeBase "file:${was.install.root}/plugins/-" {
    permission java.security.AllPermission;
};
grant codeBase "file:${was.install.root}/classes/-" {
    permission java.security.AllPermission;
};
grant codeBase "file:${was.install.root}/installedConnectors/-" {
    permission java.security.AllPermission;
};
grant codeBase "file:${user.install.root}/installedConnectors/-" {
    permission java.security.AllPermission;
};

grant codeBase "file:${was.install.root}/installedChannels/-" {
    permission java.security.AllPermission;
};

grant codeBase "file:${was.install.root}/util/-" {
    permission java.security.AllPermission;
};

grant codeBase "file:${user.install.root}/lib/-" {
    permission java.security.AllPermission;
};

grant codeBase "file:${user.install.root}/classes/-" {
    permission java.security.AllPermission;
};

// J2EE 1.4 permissions for client container WebSphere Application Server applications
// in $WAS_HOME/installedApps
grant codeBase "file:${user.install.root}/installedApps/-" {
    //Application client permissions
    permission java.awt.AWTPermission "accessClipboard";
    permission java.awt.AWTPermission "accessEventQueue";
    permission java.awt.AWTPermission "showWindowWithoutWarningBanner";
    permission java.lang.RuntimePermission "exitVM";
    permission java.lang.RuntimePermission "loadLibrary";
    permission java.lang.RuntimePermission "queuePrintJob";
    permission java.net.SocketPermission "*", "connect";
    permission java.net.SocketPermission "localhost:1024-", "accept,listen";
    permission java.io.FilePermission "*", "read,write";
    permission java.util.PropertyPermission "*", "read";
};
```

```

};

// J2EE 1.4 permissions for client container - expanded ear file code base
grant codeBase "file:${com.ibm.websphere.client.applicationclient.archivedir}/-" {
    permission java.awt.AWTPermission "accessClipboard";
    permission java.awt.AWTPermission "accessEventQueue";
    permission java.awt.AWTPermission "showWindowWithoutWarningBanner";
    permission java.lang.RuntimePermission "exitVM";
    permission java.lang.RuntimePermission "loadLibrary";
    permission java.lang.RuntimePermission "queuePrintJob";
    permission java.net.SocketPermission "*", "connect";
    permission java.net.SocketPermission "localhost:1024-", "accept,listen";
    permission java.io.FilePermission "*", "read,write";
    permission java.util.PropertyPermission "*", "read";
};

```

All of the client containers and applets on the local node are granted the updated permissions when they start. If some client containers or applets on a node require permissions that are not defined as defaults in the `java.policy` file and the default `client.policy` file, update the `client.policy` file. The missing permission creates the `java.security.AccessControlException` exception. The missing permission is listed in the exception data, for example,

```

java.security.AccessControlException: access denied (java.io.FilePermission
app_server_root/Base/lib/mail-impl.jar read)

```

The previous two lines of sample code are one continuous line, but presented as such for illustrative purposes only.

When a client program receives this exception and adding this permission is justified, add a permission to the `client.policy` file, for example, `grant codebase "file:user_client_installed_location" { permission java.io.FilePermission "app_server_root/Base/lib/mail-impl.jar", "read"; }`.

To decide whether to add a permission, refer to “Access control exception” on page 70.

If you update the policy file, you must restart the browser and any client applications.

Developing with programmatic security APIs for Web applications

Use this information to programmatically secure APIs for Web applications.

Programmatic security is used by security-aware applications when declarative security alone is not sufficient to express the security model of the application. Programmatic security consists of the following methods of the `HttpServletRequest` interface:

getRemoteUser

Returns the user name that the client used for authentication. Returns `null` if no user is authenticated.

isUserInRole

(String role name): Returns `true` if the remote user is granted the specified security role. If the remote user is not granted the specified role, or if no user is authenticated, it returns `false`.

getUserPrincipal

Returns the `java.security.Principal` object that contains the remote user name. If no user is authenticated, it returns `null`.

You can configure several options for Web authentication that determine how the Web client interacts with protected and unprotected Uniform Resource Identifiers (URI). Also, you can specify whether WebSphere Application Server challenges the Web client for basic authentication information if the certificate authentication for the HTTPS client fails. For more information, see “Authentication mechanisms” on page 170.

When the `isUserInRole` method is used, declare a `security-role-ref` element in the deployment descriptor with a `role-name` subelement containing the role name that is passed to this method. Because actual roles are created during the assembly stage of the application, you can use a logical role as the role name and provide enough hints to the assembler in the description of the `security-role-ref` element to link that role to the actual role. During assembly, the assembler creates a `role-link` subelement to link the role name to the actual role. Creation of a `security-role-ref` element is possible if an assembly tool such as Rational Application Developer (RAD) is used. You also can create the `security-role-ref` element during assembly stage using an assembly tool.

1. Add the required security methods in the servlet code.
2. Create a `security-role-ref` element with the **role-name** field. If a `security-role-ref` element is not created during development, make sure it is created during the assembly stage.

A programmatically secured servlet application.

This step is required to secure an application programmatically. This action is particularly useful when a Web application needs to access external resources and wants to control the access to external resources using its own authorization table (external-resource to remote-user mapping). In this case, use the `getUserPrincipal` or the `getRemoteUser` methods to get the remote user and then it can consult its own authorization table to perform authorization. The remote user information also can help retrieve the corresponding user information from an external source such as a database or from an enterprise bean. You can use the `isUserInRole` method in a similar way.

After development, a `security-role-ref` element can be created:

```
<security-role-ref>
  <description>Provide hints to assembler for linking this role
    name to an actual role here<\description>
  <role-name>Mgr<\role-name>
</security-role-ref>
```

During assembly, the assembler creates a `role-link` element:

```
<security-role-ref>
  <description>Hints provided by developer to map the role
    name to the role-link</description>
  <role-name>Mgr</role-name>
  <role-link>Manager</role-link>
</security-role-ref>
```

You can add programmatic servlet security methods inside any servlet `doGet`, `doPost`, `doPut`, and `doDelete` service methods. The following example depicts using a programmatic security API:

```
public void doGet(HttpServletRequest request,
  HttpServletResponse response) {

  ....

  // to get remote user using getUserPrincipal()
  java.security.Principal principal = request.getUserPrincipal();
  String remoteUser = principal.getName();

  // to get remote user using getRemoteUser()
  remoteUser = request.getRemoteUser();

  // to check if remote user is granted Mgr role
  boolean isMgr = request.isUserInRole("Mgr");

  // use the above information in any way as needed by
  // the application
  ....
}
```

After developing an application, use an assembly tool to create roles and to link the actual roles to role names in the security-role-ref elements. For more information, see “Securing Web applications using an assembly tool” on page 923.

getRemoteUser and getAuthType methods

The `getRemoteUser` and `getAuthType` methods are methods of the `javax.servlet.http.HttpServletRequest` interface. If the user has been authenticated, the `getRemoteUser` method returns the login of the user that makes the request. If the user is not authenticated, the `getRemoteUser` method returns null. The `getAuthType` method returns the name of the authentication scheme that is used to protect the servlet (for example, BASIC or SSL). If the servlet is not protected, the `getAuthType` method returns null.

For both methods, the data that is returned depends upon whether security is enabled in the application server where the servlet is deployed. The following possibilities exist:

- If security is not enabled, a servlet is requested and it is configured with Web server protection. The `getRemoteUser` method returns the login and `getAuthType` method returns the authentication scheme.
- If security is enabled and a servlet is requested, both methods return null when WebSphere Application Server protection is not configured for the servlet.
- If security is enabled, a servlet is requested, and the servlet is configured with WebSphere Application Server protection, then the `getRemoteUser` method returns the login and the `getAuthType` method returns the configured authentication scheme.

Attention: You can disable security at the application server level by overriding the administrative security setting. For more information, see “Securing specific application servers” on page 82.

Example: Web application code

The following example depicts a Web application or servlet using the programmatic security model.

This example illustrates one use and not necessarily the only use of the programmatic security model. The application can use the information that is returned by the `getUserPrincipal`, `isUserInRole`, and the `getRemoteUser` methods in any other way that is meaningful to that application. Using the declarative security model whenever possible is strongly recommended.

File : `HelloServlet.java`

```
public class HelloServlet extends javax.servlet.http.HttpServlet {

    public void doPost(
        javax.servlet.http.HttpServletRequest request,
        javax.servlet.http.HttpServletResponse response)
        throws javax.servlet.ServletException, java.io.IOException {
    }

    public void doGet(
        javax.servlet.http.HttpServletRequest request,
        javax.servlet.http.HttpServletResponse response)
        throws javax.servlet.ServletException, java.io.IOException {

        String s = "Hello";

        // get remote user using getUserPrincipal()
        java.security.Principal principal = request.getUserPrincipal();
        String remoteUserName = "";
        if( principal != null )
            remoteUserName = principal.getName();
        // get remote user using getRemoteUser()
        String remoteUser = request.getRemoteUser();

        // check if remote user is granted Mgr role
        boolean isMgr = request.isUserInRole("Mgr");

        // display Hello username for managers and bob.
```

```

        if ( isMgr || remoteUserName.equals("bob") )
            s = "Hello " + remoteUserName;

String message = "<html> \n" +
    "<head><title>Hello Servlet</title></head>\n" +
    "<body> /n +"
    "<h1> " +s+ </h1>/n " +
byte[] bytes = message.getBytes();

// displays "Hello" for ordinary users
// and displays "Hello username" for managers and "bob".
response.getOutputStream().write(bytes);
}
}

```

After developing the servlet, you can create a security role reference for the HelloServlet servlet as shown in the following example:

```

<security-role-ref>
    <description> </description>
    <role-name>Mgr</role-name>
</security-role-ref>

```

Web authentication settings

Use this page to specify the Web authentication settings that are associated with a Web client.

To view this administrative console page, complete the following steps:

1. Click **Security > Secure administration and applications**.
2. Under Authentication, expand **Web security** and click **General settings**.

You can override the global Web authentication setting that you select on this panel by specifying a system property on the server level. To specify the system property, complete the following steps:

1. Click **Servers > Application servers > server_name**.
2. Under Server infrastructure, click **Java and Process Management > Process definition**.
3. Under Additional properties, click **Java Virtual Machine > Custom properties > New**

You can specify the following system properties on the server level for Web authentication.

Table 17. Web authentication system property values

Property name	Value	Explanation
com.ibm.wsspi.security.web.webAuthReq	lazy	This value is equivalent to the Authenticate only when the URI is protected option.
com.ibm.wsspi.security.web.webAuthReq	persisting	This value is equivalent to the Use available authentication data when an unprotected URI is accessed option.
com.ibm.wsspi.security.web.webAuthReq	always	This value is equivalent to the Authenticate when any URI is accessed option.
com.ibm.wsspi.security.web.failOverToBasicAuth	true	This value is equivalent to the Default to basic authentication when certificate authentication for the HTTPS client fails option.

Authenticate only when the URI is protected:

The application server challenges the Web client to provide authentication data when the Web client accesses a Uniform Resource Identifier (URI) that is protected by a Java 2 Platform, Enterprise Edition (J2EE) role. The authenticated identity is available only when the Web client accesses a protected URI.

This option is the default J2EE Web authentication behavior that is also available in previous releases of WebSphere Application Server.

Default: Enabled

Use available authentication data when an unprotected URI is accessed:

The Web client can access validated authenticated data that it previously could not access. This option enables the Web client to call the `getRemoteUser`, `isUserInRole`, and `getUserPrincipal` methods to retrieve an authenticated identity from an unprotected URI.

When you select this option with the **Authenticate only when the URI is protected** option, the Web client can use authenticated data when the URI is protected or not protected.

Important: This option does not challenge the Web client to provide authenticated data if the Web client accesses an unprotected URI without authenticated data.

Default: Disabled

Authenticate when any URI is accessed:

The Web client must provide authentication data regardless of whether the URI is protected.

Default: Disabled

Default to basic authentication when certificate authentication for the HTTPS client fails:

When the required HTTPS client certificate authentication fails, the application server uses the basic authentication method to challenge the Web client to provide a user ID and password.

The HTTP client certification authentication that is performed by the application server security is different from the client authentication that is performed by the Web server plug-in. If you configure the Web server plug-in for mutual authentication and client authentication fails, the following situations will occur:

- The Web server produces a error and the Web request is not processed by application server security.
- The application server cannot fail over to basic authentication.

Default: Disabled

Developing with programmatic APIs for EJB applications

Use this topic to programmatically secure your Enterprise JavaBeans (EJB) applications.

Programmatic security is used by security-aware applications when declarative security alone is not sufficient to express the security model of the application. The `javax.ejb.EJBContext` application programming interface (API) provides two methods whereby the bean provider can access security information about the enterprise bean caller.

- **IsCallerInRole**(String rolename): Returns `true` if the bean caller is granted the security role that is specified by role name. If the caller is not granted the specified role, or if the caller is not authenticated, it returns `false`. If the specified role is granted Everyone access, it always returns `true`.

- **getCallerPrincipal**: Returns the `java.security.Principal` object that contains the bean caller name. If the caller is not authenticated, it returns a principal that contains an unauthorized name.

You can enable a login module to indicate which principal class is returned by these calls.

When the `isCallerInRole` method is used, declare a `security-role-ref` element in the deployment descriptor with a `role-name` that is subelement containing the role name that is passed to this method. Because actual roles are created during the assembly stage of the application, you can use a logical role as the role name and provide enough hints to the assembler in the description of the `security-role-ref` element to link that role to an actual role. During assembly, the assembler creates a `role-link` subelement to link the `role-name` to the actual role. Creation of a `security-role-ref` element is possible if an assembly tool such as Rational Application Developer (RAD) is used. You also can create the `security-role-ref` element during the assembly stage using an assembly tool.

1. Add the required security methods in the EJB module code.
2. Create a `security-role-ref` element with a `role-name` field for all the role names used in the `isCallerInRole` method. If a `security-role-ref` element is not created during development, make sure it is created during the assembly stage.

Performing the previous steps result in a programmatically secured EJB application.

Hard coding security policies in applications is strongly discouraged. The Java 2 Platform, Enterprise Edition (J2EE) security model capabilities of declaratively specifying security policies is encouraged wherever possible. Use these APIs to develop security-aware EJB applications.

Using J2EE security model capabilities to specify security policies declaratively is useful when an EJB application wants to access external resources and wants to control the access to these external resources using its own authorization table (external-resource to user mapping). In this case, use the `getCallerPrincipal` method to get the caller identity and then the application can consult its own authorization table to perform authorization. The caller identification also can help retrieve the corresponding user information from an external source, such as database or from another enterprise bean. You can use the `isCallerInRole` method in a similar way.

After development, you can create a `security-role-ref` element:

```
<security-role-ref>
<description>Provide hints to assembler for linking this role-name to
actual role here</description>
<role-name>Mgr</role-name>
</security-role-ref>
```

During assembly, the assembler creates a `role-link` element:

```
<security-role-ref>
<description>Hints provided by developer to map role-name to role-link</description>
<role-name>Mgr</role-name>
<role-link>Manager</role-link>
</security-role-ref>
```

You can add programmatic EJB component security methods for example `isCallerInRole` and `getCallerPrincipal`, inside any business methods of an enterprise bean. The following example of programmatic security APIs includes a session bean:

```
public class aSessionBean implements SessionBean {

    .....

    // SessionContext extends EJBContext. If it is entity bean use EntityContext
    javax.ejb.SessionContext context;

    // The following method will be called by the EJB container
```

```

// automatically
public void setSessionContext(javax.ejb.SessionContext ctx) {
    context = ctx; // save the session bean's context
}

....

private void aBusinessMethod() {
    ....

// to get bean's caller using getCallerPrincipal()
java.security.Principal principal = context.getCallerPrincipal();
String callerId= principal.getName();

// to check if bean's caller is granted Mgr role
boolean isMgr = context.isCallerInRole("Mgr");

// use the above information in any way as needed by the
//application

....
}

....
}

```

After developing an application, use an assembly tool to create roles and to link the actual roles to role names in the security-role-ref elements. For more information, see “Securing enterprise bean applications” on page 943.

Example: Enterprise bean application code

The following Enterprise JavaBeans (EJB) component example illustrates the use of the `isCallerInRole` and the `getCallerPrincipal` methods in an EJB module.

Using that declarative security is recommended. The following example is one way of using the `isCallerInRole` and the `getCallerPrincipal` methods. The application can use this result in any way that is suitable.

A remote interface

File : Hello.java

```

package tests;
import java.rmi.RemoteException;
/**
 * Remote interface for Enterprise Bean: Hello
 */
public interface Hello extends javax.ejb.EJBObject {
    public abstract String getMessage()throws RemoteException;
    public abstract void setMessage(String s)throws RemoteException;
}

```

A home interface

File : HelloHome.java

```

package tests;
/**
 * Home interface for Enterprise Bean: Hello
 */
public interface HelloHome extends javax.ejb.EJBHome {
/**

```

```

    * Creates a default instance of Session Bean: Hello
    */
    public tests.Hello create() throws javax.ejb.CreateException,
        java.rmi.RemoteException;
}

```

A bean implementation

File : HelloBean.java

```

package tests;
/**
 * Bean implementation class for Enterprise Bean: Hello
 */
public class HelloBean implements javax.ejb.SessionBean {
    private javax.ejb.SessionContext mySessionCtx;
    /**
     * getSessionContext
     */
    public javax.ejb.SessionContext getSessionContext() {
        return mySessionCtx;
    }
    /**
     * setSessionContext
     */
    public void setSessionContext(javax.ejb.SessionContext ctx) {
        mySessionCtx = ctx;
    }
    /**
     * ejbActivate
     */
    public void ejbActivate() {
    }
    /**
     * ejbCreate
     */
    public void ejbCreate() throws javax.ejb.CreateException {
    }
    /**
     * ejbPassivate
     */
    public void ejbPassivate() {
    }
    /**
     * ejbRemove
     */
    public void ejbRemove() {
    }

    public java.lang.String message;

    //business methods

    // all users can call getMessage()
    public String getMessage() {
        return message;
    }

    // all users can call setMessage() but only few users can set new message.
    public void setMessage(String s) {

```

```

// get bean's caller using getCallerPrincipal()
java.security.Principal principal = mySessionCtx.getCallerPrincipal();
java.lang.String callerId= principal.getName();

// check if bean's caller is granted Mgr role
boolean isMgr = mySessionCtx.isCallerInRole("Mgr");

// only set supplied message if caller is "bob" or caller is granted Mgr role
if ( isMgr || callerId.equals("bob") )
    message = s;
else
    message = "Hello";
}
}

```

After the development of the entity bean, create a security role reference in the deployment descriptor under the session bean, Hello:

```

<security-role-ref>
  <description>Only Managers can call setMessage() on this bean (Hello)</description>
  <role-name>Mgr</role-name>
</security-role-ref>

```

For an explanation of how to create a <security-role-ref> element, see “Securing enterprise bean applications” on page 943. Use the information under Map security-role-ref and role-name to role-link to create the element.

Customizing Web application login

You can create a form login page and an error page to authenticate a user.

A Web client or a browser can authenticate a user to a Web server using one of the following mechanisms:

- **HTTP basic authentication:** A Web server requests the Web client to authenticate and the Web client passes a user ID and a password in the HTTP header.
- **HTTPS client authentication:** This mechanism requires a user (Web client) to possess a public key certificate. The Web client sends the certificate to a Web server that requests the client certificates. This authentication mechanism is strong and uses the Hypertext Transfer Protocol with Secure Sockets Layer (HTTPS) protocol.
- **Form-based Authentication:** A developer controls the look and feel of the login screens using this authentication mechanism.

The Hypertext Transfer Protocol (HTTP) basic authentication transmits a user password from the Web client to the Web server in simple base64 encoding. Form-based authentication transmits a user password from the browser to the Web server in plain text. Therefore, both HTTP basic authentication and form-based authentication are not very secure unless the HTTPS protocol is used.

The Web application deployment descriptor contains information about which authentication mechanism to use. When form-based authentication is used, the deployment descriptor also contains entries for login and error pages. A login page can be either an HTML page or a JavaServer Pages (JSP) file. This login page displays on the Web client side when a secured resource (servlet, JSP file, HTML page) is accessed from the application. On authentication failure, an error page displays. You can write login and error pages to suit the application needs and control the look and feel of these pages. During assembly of the application, an assembler can set the authentication mechanism for the application and set the login and error pages in the deployment descriptor.

Form login uses the servlet `sendRedirect` method, which has several implications for the user. The `sendRedirect` method is used twice during form login:

- The `sendRedirect` method initially displays the form login page in the Web browser. It later redirects the Web browser back to the originally requested protected page. The `sendRedirect(String URL)` method tells the Web browser to use the HTTP GET request to get the page that is specified in the Web address. If HTTP POST is the first request to a protected servlet or JavaServer Pages (JSP) file, and no previous authentication or login occurred, then HTTP POST is not delivered to the requested page. However, HTTP GET is delivered because form login uses the `sendRedirect` method, which behaves as an HTTP GET request that tries to display a requested page after a login occurs.
 - Using HTTP POST, you might experience a scenario where an unprotected HTML form collects data from users and then posts this data to protected servlets or JSP files for processing, but the users are not logged in for the resource. To avoid this scenario, structure your Web application or permissions so that users are forced to use a form login page before the application performs any HTTP POST actions to protected servlets or JSP files.
1. Create a form login page with the required look and feel, including the required elements to perform form-based authentication. For an example, see “Example: Form login.”
 2. Create an error page. You can program error pages to retry authentication or to display an appropriate error message.
 3. Place the login page and error page in the Web archive (.war) file relative to the top directory. For example, if the login page is configured as `/login.html` in the deployment descriptor, place it in the top directory of the WAR file. An assembler can also perform this step using the assembly tool.
 4. Create a form logout page and insert it to the application only when the Web application requires a form-based authentication mechanism.

See the “Example: Form login” article for sample form login pages.

The WebSphere Application Server Samples Gallery provides a form login Sample that demonstrates how to use the WebSphere Application Server login facilities to implement and configure form login procedures. The Sample integrates the following technologies to demonstrate the WebSphere Application Server and Java 2 Platform, Enterprise Edition (J2EE) login functionality:

- J2EE form-based login
- J2EE servlet filter with login
- IBM extension: form-based login

The form login sample is part of the Technology Samples package. For more information on how to access the form login sample, see [Accessing the Samples \(Samples Gallery\)](#).

After developing login and error pages, add them to the Web application. Use the assembly tool to configure an authentication mechanism and insert the developed login page and error page in the deployment descriptor of the application.

Example: Form login

This article provides several examples pertaining to form login.

For the authentication to proceed appropriately, the action of the login form must always have the `j_security_check` action. The following example shows how to code the form into the HTML page:

```
<form method="POST" action="j_security_check">
<input type="text" name="j_username">
<input type="text" name="j_password">
<\form>
```

Use the `j_username` input field to get the user name, and use the `j_password` input field to get the user password.

On receiving a request from a Web client, the Web server sends the configured form page to the client and preserves the original request. When the Web server receives the completed form page from the Web client, the server extracts the user name and password from the form and authenticates the user. On successful authentication, the Web server redirects the call to the original request. If authentication fails, the Web server redirects the call to the configured error page.

The following example depicts a login page in HTML (login.html):

```
<!DOCTYPE HTML PUBLIC "-//W3C/DTD HTML 4.0 Transitional//EN">
<html>
<META HTTP-EQUIV = "Pragma" CONTENT="no-cache">
<title> Security FVT Login Page </title>
<body>
<h2>Form Login</h2>
<FORM METHOD=POST ACTION="j_security_check">
<p>
<font size="2"> <strong> Enter user ID and password: </strong></font>
<BR>
<strong> User ID</strong> <input type="text" size="20" name="j_username">
<strong> Password </strong> <input type="password" size="20" name="j_password">
<BR>
<BR>
<font size="2"> <strong> And then click this button: </strong></font>
<input type="submit" name="login" value="Login">
</p>

</form>
</body>
</html>
```

The following example depicts an error page in a JSP file:

```
<!DOCTYPE HTML PUBLIC "-//W3C/DTD HTML 4.0 Transitional//EN">
<html>
<head><title>A Form login authentication failure occurred</head></title>
<body>
<H1><B>A Form login authentication failure occurred</H1></B>
<P>Authentication may fail for one of many reasons. Some possibilities include:
<OL>
<LI>The user-id or password may be entered incorrectly; either misspelled or the
wrong case was used.
<LI>The user-id or password does not exist, has expired, or has been disabled.
</OL>
</P>
</body>
</html>
```

After an assembler configures the Web application to use form-based authentication, the deployment descriptor contains the login configuration as shown:

```
<login-config id="LoginConfig_1">
<auth-method>FORM</auth-method>
<realm-name>Example Form-Based Authentication Area</realm-name>
<form-login-config id="FormLoginConfig_1">
<form-login-page>/login.html</form-login-page>
<form-error-page>/error.jsp</form-error-page>
</form-login-config>
</login-config>
```

A sample Web application archive (WAR) file directory structure that shows login and error pages for the previous login configuration follows:

```
META-INF
  META-INF/MANIFEST.MF
  login.html
```

```
error.jsp
WEB-INF/
WEB-INF/classes/
WEB-INF/classes/aServlet.class
```

Form logout

Form logout is a mechanism to log out without having to close all Web-browser sessions. After logging out of the form logout mechanism, access to a protected Web resource requires re-authentication. This feature is not required by J2EE specifications, but it is provided as an additional feature in WebSphere Application Server security.

Suppose that you want to log out after logging into a Web application and perform some actions. A form logout works in the following manner:

1. The logout-form URI is specified in the Web browser and loads the form.
2. The user clicks **Submit** on the form to log out.
3. The WebSphere security code logs the user out.
4. Upon logout, the user is redirected to a logout exit page.

Form logout does not require any attributes in a deployment descriptor. The form-logout page is an HTML or a JavaServer Pages (JSP) file that is included with the Web application. The form-logout page is like most HTML forms except that like the form-login page, the form-logout page has a special post action. This post action is recognized by the Web container, which dispatches the post action to a special internal form-logout servlet. The post action in the form-logout page must be `ibm_security_logout`.

You can specify a logout-exit page in the logout form and the exit page can represent an HTML or a JSP file within the same Web application to which the user is redirected after logging out. Additionally, the logout-exit page permits a fully qualified URL in the form of `http://hostname:port/URL`. The logout-exit page is specified as a parameter in the form-logout page. If no logout-exit page is specified, a default logout HTML message is returned to the user.

Here is a sample form logout HTML form. This form configures the logout-exit page to redirect the user back to the login page after logout.

```
<!DOCTYPE HTML PUBLIC "-//W3C/DTD HTML 4.0 Transitional//EN">
<html>
  <META HTTP-EQUIV = "Pragma" CONTENT="no-cache">
  <title>Logout Page </title>
  <body>
    <h2>Sample Form Logout</h2>
    <FORM METHOD=POST ACTION="ibm_security_logout" NAME="logout">
      <p>
        <BR>
        <BR>
        <font size="2"><strong> Click this button to log out: </strong></font>
        <input type="submit" name="logout" value="Logout">
        <INPUT TYPE="HIDDEN" name="logoutExitPage" VALUE="/login.html">
      </p>
    </form>
  </body>
</html>
```

The WebSphere Application Server Samples Gallery provides a form login Sample that demonstrates how to use the WebSphere Application Server login facilities to implement and configure form login procedures. The Sample integrates the following technologies to demonstrate the WebSphere Application Server and Java 2 Platform, Enterprise Edition (J2EE) login functionality:

- J2EE form-based login
- J2EE servlet filter with login
- IBM extension: form-based login

The form login Sample is part of the Technology Samples package.

Developing servlet filters for form login processing

You can control the look and feel of the login screen using the form-based login mechanism. In form-based login, you specify a login page that is used to retrieve the user ID and password information. You also can specify an error page that displays when authentication fails.

If additional authentication or additional processing is required before and after authentication, servlet filters are an option. Servlet filters can dynamically intercept requests and responses to transform or to use the information that is contained in the requests or responses. One or more servlet filters can be attached to a servlet or to a group of servlets. Servlet filters also can attach to JavaServer Pages (JSP) files and HTML pages. All of the attached servlet filters are called before the servlet is invoked.

Both form-based login and servlet filters are supported by any servlet Version 2.3 specification-complaint Web container. The form login servlet performs the authentication and servlet filters perform additional authentication, auditing, or logging information.

To perform pre-login and post-login actions using servlet filters, configure these filters for either form login page support or for the `/j_security_check` URL. The `j_security_check` is posted by a form login page with the `j_username` parameter that contains the user name and the `j_password` parameter that contains the password. A servlet filter can use the user name parameter and password information to perform more authentication or other special needs.

1. A servlet filter implements the `javax.servlet.Filter` class. Implement three methods in the filter class:
 - **init(javax.servlet.FilterConfig cfg)**. This method is called by the container once, when the servlet filter is placed into service. The `FilterConfig` passed to this method contains the init-parameters of the servlet filter. Specify the init-parameters for a servlet filter during configuration using the assembly tool.
 - **destroy**. This method is called by the container when the servlet filter is taken out of a service.
 - **doFilter(ServletRequest req, ServletResponse res, FilterChain chain)**. This method is called by the container for every servlet request that maps to this filter before invoking the servlet. The `FilterChain` chain that is passed to this method can be used to invoke the next filter in the chain of filters. The original requested servlet runs when the last filter in the chain calls the `chain.doFilter` method. Therefore, all filters call the `chain.doFilter` method for the original servlet to run after filtering. If an additional authentication check is implemented in the filter code and results in failure, the original servlet does not run. The `chain.doFilter` method is not called and can be redirected to some other error page.
2. If a servlet maps to many servlet filters, servlet filters are called in the order that is listed in the `web.xml` deployment descriptor of the application. Place the servlet filter class file in the `WEB-INF/classes` directory of the application.

An example of a servlet filter follows: This login filter can map to the `/j_security_check` URL to perform pre-login and post-login actions.

```
import javax.servlet.*;
public class LoginFilter implements Filter {
    protected FilterConfig filterConfig;
    // Called once when this filter is instantiated.
    // If mapped to j_security_check, called
    // very first time j_security_check is invoked.
    public void init(FilterConfig filterConfig) throws ServletException {
        this.filterConfig = filterConfig;
    }
    public void destroy() {
        this.filterConfig = null;
    }
    // Called for every request that is mapped to this filter.
    // If mapped to j_security_check,
    // called for every j_security_check action
```

```

public void doFilter(ServletRequest request,
ServletResponse response, FilterChain chain)
    throws java.io.IOException, ServletException {
    // perform pre-login action here
    chain.doFilter(request, response);
    // calls the next filter in chain.
    // j_security_check if this filter is
    // mapped to j_security_check.
    // perform post-login action here.
    }
}

```

Example of servlet filters

This example illustrates one way that the servlet filters can perform pre-login and post-login processing during form login.

Servlet filter source code: LoginFilter.java

```

/**
 * A servlet filter example: This example filters j_security_check and
 * performs pre-login action to determine if the user trying to log in
 * is in the revoked list. If the user is on the revoked list, an error is
 * sent back to the browser.
 *
 * This filter reads the revoked list file name from the FilterConfig
 * passed in the init() method. It reads the revoked user list file and
 * creates a revokedUsers list.
 *
 * When the doFilter method is called, the user logging in is checked
 * to make sure that the user is not on the revoked Users list.
 */

import javax.servlet.*;
import javax.servlet.http.*;
import java.io.*;

public class LoginFilter implements Filter {

    protected FilterConfig filterConfig;

    java.util.List revokeList;

    /**
     * init() : init() method called when the filter is instantiated.
     * This filter is instantiated the first time j_security_check is
     * invoked for the application (When a protected servlet in the
     * application is accessed).
     */
    public void init(FilterConfig filterConfig) throws ServletException {
        this.filterConfig = filterConfig;

        // read revoked user list
        revokeList = new java.util.ArrayList();
        readConfig();
    }

    /**
     * destroy() : destroy() method called when the filter is taken
     * out of service.
     */
    public void destroy() {
        this.filterConfig = null;
        revokeList = null;
    }

    /**
     * doFilter() : doFilter() method called before the servlet to
     * which this filter is mapped is invoked. Since this filter is
     * mapped to j_security_check, this method is called before

```

```

    * j_security_check action is posted.
    */
    public void doFilter(ServletRequest request, ServletResponse response,
        FilterChain chain) throws java.io.IOException, ServletException {

        HttpServletRequest req = (HttpServletRequest)request;
        HttpServletResponse res = (HttpServletResponse)response;

        // pre login action

        // get username
        String username = req.getParameter("j_username");

        // if user is in revoked list send error
        if ( revokeList.contains(username) ) {
            res.sendError(javax.servlet.http.HttpServletResponse.SC_UNAUTHORIZED);
            return;
        }

        // call next filter in the chain : let j_security_check authenticate
        // user
        chain.doFilter(request, response);

        // post login action
    }

    /**
     * readConfig() : Reads revoked user list file and creates a revoked
     * user list.
     */
    private void readConfig() {
        if ( filterConfig != null ) {

            // get the revoked user list file and open it.
            BufferedReader in;
            try {
                String filename = filterConfig.getInitParameter("RevokedUsers");
                in = new BufferedReader( new FileReader(filename));
            } catch ( FileNotFoundException fnfe) {
                return;
            }

            // read all the revoked users and add to revokeList.
            String userName;
            try {
                while ( (userName = in.readLine()) != null )
                    revokeList.add(userName);
            } catch (IOException ioe) {
            }

        }
    }
}
}
}

```

Important: In the previous code sample, the line that begins `public void doFilter(ServletRequest request` is broken into two lines for illustrative purposes only. The `public void doFilter(ServletRequest request` line and the line after it are one continuous line.

An example of the `web.xml` file that shows the `LoginFilter` filter configured and mapped to the `j_security_check` URL:

```

<filter id="Filter_1">
    <filter-name>LoginFilter</filter-name>
    <filter-class>LoginFilter</filter-class>
    <description>Performs pre-login and post-login operation</description>

```

```

    <init-param>
    <param-name>RevokedUsers</param-name>
    <param-value>c:\WebSphere\AppServer\installedApps\
                <app-name>\revokedUsers.lst</param-value>
    </init-param>
</filter-id>

<filter-mapping>
  <filter-name>LoginFilter</filter-name>
  <url-pattern>/j_security_check</url-pattern>
</filter-mapping>

```

An example of a revoked user list file:

```

user1
cn=user1,o=ibm,c=us
user99
cn=user99,o=ibm,c=us

```

Configuring servlet filters

IBM Rational Application Developer or an assembly tool can configure the servlet filters. Two steps are involved in configuring a servlet filter.

1. Name the servlet filter and assign the corresponding implementation class to the servlet filter.

Optionally, assign initialization parameters that get passed to the init method of the servlet filter. After configuring the servlet filter, the `web.xml` application deployment descriptor contains a servlet filter configuration similar to the following example:

```

<filter id="Filter_1">
  <filter-name>LoginFilter</filter-name>
  <filter-class>LoginFilter</filter-class>
  <description>Performs pre-login and post-login
    operation</description>
  <init-param>// optional
    <param-name>ParameterName</param-name>
    <param-value>ParameterValue</param-value>
  </init-param>
</filter>

```

2. Map the servlet filter to a URL or a servlet.

After mapping the servlet filter to a URL or a servlet, the `web.xml` application deployment descriptor contains servlet mapping similar to the following example:

```

<filter-mapping>
  <filter-name>LoginFilter</filter-name>
  <url-pattern>/j_security_check</url-pattern>
  // can be servlet <servlet>servletName</servlet>
</filter-mapping>

```

You can use servlet filters to replace the CustomLoginServlet servlet, and to perform additional authentication, auditing, and logging.

The WebSphere Application Server Samples Gallery provides a form login sample that demonstrates how to use the WebSphere Application Server login facilities to implement and configure form login procedures. The sample integrates the following technologies to demonstrate the WebSphere Application Server and Java 2 Platform, Enterprise Edition (J2EE) login functionality:

- J2EE form-based login
- J2EE servlet filter with login
- IBM extension: form-based login

The form login sample is part of the Technology Samples package. For more information on how to access the form login sample, see [Accessing the Samples \(Samples Gallery\)](#).

Customizing application login with Java Authentication and Authorization Service

The following topics are covered in this section:

- Developing programmatic logins with the Java Authentication and Authorization Service (JAAS)
- Configuring programmatic logins for JAAS
- Configuring a server-side Java Authentication and Authorization Service authentication and login configuration

Developing programmatic logins with the Java Authentication and Authorization Service

Use this topic to develop programmatic logins with the Java Authentication and Authorization Service.

Java Authentication and Authorization Service (JAAS) represents the strategic application programming interfaces (API) for authentication.

JAAS replaces the Common Object Request Broker Architecture (CORBA) programmatic login application programming interfaces (APIs).

WebSphere Application Server provides some extension to JAAS:

- Refer to the Developing applications that use CosNaming (CORBA Naming interface) article for details on how to set up the environment for thin client applications to access remote resources on a server.
- If the application uses a custom JAAS login configuration, verify that the JAAS login configuration is properly defined. See “Configuring programmatic logins for Java Authentication and Authorization Service” on page 567 for details.
- Some of the JAAS APIs are protected by Java 2 security permissions. If these APIs are used by application code, verify that these permissions are added to the application `was.policy` file.

For details, see the following articles:

- “Adding the `was.policy` file to applications” on page 540
- “Using PolicyTool to edit policy files” on page 528
- “Configuring the `was.policy` file” on page 535

For more details on which APIs are protected by Java 2 security permissions, check the IBM Developer Kit, Java Technology Edition; JAAS and WebSphere Application Server public APIs documentation in Security: Resources for learning.

Some of the APIs that are used in the sample code in this documentation and the Java 2 security permissions that are required by these APIs are in the following list:

- `javax.security.auth.login.LoginContext` constructors are protected by the `javax.security.auth.AuthPermission "createLoginContext"` object.
 - `javax.security.auth.Subject.doAs` and `com.ibm.websphere.security.auth.WSSubject.doAs` methods are protected by the `javax.security.auth.AuthPermission "doAs"` object.
 - `javax.security.auth.Subject.doAsPrivileged` and `com.ibm.websphere.security.auth.WSSubject.doAsPrivileged` methods are protected by the `javax.security.auth.AuthPermission "doAsPrivileged"` object.
- **Enhanced model to Java 2 Platform, Enterprise Edition (J2EE) resources for authorization checks.**

Due to a design oversight in JAAS Version 1.0, the `javax.security.auth.Subject.getSubject` method does not return the Subject that is associated with the running thread inside a `java.security.AccessController.doPrivileged` code block. This oversight can present inconsistent behavior, which might have unwanted effects. The `com.ibm.websphere.security.auth.WSSubject` class provides a workaround to associate a Subject to a running thread. The `com.ibm.websphere.security.auth.WSSubject` class extends the JAAS model to Java 2 Platform, Enterprise Edition (J2EE) resources for authorization checks. If the Subject associates with the running

thread within the `com.ibm.websphere.security.auth.WSSubject.doAs` method or if the `com.ibm.websphere.security.auth.WSSubject.doAsPrivileged` code block contains product credentials, the Subject is used for J2EE resource authorization checks.

- **User interface support for defining new JAAS login configuration.**

You can configure a JAAS login configuration in the administrative console and store the JAAS login configuration in a configuration repository. Applications can define a new JAAS login configuration in the administrative console and the data is persisted in the configuration repository. However, WebSphere Application Server still supports the default JAAS login configuration format (plain text file) that is provided by the JAAS default implementation. If duplicate login configurations are defined in both the configuration repository and the plain text file format, the one in the repository takes precedence.

Advantages to defining the login configuration in the configuration repository includes:

- Administrative console support in defining JAAS login configuration
- Central management of the JAAS login configuration
- Distribution of the JAAS login configuration

- **Application support for programmatic authentication.**

WebSphere Application Server provides JAAS login configurations for applications to perform programmatic authentication to the WebSphere security runtime. These configurations perform authentication to the WebSphere Application Server-configured authentication mechanism (Simple WebSphere Authentication Mechanism (SWAM) or Lightweight Third Party Authentication (LTPA)) and user registry (Local OS, Lightweight Directory Access Protocol (LDAP), custom registries, or federated repositories) based on the authentication data that is supplied. The authenticated Subject from these JAAS login configurations contains the required principal and credentials that the WebSphere security runtime can use to perform authorization checks on J2EE role-based protected resources.

Note: SWAM is deprecated in WebSphere Application Server Version 6.1 and will be removed in a future release.

Here are the JAAS login configurations that are provided by WebSphere Application Server:

- **WSLogin JAAS login configuration.** A generic JAAS login configuration can use Java clients, client container applications, servlets, JavaServer Pages (JSP) files, and Enterprise JavaBeans (EJB) components to perform authentication based on a user ID and password, or a token to the security runtime for WebSphere Application Server. However, this configuration does not honor the `CallbackHandler` handler that is specified in the client container deployment descriptor.
- **ClientContainer JAAS login configuration.** This JAAS login configuration honors the `CallbackHandler` handler that is specified in the client container deployment descriptor. The login module of this login configuration uses the `CallbackHandler` handler in the client container deployment descriptor if one is specified, even if the application code specified one callback handler in the login context. This is for a client container application.

A Subject authenticated with the previously mentioned JAAS login configurations contains a `com.ibm.websphere.security.auth.WSPPrincipal` principal and a `com.ibm.websphere.security.cred.WSCredential` credential. If the authenticated Subject is passed in the `com.ibm.websphere.security.auth.WSSubject.doAs` or the other `doAs` methods, the product security runtime can perform authorization checks on J2EE resources based on the `com.ibm.websphere.security.cred.WSCredential` Subject.

- **Customer-defined JAAS login configurations.**

You can define other JAAS login configurations to perform programmatic authentication to your authentication mechanism. See the “Configuring programmatic logins for Java Authentication and Authorization Service” on page 567 for details. For the product security runtime to perform authorization checks, the subjects from these customer-defined JAAS login configurations must contain the required principal and credentials.

- **Naming requirements for programmatic login on a pure Java client.**

When programmatic login occurs on a pure Java client and the property `com.ibm.CORBA.validateBasicAuth` equals `true`, it is necessary for the security code to know where the `SecurityServer` resides. Typically, the default `InitialContext` is sufficient when a `java.naming.provider.url` property is set as a system property or when the property is set in the `jndi.properties` file. In other

cases it is not desirable to have the same `java.naming.provider.url` properties set in a system-wide scope. In this case, there is a need to specify security specific bootstrap information in the `sas.client.props` file. The following steps present the order of precedence for determining how to find the `SecurityServer` in a pure Java client:

1. Use the `sas.client.props` file and look for the following properties:

```
com.ibm.CORBA.securityServerHost=myhost.mydomain
com.ibm.CORBA.securityServerPort=mybootstrap port
```

If you specify these properties, you are guaranteed that security looks here for the `SecurityServer`. The host and port specified can represent any valid WebSphere host and bootstrap port. The `SecurityServer` resides on all server processes and therefore it is not important which host or port you choose. If specified, the security infrastructure within the client process look up the `SecurityServer` based on the information in the `sas.client.props` file.

2. Place the following code in your client application to get a new `InitialContext()`:

```
...
import java.util.Hashtable;
import javax.naming.Context;
import javax.naming.InitialContext;
...

// Perform an InitialContext and default lookup prior to logging
// in so that target realm and bootstrap host/port can be
// determined for SecurityServer lookup.

    Hashtable env = new Hashtable();
    env.put(Context.INITIAL_CONTEXT_FACTORY, "
        com.ibm.websphere.naming.WsnInitialContextFactory");
    env.put(Context.PROVIDER_URL,
        "corbaloc:iiop:myhost.mycompany.com:2809");
    Context initialContext = new InitialContext(env);
    Object obj = initialContext.lookup("");

    // programmatic login code goes here.
```

Complete this step prior to running any programmatic login. It is in this code that you specify a URL provider for your naming context, but it must point to a valid WebSphere Application Server within the cell to which you are authenticating. Pointing to one cell allows thread specific programmatic logins going to different cells to have a single system-wide `SecurityServer` location.

3. Use the new default `InitialContext()` method relying on the naming precedence rules. These rules are defined in the article, Example: Getting the default initial context.

See the “Example: Programmatic logins” article.

Example: Programmatic logins

This example illustrates how application programs can perform a programmatic login using Java Authentication and Authorization Service (JAAS).

```
LoginContext lc = null;
```

```
try {
    lc = new LoginContext("WSLogin",
        new WSCallbackHandlerImpl("userName", "password"));
} catch (LoginException le) {
    System.out.println("Cannot create LoginContext. " + le.getMessage());
    // Insert the error processing code
} catch (SecurityException se) {
    System.out.println("Cannot create LoginContext." + se.getMessage());
    // Insert the error processing code
```

```

}

try {
    lc.login();
} catch(LoginException le) {
    System.out.println("Fails to create Subject. " + le.getMessage());
    // Insert the error processing code
}

```

As shown in the example, the new login context is initialized with the `WSLogin` login configuration and the `WSCallbackHandlerImpl` callback handler. Use the `WSCallbackHandlerImpl` instance on a server-side application where you do not want prompting. A `WSCallbackHandlerImpl` instance is initialized by the specified user ID, password, and realm information. The present `WSLoginModuleImpl` class implementation that is specified by the `WSLogin` login configuration can only retrieve authentication information from the specified callback handler. You can construct a login context with a `Subject` object, but the `Subject` is disregarded by the present `WSLoginModuleImpl` implementation. For product client-container applications, replace `WSLogin` login configuration by `ClientContainer` login configuration, which specifies the `WSClientLoginModuleImpl` implementation that is tailored for client container requirements.

For a pure Java application client, the product provides two other callback handler implementations: `WSStdinCallbackHandlerImpl` and `WSGUICallbackHandlerImpl`, which prompt for user ID, password, and realm information on the command line and pop-up panel, respectively. You can choose either of these product callback handler implementations, depending on the particular application environment. You can develop a new callback handler if neither of these implementations fit your particular application requirement.

You also can develop your own login module if the default `WSLoginModuleImpl` implementation fails to meet all your requirements. This product provides utility functions that the custom login module can use, which are described in the next section.

In cases where no `java.naming.provider.url` property is set as a system property or in the `jndi.properties` file, a default `InitialContext` context does not function if the product server is not at the `server_name:2809` location. In this situation, construct a new `InitialContext` context programmatically ahead of the JAAS login. JAAS needs to know where the security server resides to verify that the entered user ID or password is correct, prior to performing a `commit` method. By constructing a new `InitialContext` context in the way specified below, the security code has the information that is needed to find the security server location and the target realm.

Attention: The first line starting with `env.put` was split into two lines for illustration purposes only.

```

import java.util.Hashtable;
import javax.naming.Context;
import javax.naming.InitialContext;
...

// Perform an InitialContext and default lookup prior to logging in so that target realm
// and bootstrap host/port can be determined for SecurityServer lookup.

Hashtable env = new Hashtable();
env.put(Context.INITIAL_CONTEXT_FACTORY,
        "com.ibm.websphere.naming.WsnInitialContextFactory");
env.put(Context.PROVIDER_URL, "corbaloc:iiop:myhost.mycompany.com:2809");
Context initialContext = new InitialContext(env);
Object obj = initialContext.lookup("");

LoginContext lc = null;
try {
    lc = new LoginContext("WSLogin",
        new WSCallbackHandlerImpl("userName", "realm", "password"));
} catch (LoginException le) {
    System.out.println("Cannot create LoginContext. " + le.getMessage());
    // insert error processing code
}

```

```

} catch(SecurityException se) {
    System.out.println("Cannot create LoginContext." + se.getMessage());
    // Insert error processing
}

try {
    lc.login();
} catch(LoginException le) {
    System.out.println("Fails to create Subject. " + le.getMessage());
    // Insert error processing code
}

```

Configuring programmatic logins for Java Authentication and Authorization Service

A new JAAS login configuration can be added and modified using the administrative console. The changes are saved in the cell-level security document and are available to all managed application servers.

Java Authentication and Authorization Service (JAAS) is a feature in WebSphere Application Server. JAAS is a collection of WebSphere Application Server strategic authentication APIs and replaces the Common Object Request Broker Architecture (CORBA) programmatic login APIs.

WebSphere Application Server provides some extensions to JAAS:

- **com.ibm.websphere.security.auth.WSSubject.** The `com.ibm.websphere.security.auth.WSSubject` API extends the JAAS authorization model to Java 2 Platform, Enterprise Edition (J2EE) resources.
- You can configure the JAAS login in the administrative console and store this login configuration in the Application Server configuration. However, WebSphere Application Server still supports the default JAAS login configuration format (plain text file) that is provided by the JAAS default implementation. If duplicate login configurations are defined in both the WebSphere Application Server configuration API and the plain text file format, the one in the WebSphere Application Server configuration API takes precedence. Advantages to defining the login configuration in the WebSphere configuration API include:
 - User interface support in defining JAAS login configuration
 - Central management of the JAAS login configuration
 - Distribution of the JAAS login configuration during installation

Due to a design oversight in JAAS Version 1.0, the `javax.security.auth.Subject.getSubject` method does not return the subject that is associated with the running thread inside a `java.security.AccessController.doPrivileged` code block. This problem presents an inconsistent behavior that might cause unfavorable results. The `com.ibm.websphere.security.auth.WSSubject` API provides a workaround to associate the subject to a running thread.

- **Proxy LoginModule.** The Proxy LoginModule loads the actual LoginModule module. The default JAAS implementation does not use the thread context class loader to load classes. The LoginModule module cannot load if the LoginModule class file is not in the application class loader or the Java extension class loader class path. Due to this class loader visibility problem, WebSphere Application Server provides a proxy LoginModule module to load the JAAS LoginModule using the thread context class loader. You do not need to place the LoginModule implementation on the application class loader or the class path for the Java extension class loader with this proxy LoginModule module.

If you do not want to use the Proxy LoginModule module, you can place the LoginModule module in the `/QIBM/UserData/Java400/ext/` directory to add it to the class path for the Java extended directories. Also, grant `*PUBLIC *RX` authority to the file. However, when you add the file to the `/QIBM/UserData/Java400/ext/` directory, the file is also added to the default class path for the Java extended directories, which is accessible to the entire operating system

JAAS login configurations are defined in the WebSphere Application Server configuration application programming interface (API) security document. Click **Security > Secure administration, applications, and infrastructure**. Under Java Authentication and Authorization Service, click **Application logins**. The following JAAS login configurations are available:

ClientContainer

Defines a login configuration and a LoginModule implementation that is similar to that of the WSLLogin configuration, but enforces the requirements of the WebSphere Application Server client container. For more information, see “Configuration entry settings for Java Authentication and Authorization Service” on page 572.

DefaultPrincipalMapping,

Defines a special LoginModule module that is typically used by J2EE connectors to map an authenticated WebSphere Application Server user identity to a set of user authentication data (user ID and password) for the specified back-end enterprise information system (EIS). For more information about J2EE Connector and the DefaultMappingModule module, refer to the J2EE security section.

WSLogin

Defines a login configuration and a LoginModule implementation that applications can use in general.

A new JAAS login configuration can be added and modified using the administrative console. The changes are saved in the cell-level security document and are available to all managed application servers. An application server restart is required for the changes to take effect at run time.

Attention: Do not remove or delete the predefined JAAS login configurations (such as, ClientContainer, WSLLogin, and DefaultPrincipalMapping). Deleting or removing them can cause other enterprise applications to fail.

1. Delete a JAAS login configuration.
 - a. Click **Security > Secure administration, applications, and infrastructure**.
 - b. Under Java Authentication and Authorization Service, click **Application logins**. The Application Login Configuration panel is displayed.
 - c. Select the check box for the login configurations to delete and click **Delete**.
2. Create a new JAAS login configuration.
 - a. Click **Security > Secure administration, applications, and infrastructure**.
 - b. Under Java Authentication and Authorization Service, click **Application logins**.
 - c. Click **New**. The Application Login Configuration panel is displayed.
 - d. Specify the alias name of the new JAAS login configuration and click **Apply**. This value is the name of the login configuration that you pass in the `javax.security.auth.login.LoginContext` implementation for creating a new `LoginContext` context.

Click **Apply** to save changes and to add the extra node name that precedes the original alias name. Clicking **OK** does not save the new changes in the `security.xml` file.
 - e. Under Additional properties, click **JAAS Login Modules**.
 - f. Click **New**.
 - g. Specify the Module class name. Specify the WebSphere Application Server proxy LoginModule module because of the limitation of the class loader visibility.
 - h. Specify the LoginModule implementation as the delegate property of the Proxy LoginModule module. The WebSphere Application Server proxy LoginModule class name is `com.ibm.ws.security.common.auth.module.proxy.WSLLoginModuleProxy`.
 - i. Select **Authentication strategy** from the list and click **Apply**.
 - j. Under Additional properties, click **Custom properties**. The Custom properties panel is displayed for the selected LoginModule.

k. Create a new property with the name `delegat` and the value of the real `LoginModule` implementation. You can specify other properties like `debug` with the `true` value. These properties are passed to the `LoginModule` class as options to the `initialize` method of the `LoginModule` instance.

l. Click **Save**.

For a Network Deployment installation, make sure that a file synchronization operation is performed to propagate the changes to other nodes.

Several locations are within the WebSphere Application Server directory structure where you can place a JAAS login module. The following list provides locations for the JAAS login module in order of recommendation:

- Within an enterprise archive (EAR) file for a specific Java 2 Platform, Enterprise Edition (J2EE) application.

If you place the login module within the EAR file, the login module is accessible by the specific application only.

- In the WebSphere Application Server-shared library.

If you place the login module in the shared library, you must specify which applications can access the module. For more information on shared libraries, see *Managing shared libraries*.

- In the Java extensions directory.

If you place the JAAS login module in the Java extensions directory, the login module is available to all applications.

Place the class file in the `/QIBM/UserData/Java400/ext` directory to add it to the class path for the Java extended directories. Also, grant `*PUBLIC *RX` authority to the file. However, when you add the file to the `/QIBM/UserData/Java400/ext` directory, you are adding the file to the default class path for the Java extended directories, which is accessible to the entire operating system

Although the Java extensions directory provides the greatest availability for the login module, place the login module in an application EAR file. If other applications need to access the same login module, consider using shared libraries.

3. Change the plain text file.

WebSphere Application Server supports the default JAAS login configuration format, which is a plain text file, that is provided by the JAAS default implementation. However, a tool is not provided that edits plain text files in this format. You can define the JAAS login configuration in the `profile_root/properties/wsjaas.conf` file. Any syntax errors can cause the incorrect parsing of the plain JAAS login configuration text file. This problem can cause other applications to fail.

Java client programs that use JAAS for authentication must invoke with the JAAS configuration file specified. This configuration file is set in the **launchClient** QShell script. If you do not use the **launchClient** script to invoke the Java client program, verify that the appropriate JAAS configuration file is passed to the Java virtual machine using the **-Djava.security.auth.login.config** flag.

A new JAAS login configuration is created or an old JAAS login configuration is removed. An enterprise application can use a newly created JAAS login configuration without restarting the application server process.

However, new JAAS login configurations that are defined in the `profile_root/properties/wsjaas.conf` file, do not refresh automatically. Restart the application servers to validate changes. These JAAS login configurations are specific to a particular node and are not available for other application servers running on other nodes.

Create new JAAS login configurations that are used by enterprise applications to perform custom authentication. Use these newly defined JAAS login configurations to perform programmatic login.

Login configuration for Java Authentication and Authorization Service

Java Authentication and Authorization Service (JAAS) is a new feature in WebSphere Application Server. JAAS is WebSphere Application Server strategic application programming interface (API) for authentication that replaces the Common Object Request Broker Architecture (CORBA) programmatic login API.

WebSphere Application Server provides some extensions to JAAS:

- **com.ibm.websphere.security.auth.WSSubject:** The `com.ibm.websphere.security.auth.WSSubject` API extends the JAAS authorization model to Java 2 Platform, Enterprise Edition (J2EE) resources. You can configure JAAS login in the administrative console or by using the scripting functions and store this configuration in the WebSphere Application Server configuration API. However, WebSphere Application Server still supports the default JAAS login configuration format, a plain text file, which is provided by the JAAS default implementation. If duplicate login configurations are defined in both the WebSphere Application Server configuration API and the plain text file format, the one in the WebSphere Application Server configuration API takes precedence. Advantages to defining the login configuration in the WebSphere configuration API include:
 - User interface support in defining JAAS login configuration
 - Central management of the JAAS login configuration
 - Distribution of the JAAS login configuration in a Network Deployment product installation

Due to a design oversight in JAAS 1.0, the `javax.security.auth.Subject.getSubject` method does not return the Subject that is associated with the running thread inside a `java.security.AccessController.doPrivileged` code block. This action can present an inconsistent behavior that is problematic. The `com.ibm.websphere.security.auth.WSSubject` extension provides a workaround to associate the Subject to the running thread. The `com.ibm.websphere.security.auth.WSSubject` extension expands the JAAS authorization model to J2EE resources.

Why WebSphere Application Server has its own subject class: You can retrieve the subjects in a `Subject.doAs` block with the `Subject.getSubject` call. However, this procedure does not work if an `AccessController.doPrivileged` call is contained within the `Subject.doAs` block. In the following example, `s1` is equal to `s`, but `s2` is null:

```
* AccessController.doPrivileged() not only truncates the Subject propagation,
* but also reduces the permissions. It does not include the JAAS security
* policy defined for the principals in the Subject.
Subject.doAs(s, new PrivilegedAction() {
    public Object run() {
        System.out.println("Within Subject.doAsPrivileged()");
        Subject s1 = Subject.getSubject(AccessController.getContext());
        AccessController.doPrivileged(new PrivilegedAction() {
            public Object run() {
                Subject s2 = Subject.getSubject(AccessController.getContext());
                return null;
            }
        });
        return null;
    }
});
```

- JAAS Login Configuration can be configured in either the administrative console or by using the scripting functions and stored in the WebSphere Application Server configuration repository. An application can define a new JAAS login configuration in the administrative console and persist the data in the configuration repository that is stored in the WebSphere Application Server configuration API. However, WebSphere Application Server still supports the default JAAS login configuration format that is provided by the JAAS default implementation. If duplicate login configurations are defined in both the WebSphere Application Server configuration API and the plain text file format, the one in the WebSphere Application Server configuration API takes precedence. The advantages to defining the login configuration in the WebSphere Application Server configuration API include:
 - UI support in defining JAAS login configuration.
 - The JAAS configuration login configuration can be managed centrally.
 - The JAAS configuration login configuration is distributed in a Network Deployment installation.
- **Proxy LoginModule:** The `Proxy.LoginModule` is a proxy to the configured user or the system-defined module that the context class loader uses to load the module instead of the system class loader. The default JAAS implementation does not use the thread context class loader to load classes. The

LoginModule module cannot be loaded if the LoginModule class file is not in the application class loader or the class loader class path for the Java extension. WebSphere Application Server provides a proxy LoginModule module to load the JAAS LoginModule using the thread context class loader. You do not need to place the LoginModule implementation on the application class loader or the class loader class path for the Java extension with this proxy LoginModule module.

Tip: Do not remove or delete the predefined JAAS login configurations (ClientContainer, WSLogin and DefaultPrincipalMapping). Deleting or removing them can cause other enterprise applications to fail.

A system administrator determines the authentication technologies, or login modules, to use for each application and configures them in a login configuration. The source of the configuration information, for example, a file or a database, is up to the current `javax.security.auth.login.Configuration` implementation. The WebSphere Application Server implementation permits the definition of the login configuration in both the WebSphere Application Server configuration API security document and in a JAAS configuration file, where the former takes precedence.

JAAS login configurations are defined in the API security document for WebSphere Application Server configuration for applications to use. To access the configurations, complete the following steps:

1. Click **Security > Secure administration, applications, and infrastructure**.
2. Under Java Authentication and Authorization Service, click **Application logins**.

The WSLogin module defines a login configuration and the LoginModule implementation that can be used by applications in general.

The ClientContainer module defines a login configuration and the LoginModule implementation that is similar to the WSLogin module, but enforces the requirements of the WebSphere Application Server client container.

The DefaultPrincipalMapping module defines a special LoginModule that is typically used by Java 2 Connector to map an authenticated WebSphere Application Server user identity to a set of user authentication data (user ID and password) for the specified back-end enterprise information system (EIS). For more information about Java 2 Connector and the DefaultMappingModule, see the Java 2 Security section.

A new JAAS login configuration can be added and modified using the administrative console. The changes are saved in the cell-level security document and are available to all managed application servers. An application server restart is required for the changes to take effect at runtime and for the client container login configuration to be made available.

WebSphere Application Server also reads JAAS configuration information from the `wsjaas.conf` file under the properties subdirectory of the root directory under which WebSphere Application Server is installed. Changes made to the `wsjaas.conf` file are used only by the local application server and take effect after the application server restarts. The JAAS configuration in the WebSphere Application Server configuration API security document takes precedence over that defined in the `wsjaas.conf` file. A configuration entry in the `wsjaas.conf` is overridden by an entry of the same alias name in the WebSphere Application Server configuration API security document.

The Java Authentication and Authorization Service (JAAS) login configuration entries in the administrative console are propagated to the server runtime when they are created, not when the configuration is saved. However, the deleted JAAS login configuration entries are not removed from the server runtime. To remove the entries, save the new configuration, then stop and restart the server.

The Samples Gallery provides a JAAS login sample that demonstrates how to use JAAS with WebSphere Application Server. The sample uses a server-side login with JAAS to authenticate a user with the security runtime for WebSphere Application Server. The sample demonstrates the following technology:

- Java 2 Platform, Enterprise Edition (J2EE) Java Authentication and Authorization Service (JAAS)
- JAAS for WebSphere Application Server
- WebSphere Application Server security

The form login sample is a component of the technology samples. For more information on how to access the form login sample, see [Accessing the Samples \(Samples Gallery\)](#).

Configuration entry settings for Java Authentication and Authorization Service

Use this page to specify a list of Java Authentication and Authorization Service (JAAS) login configurations for the application code to use, including Java 2 Platform, Enterprise Edition (J2EE) components such as enterprise beans, JavaServer Pages (JSP) files, servlets, resource adapters, and message-driven beans (MDBs).

To view this administrative console page, complete the following steps:

1. Click **Security > Secure administration, applications, and infrastructure**.
2. Under Authentication, click **Java Authentication and Authorization Service > Application logins**.

Read the JAAS specifications before you begin defining additional login modules for authenticating to the application server security run time. You can define additional login configurations for your applications. However, if the application server LoginModule `com.ibm.ws.security.common.auth.module.WSLoginModuleImpl` module is not used or the LoginModule module does not produce a credential that is recognized by the application server. The application server security run time cannot use the authenticated subject from these login configurations for an authorization check for resource access.

You must invoke Java client programs that use Java Authentication and Authorization Service (JAAS) for authentication with a JAAS configuration file that is specified. The application server supplies the default JAAS configuration file in the `profile_root/properties/wsjaas_client.conf` file. This configuration file is set in the `launchClient Qshell` script.

ClientContainer:

Specifies the login configuration used by the client container application, which uses the CallbackHandler API that is defined in the client container deployment descriptor.

The ClientContainer configuration is the default login configuration for the application server. Do not remove this default, as other applications that use it fail.

Default: ClientContainer

DefaultPrincipalMapping:

Specifies the login configuration that is used by Java 2 Connectors to map users to principals that are defined in the J2C authentication data entries.

The ClientContainer configuration is the default login configuration for the application server. Do not remove this default, as other applications that use it fail.

Default: ClientContainer

WSLogin:

Indicates whether all of the applications can use the WSLogin configuration to perform authentication for the application server security run time.

This login configuration does not honor the CallbackHandler handler that is defined in the client container deployment descriptor. To use this functionality, use the ClientContainer login configuration.

The WSLLogin configuration is the default login configuration for the application server. Do not remove this default because other administrative applications that use it fail. This login configuration authenticates users for the application server security run time. Use the credentials from the authenticated subject that are returned from this login configuration as an authorization check for access to application server resources.

Default: ClientContainer

System login configuration entry settings for Java Authentication and Authorization Service

Use this page to specify a list of Java Authentication and Authorization Service (JAAS) system login configurations.

To view this administrative console page, complete the following steps:

1. Click **Security > Secure administration, applications, and infrastructure**.
2. Under Authentication, click **Java Authentication and Authorization Service > System logins**.

Read the Java Authentication and Authorization Service documentation before you begin defining additional login modules for authenticating to the application server security runtime. Do not remove the following system login modules:

- RMI_INBOUND
- WEB_INBOUND
- DEFAULT
- RMI_OUTBOUND
- SWAM
- wssecurity.IDAssertion
- wssecurity.signature
- wssecurity.PKCS7
- wssecurity.PkiPath
- wssecurity.UsernameToken
- wssecurity.X509BST
- LTPA
- LTPA_WEB

RMI_INBOUND, WEB_INBOUND, DEFAULT:

Processes inbound login requests for Remote Method Invocation (RMI), Web applications, and most of the other login protocols.

RMI_INBOUND

This login configuration handles logins for inbound RMI requests. Typically, these logins are requests for authenticated access to Enterprise JavaBeans (EJB) files. When using the RMI connector, these logins might be requests for Java Management Extensions (JMX).

WEB_INBOUND

This login configuration handles logins for Web application requests, which include servlets and JavaServer Pages (JSP) files. This login configuration can interact with the output that is generated from a trust association interceptor (TAI), if configured. The Subject that is passed into the WEB_INBOUND login configuration might contain objects that are generated by the TAI.

DEFAULT

This login configuration handles the logins for inbound requests that are made by most of the other protocols and internal authentications.

These three login configurations will pass in the following callback information, which is handled by the login modules within these configurations. These callbacks are not passed in at the same time. However, the combination of these callbacks determines how the application server authenticates the user.

Callback

```
callbacks[0] = new javax.security.auth.callback.  
NameCallback("Username: ");
```

Responsibility

Collects the user name that is provided during a login. This information can be the user name for the following types of logins:

- User name and password login, which is known as *basic authentication*.
- User name only for identity assertion.

Callback

```
callbacks[1] = new javax.security.auth.callback.  
PasswordCallback("Password: ", false);
```

Responsibility

Collects the password that is provided during a login.

Callback

```
callbacks[2] = new com.ibm.websphere.security.auth.callback.  
WSCredTokenCallbackImpl("Credential Token: ");
```

Responsibility

Collects the Lightweight Third Party Authentication (LTPA) token or other token type during a login. Typically, this information is present when a user name and a password are not present.

Callback

```
callbacks[3] = new com.ibm.wsspi.security.auth.callback.  
WSTokenHolderCallback("Authz Token List: ");
```

Responsibility

Collects the ArrayList list of the TokenHolder objects that are returned from the call to the WSOpaqueTokenHelper. The callback uses the createTokenHolderListFromOpaqueToken method with the Common Secure Interoperability version 2 (CSIv2) authorization token as input.

Restriction: This callback is present only when the **Security Attribute Propagation** option is enabled and this login is a propagation login. In a propagation login, sufficient security attributes are propagated with the request to prevent having to access the user registry for additional attributes. You must enable security attribute propagation for both the outbound and inbound authentication.

You can enable the **Security attribute propagation** option for CSIv2 outbound authentication by completing the following steps:

1. Click **Security > Secure administration, applications, and infrastructure**.
2. Under Authentication, expand RMI/IIOP security and click **CSIv2 outbound authentication**.
3. Enable the **Security attribute propagation** option.

You can enable the **Security attribute propagation** option for CSIv2 inbound authentication by completing the following steps:

1. Click **Security > Secure administration, applications, and infrastructure**.

2. Under Authentication, expand RMI/IIOP security and click **CSiv2 inbound authentication**.
3. Enable the **Security attribute propagation** option.

In system login configurations, the application server authenticates the user based upon the information that is collected by the callbacks. However, a custom login module does not need to act upon any of these callbacks. The following list explains the typical combinations of these callbacks:

- The `callbacks[0] = new javax.security.auth.callback.NameCallback("Username: ");` callback only
This callback occurs for CSiv2 identity assertion; Web and CSiv2 X509 certificate logins; old-style trust association interceptor logins, and so on. In Web and CSiv2 X509 certificate logins, the application server maps the certificate to a user name. This callback is used by any login type that establishes trust with the user name only.
- Both the `callbacks[0] = new javax.security.auth.callback.NameCallback("Username: ");` callback and the `callbacks[1] = new javax.security.auth.callback.PasswordCallback("Password: ", false);` callbacks.

This combination of callbacks is typical for basic authentication logins. Most user authentications occur using these two callbacks.

- The `callbacks[2] = new com.ibm.websphere.security.auth.callback.WSCredTokenCallbackImpl("Credential Token: ");` only
This callback is used to validate a Lightweight Third Party Authentication (LTPA) token. This validation typically occurs during a single sign-on (SSO) or downstream login. Any time a request originates from the application server, instead of a pure client, the LTPA token flows to the target server. For single sign-on (SSO), the LTPA token is received in the cookie and the token is used for login. If a custom login module needs the user name from an LTPA token, the module can use the following method to retrieve the unique ID from the token:

```
com.ibm.wsspi.security.token.WSSecurityPropagationHelper.  
validateLTPAToken(byte[])
```

After retrieving the unique ID, use the following method to get the user name:

```
com.ibm.wsspi.security.token.WSSecurityPropagationHelper.  
getUserFromUniqueID(uniqueID)
```

Important: Any time a custom login module is plugged in ahead of the application server login modules and it changes the identity using a credential mapping service, it is important that this login module validates the LTPA token, if present. Calling the following method is sufficient to validate the trust in the LTPA token:

```
com.ibm.wsspi.security.token.WSSecurityPropagationHelper.  
validateLTPAToken(byte[])
```

The receiving server must have the same LTPA keys as the sending server for this validation to be successful. A security exposure is possible if you do not validate this LTPA token, when present.

- A combination of any of the previously mentioned callbacks plus the `callbacks[3] = new com.ibm.wsspi.security.auth.callback.WSTokenHolderCallback("Authz Token List: ");` callback.
This callback indicates that some propagated attributes arrived at the server. The propagated attributes still require one of the following authentication methods:
 - `callbacks[0] = new javax.security.auth.callback.NameCallback("Username: ");`
 - `callbacks[1] = new javax.security.auth.callback.PasswordCallback("Password: ", false);`

```
– callbacks[2] = new com.ibm.websphere.security.auth.callback.  
  WSCredTokenCallbackImpl("Credential Token: ");
```

If the attributes are added to the Subject from a pure client, then the NameCallback and PasswordCallback callbacks authenticate the information and the objects that are serialized in the token holder are added to the authenticated Subject.

If both CSiv2 identity assertion and propagation are enabled, the application server uses the NameCallback callback and the token holder, which contains all of the propagated attributes, to deserialize most of the objects. The application server uses the NameCallback callback because trust is established with the servers that you indicate in the CSiv2 trusted server list. To specify trusted servers, complete the following steps:

1. Click **Security > Secure administration, applications, and infrastructure**.
2. Under Authentication, click **CSiv2 inbound authentication**.

A custom login module needs to handle custom serialization. For more information, see "Security attribute propagation" in the information center.

In addition to the callbacks that are defined previously, the WEB_INBOUND login configuration can contain the following additional callbacks only:

Callback

```
callbacks[4] = new com.ibm.websphere.security.auth.callback.  
  WSServletRequestCallback("HttpServletRequest: ");
```

Responsibility

Collects the HTTP servlet request object, if presented. This callback enables login modules to retrieve information from the HTTP request to use during a login.

Callback

```
callbacks[5] = new com.ibm.websphere.security.auth.callback.  
  WSServletResponseCallback("HttpServletResponse: ");
```

Responsibility

Collects the HTTP servlet response object, if presented. This callback enables login modules to add information into the HTTP response as a result of the login. For example, login modules might add the SingleSignonCookie cookie to the response.

Callback

```
callbacks[6] = new com.ibm.websphere.security.auth.callback.  
  WSApplicationContextCallback("ApplicationContextCallback: ");
```

Responsibility

Collects the Web application context used during the login. This callback consists of a hashtable, which if present contains the application name and the redirected Web address.

Callback

```
callbacks[7] = new WSRealmNameCallbackImpl("Realm Name: ", <default_realm>);
```

Responsibility

Collects the realm name for the login information. The realm information might not always be provided and should be assumed to be the current realm if it is not provided.

Callback

```
callbacks[8] = new WSX509CertificateChainCallback("X509Certificate[]: ");
```

Responsibility

If the login source is an X509Certificate from SSL client authentication, this callback contains the certificate that was validated by SSL. The ltpaLoginModule calls the same mapping functions as in previous releases. Once it is passed into the login, it provides a custom login module with the opportunity to map the certificate in a custom way. It then perform a hashtable login (see "Example: Custom login module for inbound mapping" on page 312 for an example of a hashtable login).

If you want to use security attribute propagation with the WEB_INBOUND login configuration, you can enable **Web inbound security attribute propagation** option on the Single sign-on panel.

1. Click **Security > Secure administration, applications, and infrastructure**.
2. Under Authentication, expand Web security and click **Single sign-on (SSO)**.
3. Select the **Web inbound security attribute propagation** option.

The following login modules are predefined for the RMI_INBOUND, WEB_INBOUND, and DEFAULT system login configurations. You can add custom login modules before, between, or after any of these login modules, but you cannot remove these predefined login modules:

- `com.ibm.ws.security.server.lm.ltpaLoginModule`

Performs the primary login when attribute propagation is either enabled or disabled. A primary login uses normal authentication information such as a user ID and password, an LTPA token, or a trust association interceptor (TAI) and a certificate distinguished name (DN). If any of the following scenarios are true, this login module is not used and the `com.ibm.ws.security.server.lm.wsMapDefaultInboundLoginModule` module performs the primary login:

- The `java.util.Hashtable` object with the required user attributes is contained in the Subject.
- The `java.util.Hashtable` object with the required user attributes is present in the `sharedState` `HashMap` of the `LoginContext`.
- The `WSTokenHolderCallback` callback is present without a specified password. If a user name and a password are present with a `WSTokenHolderCallback` callback, which indicates propagated information, the request likely originates from either a pure client or a server from a different realm that mapped the existing identity to a user ID and password.

- `com.ibm.ws.security.server.lm.wsMapDefaultInboundLoginModule`

This login module performs the primary login using the normal authentication information if any of the following conditions are true:

- A `java.util.Hashtable` object with required user attributes is contained in the Subject.
- A `java.util.Hashtable` object with required user attributes is present in the `sharedState` `HashMap` of the `LoginContext` context.
- The `WSTokenHolderCallback` callback is present without a `PasswordCallback` callback.

When the `java.util.Hashtable` object is present, the login module maps the object attributes into a valid Subject. When the `WSTokenHolderCallback` callback is present, the login module deserializes the byte token objects and regenerates the serialized Subject contents. The `java.util.Hashtable` hashtable takes precedence over all of the other forms of login. Be careful to avoid duplicating or overriding what the application server might have propagated previously.

By specifying a `java.util.Hashtable` hashtable to take precedence over other authentication information, the custom login module must have already verified the LTPA token, if present, to establish sufficient trust. The custom login module can use the `com.ibm.wsspi.security.token.WSSecurityPropagationHelper.validationLTPAToken(byte[])` method to validate the LTPA token present in the `WSCredTokenCallback` callback. Failure to validate the LTPA token presents a security risk.

For more information on adding a hashtable containing well-known and well-formed attributes used by the application server as sufficient login information, see "Configuring inbound identity mapping" in the information center.

RMI_OUTBOUND:

Processes Remote Method Invocation (RMI) requests that are sent outbound to another server when either the `com.ibm.CSI.rmiOutboundLoginEnabled` or the `com.ibm.CSIOutboundPropagationEnabled` properties are true.

These properties are set in the CSv2 authentication panel. To access the panel, complete the following steps:

1. Click **Security > Secure administration, applications, and infrastructure**.
2. Under Authentication, expand RMI/IOP security and click **CSiv2 outbound authentication**.

To set the `com.ibm.CSI.rmiOutboundLoginEnabled` property, select **Custom outbound mapping**. To set the `com.ibm.CSIOutboundPropagationEnabled` property, select the **Security attribute propagation** option.

This login configuration determines the security capabilities of the target server and its security domain. For example, if the application server Version 5.1.1 or later (or 5.1.0.2 for z/OS) communicates with a Version 5.x Application Server, then the Version 5.1.1 Application Server sends the authentication information only, using an LTPA token, to the Version 5.x Application Server. However, if WebSphere Application Server Version 5.1.1 or later communicates with a Version 5.1.x Application Server, the authentication and authorization information is sent to the receiving application server if propagation is enabled at both the sending and receiving servers. When the application server sends both the authentication and authorization information downstream, the application server removes the need to access the user registry again and look up the security attributes of the user for authorization purposes. Additionally, any custom objects that are added at the sending server are present in the Subject at the downstream server.

The following callback is available in the RMI_OUTBOUND login configuration. You can use the `com.ibm.wsspi.security.csiv2.CSiv2PerformPolicy` object that is returned by this callback to query the security policy for this particular outbound request. This query can help determine if the target realm is different than the current realm and if the application server must map the realm. For more information, see "Configuring outbound mapping to a different target realm" in the information center.

Callback

```
callbacks[0] = new WSPolicyCallback("Protocol Policy Callback: ");
```

Responsibility

Provides protocol-specific policy information for the login modules on this outbound invocation. This information is used to determine the level of security, including the target realm, target security requirements, and coalesced security requirements.

The following method obtains the `CSiv2PerformPolicy` policy from this specific login module:

```
csiv2PerformPolicy = (CSiv2PerformPolicy)  
( (WSPolicyCallback)callbacks[0] ).getProtocolPolicy();
```

A different protocol other than RMI might have a different type of policy object.

The following login module is predefined in the RMI_OUTBOUND login configuration. You can add custom login modules before, between, or after any of these login modules, but you cannot remove these predefined login modules.

com.ibm.ws.security.lm.wsMapCSiv2OutboundLoginModule

Retrieves the following tokens and objects before creating an opaque byte that is sent to another server by using the Common Secure Interoperability Version 2 (CSiv2) authorization token layer:

- Forwardable `com.ibm.wsspi.security.token.Token` implementations from the Subject
- Serializable custom objects from the Subject
- Propagation tokens from the thread

You can use a custom login module prior to this login module to perform credential mapping. However, it is recommended that the login module change the contents of the Subject that is passed in during the login phase. If this recommendation is followed, the login modules are processed after this login module acts on the new Subject contents.

For more information, see "Configuring outbound mapping to a different target realm" in the information center.

SWAM:

Processes login requests in a single server environment when Simple WebSphere Authentication Mechanism (SWAM) is used as the authentication method.

SWAM does not support forwardable credentials. When SWAM is the authentication method, the application server cannot send requests from server to server. In this case, you must use LTPA.

Note: The SWAM login configuration is deprecated and will be removed in a future release.

wssecurity.IDAssertion:

Processes login configuration requests for Web services security using identity assertion.

This login configuration is for Version 5.x systems. For more information, see "Identity assertion authentication method" in the information center.

wssecurity.PKCS7:

Verifies an X.509 certificate with a certificate revocation list in a Public Key Cryptography Standards #7 (PKCS7) object.

This login configuration is for Version 6.0.x systems.

wssecurity.PkiPath:

Verifies an X.509 certificate with a public key infrastructure (PKI) path.

This login configuration is for Version 6.0.x systems.

wssecurity.signature:

Processes login configuration requests for Web services security using digital signature validation.

This login configuration is for Version 5.x systems.

wssecurity.UsernameToken:

Verifies basic authentication (user name and password).

This login configuration is for Version 6.0.x systems.

wssecurity.X509BST:

Verifies an X.509 binary security token (BST) by checking the validity of the certificate and the certificate path.

This login configuration is for Version 6.0.x systems.

LTPA_WEB:

Processes login requests to components in the Web container such as servlets and JavaServer pages (JSP) files.

The `com.ibm.ws.security.web.AuthenLoginModule` login module is predefined in the LTPA login configuration. You can add custom login modules before or after this module in the `LTPA_WEB` login configuration.

The LTPA_WEB login configuration can process the HttpServletRequest object, the HttpServletResponse object, and the Web application name that are passed in using a callback handler. For more information, see "Example: Customizing a server-side Java Authentication and Authorization Service authentication and logon configuration" in the information center.

LTPA:

Processes login requests that are not handled by the LTPA_WEB login configuration.

This login configuration is used by WebSphere Application Server Version 5.1 and previous versions.

The com.ibm.ws.security.server.Im.ItpaLoginModule login module is predefined in the LTPA login configuration. You can add custom login modules before or after this module in the LTPA login configuration. For more information, see "Example: Customizing a server-side Java Authentication and Authorization Service authentication and logon configuration" in the information center.

Login module settings for Java Authentication and Authorization Service

Use this page to define the login module for a Java Authentication and Authorization Service (JAAS) login configuration.

You can define the JAAS login modules for application and system logins. To define these login modules in the administrative console, complete the following steps:

1. Click **Security > Secure administration, applications, and infrastructure**.
2. Under Authentication, click **Java Authentication and Authorization Service > Application logins** or **System logins > alias_name**.
3. Under Additional properties, click **JAAS login modules**.

Module class name:

Specifies the class name of the given login module.

Data type: String

Use login module proxy:

Specifies that the Java Authentication and Authorization Service (JAAS) loads the login module proxy class. JAAS then delegates calls to the login module classes that are defined in the Module class name field.

Use this option when you use both Version 5.x and Version 6 Application Servers in the same environment. If you migrate a Version 5.x Application Server to Version 6, WebSphere Application Server Version 6 automatically enables this option. If you have Version 6 only cells in your environment, you might choose to deselect this option.

Default: Enabled

Proxy class name:

Specifies the name of the proxy login module class.

The default login modules that are defined by the application server use the com.ibm.ws.security.common.auth.module.WSLoginModuleProxy proxy LoginModule class. This proxy class loads the application server login module with the thread context class loader and delegates all the operations to the real login module implementation. The real login module implementation is specified as

the delegate option in the option configuration. The proxy class is needed because the Developer Kit application class loaders do not have visibility of the application server product class loaders.

Data type: String

Authentication strategy:

Specifies the authentication behavior as authentication proceeds down the list of login modules.

A Java Authentication and Authorization Service (JAAS) authentication provider supplies the authentication strategy. In JAAS, an authentication strategy is implemented through the LoginModule interface.

Data type: String
Default: Required
Range: Required, Requisite, Sufficient and Optional

Required

The LoginModule module is required to succeed. Whether authentication succeeds or fails, the process still continues down the LoginModule list for each realm.

Requisite

The LoginModule module is required to succeed. If authentication is successful, the process continues down the LoginModule list in the realm entry. If authentication fails, control immediately returns to the application. Authentication does not proceed down the LoginModule list.

Sufficient

The LoginModule module is not required to succeed. If authentication succeeds, control immediately returns to the application. Authentication does not proceed down the LoginModule list. If authentication fails, the process continues down the list.

Optional

The LoginModule module is not required to succeed. Whether authentication succeeds or fails, the process still continues down the LoginModule list.

Specify additional options by clicking **Custom Properties** under Additional Properties. These name and value pairs are passed to the login modules during initialization. This process is one of the mechanisms that is used to pass information to login modules.

Module order:

Specifies the order in which the Java Authentication and Authorization Service (JAAS) login modules are processed.

Click **Set Order** to change the processing order of the login modules.

Login module order settings for Java Authentication and Authorization Service

Use this page to specify the order in which the application server processes the login configuration modules.

You can specify the order of the login modules for application and system logins. To define these login modules in the administrative console, complete the following steps:

1. Click **Security > Secure administration, applications, and infrastructure**.
2. Under Authentication, click **Java Authentication and Authorization Service > Application logins** or **System logins > alias**. You can create a new configuration by clicking **New**.
3. Under Additional properties, click **JAAS login modules**.
4. Click **Set order**.

When you select one of the JAAS login module class names, you can move that class name up and down the list. After you click **OK** and save the changes, the new order is reflected on either the Application login configuration or the System login configuration panel.

Login configuration settings for Java Authentication and Authorization Service

Use this page to configure application login configurations.

To view this administrative console page, complete the following steps:

1. Click **Security > Secure administration, applications, and infrastructure**.
2. Under Authentication, click **Java Authentication and Authorization Service > Application logins or System logins > alias_name**.

Click **Apply** to save changes and to add the extra node name that precedes the original alias name. Clicking **OK** does not save the new changes in the security.xml file.

Alias:

Specifies the alias name of the application login.

Do not use the forward slash character (/) in the alias name when defining JAAS login configuration entries. The JAAS login configuration parser cannot process the forward slash character.

Data type: String

Managing J2EE Connector Architecture authentication data entries

This task creates and deletes Java 2 Connector (J2C) authentication data entries.

Java 2 Platform, Enterprise Edition (J2EE) Connector authentication data entries are used by resource adapters and Java DataBase Connectivity (JDBC) data sources. A J2EE Connector authentication data entry contains authentication data, which includes the following information:

Alias An identifier that identifies the authentication data entry. When configuring resource adapters or data sources, the administrator can specify which authentication data to choose using the corresponding alias.

User ID

A user identity of the intended security domain. For example, if a particular authentication data entry is used to open a new connection to DB2, this entry contains a DB2 user identity.

Password

The password of the user identity is encoded in the configuration repository.

Description

A short text description.

1. Delete a J2C authentication data entry.
 - a. Click **Security > Secure administration, applications, and infrastructure**.
 - b. Under Java Authentication and Authorization Service, click **J2C authentication data**. The **J2C Authentication Data Entries** panel is displayed.
 - c. Select the check boxes for the entries to delete and click **Delete**. Before deleting or removing an authentication data entry, make sure that it is not used or referenced by any resource adapter or data source. If the deleted authentication data entry is used or referenced by a resource, the application that uses the resource adapter or the data source fails to connect to the resources.
2. Create a new J2C authentication data entry.
 - a. Click **Security > Secure administration, applications, and infrastructure**.
 - b. Under Java Authentication and Authorization Service, click **J2C authentication data**. The **J2C Authentication Data Entries** panel is displayed.
 - c. Click **New**.

- d. Enter a unique alias, a valid user ID, a valid password, and a short description (optional).
- e. Click **OK** or **Apply**. No validation for the user ID and password is required.
- f. Click **Save**.

Make sure that a file synchronized operation is performed to propagate the changes to other nodes.

A new J2C authentication data entry is created or an old entry is removed. The newly created entry is visible without restarting the application server process to use in the data source definition. But the entry is only in effect after the server is restarted. Specifically, the authentication data is loaded by an application server when starting an application and is shared among applications in the same application server.

If you create or update a data source that points to a newly created J2C authentication data alias, the test connection fails to connect until you restart the deployment manager. After you restart the deployment manager, the J2C authentication data is reflected in the run-time configuration. Any changes to the J2C authentication data fields require a deployment manager restart for the changes to take effect. The node agent must also be restarted.

This step defines authentication data that you can share among resource adapters and data sources. Use the authentication data entry that is defined in the resource adapters or the data sources.

Java 2 Connector authentication data entry settings:

Use this page as a central place for administrators to define authentication data, which includes user identities and passwords. These values can reference authentication data entries by resource adapters, data sources, and other configurations that require authentication data using an alias.

You can display this page directly from the Java Authentication and Authorization Service (JAAS) configuration page or from other pages for resources that use J2EE Connector (J2C) authentication data entries. To view this administrative page, complete the following steps:

1. Click **Security > Secure administration, applications, and infrastructure**.
2. Under Authentication, click **Java Authentication and Authorization Service > J2C authentication data**.

Deleting authentication data entries: Be careful when deleting authentication data entries. If the deleted authentication data is used by other configurations, the initializing resources process fails.

Define a new authentication data entry by clicking **New**.

Alias:

Specifies the name of the authentication data entry.

Data type:	String
Units:	String
Default:	None

User ID:

Specifies the user identity.

Data type:	String
-------------------	--------

Password:

Specifies the password that is associated with the user identity.

This field is not available on the collections panel. However, the panel is available when you create a new J2C authentication data entry.

Data type: String

Description:

Specifies an optional description of the authentication data entry. For example, this authentication data entry is used to connect to DB2.

Data type: String

J2C principal mapping modules:

You can develop your own J2EE Connector (J2C) mapping module if your application requires more sophisticated mapping functions. The mapping login module that you might have developed on WebSphere Application Server Version 5.x is still supported in WebSphere Application Server Version 6.0.x and later.

You can use the Version 5.x login modules in the connection factory mapping configuration. These login modules can also be used in the reference mapping configuration for the resource manager connection factory. A version 5.x mapping login module is not able to use the custom mapping properties.

If you want to develop a new mapping login module in Version 6.0.x and later, use the programming interface that is described in the following sections.

transition: Migrate your Version 5.x mapping login module to use the new programming model and the new custom properties as well as the mapping configuration isolation at application scope. Note that mapping login modules that are developed using WebSphere Application Server Version 6.0.x cannot be used in the deprecated mapping configuration for the resource connection factory.

Invoking the login module for the resource reference mapping

A `com.ibm.wsspi.security.auth.callback.WSMappingCallbackHandler` class, which implements the `javax.security.auth.callback.CallbackHandler` interface, is a new WebSphere Application Service Provider Programming Interface (SPI) in WebSphere Application Server Version 6.0.x.

Application code uses the `com.ibm.wsspi.security.auth.callback.WSMappingCallbackHandlerFactory` helper class to retrieve a `CallbackHandler` object:

```
package com.ibm.wsspi.security.auth.callback;

public class WSMappingCallbackHandlerFactory {
    private WSMappingCallbackHandlerFactory;
    public static CallbackHandler getMappingCallbackHandler(
ManagedConnectionFactory mcf,
HashMap mappingProperties);
}
```

The `WSMappingCallbackHandler` class implements the `CallbackHandler` interface:

```
package com.ibm.wsspi.security.auth.callback;

public class WSMappingCallbackHandler implements CallbackHandler {
    public WSMappingCallbackHandler(ManagedConnectionFactory mcf,
```

```

HashMap mappingProperties);
public void handle(Callback[] callbacks) throws IOException,
    UnsupportedCallbackException;
}

```

The `WSMappingCallbackHandler` handler can manage two new callback types that are defined in Version 6.0.x:

```

com.ibm.wsspi.security.auth.callback.WSManagedConnectionFactoryCallback
com.ibm.wsspi.security.auth.callback.WSMappingPropertiesCallback

```

The new login modules use the two callback types that are used at the reference mapping configuration for the resource manager connection factory. The `WSManagedConnectionFactoryCallback` callback provides a `ManagedConnectionFactory` instance that you set in the `PasswordCredential` credential. With this setting, the `ManagedConnectionFactory` instance can determine whether a `PasswordCredential` instance is used for signon to the target Enterprise Information Systems (EIS) instance. The `WSMappingPropertiesCallback` callback provides a hash map that contains custom mapping properties. The `com.ibm.mapping.authDataAlias` property name is reserved for setting the authentication data alias.

The WebSphere Application Server `WSMappingCallbackHandle` handle continues to support the two WebSphere Application Server Version 5.x callback types that older mapping login modules can use. The two callbacks defined can be used only by login modules that the login configuration uses at the connection factory. For backward compatibility, WebSphere Application Server Version 6.0.x and later passes the authentication data alias, if defined in the list of custom properties under the `com.ibm.mapping.authDataAlias` property name using the `WSAuthDataAliasCallback` callback to Version 5.x login modules:

```

com.ibm.ws.security.auth.j2c.WSManagedConnectionFactoryCallback
com.ibm.ws.security.auth.j2c.WSAuthDataAliasCallback

```

Invoking the login module for the connection factory mapping

The `WSPrincipalMappingCallbackHandler` class handles two callback types:

```

com.ibm.wsspi.security.auth.callback.WSManagedConnectionFactoryCallback
com.ibm.wsspi.security.auth.callback.WSMappingPropertiesCallback

```

The `WSPrincipalMappingCallbackHandler` handler and the two callbacks are deprecated in WebSphere Application Server Version 6.

Passing the mapping properties for the resource reference to the mapping login module

You can pass arbitrary custom properties to your mapping login module. The following example shows how the WebSphere Application Server default mapping login module looks for the authentication data alias property.

```

try {
    wspm_callbackHandler.handle(callbacks);
    String userID = null;
    String password = null;
    String alias = null;
    wspm_properties = ((WSMappingPropertiesCallback)callbacks[1]).getProperties();

    if (wspm_properties != null) {
        alias = (String) wspm_properties.get(com.ibm.wsspi.security.auth.callback.
            Constants.MAPPING_ALIAS);
        if (alias != null) {
            alias = alias.trim();
        }
    }
} catch (UnsupportedCallbackException unsupportedcallbackexception) {
    . . . // error handling
}

```

The default mapping login module for WebSphere Application Server Version 6.0.x requires one mapping property to define the authentication data alias. The mapping property, which is called `MAPPING_ALIAS`, is defined in the `Constants.class` file in the `com.ibm.wsspi.security.auth.callback` package.

```
MAPPING_ALIAS = "com.ibm.mapping.authDataAlias"
```

When you click **Use default method > Select authentication data entry authentication** on the Map resource references to resources panel, the administrative console automatically creates a `MAPPING_ALIAS` entry with the selected authentication data alias value in the mapping properties. If you create your own custom login configuration and then use the default mapping login module, you must set this property manually on the mapping properties for the resource factory reference.

In a custom login module, you can use the `WSSubject.getRunAsSubject` method to retrieve the subject that represents the identity of the current running thread. The identity of the current running thread is known as the *RunAs* identity. The *RunAs* subject typically contains a `WSPrincipal` principal in the principal set and a `WSCredential` credential in the public credential set. The subject instance that is created by your mapping module contains a `Principal` instance in the principals set and a `PasswordCredential` credential or an `org.ietf.jgss.GSSCredential` instance in the set of private credentials.

The `GenericCredential` interface that is defined in Java Cryptography Architecture (JCA) Specification Version 1.0 is removed in the JCA Version 1.5 specification. The `GenericCredential` interface is supported by WebSphere Application Server Version 6.0.x to support older resource adapters that might be programmed to the `GenericCredential` interface.

Customizing an application login to perform an identity assertion

Using the Java Authentication and Authorization Service (JAAS) login framework, you can create a JAAS login configuration that can be used to perform login to an identity assertion.

You can allow an application or system provider to perform an identity assertion with trust validation. To do this, you use the JAAS login framework, where trust validation is accomplished in one login module and credential creation is accomplished in another module. The two custom login modules allow you to create a JAAS login configuration that can be used to perform a login to an identity assertion.

Two custom login modules are required:

User implemented trust association login module (trust validation)

The user implemented trust association login module performs whatever trust verification the user requires. When trust is verified, the trust verification status and the login identity should be put into a map in the share state of the login module so that the credential creation login module can use the information. This map should be stored in the property:

```
com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule.state  
(which consists of)
```

```
com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule.trusted  
(which is set to true if trusted and false if not trusted)
```

```
com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule.principal  
(which contains the principal of the identity)
```

```
com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule.certificates  
(which contains the certificate of the identity)
```

Identity assertion login module (credential creation)

The `com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule` performs the

credential creation. This module relies on the trust state information being in the login context's shared state. This login module is protected by the Java 2 security runtime permissions for:

- `com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule.initialize`
- `com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule.login`

The identity assertion login module looks for the trust information in the shared state property, `com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule.state`, which contains the trust status and the identity to login and should include:

`com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule.trusted`
(which when **true** indicates trusted and **false** when not trusted)

`com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule.principal`
(which contains the principal of the identity to login, if using a principal)

`com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule.certificates`
(which contains a array of a certificate chain that contains the identity to login, if using a certificate)

A `WSLoginFailedException` is returned if the state, trust, or identity information is missing. The login module then performs a login of the identity, and the subject will contain the new identity

1. Delegate trust validation to a user implemented plug point. Trust validation must be accomplished in a custom login module. This custom login module should perform any trust validation required, then set the trust and identity information in the shared state to be passed on to the identity assertion login module. A map is required in the shared state key, `com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule.state`. If the state is missing then a `WSLoginFailedException` is thrown by the `IdentityAssertionLoginModule`. This map must include:
 - A trust key called `com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule.trust`. If the key is set to **true**, then trust is established. If the key is set to **false**, then no trust is established. If the trust key is not set to true, then the `IdentityAssertionLoginModule` will throw a `WSLoginFailedException`.
 - An identity key is set: A `java.security.Principal` can be set in the `com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule.principal` key.
 - Or a `java.security.cert.X509Certificate[]` can be set in the `com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule.certificates` key

If both a principal and certificate are supplied, then the principal is used and a warning is issued.

2. Create a new JAAS configuration for application logins The JAAS configuration will contain the user implemented trust validation custom login module and the `IdentityAssertionLoginModule`. Then to configure an application login configuration, perform the following on the administration console:
 - a. Expand **Security > Secure administration, applications, and infrastructure**
 - b. Expand **Java authentication and authorization services > Application logins**
 - c. Select **New**.
 - d. Give the JAAS configuration an alias.
 - e. Click **Apply**.
 - f. Select **JAAS Login Modules**
 - g. Select **New**.
 - h. Enter the **Module class name** of the user implemented trust validation custom login module.
 - i. Click **Apply**.
 - j. Enter the **Module class name** of `com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule`

- k. Make sure the **Module class name** classes are in the correct order. The user implemented trust validation login module should be first and the IdentityAssertionLoginModule should be the second class in the list.
- l. Click **Save**.

This JAAS configuration is then used by the application to perform an Identity Assertion.

3. Perform the programmable identity assertion. A program can now use the JAAS login configuration to perform a programmatic identity assertion. The application program can create a login context for the JAAS configuration created in step 2, then login to that login context with the identity they would assert to. If the login is successful then that identity can be set in the current running process. Here is an example of how such code would operate:

```
MyCallbackHandler handler = new MyCallbackHandler(new MyPrincipal("Joe"));
LoginContext lc = new LoginContext("MyAppLoginConfig", handler);
lc.login(); //assume successful
Subject s = lc.getSubject();
WSSubject.setRunAsSubject(s);
// From here on , the runas identity is "Joe"
```

Using the JAAS login framework and two user implemented login modules, you can create a JAAS login configuration that can be used to perform login to an identity assertion.

Customization of a server-side Java Authentication and Authorization Service authentication and login configuration

WebSphere Application Server supports plugging in a custom Java Authentication and Authorization Service (JAAS) login module before or after the WebSphere Application Server system login module. However, WebSphere Application Server does not support the replacement of the WebSphere Application Server system login modules, which are used to create the WSCredential credential and WSPincipal principal in the Subject. By using a custom login module, you can either make additional authentication decisions or add information to the Subject to make additional, potentially finer-grained, authorization decisions inside a Java 2 Platform, Enterprise Edition (J2EE) application.

WebSphere Application Server enables you to propagate information downstream that is added to the Subject by a custom login module. For more information, see “Security attribute propagation” on page 188. To determine which login configuration to use for plugging in your custom login modules, see the descriptions of the login configurations that are located in the “System login configuration entry settings for Java Authentication and Authorization Service” on page 573.

WebSphere Application Server supports the modification of the system login configuration through the administrative console and by using the wsadmin scripting utility. To configure the system login configuration using the administrative console, click **Security > Secure administration, applications, and infrastructure**. Under Java Authentication and Authorization Service, click **System logins**.

Refer to the following code sample to configure a system login configuration using the wsadmin tool. The following sample Jacl script adds a custom login module into the Lightweight Third-party Authentication (LTPA) Web system login configuration:

Attention: Lines 32, 33, and 34 in the following code sample are split into two lines.

```
1. #####
2. #
3. # Open security.xml
4. #
5. #####
6.
7.
8. set sec [$AdminConfig getid /Cell:hillside/Security:/]
9.
10.
```

```

11. #####
12. #
13. # Locate systemLoginConfig
14. #
15. #####
16.
17.
18. set slc [$AdminConfig showAttribute $sec systemLoginConfig]
19.
20. set entries [lindex [$AdminConfig showAttribute $slc entries] 0]
21.
22.
23. #####
24. #
25. # Append a new LoginModule to LTPA_WEB
26. #
27. #####
28.
29. foreach entry $entries {
30. set alias [$AdminConfig showAttribute $entry alias]
31. if {$alias == "LTPA_WEB"} {
32. set newJAASLoginModuleId [$AdminConfig create JAASLoginModule
    $entry {moduleName
    "com.ibm.ws.security.common.auth.module.proxy.WSLoginModuleProxy"}}]
33. set newPropertyId [$AdminConfig create Property
    $newJAASLoginModuleId {{name delegate}{value
    "com.ABC.security.auth.CustomLoginModule"}}]
34. $AdminConfig modify $newJAASLoginModuleId
    {{authenticationStrategy REQUIRED}}
35. break
36. }
37. }
38.
39.
40. #####
41. #
42. # save the change
43. #
44. #####
45.
46. $AdminConfig save
47.

```

Attention: The wsadmin scripting utility inserts a new object to the end of the list. To insert the custom login module before the AuthenLoginModule login module, delete the AuthenLoginModule login module and recreate it after inserting the custom login module. Save the sample script into a sample.jacl file, and run the sample script using the following command:

```
wsadmin -f sample.jacl
```

You can use the following sample Jacl script to remove the current LTPA_WEB login configuration and all the login modules:

```

48. #####
49. #
50. # Open security.xml
51. #
52. #####
53.
54.
55. set sec [$AdminConfig getid /Cell:hillside/Security:/]
56.
57.

```

```

58. #####
59. #
60. # Locate systemLoginConfig
61. #
62. #####
63.
64.
65. set slc [$AdminConfig showAttribute $sec systemLoginConfig]
66.
67. set entries [lindex [$AdminConfig showAttribute $slc entries] 0]
68.
69.
70. #####
71. #
72. # Remove the LTPA_WEB login configuration
73. #
74. #####
75.
76. foreach entry $entries {
77.     set alias [$AdminConfig showAttribute $entry alias]
78.     if {$alias == "LTPA_WEB"} {
79.         $AdminConfig remove $entry
80.         break
81.     }
82. }
83.
84.
85. #####
86. #
87. # save the change
88. #
89. #####
90.
91. $AdminConfig save

```

You can use the following sample Jacl script to recover the original LTPA_WEB configuration:

Attention: Lines 122, 124, and 126 in the following code sample are split into two or more lines for illustrative purposes only.

```

92. #####
93. #
94. # Open security.xml
95. #
96. #####
97.
98.
99. set sec [$AdminConfig getid /Cell:hillside/Security:/]
100.
101.
102. #####
103. #
104. # Locate systemLoginConfig
105. #
106. #####
107.
108.
109. set slc [$AdminConfig showAttribute $sec systemLoginConfig]
110.
111. set entries [lindex [$AdminConfig showAttribute $slc entries] 0]
112.
113.
114.

```

```

115. #####

134. #
135. #####
136.
137. $AdminConfig save

```

The WebSphere Application Server Version ItpaLoginModule and AuthenLoginModule login modules use the shared state to save state information so that custom login modules can modify the information. The ItpaLoginModule login module initializes the callback array in the login method using the following code. The callback array is created by the ItpaLoginModule login module only if an array is not defined in the shared state area. In the following code sample, the error handling code is removed to make the sample concise. If you insert a custom login module before the ItpaLoginModule login module, the custom login module might follow the same style to save the callback into the shared state.

Attention: In the following code sample, several lines of code are split into two lines for illustrative purposes only.

```

138.     Callback callbacks[] = null;
139.     if (!sharedState.containsKey(
        com.ibm.wsspi.security.auth.callback.Constants.
        CALLBACK_KEY)) {
140.         callbacks = new Callback[3];
141.         callbacks[0] = new NameCallback("Username: ");
142.         callbacks[1] = new PasswordCallback("Password: ", false);
143.         callbacks[2] = new com.ibm.websphere.security.auth.callback.
            WSCredTokenCallbackImpl( "Credential Token: ");
144.         try {
145.             callbackHandler.handle(callbacks);
146.         } catch (java.io.IOException e) {
147.             . . .
148.         } catch (UnsupportedCallbackException uce) {
149.             . . .
150.         }
151.         sharedState.put(
            com.ibm.wsspi.security.auth.callback.Constants.CALLBACK_KEY,
            callbacks);
152.     } else {

```

```

153.         callbacks = (Callback [])
                sharedState.get( com.ibm.wsspi.security.auth.callback.
154.         Constants.CALLBACK_KEY);
    }

```

The `ltpaLoginModule` and `AuthenLoginModule` login modules generate both a `WSPPrincipal` object and a `WSCredential` object to represent the authenticated user identity and security credentials. The `WSPPrincipal` and `WSCredential` objects also are saved in the shared state. A JAAS login uses a two-phase commit protocol.

First, the login methods in login modules, which are configured in the login configuration, are called. Then, their commit methods are called. A custom login module, which is inserted after the `ltpaLoginModule` and the `AuthenLoginModule` login modules, can modify the `WSPPrincipal` and `WSCredential` objects before these objects are committed. The `WSCredential` and `WSPPrincipal` objects must exist in the Subject after the login is completed. Without these objects in the Subject, WebSphere Application Server run-time code rejects the Subject to make security decisions.

`AuthenLoginModule` uses the following code to initialize the callback array:

Attention: In the following code sample, several lines of code are split into two lines for illustrative purposes only.

```

155.     Callback callbacks[] = null;
156.     if (!sharedState.containsKey(
                com.ibm.wsspi.security.auth.callback.Constants.
                CALLBACK_KEY)) {
157.         callbacks = new Callback[6];
158.         callbacks[0] = new NameCallback("Username: ");
159.         callbacks[1] = new PasswordCallback("Password: ", false);
160.         callbacks[2] =
                new com.ibm.websphere.security.auth.callback.WSCredTokenCallbackImpl(
                "Credential Token: ");
161.         callbacks[3] =
                new com.ibm.wsspi.security.auth.callback.WSServletRequestCallback(
                "HttpServletRequest: ");
162.         callbacks[4] =
                new com.ibm.wsspi.security.auth.callback.WSServletResponseCallback(
                "HttpServletResponse: ");
163.         callbacks[5] =
                new com.ibm.wsspi.security.auth.callback.WSApplicationContextCallback(
                "ApplicationContextCallback: ");
164.         try {
165.             callbackHandler.handle(callbacks);
166.         } catch (java.io.IOException e) {
167.             . . .
168.         } catch (UnsupportedCallbackException uce {
169.             . . .
170.         }
171.         sharedState.put( com.ibm.wsspi.security.auth.callback.
                Constants.CALLBACK_KEY, callbacks);
172.     } else {
173.         callbacks = (Callback []) sharedState.get(
                com.ibm.wsspi.security.auth.callback.
                Constants.CALLBACK_KEY);
174.     }

```

Three more objects, which contain callback information for the login, are passed from the Web container to the `AuthenLoginModule` login module: a `java.util.Map`, an `HttpServletRequest`, and an `HttpServletResponse` object. These objects represent the Web application context. The WebSphere Application Server Version 5.1 application context, `java.util.Map` object, contains the application name and the error page web

address. You can obtain the application context, `java.util.Map` object, by calling the `getContext` method on the `WSAppContextCallback` object. The `java.util.Map` object is created with the following deployment descriptor information.

Attention: In the following code sample, several lines of code are split into two lines for illustrative purposes only.

```
175.     HashMap appContext = new HashMap(2);
176.     appContext.put(
        com.ibm.wsspi.security.auth.callback.Constants.WEB_APP_NAME,
        web_application_name);
177.     appContext.put(
        com.ibm.wsspi.security.auth.callback.Constants.REDIRECT_URL,
        errorPage);
```

The application name and the `HttpServletRequest` object might be read by the custom login module to perform mapping functions. The error page of the form-based login might be modified by a custom login module. In addition to the JAAS framework, WebSphere Application Server supports the trust association interface (TAI).

Other credential types and information can be added to the caller `Subject` during the authentication process using a custom login module. The third-party credentials in the caller `Subject` are managed by WebSphere Application Server as part of the security context. The caller `Subject` is bound to the running thread during the request processing. When a Web or an Enterprise JavaBeans (EJB) module is configured to use the caller identity, the user identity is propagated to the downstream service in an EJB request. The `WSCredential` credential and any third-party credentials in the caller `Subject` are not propagated downstream. Instead, some of the information can be regenerated at the target server based on the propagated identity. Add third-party credentials to the caller `Subject` at the authentication stage. The caller `Subject`, which is returned from the `WSSubject.getCallerSubject` method, is read-only and cannot be modified. For more information on the `WSSubject` subject, see “Example: Getting the caller subject from the thread” on page 603.

Custom login module development for a system login configuration

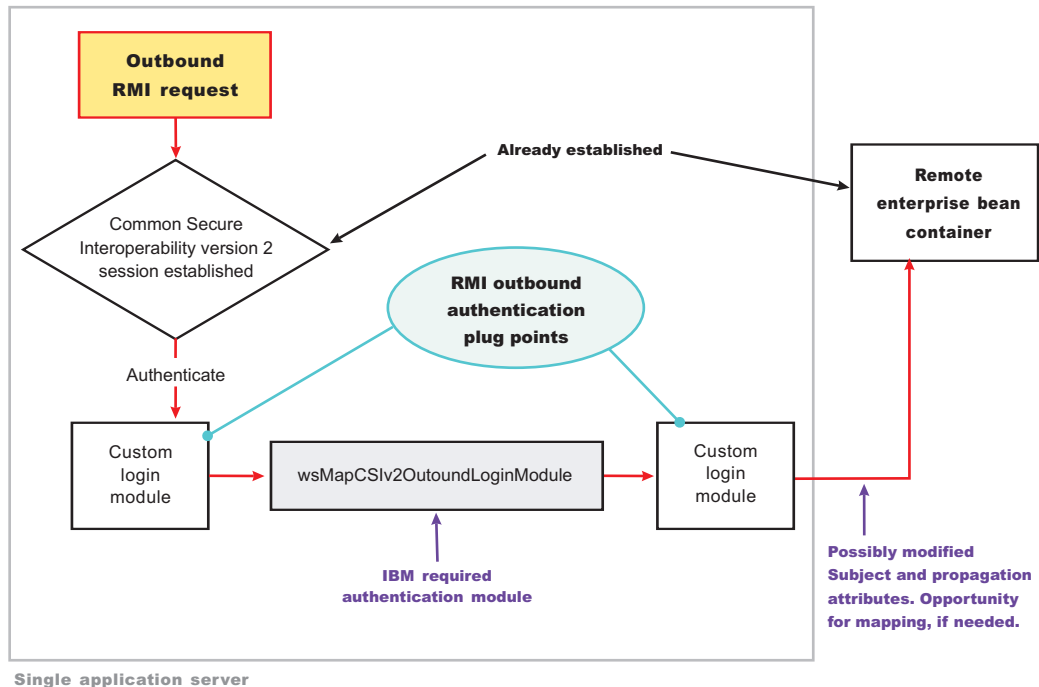

For WebSphere Application Server, multiple Java Authentication and Authorization Service (JAAS) plug-in points exist for configuring system logins. WebSphere Application Server uses system login configurations to authenticate incoming requests, outgoing requests, and internal server logins.

Application login configurations are called by Java 2 Platform, Enterprise Edition (J2EE) applications for obtaining a `Subject` that is based on specific authentication information. This login configuration enables the application to associate the `Subject` with a specific protected remote action. The `Subject` is picked up on the outbound request processing. The following list identifies the main system plug-in points. If you write a login module that adds information to the `Subject` of a system login, these are the main login configurations to plug in:

- `WEB_INBOUND`
- `RMI_OUTBOUND`
- `RMI_INBOUND`
- `DEFAULT`

WEB_INBOUND login configuration

The `WEB_INBOUND` login configuration authenticates Web requests. Figure 1 shows an example of a configuration using a trust association interceptor (TAI) that creates a `Subject` with the initial information that is passed into the `WEB_INBOUND` login configuration. If the trust association interceptor is not configured, the authentication process goes directly to the `WEB_INBOUND` system login configuration,

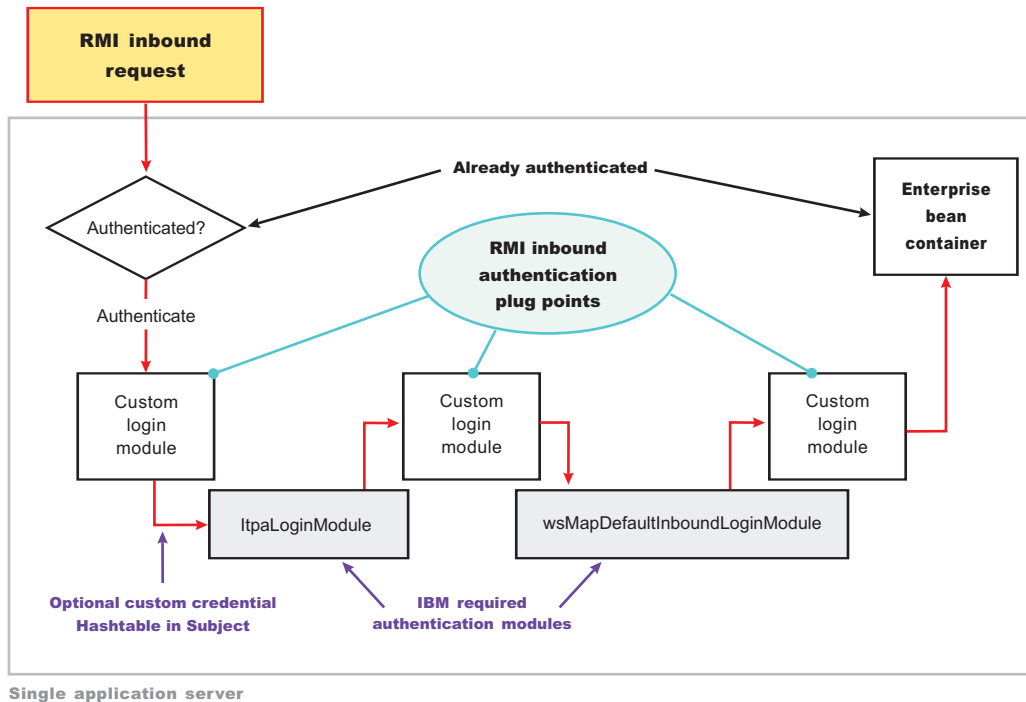

For more information on the RMI_OUTBOUND login configuration, including its associated callbacks, see "RMI_OUTBOUND" in "System login configuration entry settings for Java Authentication and Authorization Service" on page 573.

RMI_INBOUND login configuration

The RMI_INBOUND login configuration is a plug point that handles inbound authentication for enterprise bean requests. WebSphere Application Server uses this plug point for either an initial login or a propagation login. For more information about these two login types, see "Security attribute propagation" on page 188. During a propagation login, this plug point is used to deserialize the information that is received from an upstream server. A custom login module can use this plug point to change the identity, handle custom tokens, add custom objects into the Subject, and so on. For more information on changing the identity using a Hashtable object, which is referenced in figure 3, see "Configuring inbound identity mapping" on page 306. Figure 3 shows where you can plug in custom login modules and shows that the ltpaLoginModule and the wsMapDefaultInboundLoginModule login modules are required.

Figure 3

For more information on the RMI_INBOUND login configuration, including its associated callbacks, see "RMI_INBOUND, WEB_INBOUND, DEFAULT" in "System login configuration entry settings for Java Authentication and Authorization Service" on page 573.

DEFAULT login configuration

The DEFAULT login configuration is a plug point that handles all of the other types of authentication requests, including administrative SOAP requests and internal authentication of the server ID. Propagation logins typically do not occur at this plug point.

For more information on the DEFAULT login configuration including its associated callbacks, see "RMI_INBOUND, WEB_INBOUND, DEFAULT" in "System login configuration entry settings for Java Authentication and Authorization Service" on page 573.

Writing a login module

When you write a login module that plugs into a WebSphere Application Server application login or system login configuration, read the JAAS programming model, which is located at: <http://java.sun.com/products/jaas>. The JAAS programming model provides basic information about JAAS. However, before writing a login module for the WebSphere Application Server environment, read the following sections in this article:

- Useable callbacks
- Shared state variables
- Initial versus propagation logins
- Sample custom login module

Useable callbacks

Each login configuration must document the callbacks that are recognized by the login configuration. However, the callbacks are not always passed data. The login configuration must contain logic to know when specific information is present and how to use the information. For example, if you write a custom login module that can plug into all four of the pre-configured system login configurations mentioned

previously, three sets of callbacks might be presented to authenticate a request. Other callbacks might be present for other reasons, including propagation and making other information available to the login configuration.

Login information can be presented in the following combinations:

User name (NameCallback) and password (PasswordCallback)

This information is a typical authentication combination.

User name only (NameCallback)

This information is used for identity assertion, trust association interceptor (TAI) logins, and certificate logins.

Token (WSCredTokenCallbackImpl)

This information is for Lightweight Third Party Authentication (LTPA) token validation.

Propagation token list (WSTokenHolderCallback)

This information is used for a propagation login.

The first three combinations are used for typical authentication. However, when the WSTokenHolderCallback callback is present in addition to one of the first three information combinations, the login is called a *propagation login*. A propagation login means that some security attributes are propagated to this server from another server. The servers can reuse these security attributes if the authentication information validates successfully. In some cases, a WSTokenHolderCallback callback might not have sufficient attributes for a full login. Check the requiresLogin method on the WSTokenHolderCallback callback to determine if a new login is required. You can always ignore the information returned by the requiresLogin method, but, as a result, you might duplicate information. The following list contains the callbacks that might be present in the system login configurations. The list includes the callback name and a description of their responsibility.

callbacks[0] = new javax.security.auth.callback.NameCallback("Username: ");

This callback handler collects the user name for the login. The result can be the user name for a basic authentication login (user name and password) or a user name for an identity assertion login.

callbacks[1] = new javax.security.auth.callback.PasswordCallback("Password: ", false);

This callback handler collects the password for the login.

callbacks[2] = new

com.ibm.websphere.security.auth.callback.WSCredTokenCallbackImpl("Credential Token: ");

This callback handler collects the Lightweight Third Party Authentication (LTPA) token or other token type for the login. This callback handler is typically present when a user name and password are not present.

callbacks[3] = new com.ibm.wsspi.security.auth.callback.WSTokenHolderCallback("Authz Token List: ");

This callback handler collects the ArrayList of TokenHolder objects that are returned from a call to the WSOpaqueTokenHelper.createTokenHolderListFromOpaqueToken API using the Common Secure Interoperability Version 2 (CSIV2) authorization token as input.

callbacks[4] = new

com.ibm.websphere.security.auth.callback.WSServletRequestCallback("HttpServletRequest: ");

This callback handler collects the HTTP servlet request object, if present. This callback handler enables login modules to get information from the HTTP request for use in the login, and is presented from the WEB_INBOUND login configuration only.

callbacks[5] = new

com.ibm.websphere.security.auth.callback.WSServletResponseCallback("HttpServletResponse: ");

This callback handler collects the HTTP servlet response object, if present. This callback handler enables login modules to put information into the HTTP response as a result of the login. An

example of this situation might be adding the SingleSignonCookie cookie to the response. This callback handler is presented from the WEB_INBOUND login configuration only.

callbacks[6] = new

com.ibm.websphere.security.auth.callback.WSAppContextCallback("ApplicationContextCallback: ");

This callback handler collects the Web application context that is used during the login. This callback handler consists of a HashMap object, which contains the application name and the redirect web address, if present. The callback handler is presented from the WEB_INBOUND login configuration only.

callbacks[7] = new WSRealmNameCallbackImpl("Realm Name: ", default_realm);

This callback handler collects the realm name for the login information. The realm information might not always be provided. If the realm information is not provided, assume that it is the current realm.

callbacks[8] = new WSX509CertificateChainCallback("X509Certificate[]: ");

This callback handler contains the certificate that was validated by Secure Sockets Layer (SSL) if the login source is an X509Certificate from SSL client authentication. The ItpaLoginModule calls the same mapping functions as WebSphere Application Server releases prior to version 6.1.

However, having it passed into the login gives a custom login module the opportunity to map the certificate in a custom way. Then, it performs a Hashtable login. See "Configuring inbound identity mapping" on page 306 for more information on a Hashtable login.

Shared state variables

Shared state variables are used to share information between login modules during the login phase. The following list contains recommendations for using the shared state variables:

- When you have a custom login module, use the shared state variables to communicate to a WebSphere Application Server login module using a documented shared state variable, as shown in the following table.
- Try not to update the Subject until the commit phase. If you call the abort method, you must remove any objects added to the Subject.
- Enable the login module that adds information into the shared state Map during login to remove this information during commit in case the same shared state is used for another login.
- If a stop or logout occurs, clean up the information in the login configuration for the shared state and the Subject.

The `com.ibm.wsspi.security.token.AttributeNameConstants.WSCREDENTIAL_PROPERTIES_KEY` shared state variable can inform the WebSphere Application Server login configurations about asserted privilege attributes. This variable references the `com.ibm.wsspi.security.cred.propertiesObject` property. Associate a `java.util.Hashtable` with this property. This hashtable contains properties that are used by WebSphere Application Server for login purposes and ignores the callback information. This hashtable enables a custom login module, which is carried out first in the login configuration to map user identities or enable WebSphere Application Server to avoid making unnecessary user registry calls if you already have the required information. For more information, see "Configuring inbound identity mapping" on page 306.

If you want to access the objects that WebSphere Application Server creates during a login, refer to the following shared state variables. The variables are set in the following login modules: `ItpaLoginModule`, `swamLoginModule`, and `wsMapDefaultInboundLoginModule`.

Shared state variable

`com.ibm.wsspi.security.auth.callback.Constants.WSPRINCIPAL_KEY`

Purpose

Specifies the `com.ibm.websphere.security.auth.WSPPrincipal` object. See the WebSphere

Application Server API documentation for application programming interface (API) usage. This shared state variable is for read-only purposes. Do not set this variable in the shared state for custom login modules.

The login module in which variables are set

ltpaLoginModule, swamLoginModule, and wsMapDefaultInboundLoginModule

Shared state variable

com.ibm.wsspi.security.auth.callback.Constants.WSCREDENTIAL_KEY

Purpose

Specifies the com.ibm.websphere.security.cred.WSCredential object. See the WebSphere Application Server API documentation for API usage. This shared state variable is for read-only purposes. Do not set this variable in the shared state for custom login modules.

Login module in which variables are set

wsMapDefaultInboundLoginModule

Shared state variable

com.ibm.wsspi.security.auth.callback.Constants.WSAUTHZTOKEN_KEY

Purpose

Specifies the default com.ibm.wsspi.security.token.AuthorizationToken object. Login modules can use this object to set custom attributes plugged in after the wsMapDefaultInboundLoginModule login module. The information set here is propagated downstream and is available to the application. See the WebSphere Application Server API documentation for API usage.

Initial versus propagation logins

As mentioned previously, some logins are considered initial logins because of the following reasons:

- It is the first time authentication information is presented to WebSphere Application Server.
- The login information is received from a server that does not propagate security attributes so this information must be gathered from a user registry.

Other logins are considered propagation logins when a WSTokenHolderCallback callback is present and contains sufficient information from a sending server to recreate all the required objects needed by WebSphere Application Server runtime. In cases where there is sufficient information for the WebSphere Application Server runtime, the information you might add to the Subject is likely to exist from the previous login. To verify if your object is present, you can get access to the ArrayList object that is present in the WSTokenHolderCallback callback, and search through this list looking at each TokenHolder getName method. This search is used to determine if WebSphere Application Server is deserializing your custom object during this login. Check the class name returned from the getName method using the String startsWith method because the runtime might add additional information at the end of the name to know which Subject is set to add the custom object after deserialization.

The following code snippet can be used in your login() method to determine when sufficient information is present. For another example, see “Configuring inbound identity mapping” on page 306.

```
// This is a hint provided by WebSphere Application Server that
// sufficient propagation information does not exist and, therefore,
// a login is required to provide the sufficient information. In this
// situation, a Hashtable login might be used.
boolean requiresLogin = ((com.ibm.wsspi.security.auth.callback.
WSTokenHolderCallback) callbacks[1]).requiresLogin();

if (requiresLogin)
{
// Check to see if your object exists in the TokenHolder list,
if not, add it.
java.util.ArrayList authzTokenList = ((WSTokenHolderCallback) callbacks[6]).
getTokenHolderList();boolean found = false;
```

```

if (authzTokenList != null)
{
Iterator tokenListIterator = authzTokenList.iterator();

while (tokenListIterator.hasNext())
{
com.ibm.wsspi.security.token.TokenHolder th = (com.ibm.wsspi.security.token.
TokenHolder) tokenListIterator.next();

if (th != null && th.getName().startsWith("com.acme.myCustomClass"))
{
found=true;
break;
}
}
if (!found)
{
// go ahead and add your custom object.
}
}
else
{
// This code indicates that sufficient propagation information is present.
// User registry calls are not needed by WebSphere Application Server to
// create a valid Subject. This code might be a no-op in your login module.
}
}

```

Sample custom login module

You can use the following sample to get ideas on how to use some of the callbacks and shared state variables.

```

{
// Defines your login module variables
com.ibm.wsspi.security.token.AuthenticationToken customAuthzToken = null;
com.ibm.wsspi.security.token.AuthenticationToken defaultAuthzToken = null;
com.ibm.websphere.security.cred.WSCredential credential = null;
com.ibm.websphere.security.auth.WSPPrincipal principal = null;
private javax.security.auth.Subject _subject;
private javax.security.auth.callback.CallbackHandler _callbackHandler;
private java.util.Map _sharedState;
private java.util.Map _options;

public void initialize(Subject subject, CallbackHandler callbackHandler,
Map sharedState, Map options)
{
_subject = subject;
_callbackHandler = callbackHandler;
_sharedState = sharedState;
_options = options;
}

public boolean login() throws LoginException
{
boolean succeeded = true;

// Gets the CALLBACK information
javax.security.auth.callback.Callback callbacks[] = new javax.security.
auth.callback.Callback[7];
callbacks[0] = new javax.security.auth.callback.NameCallback(
"Username: ");
callbacks[1] = new javax.security.auth.callback.PasswordCallback(
"Password: ", false);
callbacks[2] = new com.ibm.websphere.security.auth.callback.
WSCredTokenCallbackImpl ("Credential Token: ");

```

```

callbacks[3] = new com.ibm.wsspi.security.auth.callback.
    WSServletRequestCallback ("HttpServletRequest: ");
callbacks[4] = new com.ibm.wsspi.security.auth.callback.
    WSServletResponseCallback ("HttpServletRequest: ");
callbacks[5] = new com.ibm.wsspi.security.auth.callback.
    WServletResponseCallback ("ApplicationContextCallback: ");
callbacks[6] = new com.ibm.wsspi.security.auth.callback.
    WTokenHolderCallback ("Authz Token List: ");

try
{
    callbackHandler.handle(callbacks);
}
catch (Exception e)
{
    // Handles exceptions
    throw new WLoginFailedException (e.getMessage(), e);
}

// Sees which callbacks contain information
uid = ((NameCallback) callbacks[0]).getName();
char password[] = ((PasswordCallback) callbacks[1]).getPassword();
byte[] credToken = ((WSCredTokenCallbackImpl) callbacks[2]).getCredToken();
javax.servlet.http.HttpServletRequest request = ((WServletRequestCallback)
    callbacks[3]).getHttpServletRequest();
javax.servlet.http.HttpServletResponse response = ((WServletResponseCallback)
    callbacks[4]).getHttpServletResponse();
java.util.Map appContext = ((WApplicationContextCallback)
    callbacks[5]).getContext();
java.util.List authzTokenList = ((WTokenHolderCallback)
    callbacks[6]).getTokenHolderList();

// Gets the SHARED STATE information
principal = (WSPrincipal) _sharedState.get(com.ibm.wsspi.security.
    auth.callback.Constants.WSPRINCIPAL_KEY);
credential = (WSCredential) _sharedState.get(com.ibm.wsspi.security.
    auth.callback.Constants.WSCREDENTIAL_KEY);
defaultAuthzToken = (AuthorizationToken) _sharedState.get(com.ibm.
    wsspi.security.auth.callback.Constants.WSAUTHZTOKEN_KEY);

// What you tend to do with this information depends upon the scenario
// that you are trying to accomplish. This example demonstrates how to
// access various different information:
// - Determine if a login is initial versus propagation
// - Deserialize a custom authorization token (For more information, see
//

```

“Security attribute propagation” on page 188 // - Add a new custom authorization token (For more information, see // “Security attribute propagation” on page 188 // - Look for a WSCredential and read attributes, if found. // - Look for a WSPrincipal and read attributes, if found. // - Look for a default AuthorizationToken and add attributes, if found. // - Read the header attributes from the HttpServletRequest, if found. // - Add an attribute to the HttpServletResponse, if found. // - Get the Web application name from the appContext, if found. // - Determines if a login is initial versus propagation. This is most // useful when login module is first. boolean requiresLogin = ((WTokenHolderCallback) callbacks[6]).requiresLogin(); // initial login - asserts privilege attributes based on user identity if (requiresLogin) { // If you are validating a token from another server, there is an // application programming interface (API) to get the uniqueID from it. if (credToken != null && uid == null) { try { String uniqueID = WSSecurityPropagationHelper.validateLTPAToken(credToken); String realm = WSSecurityPropagationHelper.getRealmFromUniqueID(uniqueID); // Now set it to the UID so you can use that to either map or // login with. uid = WSSecurityPropagationHelper.getUserFromUniqueID(uniqueID); } catch (Exception e) { // handle exception } } // Adds a Hashtable to shared state. // Note: You can perform custom mapping on the NameCallback value returned // to change the identity based upon your own mapping rules. uid = mapUser(uid); // Gets the default InitialContext for this server. javax.naming.InitialContext ctx = new javax.naming.InitialContext(); // Gets the local UserRegistry object.

```

com.ibm.websphere.security.UserRegistry reg = (com.ibm.websphere.security. UserRegistry)
ctx.lookup("UserRegistry"); // Gets the user registry uniqueID based on the uid specified in the //
NameCallback. String uniqueid = reg.getUniqueUserId(uid); uid =
WSSecurityPropagationHelper.getUserFromUniqueID (uniqueid); // Gets the display name from the user
registry based on the uniqueID. String securityName = reg.getUserSecurityName(uid); // Gets the groups
associated with this uniqueID. java.util.List groupList = reg.getUniqueGroupIds(uid); // Creates the
java.util.Hashtable with the information you gathered from // the UserRegistry. java.util.Hashtable hashtable
= new java.util.Hashtable(); hashtable.put(com.ibm.wsspi.security.token.AttributeNameConstants.
WSCREDENTIAL_UNIQUEID, uniqueid);
hashtable.put(com.ibm.wsspi.security.token.AttributeNameConstants. WSCREDENTIAL_SECURITYNAME,
securityName); hashtable.put(com.ibm.wsspi.security.token.AttributeNameConstants.
WSCREDENTIAL_GROUPS, groupList); // Adds a cache key that is used as part of the lookup mechanism
for // the created Subject. The cache key can be an Object, but should // implement the toString() method.
Make sure the cacheKey contains // enough information to scope it to the user and any additional //
attributes that you use. If you do not specify this property the // Subject is scoped to the
WSCREDENTIAL_UNIQUEID returned, by default.
hashtable.put(com.ibm.wsspi.security.token.AttributeNameConstants. WSCREDENTIAL_CACHE_KEY,
"myCustomAttribute" + uniqueid); // Adds the hashtable to the sharedState of the Subject.
_sharedState.put(com.ibm.wsspi.security.token.AttributeNameConstants.
WSCREDENTIAL_PROPERTIES_KEY,hashtable); } // propagation login - process propagated tokens else
{ // - Deserializes a custom authorization token. For more information, see // "Security attribute
propagation" on page 188. // This can be done at any login module plug in point (first, // middle, or last). if
(authzTokenList != null) { // Iterates through the list looking for your custom token for (int i=0;
i<authzTokenList.size(); i++) { TokenHolder tokenHolder = (TokenHolder)authzTokenList.get(i); // Looks for
the name and version of your custom AuthorizationToken // implementation if
(tokenHolder.getName().equals("com.ibm.websphere.security.token. CustomAuthorizationTokenImpl") &&
tokenHolder.getVersion() == 1) { // Passes the bytes into your custom AuthorizationToken constructor // to
deserialize customAuthzToken = new com.ibm.websphere.security.token.
CustomAuthorizationTokenImpl(tokenHolder.getBytes()); } } // - Adds a new custom authorization token
(For more information, // see "Security attribute propagation" on page 188) // This can be done at any login
module plug in point (first, middle, // or last). else { // Gets the PRINCIPAL from the default
AuthenticationToken. This must // match all of the tokens. defaultAuthToken =

getPrivateCredentials(). contains(customAuthzTokenPriv))) {
_subject.getPrivateCredentials().remove(customAuthzTokenPriv); } } catch (Exception e) { throw new
WSLoginFailedException (e.getMessage(), e); } return null; } }); } catch (Exception e) { throw new
WSLoginFailedException (e.getMessage(), e); } } return succeeded; } }

```

After developing your custom login module for a system login configuration, you can configure the system login using either the administrative console or using the wsadmin utility. To configure the system login using the administrative console, click **Security > Secure administration, applications, and infrastructure**. Under Java Authentication and Authorization Service, click **System logins**. For more information on using the wsadmin utility for system login configuration, see “Customization of a server-side Java Authentication and Authorization Service authentication and login configuration” on page 588. Also refer to the “Customization of a server-side Java Authentication and Authorization Service authentication and login configuration” on page 588 article for information on system login modules and to determine whether to add additional login modules.

Example: Getting the caller subject from the thread

The Caller subject (or “received subject”) contains the user authentication information that is used in the call for this request. This subject is returned after issuing the WSSubject.getCallerSubject application programming interface (API) to prevent replacing existing objects. The subject is marked read-only. This API can be used to get access to the WSCredential credential so that you can put or set data in the hashmap within the credential.

Most data within the subject is not propagated downstream to another server. Only the credential token within the WSCredential credential is propagated downstream and a new caller subject is generated.

```
try
{
    javax.security.auth.Subject caller_subject;
    com.ibm.websphere.security.cred.WSCredential caller_cred;

    caller_subject = com.ibm.websphere.security.auth.WSSubject.getCallerSubject();

    if (caller_subject != null)
    {
        caller_cred = caller_subject.getPublicCredentials
            (com.ibm.websphere.security.cred.WSCredential.class).iterator().next();
        String CALLERDATA = (String) caller_cred.get ("MYKEY");
        System.out.println("My data from the Caller credential is: " + CALLERDATA);
    }
}
catch (WSSecurityException e)
{
    // log error
}
catch (Exception e)
{
    // log error
}
```

Requirement: You need the following Java 2 security permissions to run this API: permission `javax.security.auth.AuthPermission "wssecurity.getCallerSubject;"`.

Example: Getting the RunAs subject from the thread

The RunAs subject or invocation subject contains the user authentication information for the RunAs mode set in the application deployment descriptor for this method.

The RunAs subject (or invocation subject) contains the user authentication information for the RunAs mode set in the application deployment descriptor for this method. This subject is marked read-only when returned from the WSSubject.getRunAsSubject application programming interface (API) to prevent replacing existing objects. You can use this API to get access to the WSCredential credential, which is documented in the API documentation, so that you can put or set data in the hashmap within the credential.

Most data within the Subject is not propagated downstream to another server. Only the credential token within the WSCredential credential is propagated downstream and a new Caller subject is generated.

```
try
{
    javax.security.auth.Subject runas_subject;
    com.ibm.websphere.security.cred.WSCredential runas_cred;

    runas_subject = com.ibm.websphere.security.auth.WSSubject.getRunAsSubject();

    if (runas_subject != null)
    {
        runas_cred = runas_subject.getPublicCredentials(
            com.ibm.websphere.security.cred.WSCredential.class).iterator().next();
        String RUNASDATA = (String) runas_cred.get ("MYKEY");
        System.out.println("My data from the RunAs credential is: " + RUNASDATA );
    }
}
```

```

}
catch (WSSecurityException e)
{
    // log error
}
catch (Exception e)
{
    // log error
}

```

Requirements: You need the Java 2 security permissions to run this API: permission `javax.security.auth.AuthPermission "wssecurity.getRunAsSubject;"`.

Example: Overriding the RunAs subject on the thread

To extend the function that is provided by the Java Authentication and Authorization Service (JAAS) application programming interfaces (APIs), you can set the RunAs subject or invocation subject with a different valid entry that is used for outbound requests on this running thread.

This extension gives you the flexibility to associate the Subject with all the remote calls on this thread whether you use a `WSSubject.doAs` method to associate the subject with the remote action. For example:

```

try
{
    javax.security.auth.Subject runas_subject, caller_subject;

    runas_subject = com.ibm.websphere.security.auth.WSSubject.getRunAsSubject();
    caller_subject = com.ibm.websphere.security.auth.WSSubject.getCallerSubject();

    // set a new RunAs subject for the thread, overriding the one declaratively set
    com.ibm.websphere.security.auth.WSSubject.setRunAsSubject(caller_subject);

    // do some remote calls

    // restore back to the previous runAsSubject
    com.ibm.websphere.security.auth.WSSubject.setRunAsSubject(runas_subject);
}
catch (WSSecurityException e)
{
    // log error
}
catch (Exception e)
{
    // log error
}

```

You need the following Java 2 security permissions to run these APIs:

- permission `javax.security.auth.AuthPermission "wssecurity.getRunAsSubject;"`;
- permission `javax.security.auth.AuthPermission "wssecurity.getCallerSubject;"`;
- permission `javax.security.auth.AuthPermission "wssecurity.setRunAsSubject;"`;

Example: User revocation from a cache

In WebSphere Application Server, Version 5.0.2 and later, revocation of a user from the security cache using an MBean interface is supported.

This procedure can be called from another JACL script. The following Java Command Language (JACL) revokes a user when given the realm and the user ID, and cycles through all the security administration

MBean instances that are returned for the entire cell when run from the deployment manager wsadmin command. The command also purges the user from the cache during each process.

Note: When a user is removed from authentication cache, the user can still login to WebSphere Application Server at any time. Removing the cache only removes the user from the runtime cache. It does not remove the user from registry, nor does it lock out the user.

Attention: In some of the following lines of code, the lines are split into two or more lines for illustrative purposes only.

Enabling identity assertion with trust validation

By enabling identity assertion with trust validation, an application can use the JAAS login configuration to perform a programmatic identity assertion.

To enable an identity assertion with trust validation, follow these steps:

1. Create a custom login module to perform a trust validation. The login module must set trust and identity information in the shared state, which is then passed on to the IdentityAssertionLoginModule. The trust and identity information is stored in a map in the shared state under the key, `com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule.state`. If this key is missing from the shared state, a `WSLoginFailedException` error is thrown by the IdentityAssertionLoginModule module. The custom login module should include the following:
 - A trust key named `com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule.trust`. If the trust key is set to `true`, trust is established. If the trust key is set to `false`, the IdentityAssertionLoginModule module creates a `WSLoginFailedException` error.
 - The identity of the `java.security.Principal` type set in the `com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule.principal` key.
 - The identity in the form of a `java.security.cert.X509Certificate[]` certificate set in the `com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule.certificates` key.

Note: If both a principal and a certificate are supplied, the principal is used, and a warning is issued.

2. Create a new Java Authentication and Authorization Service (JAAS) configuration for application logins. It contains the user-implemented trust validation custom login module and the IdentityAssertionLoginModule module. To configure an application login configuration from the administrative console, complete the following steps:
 - a. Click **Security > Secure administration, applications, and infrastructure**.
 - b. Under Java Authentication and Authorization Service, click **Application logins > New**.
 - c. Supply the JAAS configuration with an alias, and then click **Apply**.
 - d. Under Additional properties, click **JAAS Login Modules > New**.
 - e. Enter the module class name of the user-implemented trust validation custom login module, and then click **Apply**.
 - f. Enter the `com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule` module class name.
 - g. Make sure that the module class name classes are in the correct order. The user-implemented trust validation login module must be the first class in the list, and the IdentityAssertionLoginModule module must be the second class.
 - h. Click **Save**. The new JAAS configuration is used by the application to perform an identity assertion.

An application can now use the JAAS login configuration to perform a programmatic identity assertion. The application can create a login context for the JAAS configuration created in step 2, then login to that login context with the identity it asserts to. If the login is successful, that identity can be set in the current running process, as in the following example:

```

MyCallbackHandler handler = new MyCallbackHandler(new MyPrincipal("Joe"));
LoginContext lc = new LoginContext("MyAppLoginConfig", handler);
lc.login(); //assume successful
Subject s = lc.getSubject();
WSSubject.setRunAsSubject(s);
// From here on, the runas identity is "Joe"

```

Secure transports with JSSE and JCE programming interfaces

This topic provides detailed information about transport security using Java Secure Socket Extension (JSSE) and Java Cryptography Extension (JCE) programming interfaces. Within this topic, there is a description of the IBM version of the Java Cryptography Extension Federal Information Processing Standard (IBMJCE/FIPS).

Java Secure Socket Extension

Java Secure Socket Extension (JSSE) provides the transport security for WebSphere Application Server. JSSE provides the application programming interface (API) framework and the implementation of the APIs for Secure Sockets Layer (SSL) and Transport Layer Security (TLS) protocols, including functionality for data encryption, message integrity, and authentication.

JSSE APIs are integrated into the Java 2 SDK, Standard Edition (J2SDK), Version 5. The API package for JSSE APIs is `javax.net.ssl.*`. Documentation for using JSSE APIs can be found in the J2SE 5 API documentation that is located at <http://java.sun.com/j2se/1.5.0/docs/api/index.html>.

Several JSSE providers ship with the J2SDK Version 5 that comes with WebSphere Application Server. The IBMJSSE provider is used in previous WebSphere Application Server releases. Associated with the IBMJSSE provider is the IBMJSSE/FIPS provider, which is used when FIPS is enabled on the server. Both of these providers do not work with the Java Message Service (JMS) and HTTP transports in WebSphere Application Server Version 6.1. These transports take advantage of the J2SDK Version 5 network input/output (NIO) asynchronous channels.

The HTTP and JMS transports use a new IBMJSSE2 provider. All other transports in WebSphere Application Server Version 6.x currently use the IBMJSSE2 provider, but can be switched to the old IBMJSSE provider, if necessary (specified in the SSL repertoire configuration).

For more information on the new IBMJSSE2 provider, please review the documentation located in the <http://www.ibm.com/developerworks/java/jdk/security/142/jsse2docs.zip> file. After it is unzipped, the JSSE2 Reference Guide can be found at [jsse2Docs/JSSE2RefGuide.html](http://www.ibm.com/developerworks/java/jdk/security/142/jsse2docs/jsse2RefGuide.html), the JSSE2 API documentation can be found at [jsse2Docs/api/index.html](http://www.ibm.com/developerworks/java/jdk/security/142/jsse2docs/api/index.html) and finally, the JSSE2 samples can be found at [jsse2Docs/samples](http://www.ibm.com/developerworks/java/jdk/security/142/jsse2docs/samples).

Customizing Java Secure Socket Extension

You can customize a number of aspects of JSSE by plugging in different implementations of Cryptography Package Provider, X509Certificate and HTTPS protocols, or specifying different default keystore files, key manager factories, and trust manager factories. The following table summarizes which aspects can be customized, what the defaults are, and which mechanisms are used to provide customization. You can customize the following key aspects:

Customizable item	Default	How to customize
X509Certificate	X509Certificate implementation from IBM	The <code>cert.provider.x509v1</code> security property
HTTPS protocol	Implementation from IBM	The <code>java.protocol.handler.pkgs</code> system property
Cryptography Package Provider	IBMJSSE	A <code>security.provider.n=</code> line in security properties file. See description.

Customizable item	Default	How to customize
Default keystore	None	The * javax.net.ssl.keyStore system property
Default truststore	jssecacerts, if it exists. Otherwise, cacerts	The * javax.net.ssl.trustStore system property
Default key manager factory	IbmX509	The ssl.KeyManagerFactory.algorithm security property
Default trust manager factory	IbmX509	The ssl.TrustManagerFactory.algorithm security property

For aspects that you can customize by setting a system property, statically set the system property by using the **-D** option of the **Java** command. You can set the system property using the administrative console, or set the system property dynamically by calling the `java.lang.System.setProperty` method in your code: `System.setProperty(propertyName, "propertyValue")`.

For aspects that you can customize by setting a Java security property, statically specify a security property value in the `profile_root/properties/java.security` properties file. The security property in the `java.security` properties file is `propertyName=propertyValue`. Dynamically set the Java security property by calling the `java.security.Security.setProperty` method in your code.

Application Programming Interface

The JSSE provides a standard application programming interface (API) that is available in packages of the `javax.net` file, `javax.net.ssl` file, and the `javax.security.cert` file. The APIs cover:

- Sockets and SSL sockets
- Factories to create the sockets and SSL sockets
- Secure socket context that acts as a factory for secure socket factories
- Key and trust manager interfaces
- Secure HTTP URL connection classes
- Public key certificate API

You can find more information documented for the JSSE APIs if you access the following information:

Version 1.4.2

1. Access the <http://www.ibm.com/developerworks/java/jdk/security/> Web site.
2. Click **Java 1.4.2**.
3. Click **Javadoc HTML documentation** in the Java Secure Socket Extension (JSSE) Guide section.

Samples using Java Secure Socket Extension

The Java Secure Socket Extension (JSSE) also provides samples to demonstrate its functionality. The Java Secure Socket Extension (JSSE) also provides samples to demonstrate its functionality. You can access the samples in the following location:

Version 1.4.2

1. Access the <http://www.ibm.com/developerworks/java/jdk/security/> Web site.
2. Click **Java 1.4.2**.
3. Click **jsse-docs_samples.zip** in the Java Secure Socket Extension (JSSE) Guide section.

Look for the following files:

Files	Description
ClientJsse.java	Demonstrates a simple client and server interaction using JSSE. All enabled cipher suites are used.
OldServerJsse.java	Back-level samples
ServerPKCS12Jsse.java	Demonstrates a simple client and server interaction using JSSE with the PKCS12 keystore file. All enabled cipher suites are used.
ClientPKCS12Jsse.java	Demonstrates a simple client and server interaction using JSSE with the PKCS12 keystore file. All enabled cipher suites are used.
UseHttps.java	Demonstrates accessing an SSL or non-SSL Web server using the Java protocol handler of the <code>com.ibm.net.ssl.www.protocol</code> class. The URL is specified with the <code>http</code> or <code>https</code> prefix. The HTML that is returned from this site is displayed.

See more instructions in the source code. Follow these instructions before you run the samples.

Permissions for Java 2 security

You might need the following permissions to run an application with JSSE: This list is for reference only.

- `java.util.PropertyPermission "java.protocol.handler.pkgs", "write"`
- `java.lang.RuntimePermission "writeFileDescriptor"`
- `java.lang.RuntimePermission "readFileDescriptor"`
- `java.lang.RuntimePermission "accessClassInPackage.sun.security.x509"`
- `java.io.FilePermission "${user.install.root}/${etc}/.keystore", "read"`
- `java.io.FilePermission "${user.install.root}/${etc}/.truststore", "read"`

For the IBMJSSE provider:

- `java.security.SecurityPermission "putProviderProperty.IBMJSSE"`
- `java.security.SecurityPermission "insertProvider.IBMJSSE"`

For the SUNJSSE provider:

- `java.security.SecurityPermission "putProviderProperty.SunJSSE"`
- `java.security.SecurityPermission "insertProvider.SunJSSE"`

Debugging

By configuring through the `javax.net.debug` system property, JSSE provides the following dynamic debug tracing: `-Djavax.net.debug=true`.

A value of `true` turns on the trace facility, provided that the debug version of JSSE is installed.

Documentation

See the Security: Resources for learning topic for documentation references to JSSE.

JCE

Java Cryptography Extension (JCE) provides cryptographic, key and hash algorithms for WebSphere Application Server. JCE provides a framework and implementations for encryption, key generation, key agreement, and Message Authentication Code (MAC) algorithms. Support for encryption includes symmetric, asymmetric, block and stream ciphers.

IBMJCE

The IBM version of the Java Cryptography Extension (IBMJCE) is an implementation of the JCE cryptographic service provider that is used in WebSphere Application Server. The IBMJCE is similar to SunJCE, except that the IBMJCE offers more algorithms:

- Cipher algorithm (AES, DES, TripleDES, PBEs, Blowfish, and so on)
- Signature algorithm (SHA1withRSA, MD5withRSA, SHA1withDSA)
- Message digest algorithm (MD5, MD2, SHA1, SHA-256, SHA-384, SHA-512)
- Message authentication code (HmacSHA1, HmacMD5)
- Key agreement algorithm (DiffieHellman)
- Random number generation algorithm (IBMSecureRandom, SHA1PRNG)
- Key store (JKS, JCEKS, PKCS12, JCERACFKS [z/OS only])
- Key store (JKS, JCEKS, PKCS12, JCERACFKS [z/OS only])

The IBMJCE belongs to the `com.ibm.crypto.provider.*` packages.

For further information, see the information on JCE on the following web site: <http://www.ibm.com/developerworks/java/jdk/security/142/>.

IBMJCEFIPS

The IBM version of the Java Cryptography Extension Federal Information Processing Standard (IBMJCEFIPS) is an implementation of the JCE cryptographic service provider that is used in WebSphere Application Server. The IBMJCEFIPS service provider implements the following:

- Signature algorithms (SHA1withDSA, SHA1withRSA)
- Cipher algorithms (AES, TripleDES, RSA)
- Key agreement algorithm (DiffieHellman)
- Key (pair) generator (DSA, AES, TripleDES, HmacSHA1, RSA, DiffieHellman)
- Message authentication code (MAC) (HmacSHA1)
- Message digest (MD5, SHA-1, SHA-256, SHA-384, SHA-512)
- Algorithm parameter generator (DiffieHellman, DSA)
- Algorithm parameter (AES, DiffieHellman, DES, TripleDES, DSA)
- Key factory (DiffieHellman, DSA, RSA)
- Secret key factory (AES, TripleDES)
- Certificate (X.509)
- Secure random (IBMSecureRandom)

Application Programming Interface

Java Cryptography Extension (JCE) has a provider-based architecture. Providers can be plugged into the JCE framework by implementing the APIs that are defined by the JCE. The JCE APIs cover:

- Symmetric bulk encryption, such as DES, RC2, and IDEA
- Symmetric stream encryption, such as RC4
- Asymmetric encryption, such as RSA
- Password-based encryption (PBE)
- Key agreement
- Message authentication codes

There is more information documented for the JCE APIs on the <http://www.ibm.com/developerworks/java/jdk/security/> Web site.

Samples using Java Cryptography Extension

There are samples located on the <http://www.ibm.com/developerworks/java/jdk/security/> Web site in the `jceDocs_samples.zip` file. Unzip the file and locate the following samples in the `jceDocs/samples` directory:

File	Description
<code>SampleDSASignature.java</code>	Demonstrates how to generate a pair of DSA keys (a public key and a private key) and use the key to digitally sign a message using the SHA1withDSA algorithm
<code>SampleMarsCrypto.java</code>	Demonstrates how to generate a Mars secret key, and how to do Mars encryption and decryption
<code>SampleMessageDigests.java</code>	Demonstrates how to use the message digest for MD2 and MD5 algorithms
<code>SampleRSACrypto.java</code>	Demonstrates how to generate an RSA key pair, and how to do RSA encryption and decryption
<code>SampleRSASignatures.java</code>	Demonstrates how to generate a pair of RSA keys (a public key and a private key) and use the key to digitally sign a message using the SHA1withRSA algorithm
<code>SampleX509Verification.java</code>	Demonstrates how to verify X509 certificates

Documentation

Refer to the Security: Resources for learning for documentation on JCE.

Configuring Federal Information Processing Standard Java Secure Socket Extension files

Use this topic to configure Federal Information Processing Standard Java Secure Socket Extension files.

In WebSphere Application Server, the Java Secure Socket Extension (JSSE) provider used is the IBMJSSE2 provider. This provider delegates encryption and signature functions to the Java Cryptography Extension (JCE) provider. Consequently, IBMJSSE2 does not need to be Federal Information Processing Standard (FIPS)-approved because it does not perform cryptography. However, the JCE provider requires FIPS-approval.

WebSphere Application Server provides a FIPS-approved IBMJCEFIPS provider that IBMJSSE2 can utilize. The IBMJCEFIPS provider that is shipped in WebSphere Application Server Version 6.1 supports the following SSL ciphers:

- `SSL_RSA_WITH_AES_128_CBC_SHA`
- `SSL_RSA_WITH_3DES_EDE_CBC_SHA`
- `SSL_RSA_FIPS_WITH_3DES_EDE_CBC_SHA`
- `SSL_DHE_RSA_WITH_AES_128_CBC_SHA`
- `SSL_DHE_RSA_WITH_3DES_EDE_CBC_SHA`
- `SSL_DHE_DSS_WITH_AES_128_CBC_SHA`
- `SSL_DHE_DSS_WITH_3DES_EDE_CBC_SHA`

Even though the IBMJSSEFIPS provider is still present, the runtime does not use this provider. If IBMJSSEFIPS is specified as a contextProvider, WebSphere Application Server automatically defaults to the IBMJSSE2 provider (with the IBMJCEFIPS provider) for supporting FIPS. When enabling the **Use the United States Federal Information Processing Standard (FIPS) algorithms** option on the server SSL certificate and key management panel, the runtime always uses IBMJSSE2, despite the contextProvider

that you specify for SSL (IBMJ SSE, IBMJ SSE2 or IBMJ SSE FIPS). Also, because FIPS requires the SSL protocol be TLS, the runtime always uses TLS when FIPS is enabled, regardless of the SSL protocol setting in the SSL repertoire. This simplifies the FIPS configuration in Version 6.1 because an administrator needs to enable only the **Use the United States Federal Information Processing Standard (FIPS) algorithms** option on the server SSL certificate and key management panel to enable all transports using SSL.

1. Click **Security > SSL certificate and key management**.
2. Select the **Use the United States Federal Information Processing Standard (FIPS) algorithms** option and click **Apply**. This option makes IBMJ SSE2 and IBMJ SSE FIPS the active providers.
3. Accommodate Java clients that must access enterprise beans.

Change the `com.ibm.security.useFIPS` property value from `false` to `true` in the `profile_root/properties/ssl.client.props` file.

4. Ensure that the `java.security` includes the provider.

Edit the `java.security` file to insert the IBMJ SSE FIPS provider (`com.ibm.crypto.fips.provider.IBMJ SSE FIPS`) before the IBMJ SSE provider, and also renumber the other providers in the provider list. The IBMJ SSE FIPS provider must be in the `java.security` file provider list.

The `java.security` file is located in the `profile_root/properties` directory.

The IBM SDK `java.security` file looks like the following example after completing this step:

```
security.provider.1=sun.security.provider.Sun
security.provider.2=com.ibm.crypto.provider.IBMJ SSE FIPS
security.provider.3=com.ibm.crypto.provider.IBMJ SSE
security.provider.4=com.ibm.jsse.IBMJ SSE Provider
security.provider.5=com.ibm.jsse2.IBMJ SSE Provider2
security.provider.6=com.ibm.security.jgss.IBMJ GSS Provider
security.provider.7=com.ibm.security.cert.IBM Cert Path
security.provider.8=com.ibm.i5os.jsse.JSSE Provider
#security.provider.8=com.ibm.crypto.pkcs11.provider.IBMPKCS11
security.provider.9=com.ibm.security.jgss.mech.spnego.IBMPNego
```

If you are using the Sun JDK, the `java.security` file looks like the following example after completing this step:

```
security.provider.1=sun.security.provider.Sun
security.provider.2=com.ibm.security.jgss.IBMJ GSS Provider
security.provider.3=com.ibm.crypto.fips.provider.IBMJ SSE FIPS
security.provider.4=com.ibm.crypto.provider.IBMJ SSE
security.provider.5=com.ibm.jsse.IBMJ SSE Provider
security.provider.6=com.ibm.jsse2.IBMJ SSE Provider2
security.provider.7=com.ibm.security.cert.IBM Cert Path
#security.provider.8=com.ibm.crypto.pkcs11.provider.IBMPKCS11
```

After completing these steps, a FIPS-approved JSSE or JCE provider offers increased encryption capabilities. However, when you use FIPS-approved providers:

- By default, Microsoft Internet Explorer might not have TLS enabled. To enable TLS, open the Internet Explorer browser and click **Tools > Internet Options**. On the Advanced tab, select the Use TLS 1.0 option.

Note: Netscape Version 4.7.x and earlier versions might not support TLS.

- IBM Directory Server Version 5.1 (and earlier versions) do not support TLS.
- If you have an administrative client that uses a SOAP connector and you enable FIPS, add the following line to the `profile_root/properties/soap.client.props` file:

```
com.ibm.ssl.contextProvider=IBMJ SSE FIPS
```

- When you select the **Use the Federal Information Processing Standard (FIPS)** option on the SSL certificate and key management panel, the Lightweight Third-Party Authentication (LTPA) token format is not backwards-compatible with previous releases of WebSphere Application Server. However, you can import the LTPA keys from a previous version of the application server.

Note: When enabling FIPS, you cannot configure cryptographic token devices in the SSL repertoires. IBMJSSE2 must use IBMJCEFIPS when utilizing cryptographic services for FIPS.

The following FIPS 140-2 approved cryptographic providers that are the only devices that are supported with the FIPS option:

- IBMJCEFIPS (certificate 376)
- IBM Cryptography for C (ICC) (certificate 384)

The relevant certificates are listed on the NIST Web site: Cryptographic Module Validation Program FIPS 140-1 and FIPS 140-2 Pre-validation List

To unconfigure the FIPS provider, reverse the changes that you made in the previous steps. After you reverse the changes, verify that you have made the following changes to the `sas.client.props`, `soap.client.props`, and `java.security` files:

- In the `ssl.client.props` file, you must change the `com.ibm.security.useFIPS` value to `false`.
- Edit the `java.security` file to remove the FIPS provider and renumber the providers as in the following example:

```
security.provider.1=sun.security.provider.Sun
#security.provider.2=com.ibm.crypto.provider.IBMJCEFIPS
security.provider.2=com.ibm.crypto.provider.IBMJCE
security.provider.3=com.ibm.jsse.IBMJSSEProvider
security.provider.4=com.ibm.jsse2.IBMJSSEProvider2
security.provider.5=com.ibm.security.jgss.IBMJGSSProvider
security.provider.6=com.ibm.security.cert.IBMCertPath
security.provider.7=com.ibm.i5os.jsse.JSSEProvider
#security.provider.8=com.ibm.crypto.pkcs11.provider.IBMPKCS11
security.provider.8=com.ibm.security.jgss.mech.spnego.IBMPNEGO
```

Implementing tokens for security attribute propagation

As part of an extensible architecture, WebSphere Application Server enables you to implement your own tokens in which to propagate security attributes.

The following topics are covered in this section:

- Implementing a custom propagation token
- Implementing a custom authorization token
- Implementing a custom a single sign-on token
- Implementing a custom authentication token
- Propagating a custom Java serializable object

Implementing a custom propagation token

This topic explains how you might create your own propagation token implementation, which is set on the running thread and propagated downstream.

The default propagation token usually is sufficient for propagating attributes that are not user-specific. Consider writing your own implementation if you want to accomplish one of the following tasks:

- Isolate your attributes within your own implementation.
- Serialize the information using custom serialization. You must deserialize the bytes at the target and add that information back on the thread by plugging in a custom login module into the inbound system login configurations. This task also might include encryption and decryption.

To implement a custom propagation token, you must complete the following steps:

1. Write a custom implementation of the PropagationToken interface. Many different methods are available for implementing the PropagationToken interface. However, make sure that the methods that are required by the PropagationToken interface and the token interface are fully implemented.

After you implement this interface, you can place it in the *profile_root/classes* directory. The *profile_root* variable is the directory and name specified for the *profilePath* parameter at profile creation. For more information on classes, see “Creating a classes subdirectory in your profile for custom classes” on page 516.

Tip: All of the token types that are defined by the propagation framework have similar interfaces. The token types are marker interfaces that implement the `com.ibm.wsspi.security.token.Token` interface. This interface defines most of the methods. If you plan to implement more than one token type, consider creating an abstract class that implements the `com.ibm.wsspi.security.token.Token` interface. All of your token implementations, including the propagation token, might extend the abstract class and then most of the work is complete.

To see an implementation of the propagation token, see “Example: `com.ibm.wsspi.security.token.PropagationToken` implementation.”

2. Add and receive the custom propagation token during WebSphere Application Server logins This task is typically accomplished by adding a custom login module to the various application and system login configurations. You also can add the implementation from an application. However, to deserialize the information, you need to plug in a custom login module, which is discussed in “Propagating a custom Java serializable object” on page 649. The `WSSecurityPropagationHelper` class has APIs that are used to set a propagation token on the thread and to retrieve the token from the thread to make updates.

The code sample in “Example: Custom propagation token login module” on page 619 shows how to determine if the login is an initial login or a propagation login. The difference between these login types is whether the `WSTokenHolderCallback` callback contains propagation data. If the callback does not contain propagation data, initialize a new custom propagation token implementation and set it on the thread. If the callback contains propagation data, look for your specific custom propagation token `TokenHolder` instance, convert the byte array back into your customer `PropagationToken` object, and set it back on the thread. The code sample shows both instances.

You can add attributes any time your custom propagation token is added to the thread. If you add attributes between requests and the `getUniqueld` method changes, the Common Secure Interoperability Version 2 (CSlv2) client session is invalidated so that it can send the new information downstream. Adding attributes between requests can affect performance. In many cases, you want the downstream requests to receive the new propagation token information.

To add the custom propagation token to the thread, call the `WSSecurityPropagationHelper.addPropagationToken` token. This call requires the WebSphereRuntimePerMission “setPropagationToken” Java 2 Security permission.

3. Add your custom login module to WebSphere Application Server system login configurations that already contain the `com.ibm.ws.security.server.lm.wsMapDefaultInboundLoginModule` login module for receiving serialized versions of your custom propagation token You can also add this login module to any of the application logins where you might want to generate your custom propagation token on the thread during the login. Alternatively, you can generate the custom `PropagationToken` implementation from within your application. However, to deserialize it, you need to add the implementation to the system login modules.

For information on how to add your custom login module to the existing login configurations, see “Custom login module development for a system login configuration” on page 593

After completing these steps, you have implemented a custom `PropagationToken`.

Example: `com.ibm.wsspi.security.token.PropagationToken` implementation

Use this file to see an example of a propagation token implementation. The following sample code does not extend an abstract class, but implements the `com.ibm.wsspi.security.token.PropagationToken` interface

directly. You can implement the interface directly, but it might cause you to write duplicate code. However, you might choose to implement the interface directly if considerable differences exist between how you handle the various token implementations.

For information on how to implement a custom propagation token, see “Implementing a custom propagation token” on page 613.

```
package com.ibm.websphere.security.token;

import com.ibm.websphere.security.WSSecurityException;

Example: Custom propagation token login module

This example shows how to determine if the login is an initial login or a propagation login.

```

public customLoginModule()
{
    public void initialize(Subject subject, CallbackHandler callbackHandler,
        Map sharedState, Map options)

```

```

{
// (For more information on what to do during initialization, see
// "Custom login module development for a system login configuration" on page 593.)
}

public boolean login() throws LoginException
{
// (For more information on what to do during login, see
// "Custom login module development for a system login configuration" on page 593.)

// Handles the WSTokenHolderCallback to see if this is an initial
// or propagation login.
Callback callbacks[] = new Callback[1];
callbacks[0] = new WSTokenHolderCallback("Authz Token List: ");

try
{
callbackHandler.handle(callbacks);
}
catch (Exception e)
{
// handle exception
}

// Receives the ArrayList of TokenHolder objects (the serialized tokens)
List authzTokenList = ((WSTokenHolderCallback) callbacks[0]).getTokenHolderList();

if (authzTokenList != null)
{
// Iterates through the list looking for your custom token
for (int i=0; i<authzTokenList.size(); i++)
{
TokenHolder tokenHolder = (TokenHolder)authzTokenList.get(i);

// Looks for the name and version of your custom PropagationToken implementation
if (tokenHolder.getName().equals("
        com.ibm.websphere.security.token.CustomPropagationTokenImpl") &&
    tokenHolder.getVersion() == 1)
{
// Passes the bytes into your custom PropagationToken constructor
// to deserialize
customPropToken = new
    com.ibm.websphere.security.token.CustomPropagationTokenImpl(tokenHolder.
        getBytes());

}
}
}
else // This is not a propagation login. Create a new instance of
// your PropagationToken implementation
{
// Adds a new custom propagation token. This is an initial login
customPropToken = new com.ibm.websphere.security.token.CustomPropagationTokenImpl();

// Adds any initial attributes
if (customPropToken != null)
{
customPropToken.addAttribute("key1", "value1");
customPropToken.addAttribute("key1", "value2");
customPropToken.addAttribute("key2", "value1");
customPropToken.addAttribute("key3", "something different");
}
}

// Note: You can add the token to the thread during commit in case
// something happens during the login.
}

```

```

public boolean commit() throws LoginException
{
    // For more information on what to do during commit, see
    // "Custom login module development for a system login configuration" on page 593
    if (customPropToken != null)
    {
        // Sets the propagation token on the thread
        try
        {
            System.out.println(tc, "*** ADDED MY CUSTOM PROPAGATION TOKEN TO THE THREAD ***");
            // Prints out the values in the deserialized propagation token
            java.util.Enumeration keys = customPropToken.getAttributeNames();
            while (keys.hasMoreElements())
            {

                        System.out.println("Key/Value: " + key + "/" + list[k]);
                }
            }
        }
        catch (Exception e)
        {
            // Handles exception
        }
    }
}

```

```
// Defines your login module variables
com.ibm.wsspi.security.token.PropagationToken customPropToken = null;
}
```

Implementing a custom authorization token

This task explains how you might create your own `AuthorizationToken` implementation, which is set in the login Subject and propagated downstream.

The default `AuthorizationToken` usually is sufficient for propagating attributes that are user-specific. Consider writing your own implementation if you want to accomplish one of the following tasks:

- Isolate your attributes within your own implementation.
- Serialize the information using custom serialization. You must deserialize the bytes at the target and add that information back on the thread. This task also might include encryption and decryption.
- Affect the overall uniqueness of the Subject using the `getUniqueID()` application programming interface (API).

To implement a custom authorization token, you must complete the following steps:

1. Write a custom implementation of the `AuthorizationToken` interface. There are many different methods for implementing the `AuthorizationToken` interface. However, make sure that the methods required by the `AuthorizationToken` interface and the token interface are fully implemented.

After you implement this interface, place it in the `profile_root/classes` directory. The `profile_root` variable is the directory and file name of the particular profile. For more information on classes, see “Creating a classes subdirectory in your profile for custom classes” on page 516.

Tip: All of the token types defined by the propagation framework have similar interfaces. Basically, the token types are marker interfaces that implement the `com.ibm.wsspi.security.token.Token` interface. This interface defines most of the methods. If you plan to implement more than one token type, consider creating an abstract class that implements the `com.ibm.wsspi.security.token.Token` interface. All of your token implementations, including the `AuthorizationToken`, might extend the abstract class and then most of the work is completed.

To see an implementation of `AuthorizationToken`, see “Example: `com.ibm.wsspi.security.token.AuthorizationToken` implementation” on page 623

2. Add and receive the custom `AuthorizationToken` during WebSphere Application Server logins This task is typically accomplished by adding a custom login module to the various application and system login configurations. However, in order to deserialize the information, you must plug in a custom login module, which is discussed in “Propagating a custom Java serializable object” on page 649. After the object is instantiated in the login module, you can add the object to the Subject during the `commit()` method.

If you only want to add information to the Subject to get propagated, see “Propagating a custom Java serializable object” on page 649. If you want to ensure that the information is propagated, want to do your own custom serialization, or want to specify the uniqueness for Subject caching purposes, then consider writing your own `AuthorizationToken` implementation.

The code sample in “Example: custom `AuthorizationToken` login module” on page 628 shows how to determine if the login is an initial login or a propagation login. The difference between these login types is whether the `WSTokenHolderCallback` contains propagation data. If the callback does not contain propagation data, initialize a new custom `AuthorizationToken` implementation and set it into the Subject. If the callback contains propagation data, look for your specific custom `AuthorizationToken` `TokenHolder` instance, convert the `byte[]` back into your custom `AuthorizationToken` object, and set it back into the Subject. The code sample shows both instances.

You can make your `AuthorizationToken` read-only in the commit phase of the login module. If you do not make the token read-only, then attributes can be added within your applications.

3. Add your custom login module to WebSphere Application Server system login configurations that already contain the `com.ibm.ws.security.server.Im.wsMapDefaultInboundLoginModule` for receiving serialized versions of your custom authorization token

Because this login module relies on information in the `sharedState` added by the `com.ibm.ws.security.server.Im.wsMapDefaultInboundLoginModule`, add this login module after `com.ibm.ws.security.server.Im.wsMapDefaultInboundLoginModule`. For information on how to add your custom login module to the existing login configurations, see “Custom login module development for a system login configuration” on page 593

After completing these steps, you have implemented a custom `AuthorizationToken`.

Example: `com.ibm.wsspi.security.token.AuthorizationToken` implementation

Use this file to see an example of a `AuthorizationToken` implementation. The following sample code does not extend an abstract class, but rather implements the `com.ibm.wsspi.security.token.AuthorizationToken` interface directly. You can implement the interface directly, but it might cause you to write duplicate code. However, you might choose to implement the interface directly if there are considerable differences between how you handle the various token implementations.

For information on how to implement a custom `AuthorizationToken`, see “Implementing a custom authorization token” on page 622.

}

```

Implementing a custom single sign-on token

You can create your own single sign-on token implementation. The single sign-on token implementation is set in the login Subject and added to the HTTP response as an HTTP cookie.

The cookie name is the concatenation of the `SingleSignonToken.getName` application programming interface (API) and the `SingleSignonToken.getVersion` API. There is no delimiter. When you add a single sign-on token to the Subject, it also gets propagated horizontally and downstream in case the Subject is used for other Web requests. You must deserialize your custom single sign-on token when you receive it from a propagation login. Consider writing your own implementation if you want to accomplish one of the following tasks:

- Isolate your attributes within your own implementation.
- Serialize the information using custom serialization. Encrypt the information because it is out to the HTTP response and is available on the Internet. You must deserialize or decrypt the bytes at the target and add that information back into the Subject.
- Affect the overall uniqueness of the Subject using the `getUniqueID` API

To implement a custom single sign-on token, complete the following steps:

1. Write a custom implementation of the `SingleSignonToken` interface.

Many different methods are available for implementing the `SingleSignonToken` interface. However, make sure the methods that are required by the `SingleSignonToken` interface and the token interface are fully implemented.

After you implement this interface, you can place it in the `profile_root/classes` directory. The `profile_root` variable is the directory and profile name specified for the `profilePath` parameter at profile creation. For more information on classes, see “Creating a classes subdirectory in your profile for custom classes” on page 516.

Tip: All of the token types that are defined by the propagation framework have similar interfaces. Basically, the token types are marker interfaces that implement the `com.ibm.wsspi.security.token.Token` interface. This interface defines most of the methods. If you plan to implement more than one token type, consider creating an abstract class that implements the `com.ibm.wsspi.security.token.Token` interface. All of your token implementations, including the single sign-on token, might extend the abstract class and then most of the work is complete.

To see an implementation of the single sign-on token, see “Example: A `com.ibm.wsspi.security.token.SingleSignonToken` implementation” on page 631

2. Add and receive the custom single sign-on token during WebSphere Application Server logins. This task is typically accomplished by adding a custom login module to the various application and system login configurations. However, to deserialize the information, you need to plug in a custom login module, which is discussed in a subsequent step. After the object is instantiated in the login module, you can add it to the Subject during the commit method.

The code sample in “Example: A custom single sign-on token login module” on page 636, shows how to determine if the login is an initial login or a propagation login. The difference is whether the `WSTokenHolderCallback` callback contains propagation data. If the callback does not contain propagation data, initialize a new custom single sign-on token implementation and set it into the Subject. Also, look for the HTTP cookie from the HTTP request if the HTTP request object is available in the callback. You can get your custom single sign-on token both from a horizontal propagation login

and from the HTTP request. However, it is recommended that you make the token available in both places because then the information arrives at any front-end application server, even if that server does not support propagation.

You can make your single sign-on token read-only in the commit phase of the login module. If you make the token read-only, additional attributes cannot be added within your applications.

Restriction:

- HTTP cookies have a size limitation so do not add too much data to this token.
 - The WebSphere Application Server runtime does not handle cookies that it does not generate, so this cookie is not used by the runtime.
 - The SingleSignonToken object, when in the Subject, does affect the cache lookup of the Subject if you return something in the getUniqueID method.
3. Get the HTTP cookie from the HTTP request object during login or from an application. The sample code that is found in “Example: An HTTP cookie retrieval” on page 638 shows how you can retrieve the HTTP cookie from the HTTP request, decode the cookie so that it is back to your original bytes, and create your custom SingleSignonToken object from the bytes.
 4. Add your custom login module to WebSphere Application Server system login configurations that already contain the `com.ibm.ws.security.server.Im.wssMapDefaultInboundLoginModule` for receiving serialized versions of your custom propagation token. Because this login module relies on information in the `sharedState` state that is added by the `com.ibm.ws.security.server.Im.wssMapDefaultInboundLoginModule` login module, add this login module after the `com.ibm.ws.security.server.Im.wssMapDefaultInboundLoginModule` login module.
For information on adding your custom login module into the existing login configurations, see “Custom login module development for a system login configuration” on page 593.

After completing these steps, you have implemented a custom single sign-on token.

Example: A `com.ibm.wsspi.security.token.SingleSignonToken` implementation

Use this file to see an example of a single sign-on implementation. The following sample code does not extend an abstract class, but implements the `com.ibm.wsspi.security.token.SingleSignonToken` interface directly. You can implement the interface directly, but it might cause you to write duplicate code. However, you might choose to implement the interface directly if considerable differences exist between how you handle the various token implementations.

For information on how to implement a custom single sign-on token, see “Implementing a custom single sign-on token” on page 630.

```

Example: An HTTP cookie retrieval

The following example shows you how to retrieve a cookie from an HTTP request, decode the cookie so that it is back to your original bytes, and create your custom SingleSignonToken object from the bytes. This example shows how to complete these steps from a login module. However, you also can complete these steps using a servlet.

For information on what to do during initialization, login and commit, see “Custom login module development for a system login configuration” on page 593.

```

public customLoginModule()
{
    public void initialize(Subject subject, CallbackHandler callbackHandler,
        Map sharedState, Map options)
    {
        _sharedState = sharedState;
    }

    public boolean login() throws LoginException
    {
        // Handles the WSTokenHolderCallback to see if this is an
        // initial or propagation login.
        Callback callbacks[] = new Callback[2];
        callbacks[0] = new WSTokenHolderCallback("Authz Token List: ");
        callbacks[1] = new WSServletRequestCallback("HttpServletRequest: ");

        try
        {
            callbackHandler.handle(callbacks);
        }
        catch (Exception e)
        {
            // Handles the exception
        }

        // receive the ArrayList of TokenHolder objects (the serialized tokens)
        List authzTokenList = ((WSTokenHolderCallback) callbacks[0]).getTokenHolderList();
        javax.servlet.http.HttpServletRequest request =
            ((WSServletRequestCallback) callbacks[1]).getHttpServletRequest();

```

Implementing a custom authentication token

This topic explains how you might create your own authentication token implementation, which is set in the login Subject and propagated downstream.

With this implementation you can specify an authentication token that can be used by a custom login module or application. Consider writing your own implementation if you want to accomplish one of the following tasks:

- Isolate your attributes within your own implementation.
- Serialize the information using custom serialization. You must deserialize the bytes at the target and add that information back on the thread. This task also might include encryption and decryption.
- Affect the overall uniqueness of the Subject using the getUniqueID application programming interface (API).

Important: Custom authentication token implementations are not used by the security runtime in WebSphere Application Server to enforce authentication. WebSphere Application Security runtime uses this token in the following situations only:

- Call the getBytes method for serialization
- Call the getForwardable method to determine whether to serialize the authentication token.
- Call the getUniqueid method for uniqueness
- Call the getName and the getVersion methods for adding serialized bytes to the token holder that is sent downstream

All of the other uses are custom implementations.

To implement a custom authentication token, you must complete the following steps:

1. Write a custom implementation of the `AuthenticationToken` interface. Many different methods are available for implementing the `AuthenticationToken` interface. However, make sure the methods that are required by the `AuthenticationToken` interface and the token interface are fully implemented. After you implement this interface, you can place it in the `install_dir/classes` directory. Alternatively, you can place the class in any private directory. However, make sure that the WebSphere Application Server class loader can locate the class and that it is granted the appropriate permissions. You can add the Java archive (JAR) file or directory that contains this class into the `server.policy` file so the class has the necessary permissions required by the server code.

Tip: All of the token types that are defined by the propagation framework have similar interfaces. The token types are marker interfaces that implement the `com.ibm.wsspi.security.token.Token` interface. This interface defines most of the methods. If you plan to implement more than one token type, consider creating an abstract class that implements the `com.ibm.wsspi.security.token.Token` interface. All of your token implementations, including the authentication token, might extend the abstract class and then most of the work is complete.

To see an implementation of the `AuthenticationToken` interface, see “Example: A `com.ibm.wsspi.security.token.AuthenticationToken` implementation.”

2. Add and receive the custom authentication token during WebSphere Application Server logins. This task is typically accomplished by adding a custom login module to the various application and system login configurations. However, to deserialize the information you must plug in a custom login module. After the object is instantiated in the login module, you can add the object to the `Subject` during the `commit` method.

If you only want to add information to the `Subject` to get propagated, see “Propagating a custom Java serializable object” on page 649. If you want to ensure that the information is propagated, do your own custom serialization, or specify the uniqueness for `Subject` caching purposes, consider writing your own authentication token implementation.

The code sample in “Example: A custom authentication token login module” on page 647, shows how to determine if the login is an initial login or a propagation login. The difference between these login types is whether the `WSTokenHolderCallback` callback contains propagation data. If the callback does not contain propagation data, initialize a new custom authentication token implementation and set it into the `Subject`. If the callback contains propagation data, look for your specific custom authentication token `TokenHolder` instance, convert the byte array back into your custom `AuthenticationToken` object, and set it back into the `Subject`. The code sample shows both instances.

You can make your authentication token read-only in the `commit` phase of the login module. If you do not make the token read-only, attributes can be added within your applications.

3. Add your custom login module to WebSphere Application Server system login configurations that already contain the `com.ibm.ws.security.server.Im.wsMapDefaultInboundLoginModule` login module for receiving serialized versions of your custom authorization token.

Because this login module relies on information in the shared state that is added by the `com.ibm.ws.security.server.Im.wsMapDefaultInboundLoginModule` login module, add this login module after the `com.ibm.ws.security.server.Im.wsMapDefaultInboundLoginModule` login module. For information on how to add your custom login module to the existing login configurations, see “Custom login module development for a system login configuration” on page 593.

After completing these steps, you have implemented a custom authentication token.

Example: A `com.ibm.wsspi.security.token.AuthenticationToken` implementation

The following example illustrates an authentication token implementation. The following sample code does not extend an abstract class, but rather implements the `com.ibm.wsspi.security.token.AuthenticationToken`

interface directly. You can implement the interface directly, but it might cause you to write duplicate code. However, you might choose to implement the interface directly if considerable differences exist between how you handle the various token implementations.

Example: A custom authentication token login module

This examples shows how to determine if the login is an initial login or a propagation login.

For information on what to do during initialization, login and commit, see “Custom login module development for a system login configuration” on page 593.

```

public customLoginModule()
{
    public void initialize(Subject subject, CallbackHandler callbackHandler,
        Map sharedState, Map options)
    {
        _sharedState = sharedState;
    }

    public boolean login() throws LoginException
    {
        // Handles the WSTokenHolderCallback to see if this is an initial or
        // propagation login.
        Callback callbacks[] = new Callback[1];
        callbacks[0] = new WSTokenHolderCallback("Authz Token List: ");

        try
        {
            callbackHandler.handle(callbacks);
        }
        catch (Exception e)
        {
            // Handles exception
        }

        // Receives the ArrayList of TokenHolder objects (the serialized tokens)
        List authzTokenList = ((WSTokenHolderCallback) callbacks[0]).getTokenHolderList();

        if (authzTokenList != null)
        {
            // Iterates through the list looking for your custom token
            for (int i=0; i<authzTokenList.size(); i++)
            {
                TokenHolder tokenHolder = (TokenHolder)authzTokenList.get(i);

                // Looks for the name and version of your custom AuthenticationToken
                // implementation
                if (tokenHolder.getName().equals("your_oid_name") && tokenHolder.getVersion() == 1)
                {
                    // Passes the bytes into your custom AuthenticationToken constructor
                    // to deserialize
                    customAuthzToken = new
                    com.ibm.websphere.security.token.
                    CustomAuthenticationTokenImpl(tokenHolder.getBytes());
                }
            }
        }
        else

Propagating a custom Java serializable object

This document describes how to add an object into the Subject from a login module and describes other infrastructure considerations to make sure that the Java object gets propagated.

Prior to completing this task, verify that security propagation is enabled in the administrative console.

With security attribute propagation enabled, you can propagate data either horizontally with single sign-on (SSO) enabled or downstream using Common Secure Interoperability Version 2 (CSIv2). When a login occurs, either through an application login configuration or a system login configuration, a custom login module can be plugged in to add Java serialized objects into the Subject during login. This document describes how to add an object into the Subject from a login module and describes other infrastructure considerations to make sure that the Java object gets propagated.

1. Add your custom Java object into the Subject from a custom login module. A two-phase process exists for each Java Authentication and Authorization Service (JAAS) login module. WebSphere Application Server completes the following processes for each login module present in the configuration:

login method

In this step, the login configuration callbacks are analyzed, if necessary, and the new objects or credentials are created.

commit method

In this step, the objects or credentials that are created during login are added into the Subject.

After a custom Java object is added into the Subject, WebSphere Application Server serializes the object on the sending server, deserializes the object on the receiving server, and adds the object back into the Subject downstream. However, some requirements exist for this process to occur successfully. For more information on the JAAS programming model, see the JAAS information provided in Security: Resources for learning.

Important: Whenever you plug a custom login module into the login infrastructure of WebSphere Application Server, make sure that the code is trusted. When you add the login module into the *profile_root/classes* directory, the login module has Java 2 Security AllPermissions permissions. For more information, see “Creating a classes subdirectory in your profile for custom classes” on page 516. However, because the login module might be run after the application code on the call stack, you might add doPrivileged code so that you do not need to add additional properties to your applications.

The following code sample shows how to add doPrivileged code. For information on what to do during initialization, login and commit, see “Custom login module development for a system login configuration” on page 593.

```

public customLoginModule()
{
    public void initialize(Subject subject, CallbackHandler callbackHandler,
        Map sharedState, Map options)
    {
    }
}

public boolean login() throws LoginException
{
    // Construct callback for the WSTokenHolderCallback so that you
    // can determine if
    // your custom object has propagated
    Callback callbacks[] = new Callback[1];
    callbacks[0] = new WSTokenHolderCallback("Authz Token List: ");
}

```

```

try
{
    _callbackHandler.handle(callbacks);
}
catch (Exception e)
{
    throw new LoginException (e.getLocalizedMessage());
}

// Checks to see if any information is propagated into this login
List authzTokenList = ((WSTokenHolderCallback) callbacks[1]).
    getTokenHolderList();

if (authzTokenList != null)
{
    for (int i = 0; i < authzTokenList.size(); i++)
    {
        TokenHolder tokenHolder = (TokenHolder)authzTokenList.get(i);

        // Look for your custom object. Make sure you use
        // "startsWith"because there is some data appended
        // to the end of the name indicating in which Subject
        // Set it belongs. Example from getName():
        // "com.acme.CustomObject (1)". The class name is
        // generated at the sending side by calling the
        // object.getClass().getName() method. If this object
        // is deserialized by WebSphere Application Server,
        // then return it and you do not need to add it here.
        // Otherwise, you can add it below.
        // Note: If your class appears in this list and does
        // not use custom serialization (for example, an
        // implementation of the Token interface described in
        // the Propagation Token Framework), then WebSphere
        // Application Server automatically deserializes the
        // Java object for you. You might just return here if
        // it is found in the list.

        if (tokenHolder.getName().startsWith("com.acme.CustomObject"))
            return true;
    }
}

// If you get to this point, then your custom object has not propagated
myCustomObject = new com.acme.CustomObject();
myCustomObject.put("mykey", "mydata");
}

public boolean commit() throws LoginException
{
    try
    {
        // Assigns a reference to a final variable so it can be used in
        // the doPrivileged block
        final com.acme.CustomObject myCustomObjectFinal = myCustomObject;
        // Prevents your applications from needing a JAAS getPrivateCredential
        // permission.
        java.security.AccessController.doPrivileged(new java.security.
            PrivilegedExceptionAction()
        {
            public Object run() throws java.lang.Exception
            {
                // Try not to add a null object to the Subject or an object
                // that already exists.
                if (myCustomObjectFinal != null && !subject.getPrivateCredentials().
                    contains(myCustomObjectFinal))
                {
                    // This call requires a special Java 2 Security permission,
                    // see the JAAS application programming interface (API)

```

```

        // documentation.
        subject.getPrivateCredentials().add(myCustomObjectFinal);
    }
    return null;
}
});
}
catch (java.security.PrivilegedActionException e)
{
    // Wraps the exception in a WSLoginFailedException
    java.lang.Throwable myException = e.getException();
    throw new WSLoginFailedException (myException.getMessage(), myException);
}
}

// Defines your login module variables
com.acme.CustomObject myCustomObject = null;
}

```

2. Verify that your custom Java class implements the `java.io.Serializable` interface. An object that is added to the Subject must be serialized if you want the object to propagate. For example, the object must implement the `java.io.Serializable` interface. If the object is not serialized, the request does not fail, but the object does not propagate. To make sure an object that is added to the Subject is propagated, implement one of the token interfaces that is defined in “Security attribute propagation” on page 188 or add attributes to one of the following existing default token implementations:

AuthorizationToken

Add attributes if they are user-specific. For more information, see “Default authorization token” on page 198.

PropagationToken

Add attributes that are specific to an invocation. For more information, see “Default propagation token” on page 192.

If you are careful adding custom objects and follow all the steps to make sure that WebSphere Application Server can serialize and deserialize the object at each hop, then it is sufficient to use custom Java objects only.

3. Verify that your custom Java class exists on all of the systems that might receive the request. When you add a custom object into the Subject and expect WebSphere Application Server to propagate the object, make sure that the class definition for that custom object exists in the `profile_root/classes` directory on all of the nodes where serialization or deserialization might occur. Also, verify that the Java class versions are the same.
4. Verify that your custom login module is configured in all of the login configurations used in your environment where you need to add your custom object during a login. Any login configuration that interacts with WebSphere Application Server generates a Subject that might be propagated outbound for an Enterprise JavaBeans (EJB) request. If you want WebSphere Application Server to propagate a custom object in all cases, make sure that the custom login module is added to every login configuration that is used in your environment. For more information, see “Custom login module development for a system login configuration” on page 593.
5. Verify that security attribute propagation is enabled on all of the downstream servers that receive the propagated information. When an EJB request is sent to a downstream server and security attribute propagation is disabled on that server, only the authentication token is sent for backwards compatibility. Therefore, you must review the configuration to verify that propagation is enabled in all of the cells that might receive requests. You must check several places in the administrative console to make sure propagation is fully enabled. For more information, see “Propagating security attributes among application servers” on page 279.
6. Add any custom objects to the propagation exclude list that you do not want to propagate. You can configure a property to exclude the propagation of objects that match specific class names, package names, or both. For example, you can have a custom object that is related to a specific process. If the

object is propagated, it does not contain valid information. You must tell WebSphere Application Server not to propagate this object. Complete the following steps to specify the object in the propagation exclude list, using the administrative console:

- a. Click **Security > Secure administration, applications, and infrastructure > Custom properties > New**.
- b. Add `com.ibm.ws.security.propagationExcludeList` in the **Name** field.
- c. Add the name of the custom object in the **Value** field. You can add a list of custom objects to the propagation exclude list, separated by a colon (:). For example, you might enter `com.acme.CustomLocalObject:com.acme.private.*`. You can enter a class name such as `com.acme.CustomLocalObject` or a package name such as `com.acme.private.*`. In this example, WebSphere Application Server does not propagate any class that equals `com.acme.CustomLocalObject` or begins with `com.acme.private`.

Although you can add custom objects to the propagation exclude list, you must be aware of a side effect. WebSphere Application Server stores the opaque token, or the serialized Subject contents, in a local cache for the life of the single sign-on (SSO) token. The life of the SSO token, which has a default of two hours, is configured in the SSO properties on the administrative console. The information that is added to the opaque token includes only the objects not in the exclude list.

If your authentication cache does not match your SSO token timeout, configure the authentication cache properties. See “Configuring the authentication cache” on page 282. It is recommended that you make your authentication cache timeout value equal to the SSO token timeout.

As a result of this task, custom Java serializable objects are propagated horizontally or downstream. For more information on the differences between horizontal and downstream propagation, see “Security attribute propagation” on page 188.

Developing a custom interceptor for trust associations

You can define the interceptor class method that you want to use. WebSphere Application Server supports two trust association interceptor interfaces: `com.ibm.websphere.security.TrustAssociationInterceptor` and `com.ibm.wsspi.security.tai.TrustAssociationInterceptor`.

If you are using a third party reverse proxy server other than Tivoli WebSEAL, you must provide an implementation class for the product interceptor interface for your proxy server. This article describes the `com.ibm.websphere.security.TrustAssociationInterceptor.java` interface that you must implement.

WebSphere Application Server version 4 and WebSphere Application Server version 5.x support the `com.ibm.websphere.security.TrustAssociationInterceptor.java` interface described in this article. WebSphere Application Server version 6.0 and later support the `com.ibm.wsspi.security.tai.TrustAssociationInterceptor` interface described in Developing a custom trust association interceptor.

Note: The Trust Association Interceptor (TAI) interface (`com.ibm.wsspi.security.tai.TrustAssociationInterceptor`) supports several new features and is different from the existing `com.ibm.websphere.security.TrustAssociationInterceptor` interface.

1. Define the interceptor class method. WebSphere Application Server provides the interceptor Java interface, `com.ibm.websphere.security.TrustAssociationInterceptor`, which defines the following methods:
 - **public boolean isTargetInterceptor(HttpServletRequest req)** creates `WebTrustAssociationException`;
 - The `isTargetInterceptor` method determines whether the request originated with the proxy server associated with the interceptor. The implementation code must examine the incoming request object and determine if the proxy server forwarding the request is a valid proxy server for this interceptor. The result of this method determines whether the interceptor processes the request or not.
 - **public void validateEstablishedTrust (HttpServletRequest req)** creates `WebTrustAssociationException`;

The `validateEstablishedTrust` method determines if the proxy server from which the request originated is trusted or not. This method is called after the `isTargetInterceptor` method. The implementation code must authenticate the proxy server. The authentication mechanism is proxy-server specific. For example, in the product implementation for the WebSEAL server, this method retrieves the basic authentication information from the HTTP header and validates the information against the user registry used by WebSphere Application Server. If the credentials are invalid, the code creates the `WebTrustAssociationException`, indicating that the proxy server is not trusted and the request is to be denied.

- **public String getAuthenticatedUsername(HttpServletRequest req)** creates `WebTrustAssociationException`;

The `getAuthenticatedUsername` method is called after trust is established between the proxy server and WebSphere Application Server. The product has accepted the proxy server authentication of the request and must now authorize the request. To authorize the request, the name of the original requestor must be subjected to an authorization policy to determine if the requestor has the necessary privilege. The implementation code for this method must extract the user name from the HTTP request header and determine if that user is entitled to the requested resource. For example, in the product implementation for the WebSEAL server, the method looks for an `iv-user` attribute in the HTTP request header and extracts the user ID associated with it for authorization.

2. Configuring the interceptor. To make an interceptor configurable, the interceptor must extend `com.ibm.websphere.security.WebSphereBaseTrustAssociationInterceptor`. Implement the following methods:

public int init (java.util.Properties props);

The `init(Properties)` method accepts a `java.util.Properties` object, which contains the set of properties required to initialize the interceptor. All the properties set for an interceptor (by using the **Custom Properties** link for that interceptor or using scripting) is sent to this method. The interceptor then can use these properties to initialize itself. For example, in the product implementation for the WebSEAL server, this method reads the hosts and ports so that a request coming in can be verified to originate from trusted hosts and ports. A return value of **0** implies that the interceptor initialization is successful. Any other value implies that the initialization is not successful and the interceptor is ignored.

Applicability of the following list

If a previous implementation of the trust association interceptor returns a different error status you can either change your implementation to match the expectations or make one of the following changes:

- Add the `com.ibm.websphere.security.trustassociation.initStatus` property in the trust association interceptor custom properties. Set the property to the value that indicates that the interceptor is successfully initialized. All of the other possible values imply failure. In case of failure, the corresponding trust association interceptor is not used.
- Add the `com.ibm.websphere.security.trustassociation.ignoreInitStatus` property in the trust association interceptor custom properties. Set the value of this property to **true**, which tells WebSphere Application Server to ignore the status of this method. If you add this property to the custom properties, WebSphere Application Server does not check the return status, which is similar to previous versions of WebSphere Application Server.

public void cleanup ();

This method is called when the application server is stopped. It is used to prepare the interceptor for termination.

public void setVersion (String s);

This method is optional. The method is used to set the version and is for informational purpose only. The default value is `Unspecified`.

You must configure the following methods implemented by the custom interceptor implementation. **This listing only shows the methods and does not include any implementation.**

```
*****  
import java.util.*;  
import javax.servlet.http.HttpServletRequest;
```

```

import com.ibm.websphere.security.*;

public class myTAImpl extends WebSphereBaseTrustAssociationInterceptor
    implements TrustAssociationInterceptor
{
    public myTAImpl ()
    {
    }

    public boolean isTargetInterceptor (HttpServletRequest req)
        creates WebTrustAssociationException
    {
        //return true if this is the target interceptor, else return false.
    }

    public void validateEstablishedTrust (HttpServletRequest req)
        creates WebTrustAssociationFailedException
    {
        //validate if the request is from the trusted proxy server.
        //throw exception if the request is not from the trusted server.
    }

    public String getAuthenticatedUsername (HttpServletRequest req)
        creates WebTrustAssociationUserException
    {
        //Get the user name from the request and if the user is
        //entitled to the requested resource
        //return the user. Otherwise, throw the exception
    }

    public int init (Properties props)
    {
        //initialize the implementation. If successful return 0, else return -1.
    }

    public void cleanup ()
    {
        //Cleanup code.
    }
}
*****

```

Note: If the `init(Properties)` method is implemented as described previously in your custom interceptor, this note does not apply to your implementation, and you can move on to the next step. Previous versions of `com.ibm.websphere.security.WebSphereBaseTrustAssociationInterceptor` include the `public int init (String propsfile)` method. This method is no longer required since the interceptor properties are not read from a file. The properties are now entered in the administrative console **Custom Properties** link of the interceptor using the administrative console or scripts. These properties then are made available to your implementation in the `init(Properties)` method. However, for backward compatibility, the `init(String)` method still is supported. The `init(String)` method is called by the default implementation of `init(Properties)` as shown in the following example.

```
// Default implementation of init(Properties props) method. A Custom
// implementation should override this.
public int init (java.util.Properties props)
{
    String type =
        props.getProperty("com.ibm.websphere.security.trustassociation.types");
    String classfile=
        props.getProperty("com.ibm.websphere.security.trustassociation."
            +type+".config");
    if (classfile != null && classfile.length() > 0 ) {
        return init(classfile);
    } else {
        return -1;
    }
}
}
```

Change your implementation to implement the `init(Properties)` method instead of relying on `init(String propsfile)` method. As shown in the previous example, this default implementation reads the properties to load the property file. The `com.ibm.websphere.security.trustassociation.types` property gets the file containing the properties by concatenating `.config` to its value.

Note: The `init(String)` method still works if you want to use it instead of implementing the `init(Properties)` method. The only requirement is that the file name containing the custom trust association properties should now be entered using the **Custom Properties** link of the interceptor in the administrative console or by using scripts. You can enter the property using *either* of the following methods. The first method is used for backward compatibility with previous versions of WebSphere Application Server.

Method 1:

The same property names used in the previous release are used to obtain the file name. The file name is obtained by concatenating the `.config` to the `com.ibm.websphere.security.trustassociation.types` property value.

If the file name is called `myTAI.properties` and is located in the `app_server_root/properties` directory, set the following properties:

- `com.ibm.websphere.security.trustassociation.types = myTAItype`
- `com.ibm.websphere.security.trustassociation.myTAItype.config = app_server_root/properties/myTAI.properties`

Method 2:

You can set the `com.ibm.websphere.security.trustassociation.initPropsFile` property in the trust association custom properties to the location of the file. For example, set the following property:

- `com.ibm.websphere.security.trustassociation.initPropsFile= app_server_root/properties/myTAI.properties`

Type the previous code as one continuous line.

The location of the properties file is fully qualified (for example, `app_server_root/properties/myTAI.properties`). Because the location can be different in a Network Deployment environment, use variables such as `${USER_INSTALL_ROOT}` to refer to the WebSphere Application Server installation directory. For example, if the file name is called `myTAI.properties` and it is located in the `app_server_root/properties` directory, then set the following properties:

3. Compile the implementation once you have implemented it. For example, `app_server_root/java/bin/javac -classpath install_root/lib/wssec.jar;<install_root>/lib/j2ee.jar myTAIImpl.java`
 - a. Copy the class file to a location in the class path (preferably the `app_server_root/lib/ext` directory).
 - b. Restart all the servers.
4. Delete the default WebSEAL interceptor in the administrative console and click **New** to add your custom interceptor. Verify that the class name is dot separated and appears in the class path.

5. Click the **Custom Properties** link to add additional properties that are required to initialize the custom interceptor. These properties are passed to the `init(Properties)` method of your implementation when it extends the `com.ibm.websphere.security.WebSphereBaseTrustAssociationInterceptor` as described in the previous step.
6. Save and synchronize (if applicable) the configuration.
7. Restart the servers for the custom interceptor to take effect.

Refer to the [Security: Resources for Learning](#) article, which references the [WebSphere Application Server version 5 Redbook](#) to view an example of a custom interceptor.

Trust association interceptor support for Subject creation

The trust association interceptor (TAI) `com.ibm.wsspi.security.tai.TrustAssociationInterceptor` interface supports several features that are different from the existing `com.ibm.websphere.security.TrustAssociationInterceptor` interface.

The TAI interface supports a multiphase, negotiated authentication process. For example, some systems require a challenge response protocol back to the client. The two key methods in this interface are:

Key method name

```
public boolean isTargetInterceptor (HttpServletRequest req)
```

The `isTargetInterceptor` method determines whether the request originated with the proxy server that is associated with the interceptor. The implementation code must examine the incoming request object and determine if the proxy server that forwards the request is a valid proxy server for this interceptor. The result of this method determines whether the interceptor processes the request.

Method result

A `true` value tells WebSphere Application Server to have the TAI handle the request.

A `false` value, tells WebSphere Application Server to ignore the TAI.

Key method name

```
public TAIResult negotiateValidateandEstablishTrust (HttpServletRequest req, HttpServletResponse res)
```

The `negotiateValidateandEstablishTrust` method determines whether to trust the proxy server from which the request originated. The implementation code must authenticate the proxy server. The authentication mechanism is proxy-server specific. For example, in the product implementation for the WebSEAL server, this method retrieves the basic authentication information from the HTTP header and validates the information against the user registry that WebSphere Application Server uses. If the credentials are not valid, the code creates the `WebTrustAssociationException` exception, which indicates that the proxy server is not trusted and the request is denied. If the credentials are valid, the code returns a `TAIResult` result, which indicates the status of the request processing with the client identity (Subject and principal name) to use for authorizing the Web resource.

Method result

Returns a `TAIResult` result, which indicates the status of the request processing. You can query the Request object and modify the Response object can be modified.

The `TAIResult` class has three static methods for creating a `TAIResult` result. The `TAIResult` create methods take an `int` type as the first parameter. WebSphere Application Server expects the result to be a valid HTTP request return code and is interpreted in one of the following ways:

- If the value is `HttpServletRequest.SC_OK`, this response tells WebSphere Application Server that the TAI completed its negotiation. The response also tells WebSphere Application Server to use the information in the `TAIResult` result to create a user identity.

- Other values tell WebSphere Application Server to return the TAI output, which is placed into the HttpServletResponse response, to the Web client. Typically, the Web client provides additional information and then places another call to the TAI.

The created TAIResults results have the following meanings:

TAIResult	Explanation
public static TAIResult create(int status);	Indicates a status to WebSphere Application Server. The status cannot be SC_OK because the identity information is provided.
public static TAIResult create(int status, String principal);	Indicates a status to WebSphere Application Server and provides the user ID or the unique ID for this user. WebSphere Application Server creates credentials by querying the user registry.
public static TAIResult create(int status, String principal, Subject subject);	Indicates a status to WebSphere Application Server, the user ID or the unique ID for the user, and a custom Subject. If the Subject contains a hashtable, the principal is ignored. The contents of the Subject become part of the eventual user Subject.

All of the following examples are within the negotiateValidateandEstablishTrust method of a TAI.

The following code sample indicates that additional negotiation is required:

```
// Modify the HttpServletResponse object
// The response code is meaningful only on the client
return TAIResult.create(HttpServletResponse.SC_CONTINUE);
```

The following code sample indicates that the TAI determined the user identity. WebSphere Application Server receives the user ID only and queries the user registry for additional information:

```
// modify the HttpServletResponse object
return TAIResult.create(HttpServletResponse.SC_OK, userid);
```

The following code sample indicates that the TAI determined the user identity. WebSphere Application Server receives the complete user information that is contained in the hashtable. For more information on the hashtable, see “Configuring inbound identity mapping” on page 306. In this code sample, the hashtable is placed in the public credential portion of the Subject:

```
// create Subject and place Hashtable in it
Subject subject = new Subject();
subject.getPublicCredentials().add(hashtable);
//the response code is meaningful only the client
return TAIResult.create(HttpServletResponse.SC_OK, "ignored", subject);
```

The following code sample indicates that an authentication failure occurred. WebSphere Application Server fails the authentication request:

```
//log error message
// ....
throw new WebTrustAssociationFailedException("TAI failed for this reason");
```

The following methods are additional methods on the TrustAssociationInterceptor interface. These methods are used for initialization, for shutdown, and for identifying the TAI to WebSphere Application Server. For more information, see the Java documentation.

Method name

```
public int initialize(Properties props)
```

Method result

This method is called during TAI initialization and is called only if custom properties are configured for the interceptor.

Method name

```
public String getVersion()
```

Method result

This method returns the version of the TAI.

Method name

```
public String getType()
```

Method result

This method returns the type of the TAI.

Method name

```
public void cleanup()
```

Method result

This method is called when stopping the WebSphere Application Server process. Stopping the WebSphere Application Server process provides an opportunity for the TAI to perform any necessary cleanup. This method is not necessary if cleanup is not required.

Plug point for custom password encryption

A plug point for custom password encryption can be created to encrypt and decrypt all passwords in WebSphere Application Server that are currently encoded or decoded using Base64-encoding.

The implementation class of this plug point has the responsibility for managing keys, determining the encryption algorithm to use, and for protecting the master secret. The WebSphere Application Server runtime stores the encrypted passwords in their existing locations, preceded with {custom:alias} tags instead of {xor} tags. The custom part of the tag indicates that it is a custom algorithm. The alias part of the tag is specified by the custom implementation, which helps to indicate how the password is encrypted. The implementation can include the key alias, encryption algorithm, encryption mode, or encryption padding.

A custom provider of this plug point must implement an interface that is designed to encrypt and decrypt passwords. The interface is called by the WebSphere Application Server runtime whenever the custom plug point is enabled. The custom algorithm becomes one of the supported algorithms when the plug point is enabled. Other supported algorithms include {xor} (standard base64 encoding) and {os400} which is used on the iSeries platform.

The following example illustrates the com.ibm.wsspi.security.crypto.CustomPasswordEncryption interface:

```
package com.ibm.wsspi.security.crypto;
public interface CustomPasswordEncryption
{
    /**
     * The encrypt operation takes a UTF-8 encoded String in the form of a byte[].
     * The byte[] is generated from String.getBytes("UTF-8").
     * An encrypted byte[] is returned from the implementation in the EncryptedInfo
     * object. Additionally, a logical key alias is returned in the EncryptedInfo
     * object which is passed back into the decrypt method to determine which key was
     * used to encrypt this password. The WebSphere Application Server runtime has
     * no knowledge of the algorithm or the key used to encrypt the data.
     *
     * @param byte[]
     * @return com.ibm.wsspi.security.crypto.EncryptedInfo
     * @throws com.ibm.wsspi.security.crypto.PasswordEncryptException
     */
    public EncryptedInfo encrypt (byte[] decrypted_bytes) throws PasswordEncryptException;
}
```

```

/**
 * The decrypt operation takes the EncryptedInfo object containing a byte[]
 * and the logical key alias and converts it to the decrypted byte[]. The
 * WebSphere Application Server runtime converts the byte[] to a String
 * using new String (byte[], "UTF-8");
 *
 * @param com.ibm.wsspi.security.crypto.EncryptedInfo
 * @return byte[]
 * @throws com.ibm.wsspi.security.crypto.PasswordDecryptException
 */
public byte[] decrypt (EncryptedInfo info) throws PasswordDecryptException;

/**
 * The following is reserved for future use and is currently not
 * called by the WebSphere Application Server runtime.
 *
 * @param java.util.HashMap
 */
public void initialize (java.util.HashMap initialization_data);
}

```

The `com.ibm.wsspi.security.crypto.EncryptedInfo` class contains the encrypted bytes with the user-defined alias that is associated with the encrypted bytes. This information is passed back into the encryption method to help determine how the password was originally encrypted.

```

package com.ibm.wsspi.security.crypto;
public class EncryptedInfo
{
    private byte[] bytes;
    private String alias;

/**
 * This constructor takes the encrypted bytes and a keyAlias as parameters.
 * This constructor is used to pass to or from the WebSphere Application Server
 * runtime to enable the runtime to associate the bytes with a specific key that
 * is used to encrypt the bytes.
 */
    public EncryptedInfo (byte[] encryptedBytes, String keyAlias)
    {
        bytes = encryptedBytes;
        alias = keyAlias;
    }

/**
 * This command returns the encrypted bytes.
 *
 * @return byte[]
 */
    public byte[] getEncryptedBytes()
    {
        return bytes;
    }

/**
 * This command returns the key alias. The key alias is a logical string that is
 * associated with the encrypted password in the model. The format is
 * {custom:keyAlias}encrypted_password. Typically, just the key alias is placed
 * here, but algorithm information can also be returned.
 *
 * @return String
 */
    public String getKeyAlias()
    {

```

```

        return alias;
    }
}

```

The encryption method is called for password processing whenever the custom class is configured and custom encryption is enabled. The decryption method is called whenever the custom class is configured and the password contains the {custom:alias} tag . The custom:alias tag is stripped prior to decryption. For more information, see Enabling custom password encryption.

Enabling custom password encryption

To view an example code sample that illustrates the `com.ibm.wsspi.security.crypto.CustomPasswordEncryption` interface, see Plug point for custom password encryption.

The encryption method is called for password processing whenever the custom class is configured and custom encryption is enabled. The decryption method is called whenever the custom class is configured and the password contains the {custom:alias} tag. The custom:alias tag is stripped prior to decryption.

- To enable custom password encryption, you must configure two properties:
 - property `com.ibm.wsspi.security.crypto.customPasswordEncryptionClass`** - Defines the custom class that implements the `com.ibm.wsspi.security.crypto.CustomPasswordEncryption` password encryption interface.
 - `com.ibm.wsspi.security.crypto.customPasswordEncryptionEnabled`** - Defines when the custom class is used for default password processing. When the `passwordEncryptionEnabled` option is not specified or set to `false`, and the `passwordEncryptionClass` class is specified, the decryption method is called whenever a {custom:alias} tag still exists in the configuration repository.
- If the custom implementation class defaults to the `com.ibm.wsspi.security.crypto.CustomPasswordEncryptionImpl` interface, and this class is present in the class path, then encryption is enabled by default. This simplifies the enablement process for all nodes. It is not necessary to define any other properties except for those that the custom implementation requires. To disable encryption, but still use this class for decryption, specify the following class.
 - `com.ibm.wsspi.security.crypto.customPasswordEncryptionEnabled=false`
- To configure custom password encryption, configure both of these properties in the `security.xml` file. The custom encryption class (`com.acme.myPasswordEncryptionClass`) must be placed in a Java archive (JAR) file in the `${APP_SERVER_ROOT}/classes` directory in all WebSphere Application Server processes. Every configuration document that contains a password (`security.xml` and any application bindings that contain RunAs passwords), must be saved before all of the passwords become encrypted with the custom encryption class .
- For client side property files such as `sas.client.props` and `soap.client.props`, use the `PropFilePasswordEncoder.bat` or `PropFilePasswordEncode.sh` script to enable custom processing. This script must have the two properties configured as system properties on the Java command line of the script. The same tools that are used for encoding and decoding can be used for encryption and decryption when custom password encryption is enabled.

Whenever a custom encryption class encryption operation is called, and it creates a run-time exception or a defined `PasswordEncryptException` exception, the WebSphere Application Server runtime uses the {xor} algorithm to encode the password. This encoding prevents the storage of the password in plain text. After the problem with the custom class has been resolved, it automatically encrypts the password the next time the configuration document is saved.

When a RunAs role is assigned a user ID and password, it currently is encoded using the WebSphere Application Server encoding function. Therefore, after the custom plug point is configured to encrypt the

passwords, it encrypts the passwords for the RunAs bindings as well. If the deployed application is moved to a cell that does not have the same encryption keys, or the custom encryption is not yet enabled, a login failure results because the password is not readable.

One of the responsibilities of the custom password encryption implementation is to manage the encryption keys. This class must decrypt any password that it encrypted. Any failure to decrypt a password renders that password to be unusable, and the password must be changed in the configuration. All encryption keys must be available for decryption there no passwords are left using those keys. The master secret must be maintained by the custom password encryption class to protect the encryption keys.

You can manage the master secret by using a stash file for the keystore, or by using a password locator that enables the custom encryption class to locate the password so that it can be locked down.

Chapter 9. Configuring security with scripting

You can configure security with scripting and the wsadmin tool.

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

If you enable security for a WebSphere Application Server cell, supply authentication information to communicate with servers.

The `sas.client.props` and the `soap.client.props` files are located in the `properties` directory for each WebSphere Application Server profile, * `profile_root/properties`, where `profile_root` is the directory that contains your profile.

- The nature of the properties file updates required for running in secure mode depend on whether you connect with a Remote Method Invocation (RMI) connector, or a SOAP connector:

- If you use a Remote Method Invocation (RMI) connector, set the following properties in the `sas.client.props` file with the appropriate values:

```
com.ibm.CORBA.loginUserId=  
com.ibm.CORBA.loginPassword=
```

Also, set the following property:

```
com.ibm.CORBA.loginSource=properties
```

The default value for this property is `prompt` in the `sas.client.props` file. If you leave the default value, a dialog box appears with a password prompt. If the script is running unattended, it appears to hang.

- If you use a SOAP connector, set the following properties in the `soap.client.props` file with the appropriate values:

```
com.ibm.SOAP.securityEnabled=true  
com.ibm.SOAP.loginUserId=  
com.ibm.SOAP.loginPassword=
```

- To specify user and password information, choose one of the following methods:
 - Specify user name and password on a command line, using the **-user** and **-password** commands. For example:

```
wsadmin -conntype RMI -port 2809 -user u1 -password secret1
```
 - Specify user name and password in the `sas.client.props` file for a RMI connector or the `soap.client.props` file for a SOAP connector.

If you specify user and password information on a command line and in the `sas.client.props` file or the `soap.client.props` file, the command line information overrides the information in the props file.

Note: On UNIX system, the use of `-password` option may result in security exposure as the password information becomes visible to the system status program such as `ps` command which can be invoked by other user to display all the running processes. Do not use this option if security exposure is a concern. Instead, specify user and password information in the `soap.client.props` file for SOAP connector or `sas.client.props` file for RMI connector. The `soap.client.props` and `sas.client.props` files are located in the `properties` directory of your WebSphere Application Server profile.

Enabling and disabling administrative security using scripting

You can use scripting to enable or disable administrative security.

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

The default profile sets up procedures so that you can enable and disable administrative security based on LocalOS registry.

- To determine if application security is enabled or disabled by looking at the value of the `appEnabled` field in the WCCM security model, use the **isAppEnabled** command, for example:

- Using Jacl:

```
$AdminTask isAppSecurityEnabled {-interactive}
```

- Using Jython:

```
AdminTask.isAppSecurityEnabled ('[-interactive]')
```

This command returns a value of `true` if `appEnabled` is set to `true`. Otherwise, returns a value of `false`.

- To determine if administrative security is enabled or disabled by looking at the value of the `enabled` field in the WCCM security model, use the **isGlobalSecurity** command, for example:

- Using Jacl:

```
$AdminTask isGlobalSecurity {-interactive}
```

- Using Jython:

```
AdminTask.isGlobalSecurity ('[-interactive]')
```

Returns a value of `true` if `enabled` is set to `true`. Otherwise, returns a value of `false`.

- To set administrative security based on the passed in value, use the **setGlobalSecurity** command. For example:

- Using Jacl:

```
$AdminTask setGlobalSecurity {-interactive}
```

- Using Jython:

```
AdminTask.setGlobalSecurity ('[-interactive]')
```

Returns a value of `true` if the `enabled` field in the WCCM security model is successfully updated. Otherwise, returns a value of `false`.

- You can use the **help** command to find out the arguments that you need to provide with this call, for example:

- Using Jacl:

```
securityon help
```

Example output:

```
Syntax: securityon user password
```

- Using Jython:

```
securityon()
```

Example output:

```
Syntax: securityon(user, password)
```

- To enable administrative security based on the LocalOS registry, use the following procedure call and arguments:

- Using Jacl:

```
securityon user1 password1
```

- Using Jython:

```
securityon('user1', 'password1')
```

- To disable administrative security based on the LocalOS registry, use the following procedure call:

- Using Jacl:

```
securityoff
```

- Using Jython:

```
securityoff()
```

Enabling and disabling LTPA authentication

There are sample scripts located in the <WAS_ROOT>/bin directory on how to enable and disable LTPA authentication. The scripts are:

- LTPA_LDAPSecurityProcs.py (python script)
- LTPA_LDAPSecurityProcs.jacl (jacl script)

Note: The scripts hard code the type of LDAP server and base distinguished name (baseDN). The LDAP server type is hardcoded as IBM_DIRECTORY_SERVER and the baseDN is hardcoded as o=ibm,cn=us.

Enabling and disabling Java 2 security using scripting

You can enable or disable Java 2 security with scripting and the wsadmin tool.

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

Perform the following steps to enable or disable Java 2 security:

1. Identify the security configuration object and assign it to the security variable:

- Using Jacl:

```
set security [$AdminConfig list Security]
```

- Using Jython:

```
security = AdminConfig.list('Security')
print security
```

Example output:

```
(cells/mycell|security.xml#Security_1)
```

2. Modify the enforceJava2Security attribute to enable or disable Java 2 security. For example:

- To enable Java 2 security:

- Using Jacl:

```
$AdminConfig modify $security {{enforceJava2Security true}}
```

- Using Jython:

```
AdminConfig.modify(security, [['enforceJava2Security', 'true']])
```

- To disable Java 2 security:

- Using Jacl:

```
$AdminConfig modify $security {{enforceJava2Security false}}
```

- Using Jython:

```
AdminConfig.modify(security, [['enforceJava2Security', 'false']])
```

3. Save the configuration changes. See the Saving configuration changes with the wsadmin tool article for more information.

4. In a network deployment environment only, synchronize the node. See the Synchronizing nodes with the wsadmin tool article for more information.

Enabling authentication in the file transfer service using scripting

You can enable authentication in the file transfer service using scripting and the wsadmin tool.

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

In WebSphere Application Server Network Deployment, V5.0.1 or later, the file transfer service is enhanced to provide role-based authentication. Two versions of the file transfer Web application are

provided. By default, the version that does not authenticate its caller is installed. This default supports compatibility between the WebSphere Application Server Network Deployment, V5.0 and V5.0.1 or later.

Turning the file transfer authentication on is recommended to prevent unauthorized use of the file transfer application; however, if you have any V5.0 clients in your Network Deployment environment, they cannot communicate with the secured file transfer application if global security is turned on.

In WebSphere Application Server V6.x, mixed cells are supported and file transfer has become a system application. If all of the nodes in the cell are of V5.0.1 or later, you can activate authentication in the file transfer service by redeploying the file transfer application at the deployment manager. The compatible version is shipped in the *app_server_root/systemApps/filetransfer.ear* directory. The secured version is provided in the *app_server_root/systemApps/filetransferSecured.ear* directory.

- A wsadmin Jacl script is provided to help you redeploy the file transfer. The script is called *redeployFileTransfer.jacl* and is located in the *app_server_root/bin* directory. After the deployment manager and all the nodes are upgraded to WebSphere Application Server Network Deployment, version 5.0.1 or later, you can deploy the secured file transfer service by running the script. The syntax for running the script from the bin directory is the following:

–

```
wsadmin -profile redeployFileTransfer.jacl -c "fileTransferAuthenticationXxx cellName nodeName serverName"
```

where Xxx is **On** or **Off**.

For Windows systems, use *wsadmin* or *wsadmin.bat*. For Linux and UNIX systems, use *wsadmin.sh*. For OS/400 systems, use *wsadmin*.

- For example, when running the script to enable use of the *filetransferSecured.ear* file, the syntax is similar to the following example:

```
wsadmin -profile redeployFileTransfer.jacl -c "fileTransferAuthenticationOn managedCell managedCellManager dmgr"
```

or

```
wsadmin -profile redeployFileTransfer.jacl -c "fileTransferAuthenticationOn baseCell base server1"
```

- If you want to go return to running the file transfer service without authentication, you can run the script as shown in the following example:

```
wsadmin -profile redeployFileTransfer.jacl -c "fileTransferAuthenticationOff baseNodeCell baseNode server1"
```

or

```
wsadmin -profile redeployFileTransfer.jacl -c "fileTransferAuthenticationOff managedCell managedCellManager dmgr"
```

You must restart the server for the change to take affect.

Propagating security policy of installed applications to a JACC provider using wsadmin scripting

It is possible that you have applications installed prior to enabling the Java Authorization Contract for Containers (JACC)-based authorization. You can start with default authorization and then move to an external provider-based authorization using JACC later.

Also, during application installation or modification you might have had problems propagating the security policy information to the JACC provider. For example, network problems might occur, the JACC provider might not be available, and so on. For these cases, the security policy of the previously installed applications does not exist in the JACC provider to make the access decisions. One choice is to reinstall the applications involved. However, you can avoid reinstalling by using the *wsadmin* scripting tool. Use this tool to propagate information to the JACC provider independent of the application installation process. The tool eliminates the need for reinstalling the applications.

The tool uses the SecurityAdmin MBean to propagate the policy information in the deployment descriptor of any installed application to the JACC provider. You can invoke this tool using wsadmin at the base application server for base and deployment manager level for Network Deployment. Note that the SecurityAdmin MBean is available only when the server is running.

Use `propagatePolicyToJACCProvider(String appNames)` to propagate the policy information in the deployment descriptor of the enterprise archive (EAR) files to the JACC provider. If the `RoleConfigurationFactory` and the `RoleConfiguration` interfaces are implemented by the JACC provider, the authorization table information in the binding file of the EAR files is also propagated to the provider. See the *Securing applications and their environment* PDF for more information about these interfaces.

The `appNames` String contains the list of application names, delimited by a colon (:), whose policy information must be stored in the provider. If a null value is passed, the policy information of the deployed applications is propagated to the provider.

Also, be aware of the following items:

- Before migrating applications to the Tivoli Access Manager JACC provider, create or import the users and groups that are in the applications to Tivoli Access Manager.
- Depending on the application or the number of applications that are propagated, you might have to increase the request time-out period either in the `soap.client.props` file in the directory `profile_root/properties` (if using SOAP) or in the `sas.client.props` file (if using RMI) for the command to complete. You can set the request time-out value to 0 to avoid the timeout problem, and change it back to the original value after the command is run.

1. Configure your JACC provider in WebSphere Application Server.

See the *Securing applications and their environment* PDF for more information.

2. Restart the server.

3. Enter the following commands:

```
//use the SecurityAdmin MBean at the Deployment Manager or the unmanaged base
//application server connect to the appropriate process (Deployment Manager or
//base application server)
wsadmin -user serverID -password serverPWD
// To get the SecurityAdmin MBean for Deployment Manager
wsadmin> set secadm [$AdminControl queryNames type=SecurityAdmin,process=dmgr,*]
// or to get the SecurityAdmin MBean for a unmanaged base application server
//(replace the process name to match your configuration)
wsadmin> set secadm [$AdminControl queryNames
    type=SecurityAdmin,process=server1,*]
// to propagate specific applications security policy information
wsadmin>set appNames [list app1:app2]
// or to propagate all applications installed
wsadmin>set appNames [list null]

// Run the command to propagate
wsadmin>$AdminControl invoke $secadm propagatePolicyToJACCProvider $appNames
```

Configuring the JACC provider for Tivoli Access Manager using the wsadmin utility

You can use the wsadmin utility to configure Tivoli Access Manager security for WebSphere Application Server.

Verify that all the managed servers, including node agents, are started. The following configuration is performed once on the deployment manager server. The configuration parameters are forwarded to managed servers, including node agents, when a synchronization is performed. The managed servers require their own restart for the configuration changes to take effect.

1. Start WebSphere Application Server.

2. At the **wsadmin** prompt, enter the following command:

```
$AdminTask configureTAM -interactive
```

You are prompted to enter the following information:

Option	Description
WebSphere Application Server node name	Specify a single node or enter an asterisk (*) to choose all nodes including the deployment manager.
Tivoli Access Manager Policy Server	Enter the name of the Tivoli Access Manager policy server and the connection port. Use the format, <i>policy_server : port</i> . The policy server communication port is set at the time of Tivoli Access Manager configuration. The default port is 7135.
Tivoli Access Manager Authorization Server	Enter the name of the Tivoli Access Manager authorization server. Use the format <i>auth_server : port : priority</i> . The authorization server communication port is set at the time of Tivoli Access Manager configuration. The default port is 7136. More than one authorization server can be specified by separating the entries with commas. Having more than one authorization server configured is useful for failover and performance. The priority value is the order of authorization server use. For example: <i>auth_server1:7136:1,auth_server2:7137:2</i> . A priority of 1 is still required when configuring against a single authorization server.
WebSphere Application Server administrator's distinguished name	Enter the full distinguished name of the WebSphere Application Server security administrator ID, as created in the "Creating the security administrative user" topic in the <i>Securing applications and their environment</i> PDF. For example: <i>cn=wasadmin,o=organization,c=country</i>
Tivoli Access Manager user registry distinguished name suffix	For example: <i>o=organization,c=country</i>
Tivoli Access Manager administrator's user name	Enter the Tivoli Access Manager administration user ID, as created at the time of Tivoli Access Manager configuration. This ID is usually, <i>sec_master</i> .
Tivoli Access Manager administrator's user password	Enter the password for the Tivoli Access Manager administrator.
Tivoli Access Manager security domain	Enter the name of the Tivoli Access Manager security domain that is used to store users and groups. If a security domain is not already established at the time of Tivoli Access Manager configuration, click Return to accept the default.
Embedded Tivoli Access Manager listening port set	WebSphere Application Server needs to listen on a TCP/IP port for authorization database updates from the policy server. More than one process can run on a particular node and machine so a list of ports is required for the processes. Enter the ports that are used as listening ports by Tivoli Access Manager clients, separated by a comma. If you specify a range of ports, separate the lower and higher values by a colon. For example, 7999, 9990:9999.

Option	Description
Defer	Set to <i>yes</i> , this option defers the configuration of the management server until the next restart. Set to <i>no</i> , configuration of the management server occurs immediately. Managed servers are configured on their next restart.

- When all information is entered, select **F** to save the configuration properties or **C** to cancel from the configuration process and discard entered information.

Now enable the JACC provider for Tivoli Access Manager- Enabling the JACC provider for Tivoli Access Manager topic in the *Securing applications and their environment* PDF.

Disabling embedded Tivoli Access Manager client using wsadmin

Follow these steps to unconfigure the Java Authorization Contract for Containers (JACC) provider for Tivoli Access Manager.

In a Network Deployment architecture, ensure that all the managed servers, including node agents, are started. Perform the following process once on the deployment management server. Details of the unconfiguration are forwarded to managed servers, including node agents, when a synchronization is performed. The managed servers require their own reboot for the configuration changes to take effect.

- Restart the deployment manager process.
- Start the wsadmin command-line utility. The wsadmin command is found in the *install_dir/bin* directory
- From the **wsadmin** prompt, enter the following command:

```
WSADMIN>$AdminTask unconfigureTAM -interactive
```

You are prompted to enter the following information:

Option	Description
WebSphere Application Server node name	Enter an asterisk (*) to select all nodes.
Tivoli Access Manager administrator user name	Enter the Tivoli Access Manager administration user ID, as created at the time of Tivoli Access Manager configuration. This name is usually, <i>sec_master</i> .
Tivoli Access Manager administrator user password	Enter the password for the Tivoli Access Manager administrator.
Force	Enter <i>yes</i> , if you want to ignore errors when unconfiguring the JACC provider for Tivoli Access Manager. Enter this option as <i>yes</i> only when the Tivoli Access Manager domain is in an irreparable state.
Defer	Enter <i>no</i> , to force the unconfiguration of the connected server. Enter <i>No</i> for the unconfiguration to proceed correctly.

- When all information is entered, enter **F** to save the properties or **C** to cancel from the unconfiguration process and discard the entered information.
- Optional:** Synchronize all nodes.
- Restart all WebSphere Application Server instances for the changes to take effect.

Creating an SSL configuration at the node scope using scripting

An Secure Socket Layer (SSL) configuration references many other configuration objects. To help you make valid selections for the new SSL configuration before you create it, view information about existing configuration objects. Information about existing objects is also useful when you create a node scoped SSL configuration using the **createSSLConfig** command of the AdminTask object.

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

To use the information in this task effectively, familiarize yourself with the instructions in the Creating a Secure Sockets Layer configuration topic in the *Securing applications and their environment* PDF. Perform the following task to create an Secure Socket Layer (SSL) configuration at the node scope:

1. List the existing configuration objects. Perform any of the following:
 - List some of the configuration objects that you may need when you create a new SSL configuration. For example, you want to see which management scopes have already been defined. If the one you need does not exist you will need to create it.

– Using Jacl:

```
$AdminTask listManagementScopes {-scopeName (cell):BIRKT40Cell102:(node):BIRKT40Node02}
```

– Using Jython:

```
AdminTask.listManagementScopes ('[-scopeName (cell):BIRKT40Cell102:(node):BIRKT40Node02]')
```

This shows an existing cell scope and existing node scope that you can use. If you want to create a different scope, use the **createManagementScope** command of the AdminTask object to define a different one. The valid scope parameters are cell, nodegroup, node, server, cluster, and endpoint. See the Central management of Secure Sockets Layer configurations topic in the *Securing applications and their environment* PDF for more information on scope definitions.

- List the key stores that exist in the configuration including key stores and trust stores.

– Using Jacl:

```
$AdminTask listKeyStores
```

– Using Jython:

```
AdminTask.listKeyStores()
```

Example output:

```
CellDefaultKeyStore(cells/BIRKT40Cell102|security.xml#KeyStore_1)
CellDefaultTrustStore(cells/BIRKT40Cell102|security.xml#KeyStore_2)
CellLTPAKeys(cells/BIRKT40Cell102|security.xml#KeyStore_3)
```

The previous example only lists the key stores for the default management scope which is also known as the cell scope. To obtain key stores for other scopes, specify the scopeName parameter, for example:

– Using Jacl:

```
$AdminTask listKeyStores {-scopeName (cell):BIRKT40Cell102:(node):BIRKT40Node02 }
```

– Using Jython:

```
$AdminTask listKeyStores ('[-scopeName (cell):BIRKT40Cell102:(node):BIRKT40Node02]')
```

Example output:

```
CellDefaultKeyStore(cells/BIRKT40Cell102|security.xml#KeyStore_1)
CellDefaultTrustStore(cells/BIRKT40Cell102|security.xml#KeyStore_2)
CellLTPAKeys(cells/BIRKT40Cell102|security.xml#KeyStore_3)
NodeDefaultKeyStore(cells/BIRKT40Cell102|security.xml#KeyStore_1134610924357)
NodeDefaultTrustStore(cells/BIRKT40Cell102|security.xml#KeyStore_1134610924377)
```

- List specific trust or key managers. Be sure to display the object name for the trust managers. You will need the object name for the SSL configuration because you can specify multiple trust manager instances.

- Using Jacl:

```
$AdminTask listTrustManagers {-scopeName (cell):BIRKT40Cell02:(node):BIRKT40Node02 -displayObjectName true }
```
- Using Jython:

```
AdminTask.listTrustManagers ('[-scopeName (cell):BIRKT40Cell02:(node):BIRKT40Node02 -displayObjectName true]')
```

Example output:

```

IbmX509(cells/BIRKT40Cell02|security.xml#TrustManager_1)
IbmPKIX(cells/BIRKT40Cell02|security.xml#TrustManager_2)
IbmX509(cells/BIRKT40Cell02|security.xml#TrustManager_1134610924357)
IbmPKIX(cells/BIRKT40Cell02|security.xml#TrustManager_1134610924377)

```

2. Create the node-scoped SSL configuration in interactive mode. Now that we have the information we need to choose from, we need to decide if these objects are sufficient or if we need to create new ones. For now, we will reuse what we've already got in the configuration and save creating new instances to task documents specific to those objects.

- Using Jacl:

```
$AdminTask createSSLConfig -interactive
```
- Using Jython:

```
AdminTask.createSSLConfig ('[-interactive]')
```

Example output:

Create a SSL Configuration.

```

*SSL Configuration Alias (alias): BIRKT40Node02SSLConfig
Management Scope Name (scopeName): (cell):BIRKT40Cell02:(node):BIRKT40Node02
Client Key Alias (clientKeyAlias): default
Server Key Alias (serverKeyAlias): default
SSL Type (type): [JSSE]
Client Authentication (clientAuthentication): [false]
Security Level of the SSL Configuration (securityLevel): [HIGH]
Enabled Ciphers SSL Configuration (enabledCiphers):
JSSE Provider (jsseProvider): [IBMJSSE2]
Client Authentication Support (clientAuthenticationSupported): [false]
SSL Protocol (sslProtocol): [SSL_TLS]
Trust Manager Object Names (trustManagerObjectNames): (cells/BIRKT40Cell02|security.xml#TrustManager_1)
*Trust Store Name (trustStoreName): NodeDefaultTrustStore
Trust Store Scope (trustStoreScopeName): (cell):BIRKT40Cell02:(node):BIRKT40Node02
*Key Store Name (keyStoreName): NodeDefaultKeyStore
Key Store Scope Name (keyStoreScopeName): (cell):BIRKT40Cell02:(node):BIRKT40Node02
Key Manager Name (keyManagerName): IbmX509
Key Manager Scope Name (keyManagerScopeName): (cell):BIRKT40Cell02:(node):BIRKT40Node02

```

Create SSL Configuration

F (Finish)
C (Cancel)

```

Select [F, C]: [F] F
WASX7278I: Generated command line: $AdminTask createSSLConfig {-alias BIRKT40Node02SSLConfig -scopeName
(cell):BIRKT40Cell02:(node):BIRKT40Node02 -clientKeyAlias default -serverKeyAlias default
-trustManagerObjectNames (cells/BIRKT40Cell02|security.xml#TrustManager_1) -trustStoreName
NodeDefaultTrustStore -trustStoreScopeName (cell):BIRKT40Cell02:(node):BIRKT40Node02 -keyStoreName
NodeDefaultKeyStore -keyStoreScopeName (cell):BIRKT40Cell02:(node):BIRKT40Node02 -keyManagerName
IbmX509 -keyManagerScopeName (cell):BIRKT40Cell02:(node):BIRKT40Node02 }

```

3. Save the configuration changes. See the Saving configuration changes with the wsadmin tool article for more information.
4. In a network deployment environment only, synchronize the node. See the Synchronizing nodes with the wsadmin tool article for more information.

The name of the SSL configuration object that you created, for example, (cells/BIRKT40Cell02|security.xml#SSLConfig_1136652770753), appears in the security.xml file.

Example security.xml file output:

```
<repertoire xmi:id="SSLConfig_1136652770753" alias="BIRKT40Node02SSLConfig" type="JSSE"
managementScope="ManagementScope_1134610924357">
<setting xmi:id="SecureSocketLayer_1136652770924" clientKeyAlias="default" serverKeyAlias="default"
clientAuthentication="false" securityLevel="HIGH" jsseProvider="IBMJSSE2" sslProtocol="SSL_TLS"
keyStore="KeyStore_1134610924357" trustStore="KeyStore_1134610924377" trustManager="TrustManager_1"
keyManager="KeyManager_1134610924357"/>
</repertoire>
```

Once you create the SSL configuration object, the next step is to use it. There are several different ways that you can associate SSL configurations with protocols, for example:

- Set the SSL configuration on the thread programmatically.
- Associate the SSL configuration with an outbound protocol or a target host and port.
- Directly associating the SSL configuration using the alias.
- Centrally managing the SSL configurations by associating them with SSL configuration groups or zones so that they are used based upon the group from where the end point exists.

Creating self-signed certificates using scripting

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

You can create self-signed certificates using the scripting and the AdminTask object. You can run the commands in interactive or batch mode. Interactive mode provides a way to discover the flags that you need to run the task in batch mode.

Certificates reside inside of key stores. To run the commands, you will need the name of the key store to be supplied. Use the **listKeyStore** command of the AdminTask object to get a list of key stores. If you need a new key store, use the **createKeyStore** command of the AdminTask object.

To create a personal key store, use the following examples:

- Interactive mode:
 - Using Jacl:
`$AdminTask createSelfSignedCertificate -interactive`
 - Using Jython:
`AdminTask.createSelfSignedCertificate ('[-interactive]')`

Example output:

```
*Key Store Name (keyStoreName): keyStore
Key Store Scope Name (keyStoreScope):
*Certificate Alias (certificateAlias): newCert
"Certificate Version" (certificateVersion): 3
*Key Size (certificateSize): [1024]
*Common Name (certificateCommonName): localhost
*Organization (certificateOrganization): workgroup
Organizational Unit (certificateOrganizationalUnit): testing
certLocality (certificateLocality): austin
State (certificateState): Texas
Zip (certificateZip): 78757
Country (certificateCountry): [US]
Validity Period (certificateValidDays): [365]
Create Self-Signed Certificate
```

```
F (Finish)
C (Cancel)
```

```
Select [F, C]: [F]
```

```
WASX7278I: Generated command line: $AdminTask createSelfSignedCertificate
{-keyStoreName keyStore -certificateAlias newCert -certificateVersion 3
-certificateCommonName localhost -certificateOrganization ibm
-certificateOrganizationalUnit testing -certificateLocality austin
-certificateState Texas -certificateZip 78757 }
true
```

At the end of the output, the batch mode parameters are provided.

- Batch mode:

- Using Jacl:

```
$AdminTask createSelfSignedCertificate {-keyStoreName keyStore
-certificateAlias newCert -certificateVersion 3 -certificateCommonName localhost
-certificateOrganization ibm -certificateOrganizationalUnit testing
-certificateLocality austin -certificateState Texas -certificateZip 78757 }
```

- Using Jython:

```
AdminTask.createSelfSignedCertificate ('[-keyStoreName keyStore
-certificateAlias newCert -certificateVersion 3 -certificateCommonName localhost
-certificateOrganization ibm -certificateOrganizationalUnit testing
-certificateLocality austin -certificateState Texas -certificateZip 78757]')
```

Automating SSL configurations using scripting

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

SSL configuration is needed for WebSphere to perform SSL connections with other servers. A SSL configuration can be configured through the Admin Console. But if an automated way to create a SSL configuration is desired then AdminTask should be used.

AdminTask can be used in a interactive mode and batch mode. For automation the batch mode options should be used. AdminTask batch mode can be called in a JACL or Python script. Interactive mode will step through all the parameter the task needs, requires ones are marked with a '*'. Before the interactive task executes the task it echoes the batch mode syntax of the task to the screen. This can be helpful when writing batch mode scripts.

There attributes needed to create an ssl configurations:

- A key store
- Default client certificate alias
- Default server certificate alias
- Trust store
- The handshake protocol
- The ciphers needed during handshake
- Supporting client authentication or not

If automating the creation of a SSL Configuration it may be needed to create some of the attribute values needed like the key store, trust store, key manager, and trust managers.

- To create a SSL configuration the createSSLConfig AdminTask can be used. To make changes to the SSL configurations use the modifySSLConfig AdminTask.

- Interactive mode:

Interactive mode steps you through all attributes and tell you the default value of the attribute if there is one. The default value is in '['] on the prompt line. The actual flag used in batch mode is in '(')' on each prompt line. If you are using the default value then the flag will not show up on the batch command line.

Using Jacl:

```
$AdminTask createSSLConfig -interactive
```

– Using Jython:

```
AdminTask.createSSLConfig ('[interactive]')
```

Example output:

```
*SSL Configuration Alias (alias): testSSLConfig
Management Scope Name (scopeName): (cell):HOSTNode01Cell:(node):HOSTNode01
